	Database Account	Enter the account of the user-created Oracle database. To perform incremental data migration, the account must have the database administrator (DBA) permission. To perform schema migration or full data migration, the account must have the owner permission on schemas.
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select **PolarDB-O**.
	DNS or IP Address	The endpoint of the destination PolarDB cluster.
	Port Number	Enter the service port number of the destination PolarDB cluster. The default port number is **1433**.
	Database Name	Enter the name of the destination database in the PolarDB cluster.
	Database Account	Enter the database account of the destination PolarDB cluster. The account must have the read and write permissions.
	Database Password	Enter the password of the destination database account. **Note** After you specify the information about the RDS instance, you can click **Test Connectivity** next to **Database Password** to check whether the information is valid. If the information is valid, the **Passed** message appears. If the **Failed** message appears, click **Check** next to **Failed**. Then, modify the information based on the check results.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. If your Oracle databases have security settings, you must manually add the CIDR blocks of DTS servers to the whitelists of the databases. To obtain the CIDR blocks of DTS servers, click **Copy to Clipboard** in the dialog

box that appears. After you add the CIDR blocks of DTS servers to the whitelist of the databases, click **Next**.

> **Note** If you do not need to configure whitelists for your Oracle databases, ignore the preceding settings and click **Next**.

6. Select the migration types and the objects to be migrated.

Setting	Description
Select the migration types	○ To perform only full data migration, select **Schema Migration** and **Full Data Migration**. ○ To ensure service continuity during data migration, select **Schema Migration**, **Full Data Migration**, and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.
Select the objects to be migrated	Select objects from the **Available** section and click the › icon to move the objects to the **Selected** section. **Note** ○ You can select columns, tables, or databases as the objects to be migrated. ○ By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. ○ If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

7. In the lower-right corner of the page, click **Precheck**.

> **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

8. After the task passes the precheck, click **Next**.

> **Note** If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.9. Migrate data from a user-created Oracle database to a PolarDB-X instance

This topic describes how to migrate data from a user-created Oracle database to a PolarDB-X instance by using Data Transmission Service (DTS). PolarDB-X is formerly known as Distributed Relational Database Service (DRDS). DTS allows you to ensure service continuity when you migrate both historical data and incremental data.

Prerequisites

- The version of the user-created Oracle database is 9i, 10g, 11g, 12c, 18c, or 19c.
- Supplemental logging, including SUPPLEMENTAL_LOG_DATA_PK and SUPPLEMENTAL_LOG_DATA_UI, is enabled for the user-created Oracle database. For more information, see Supplemental Logging.
- The user-created Oracle database is running in ARCHIVELOG mode. Archived log files are accessible and a suitable retention period is set for archived log files. For more information, see Managing Archived Redo Log Files.

Precautions

- DTS cannot migrate schemas from a user-created Oracle database to a PolarDB-X instance.

  > **Note** During schema migration, DTS migrates the schemas of the required objects, such as tables, from the source database to the destination database.

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the loads of the database servers. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- If you perform a primary/secondary switchover on the source database when the data migration task is running, the task fails.

Migration types

- Full data migration

  DTS migrates historical data of the required objects from the source Oracle database to the destination database.

- Incremental data migration

  After full data migration is complete, DTS retrieves redo log files from the source Oracle database. Then, DTS synchronizes incremental data from the source Oracle database to the destination database.

  > **Note** The following SQL operations can be synchronized during incremental data migration: INSERT, DELETE, and UPDATE. Data definition language (DDL) operations cannot be synchronized during incremental data migration.

Procedure

1. Create databases and tables in the destination PolarDB-X instance based on the schemas of the source

tables.

> **Note** The data types of Oracle and PolarDB-X do not have one-to-one correspondence. You must create the corresponding data types in the destination PolarDB-X instance. For more information, see Data type mappings between heterogeneous databases.

2. Create a data migration instance.
3. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
4. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	If the instance type is set to **User-Created Database with Public IP Address**, you do not need to specify the **instance region**.
	Database Type	Select **Oracle**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the user-created Oracle database. In this example, enter the public IP address.
	Port Number	Enter the service port number of the user-created Oracle database. The default port number is **1521**.
	Instance Type	○ **Non-RAC Instance**: If you select this option, you must specify the **SID**. ○ **RAC or PDB Instance**: If you select this option, you must specify the **Service Name**.
	Database Account	Enter the account of the user-created Oracle database. To perform incremental data migration, the account must have the database administrator (DBA) permission. To perform schema migration or full data migration, the account must have the owner permission on schemas.
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select **DRDS Instance**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the destination PolarDB-X instance.
	Database Account	Enter the database account of the destination PolarDB-X instance. The account must have the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

5. In the lower-right corner of the page, click **Set Whitelist and Next**.

6. If your Oracle databases have security settings, you must manually add the CIDR blocks of DTS servers to the whitelists of the databases. To obtain the CIDR blocks of DTS servers, click **Copy to Clipboard** in the dialog box that appears. After you add the CIDR blocks of DTS servers to the whitelist of the databases, click **Next**.

   > **Note** If you do not need to configure whitelists for your Oracle databases, ignore the preceding settings and click **Next**.

7. Select the migration types and the objects to be migrated.

Setting	Description
Select the migration types	◦ To perform only full data migration, select only **Full Data Migration**. ◦ To ensure service continuity during data migration, select both **Full Data Migration** and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.
Select the objects to be migrated	Select one or more objects from the **Available** section and click the › icon to move the objects to the **Selected** section. **Note** ◦ You can select columns, tables, or databases as the objects to be migrated. ◦ By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. ◦ If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

8. In the lower-right corner of the page, click **Precheck**.

   > **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. After the task passes the precheck, click **Next**.

> **Note** If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.10. Migrate data between ApsaraDB RDS for PostgreSQL instances

This topic describes how to migrate data between ApsaraDB RDS for PostgreSQL instances by using Data Transmission Service (DTS). DTS supports schema migration, full data migration, and incremental data migration. You can select all of the supported migration types to ensure service continuity.

Prerequisites

The network type of both the source and destination ApsaraDB RDS for PostgreSQL instances is VPC.

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the loads of the database servers. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- To ensure that the delay time of incremental data migration is accurate, DTS adds a heartbeat table named *dts_postgres_heartbeat* to the source database.
- During incremental data migration, DTS creates a replication slot for the source database. The replication slot is prefixed with `dts_sync_`. DTS automatically clears historical replication slots every 90 minutes to reduce storage usage.

  > **Note** If the migration task is released or fails, DTS automatically clears the replication slot. If a primary/secondary switchover is performed on the source ApsaraDB RDS for PostgreSQL instance, you must log on to the secondary database to clear the replication slot.

- If a data migration task fails, DTS automatically resumes the task. Before you switch your workloads to the destination instance, stop or release the data migration task. Otherwise, the data in the source instance will overwrite the data in the destination instance after the task is resumed.

Limits

- A single data migration task can migrate data from only one database. To migrate data from multiple databases, you must create a data migration task for each database.
- During incremental data migration, DTS migrates only data manipulation language (DML) operations. DML operations include INSERT, DELETE, and UPDATE.

Data migration process

The following table describes how DTS migrates the schemas and data of the source PostgreSQL database. The process prevents data migration failures that are caused by dependencies between objects.

Data migration process	Description
1. Schema migration	DTS migrates the schemas of tables, views, sequences, functions, user-defined types, rules, domains, operations, and aggregates to the destination database. **Note** DTS does not migrate functions that are written in the C programming language.
2. Full data migration	DTS migrates historical data of the required objects to the destination database.
3. Schema migration	DTS migrates the schemas of triggers and foreign keys to the destination database.
4. Incremental data migration	DTS migrates incremental data of the required objects to the destination database. **Note** Incremental data migration does not support the BIT data type.

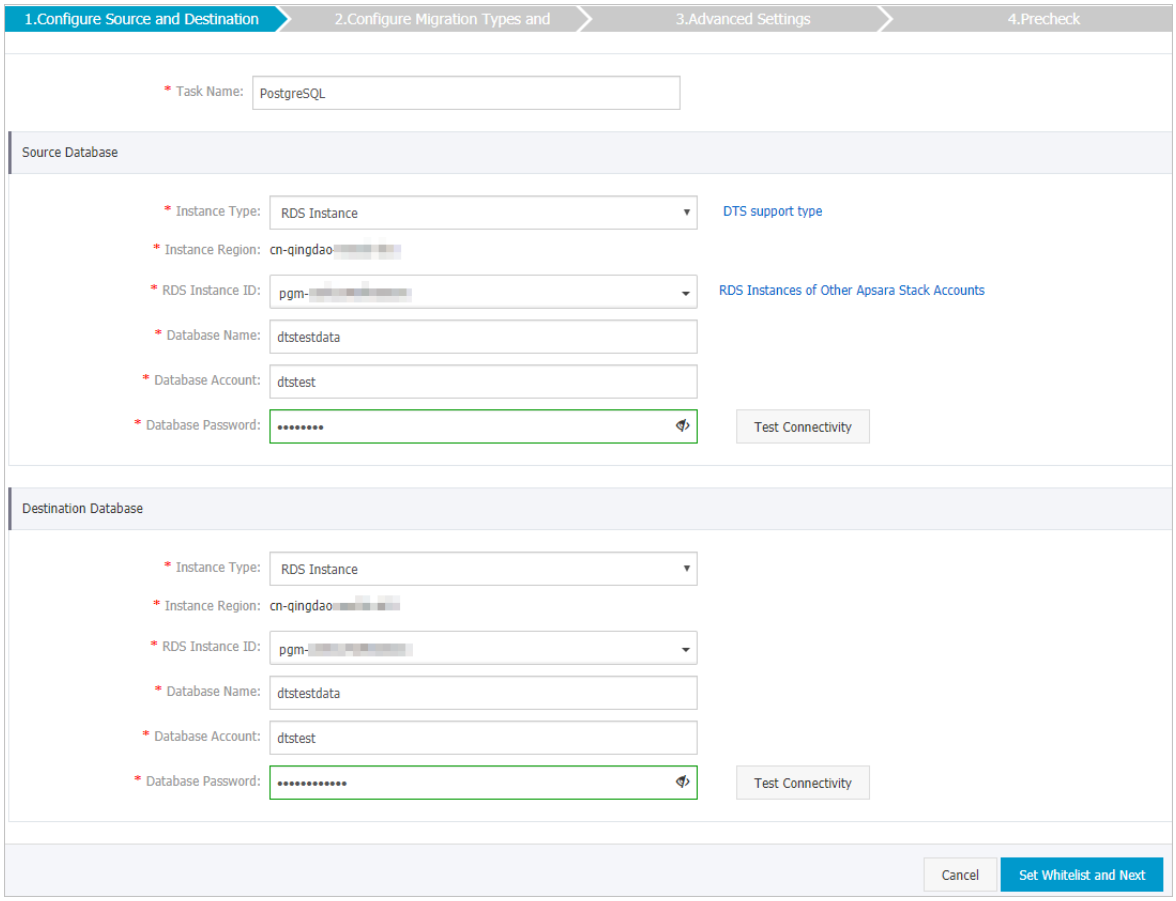
Before you begin

If you need to perform incremental data migration, you must perform the following steps: Log on to the ApsaraDB RDS console. Click the ID of the source ApsaraDB RDS for PostgreSQL instance. In the left-side navigation pane, click **Parameters**. Find the wal_level parameter and change the value to logical.

Warning After you change the value of the `wal_level` parameter, you must restart the instance to apply the change. We recommend that you evaluate the impact on your business and change the parameter setting during off-peak hours.

Procedure

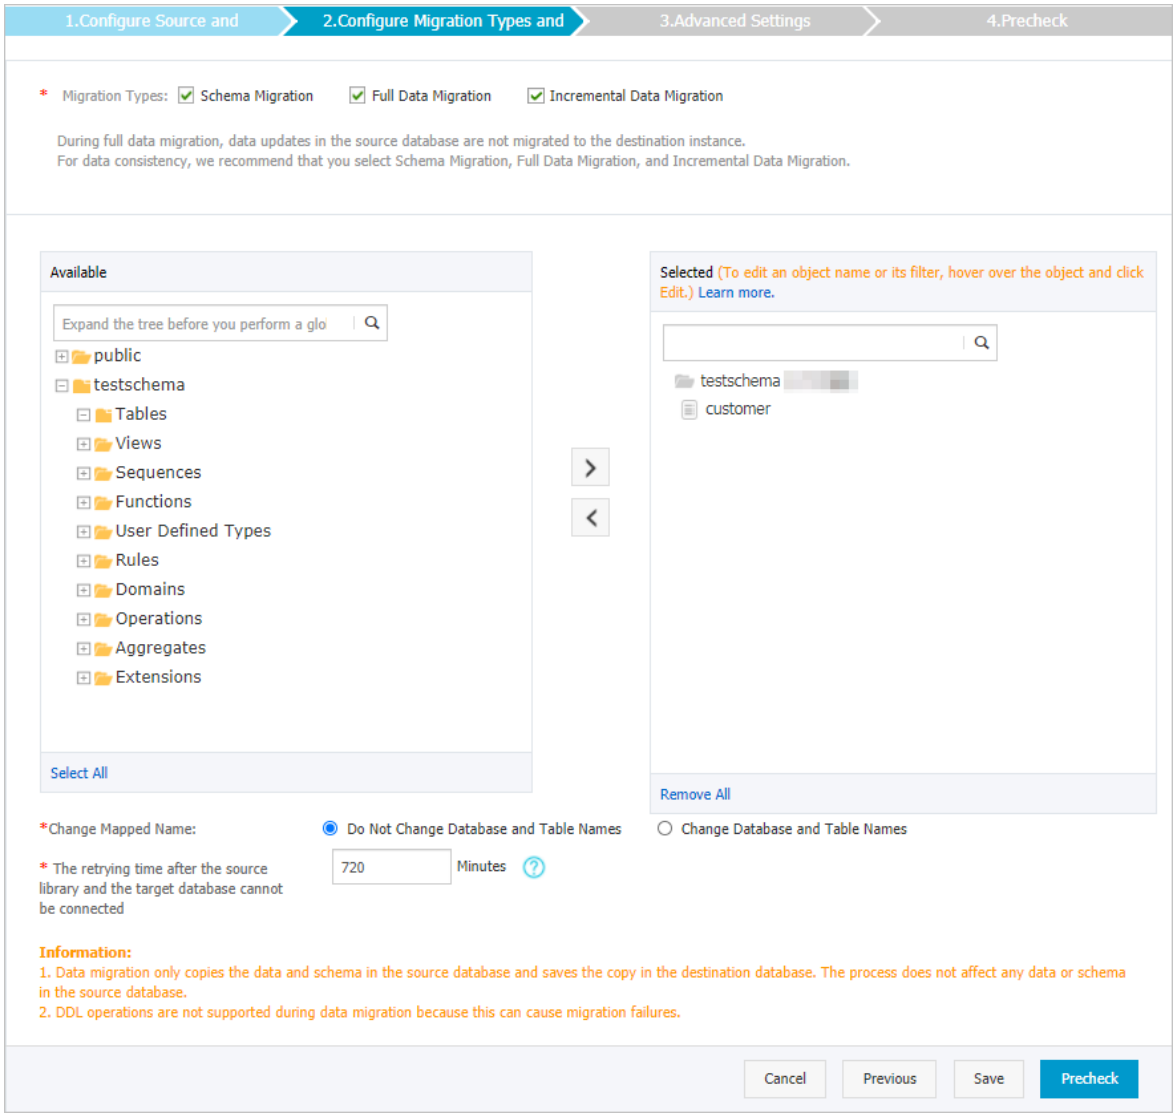
1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Configure the source and destination databases.



Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select **RDS Instance**.
	Instance Region	Select the region where the source ApsaraDB RDS for PostgreSQL instance resides.
	RDS Instance ID	Select the ID of the source ApsaraDB RDS for PostgreSQL instance.
	Database Name	Enter the name of the source database.
	Database Account	Enter the database account of the source ApsaraDB RDS for PostgreSQL instance. The account must have the read and write permissions on the source database.
	Database Password	Enter the password of the source database account.
	Instance Type	Select **RDS Instance**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	RDS Instance ID	Select the ID of the destination ApsaraDB RDS for PostgreSQL instance.

Section	Parameter	Description
Destination Database	Database Name	Enter the name of the destination database. **Note** The name of the destination database can be different from the name of the source database.
	Database Account	Enter the database account of the destination ApsaraDB RDS for PostgreSQL instance. The account must have the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Select the migration types and the objects to be migrated.



Setting	Description
Select the migration types	◦ To perform only full data migration, select **Schema Migration** and **Full Data Migration**. ◦ To ensure service continuity during data migration, select **Schema Migration**, **Full Data Migration**, and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.
Select the objects to be migrated	Select objects from the **Available** section and click the icon to move the objects to the **Selected** section. **Note** ◦ You can select columns, tables, or databases as the objects to be migrated. ◦ By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. ◦ If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

6. In the lower-right corner of the page, click **Precheck**.

   Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. After the task passes the precheck, click **Next**.

   Note If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.11. Migrate data between PolarDB clusters

This topic describes how to migrate data between PolarDB clusters by using Data Transmission Service (DTS).

Prerequisites

.

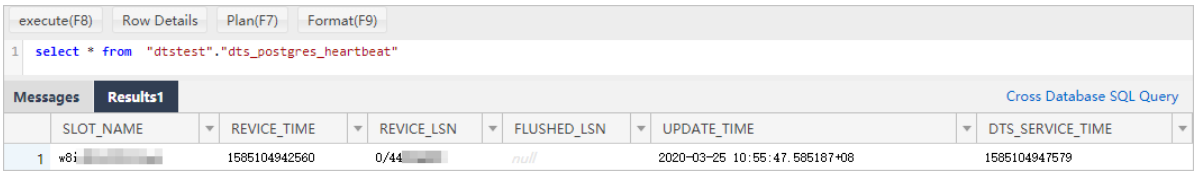
The tables to be migrated from the source PolarDB cluster contain primary keys or UNIQUE NOT NULL indexes.

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the loads of the database servers. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- A single data migration task can migrate data from only one database. To migrate data from multiple databases, you must create a data migration task for each database.
- If you select a schema as the object to be migrated and create a table in the schema or run the RENAME command to rename the table, you must run the `ALTER TABLE schema.table REPLICA IDENTITY FULL;` command before you write data to the table.

  > **Note** Replace the `schema` and `table` in the preceding sample command with the actual schema name and table name.

- To ensure that the delay time of data migration is accurate, DTS adds a heartbeat table named `dts_postgres_heartbeat` to the source database. The following figure shows the schema of the heartbeat table.



- If a data migration task fails, DTS automatically resumes the task. Before you switch your workloads to the destination database, stop or release the data migration task. Otherwise, the data from the source database will overwrite the data in the destination database after the task is resumed.

Migration types

Migration type	Description
Schema migration	DTS migrates the schemas of the required objects from the source database to the destination PolarDB cluster. DTS supports schema migration for the following types of objects: table, view, synonym, trigger, stored procedure, function, package, and user-defined type. **Notice** However, if an object contains triggers, data will become inconsistent between the source and destination databases.
Full data migration	DTS migrates historical data of the required objects from the source database to the destination PolarDB cluster. **Notice** During schema migration and full data migration, do not perform data definition language (DDL) operations on the required objects. Otherwise, the objects may fail to be migrated.

Migration type	Description
Incremental data migration	DTS retrieves redo log files from the source database. Then, DTS synchronizes incremental data from the source database to the destination PolarDB cluster. DTS can synchronize data manipulation language (DML) operations, including INSERT, UPDATE, and DELETE operations. DTS cannot synchronize DDL operations. Incremental data migration allows you to ensure service continuity when you migrate data between PolarDB clusters.

Procedure

1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select **User-Created Database with Public IP Address**. You cannot select PolarDB cluster as the instance type.
	Instance Region	If the instance type is set to **User-Created Database with Public IP Address**, you do not need to specify the **instance region**.
	Database Type	Select **PolarDB-O**.
	DNS or IP Address	The endpoint of the source PolarDB cluster.
	Port Number	Enter the service port number of the PolarDB cluster. The default port number is **3433**.
	Database Name	Enter the name of the source database.
	Database Account	Enter the initial account of the source PolarDB cluster.
	Database Password	Enter the password of the source database account. **Note** After you specify the information about the self-managed Oracle database, you can click **Test Connectivity** next to **Database Password** to check whether the information is valid. If the information is valid, the **Passed** message appears. If the **Failed** message appears, click **Check** next to **Failed**. Then, modify the information based on the check results.
	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select **PolarDB-O**.

Section	Parameter	Description
Destination Database	DNS or IP Address	The endpoint of the destination PolarDB cluster.
	Port Number	Enter the service port number of the destination PolarDB cluster. The default port number is **1433**.
	Database Name	Enter the name of the destination database.
	Database Account	Enter the database account of the destination PolarDB cluster. The account must have the read and write permissions.
	Database Password	Enter the password of the destination database account. **Note** After you specify the information about the RDS instance, you can click **Test Connectivity** next to **Database Password** to check whether the information is valid. If the information is valid, the **Passed** message appears. If the **Failed** message appears, click **Check** next to **Failed**. Then, modify the information based on the check results.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Select the migration types and the objects to be migrated.

Setting	Description
Select the migration types	◦ To perform only full data migration, select **Schema Migration** and **Full Data Migration**. ◦ To ensure service continuity during data migration, select **Schema Migration**, **Full Data Migration**, and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.

Setting	Description
Select the objects to be migrated	Select objects from the **Available** section and click the icon to move the objects to the **Selected** section. **Note** • You can select columns, tables, or databases as the objects to be migrated. • By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. • If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

6. In the lower-right corner of the page, click **Precheck**.

   Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. After the task passes the precheck, click **Next**.

   Note If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.12. Migrate data from a PolarDB cluster to a user-created Oracle database

This topic describes how to migrate data from a PolarDB cluster to a user-created Oracle database by using Data Transmission Service (DTS).

Prerequisites

The destination Oracle database is created. The schema of the Oracle database is the same as the schema of the source database in the PolarDB cluster. This is because DTS does not support schema migration from a PolarDB cluster to a user-created Oracle database.

Permissions required for database accounts

Migration types	Full data migration	Incremental data migration
Source PolarDB cluster	The read and write permissions	The read and write permissions
Destination Oracle database	The read and write permissions	The read and write permissions

Procedure

1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Configure the source and destination instances.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select **User-Created Database with Public IP Address**. You cannot select PolarDB cluster as the instance type.
	Instance Region	If the instance type is set to **User-Created Database with Public IP Address**, you do not need to specify the **instance region**.
	Database Type	Select **PolarDB-O**.
	DNS or IP Address	Enter the endpoint of the source PolarDB cluster.
	Port Number	Enter the service port number of the source PolarDB cluster. The default port number is **1521**.
	Database Name	Enter the name of the source database.
	Database Account	Enter an account that has the read and write permissions on the source database.

Section	Parameter	Description
	Database Password	Enter the password of the source database account. **Note** After you specify the information about the self-managed Oracle database, you can click **Test Connectivity** next to **Database Password** to check whether the information is valid. If the information is valid, the **Passed** message appears. If the **Failed** message appears, click **Check** next to **Failed**. Then, modify the information based on the check results.
Destination Database	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select **Oracle**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the user-created Oracle database.
	Port Number	Enter the service port number of the user-created Oracle database. The default port number is **1521**.
	Instance Type	○ **Non-RAC Instance**: If you select this option, you must specify the **SID**. ○ **RAC or PDB Instance**: If you select this option, you must specify the **Service Name**.
	Database Account	Enter an account that has the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account. **Note** After you specify the information about the RDS instance, you can click **Test Connectivity** next to **Database Password** to check whether the information is valid. If the information is valid, the **Passed** message appears. If the **Failed** message appears, click **Check** next to **Failed**. Then, modify the information based on the check results.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Select the migration types and the objects to be migrated.

Setting	Description

Setting	Description
Select the migration types	◦ To perform only full data migration, select only **Full Data Migration**. ◦ To ensure service continuity during data migration, select both **Full Data Migration** and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.
Select the objects to be migrated	Select one or more objects from the **Available** section and click the › icon to move the objects to the **Selected** section. **Note** ◦ You can select columns, tables, or databases as the objects to be migrated. ◦ By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. ◦ If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

6. In the lower-right corner of the page, click **Precheck**.

   Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. After the task passes the precheck, click **Next**.

   Note If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.13. Migrate data from a PolarDB cluster to a user-created Kafka cluster

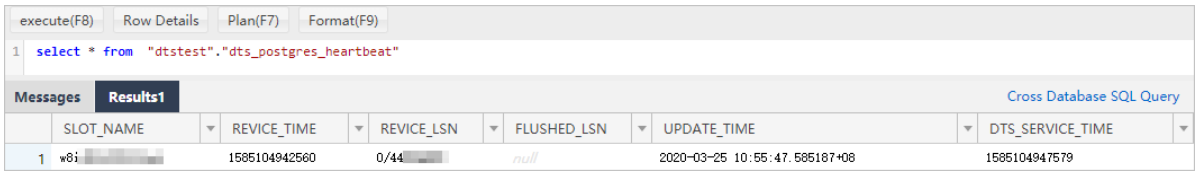
Kafka is a distributed message queue service that features high throughput and high scalability. Kafka is widely used for big data analytics such as log collection, data aggregation, streaming processing, and online and offline analysis. It is important for the big data ecosystem. This topic describes how to migrate data from a PolarDB cluster to a user-created Kafka cluster by using Data Transmission Service (DTS). The data migration feature allows you to extend message processing capabilities.

Prerequisites

The tables to be migrated from the source PolarDB cluster contain primary keys or UNIQUE NOT NULL indexes.

Precautions

- DTS can migrate only incremental data from a PolarDB cluster to a user-created Kafka cluster.
- A single data migration task can migrate data from only one database. To migrate data from multiple databases, you must create a data migration task for each database.
- To ensure that the delay time of data migration is accurate, DTS adds a heartbeat table named `dts_postgres_heartbeat` to the source database. The following figure shows the schema of the heartbeat table.



Procedure

1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Configure the source and destination instances.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select **User-Created Database with Public IP Address**. You cannot select PolarDB cluster as the instance type.
	Instance Region	If the instance type is set to **User-Created Database with Public IP Address**, you do not need to specify the **instance region**.
	Database Type	Select **PolarDB-O**.
	DNS or IP Address	Enter the endpoint of the source PolarDB cluster.
	Port Number	Enter the service port number of the source PolarDB cluster. The default port number is **1521**.
	Database Name	Enter the name of the source database.
	Database Account	Enter the privileged account of the source PolarDB cluster.

Section	Parameter	Description
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select **Kafka**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the Kafka cluster. In this example, enter the public IP address.
	Port Number	Enter the service port number of the Kafka cluster. The default port number is 9092.
	Database Account	Enter the username that is used to log on to the Kafka cluster. If no authentication is enabled for the Kafka cluster, you do not need to enter the username.
	Database Password	Enter the password of the database account. If no authentication is enabled for the Kafka cluster, you do not need to enter the password.
	Topic	Click **Get Topic List**, and select a topic name from the drop-down list.
	Kafka Version	Select the version of the user-created Kafka cluster. **Note** You cannot select Kafka 2.0 in the DTS console. If you are using Kafka 2.0, you must select Kafka 1.0.
	Encryption	Select **Non-encrypted** or **SCRAM-SHA-256** based on your business and security requirements.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Select the migration type and the objects to be migrated.

Setting	Description
Select the migration type	Select **Incremental Data Migration**.
Select the objects to be migrated	Select one or more tables from the **Available** section and click the icon to move the tables to the **Selected** section. You can select only tables as the objects to be migrated.

6. In the lower-right corner of the page, click **Precheck**.

Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. After the task passes the precheck, click **Next**.

> **Note** If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.14. Migrate data between user-created Redis databases

This topic describes how to migrate data between user-created Redis databases by using Data Transmission Service (DTS).

Prerequisites

- The version of the source Redis database is 2.8, 3.0, 3.2, 4.0, or 5.0.
- The source Redis database uses the standalone architecture rather than the cluster architecture.
- The `PSYNC` or `SYNC` command can be executed on the source Redis database.

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the loads of the database servers. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- If the data eviction policy (`maxmemory-policy`) of the destination database is not set to `noeviction` , data may become inconsistent between the source and destination databases. For more information, see Eviction policies.
- If you run the EVAL or EVALSHA command to call Lua scripts, DTS cannot identify whether these Lua scripts are executed on the destination database. During incremental data migration, the destination database does not explicitly return the execution results of Lua scripts.
- When you run the `PSYNC` or `SYNC` command to transmit data of the LIST type, DTS does not perform the `flush` operation on the existing data. Therefore, the destination database may contain duplicate data records.
- Migration latency is the difference between the timestamp of the latest migrated data in the destination database and the current timestamp in the source database. If no data manipulation language (DML) operations are performed on the source database for a long time, the migration latency displayed in the DTS console may be inaccurate. If the latency of the migration task is too high, you can perform a DML operation on the source database to update the latency.

> **Note** If you select an entire database as the object to be migrated, you can create a heartbeat table. The heartbeat table is updated or receives data every second.

Migration types

- Full data migration: DTS migrates historical data of the required objects from the source database to the destination database.
- Incremental data migration: DTS migrates incremental data from the source database to the destination database in real time.

Operations that can be synchronized during incremental data migration

- APPEND
- BITOP, BLPOP, BRPOP, and BRPOPLPUSH
- DECR, DECRBY, and DEL

- EVAL, EVALSHA, EXEC, EXPIRE, and EXPIREAT
- FLUSHALL and FLUSHDB
- GEOADD and GETSET
- HDEL, HINCRBY, HINCRBYFLOAT, HMSET, HSET, and HSETNX
- INCR, INCRBY, and INCRBYFLOAT
- LINSERT, LPOP, LPUSH, LPUSHX, LREM, LSET, and LTRIM
- MOVE, MSET, MSETNX, and MULTI
- PERSIST, PEXPIRE, PEXPIREAT, PFADD, PFMERGE, PSETEX, and PUBLISH
- RENAME, RENAMENX, RESTORE, RPOP, RPOPLPUSH, RPUSH, and RPUSHX
- SADD, SDIFFSTORE, SELECT, SET, SETBIT, SETEX, SETNX, SETRANGE, SINTERSTORE, SMOVE, SPOP, SREM, and SUNIONSTORE
- ZADD, ZINCRBY, ZINTERSTORE, ZREM, ZREMRANGEBYLEX, ZUNIONSTORE, ZREMRANGEBYRANK, and ZREMRANGEBYSCORE

Before you begin

To ensure that incremental data migration tasks run as expected, we recommend that you remove the limit on the replication output buffer for the source database. This topic uses a Linux server as an example.

> **Note** If you perform only full data migration, skip the following steps.

1. Use the redis-cli program to connect to the source database.

   > **Note** You can use the redis-cli program after you install the Redis client. For more information, see Redis community official website.

   ```
   redis-cli -h <host> -p <port> -a <password>
   ```

   > **Note**
   > - <host>: the endpoint that is used to connect to the source database. You can use 127.0.0.1 in this example.
   > - <port>: the service port number of the source database. The default port number is 6379.
   > - <password>: the password of the source database.

   Example:

   ```
   redis-cli -h 127.0.0.1 -p 6379 -a Test123456
   ```

2. Run the following command to remove the limit on the replication output buffer:

   ```
   config set client-output-buffer-limit 'slave 0 0 0'
   ```

Procedure

1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Configure a task name.

   DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
4. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	If the instance type is set to **User-Created Database with Public IP Address**, you do not need to specify the **instance region**.
	Database Type	Select **Redis**.
	Instance Mode	The value of this parameter is set to **Standalone** and cannot be changed to Cluster.
	Hostname or IP Address	Enter the endpoint that is used to connect to the source database.
	Port Number	Enter the service port number of the source database. The default port number is **6379**.
	Database Password	Enter the password of the source database. If password verification is disabled for the source database, you do not need to enter the password. **Note** After you specify the source database parameters, click **Test Connectivity** next to **Database Password** to verify whether the specified parameters are valid. If the specified parameters are valid, the **Passed** message appears. If the **Failed** message appears, click **Check** next to **Failed**. Modify the source database parameters based on the check results.
Destination Database	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select **Redis**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the destination database.
	Port Number	Enter the service port number of the destination database. The default port number is **6379**.

Section	Parameter	Description
	Database Password	Enter the password of the destination database. If password verification is disabled for the destination database, you do not need to enter the password. **Note** After you specify the destination database parameters, click **Test Connectivity** next to **Database Password** to verify whether the specified parameters are valid. If the specified parameters are valid, the **Passed** message appears. If the **Failed** message appears, click **Check** next to **Failed**. Modify the destination database parameters based on the check results.

5. In the lower-right corner of the page, click **Set Whitelist and Next**.
6. If a whitelist is configured for the user-created Redis database, you must manually add the CIDR blocks of DTS servers to the whitelist of the database. To obtain the CIDR blocks of DTS servers, click **Copy to Clipboard** in the dialog box that appears. After you add the CIDR blocks of DTS servers to the whitelist of the database, click **Next**.

   Note If you do not need to configure a whitelist for the user-created Redis database, ignore the preceding settings and click **Next**.

7. Select the migration types and the objects to be migrated.

Setting	Description
Select the migration types	○ To perform only full data migration, select only **Full Data Migration**. ○ To ensure service continuity during data migration, select both **Full Data Migration** and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.

Setting	Description
Select the objects to be migrated	Select one or more objects from the **Available** section and click the icon to move the objects to the **Selected** section. **Note** • You can select columns, tables, or databases as the objects to be migrated. • By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. • If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

8. In the lower-right corner of the page, click **Precheck**.

   Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. After the task passes the precheck, click **Next**.

   Note If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.15. Migrate data between user-created MongoDB databases

This topic describes how to migrate data between user-created MongoDB databases by using Data Transmission Service (DTS).

Prerequisites

The version of the source MongoDB database is 3.0, 3.2, 3.4, 3.6, 4.0, or 4.2.

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the loads of the database servers. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- If you need to migrate incremental data from a standalone MongoDB database, you must enable oplog. A standalone MongoDB database contains only a primary node. For more information, see Preparation for a standalone MongoDB database.
- If the source database uses the sharded cluster architecture, you must configure a data migration task for each shard.

Migration types

Migration type	Description
Full data migration	DTS migrates historical data of the required objects from the source database to the destination database. **Note** The following types of objects are supported: database, collection, and index.
Incremental data migration	After full data migration is complete, DTS migrates incremental data from the source database to the destination database in real time. **Note** • The create and delete operations that are performed on databases, collections, and indexes can be migrated. • The create, delete, and update operations that are performed on documents can be migrated.

Preparation for a standalone MongoDB database

If you need to migrate incremental data from a standalone MongoDB database, you must enable oplog. A standalone MongoDB database contains only a primary node. If you do not need to perform incremental data migration, skip the following steps.

Note To enable oplog, you must restart the MongoDB service. We recommend that you enable oplog during off-peak hours.

1. Use Mongo Shell to connect to the source database.
2. Run the following commands to shut down the MongoDB service:

```
use admin
db.shutdownServer()
```

3. Run the following command to start the MongoDB service from the backend as a replica set:

```
mongod --port 27017 --dbpath /var/lib/mongodb --logpath /var/log/mongodb/mongod.log --replSet rs0
--bind_ip 0.0.0.0 --auth --fork
```

> **Note**
> - The database path used by the preceding command is */var/lib/mongodb*. The log file path is */var/log/mongodb/mongod.log*. You must specify the paths based on your needs.
> - The command uses `0.0.0.0` as the associated IP address of the MongoDB service. This allows you to access the database by using all IP addresses. After the migration is complete, run the `kill` command to end the process, and start the MongoDB service by using the original configuration file.
> - The command enables authentication. You can access the database only after you pass the authentication.

4. Use Mongo Shell to connect to the source database again.
5. Run the following commands to initialize the replica set:

```
use admin
rs.initiate()
```

6. Wait until the role of the current node changes to primary, which indicates that oplog is enabled.

> **Note** You can run the `rs.printReplicationInfo()` command to view the status of oplog.

Procedure

1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	If the instance type is set to **User-Created Database with Public IP Address**, you do not need to specify the **instance region**.
	Database Type	Select **MongoDB**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the source database.
	Port Number	Enter the service port number of the source database.
	Database Name	Enter the name of the authentication database. The database account is created in this database.
	Database Account	Enter the account of the source database. The account must have the read permissions on the source database, admin database, and local database.

Section	Parameter	Description
	Database Password	Enter the password of the source database account. **Note** After you specify the source database parameters, click **Test Connectivity** next to **Database Password** to verify whether the specified parameters are valid. If the specified parameters are valid, the **Passed** message appears. If the **Failed** message appears, click **Check** next to **Failed**. Modify the source database parameters based on the check results.
Destination Database	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select **MongoDB**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the destination database.
	Port Number	Enter the service port number of the destination database.
	Database Name	Enter the name of the authentication database. The database account is created in this database. **Note** If the database account is root, enter admin.
	Database Account	Enter the account of the destination database. The account must have the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account. **Note** After you specify the destination database parameters, click **Test Connectivity** next to **Database Password** to verify whether the specified parameters are valid. If the specified parameters are valid, the **Passed** message appears. If the **Failed** message appears, click **Check** next to **Failed**. Modify the destination database parameters based on the check results.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. If a whitelist is configured for the user-created MongoDB database, you must manually add the CIDR blocks of DTS servers to the whitelist of the database. To obtain the CIDR blocks of DTS servers, click **Copy to Clipboard** in the dialog box that appears. After you add the CIDR blocks of DTS servers to the whitelist of the database, click **Next**.

   Note If you do not need to configure a whitelist for the user-created MongoDB database, ignore the preceding settings and click **Next**.

6. Select the migration types and the objects to be migrated.

Setting	Description
Select the migration types	◦ To perform only full data migration, select only **Full Data Migration**. ◦ To ensure service continuity during data migration, select both **Full Data Migration** and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.
Select the objects to be migrated	Select one or more objects from the **Available** section and click the › icon to move the objects to the **Selected** section. **Note** ◦ You can select columns, tables, or databases as the objects to be migrated. ◦ By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. ◦ If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

7. In the lower-right corner of the page, click **Precheck**.

   Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the ⓘ icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

8. After the task passes the precheck, click **Next**.

   Note If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.4. Manage data migration tasks

18.1.3.4.1. Object name mapping

Data Transmission Service (DTS) provides the object name mapping feature. You can use this feature to change the names of one or more objects that are migrated to the destination instance. This topic describes how to use the object name mapping feature when you configure a data migration task.

Limits

You can use the object name mapping feature only when a data migration task is configured and the current step is **Configure Migration Types and Objects**.

> **Note** Do not use the object name mapping feature after a data migration task is started. Otherwise, data may fail to be migrated.

Procedure

1. In the **Configure Migration Types and Objects** step, move the required objects to the **Selected** section, move the pointer over a database or table, and then click **Edit**.
2.
3.
4.

18.1.3.4.2. Specify an SQL condition to filter data

This topic describes how to specify an SQL condition to filter the data of a specific table when you configure a data migration task.

The SQL condition takes effect only within the table that you select. DTS migrates only the data that meets the SQL condition to the destination database. This feature is applicable to scenarios such as regular data migration and table partitioning.

Limits

An SQL condition applies only to full data migration. If you select **incremental data migration** as the migration type, the SQL condition does not filter incremental data.

Specify an SQL condition

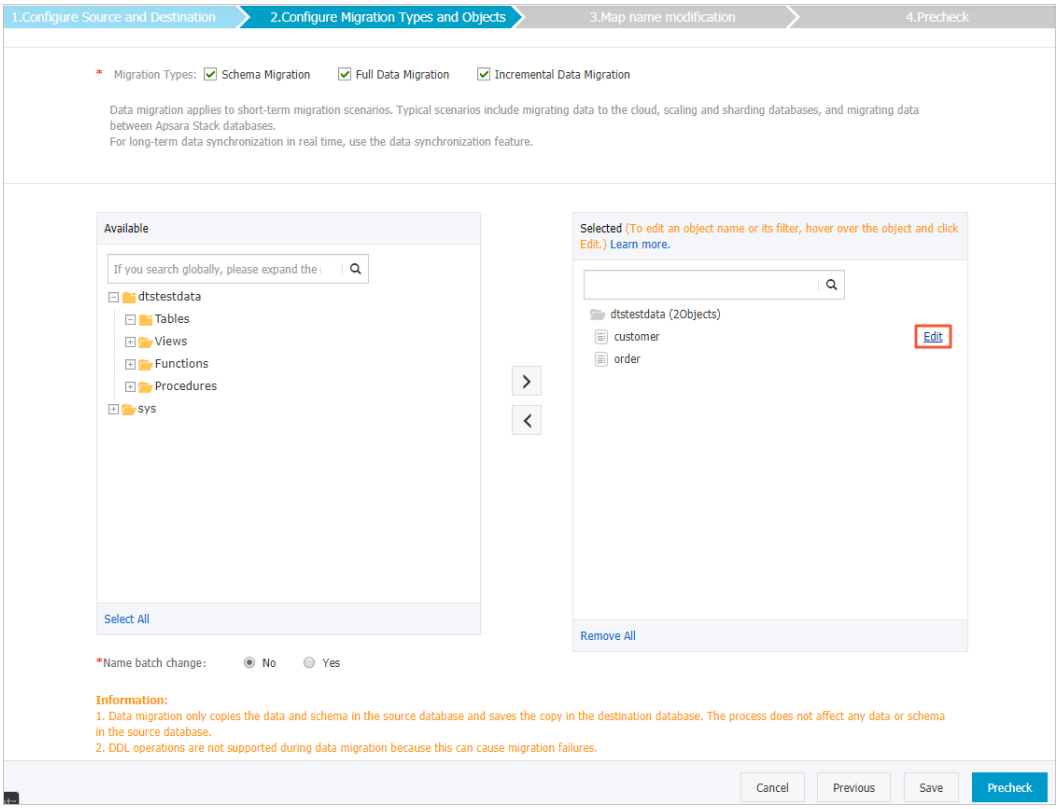
You can specify an SQL condition in the **Configure Migration Types and Objects** step when you configure a data migration task.

To filter the data of a specific table by using an SQL condition, you must select the table as the object that you want to migrate. You cannot select a database as the object. To specify an SQL condition, perform the following steps.

Procedure

1. In the **Configure Migration Types and Objects** step, move the pointer over a table in the **Selected** section. The **Edit** button appears, as shown in Edit button.

   Edit button



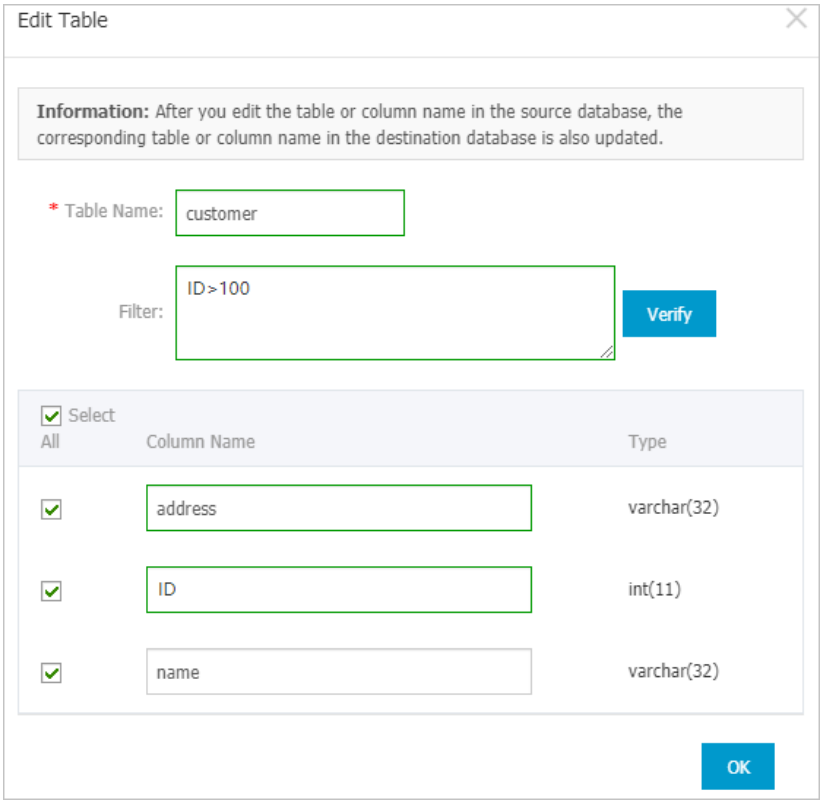
2. Click **Edit**. The Edit Table dialog box appears.

Modify an SQL condition

The SQL conditions in DTS are the same as the standard SQL WHERE conditions for databases. You can use SQL conditions to perform operations and run basic functions.

Enter an SQL condition in the text box. For example, you can enter id>1000 to migrate the records whose IDs are greater than 1,000 to the destination instance, as shown in Modify an SQL condition.

Modify an SQL condition



After the SQL condition is specified, click **OK**.

18.1.3.4.3. Troubleshoot a failed data migration task

This topic describes how to troubleshoot a failed data migration task. You can use this feature if your data migration task is in the **Migration Failed** state during schema migration or full data migration.

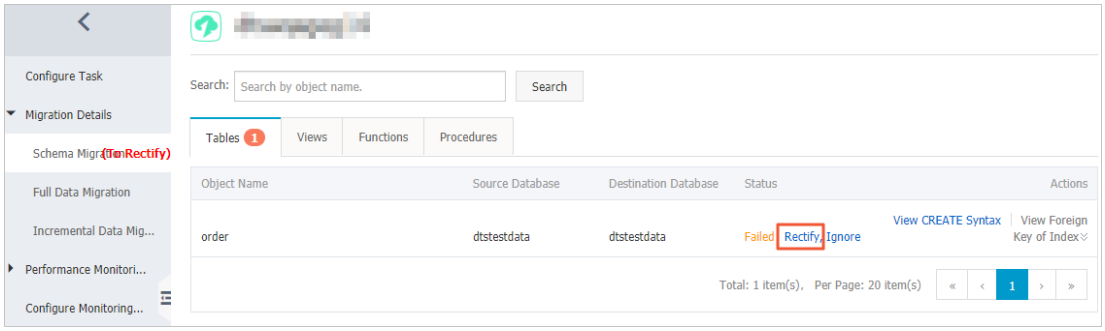
Troubleshoot a failed task during schema migration

DTS supports data migration between heterogeneous data sources. However, if you migrate data of unsupported types to the destination instance during schema migration, the task may fail.

1. Log on to the DTS console.
2. In the left-side navigation pane, click **Data Migration**.
3. Use one of the following methods to troubleshoot the failed task:
   - Method 1
     a. Find the task and click **View Cause and Rectify**.

     b. Troubleshoot the issue based on the cause that is displayed in the View Cause and Rectify message. For example, you can troubleshoot an issue by modifying the schema syntax.
     c. Click **Restart Task**.
   - Method 2
     a. Click the instance ID or task name.
     b. In the left-side navigation pane, choose **Migration Details > Schema Migration**.

c. On the **Schema Migration** page, find the object that causes the migration failure and click **Rectify** in the Status column.



d. Troubleshoot the issue based on the cause that is displayed in the **Rectify** dialog box. For example, you can troubleshoot an issue by modifying the schema syntax.

e. Click **Rectify**.

> **Note**
> - If the failure persists, the **Rectify** dialog box does not close and shows the failure cause. You must continue troubleshooting based on the failure cause until the troubleshooting is successful.
> - If the troubleshooting is successful, the **Schema Migration** page appears and the status of the object changes to **Finished**.

4. If no objects are in the Failed state, DTS proceeds with the data migration task, for example, entering the full data migration process.

Troubleshoot a failed task during full data migration

1. Log on to the DTS console.
2. In the left-side navigation pane, click **Data Migration**.
3. Find the task and click **View Cause and Rectify**.

   DTS allows you to troubleshoot a task that fails during full data migration due to the following reasons.

   > **Note** If a task fails during full data migration due to other reasons, DTS provides only the **Ignore** option. The object that causes the failure is not migrated to the destination database.

   - The connection to the source or destination database failed or timed out.

     Troubleshoot the issue, make sure that the connection is successful, and then click **Restart Task**.
   - The storage space of the destination instance is insufficient or the instance is locked.

     Upgrade the specification of the destination instance or clear the log space, and then click **Restart Task**.
   - MyISAM tables in the source database are corrupted.

     Troubleshoot the issue in the source database, and then click **Restart Task**.
4. In the dialog box that appears, troubleshoot the issue based on the failure cause.
5. Click **Restart Task**.

18.1.3.5. Precheck items

18.1.3.5.1. Source database connectivity

DTS checks whether DTS servers can connect to the source database. DTS creates a connection to the source database by using the JDBC protocol. If the connection fails, the data migration task fails to pass the connectivity check.

The migration task may fail to pass the connectivity check because of the following reasons:

- The database account or password that is specified in the data migration task is invalid.

  Troubleshooting:

  Find a server that can connect to the source database. On the server, enter the database account and password that are specified in the data migration task to check whether the account and password are valid. If the database account or password is invalid, the following error message is displayed: Access deny.

  Solution:

  Log on to the DTS console, modify the database account and password, and then run a precheck again.

- The DTS servers are disallowed to access the source database.

  Troubleshooting:

  - Find a server that can connect to the source database. On the server, enter the database account and password that are specified in the data migration task to check whether the connection is successful. Only authorized DTS servers can connect to the source database. If the CIDR block of a DTS server is not included in the whitelist of the source database, the DTS server cannot connect to the source database.
  - If the source database is a MySQL database, use a MySQL client to connect to the database and run the `SELECT HOST FROM mysql.user WHERE user='Account', password='Password';` command. If the CIDR blocks of DTS servers are not included in the whitelist of the source database, the query result of the preceding command is not %.

  Solution:

  - If the source database is a MySQL database, run the `GRANT ALL ON . TO 'Account'@''%' IDENTIFIED BY 'Password';` command to authorize the database account. Replace Account and Password in the preceding command with your database account and password. After the account is authorized, run a precheck again.

- A firewall is configured on the source database server.

  Troubleshooting: If the server where the source database resides runs Linux, run the `iptables -L` command in the shell to check whether a firewall is configured for the server. If the server where the source database resides runs Windows, find Windows Defender Firewall from the Control Panel and check whether a firewall is configured for the server.

  Solution:

  Disable the firewall and run a precheck again.

- The network between DTS servers and the source database is unavailable.

  If the failure persists, you can check whether the network between DTS servers and the source database is available. In this case, we recommend that you contact Alibaba Cloud engineers by submitting a ticket.

18.1.3.5.2. Check the destination database connectivity

This check item checks whether the DTS server can connect to the destination database for migration. DTS creates a connection to the destination database by using the JDBC protocol. If the connection fails, the check item fails.

The destination database connectivity precheck may fail for the following reasons:

- An incorrect account or password is provided when a migration task is created.

  Diagnostics:

On any network-ready server that can connect to the destination database, use the account and password specified for creating the migration task to connect to the destination database through client software. Check whether the connection succeeds. If an error is reported for the connection and the error message contains Access deny, the account or password is incorrect.

Troubleshooting:

Modify the migration task in the DTS console, correct the account and password, and perform the precheck again.

- There is no connectivity between the DTS server and destination database.

  If you check that the password and account are correct, the check item may fail because there is no connectivity between the DTS server and the destination database. In this case, contact the DTS engineers on duty.

18.1.3.5.3. Binary logging configurations of the source database

Whether binary logging is enabled in the source database

This item is checked only when you migrate incremental data between MySQL databases. DTS checks whether binary logging is enabled in the source database. If binary logging is disabled in the source database, the check result is Failed.

Troubleshooting: Run the `log_bin=mysql_bin` command to modify the configuration file of the source database. Restart the source database and run a precheck again.

Binary log format of the source database

This item is checked only when you migrate incremental data between MySQL databases. DTS checks whether the binary log format is set to ROW in the source database. If the binary log format is not set to ROW in the source database, the check result is Failed.

Troubleshooting: Run the `set global binlog_format=ROW` command in the source database and run a precheck again. We recommend that you restart the MySQL process. Otherwise, data loss may occur because sessions will continue to be written in a non-ROW mode.

Binary log files in the source database

This item is checked only when you migrate incremental data between MySQL databases. DTS checks whether specific binary log files are removed from the source database. If binary log files in the source database are incomplete, the check result is Failed.

Troubleshooting: Run the `PURGE BINARY LOGS TO 'The name of the first binary log file that is not deleted'` command in the source database and run a precheck again.

To find the binary log files that are removed from the source database, click the info icon next to the failed item. In the **View Details** dialog box, the names of deleted binary log files are displayed.

Parameter binlog_row_image of the source database

This item is checked only when you migrate incremental data between MySQL databases. DTS checks whether the value of the binlog_row_image parameter in the source database is set to FULL. This parameter indicates whether the full image is recorded. If the full image is not recorded in binary log files of the source database, the check result is Failed.

Troubleshooting: Run the `set global binlog_row_image=FULL` command in the source database and run a precheck again.

18.1.3.5.4. Integrity of the FOREIGN KEY constraints

DTS checks whether the parent table on which a child table depends is included in the selected objects. The precheck allows DTS to protect the integrity of the FOREIGN KEY constraints.

If the parent table on which a child table depends is not included in the selected objects, the check result is Failed.

Troubleshooting:

- Do not migrate the child tables that cause the check failure. To do this, remove these child tables from the selected objects and run a precheck again.
- Migrate the parent tables rather than the child tables. To do this, add the parent tables to the selected objects and run a precheck again.
- Delete the foreign key dependencies between the parent and child tables in the source database and run a precheck again.

18.1.3.5.5. Existence of FEDERATED tables

This item is checked only when you migrate incremental data between MySQL databases. DTS checks whether the source database contains storage engines that are not supported by incremental data migration. Incremental data migration does not support the FEDERATED and MRG_MyISAM storage engines.

If **the FEDERATED storage engine is used by specific tables in the source database**, the check result is Failed.

If **the MRG_MyISAM storage engine is used by specific tables in the source database**, the check result is Failed.

Solution:

Remove the tables that use the FEDERATED or MRG_MyISAM storage engine from the selected objects. Then, create a separate migration task to perform schema migration and full data migration for these tables.

18.1.3.5.6. Permissions

Source database permissions

DTS checks whether the account of the source database has the required permissions to perform data migration. For information about the permissions that are required by each type of database, see the topics about how to configure data migration tasks.

Destination database permissions

DTS checks whether the account of the destination database has the required permissions to perform data migration. For information about the permissions that are required by each type of database, see the topics about how to configure data migration tasks.

18.1.3.5.7. Object name conflict

This check item checks for duplicate object names in the destination and source database. If this check item fails, an object in the destination RDS instance has the same name as an object to be migrated. This causes the migration to fail.

When this check item fails, an error message is displayed indicating that an object in the destination database has the same name as an object to be migrated from the source database.

Troubleshooting:

- Use the database and table name mapping feature provided by DTS to migrate the object to be migrated to another object with a different name in the destination database.

- In the destination database, delete or rename the object that has the same name as the object to be migrated.
- Modify the migration task and delete that object to be migrated from the list of objects to be migrated. Do not migrate this object.

18.1.3.5.8. Schema existence

This check item checks whether the database to be migrated exists in the destination RDS instance. If no, DTS creates one automatically. However, under the following circumstances, the automatic database creation fails, and this check item prompts a failure:

- The database name contains characters other than lowercase letters, digits, underscores (_), and hyphens (-).

  The cause of the precheck failure is that the name of the **source database** does not comply with the requirements of RDS.

  Troubleshooting: On the database management page of the RDS console, create a database that complies with the requirements of RDS and grant the migration account the read and write permissions on the new database. Use the database name mapping feature provided by DTS to map the source database to the new database. Then, perform the precheck again.

- The character set of the database is not UTF8, GBK, Latin1, or UTF-8MB4.

  The cause of the precheck failure is that the character set of the **source database** does not comply with the requirements of RDS.

  Troubleshooting: On the database management page of the RDS console, create a database that complies with the requirements of RDS and grant the migration account the read and write permissions on the new database. If the new database and the database to be migrated have different names, you can use the database name mapping feature of DTS to map the database to be migrated to the new database. Then re-run the precheck.

- The migration account of the destination database has no read and write permissions on the database to be migrated.

  The cause of the precheck failure is that you are not authorized to operate on the **source database**.

  Troubleshooting: On the database management page of the RDS console, click the Account Management tab. Grant the migration account the read and write permissions on the source database. Then, perform the precheck again.

18.1.3.5.9. Value of server_id in the source database

This item is checked only when you migrate incremental data between MySQL databases. DTS checks whether the value of **server-id** in the source database is set to an integer greater than 1.

If the check result is Failed, run the `set global server_id='An integer greater than 1'` command in the source database and perform a precheck again.

18.1.3.5.10. Source database version

DTS checks whether the version of the source database is supported. The table Source database types and versions lists the source database versions that are supported by DTS.

Source database types and versions

Source database type	Supported version
MySQL	5.0, 5.1, 5.5, 5.6, and 5.7. Only 5.1, 5.5, 5.6, and 5.7 are supported for incremental data migration.

If the check result is Failed, you must upgrade or downgrade the source database to a supported version before you perform a precheck again.

18.1.3.6. Data type mappings between heterogeneous databases

Heterogeneous databases support different data types. During schema migration, Data Transmission Service (DTS) converts the data types of the source database into those of the destination database. This topic lists the data type mappings for you to evaluate the impact of data migration on your business.

Data migration from a user-created Oracle database to a user-created MySQL database or an ApsaraDB RDS for MySQL instance

Data type in the Oracle database	Data type in the MySQL database	Supported by DTS
varchar2(n [char/byte])	varchar(n)	Yes
nvarchar2[(n)]	national varchar[(n)]	Yes
char[(n [byte/char])]	char[(n)]	Yes
nchar[(n)]	national char[(n)]	Yes
number[(p[,s])]	decimal[(p[,s])]	Yes
float(p)]	double	Yes
long	longtext	Yes
date	datetime	Yes
binary_float	decimal(65,8)	Yes
binary_double	double	Yes
timestamp[(fractional_seconds_precision)]	datetime[(fractional_seconds_precision)]	Yes
timestamp[(fractional_seconds_precision)]with localtimezone	datetime[(fractional_seconds_precision)]	Yes
timestamp[(fractional_seconds_precision)]with localtimezone	datetime[(fractional_seconds_precision)]	Yes
clob	longtext	Yes
nclob	longtext	Yes
blob	longblob	Yes
raw	varbinary(2000)	Yes
long raw	longblob	Yes
bfile	N/A	No
interval year(year_precision) to month	N/A	No
interval day(day_precision)to second[(fractional_seconds_precision)]	N/A	No

Note

- A char column with a length greater than 255 bytes is converted to the varchar(n) type.
- Data types such as bfile, interval year to month, and interval day to second in Oracle databases are not supported in MySQL databases. They cannot be converted to data types supported by the destination database during schema migration.

  The schema migration fails if the table to be migrated contains these three data types. You must make sure that columns with these three data types are excluded from the objects to be migrated.
- The timestamp data type of MySQL databases does not contain the time zone information. However, the timestamp with time zone and timestamp with local time zone data types in Oracle databases provide time zone information. Therefore, DTS converts the values of these data types based on the time zone to UTC time for storage in the destination instance.

Data migration from a user-created Oracle database to a PolarDB-X instance

Oracle data type	PolarDB-X data type	Supported by DTS
varchar2(n [char/byte])	varchar(n)	Yes
nvarchar2[(n)]	national varchar[(n)]	Yes
char[(n [byte/char])]	char[(n)]	Yes
nchar[(n)]	national char[(n)]	Yes
number[(p[,s])]	decimal[(p[,s])]	Yes
float(p)]	double	Yes
long	longtext	Yes
date	datetime	Yes
binary_float	decimal(65,8)	Yes
binary_double	double	Yes
timestamp[(fractional_seconds_precision)]	datetime[(fractional_seconds_precision)]	Yes
timestamp[(fractional_seconds_precision)]with localtimezone	datetime[(fractional_seconds_precision)]	Yes
timestamp[(fractional_seconds_precision)]with localtimezone	datetime[(fractional_seconds_precision)]	Yes
clob	longtext	Yes
nclob	longtext	Yes
blob	longblob	Yes
raw	varbinary(2000)	Yes
long raw	longblob	Yes

Oracle data type	PolarDB-X data type	Supported by DTS
bfile	None	No
interval year(year_precision) to month	None	No
interval day(day_precision)to second[(fractional_seconds_precision)]	None	No

Note

- If a char field in the Oracle database is greater than 255 bytes in length, DTS converts this field to the varchar(n) type in the PolarDB-X instance.
- The timestamp data type of PolarDB-X does not contain the time zone information. However, the timestamp with time zone and timestamp with local time zone data types in Oracle databases provide the time zone information. Therefore, DTS converts the values of these data types into UTC time in the destination PolarDB-X instance.

Data migration from a user-created Oracle database to a PolarDB cluster

Oracle data type	PolarDB data type	Supported by DTS
varchar2(n [char/byte])	varchar2[(n)]	Yes
nvarchar2[(n)]	nvarchar2[(n)]	Yes
char[(n [byte/char])]	char[(n)]	Yes
nchar[(n)]	nchar[(n)]	Yes
number[(p[,s])]	number[(p[,s])]	Yes
float(p)]	double precision	Yes
long	long	Yes
date	date	Yes
binary_float	real	Yes
binary_double	double precision	Yes
timestamp[(fractional_seconds_precision)]	timestamp[(fractional_seconds_precision)]	Yes
timestamp[(fractional_seconds_precision)]with time zone	timestamp[(fractional_seconds_precision)]with time zone	Yes
timestamp[(fractional_seconds_precision)]with local time zone	timestamp[(fractional_seconds_precision)]with time zone	Yes
clob	clob	Yes
nclob	nclob	Yes
blob	blob	Yes

Oracle data type	PolarDB data type	Supported by DTS
raw	raw(size)	Yes
long raw	long raw	Yes
bfile	None	No
interval year(year_precision) to month	interval year to month	No
interval day(day_precision) to second[(fractional_seconds_precision)]	interval day to second[(fractional_seconds_precision)]	No

Note PolarDB does not support the timestamp[(fractional_seconds_precision)]with local time zone data type. DTS converts the data of this type into UTC time and then stores the data in the destination PolarDB cluster by using the timestamp[(fractional_seconds_precision)]with time zone data type.

18.1.4. Data synchronization

18.1.4.1. Database types, initial synchronization types, and synchronization topologies

You can use Data Transmission Service (DTS) to synchronize data between various data sources. This topic describes the database types, initial synchronization types, and synchronization topologies that are supported by DTS.

Source database	Destination database	Initial synchronization type	Synchronization topology
• User-created MySQL database 5.1, 5.5, 5.6, and 5.7 • RDS MySQL	User-created MySQL database 5.1, 5.5, 5.6, and 5.7	Initial schema synchronization Initial full data synchronization	One-way synchronization Two-way synchronization
	RDS MySQL 5.6 and 5.7	Initial schema synchronization Initial full data synchronization	One-way synchronization Two-way synchronization
	AnalyticDB for MySQL 2.0 and 3.0	Initial schema synchronization Initial full data synchronization	One-way synchronization

5.6 and 5.7 Source database	Destination database	Initial synchronization type	Synchronization topology
	AnalyticDB for PostgreSQL 4.3 and 6.0	Initial schema synchronization Initial full data synchronization	One-way synchronization
	Datahub	Initial schema synchronization	One-way synchronization
	MaxCompute	Initial schema synchronization Initial full data synchronization	One-way synchronization
Cloud Native Distributed Database PolarDB-X (formerly known as DRDS)	Cloud Native Distributed Database PolarDB-X	Initial full data synchronization	One-way synchronization
	Datahub	Initial schema synchronization	One-way synchronization
	AnalyticDB for MySQL 2.0 and 3.0	Initial schema synchronization Initial full data synchronization	One-way synchronization

18.1.4.2. Create a data synchronization instance

Before you configure a task to synchronize data, you must create a data synchronization instance. This topic describes how to create a data synchronization instance in the Data Transmission Service (DTS) console.

Procedure

1. Log on to the DTS console.
2. In the left-side navigation pane, click **Data Synchronization**.
3. In the upper-right corner of the page, click **Create Synchronization Task**.
4. In the Create DTS Instances dialog box, set the required parameters.

Parameter	Description
Source Instance Region	Select the region where the source instance resides.
Source Instance Type	Select the type of the source instance. ○ **MySQL**: a user-created MySQL database or an ApsaraDB RDS for MySQL instance ○ **Drds**: a Cloud Native Distributed Database PolarDB-X instance (formerly known as DRDS)

Parameter	Description
Destination Instance Region	Select the region where the destination instance resides.
Destination Instance Type	Select the type of the destination instance. ○ **MySQL**: a user-created MySQL database or an ApsaraDB RDS for MySQL instance ○ **AnalyticDB**: AnalyticDB for MySQL ○ **MaxCompute** ○ **DataHub** ○ **Drds**: a Cloud Native Distributed Database PolarDB-X instance (formerly known as DRDS) ○ **AnalyticDB for PostgreSQL**: AnalyticDB for PostgreSQL
Synchronization Mode	Two-way synchronization is available only when you select **MySQL** as the type of both the source and destination instances.
Instances to Create	Set the number of data synchronization instances that you want to create at a time. The default value is 1.

Note In the Create DTS Instances dialog box, you can view the total number of instances, the number of existing instances, and the number of instances that can be created.

5. Click **Create**.

18.1.4.3. Synchronization topologies

The data synchronization feature supports multiple types of synchronization topologies. You can select a topology for your data synchronization instances based on your business requirements. This topic describes the synchronization topologies that are supported by DTS and how to use these topologies.

One-way synchronization

To ensure data consistency for one-way synchronization, we recommend that you perform only read operations on the objects in the destination instance. Do not modify the objects.

Topology type	Topology	Description
One-way one-to-one synchronization		None

Topology type	Topology	Description
One-way one-to-many synchronization		You must purchase multiple synchronization instances to implement one-way one-to-many synchronization. For example, if you want to synchronize data from Instance A to Instance B, C, and D, you must purchase three synchronization instances.
One-way cascade synchronization		You must purchase multiple synchronization instances to implement one-way cascade synchronization. For example, if you want to synchronize data from Instance A to Instance B and then from Instance B to Instance C, you must purchase two synchronization instances.
One-way many-to-one synchronization		You must purchase multiple synchronization instances to implement one-way many-to-one synchronization. For example, if you want to synchronize data from Instance B, C, and D to Instance A, you must purchase three synchronization instances. **Note** To ensure data consistency, you must select different objects for these synchronization instances.

Two-way synchronization

DTS supports two-way data synchronization only between two MySQL databases. DTS does not support two-way data synchronization between multiple MySQL databases.

Topology type	Topology	Description

Topology type	Topology	Description
Two-way one-to-one synchronization		To ensure data consistency, make sure that records with the same primary key, business primary key, or unique key are updated only on one of the instances.

18.1.4.4. Configure data synchronization tasks

18.1.4.4.1. Configure data synchronization between ApsaraDB RDS for MySQL instances

This topic describes how to configure one-way data synchronization between ApsaraDB RDS for MySQL instances.

Prerequisites

The source and destination ApsaraDB RDS for MySQL instances are created.

Precautions

- DTS uses the read and write resources of the source and destination databases during initial full data synchronization. This may increase the load of the database server. Before you synchronize data, evaluate the impact of data synchronization on the performance of the source and destination databases. We recommend that you synchronize data during off-peak hours.
- If you select one or more tables (not a database) as the required objects, do not use gh-ost or pt-online-schema-change to perform data definition language (DDL) operations on the tables during data synchronization. Otherwise, data may fail to be synchronized.
-
- During initial full data synchronization, concurrent INSERT operations cause fragmentation in the tables of the destination instance. After initial full data synchronization, the tablespace of the destination instance is larger than that of the source instance.

Supported synchronization topologies

DTS supports one-way synchronization and two-way synchronization. For more information, see Synchronization topologies.

SQL operations that can be synchronized

Limits

- Incompatibility with triggers

  If you select a database as the object and the database contains a trigger that updates a table, data inconsistency may occur. To solve this issue, you must delete the trigger in the destination database.

- Limits on RENAME TABLE operations

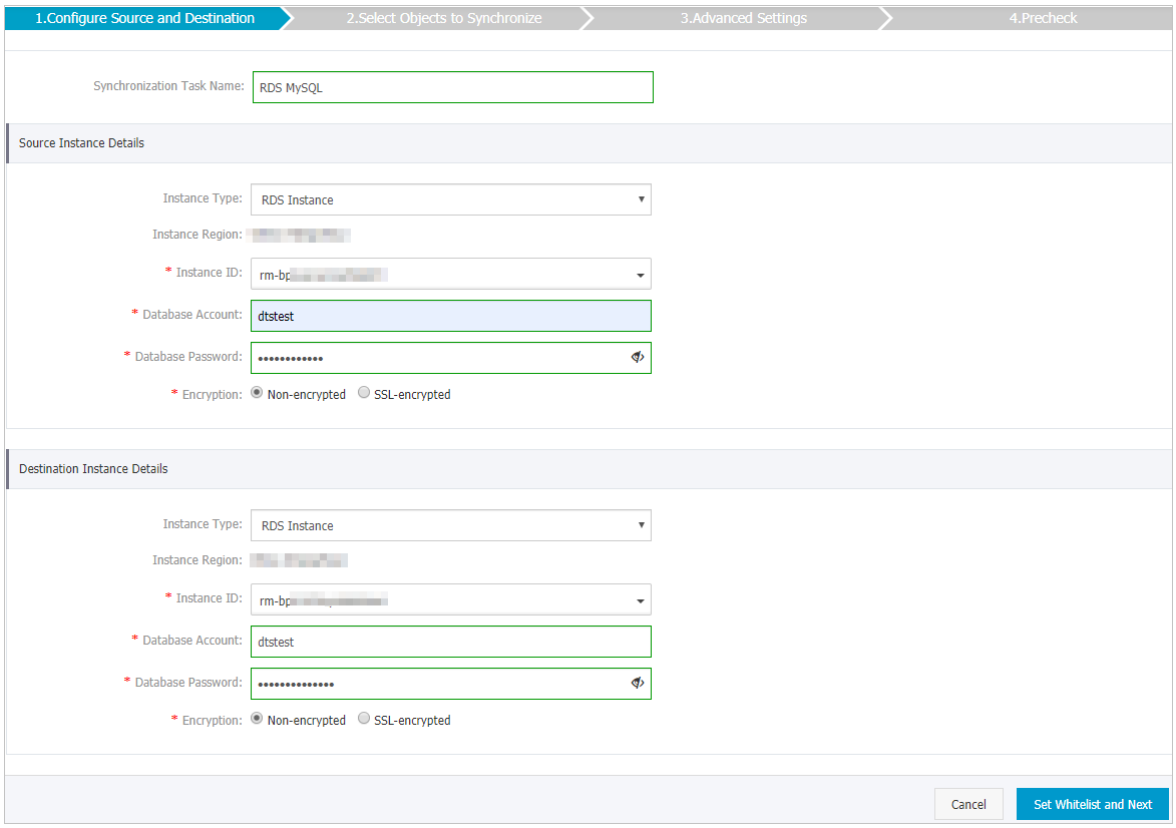
  RENAME TABLE operations may cause data inconsistency between the source and destination databases. For example, if you select a table as the object and rename the table during data synchronization, the data of this table is not synchronized to the destination database. To avoid this situation, you can select the database to which this table belongs as the object when you configure the data synchronization task.

Procedure

1. Create a data synchronization instance.

   > **Note** When you create the data synchronization instance, set both Source Instance Type and Destination Instance Type to **MySQL**, and set Synchronization Mode to **One-Way Synchronization**.

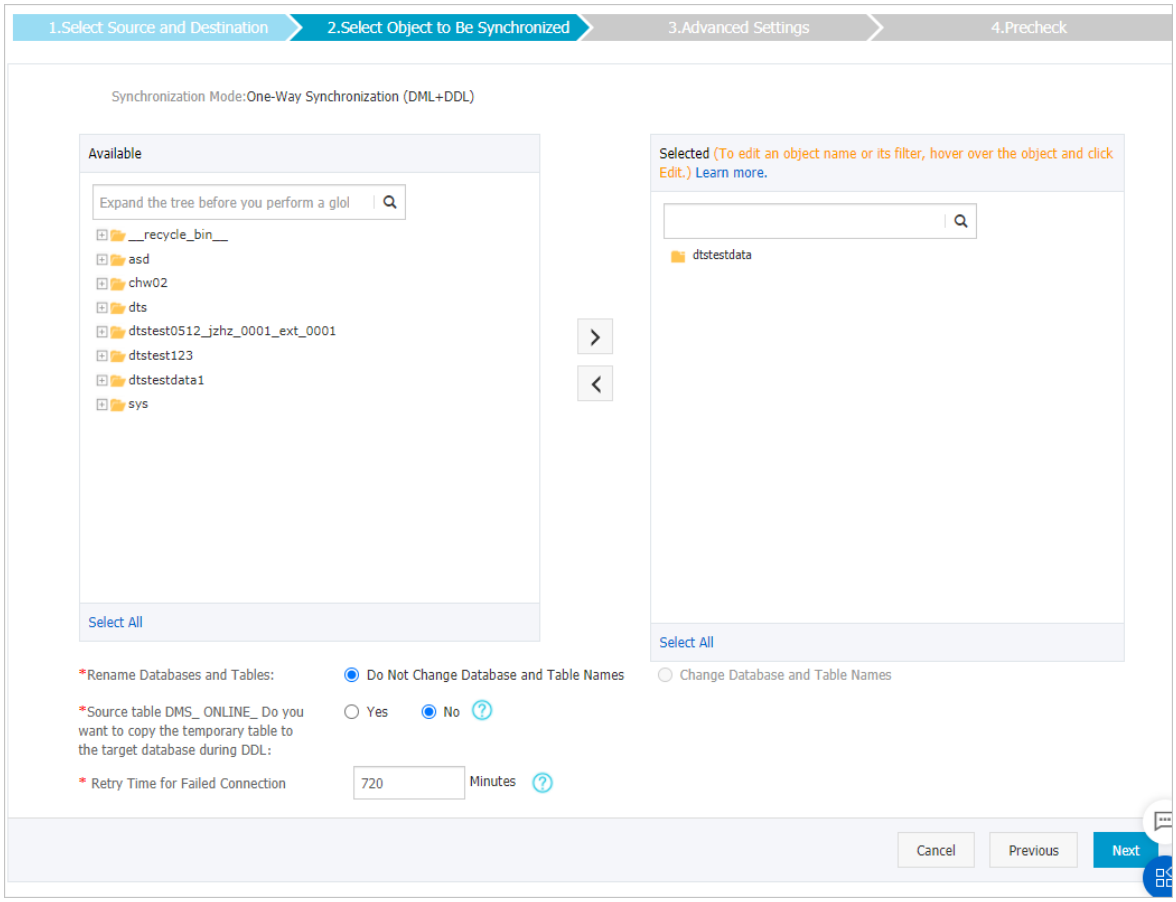
2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.
3. Configure the source and destination instances.



Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
	Instance Type	Select **RDS Instance**.

Section	Parameter	Description
Source Instance Details	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Instance ID	Select the ID of the source RDS instance.
	Database Account	Enter the database account of the source RDS instance. **Note** If the database engine of the source RDS instance is **MySQL 5.6**, you do not need to configure the **database account** or **database password**.
	Database Password	Enter the password of the source database account.
	Encryption	Select an encryption method. If you select **SSL-encrypted**, you must enable SSL encryption for the RDS instance before you configure the data synchronization task.
Destination Instance Details	Instance Type	Select **RDS Instance**.
	Instance Region	The region of the source instance. The region is the same as the destination region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Instance ID	Select the ID of the destination RDS instance.
	Database Account	Enter the database account of the destination RDS instance. **Note** If the database engine of the destination RDS instance is **MySQL 5.6**, you do not need to configure the **database account** or **database password**.
	Database Password	Enter the password of the destination database account.
	Encryption	Select an encryption method. If you select **SSL-encrypted**, you must enable SSL encryption for the RDS instance before you configure the data synchronization task.

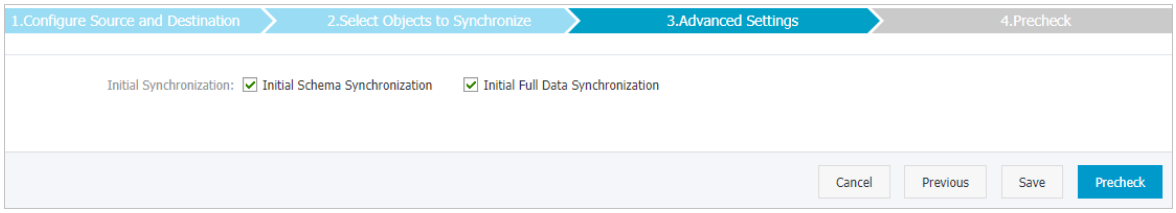
4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Select the processing mode of conflicting tables, and the objects that you want to synchronize.



Parameter	Description
Processing Mode In Existed Target Table	◦ **Pre-check and Intercept**: checks whether the destination database contains tables that have the same names as tables in the source database. If the source and destination databases do not contain identical table names, the precheck is passed. Otherwise, an error is returned during precheck and the data synchronization task cannot be started. ◦ **Ignore**: skips the precheck for identical table names in the source and destination databases. **Warning** If you select **Ignore**, data consistency is not guaranteed and your business may be exposed to potential risks. ▪ DTS does not synchronize the data records that have the same primary keys as the data records in the destination database during initial data synchronization. This occurs if the source and destination databases have the same schema. However, DTS synchronizes these data records during incremental data synchronization. ▪ If the source and destination databases have different schemas, initial data synchronization may fail. In this case, only specific columns are synchronized or the data synchronization task fails.

Parameter	Description
Select Objects	Select objects (tables or a database) from the **Available** section and click the icon to move the objects to the **Selected** section. **Note** • If you select a database as the object to be synchronized, all schema changes in the database are synchronized to the destination database. • After an object is synchronized to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are synchronized to the destination instance. For more information, see Specify the name of an object in the destination instance.

6. In the lower-right corner of the page, click **Next**.
7. Configure initial synchronization.



Note Initial synchronization includes initial schema synchronization and initial full data synchronization. If you select both **Initial Schema Synchronization** and **Initial Full Data Synchronization**, DTS synchronizes the schemas and historical data of the required objects before DTS synchronizes incremental data.

8. In the lower-right corner of the page, click **Precheck**.

Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. Close the **Precheck** dialog box after the following message is displayed: **The precheck is passed.** Then, DTS performs initial synchronization.

18.1.4.4.2. Synchronize data from an ApsaraDB RDS for MySQL instance to a MaxCompute project

MaxCompute (formerly known as ODPS) is a fast and fully managed computing platform for large-scale data warehousing. MaxCompute can process exabytes of data. This topic describes how to synchronize data from an ApsaraDB RDS for MySQL instance to a MaxCompute project by using Data Transmission Service (DTS).

Precautions

- DTS uses the read and write resources of the source and destination databases during initial full data synchronization. This may increase the load of the database server. Before you synchronize data, evaluate the impact of data synchronization on the performance of the source and destination databases. We recommend

that you synchronize data during off-peak hours.

- If you select one or more tables (not a database) as the required objects, do not use gh-ost or pt-online-schema-change to perform data definition language (DDL) operations on the tables during data synchronization. Otherwise, data may fail to be synchronized.
- You can select only tables as the objects to be synchronized.
- MaxCompute does not support the PRIMARY KEY constraint. If network errors occur, DTS may synchronize duplicate data records to MaxCompute.

SQL operations that can be synchronized

- Data definition language (DDL) operation: ADD COLUMN
- Data manipulation language (DML) operations: INSERT, UPDATE, and DELETE

Synchronization process

1. Initial schema synchronization

   DTS synchronizes the schemas of the required objects from the source database to MaxCompute. During initial schema synchronization, DTS adds the _base suffix to the end of the source table name. For example, if the name of the source table is customer, the name of the table in MaxCompute is customer_base.

2. Initial full data synchronization

   DTS synchronizes the historical data of the table from the source database to the destination table in MaxCompute. For example, the customer table in the source database is synchronized to the customer_base table in MaxCompute. The data is the basis for subsequent incremental synchronization.

   > **Note** The destination table that is suffixed with _base is known as a full baseline table.

3. Incremental data synchronization

   DTS creates an incremental data table in MaxCompute. The name of the incremental data table is suffixed with _log, for example, customer_log. Then, DTS synchronizes the incremental data that was generated in the source database to the incremental data table.

   > **Note** For more information, see Schema of an incremental data table.

Procedure

1. Create a data synchronization instance.

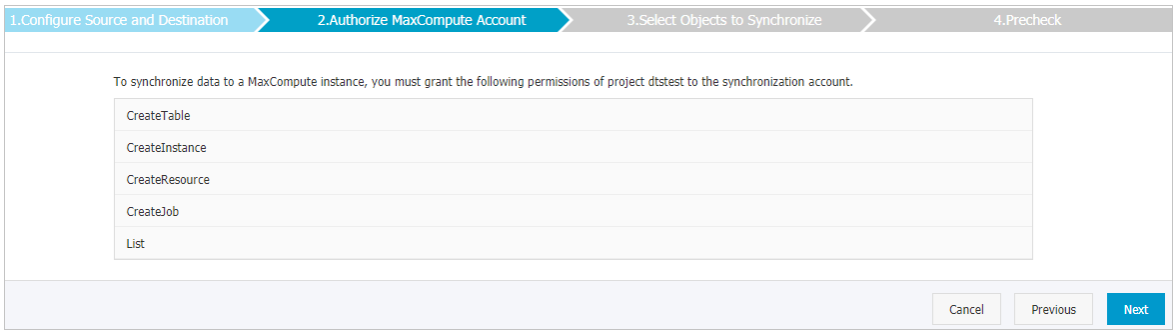
   > **Note** When you create the data synchronization instance, set Source Instance Type to **MySQL**, set Destination Instance Type to **MaxCompute**, and set Synchronization Mode to **One-Way Synchronization**.

2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.
3. Configure the source and destination instances.

Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.

Section	Parameter	Description
Source Instance Details	Instance Type	Select **RDS Instance**.
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Instance ID	Select the ID of the source RDS instance.
	Database Account	Enter the database account of the source RDS instance. **Note** If the database engine of the source RDS instance is **MySQL 5.5** or **MySQL 5.6**, you do not need to configure the **database account** or **database password**.
	Database Password	Enter the password of the source database account.
	Encryption	Select **Non-encrypted** or **SSL-encrypted**. If you select **SSL-encrypted**, you must enable SSL encryption for the RDS instance before you configure the data synchronization task.
Destination Instance Details	Instance Type	This parameter is set to **MaxCompute** and cannot be changed.
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Project	The name of the MaxCompute project.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. In the lower-right corner of the page, click **Next**. In this step, the permissions on the MaxCompute project are granted to the synchronization account.



6. Configure the synchronization policy and objects.
7. In the lower-right corner of the page, click **Precheck**.

Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

8. Close the **Precheck** dialog box after the following message is displayed: **The precheck is passed.** Then, DTS performs initial synchronization.

Schema of an incremental data table

DTS synchronizes incremental data that is generated in the source MySQL database to the incremental data table in MaxCompute. The incremental data table stores incremental data and specific metadata. The following figure shows the schema of an incremental data table.

	A	B	C	D	E	F	G	H	I	J	K	L
1	id	register_time	address	record_id	operation_flag	utc_timestamp	before_flag	after_flag	modifytime_year	modifytime_month	modifytime_day	modifytime_hour
2	10000	2018-02-03 01:38:01	[redacted]	1565[redacted]0333	U	156[redacted]655	Y	N	2019	08	16	16
3	10000	2018-02-03 01:38:01	[redacted]	1565[redacted]0333	U	156[redacted]655	N	Y	2019	08	16	16
4	9999	2016-11-18 11:44:54	[redacted]	1565[redacted]0419	D	156[redacted]845	Y	N	2019	08	16	16
5	10001	2018-12-23 05:11:59	[redacted]	1565[redacted]0435	I	156[redacted]878	N	Y	2019	08	16	16

> **Note** In the example, the `modifytime_year`, `modifytime_month`, `modifytime_day`, `modifytime_hour`, and `modifytime_minute` fields form the partition key.

The following table describes the schema of an incremental data table.

Field	Description
record_id	The ID of the incremental log entry. **Note** • The ID auto-increments for each new log entry. • If an UPDATE operation is performed, DTS generates two incremental log entries for the operation. The two incremental log entries have the same record ID.
operation_flag	The operation type. Valid values: • I: an INSERT operation. • D: a DELETE operation. • U: an UPDATE operation.
utc_timestamp	The operation timestamp. It is also the timestamp of the binary log file. The timestamp is in the UTC format.
before_flag	Indicates whether the column values are pre-update values. Valid values: Y and N.
after_flag	Indicates whether the column values are post-update values. Valid values: Y and N.

Additional information about the before_flag and after_flag fields

For different operation types, the **before_flag** and **after_flag** fields of an incremental log entry are defined as follows:

- INSERT

  For an INSERT operation, the column values are the newly inserted record values (post-update values). The value of the before_flag field is N and the value of the after_flag field is Y.

	A	B	C	D	E	F	G	H	I	J	K	L
1	id	register_time	address	record_id	operation_flag	utc_timestamp	before_flag	after_flag	modifytime_year	modifytime_month	modifytime_day	modifytime_hour
5	10001	2018-12-23 05:11:59	[redacted]	15[redacted]0435	I	156[redacted]878	N	Y	2019	08	16	16

- UPDATE

  DTS generates two incremental log entries for an UPDATE operation. The two incremental log entries have the same values for the record_id, operation_flag, and dts_utc_timestamp fields.

  The second log entry records the pre-update values, so the value of the before_flag field is Y and the value of the after_flag field is N. The second log entry records the post-update values, so the value of the before_flag field is N and the value of the after_flag field is Y.

	A	B	C	D	E	F	G	H	I	J	K	L
1	id	register_time	address	record_id	operation_flag	utc_timestamp	before_flag	after_flag	modifytime_year	modifytime_month	modifytime_day	modifytime_hour
2	10000	2018-02-03 01:38:01	[redacted]	156[redacted]00333	U	15[redacted]4655	Y	N	2019	08	16	16
3	10000	2018-02-03 01:38:01	[redacted]	156[redacted]00333	U	15[redacted]4655	N	Y	2019	08	16	16

- DELETE

  For a DELETE operation, the column values are the deleted record values (pre-update values). The value of the before_flag field is Y and the value of the after_flag field is N.

	A	B	C	D	E	F	G	H	I	J	K	L
1	id	register_time	address	record_id	operation_flag	utc_timestamp	before_flag	after_flag	modifytime_year	modifytime_month	modifytime_day	modifytime_hour
4	9999	2016-11-18 11:44:54	[redacted]	156[redacted]000419	D	156[redacted]845	Y	N	2019	08	16	16

Merge a full baseline table and incremental data table

After a data synchronization task is started, DTS creates a full baseline table and an incremental data table in MaxCompute. You can use SQL statements to merge the two tables. This allows you to obtain the full data at a specific time point.

This section describes how to merge data for the customer table. The following figure shows the schema of the customer table.

	Field	Type	Null	Key	Default	Extra
1	id	int(11)	NO	PRI	null	
2	register_time	timestamp	YES		null	
3	address	varchar(32)	YES		null	

1. Create a table in MaxCompute based on the schema of the source table. The table is used to store the merged data.

   For example, you can obtain full data of the customer table at the `1565944878` time point. Run the following SQL statements to create the required table:

   ```
   CREATE TABLE `customer_1565944878` (
       `id` bigint NULL,
       `register_time` datetime NULL,
       `address` string);
   ```

   > **Note** For more information about the data types that are supported by MaxCompute, see MaxCompute User Guide.

2. Run the following SQL statements in MaxCompute to merge the full baseline table and incremental data table and obtain full data at a specific time point:

```
set odps.sql.allow.fullscan=true;
insert overwrite table <result_storage_table>
select <col1>,
       <col2>,
       <colN>
  from(
select row_number() over(partition by t.<primary_key_column>
 order by record_id desc, after_flag desc) as row_number, record_id, operation_flag, after_flag,
<col1>, <col2>, <colN>
  from(
select incr.record_id, incr.operation_flag, incr.after_flag, incr.<col1>, incr.<col2>,incr.<colN>
  from <table_log> incr
 where utc_timestamp< <timestamp>
 union all
select 0 as record_id, 'I' as operation_flag, 'Y' as after_flag, base.<col1>, base.<col2>,base.<c
olN>
  from <table_base> base) t) gt
where record_num=1
  and after_flag='Y'
```

> **Note**
>
> - <result_storage_table>: the name of the table that stores the merged data.
> - <col1>/<col2>/<colN>: the names of the columns in the table to be merged.
> - <primary_key_column>: the name of the primary key column in the table to be merged.
> - <table_log>: the name of the incremental data table.
> - <table_base>: the name of the full baseline table.
> - <timestamp>: the timestamp that is generated when full data is obtained.

Run the following SQL statements to obtain full data of the customer table at the `1565944878` time point:

```
set odps.sql.allow.fullscan=true;
insert overwrite table customer_1565944878
select id,
       register_time,
       address
  from(
select row_number() over(partition by t.id
 order by record_id desc, after_flag desc) as row_number, record_id, operation_flag, after_flag,
id, register_time, address
  from(
select incr.record_id, incr.operation_flag, incr.after_flag, incr.id, incr.register_time, incr.ad
dress
  from customer_log incr
 where utc_timestamp< 1565944878
 union all
select 0 as record_id, 'I' as operation_flag, 'Y' as after_flag, base.id, base.register_time, bas
e.address
  from customer_base base) t) gt
 where gt.row_number= 1
   and gt.after_flag= 'Y';
```

3. Query the merged data from the customer_1565944878 table.

	A	B	C
1	id	register_time	address
2	1	2017-12-09 14:00:12	
3	2	2017-11-16 21:17:39	
4	3	2019-01-29 07:56:20	

18.1.4.4.3. Synchronize data from an ApsaraDB RDS for MySQL instance to an AnalyticDB for MySQL cluster

AnalyticDB for MySQL is a real-time online analytical processing (RT-OLAP) service that is developed by Alibaba Cloud for online data analysis with high concurrency. This topic describes how to synchronize data from an ApsaraDB RDS for MySQL instance to an AnalyticDB for MySQL cluster by using Data Transmission Service (DTS). After you synchronize data, you can use AnalyticDB for MySQL to build internal business intelligence (BI) systems, interactive query systems, and real-time report systems.

Prerequisites

- The tables that you want to synchronize from the ApsaraDB RDS for MySQL instance contain primary keys.
- The destination AnalyticDB for MySQL cluster has sufficient storage space.

Precautions

- DTS uses the read and write resources of the source and destination databases during initial full data synchronization. This may increase the load of the database server. Before you synchronize data, evaluate the impact of data synchronization on the performance of the source and destination databases. We recommend that you synchronize data during off-peak hours.
- If you select one or more tables (not a database) as the required objects, do not use gh-ost or pt-online-schema-change to perform data definition language (DDL) operations on the tables during data synchronization. Otherwise, data may fail to be synchronized.
- If the disk space usage of nodes in an AnalyticDB for MySQL cluster reaches 80%, the cluster is locked. We recommend that you estimate the required disk space based on the objects to be synchronized. You must ensure that the destination cluster has sufficient storage space.

SQL operations that can be synchronized

- Data definition language (DDL) operations: CREATE TABLE, DROP TABLE, RENAME TABLE, TRUNCATE TABLE, ADD COLUMN, and DROP COLUMN
- Data manipulation language (DML) operations: INSERT, UPDATE, and DELETE

> **Note** We recommend that you do not change the data type of fields in the source table during data synchronization. Otherwise, DTS generates an error message and stops the data synchronization task.

Data type mappings

The data types of ApsaraDB RDS for MySQL and AnalyticDB for MySQL do not have one-to-one correspondence. During initial schema synchronization, DTS converts the data types of the source database into those of the destination database. The following table lists the data types that DTS can convert.

Data type of ApsaraDB RDS for MySQL	Data type of AnalyticDB for MySQL
BIGINT UNSIGNED	DECIMAL(20,0)
BINARY	VARBINARY
BIT	VARCHAR

Data type of ApsaraDB RDS for MySQL	Data type of AnalyticDB for MySQL
BLOB	VARBINARY
CHAR	VARCHAR
DATE	DATE
DATETIME	DATETIME
DECIMAL	DECIMAL
DOUBLE	DOUBLE
ENUM	VARCHAR
FLOAT	FLOAT
GEOMETRY	VARBINARY
GEOMETRYCOLLECTION	VARBINARY
INT UNSIGNED	BIGINT
INTEGER	INT
JSON	JSON
LINESTRING	VARBINARY
LONGBLOB	VARBINARY
LONGTEXT	VARCHAR
MEDIUMBLOB	VARBINARY
MEDIUMINT	INT
MEDIUMINT UNSIGNED	INT
MEDIUMTEXT	VARCHAR
MULTILINESTRING	VARBINARY
MULTIPOINT	VARBINARY
MULTIPOLYGON	VARBINARY
NUMBERIC	DECIMAL
POINT	VARBINARY
POLYGON	VARBINARY
SET	VARCHAR
SMALLINT UNSIGNED	INT
TEXT	VARCHAR

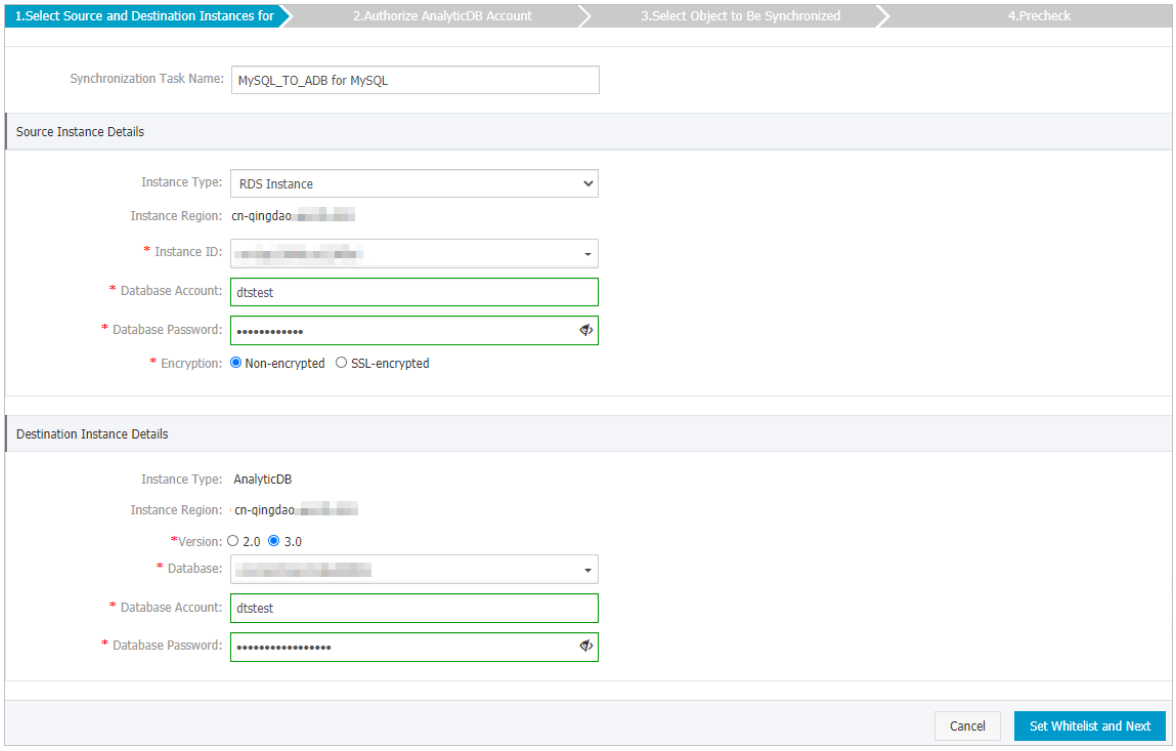
Data type of ApsaraDB RDS for MySQL	Data type of AnalyticDB for MySQL
TIME	TIME
TIMESTAMP	TIMESTAMP
TINYBLOB	VARBINARY
TINYINT UNSIGNED	SMALLINT
TINYTEXT	VARCHAR
VARBINARY	VARBINARY
VARCHAR	VARCHAR
YEAR	INT

Procedure

1. Create a data synchronization instance.

   > **Note** When you create the data synchronization instance, set Source Instance Type to **MySQL**, set Destination Instance Type to **AnalyticDB**, and set Synchronization Mode to **One-Way Synchronization**.

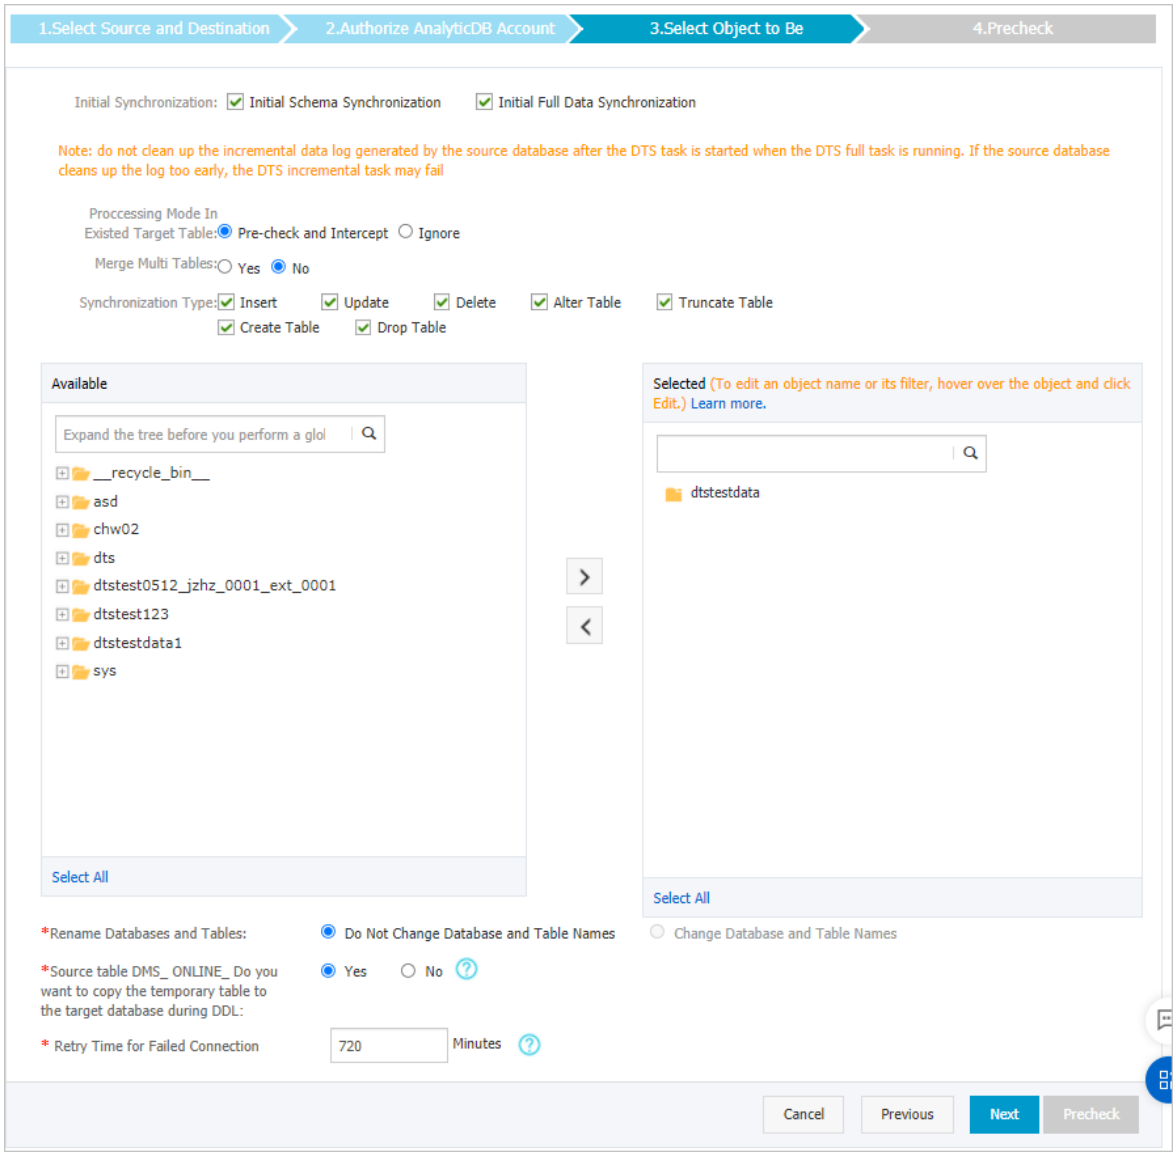
2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.
3. Configure the source and destination instances.



Section	Parameter	Description

Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Instance Details	Instance Type	Select **RDS Instance**.
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Instance ID	Select the ID of the source RDS instance.
	Database Account	Enter the database account of the source RDS instance. The account must have the REPLICATION CLIENT permission, the REPLICATION SLAVE permission, the SHOW VIEW permission, and the permission to perform SELECT operations on the required objects. **Note** If the database engine of the source RDS instance is **MySQL 5.5** or **MySQL 5.6**, you do not need to configure the **database account** or **database password**.
	Database Password	Enter the password of the source database account.
	Encryption	Select an encryption method. If you select **SSL-encrypted**, you must enable SSL encryption for the RDS instance before you configure the data synchronization task.
Destination Instance Details	Instance Type	This parameter is set to **AnalyticDB** and cannot be changed.
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Version	Select **3.0**.
	Database	Select the ID of the destination AnalyticDB for MySQL cluster.
	Database Account	Enter the database account of the destination AnalyticDB for MySQL cluster. The account must have the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Configure the synchronization policy and objects.

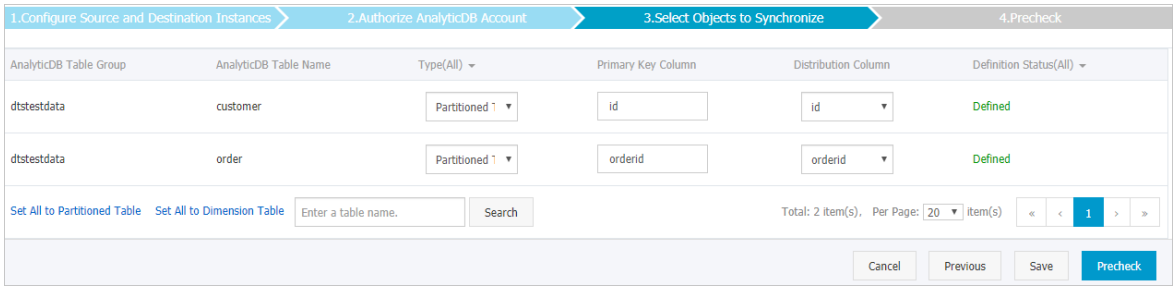


Parameter	Description
Initial Synchronization	You must select both **Initial Schema Synchronization** and **Initial Full Data Synchronization** in most cases. After the precheck, DTS synchronizes the schemas and data of the required objects from the source instance to the destination cluster. The schemas and data are the basis for subsequent incremental synchronization.

Parameter	Description
Processing Mode In Existed Target Table	◦ **Pre-check and Intercept**: checks whether the destination database contains tables that have the same names as tables in the source database. If the source and destination databases do not contain identical table names, the precheck is passed. Otherwise, an error is returned during precheck and the data synchronization task cannot be started. ◦ **Ignore**: skips the precheck for identical table names in the source and destination databases. **Warning** If you select **Ignore**, data consistency is not guaranteed and your business may be exposed to potential risks. ▪ DTS does not synchronize the data records that have the same primary keys as the data records in the destination database during initial data synchronization. This occurs if the source and destination databases have the same schema. However, DTS synchronizes these data records during incremental data synchronization. ▪ If the source and destination databases have different schemas, initial data synchronization may fail. In this case, only specific columns are synchronized or the data synchronization task fails.
Merge Multi Tables	◦ If you select **Yes**, DTS adds the `__dts_data_source` column to each table to record data sources. In this case, DDL operations cannot be synchronized. ◦ **No** is selected by default. In this case, DDL operations can be synchronized. **Note** You can merge the data source columns based on tasks rather than tables. To merge only the data source columns of specific tables, you can create two data synchronization tasks.
Synchronization Type	Select the types of operations that you want to synchronize based on your business requirements. All operation types are selected by default. **Note** Only the INSERT, UPDATE, DELETE, and ADD COLUMN operations can be synchronized.

Parameter	Description
Select Objects	Select objects (tables or a database) from the **Available** section and click the icon to move the objects to the **Selected** section. **Note** • If you select a database as the object to be synchronized, all schema changes in the database are synchronized to the destination database. • After an object is synchronized to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are synchronized to the destination instance. For more information, see Specify the name of an object in the destination instance.

6. In the lower-right corner of the page, click **Next**.
7. Specify a type for the tables that you want to synchronize to the destination database.



Note After you select **Initial Schema Synchronization**, you must specify the **type**, **primary key column**, and **partition key column** for the tables that you want to synchronize to AnalyticDB for MySQL.

8. In the lower-right corner of the page, click **Precheck**.

Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. Close the **Precheck** dialog box after the following message is displayed: **The precheck is passed.** Then, DTS performs initial synchronization.

18.1.4.4.4. Synchronize data from an ApsaraDB RDS for MySQL instance to an AnalyticDB for PostgreSQL instance

This topic describes how to synchronize data from an ApsaraDB RDS for MySQL instance to an AnalyticDB for PostgreSQL instance by using Data Transmission Service (DTS). The data synchronization feature allows you to transfer and analyze data with ease.

Prerequisites

- The tables that you want to synchronize contain primary keys.
- An AnalyticDB for PostgreSQL instance is created.

Precautions

- If you select one or more tables (not a database) as the required objects, do not use gh-ost or pt-online-schema-change to perform data definition language (DDL) operations on the tables during data synchronization. Otherwise, data may fail to be synchronized.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- Only one-way synchronization is supported.

Limits

- You can select only tables as the objects to be synchronized.
- DTS does not synchronize the schemas of the required objects from the source database to the destination database.
- DTS does not synchronize the following types of data: JSON, GEOMETRY, CURVE, SURFACE, MULTIPOINT, MULTILINESTRING, MULTIPOLYGON, GEOMETRYCOLLECTION, and BYTEA.

SQL operations that can be synchronized

- Data manipulation language (DML) operations: INSERT, UPDATE, and DELETE
- Data definition language (DDL) operations: ALTER TABLE, ADD COLUMN, DROP COLUMN, and RENAME COLUMN

> **Note** The CREATE TABLE and DROP TABLE operations are not supported. To synchronize data from a new table, you must add the table to the selected objects. For more information, see Add objects to be synchronized.

Term mappings

Term in ApsaraDB RDS for MySQL	Term in AnalyticDB for PostgreSQL
Database	Schema
Table	Table

Create a data structure in the destination instance

Create a database, schema, and table in the destination AnalyticDB for PostgreSQL instance based on the data structure of the source RDS instance.

Configure a data synchronization task

1. Create a data synchronization instance.

> **Note** When you create the data synchronization instance, set Source Instance Type to **MySQL**, set Destination Instance Type to **AnalyticDB for PostgreSQL**, and set Synchronization Mode to **One-Way Synchronization**.

2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.
3. Configure the source and destination instances.

Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Instance Details	Instance Type	Select **RDS Instance**.
	Instance Region	The region where the source RDS instance resides.
	Instance ID	Select the ID of the source RDS instance.
	Encryption	Select **Non-encrypted** or **SSL-encrypted**. **Note** If you select **SSL-encrypted**, you must enable SSL encryption for the RDS instance before you configure the data synchronization task.
Destination Instance Details	Instance Type	This parameter is set to **AnalyticDB for PostgreSQL** and cannot be changed.
	Instance Region	The region where the destination instance resides.
	Instance ID	Select the ID of the destination AnalyticDB for PostgreSQL instance.
	Database Name	Enter the name of the destination database.
	Database Account	Enter the database account of the destination AnalyticDB for PostgreSQL instance. **Note** The database account must have the SELECT, INSERT, UPDATE, DELETE, COPY, TRUNCATE, and ALTER TABLE permissions.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Wait until the synchronization account is created. Then, click **Next**.
6. Configure the synchronization policy and objects.

Section	Parameter	Description
Synchronization policy	Initial Synchronization	Select **Initial Full Data Synchronization**. **Note** DTS synchronizes the historical data of the required objects from the source instance to the destination instance. The historical data is the basis for subsequent incremental synchronization.
	Processing Mode In Existed Target Table	◦ **Pre-Check and intercept** (Selected by default) Checks the **Schema Name Conflict** item and generates an error message if the destination table contains data. ◦ **Clear Target Table** Skips the **Schema Name Conflict** item during the precheck. Clears the data in the destination table before initial full data synchronization. If you want to synchronize your business data after testing the data synchronization task, you can select this mode. ◦ **Ignore** Skips the **Schema Name Conflict** item during the precheck. Adds data to the existing data during initial full data synchronization. If you want to synchronize data from multiple tables to one table, you can select this mode.
	Synchronization Type	◦ **Insert** ◦ **Update** ◦ **Delete** ◦ **AlterTable** **Note** Select the types of operations that you want to synchronize based on your business requirements.
Select Objects	N/A	You can select only tables as the objects to be synchronized. You can use the object name mapping feature to change the names of the columns that are synchronized to the destination database. For more information, see Specify the name of an object in the destination instance. **Note** The CREATE TABLE operation is not supported. To synchronize data from a new table, you must add the table to the selected objects. For more information, see Add objects to be synchronized.

7. In the lower-right corner of the page, click **Precheck**.

   > **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

8. Close the **Precheck** dialog box after the following message is displayed: **The precheck is passed.** Then, DTS performs initial synchronization.

18.1.4.4.5. Synchronize data between Cloud Native Distributed Database PolarDB-X instances

Cloud Native Distributed Database PolarDB-X is formerly known as Distributed Relational Database Service (DRDS). It is compatible with the MySQL protocol and syntax, and supports automatic sharding, online smooth scaling, auto scaling, and transparent read/write splitting. This topic describes how to synchronize data between Cloud Native Distributed Database PolarDB-X instances by using Data Transmission Service (DTS).

Prerequisites

The tables that you want to synchronize contain primary keys.

Precautions

- DTS uses the read and write resources of the source and destination databases during initial full data synchronization. This may increase the load of the database server. Before you synchronize data, evaluate the impact of data synchronization on the performance of the source and destination databases. We recommend that you synchronize data during off-peak hours.
- We recommend that you do not change the network type of the Cloud Native Distributed Database PolarDB-X instances during data synchronization.

  > **Note** After you change the network type of a Cloud Native Distributed Database PolarDB-X instance during data synchronization, you must submit a ticket to resume the data synchronization instance.

- We recommend that you do not scale up or down the databases in the Cloud Native Distributed Database PolarDB-X instances. Otherwise, data may fail to be synchronized.

Supported synchronization topologies

DTS supports the following synchronization topologies: one-way one-to-one synchronization, one-way one-to-many synchronization, one-way cascade synchronization, and one-way many-to-one synchronization. For more information, see Synchronization topologies.

SQL operations that can be synchronized

The INSERT, UPDATE, and DELETE operations can be synchronized.

Before you begin

Create a database and tables in the destination instance based on the schemas of the objects in the source instance. This is because DTS does not support **initial schema synchronization** between Cloud Native Distributed Database PolarDB-X instances.

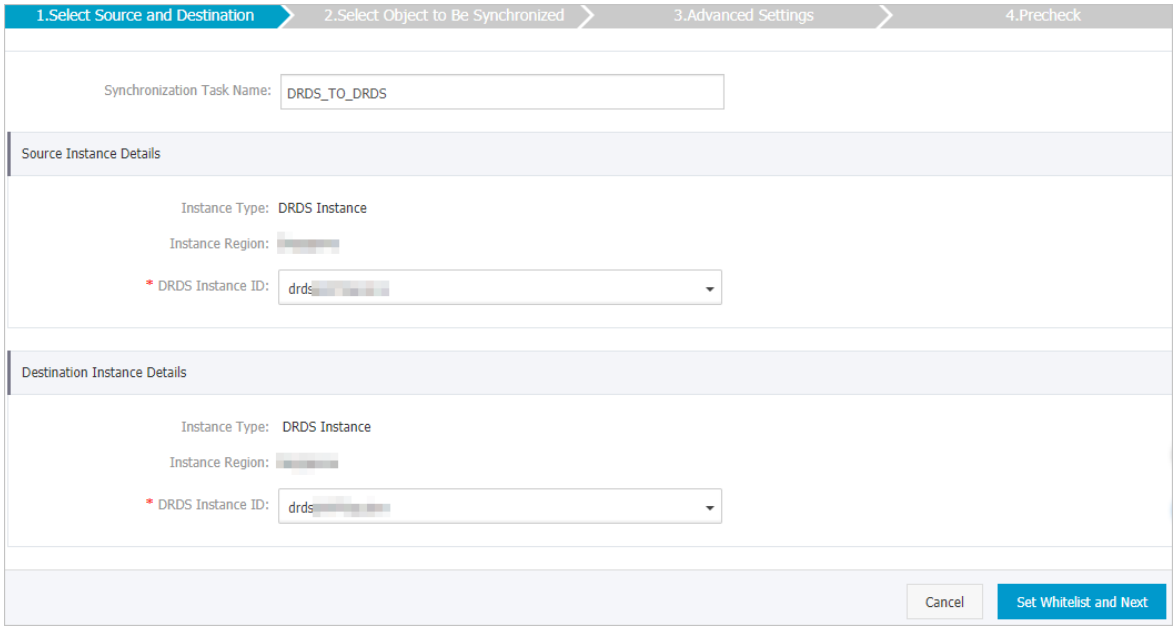
> **Note** During **initial schema synchronization**, DTS synchronizes the schemas of the required objects from the source database to the destination database.

Procedure

1. Create a data synchronization instance.

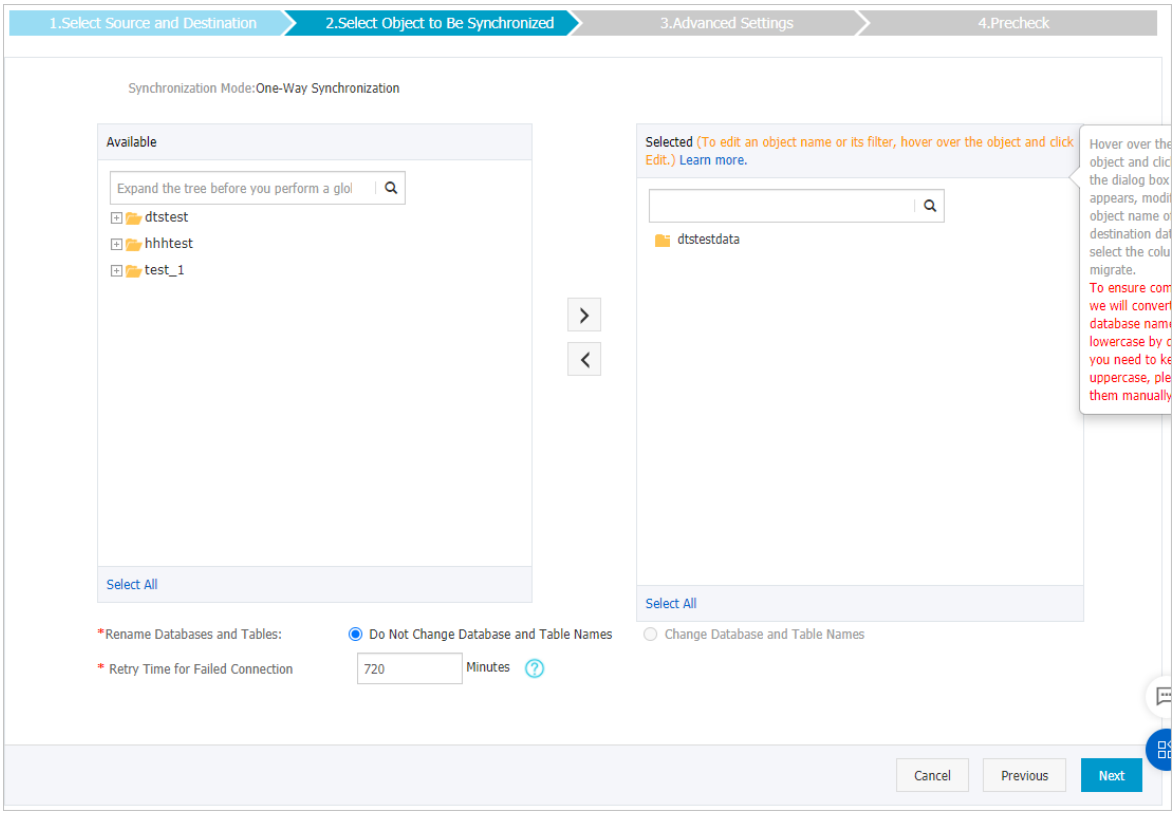
   > **Note** When you create the data synchronization instance, set both Source Instance Type and Destination Instance Type to **Drds**, and set Synchronization Mode to **One-Way Synchronization**.

2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.
3. Configure the source and destination instances.



Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Instance Details	Instance Type	This parameter is set to **DRDS Instance** and cannot be changed.
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the source Cloud Native Distributed Database PolarDB-X instance.
Destination Instance Details	Instance Type	This parameter is set to **DRDS Instance** and cannot be changed.
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the destination Cloud Native Distributed Database PolarDB-X instance.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Configure the synchronization policy and objects.



Parameter	Description
Processing Mode In Existed Target Table	○ **Pre-check and Intercept**: checks whether the destination tables are empty. If the destination tables are empty, the precheck is passed. If the tables are not empty, an error is returned during the precheck and the data synchronization task cannot be started. ○ **Ignore**: skips the check for empty destination tables. **Warning** If you select **Ignore**, data consistency is not guaranteed and your business may be exposed to potential risks. ■ If the source and destination databases have the same schema, DTS does not synchronize the data records that have the same primary keys as the data records in the destination database. ■ If the source and destination databases have different schemas, initial data synchronization may fail. In this case, only specific columns are synchronized or the data synchronization task fails.

Parameter	Description
Select Objects	Select tables from the **Available** section and click the icon to move the tables to the **Selected** section. **Note** - You can select only tables as the objects to be synchronized. - After an object is synchronized to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are synchronized to the destination instance. For more information, see Specify the name of an object in the destination instance.

6. Click **Next**.
7. Specify whether you want to perform initial full data synchronization.

   Note During **initial full data synchronization**, DTS synchronizes the historical data of the required objects from the source database to the destination database. If you do not select Initial Full Data Synchronization, DTS does not synchronize the historical data.

8. In the lower-right corner of the page, click **Precheck**.

   Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. Close the **Precheck** dialog box after the following message is displayed: **The precheck is passed.** Then, DTS performs initial synchronization.

18.1.4.4.6. Synchronize data from a Cloud Native Distributed Database PolarDB-X instance to an AnalyticDB for MySQL cluster

This topic describes how to synchronize data from a Cloud Native Distributed Database PolarDB-X instance to an AnalyticDB for MySQL cluster by using Data Transmission Service (DTS).

Prerequisites

The tables that you want to synchronize contain primary keys.

Precautions

- If you select one or more tables (not a database) as the required objects, do not use gh-ost or pt-online-schema-change to perform data definition language (DDL) operations on the tables during data synchronization. Otherwise, data may fail to be synchronized.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- Only one-way synchronization is supported.

Supported synchronization topologies

DTS supports the following synchronization topologies: one-way one-to-one synchronization, one-way one-to-many synchronization, and one-way many-to-one synchronization. For more information, see Synchronization topologies.

SQL operations that can be synchronized

INSERT, UPDATE, and DELETE

Data type mappings

The data types of ApsaraDB RDS for MySQL and AnalyticDB for MySQL do not have one-to-one correspondence. During initial schema synchronization, DTS converts the data types of the source database into those of the destination database. The following table lists the data types that DTS can convert.

Data type of ApsaraDB RDS for MySQL	Data type of AnalyticDB for MySQL
BIGINT UNSIGNED	DECIMAL(20,0)
BINARY	VARBINARY
BIT	VARCHAR
BLOB	VARBINARY
CHAR	VARCHAR
DATE	DATE
DATETIME	DATETIME
DECIMAL	DECIMAL
DOUBLE	DOUBLE
ENUM	VARCHAR
FLOAT	FLOAT
GEOMETRY	VARBINARY
GEOMETRYCOLLECTION	VARBINARY
INT UNSIGNED	BIGINT
INTEGER	INT
JSON	JSON
LINESTRING	VARBINARY
LONGBLOB	VARBINARY
LONGTEXT	VARCHAR
MEDIUMBLOB	VARBINARY
MEDIUMINT	INT

Data type of ApsaraDB RDS for MySQL	Data type of AnalyticDB for MySQL
MEDIUMINT UNSIGNED	INT
MEDIUMTEXT	VARCHAR
MULTILINESTRING	VARBINARY
MULTIPOINT	VARBINARY
MULTIPOLYGON	VARBINARY
NUMBERIC	DECIMAL
POINT	VARBINARY
POLYGON	VARBINARY
SET	VARCHAR
SMALLINT UNSIGNED	INT
TEXT	VARCHAR
TIME	TIME
TIMESTAMP	TIMESTAMP
TINYBLOB	VARBINARY
TINYINT UNSIGNED	SMALLINT
TINYTEXT	VARCHAR
VARBINARY	VARBINARY
VARCHAR	VARCHAR
YEAR	INT

Procedure

1. Create a data synchronization instance.

   > **Note** When you create the data synchronization instance, set Source Instance Type to **Drds**, set Destination Instance Type to **AnalyticDB**, and set Synchronization Mode to **One-Way Synchronization**.

2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.
3. Configure the source and destination instances.

Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.

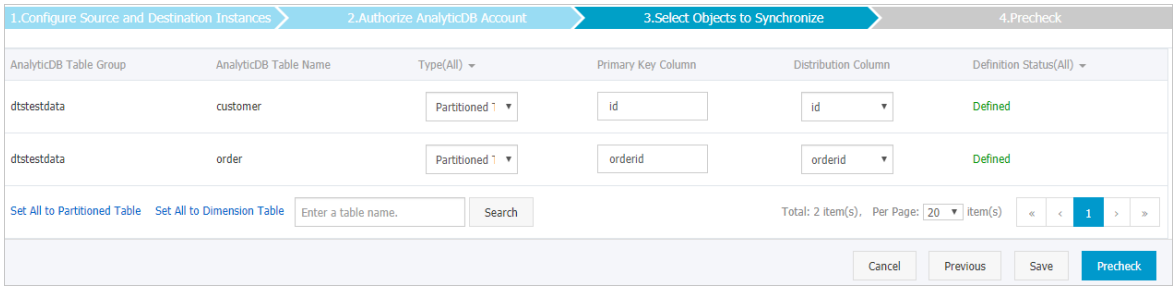
Section	Parameter	Description
Source Instance Details	Instance Type	This parameter is set to **DRDS Instance** and cannot be changed.
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the source Cloud Native Distributed Database PolarDB-X instance.
Destination Instance Details	Instance Type	This parameter is set to **AnalyticDB** and cannot be changed.
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Version	Select **3.0**.
	Database	Select the ID of the destination AnalyticDB for MySQL cluster.
	Database Account	Enter the database account of the destination AnalyticDB for MySQL cluster.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Configure the synchronization policy and objects

Section	Parameter	Description
Synchronization policy	Initial Synchronization	You must select both **Initial Schema Synchronization** and **Initial Full Data Synchronization** in most cases. After the precheck, DTS synchronizes the schemas and data of the required objects from the source instance to the destination cluster. The schemas and data are the basis for subsequent incremental synchronization.
	Processing Mode In Existed Target Table	◦ **Clear Target Table** Skips the **Schema Name Conflict** item during the precheck. Clears the data in the destination table before initial full data synchronization. If you want to synchronize your business data after testing the data synchronization task, you can select this mode. ◦ **Ignore** Skips the **Schema Name Conflict** item during the precheck. Adds data to the existing data during initial full data synchronization. If you want to synchronize data from multiple tables to one table, you can select this mode.

Section	Parameter	Description
	Synchronization Type	Select the types of operations that you want to synchronize based on your business requirements. ○ **Insert** ○ **Update** ○ **Delete**
Select Objects	N/A	Select tables from the **Available** section and click the icon to move the tables to the **Selected** section. **Note** ○ You can select only tables as the objects to be synchronized. ○ You can use the object name mapping feature to change the names of the columns that are synchronized to the destination database. For more information, see Specify the name of an object in the destination instance.

6. Click **Next**.
7. Specify a type for the tables that you want to synchronize to the destination database.



Note After you select **Initial Schema Synchronization**, you must specify the **type**, **primary key column**, and **partition key column** for the tables that you want to synchronize to AnalyticDB for MySQL.

8. In the lower-right corner of the page, click **Precheck**.

Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. Close the **Precheck** dialog box after the following message is displayed: **The precheck is passed.** Then, DTS performs initial synchronization.

18.1.4.4.7. Synchronize data from a Cloud Native Distributed Database PolarDB-X instance to a DataHub instance

This topic describes how to synchronize data from a Cloud Native Distributed Database PolarDB-X instance to a DataHub instance by using Data Transmission Service (DTS). After you synchronize data, you can use big data services such as Realtime Compute to analyze data in real time.

Prerequisites

- The tables that you want to synchronize have PRIMARY KEY or UNIQUE constraints.
- A DataHub project is created to receive the synchronized data.

Precautions

- If you select one or more tables (not a database) as the required objects, do not use gh-ost or pt-online-schema-change to perform data definition language (DDL) operations on the tables during data synchronization. Otherwise, data may fail to be synchronized.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- Only one-way synchronization is supported.

Limits

- You can select only tables as the objects to be synchronized.
- Initial full data synchronization is not supported. DTS does not synchronize the historical data of the required objects from the source PolarDB-X instance to the destination DataHub instance.
- DTS does not synchronize data definition language (DDL) operations to the destination database. If you perform a DDL operation on the source PolarDB-X instance during data synchronization, data fails to be synchronized. To solve this issue, you must modify the related topic in the destination DataHub instance and then restart the data synchronization task.

SQL operations that can be synchronized

INSERT, UPDATE, and DELETE

Procedure

1. Create a data synchronization instance.

   > **Note** When you create the data synchronization instance, set Source Instance Type to **Drds**, set Destination Instance Type to **Datahub**, and set Synchronization Mode to **One-Way Synchronization**.

2. Find the data synchronization instance, and click **Configure Synchronization Channel** in the **Actions** column.
3. Configure the source and destination instances.

Section	Parameter	Description
N/A	Synchronization Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Instance Details	Instance Type	This parameter is set to **DRDS Instance** and cannot be changed.
	Instance Region	The region of the source instance. The region is the same as the source region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the source Cloud Native Distributed Database PolarDB-X instance.

Section	Parameter	Description
Destination Instance Details	Instance Type	This parameter is set to **DataHub** and cannot be changed.
	Instance Region	The region of the destination instance. The region is the same as the destination region that you selected when you created the data synchronization instance. You cannot change the value of this parameter.
	Project	Select the name of the DataHub project.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Configure the synchronization policy and objects.

Parameter	Description
Initial Synchronization	Select **Initial Schema Synchronization**. **Note** After you select **Initial Schema Synchronization**, DTS synchronizes the schemas of the required objects (such as tables) to the destination DataHub instance.
Select Objects	Select objects from the **Available** section and click the › icon to move the objects to the **Selected** section. **Note** ◦ You can select only tables as the objects to be synchronized. ◦ You can use the object name mapping feature to change the names of the columns that are synchronized to the destination database. For more information, see Specify the name of an object in the destination instance.

6. In the lower-right corner of the page, click **Precheck**.

Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. Close the **Precheck** dialog box after the following message is displayed: **The precheck is passed.** Then, DTS performs initial synchronization.

18.1.4.4.8. Configure two-way data synchronization between RDS instances

18.1.4.4.8.1. Overview

DTS supports two-way real-time data synchronization between RDS instances on any two clouds. This section describes how to use DTS to create a two-way synchronization task between two ApsaraDB RDS for MySQL instances for active geo-redundancy, geo-disaster recovery, and other scenarios.

18.1.4.4.8.2. Supported synchronization statements

Two-way synchronization between ApsaraDB RDS for MySQL instances supports all DML updates (including INSERT, UPDATE, and DELETE) and the following DDL updates:

- ALTER TABLE, ALTER VIEW, ALTER FUNCTION, and ALTER PROCEDURE
- CREATE DATABASE, CREATE SCHEMA, CREATE INDEX, CREATE TABLE, CREATE PROCEDURE, CREATE FUNCTION, CREATE TRIGGER, CREATE VIEW, and CREATE EVENT
- DROP FUNCTION, DROP EVENT, DROP INDEX, DROP PROCEDURE, DROP TABLE, DROP TRIGGER, and DROP VIEW
- RENAME TABLE and TRUNCATE TABLE

> **Note** To ensure the stability of a two-way synchronization channel, you can synchronize DDL updates on the same table in only one direction.
>
> For example, for two-way synchronization, you must enable DDL synchronization in either the **A-to-B** or **B-to-A** direction. If DDL synchronization is configured in one direction, it is not supported in the reverse direction. You can only perform DML synchronization.

18.1.4.4.8.3. Detect and resolve conflicts

To ensure data consistency, for two-way synchronized instances, make sure that records with the same primary key, business primary key, or unique key are updated only on one of the instances. If you unexpectedly update a record with the same primary key, business primary key, or unique key on both instances that are two-way synchronized, a synchronization conflict occurs. To maximize the stability of two-way synchronized instances, DTS supports detecting and resolving data conflicts.

Considerations

During two-way synchronization, the system time of the source and destination instances may not be the same. Additionally, synchronization delays may occur. For these reasons, DTS cannot guarantee that its conflict detection mechanism can completely prevent data conflicts. You must refactor certain business logic to ensure that records of the same primary key, business primary key, or unique key are updated only on one of the instances that are two-way synchronized.

Supported conflict types

Currently, DTS supports detecting the following conflict types:

- Uniqueness conflicts caused by INSERT operations

  A uniqueness conflict occurs when the synchronization of an inserted row violates the unique constraint. For example, if two instances in two-way synchronization insert a record with the same primary key value at almost the same time, one of the inserted records fails to be synchronized because a record with the same primary key value already exists in the destination instance.

- Inconsistent records caused by UPDATE operations

  Update conflicts occur in the following scenarios:

  - The records to be updated do not exist in the destination instance. If the records to be updated do not exist, DTS automatically changes the UPDATE operation to the INSERT operation and inserts these records to the destination instance. In this case, duplicate unique key values may occur.
  - The primary keys or unique keys of the records to be updated conflict with each other.

- A DELETE operation is made on non-existent records

  A delete conflict occurs when the records to be deleted do not exist in the destination instance.

  In this case, DTS automatically ignores the DELETE operation regardless of the conflict resolution policy that you have configured.

Supported conflict resolution policies

For the preceding synchronization conflicts, DTS provides the following resolution policies. You can select a conflict resolution policy as required when configuring two-way synchronization.

- TaskFailed: The synchronization task reports an error and automatically exits the process in case of a conflict.

  When the synchronization encounters a conflict of the preceding types, the synchronization task reports an error and automatically exits the process. The task enters a failed state and you must manually resolve the conflict. This method is the default conflict resolution policy.

- Ignore: The records in the destination instance are used in case of a conflict.

  When the synchronization encounters a conflict of the preceding types, the synchronization task skips the current synchronization statement and continues the process. The records in the destination instance are used.

- Overwrite: The conflict records in the destination instance are overwritten in case of a conflict.

  When the synchronization encounters a conflict of the preceding types, the conflict records in the destination instance are overwritten.

18.1.4.4.8.4. Synchronization restrictions

This section describes the restrictions in cross-cloud data synchronization using DTS.

Restrictions in data sources

Currently, only ApsaraDB RDS for MySQL instances support two-way synchronization. Other heterogeneous data sources do not support two-way synchronization.

The destination instance cannot be an RDS instance that runs in standard access mode and has only a public network address.

Restrictions in synchronization architecture

Currently, DTS only supports two-way synchronization between two ApsaraDB RDS for MySQL instances. Two-way synchronization between more than two instances is not supported.

Feature restrictions

- Incompatible with triggers

  When you synchronize an entire database and the database contains a trigger that updates the synchronization table, the synchronized data may be inconsistent.

  For example, the object to be synchronized is database A that contains table a and table b. Table a has a trigger that inserts a row to table b after the row is inserted to table a. In this case, if an INSERT operation is performed on table a in the source instance during synchronization, the data in table b is inconsistent between the source and destination instances.

  To resolve this problem, you must delete the trigger in the destination instance, so that the data in table b is only synchronized from the source instance.

- Restrictions in the RENAME TABLE operation

  The RENAME TABLE operation may result in inconsistent synchronization data. For example, if the object to be synchronized only includes table a and the **rename a to b** command is executed in the source instance during synchronization, subsequent operations to the renamed table b are not synchronized to the destination database. To solve this problem, you can synchronize the entire database where table a and table b are stored.

- Restrictions in DDL synchronization direction

To ensure the stability of a two-way synchronization channel, you can synchronize DDL updates on the same table in only one direction. For example, in A-to-B and B-to-A synchronization, you can implement DDL synchronization in either the **A-to-B** or **B-to-A** direction. If DDL synchronization is configured in one direction, it is not supported in the reverse direction.

18.1.4.4.8.5. Configure two-way data synchronization between ApsaraDB RDS for MySQL instances across regions

This topic describes how to configure two-way data synchronization between ApsaraDB RDS for MySQL instances across regions.

Prerequisites

The source and destination ApsaraDB RDS for MySQL instances are created.

Procedure

1. Log on to the DTS console.
2. In the left-side navigation pane, click **Data Synchronization**.
3. On the **Synchronization Tasks** page, click **Create Synchronization Task** in the upper-right corner.

   > **Note**
   >
   > Source Instance Region: Select the region where the source RDS instance resides.
   >
   > Source Instance Type: Select the type of the source instance. In this example, select MySQL.
   >
   > Destination Instance Region: Select the region where the destination RDS instance resides.
   >
   > Destination Instance Type: Select the type of the destination instance. In this example, select MySQL.
   >
   > Synchronization Mode: Select the synchronization mode. In this example, select Two-Way Synchronization.
   >
   > Instances to Create: Set the number of instances that you want to create.

4. After you configure the preceding information, click **Create**.

   After you create a synchronization instance, go back to the **Synchronization Tasks** page. The new synchronization instance is in the Not Configured state and contains two synchronization tasks. You can configure two-way synchronization for the tasks.

5. Find one of the created synchronization tasks and click **Configure Synchronization Channel** in the Actions column.
6. Configure the parameters for the data synchronization task.
   - Synchronization Task Name

     We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
   - RDS instance ID

     You must specify the ID of the Apsara Stack tenant account to which the destination RDS instance belongs. You can then select an RDS instance ID from the Instance ID drop-down list.

     After you complete the preceding configurations, click **Set Whitelist and Next** to configure the RDS instance whitelists.
7. Configure the RDS instance whitelists.

In this step, DTS adds the CIDR blocks of DTS servers to the whitelists of the source and destination RDS instances. This ensures that DTS servers can connect to the RDS instances and the data synchronization task can be created.

We recommend that you do not remove the CIDR blocks of DTS servers from the whitelists of the RDS instances. This ensures the stability of the data synchronization task.

Click **Next** to create a data synchronization account.

8. Create a data synchronization account in the destination RDS instance.

   Create a data synchronization account named dtssyncwriter in the destination RDS instance. Do not delete the account during data synchronization. Otherwise, an interruption occurs.

9. Configure the synchronization policies and select the objects that you want to synchronize.

   After you create a data synchronization account, you must configure the synchronization policies and select the objects that you want to synchronize.

   - Exclude DDL Statements

     Specify whether to synchronize DDL statements in a specific direction. To include DDL statements, select **No**. To exclude DDL statements, select **Yes**. If you select No, DTS does not synchronize the DDL operations that are performed on a table in the opposite direction.

   - DML Statements for Synchronization

     Select the types of DML operations that you want to synchronize. By default, **Insert**, **Update**, and **Delete** are selected.

   - Conflict Resolution Policy

     Select the resolution policy for synchronization conflicts. By default, **TaskFailed** is selected.

     For example, if Node A is the primary business center and Node B is a secondary business center, you must give the priority to Node A. You must set the conflict resolution policy in the A-to-B direction to **Overwrite** and that in the B-to-A direction to **Ignore**.

   - Select Objects

     You can select databases and tables as the objects to be synchronized.

     If you select an entire database, all schema changes such as the CREATE TABLE and DROP VIEW operations that performed on the objects in the database are synchronized to the destination database.

     If you select a table, only the DROP TABLE, ALTER TABLE, TRUNCATE TABLE, RENAME TABLE, CREATE INDEX, and DROP INDEX operations that performed on this table are synchronized to the destination database.

10. Configure initial synchronization.

    Initial synchronization is the first step to start the synchronization task. During initial synchronization, DTS synchronizes the schemas and data of the required objects from the source instance to the destination instance. The schemas and data are the basis for subsequent incremental synchronization.

    Initial synchronization includes **initial schema synchronization** and **initial full data synchronization**. You must select both **Initial Schema Synchronization** and **Initial Full Data Synchronization** in most cases.

    If the tables to be synchronized in one direction are also included in the objects to be synchronized in the opposite direction, DTS does not synchronize these tables during initial synchronization.

11. Run a precheck.

    After the data synchronization task is configured, DTS performs a precheck. Close the **Precheck** dialog box after the task passes the precheck.

    After the task is started, the task list appears. The task is in the **Performing Initial Sync** state. The duration of the initial synchronization depends on the data volume of the objects that you want to synchronize. After initial synchronization, the task status changes to **Synchronizing**. This indicates that the data synchronization task is created.

After the task is configured in one direction, the source and destination RDS instances of the task in the opposite direction cannot be changed.

12. Repeat steps 5 to 11 to configure the data synchronization task in the opposite direction.

18.1.4.5. Manage data synchronization instances

18.1.4.5.1. Specify the name of an object in the destination instance

After an object, such as a database or table, is synchronized from the source instance to the destination instance, the name of the object remains unchanged. You can use the object name mapping feature provided by DTS to specify a different name for the object in the destination instance.

Notes

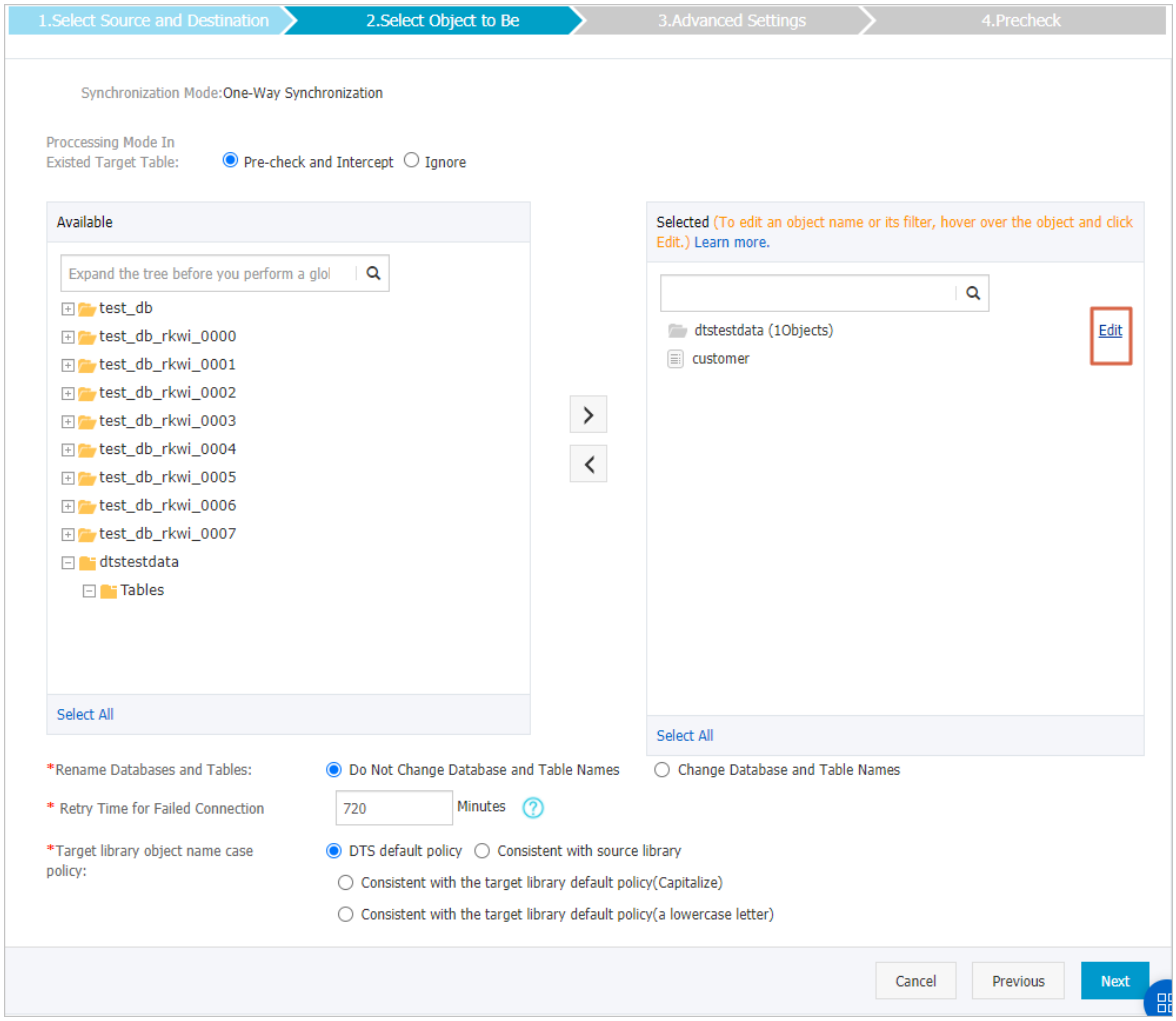
You can perform this operation only when a data synchronization task is configured and the current process is **Select Objects to Synchronize**.

> **Note** Do not perform this operation after the data synchronization task is started. Otherwise, the synchronization may fail.

Procedure

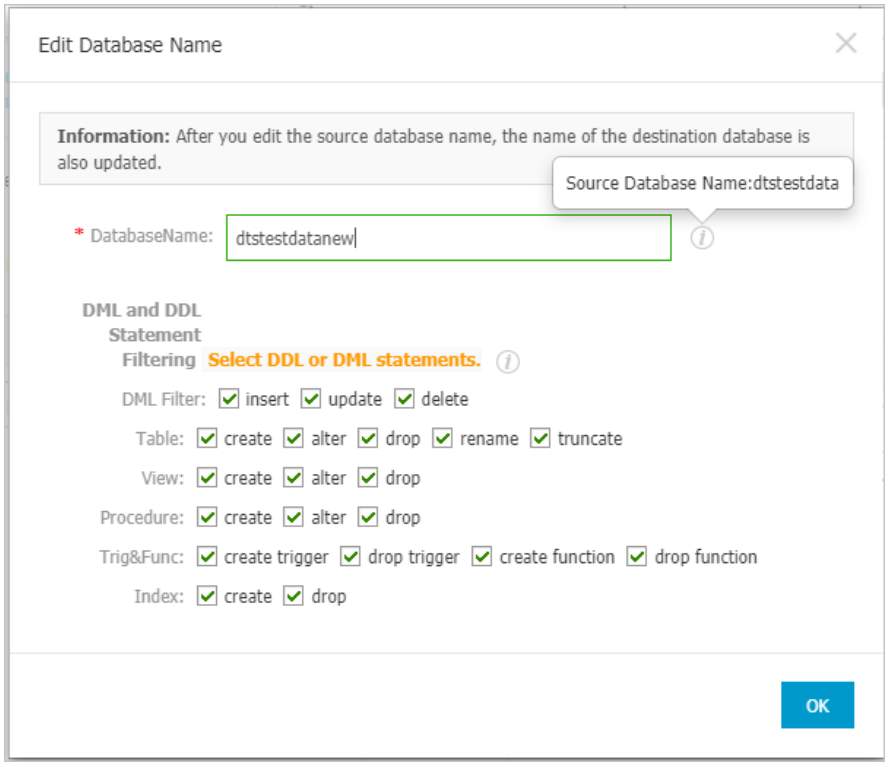
1. On the **Select Objects to Synchronize** page, move the required objects to the **Selected** section, move the pointer over a database or table, and then click **Edit**.

   > **Note** Different database types support different objects. If **Edit** appears when you move the pointer over the target object, the operation is supported.



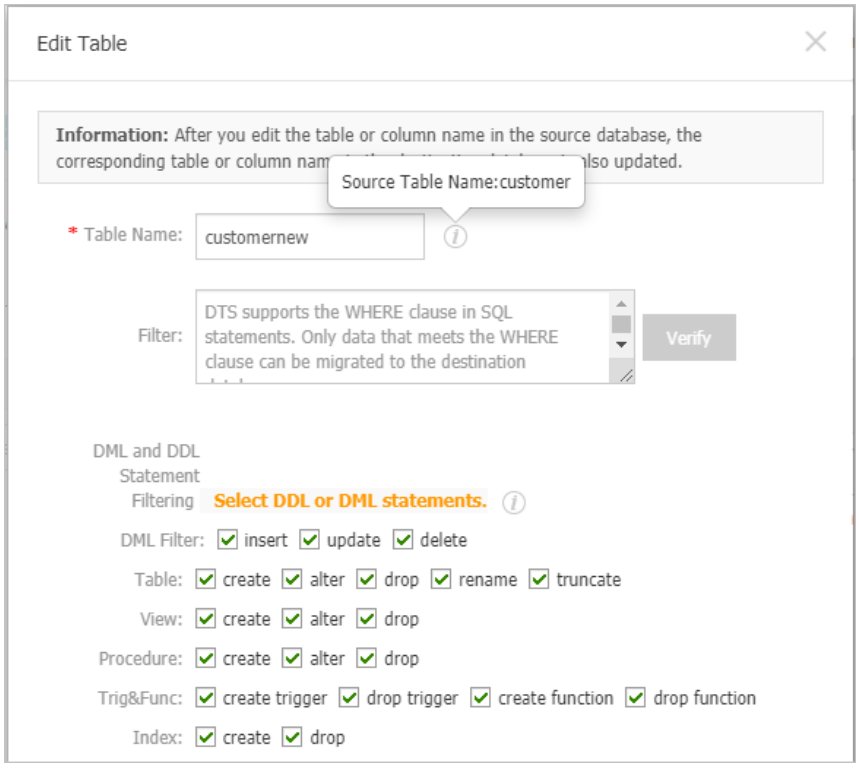
2. In the dialog box that appears, specify a name for the object in the destination instance.
   - Database name mapping

     In the **Edit Database Name** dialog box that appears, enter the database name that you want to use in the destination instance.



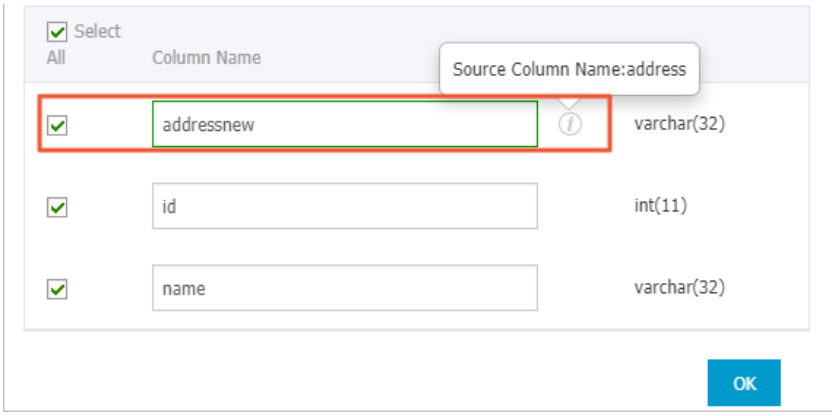
- Table name mapping

  In the **Edit Table** dialog box that appears, enter the table name that you want to use in the destination instance.



- Column name mapping

  In the **Edit Table** dialog box that appears, enter a new name for each column.



Note In this step, you can deselect columns that do not need to be synchronized.

3. Click **OK**.
4. Configure other parameters that are required for the data synchronization task.

18.1.4.5.2. Check the synchronization performance

DTS provides the trend charts of data synchronization tasks based on three performance metrics: bandwidth, synchronization speed (TPS), and synchronization delay. You can view the running status of data synchronization tasks in the DTS console.

1. Log on to the DTS console.
2. In the left-side navigation pane, click **Data Synchronization**.
3. On the Synchronization Tasks page, click the ID of the data synchronization task that you want to check.

   The task details page appears.
4. On the task details page, click **Synchronization Performance** in the left-side navigation pane.
5. View the trend charts of synchronization performance.

   DTS provides the trend charts of data synchronization tasks based on three performance metrics: bandwidth, synchronization speed (TPS), and synchronization delay.

   - Bandwidth: the bandwidth of data that the data writing module pulls from the data pulling module per second. Unit: MB/s.
   - Synchronization speed (TPS): the number of transactions that DTS synchronizes to the destination instance per second.
   - Synchronization delay: the difference between the timestamp of the latest synchronized data in the destination instance and the current timestamp in the source instance. Unit: milliseconds.

18.1.4.5.3. Add objects to a data synchronization task

When a data synchronization task is running, you can add objects to the task or remove objects from the task. This topic describes how to add objects to a data synchronization task in the DTS console.

Limits

You can modify the required objects only when the data synchronization task is in the **Synchronizing** or **Synchronization Failed** state.

Start time of data synchronization

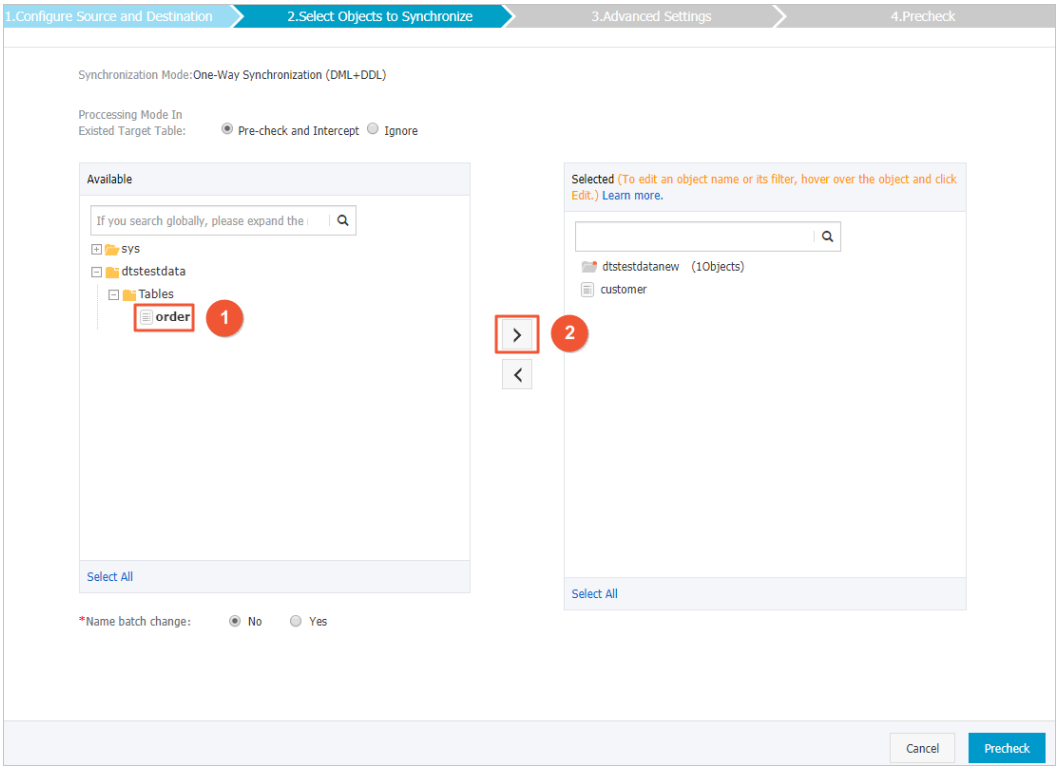
The time when DTS synchronizes data of new objects depends on whether initial synchronization is specified for the data synchronization task.

- If initial synchronization is specified, DTS synchronizes schemas and historical data, and then synchronizes incremental data.
- If initial synchronization is not specified, DTS synchronizes data after incremental data is generated on the source instance.

Procedure

1. Log on to the DTS console.
2. In the left-side navigation pane, click **Data Synchronization**.
3. Find the data synchronization task and choose **More > Modify Objects to Synchronize** in the Actions column.
4. On the **Select Objects to Synchronize** tab, add objects based on your needs, as shown in Add objects to a data synchronization task.

   Add objects to a data synchronization task



5. Click **Precheck**.

   After the task passes the precheck, the objects are added to the data synchronization task.

   After the objects are added, if initial synchronization is specified for the data synchronization task, the task status changes from **Synchronizing** to **Synchronizing (The initial synchronization of the new objects is being performed.)**.

> **Note** You can click **View More** to view the initial synchronization progress of the new objects. After the initial synchronization on the new objects is complete, the task status returns to **Synchronizing**.

18.1.4.5.4. Remove objects from a data synchronization task

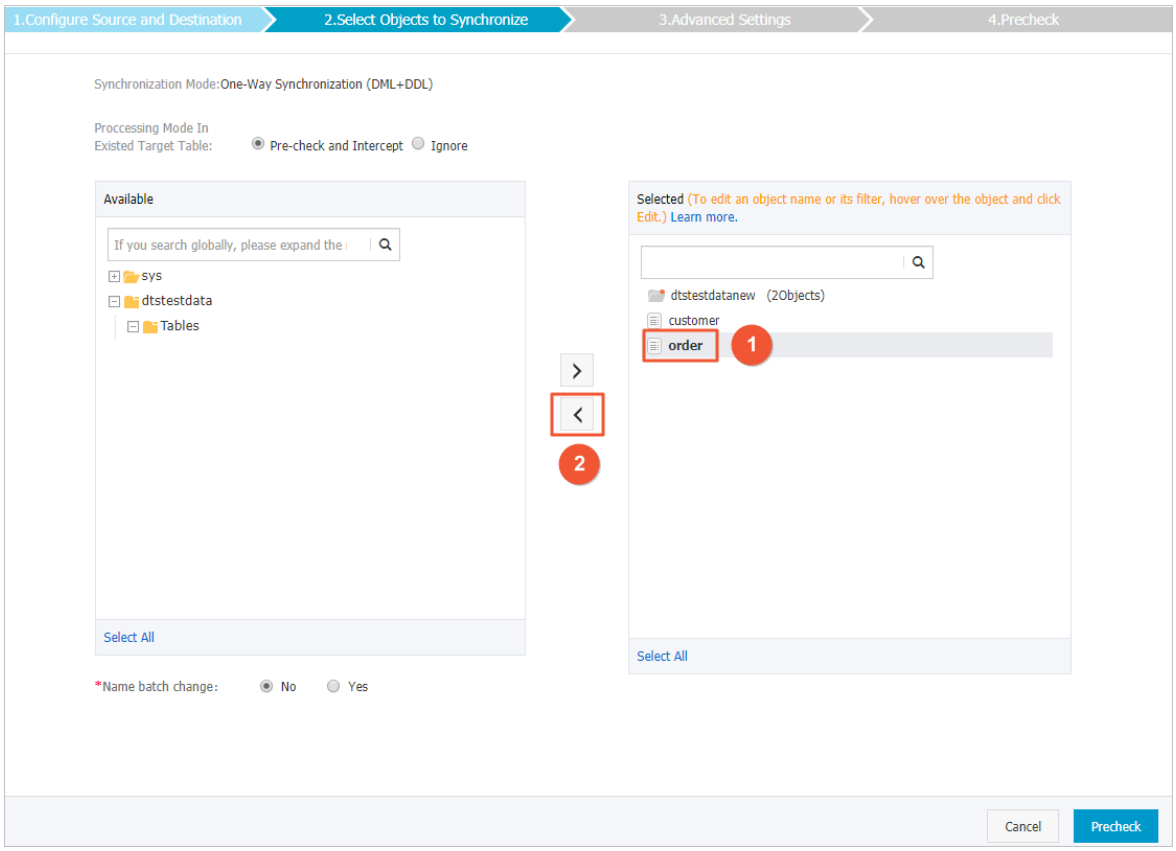
When a data synchronization task is running, you can add objects to the task or remove objects from the task. This topic describes how to remove objects from a data synchronization task in the DTS console.

Limits

You can modify the required objects only when the data synchronization task is in the **Synchronizing** or **Synchronization Failed** state.

Procedure

1. Log on to the DTS console.
2. In the left-side navigation pane, click **Data Synchronization**.
3. Find the data synchronization task and choose **More > Modify Objects to Synchronize** in the Actions column.
4. On the **Select Objects to Synchronize** tab, remove objects based on your needs.



5. Click **Precheck** to run a precheck.

18.1.4.5.5. Troubleshoot precheck failures

Before Data Transmission Service (DTS) runs a data synchronization task, DTS performs a precheck. This topic describes the precheck items and how to troubleshoot precheck failures.

Source database connectivity

- Description

  DTS checks whether DTS servers can connect to the source RDS instance. DTS creates a connection to the source RDS instance by using the JDBC protocol. If the connection fails, the task fails to pass the precheck.

- Cause of failure
  - DTS does not support data synchronization between RDS instances in the region where the source instance resides.
  - The database account or password of the source instance is invalid.

- Solution

  Submit a ticket and contact Alibaba Cloud technical support.

Destination database connectivity

- Description

  DTS checks whether DTS servers can connect to the destination RDS instance. DTS creates a connection to the destination RDS instance by using the JDBC protocol. If the connection fails, the task fails to pass the precheck.

- Cause of failure
  - DTS does not support data synchronization between RDS instances in the region where the destination instance resides.
  - The database account or password of the destination instance is invalid.
- Solution

  Submit a ticket and contact Alibaba Cloud technical support.

Source database version

- Description

  DTS checks whether:

  i. The database version of the source RDS instance is supported by the data synchronization feature.

  ii. The database version of the destination RDS instance is the same as the database version of the source RDS instance.

- Cause of failure
  - The database version of the source RDS instance is earlier than the supported database versions. The data synchronization feature supports the following database versions: MySQL 5.1, 5.5, 5.6, and 5.7.
  - The database version of the destination RDS instance is earlier than the database version of the source RDS instance.
- Solution
  - If the database version of the source RDS instance is earlier than the supported database versions, upgrade the source RDS instance to MySQL 5.6 or 5.7 in the RDS console. Then, create a data synchronization task again.
  - If the database version of the destination RDS instance is earlier than the database version of the source RDS instance, upgrade the destination RDS instance to MySQL 5.6 or 5.7 in the RDS console. Then, create a data synchronization task again.

Database existence

DTS checks whether the destination database already exists in the destination instance. If the destination database does not exist in the destination instance, DTS automatically creates a database. However, DTS fails to create the database and reports a failure under the following circumstances:

- The database name contains characters other than lowercase letters, digits, underscores (_), and hyphens (-).
- The character set of the database is not UTF-8, GBK, Latin1, or UTF-8MB4.
- The account of the destination database does not have the read/write permissions on the source database.

  If the data source is an RDS instance, the task passes the precheck.

Source database permissions

DTS checks whether the account of the source database has the required permissions. If the account does not have the required permissions, the task fails to pass the precheck. If the source database is an RDS instance, the task passes the precheck.

Destination database permissions

- Description

  DTS checks whether the account of the destination database has the required permissions. If the account does not have the required permissions, the task fails to pass the precheck.

- Cause of failure
  - DTS fails to create a database account in the destination RDS instance.
  - DTS fails to grant the read/write permissions to the database account of the destination RDS instance.

- Solution

  Submit a ticket and contact Alibaba Cloud technical support.

Object name conflict

- Description

  DTS checks object names only if you select initial synchronization for a data synchronization task. DTS checks whether an object that you want to synchronize has the same name as an object in the destination RDS instance.

- Cause of failure

  If an object in the destination RDS instance has the same name as the object that you want to synchronize, the task fails to pass the precheck.

- Solution
  - Remove the conflicting object from the destination database.
  - Then, create a data synchronization task again. Select both Initial Schema Synchronization and Initial Full Data Synchronization.

Value of server_id in the source database

DTS checks whether the value of the server_id parameter in the source database is set to an integer that is greater than or equal to 2. If the data source is an RDS instance, the task passes the precheck.

Whether binary logging is enabled for the source database

DTS checks whether the binary logging feature is enabled for the source database. If the binary logging feature is disabled for the source database, the task fails to pass the precheck. If the data source is an RDS instance, the task passes the precheck.

Binary log format of the source database

DTS checks whether the binary log format of the source database is set to ROW. If the binary log format of the source database is not set to ROW, the task fails to pass the precheck. If the data source is an RDS instance, the task passes the precheck.

Integrity of the FOREIGN KEY constraints

- Description

  DTS checks whether the parent tables and child tables that have referential relationships with each other are all included in the required objects. The precheck allows DTS to protect the integrity of the FOREIGN KEY constraints.

- Cause of failure

  One or more child tables are included in the required objects. However, the parent tables that are referenced by the child tables are not included in the required objects. This impairs the integrity of the FOREIGN KEY constraints.

- Solution

  The following solutions are available:

  - Create a data synchronization task again and do not synchronize the child tables that fail to pass the precheck.
  - Create a data synchronization task again and add the parent tables to the required objects.
  - Remove the FOREIGN KEY constraints from the child tables that fail to pass the precheck. Then, create a data synchronization task again.

Storage engine

- Description

  DTS checks whether the required objects use the storage engines that are not supported by the data synchronization feature, such as FEDERATED, MRG_MyISAM, and TokuDB.

- Cause of failure

  If the storage engine of a source table is FEDERATED, MRG_MyISAM, or TokuDB, the task fails to pass the precheck.

- Solution

  Change the unsupported storage engine to InnoDB and create a data synchronization task again.

Character set

- Description

  DTS checks whether the required objects use the character sets that are not supported by the data synchronization feature, such as the UCS-2 character set.

- Cause of failure

  If the character sets used by the required objects are not supported by the data synchronization feature, the task fails to pass the precheck.

- Solution

  Change the unsupported character sets to UTF-8, GBK, or Latin1. Then, create a data synchronization task again.

Complicated topologies

- Description

  DTS checks whether the topology that you specify for the source and destination RDS instances is supported.

- Cause of failure
  - The source RDS instance in the current task is being used as the destination instance of another task.
  - The destination RDS instance in the current task is being used as the source or destination instance of another task.
  - The objects that you want to synchronize in the current task are being synchronized by an existing task. The two tasks have the same source and destination RDS instances.

- Solution
  - If the task that you want to create has the same source and destination RDS instances as an existing task, you can add the required objects to the existing task. You do not need to create another task to synchronize these objects.
  - If the task that you want to create conflicts with an existing task, wait until the existing task is completed before you create a data synchronization task again.

Format of the MySQL database password

DTS checks whether the format of the password that is used to access the source database is no longer valid. If the data source is an RDS instance, the task passes the precheck.

18.1.5. Change tracking

18.1.5.1. Overview

You can use Data Transmission Service (DTS) to track data changes from ApsaraDB RDS for MySQL instances in real time. This feature applies to the following scenarios: lightweight cache updates, business decoupling, asynchronous data processing, and synchronization of extract, transform, and load (ETL) operations.

Supported databases

- User-created MySQL databases or ApsaraDB RDS for MySQL
- PolarDB-X (formerly known as DRDS)
- User-created Oracle database

Objects for change tracking

The objects for change tracking include tables and databases.

In change tracking, data changes include data manipulation language (DML) operations and data definition language (DDL) operations. When you configure change tracking, you must select operation types.

Change tracking tasks

A change tracking task is the basic unit of change tracking and data consumption. To track data changes from an RDS instance, you must create a change tracking task in the DTS console for the RDS instance. The change tracking task pulls data changes from the RDS instance in real time and locally stores the data changes. You can use the DTS SDK to consume the tracked data. You can also create, manage, or delete change tracking tasks in the DTS console.

18.1.5.2. Create a change tracking instance

Before you configure a task to track data changes, you must create a change tracking instance. This topic describes how to create a change tracking instance in the Data Transmission Service (DTS) console.

Procedure

1. Log on to the DTS console.
2. In the left-side navigation pane, click **Change Tracking**.
3. In the upper-right corner, click **Create Change Tracking Task**.
4. In the Create DTS Instances dialog box, select a region, and enter the number of change tracking instances that you want to create.

   > **Note** In the Create DTS Instances dialog box, you can view the total number of instances, the number of existing instances, and the number of instances that can be created.

5. Click **Create**.

18.1.5.3. Configure change tracking tasks

18.1.5.3.1. Track data changes from a user-created MySQL database or an ApsaraDB RDS for MySQL instance

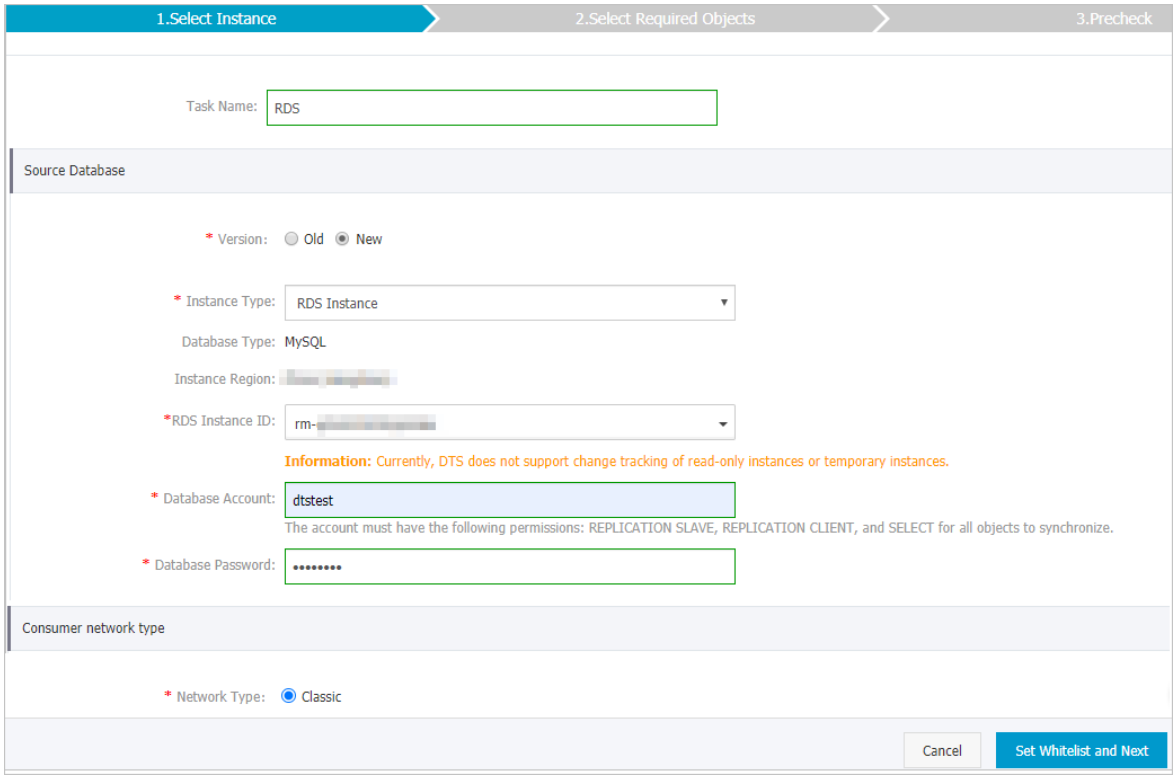
You can use Data Transmission Service (DTS) to track data changes in real time. This feature applies to the following scenarios: lightweight cache updates, business decoupling, asynchronous data processing, and synchronization of extract, transform, and load (ETL) operations. This topic describes how to track data changes from a user-created MySQL database or an ApsaraDB RDS for MySQL instance.

Prerequisites

The database version is 5.1, 5.5, 5.6, or 5.7.

Procedure

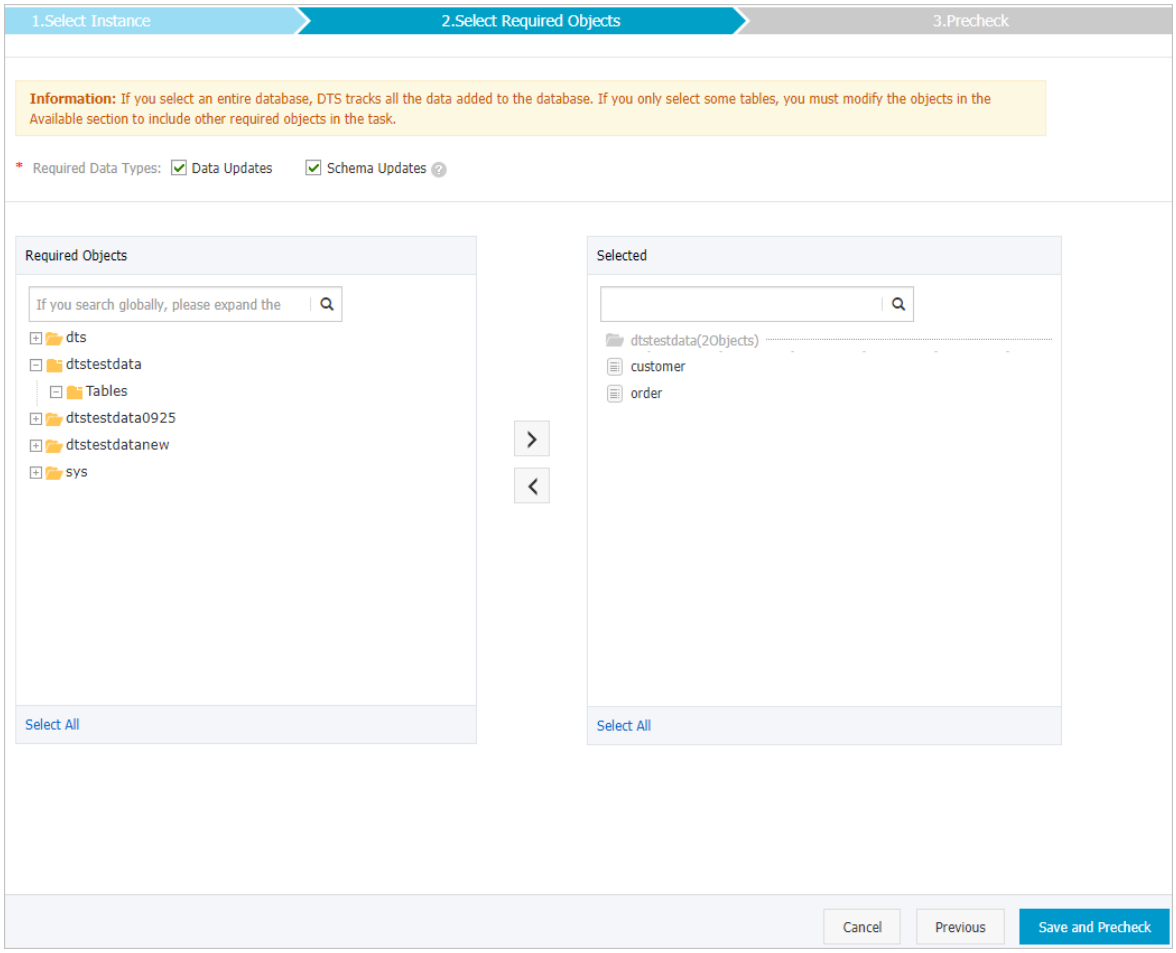
1.
2.
3. Configure the source database.



Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
	Version	Select a version based on your business requirements: ○ If the source database is a user-created MySQL database, select **Old**. ○ If the source database is ApsaraDB RDS for MySQL, select **New**. **Note** You can follow the same procedure to configure a change tracking task when you select Old or New. In this example, select New.
	Instance Type	Select **RDS Instance**.
	Database Type	This parameter is set to **MySQL** and cannot be changed.

Section	Parameter	Description
Source Database	Instance Region	The source region that you selected when you created the change tracking instance. You cannot change the value of this parameter.
	RDS Instance ID	Select the ID of the RDS instance from which you want to track data changes. **Note** A read-only instance or temporary instance cannot be used as the source instance for change tracking.
	Database Account	Enter the database account of the source RDS instance. **Note** • The account must have the SELECT permission on the required objects, the REPLICATION SLAVE permission, and the REPLICATION CLIENT permission. • If the database engine of the source RDS instance is **MySQL 5.5** or **MySQL 5.6**, you do not need to configure the **database account** or **database password**.
	Database Password	Enter the password of the source database account.
Consumer Network Type	Network Type	**Classic** is selected by default. **Note** • This parameter is available only if the Version parameter is set to **New**. • If you track data changes over internal networks, the network latency is minimal.

4.
5. Select the data change types and objects.



6.
7.

What's next

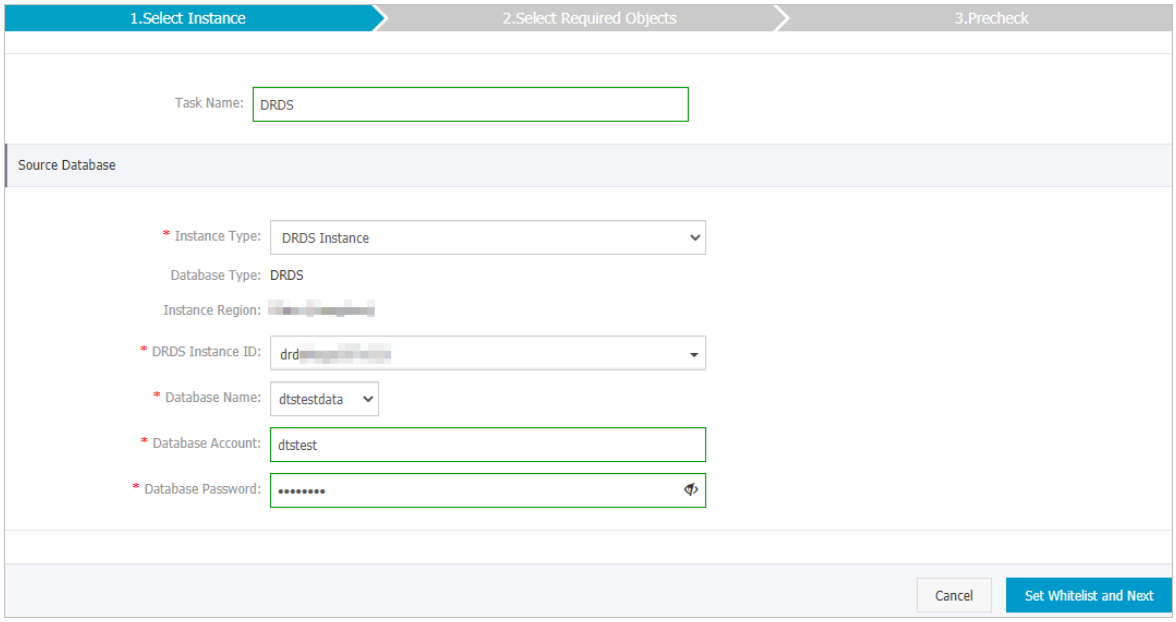
- Previous change tracking feature: Run the SDK demo code
- New change tracking feature: Use a Kafka client to consume tracked data

18.1.5.3.2. Track data changes from a PolarDB-X instance

You can use Data Transmission Service (DTS) to track data changes in real time. This feature applies to the following scenarios: lightweight cache updates, business decoupling, asynchronous data processing, and synchronization of extract, transform, and load (ETL) operations. This topic describes how to track data changes from a PolarDB-X instance. PolarDB-X is formerly known as Distributed Relational Database Service (DRDS).

Procedure

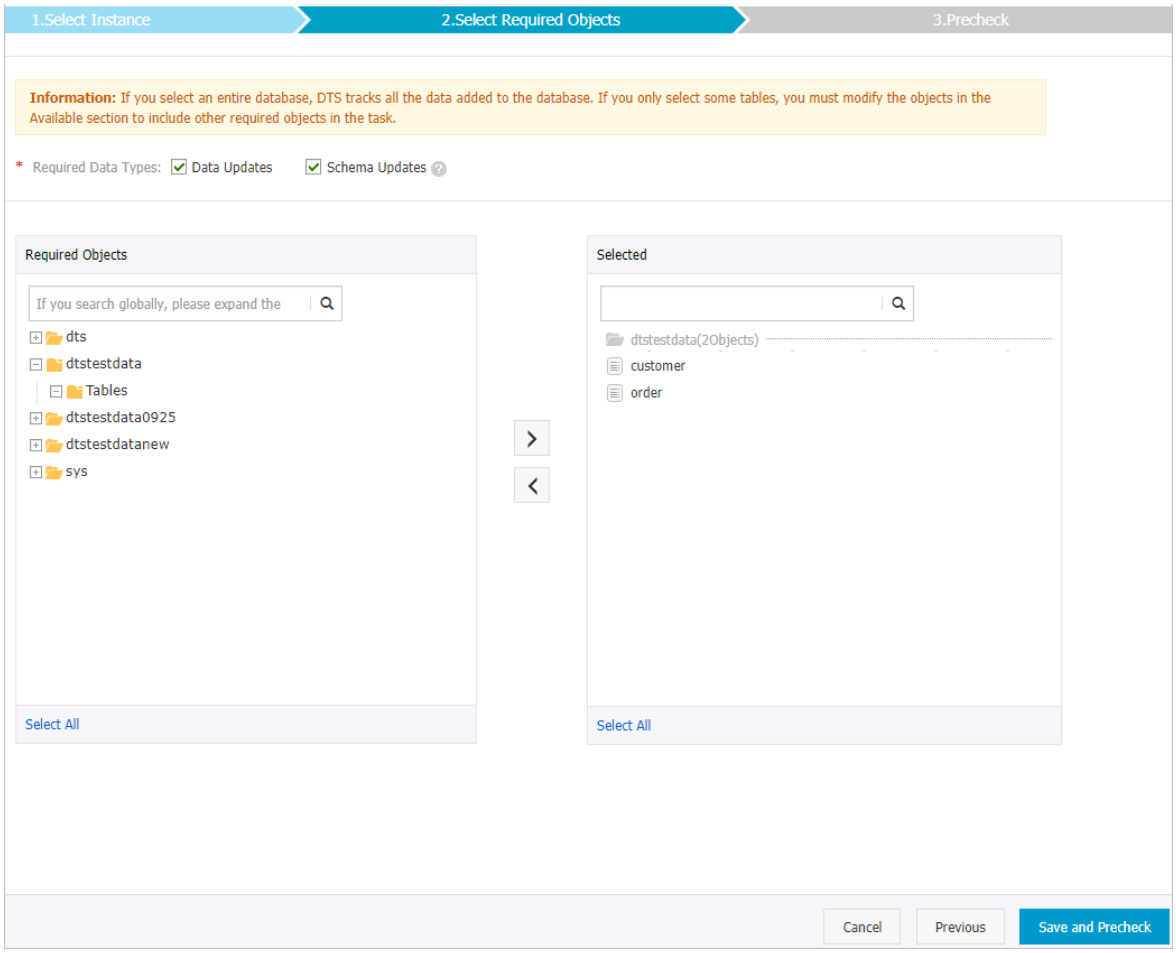
1.
2.
3. Configure the source database.



Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	This parameter is set to **DRDS Instance** and cannot be changed.
	Database Type	This parameter is set to **DRDS** and cannot be changed.
	Instance Region	The region of the source instance. The region is the same as the region that you selected when you created the change tracking task. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the PolarDB-X instance.
	Database Name	Select the ID of the source database in the PolarDB-X instance.
	Database Account	Enter the database account of the PolarDB-X instance.
	Database Password	Enter the password of the source database account.

4.

5. Select the data change types and objects.



6.
7.

18.1.5.3.3. Track data changes from a user-created Oracle database

You can use Data Transmission Service (DTS) to track data changes in real time. This feature applies to the following scenarios: lightweight cache updates, business decoupling, and synchronization of extract, transform, and load (ETL) operations. This topic describes how to track data changes from a user-created Oracle database.

Prerequisites

- The version of the user-created Oracle database is 9i, 10g, 11g, 12c, 18c, or 19c.
- Supplemental logging, including SUPPLEMENTAL_LOG_DATA_PK and SUPPLEMENTAL_LOG_DATA_UI, is enabled for the user-created Oracle database. For more information, see Supplemental Logging.
- The user-created Oracle database is running in ARCHIVELOG mode. Archived log files are accessible and a suitable retention period is set for archived log files. For more information, see Managing Archived Redo Log Files.

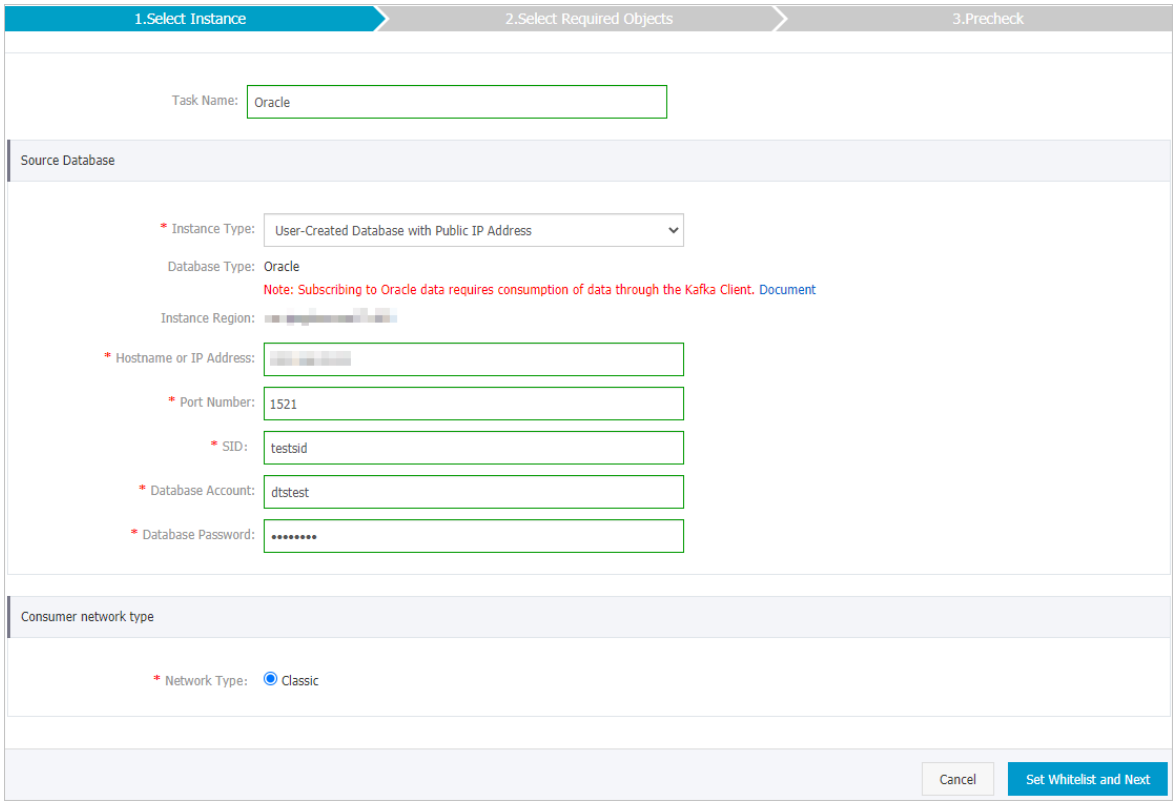
Precautions

- DTS does not track data definition language (DDL) operations that are performed by gh-ost or pt-online-schema-change. Therefore, the change tracking client may fail to write the consumed data to the destination tables due to schema conflict.

- If the source database is used in another task, for example, it is used in a running data migration task, DTS may track data changes of other objects. In this case, you must use the change tracking client to filter the tracked data.
- If you perform a primary/secondary switchover on the source database when the change tracking task is running, the task fails.

Procedure

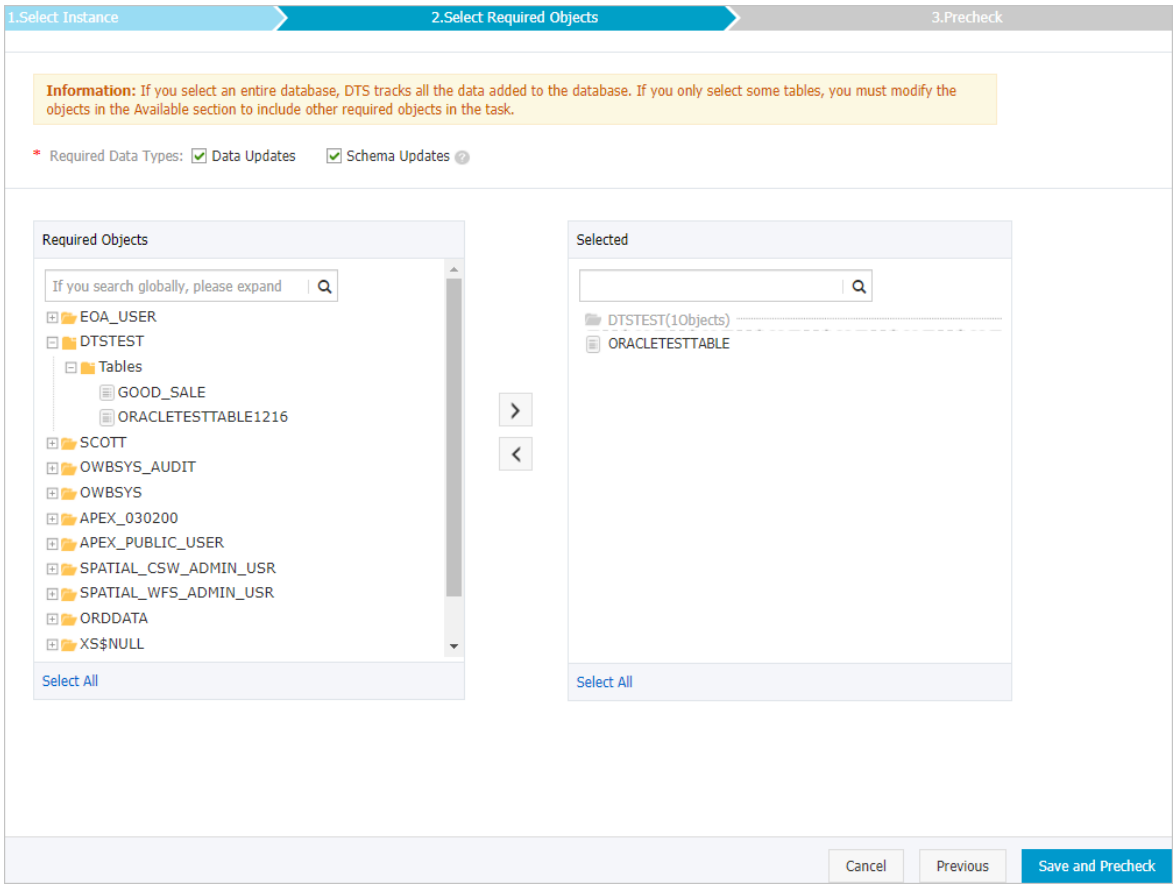
1. Create a change tracking instance.
2. Find the change tracking instance that you created, and click **Configure Channel** in the **Actions** column.
3. Configure the source database and network type.



Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select an instance type based on the deployment of the source database. In this example, select **User-Created Database with Public IP Address**.
	Database Type	This parameter is set to Oracle and cannot be changed.
	Instance Region	The source region that you selected when you created the change tracking instance. You cannot change the value of this parameter.
	Hostname or IP Address	Enter the hostname or IP address of the user-created Oracle database.
	Port Number	Enter the service port number of the user-created Oracle database.
	SID	Enter the system ID (SID) of the user-created Oracle database.

Section	Parameter	Description
	Database Account	Enter the account of the user-created Oracle database. **Note** The account must have the database administrator (DBA) permission.
	Database Password	Enter the password of the source database account.
Consumer Network Type	N/A	**Classic** is selected by default. **Note** If you track data changes over internal networks, the network latency is minimal.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. Select the data change types and objects.



Parameter	Description

Parameter	Description
Required Data Types	◦ **Data Updates** DTS tracks data updates of the selected objects, including the INSERT, DELETE, and UPDATE operations. ◦ **Schema Updates** DTS tracks the create, delete, and modify operations that are performed on all object schemas of the source instance. You must use the change tracking client to filter the required data. **Note** ◦ If you select a database as the object, DTS tracks data changes of all objects, including new objects in the database. ◦ If you select a table as the object, DTS only tracks data changes of this table. In this case, if you want to track data changes of another table, you must add the table to the required objects. For more information, see Modify the objects for change tracking.
Required Objects	Select tables or databases from the **Required Objects** section and click the › icon to move them to the **Selected** section.

6. In the lower-right corner of the page, click **Save and Precheck**.

   Note You can start a change tracking task only after the task passes the precheck. If the task fails to pass the precheck, click the ⓘ icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

7. Close the **Precheck** dialog box after the following message is displayed: **The precheck is passed.** After the change tracking task is configured, DTS performs initial change tracking, which takes about 1 minute. After the initial change tracking is complete, you can consume the tracked data.

What's next

Use a Kafka client to consume tracked data

18.1.5.4. Manage change tracking tasks

18.1.5.4.1. Modify the consumption checkpoint

During data consumption, you can modify the consumption checkpoint of a change tracking task based on your business requirements. After you modify the consumption checkpoint, the downstream SDK client will consume the data that is generated after the specified time.

Prerequisites

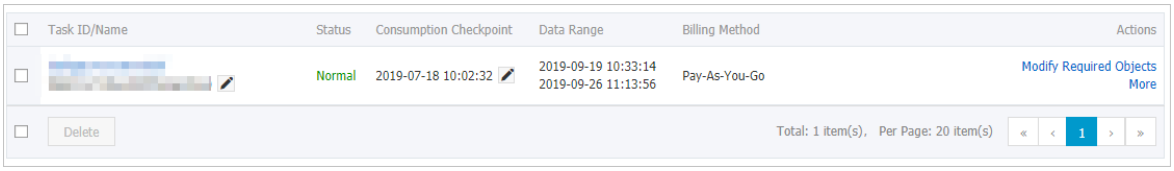
A change tracking task is created. For more information, see Track data changes from a user-created MySQL database or an ApsaraDB RDS for MySQL instance (previous version) or Track data changes from a PolarDB-X instance.

Procedure

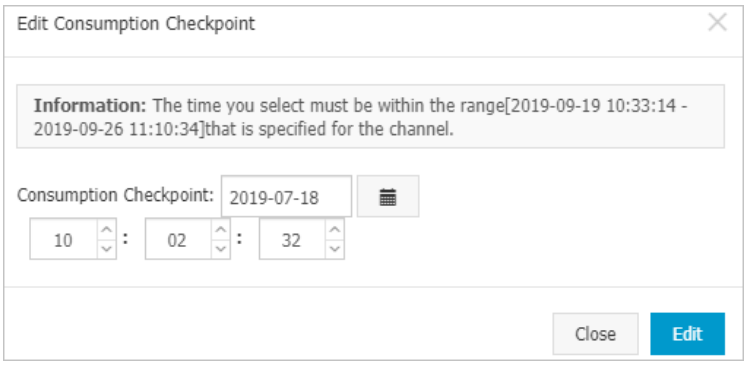
1. Stop all downstream SDK consumption processes.

> **Note** We recommend that you perform this operation during off-peak hours to avoid service interruption.

2. Log on to the DTS console.
3. In the left-side navigation pane, click **Change Tracking**.
4. Find the change tracking task, move the pointer over the **Consumption Checkpoint** column, and then click the icon.



5. In the Modify Consumption Checkpoint dialog box, specify a new consumption checkpoint.



> **Note** The selected time range must be within the time range of the tracked data. For more information, see the prompt in the dialog box.

6. Click **Modify**.
7. Restart the downstream SDK consumption processes.
   The downstream SDK client tracks data changes from the new consumption checkpoint.

18.1.5.4.2. Modify the objects for change tracking

DTS allows you to add or remove the objects for change tracking in the consumption process. This topic describes how to modify the objects for change tracking.

Procedure

1. Log on to the DTS console.
2. In the left-side navigation pane, click **Change Tracking**.
3. Find the change tracking task, and click **Modify Required Objects** in the **Actions** column.
4. In the **Select Required Objects** step, add or remove the objects for change tracking.
   - Add the objects for change tracking

     In the **Required Objects** section, select one or more objects and click the › icon to add the objects to the **Selected** section.
   - Remove the objects for change tracking

In the **Selected** section, select one or more objects and click the icon to move the objects to the **Required Objects** section.

5. In the lower-right corner of the page, click **Save and Precheck**.

18.1.5.4.3. Create a consumer group

You can manage consumer groups of a change tracking task in the DTS console. This topic describes how to create a consumer group.

Prerequisites

A change tracking task is created. For more information, see Track data changes from a user-created MySQL database or an ApsaraDB RDS for MySQL instance (new version) or Track data changes from a PolarDB-X instance.

Note

- You can create multiple consumer groups (up to 20) in a change tracking instance to repeatedly consume data.
- A consumer group consumes each message only once, and only one consumer can consume data.

Procedure

1. Log on to the DTS console.
2. In the left-side navigation pane, click **Change Tracking**.
3. Find the change tracking task and click the task ID.
4. In the left-side navigation pane, click **Consume Data**.
5. On the **Consume Data** page, click **Add Consumer Group** in the upper-right corner.
6. In the dialog box that appears, set the parameters for the consumer group.

Parameter	Description
Consumer Group Name	Enter a new name for the consumer group. We recommend that you use an informative name for easy identification.
Username	Enter the username of the consumer group. ○ A username must contain one or more of the following character types: uppercase letters, lowercase letters, digits, and underscores (_). ○ The username must be 1 to 16 characters in length.
Password	Enter the password that corresponds to the username of the consumer group. ○ A password must contain two or more of the following character types: uppercase letters, lowercase letters, digits, and special characters. ○ The password must be 8 to 32 characters in length.
Confirm Password	Enter the new password again.

7. Click **Create**.

18.1.5.4.4. Manage consumer groups

You can manage consumer groups of a change tracking task in the DTS console. This topic describes how to modify the password of a consumer group and how to delete a consumer group.

Prerequisites

Create a consumer group

Procedure

1. Log on to the DTS console.
2. In the left-side navigation pane, click **Change Tracking**.
3. Find the change tracking task and click the task ID.
4. In the left-side navigation pane, click **Consume Data**.
5. Modify the password of a consumer group or delete a consumer group.

   Modify the password of a consumer group

   i. On the **Consume Data** page, find the target consumer group and click **Modify Password** in the **Actions** column.

   
   ii. In the **Modify Password** dialog box that appears, enter the **old password** and **new password**, and enter the new password again in the **Confirm Password** field.

   > Note
   > - A password must contain two or more of the following character types: uppercase letters, lowercase letters, digits, and special characters.
   > - The password must be 8 to 32 characters in length.

   iii. Click **Modify**.

   Delete a consumer group

   > Note After a consumer group is deleted, the data in the group will be cleared and cannot be recovered. We recommend that you use caution when performing this operation.

   i. On the **Consume Data** page, find the target consumer group and click **Delete** in the **Actions** column.

   ii. In the **Delete Consumer Group** message that appears, click **OK**.

18.1.5.5. Use the SDK to consume tracked data

18.1.5.5.1. Methods provided by SDK

You can use the SDK demo code that is provided by DTS to consume tracked data. This topic describes the methods that are available for the SDK classes.

Methods of the RegionContex class

Method	Description

Method	Description
`setAccessKey(accessKey)`	Specifies the AccessKey ID of the Alibaba Cloud account to which the source instance belongs.
`setSecret(AccessKeySecret)`	Specifies the AccessKey secret of the Alibaba Cloud account to which the source instance belongs.
`setUsePublicIp(usePublicIp)`	Specifies whether to track data changes over the Internet. **Note** DTS can track data changes only over the Internet. Therefore, set the usePublicIp parameter to `true`.
`context.setUseBinary(boolean useBinary)`	Specifies whether to enable the binary packaging feature. Valid values: True and False. We recommend that you enable this feature to improve consumption performance.
`context.setUseDrcNet(boolean useDrcNet)`	Specifies whether to enable the network optimization feature. Valid values: True and False. We recommend that you enable this feature to improve consumption performance.

Methods of the ClusterClient class

Method	Description
`void addConcurrentListener(ClusterListener arg0)`	Adds a downstream listener to retrieve data changes from a change tracking instance. **Note** The `ClusterListener arg0` parameter specifies an object of the `ClusterListener` class.
`void askForGUID(String arg0)`	Retrieves data changes from a change tracking instance. Set the String arg0 parameter to the ID of the change tracking instance.
`List<ClusterListener> getConcurrentListeners()`	Queries the list of listeners in a ClusterClient object. The return type is `List <ClusterListener>`.
`void start()`	Starts the SDK client to start change tracking.
`void stop()`	Stops the SDK client to stop change tracking. **Note** Data pulling and notification callback are performed in the same thread of the SDK client. If the consumption code of the notify() method contains a function that prevents signal interruptions, the stop() function may fail to terminate the SDK client.

Methods of the ClusterListener class

The `void notify(List<ClusterMessage> arg0)` method specifies the consumption mode of tracked data. When the DTS SDK receives the data, it uses the notify() function to notify a ClusterListener object to consume the data. Then, the SDK displays the data on the screen.

Methods of the ClusterMessage class

> **Note** Each ClusterMessage object stores the data record of a transaction. Each data record in the transaction is stored by using a Record object.

Method	Description
`Record getRecord()`	Retrieves a change record from a ClusterMessage object. The change record contains an entry in the binary log file, such as a BEGIN, COMMIT, UPDATE, or INSERT operation.
`void ackAsConsumed`	After the data consumption is complete, you must call this method to send an ACK packet to instruct the DTS server to update the consumer offset. This ensures the integrity of the consumed data after an abnormal SDK client restarts. **Note** If a downstream SDK client restarts after a breakdown, the client resumes change tracking from the last consumer offset.

Methods of the Record class

The `String getAttribute(String key)` method retrieves the attribute values in a Record object. The following table describes the parameters that are available when you call this method.

Parameter	Description
`record_id`	The ID of the record. **Note** The record ID may not increment during the change tracking process.
`instance`	The endpoint that is used to connect to the database instance. The format is <IP address>:<Port number>.
`source_type`	The engine type of the database instance. The value is set to MySQL.
`source_category`	The type of the record. The value is set to full_recorded.
`timestamp`	The binlog timestamp that is generated when the SQL statement is executed in the source database.

Parameter	Description
`checkpoint`	The checkpoint of the binary log file. The format is `binlog_offset@binlog_file`. **Note** The `binlog_offset` parameter indicates the offset of a record in the binary log file. The `binlog_file` parameter indicates the numerical suffix of the binary log file. For example, if the name of a binary log file is mysql-bin.0008, the value of the binlog_file parameter is 8.
`record_type`	The operation type. Valid values: insert, update, delete, replace, ddl, begin, commit, and heartbeat. **Note** A heartbeat record indicates the heartbeat table that is defined by DTS. The system generates one heartbeat record per second to detect whether the change tracking instance is running as expected.
`db`	The name of the database.
`table_name`	The name of the table.
`record_recording`	The encoding format.
`primary`	The name of the primary key column. If the primary key is a composite key, separate column names with commas (,).
`fields_enc`	The encoding of each field value. Separate fields with commas (,). **Note** If a field value is not of the character type, the encoding of this field value is null.

The following table lists the methods that are preset in the SDK demo code. You can call these methods to retrieve the attribute values in a Record object.

Method	Description
`Type getOpt()`	Queries the operation type.
`String getCheckpoint()`	Queries the checkpoint of the binary log file.
`String gettimestamp()`	Queries the timestamp of the binary log file.
`String getDbname()`	Queries the database name.
`String getTablename()`	Queries the table name.

Method	Description
`String getPrimaryKeys()`	Queries the name of the primary key column.
`DBType getDbType()`	Queries the database type.
`String getServerId()`	Queries the endpoint that is used to connect to the database instance.
`int getFieldCount()`	Queries the number of fields.
`List<Field> getFieldList()`	Queries the definitions of all fields, the pre-change image values, and the post-change image values. For more information, see Methods of the Field class.
`Boolean isFirstInLogevent()`	Checks whether the record is the first transaction log in a large volume of data changes. The return value is True or False.

Methods of the Field class

Method	Description
`String getEncoding()`	Obtains the encoding format of the field value.
`String getFieldname()`	Queries the name of the field.
`Type getType()`	Queries the data type of the field.
`ByteString getValue()`	Queries the value of the field. The return type is ByteString. If the field is not specified, the method returns `NULL`.
`Boolean isPrimary()`	Checks whether the field is a primary key column. The return value is True or False.

18.1.5.5.2. Quick start

This section describes how to use the DTS Java SDK to perform some basic operations.

Initialize a RegionContext object

A RegionContext object stores the settings of authentication credentials and network access mode. The following code shows how to initialize a RegionContext object.

```
import java.util.List;
import com.aliyun.drc.clusterclient.ClusterClient;
import com.aliyun.drc.clusterclient.DefaultClusterClient;
import com.aliyun.drc.clusterclient.RegionContext;
public class MainClass
{
      public static void main(String[] args) throws Exception {
        // Create a RegionContext object.
          RegionContext context = new RegionContext();
          context.setAccessKey("<AccessKey>");
          context.setSecret("<AccessKeySecret>");
          context.setUsePublicIp(true);
          // Create a ClusterClient object.
          final ClusterClient client = new DefaultClusterClient(context);
          // Other invocation code.
          ...
    }
}
```

Initialize a Listener object

Data consumption is implemented by using an object of the Listener class. After you initialize the ClusterClient object, you must add a Listener object. The Listener object uses the notify() method to receive and consume the tracked data. The following code shows how to display the tracked data on the screen.

```
import com.aliyun.drc.clusterclient.ClusterClient;
import com.aliyun.drc.clusterclient.ClusterListener;
import com.aliyun.drc.clusterclient.DefaultClusterClient;
import com.aliyun.drc.clusterclient.RegionContext;
import com.aliyun.drc.clusterclient.message.ClusterMessage;
public class MainClass
{
    public static void main(String[] args) throws Exception {
        // Initialize the RegionContext object.
        ...
        //Initialize the ClusterClient object.
        ...
        ClusterListener listener = new ClusterListener(){
             @Override
             public void notify(List<ClusterMessage> messages) throws Exception {
                  for (ClusterMessage message : messages) {
                    // Display the tracked data on the screen.
                      System.out.println(message.getRecord() + ":" + message.getRecord().getTablename
() + ":"
                      + message.getRecord().getOpt());
                      // Call the following method to send an ACK packet to the DTS server.
                      message.ackAsConsumed();
               }
      }
     }
}
```

DTS saves the consumption checkpoints of the SDK to the DTS server. This simplifies disaster recovery during the use of the SDK. The ackAsConsumed() method sends the checkpoint and timestamp of the latest data record that was consumed by the DTS SDK to the DTS server. If the SDK restarts due to an error, the SDK obtains the consumption checkpoint from the DTS server. The SDK resumes data consumption from the checkpoint. This ensures that the SDK does not consume duplicate data.

Start the ClusterClient object

Use the following code:

```
import java.util.List;
import com.aliyun.drc.clusterclient.ClusterClient;
import com.aliyun.drc.clusterclient.ClusterListener;
import com.aliyun.drc.clusterclient.DefaultClusterClient;
import com.aliyun.drc.clusterclient.RegionContext;
import com.aliyun.drc.clusterclient.message.ClusterMessage;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
public class MainClass
{
   public static void main(String[] args) throws Exception {
    // Initialize the RegionContext object.
    ...
    // Initialize the ClusterClient object.
    ...
    // Initialize the ClusterListener object.
    ...
    // Add a Listener class.
      client.addConcurrentListener(listener);
      // Specify the ID of the change tracking instance.
      client.askForGUID("dts_rdsrjiei2u2afnb_DSF");
      // Start a background thread. The main thread cannot exit.
      client.start();
}
```

The askForGUID() method sets the ID of the change tracking instance. You can obtain the ID of the change tracking instance from the DTS console. After the ID of the change tracking instance is specified in the askForGUID() method, the SDK retrieves incremental data from this instance.

Before you can start a ClusterClient object, you must add a Listener class to the ClusterClient object. When the ClusterClient object pulls incremental data from the change tracking instance, it also calls the notify() method of the Listener class to consume data.

18.1.5.5.3. Parse tracked SQL statements

You can use the DTS SDK to track data changes. DTS records the tracked data changes in a custom format. This topic describes how to parse various types of SQL statements.

Parse a DDL statement

If a data definition language (DDL) operation is performed in the source database, the operation type of the data record is DDL. The DDL statement is stored in the value of the first column. You can use the following sample code to parse the DDL statement:

```
String ddl_string;
Record.Type type=record.getOpt();
if(type.equals(Record.Type.DDL)){
    List<DataMessage.Record.Field> fields = record.getFieldList();
    ddl_string = fields.get(0).getValue().toString();
}
```

Parse an INSERT statement

If an INSERT operation is performed in the source database, the operation type of the data record is INSERT. You can use the following sample code to parse the INSERT statement:

```
StringBuilder insert_string=new StringBuilder();
Record.Type type=record.getOpt();
DataMessage.Record.Field field;
StringBuilder FieldName=new StringBuilder();
StringBuilder FieldValue = new StringBuilder();
if(type.equals(Record.Type.INSERT)){
       int i=0;
       List<DataMessage.Record.Field> fields = record.getFieldList();
       for (; i < fields.size(); i++) {
              field = fields.get(i);                                    FieldName.append('`'+field.get
Fieldname().toLowerCase()+'`');
              FieldValue.append("'"+field.getValue()+"'");
              if (i ! = fields.size() - 1) {
                     FieldName.append(',');
                     FieldValue.append(',');
              }
        }
        insert_string.append("insert "+ record.getTablename()+"("+FieldName.toString()+") values("+Fi
eldValue.toString()+");");
}
```

Parse an UPDATE statement

If an UPDATE operation is performed in the source database, the operation type of the data record is UPDATE. The field values prior to the UPDATE operation are stored in `Record.getFieldList()` entries with even indexes. The field values after the UPDATE operation are stored in Record.getFieldList() entries with odd indexes.

If the UPDATE operation is performed on a table that has a primary key, you can use the following sample code to parse the UPDATE statement:

```
StringBuilder update_string=new StringBuilder();
Record.Type type=record.getOpt();
DataMessage.Record.Field field;
StringBuilder SetValue = new StringBuilder();
StringBuilder WhereCondition = new StringBuilder();
String ConditionStr;
boolean hasPk=false;
boolean pkMode=false;
boolean hasSet=false;
if(type.equals(Record.Type.UPDATE)){
    int i=0;
    DataMessage.Record.Field OldField = null;
    DataMessage.Record.Field NewField = null;
    List<DataMessage.Record.Field> fields = record.getFieldList();
    for (; i <fields.size() ; i++) {
        if (i % 2 == 0) {
            OldField = fields.get(i);
            continue;
        }
    NewField = fields.get(i);
    field = NewField;
    if (field.isPrimary()) {
        if (hasPk) {
            WhereCondition.append(" and ");
        }
        //where old value
```

```
        ConditionStr = getFieldValue(OldField);
        if(ConditionStr==null){                                    WhereCondition.append("`"+fie
ld.getFieldname().toLowerCase()+"`" + " " + "is null");
        }else{
               WhereCondition.append("`"+field.getFieldname().toLowerCase()+"`"+" = "+ "'"+OldField.g
etValue()+"'");
         }
        hasPk = true;
    }
    if (hasSet) {
        SetValue.append(",");
    }
      SetValue.append("`"+field.getFieldname().toLowerCase()+"`" + " = " + "'"+field.getValue()+"'");
    String setStr = getFieldValue(field);
    hasSet = true;
    }
    update_string.append("Update "+record.getTablename() +" Set " + SetValue + " Where "+WhereConditi
on +";");
}
protected String getFieldValue(Field field) throws Exception {
    ByteString byteString = field.getValue();
    if (byteString == null) {
        return null;
    }
    else {
        String value;
        if (field.getType() == com.aliyun.drc.client.message.DataMessage.Record.Field.Type.STRING &&
field.getEncoding() ! = null && field.getEncoding() ! = "ASCII") {
            value = field.getValue().toString(field.getEncoding());
        }
        else {
          value = byteString.toString();
        }
        return value;
    }
}
```

Parse a DELETE statement

If a DELETE operation is performed in the source database, the operation type of the data record is DELETE. If the DELETE operation is performed on a table that has a primary key, you can use the following sample code to parse the DELETE statement:

```
StringBuilder delete_string=new StringBuilder();
Record.Type type=record.getOpt();
DataMessage.Record.Field field;
StringBuilder FieldName=new StringBuilder();
StringBuilder FieldValue = new StringBuilder();
StringBuilder DeleteCondition = new StringBuilder();
boolean hasPk=false;
boolean pkMode=false;
if(type.equals(Record.Type.DELETE)){
   int i=0;
   List<DataMessage.Record.Field> fields = record.getFieldList();
   delete_string.append("Delete From" + record.getTablename() + "where");
   // Check whether the table has a primary key.
   if (record.getPrimaryKeys() ! = null) {
             pkMode = record.getPrimaryKeys().length() > 0 ? true : false;
   }
   for (; i < fields.size(); i++) {
            if ((pkMode && ! field.isPrimary())) {
                    continue;
            }
            if (hasPk) {
                    delete_string.append(" and ");
            }
            delete_string.append(field.getFieldname() + "=" + field.getValue());
            hasPk = true;
    }
    delete_string.append(";");
}
```

Parse a REPLACE statement

If a REPLACE operation is performed in the source database, the operation type of the data record is UPDATE or INSERT.

- If the value specified in the REPLACE statement does not exist, the operation type of the data record is INSERT.
- If the value specified in the REPLACE statement exists, the operation type of the data record is UPDATE.

Parse a BEGIN statement

If a BEGIN operation is performed in the source database, the operation type of the data record is BEGIN. You do not need to perform operations on fields because the BEGIN statement does not modify fields. You only need to check that the operation is a BEGIN operation. You can use the following sample code to parse the BEGIN statement:

```
StringBuilder sql_string = new StringBuilder();
Record.Type type = record.getOpt();
if(type.equals(Record.Type.BEGIN)){
        sql_string.append("Begin");
}
```

Parse a COMMIT statement

If a COMMIT operation is performed in the source database, the operation type for the data record is COMMIT. You do not need to perform operations on fields because the COMMIT statement does not modify fields. You only need to check that the operation is a COMMIT operation. You can use the following sample code to parse the COMMIT statement:

```
StringBuilder sql_string = new StringBuilder();
Record.Type type = record.getOpt();
if(type.equals(Record.Type.COMMIT)){
        sql_string.append("commit");
}
```

18.1.5.5.4. Run the SDK demo code

This section describes how to run the demo code provided by the DTS console.

1. Create an AccessKey.

   Your account must pass the AccessKey authentication before you can use an SDK to connect to a subscription channel. Therefore, before using the SDK, you must obtain an AccessKey. For more information, see the "**Obtain an AccessKey**" section of the *DTS Developer Guide* .

2. Install the Java SDK.

   The development environment supported by the DTS Java SDK is J2SE Development Kit (JDK) V1.5 or later.

   For an Eclipse project, you can follow these steps to install the Java SDK:

   i. Click **View Example Code** and download the SDK package *consumer.jar*.

   ii. Import the JAR package to an Eclipse project as follows:

   In Eclipse, right-click your project and choose **Properties > Java Build Path > Libraries > Add External JARs**. Select the path for storing the *consumer.jar* package consumer.jar.

   iii. Select the *consumer.jar* package and click **OK**.

   Then you can use the DTS Java SDK in the project.

3. Run the demo code.

   DTS provides the SDK demo code. You can copy the demo code by using the View Demo Code option in the DTS console. For an Eclipse project, you can follow these steps to run the demo code:

   i. Create a class named MainClass in the src directory of the Eclipse project.

   ii. Open the generated Java file *MainClass* and delete the code template.

   iii. Paste the demo code into the *MainClass* file.

   iv. Modify the AccessKeyId, AccessKeySecret, and subscription channel ID in the demo code.

   Change the marked parts in the preceding demo code to the AccessKeyId, AccessKeySecret, and subscription channel ID of your account.

   You can obtain the subscription channel ID from the DTS console.

   v. In Eclipse, right-click the demo file and choose **Run as > Java Application** to run the demo code.

18.1.5.6. Use a Kafka client to consume tracked data

This topic describes how to use the demo code of a Kafka client to consume tracked data. The change tracking feature of the new version allows you to consume tracked data by using a Kafka client from V0.11 to V1.1.

Prerequisites

- A change tracking task is created. For more information, see Track data changes from a user-created MySQL database or an ApsaraDB RDS for MySQL instance (new version) or Track data changes from a PolarDB-X instance.
- One or more consumer groups are created. For more information, see Create a consumer group.

Download and run the demo code of the Kafka client

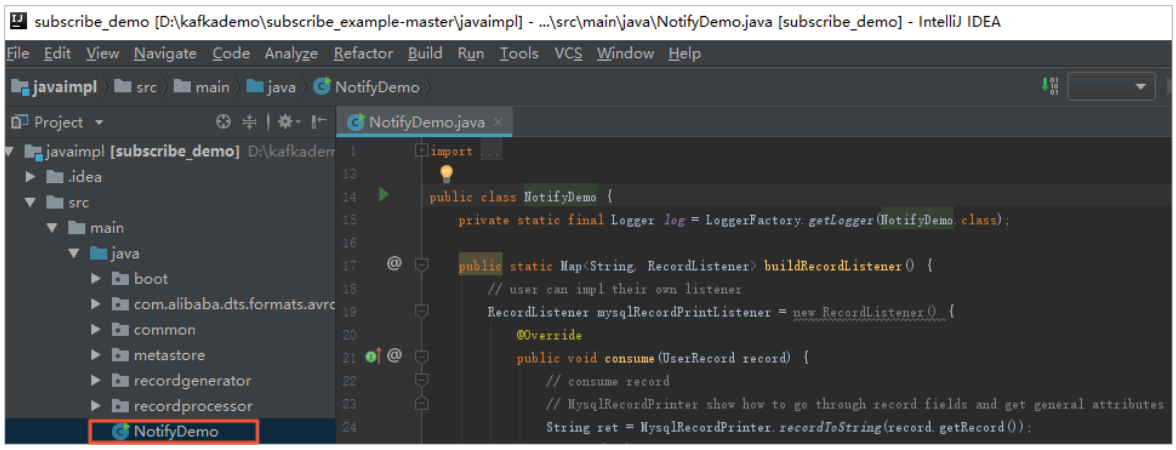
Click here to download the demo code of the Kafka client.

Download and run the demo code of the Kafka client

Step	File or directory
1. Use the native Kafka consumer to obtain incremental data from the change tracking instance.	subscribe_example-master/javaimpl/src/main/java/recordgenerator/
2. Deserialize the image of the incremental data, and obtain attributes such as the pre-image and post-image.	subscribe_example-master/javaimpl/src/main/java/boot/MysqlRecordPrinter.java
3. Convert the dataTypeNumber values in the deserialized data into MySQL or Oracle data types. **Note** For more information, see Mappings between MySQL data types and dataTypeNumber values and Mappings between Oracle data types and dataTypeNumber values.	subscribe_example-master/javaimpl/src/main/java/recordprocessor/mysql/

Procedure

1. Download the demo code of the Kafka client, and then decompress the package.
2. Open IntelliJ IDEA. In the window that appears, click **Open**.
3. In the dialog box that appears, go to the directory in which the downloaded demo code resides. Find the *pom.xml* file.
4. In the dialog box that appears, select **Open as Project**.
5. On the IntelliJ IDEA page, expand folders to find the demo file of the Kafka client, and double-click the file. The file name is *NotifyDemo.java*.



6. Set the parameters in the *NotifyDemo.java* file.

Parameter	Description	Method to obtain

Parameter	Description	Method to obtain
USER_NAME	The username of the consumer group. **Warning** If you are not using the Kafka client that is described in this topic, you must specify the username in the following format: `<Consumer group account>-<Consumer group ID>`, for example, `dtstest-dtsae******bpv`. Otherwise, the connection fails.	In the DTS console, click the instance ID, and then click **Data Consume**. You can obtain the **Consumer Group ID** and the corresponding **Account** information. **Note** The password of the consumer group account is specified when you create a consumer group.
PASSWORD_NAME	The password of the account.	
SID_NAME	The ID of the consumer group.	
GROUP_NAME	The name of the consumer group. Set this parameter to the consumer group ID.	
KAFKA_TOPIC	The topic of the change tracking task.	In the DTS console, click the instance ID. On the **Track Data Changes** page, you can obtain the **tracked topic**, network address, and port number.
KAFKA_BROKER_URL_NAME	The network address and port number of the change tracking task. **Note** If you track data changes over internal networks, the network latency is minimal. This is applicable if the ECS instance where you deploy the Kafka client belongs to the same VPC or classic network as the change tracking instance.	
INITIAL_CHECKPOINT_NAME	The consumer offset of consumed data. The value is a UNIX timestamp. **Note** You must save the consumer offset. If the consumption process is interrupted, you can specify the consumer offset on the change tracking client to resume data consumption. This allows you to prevent against data loss. When you start the change tracking client, you can specify the consumer offset to consume data on demand.	When you use the Kafka client to track data changes for the first time, convert the required time point into a UNIX timestamp.

Parameter	Description	Method to obtain
USE_CONFIG_CHECKPOINT_NAME	Default value: *true*. The default value indicates that the client is forced to consume data from the specified consumer offset. This allows you to retain the data that is received but not processed.	None.

7. On the top of the IntelliJ IDEA page, choose **Run > Run** to run the client.

> **Note** When you run IntelliJ IDEA for the first time, it loads and installs the relevant dependency.

Mappings between MySQL data types and dataTypeNumber values

Mappings between Oracle data types and dataTypeNumber values

19.Data Management (DMS)

19.1. User Guide

19.1.1. What is DMS?

Data Management (DMS) is a fully managed service that is provided by Alibaba Cloud. This service allows you to manage data, schema, development procedures, development specifications, users, and permissions. DMS also provides security control to ensure secure access to databases.

Supported databases

- Relational databases: MySQL, SQL Server, PostgreSQL, PolarDB-X (previously called DRDS), Oracle, and ApsaraDB for OceanBase.
- NoSQL databases: KVStore for Redis and ApsaraDB for MongoDB.
- Analytical databases: AnalyticDB for MySQL and AnalyticDB for PostgreSQL.

Features

- DMS provides support for the entire process of database development. The process includes the following stages: 1. Design table structures in an on-premises environment based on the predefined design specification. 2. Publish and produce SQL reviews that are included in code and schemas to a specified environment on demand. The preceding operations are performed before the code is released. These SQL reviews in code are used to add, remove, modify, or query rows.
- DMS provides fine-grained access control at the database, table, and field levels. You can perform all the required operations on databases in the DMS console. These operations can be traced and audited.
- DMS allows you to configure the required operation specifications and approval processes for multiple modules. These modules include the schema design, data changes, data export, and permission requests.
- DMS provides an integrated platform that connects database development with database interaction. You can manage databases without the need to use database accounts and passwords to switch between database endpoints at a high frequency.
- DMS provides the task orchestration feature. This feature allows you to orchestrate and schedule SQL tasks for databases on a regular basis. You can use this feature to perform the required operations with ease. For example, you can transfer historical data, analyze periodical reports, and generate analytical results.

19.1.2. Quick start

19.1.2.1. Log on to the DMS console

This topic describes how to log on to the DMS console by using Google Chrome.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

> **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
>
> - Uppercase or lowercase letters
> - Digits
> - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, move the pointer over **Products** and click **Data Management** under **Database Services**.
5. Set the **Organization** and **Region** parameters and click **DMS**.

> **Note** If you log on to the DMS console as a DMS administrator and your account is added to multiple tenants, you can move the pointer over the
>
> 
>
> icon in the upper-right corner and click **Switch tenant** to switch to another tenant.

19.1.2.2. Register database instances with DMS

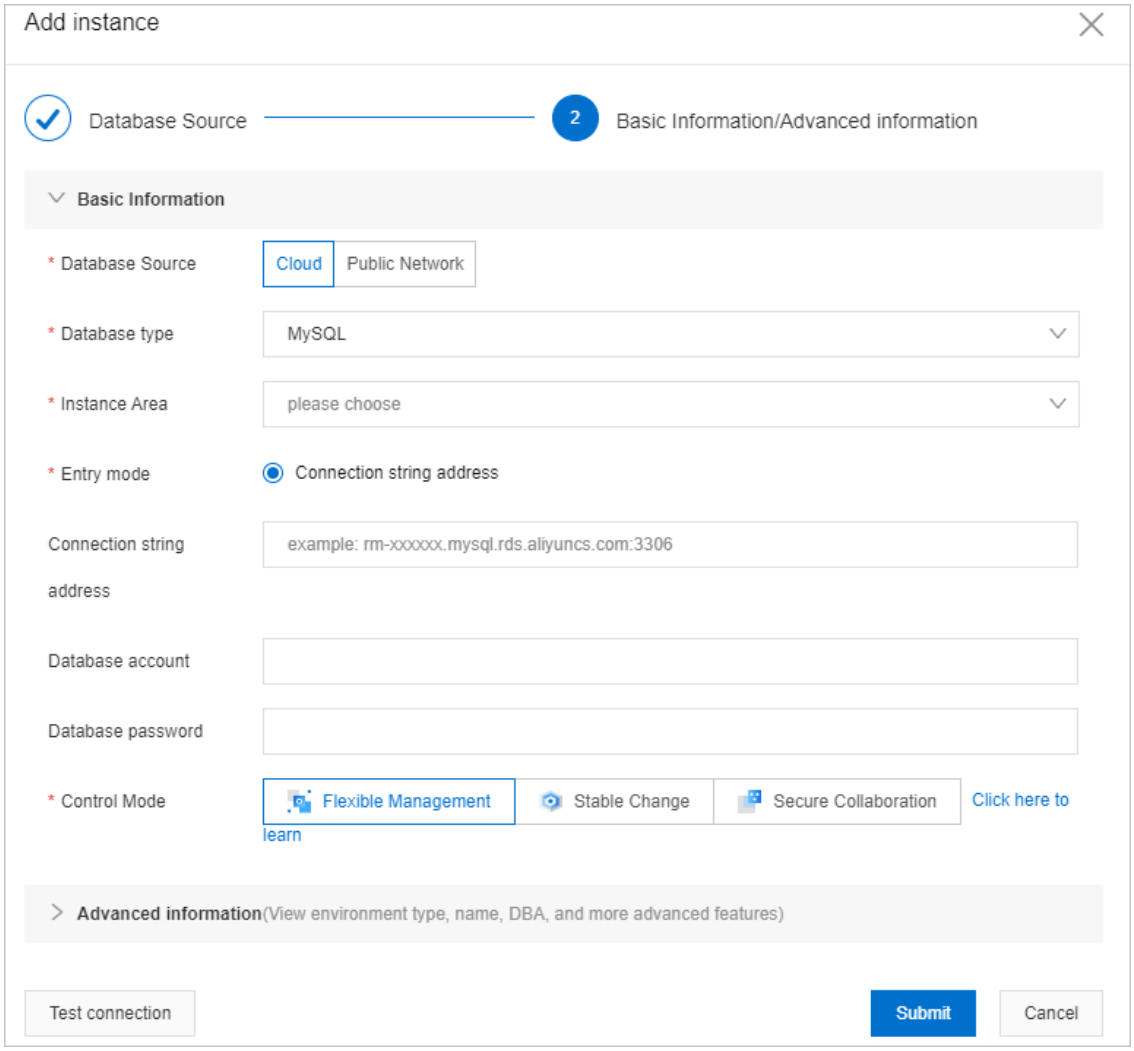
To manage database instances in DMS, you must register the database instances with DMS. DMS allows you to register ApsaraDB instances and self-managed database instances that are hosted over the Internet. This topic shows you how to register an ApsaraDB RDS for MySQL instance with DMS.

Procedure

1. Log on to the DMS console.
2. In the left-side navigation pane, move the pointer over **Add instance / Batch entry** and select Add instance.

> **Note** You can also move the pointer over the + icon in the left-side navigation pane and select Add instance.

3. In the Add instance dialog box, click the **Cloud** tab.
4. On the Cloud tab, select a database type.
5. In the Add instance dialog box, set the parameters as required. This example shows you how to register an ApsaraDB RDS for MySQL instance with DMS.



Section	Parameter	Description
Basic Information	**Database source**	The source of the database instance. In this example, select **Cloud**.
	Database type	The type of the database instance. In this example, select **MySQL**.
	Instance Area	The region where the database instance resides.
	Entry mode	The method that you use to log on to the database instance. Default value: **Connection string address**. This value cannot be changed.
	Connection string address	The endpoint of the database instance. The endpoint contains information about a port number.
	Database account	The username that you use to log on to the database instance.
	Database password	The password that you use to log on to the database instance.

Section	Parameter	Description
	Control Mode	The control mode that is used to manage the database instance. For more information, see Control modes. **Note** If you set this parameter to **Security Collaboration**, you must set the **Security Rules** parameter.
Advanced information	**Environment type**	The environment of the database instance.
	Instance Name	The name that you specify for the instance.
	Enable DSQL	Specifies whether to enable the cross-database query feature. To enable the cross-database query feature, you must specify a database link name. For more information, see Cross-database query.
	OnlineDDL	Specifies whether to allow the database instance to change schemas without locking tables.
	DBA	The database administrator (DBA) of the database instance. The DBA can grant permissions to users.
	query timeout(s)	The timeout period for the execution of an SQL query statement. If the execution of an SQL query statement lasts longer than the specified timeout period, the execution of the statement is terminated to protect the database.
	export timeout(s)	The timeout period for the execution of an SQL export statement. If the execution of an SQL export statement lasts longer than the specified timeout period, the execution of the statement is terminated to protect the database.

6. After you complete the configurations, click **Test connection** in the lower-left corner of the **Basic Information** section.

   Note If the connectivity test fails, check the specified parameter values based on the error message.

7. Click **Submit**.

Result

After the preceding steps are performed, the ApsaraDB instance is registered with DMS. You can view and manage your database instance in the left-side navigation pane of the DMS console.

19.1.2.3. Add a user

DMS provides the user management feature that allows you to add users and assign roles based on your business requirements.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **System Management > User**.

> **Note** On the User tab, you can edit, enable, disable, and remove existing users.

3. Click **New**.
4. In the Add User dialog box, set the parameters that are described in the following table.

Parameter	Description
Alibaba Cloud Account	The ID of an Apsara Stack tenant account or a RAM user. You can enter one of the following IDs: ○ The ID of another Apsara Stack tenant account. You can obtain this ID from the account owner. ○ The ID of a RAM user. You can view this ID in the Apsara Uni-manager Operations Console.
Role	The role that you want to assign to the user based on your business requirements. You can assign one or more of the following roles: ○ A regular user ○ A DBA ○ A DMS administrator ○ A security administrator **Note** For more information about the features that are supported by each role, see Features that are supported by each role.

5. Click **OK**.

19.1.3. Control modes

DMS provides three control modes for you to manage instances: Flexible Management, Stable Change, and Security Collaboration. You can specify a control mode for each instance.

Control mode	Description	Scenario	Logon method
Flexible management	This control mode allows you to manage the visualized data and schemas of multiple types of databases. It also provides a variety of data management solutions. This simplifies the use of databases and facilitates management.	• Database instances do not require strict control. • Database instances are used by a single user.	A database account and the related password.
Stable change	• This control mode provides multiple solutions to ensure database reliability. These solutions allow you to change data without the need to lock the related table or schema. • All features that are included in the flexible management control mode are available.	• Database instances require a high level of availability. This ensures that these database instances function as expected for an extended period of time. • Database instances are used by a small-sized group that includes multiple users.	A database account and the related password.

Control mode	Description	Scenario	Logon method
Security collaboration	• This control mode provides multiple solutions to ensure data security. These solutions include fine-grained access control at the database, table, or field level and sensitive data management. • This control mode allows you to produce enterprise-specific database DevOps solutions through custom design specifications and approval processes. • All features that are included in the flexible management and stable change control modes are available.	• Ensure the data security of database instances. • Implement strict access control over development or change workflows. • Manage compliance for enterprises.	Logon-free through authorization.

Note The instances that are managed in Stable Change mode consume the billing quota of the instances that are managed in Security Collaboration mode.

19.1.4. Features that are supported by each role

DMS provides the following roles: regular user, DBA, security administrator, and DMS administrator. This topic describes the features that are supported by each role.

Category	Feature	Regular user	DBA	Security administrator	DMS administrator	Description
Permission	Permission management	√	√	√	√	You can use this feature to apply for permissions on instances, databases, tables, and sensitive fields. You can also view permissions that you have.
	Data Changes	√	√	√	√	You can use this feature to initialize data for a newly published project, clean up historical data, fix bugs, or run a test.
	Data Import	√	√	√	√	You can use this feature to import a large amount of data to your databases at a time.
	Data Export	√	√	√	√	You can use this feature to export a large amount of data for analysis or export the required data.
	Data Tracking	√	√	√	√	If specific data fails to meet your requirements due to reasons such as misoperation, you can use this feature to restore data to the normal state.

Category	Feature	Regular user	DBA	Security administrator	DMS administrator	Description
Data Plans	Test Data Generate	√	√	√	√	Some business scenarios may require frequent data preparation. In this case, you can use this feature to generate test data to ensure data security and discreteness and improve production efficiency.
	Data Warehouse Development	√	√	√	√	DMS uses a database as a computing engine and integrates various tools and services, such as Data Transmission Service (DTS) and Data Lake Analytics (DLA), in the database ecosystem for data warehouse development. You can use this feature to develop and manage data warehouses in DMS with ease.
	Data Service	√	√	√	√	You can use this feature to export data at the field or row level, display data in a visualized manner, and publish API operations to the Alibaba Cloud Marketplace for sale.
	Database Clone	√	√	√	√	You can use this feature to clone MySQL databases.
Schemas	Schema Design	√	√	√	√	When you develop or optimize projects or process new business requirements, you can use this feature to change schemas. For example, you can use this feature to create a table or modify an existing table.
	Table Sync	√	√	√	√	You can use this feature to compare and synchronize the schemas of tables in different environments, such as online and offline environments. This feature helps ensure the consistency of schemas.
Optimization	SQL Review	√	√	√	√	You can use this feature to prevent SQL statements that do not use indexes or do not conform to database development standards. This feature helps protect against SQL injection attacks.
SQLConsole	Single Database query	√	√	√	√	You can write SQL statements to query data in a single database. This feature can be used to verify business code, analyze product effects, and identify issues in an online environment.

Category	Feature	Regular user	DBA	Security administrator	DMS administrator	Description
	Cross-database Query	√	√	√	√	You can use this feature to perform join queries across online heterogeneous databases that are deployed in different environments.
System Management	Instance management	×	√	×	√	You can use this feature to manage instances. For example, you can register, view, or edit instances.
	User management	×	×	×	√	You can use this feature to manage users. For example, you can add, view, or edit users as needed.
	Task management	×	√	×	√	You can use this feature to manage tasks. For example, you can create, start, or stop tasks.
	Configuration management	×	×	×	√	You can use this feature to view and modify system configurations, or view the historical modifications of the configurations.
Security management	Security Rules	×	√	×	√	You can use this feature to configure security rules. Only SQL statements that conform to the security rules can be executed.
	Approval Processes	×	√	×	√	Approval processes are associated with security rules. You can configure different approval processes for different types of tickets.
	Operation Logs	×	√	√	√	Operations logs record data changes. Each record contains information such as the user who performed the operation, operation details, and time at which the operation was performed. You can use this feature to track historical user operations at any time.
	Access IP Whitelists	×	×	×	√	After you configure an access IP whitelist, only the IP addresses or Classless Inter-Domain Routing (CIDR) blocks in the whitelist can access the resources within your DMS tenant. This effectively enhances data security.
	Sensitive Data	×	√	√	√	You can use this feature to manage sensitive data. For example, you can use algorithms to de-identify sensitive data or adjust the security levels of sensitive data.

Category	Feature	Regular user	DBA	Security administrator	DMS administrator	Description
Tickets	Ticket management	√	√	√	√	You can use this feature to configure notification methods. DMS can notify you of the approval or execution status of tickets by using DingTalk notifications or emails.

19.1.5. Apply for permissions

In DMS, you can apply for the query, change, or export permission on a database, table, or column. After the database owner approves your application, you can perform data query, change, or export operations.

Permissions

- Query permission: the permission to execute SQL statements in the SQLConsole to query the data of the object on which you want to apply for the permission.
- Change permission: the permission to submit tickets to change data or synchronize data in a database or table. You cannot change data without approval.
- Export permission: the permission to submit tickets to export data from the object on which you want to apply for the permission. You cannot export data without approval.

Permission categories that are supported by each control mode

Permission category	Description	Control mode		
		Flexible Management	Stable Change	Security Collaboration
Instance-Login	You must first obtain the permission to access an instance and then use the preset database account and password to log on to the instance.	√	√	×
Database-Permission	Database permissions are divided into three types: query, export, and change permissions. After you are granted permissions on a database, you have access to all data in the database except sensitive fields and the tables where specific data rows are managed. You also have access to tables that are newly created in the database. • Query permission: You can execute SQL statements in the SQLConsole to query data. • Change permission: You can submit data change and data import tickets. • Export permission: You can submit data export tickets.	×	×	√

Permission category	Description	Control mode		
		Flexible Management	Stable Change	Security Collaboration
Table-Permission	Table permissions are divided into three types: query, export, and change permissions. After you are granted permissions on a table, you have access to all data in the table except sensitive fields. • Query permission: You can execute SQL statements in the SQLConsole to query data. • Change permission: You can submit data change and data import tickets. • Export permission: You can submit data export tickets.	×	×	√
Sensitive Column-Permission	Sensitive field permissions are divided into three types: query, export, and change permissions. After you are granted permissions on sensitive fields in a table, you have access to all data in the table including sensitive fields. Before you apply for permissions on specific sensitive fields, you must have access to the database and table that contain the sensitive fields. • Query permission: You can execute SQL statements in the SQLConsole to query data. • Change permission: You can submit data change and data import tickets. • Export permission: You can submit data export tickets.	×	×	√
Database-OWNER	• The owner of a database can manage permissions on the database. For example, the owner of a database can grant or revoke permissions on the database or the tables in the database. • The owner of a database can query all data in the database except sensitive or confidential fields. The owner of a database can also submit tickets to perform operations on the data and schemas in the database without the need to apply for permissions. • DMS automatically identifies database owners and then assign them to the owner nodes in approval processes.	√	√	√
Table-OWNER	• The owner of a table can manage permissions on the table. For example, the owner of a table can grant or revoke permissions on the table. • The owner of a table can query all data in the table except sensitive or confidential fields.	√	√	√

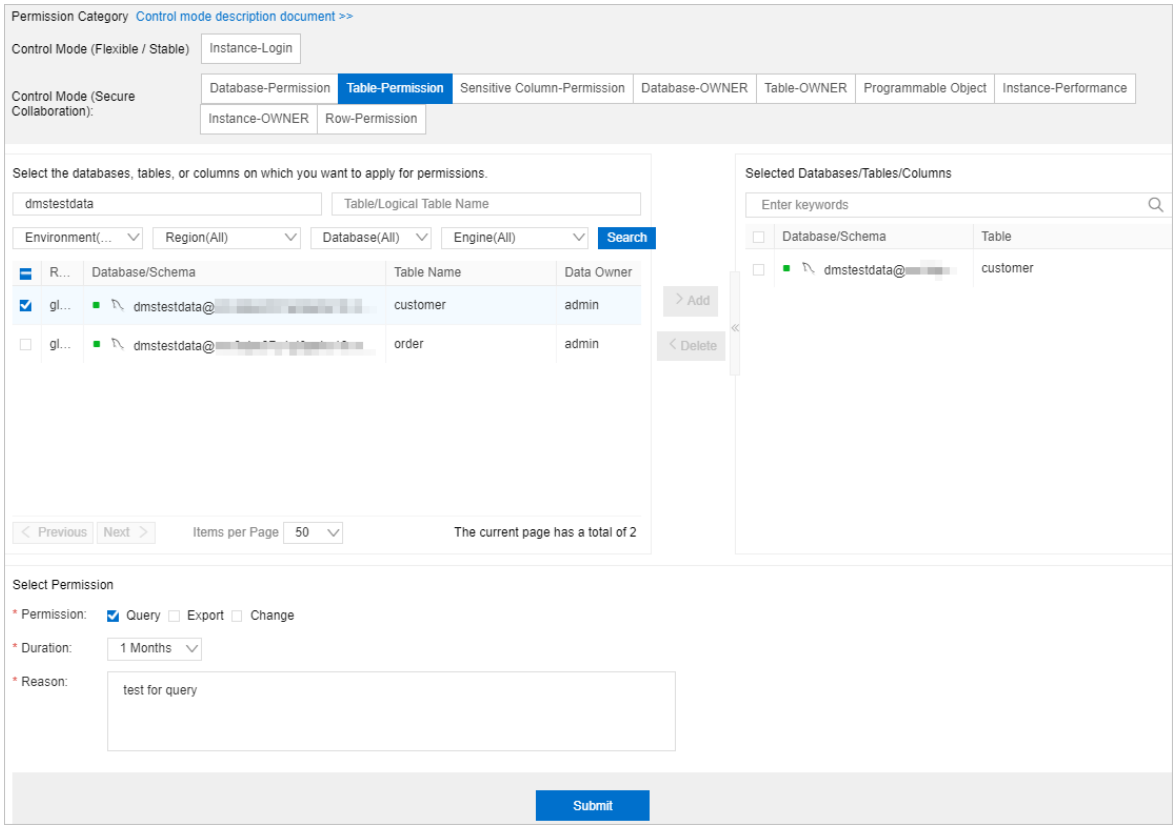
Permission category	Description	Control mode		
		Flexible Management	Stable Change	Security Collaboration
Programmable Object	Permissions on programmable objects are divided into three types: query, export, and change permissions. • Query permission: You can execute SQL statements in the SQLConsole to query data. • Change permission: You can submit data change and data import tickets. • Export permission: You can submit data export tickets.	×	×	×
Instance-Performance	You can apply for permissions to view the performance of instances that are managed in Security Collaboration mode.	×	×	√
Instance-OWNER	• The owner of an instance can manage permissions on the instance. For example, the owner of an instance can grant or revoke permissions on the instance. • The owner of an instance can query all data in the databases of the instance except sensitive or confidential fields. The owner of an instance can also submit tickets to perform operations on the data and schemas in the instance without the need to apply for permissions.	√	√	√
Row-Permission	Row permissions are divided into three types: query, export, and change permissions. You can apply for permissions on specific values of a managed field in a table. You can also apply for permissions on all values of a managed field in a table. • Query permission: You can execute SQL statements in the SQLConsole to query data. • Change permission: You can submit data change and data import tickets. • Export permission: You can submit data export tickets.	×	×	×

Apply for permissions

1. Log on to the DMS console.
2. In the top navigation bar, choose **Permission > Apply Permission** and select the permission category for which you want to apply. For more information about permission categories, see the Permission categories that are supported by each control mode table in this topic.

   > **Note** You can also enter a database name or a table name in the search box of the top navigation bar to search for a database or table. In the search results, find the database or table on which you want to apply for permissions and click **Access apply** in the **Actions** column.

3. Configure the information about the permission for which you want to apply.



i. Select the category of the permission for which you want to apply.

ii. Select the databases, tables, or columns on which you want to apply for permissions.

> **Note** Enter keywords, specify filter conditions, and then click Search to search for databases or tables. The keywords that you enter can contain percent signs (%) as wildcards. In the search results, select the databases or tables on which you want to apply for permissions and click Add.

iii. Select the type of permission for which you want to apply, specify the duration for which you want to have the permission, and then enter the reason for applying for the permission.

4. Click **Submit** and wait for approval.

> **Note** You can view the status of the ticket in the My Tickets section of the **Workbench** tab.

Manage permissions

Management type	Operation	Description
Active management	Release permissions	On the Workbench tab, click **Effective Permissions** in the Permissions section. Select the object for which you want to release permissions and click **Release Permission**.
	Renew permissions	On the Workbench tab, click **Expiring Permissions** in the Permissions section to view and check the permissions that will expire soon. If you want to renew a specific permission, submit a ticket to apply for the permission.
Passive management	N/A	The owner of a database can view and check the rationality of permissions that are granted to users at any time and manage the permissions.

> **Note** Assume that you have applied for, released, revoked, or granted permissions. You can view all these permission operations in operations logs. To view the operations logs, choose **System Management** > **Security** > **Operation Logs** in the top navigation bar.

19.1.6. Data plans

19.1.6.1. Change data

DMS provides the data change module that allows you to change data. This topic describes how to use this module to change data.

Context

DMS allows you to submit data change tickets to initialize data for a newly published project, clear historical data, fix bugs, or run a test. The operations that you can perform to change data include, but are not limited to, insert, update, delete, or truncate operations.

Data change features

Feature	Description
Normal Data Modify	You can use the Normal Data Modify feature to perform the following data changes: • Perform normal data changes. • Perform lock-free schema changes. You can perform such operations to change character sets and collations for tables, adjust time zones, and change column data types. Compared with normal data change operations, such operations can be performed to achieve the following benefits: ◦ Allows you to change schemas without affecting business. ◦ Avoids latency in synchronization between primary and secondary databases that occurs when schemas are changed by using native online data definition language (DDL) operations. ◦ Reclaims tablespaces and reduces fragmentation rates without locking tables. You no longer need to use the OPTIMIZE TABLE statement that causes tables to be locked. **Note** You can use this feature only for MySQL databases. Before you use this feature, you must set the OnlineDDL parameter in the **Advanced information** section to Open(DMS OnlineDDL first) when you register or edit an instance. For more information, see Register database instances with DMS.
Lock-Free Data Modify	You can use this feature to change a large amount of data. For example, you can use this feature to delete historical data and update all fields in a table. The SQL statements for data changes are divided and executed in different batches based on the primary key or unique key. This limits the consumption of database performance and space. **Note** You can use this feature only for MySQL databases.
History Data Clean	You can use this feature to regularly clean historical data to prevent the accumulation of historical data from affecting the stability of the production environment. **Note** You can use this feature only for MySQL databases.

Feature	Description
Programmable Object	Databases provide programmable objects such as stored functions and stored procedures. This feature allows you to use the programmable objects to standardize management processes and provide audit records.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Plans > Data Changes** and select the data change feature that you want to apply.

   > **Note** This example shows you how to use the **Normal Data Modify** feature.

3. Set the parameters on the Data Change Ticket Application tab.

Parameter	Description
Reason Category	The reason for the data change. This helps you find the ticket in subsequent operations.
Business Background	The purpose or objective of the data change. This reduces unnecessary communication.
Change Stakeholder	The stakeholders of the data change. All specified stakeholders can view the ticket details and assist in the approval process. Irrelevant users other than DMS administrators and DBAs are not allowed to view the ticket details.
Execution Method	The way in which you want the ticket to be submitted for execution based on your business requirements.
Database	The database on which you have the change permission. You cannot submit a data change ticket if you have only permissions to query data in the database or change data in tables.
Affected Rows	The estimated number of data rows to be affected by the data change. To obtain the actual number of affected rows, you can use the COUNT function in SQL statements on the SQLConsole tab.
SQL Statements for Change	The executable SQL statements for changing data. You can write the SQL statements in the field or upload an SQL script to provide the SQL statements. DMS checks whether the syntax of the SQL statements is valid when you submit the ticket. If the syntax is invalid, you cannot submit the ticket.
SQL Statements for Rollback	The executable SQL statements for rolling back the data change operation. You can write the SQL statements in the field or upload an SQL script to provide the SQL statements.
Attachments	The images or files that are uploaded to add more information about the data change.

4. After you complete the configurations, click **Submit**.
5. After your ticket passes the precheck, click **Submit for Approval**. In the message that appears, click **OK**.
6. After the ticket is approved, click **Execute Change**.
7. Set the Execute Immediately parameter and click **Confirm Execution**.

> **Note** By default, the Execute Immediately switch is turned on. You can turn off **Execute Immediately** and specify a point in time for DMS to automatically run the task.

8. Wait until the execution is complete.

19.1.6.2. Import data

DMS provides the data import feature that allows you to import large amounts of data to a database in a quick manner. This helps you save manpower and resources.

Supported databases

- MySQL
- PolarDB-X

Supported file formats

- TXT files. Each TXT file for importing data can be up to 5 GB in size.
- SQL scripts. Each SQL script for importing data can be up to 5 GB in size.

> **Note** By default, you can use only INSERT and REPLACE statements to import data to database instances that are managed in Security Collaboration mode. If you want to use other SQL statements to import data, modify the security rules for data import as a DBA or DMS administrator. To modify the security rules, click the **SQL Correct** tab on the **Security Rules** tab and set the Checkpoints parameter to **Batch Data import rules**.

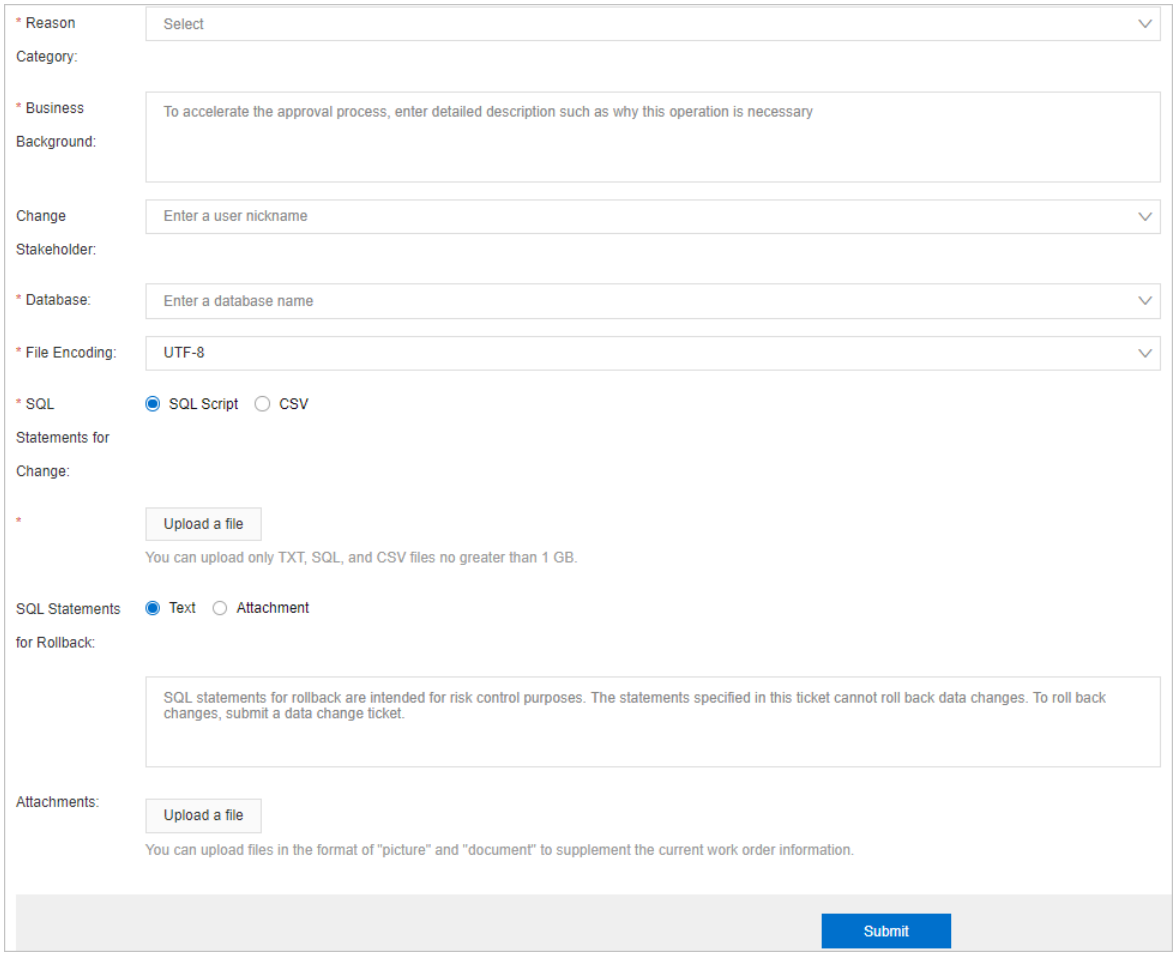
- CSV files. Values in a CSV file must be separated by commas (,). The first row must be field names.

Usage notes

- If you need to use SQL statements to import only a small amount of data, we recommend that you submit a Normal Data Modify or Lock-Free Data Modify ticket to ensure stable data change. For more information, see Change data.
- If you submit a Large Data Import ticket to import a large amount of data to a table, the table will be locked even if you set the OnlineDDL parameter to Open(DMS OnlineDDL first) for the database instance.
- We recommend that you use SQL statements with better performance to import a large amount of data, such as INSERT, UPDATE, and DELETE statements. Indexes of primary keys are used in the UPDATE and DELETE statements.
- By default, you can use only INSERT and REPLACE statements to import data to database instances that are managed in Security Collaboration mode. If you want to use other SQL statements to import data, modify the security rules for data import as a DBA or DMS administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Plans > Data Import**.
3. On the Large Data Import tab, set the parameters that are described in the following table.



Parameter	Description
Reason Category	The reason for the data import. This helps you find the ticket in subsequent operations.
Business Background	The purpose or objective of the data import. This reduces unnecessary communication.
Change Stakeholder	The stakeholders of the data import. All specified stakeholders can view the ticket details and assist in the approval process. Irrelevant users other than DMS administrators and DBAs are not allowed to view the ticket details.
Database	The database on which you have the change permission. You cannot submit a data import ticket if you have only permissions to query data in the database or change data in tables.
File Encoding	The encoding algorithm to be used by the database.
SQL Statements for Change	The executable SQL statements for importing data. You can upload a file to provide the SQL statements. DMS checks whether the syntax of the SQL statements is valid when you submit the ticket. If the syntax is invalid, you cannot submit the ticket.
SQL Statements for Rollback	The executable SQL statements for rolling back the data import operation. You can write the SQL statements in the field or upload an SQL script to provide the SQL statements.
Attachments	The images or files that are uploaded to add more information about the data import.

Parameter	Description

4. After you configure the settings, click **Submit**.
5. After your ticket passes the precheck, click **Submit for Approval**. In the message that appears, click **OK**.
6. After the ticket is approved, click **Execute Change**.
7. Set the Execute Immediately parameter and click **Confirm Execution**.

> **Note** By default, the Execute Immediately switch is turned on. You can turn off the **Execute Immediately** switch and specify a point in time to run the ticket. The system automatically runs the ticket at the specified point in time.

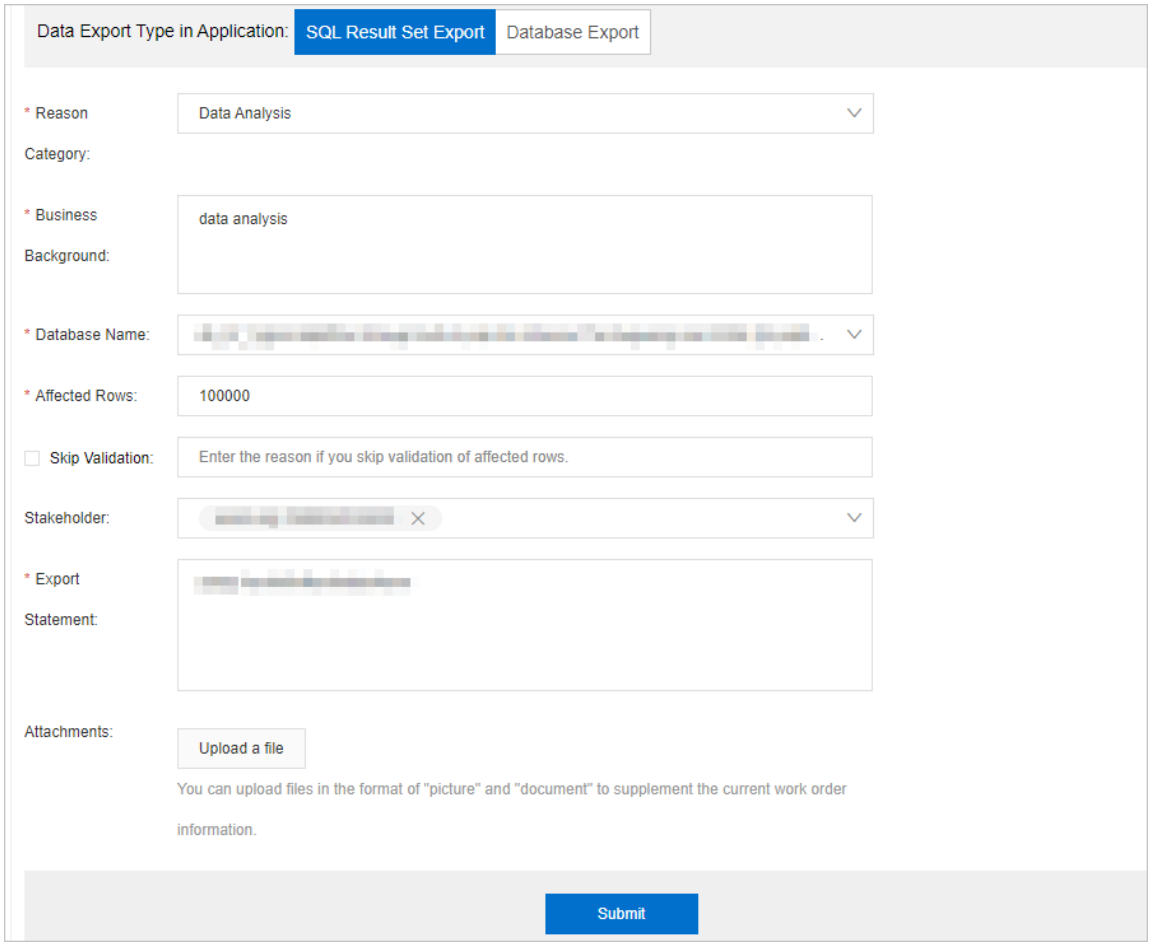
8. Wait until the execution is completed.

19.1.6.3. Export data

DMS provides the data export feature. You can use this feature to export a database or SQL result sets for data analysis.

Procedure

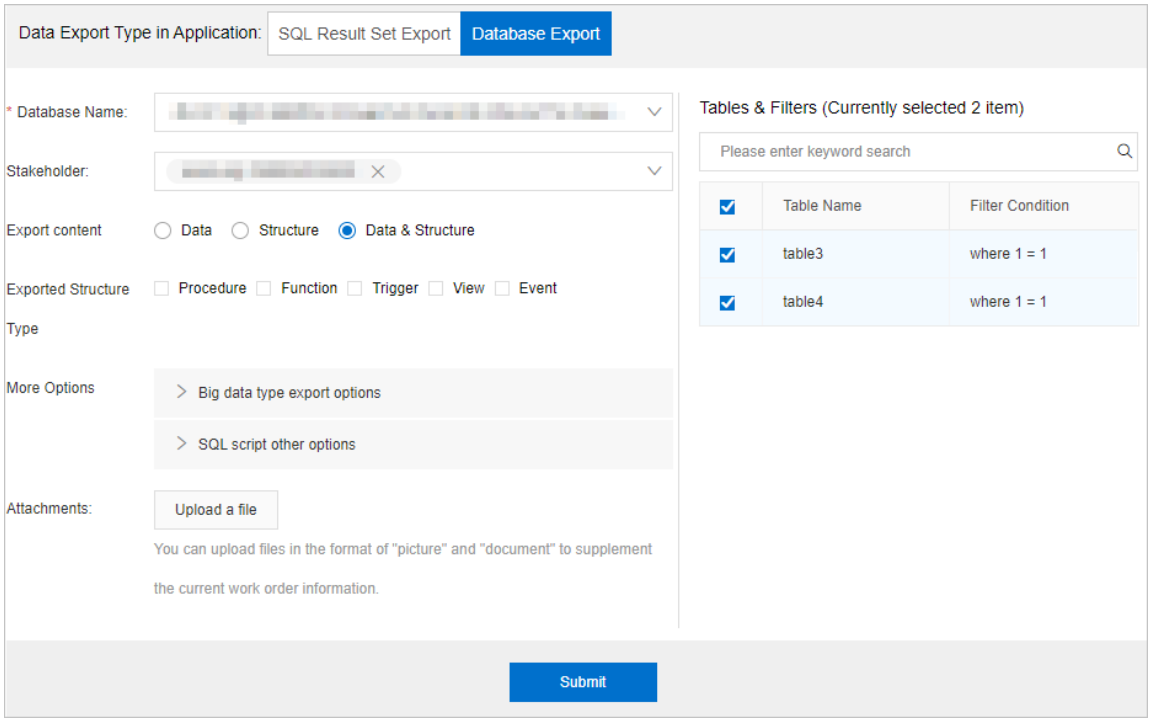
1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Plans > Data Export**.
3. Select **SQL Result Set Export** or **Database Export** based on your business requirements.
4. On the Data Export Ticket Application tab, set the parameters as required.
   - Set the parameters on the SQL Result Set Export tab



Parameter	Description
Reason Category	The reason for the data export. This helps you find the ticket in subsequent operations.
Business Background	The purpose or objective of the data export. This reduces unnecessary communication.
Database Name	The database on which you have the export permission.
Affected Rows	The estimated number of data rows to be affected by the data export. To obtain the actual number of affected rows, you can use the `COUNT` function in SQL statements on the SQLConsole tab.
Skip Validation	Specifies whether to skip validation. If you select **Skip Validation**, you must enter a reason in the field next to the check box. **Warning** If you select **Skip Validation**, DMS does not check the number of rows to be affected by the data export. If a large amount of data is exported, your business may be affected. Proceed with caution.
Stakeholder	The stakeholders of the data export. All specified stakeholders can view the ticket details and assist in the approval process. Irrelevant users other than DMS administrators and DBAs are not allowed to view the ticket details.

Parameter	Description
Export Statement	The executable SQL statements for exporting data. Example: `select * from testtable`. DMS checks whether the syntax of the SQL statements is valid when you submit the ticket. If the syntax is invalid, you cannot submit the ticket.
Attachments	The images or files that are uploaded to add more information about the data export.

- Set the parameters on the Database Export tab



Parameter	Description
Database Name	The database on which you have the export permission. After you select the database, select the table where you want to export data and configure filter conditions in the Tables & Filters section.
Reason Category	The reason for the data export. This helps you find the ticket in subsequent operations.
Business Background	The purpose or objective of the data export. This reduces unnecessary communication.
Stakeholder	The stakeholders of the data export. All specified stakeholders can view the ticket details and assist in the approval process. Irrelevant users other than DMS administrators and DBAs are not allowed to view the ticket details.
Export content	The data content that you want to export based on your business requirements. Valid values: **Data**, **Structure**, and **Data & Structure**.
Exported Structure Type	The type of structure to be exported based on your business requirements.

Parameter	Description
More Options	The other objects that you want to export. Those objects are grouped into two export categories named **Big data type export options** and **SQL script other options**. You can click one of the categories and select a specific object as required.
Attachments	The images or files that are uploaded to add more information about the data export.

5. After you complete the configurations, click **Submit** and wait for approval.

   > **Note** When you export an SQL result set, DMS prechecks the SQL statements. After the SQL statements pass the precheck, click **Submit for Approval**. In the message that appears, click **OK**.

6. After your ticket is approved, go to the **Workbench** tab and click **Submitted Tickets** in the My Tickets section.
7. Find the data export ticket that you have submitted and click the ticket number.
8. In the **Execute/Automatic Execution** section, click **Download Exported File**.

19.1.6.4. Generate test data

DMS provides the Test Data Generate feature that allows you to generate data in a quick manner. You can generate test data for functional or performance tests.

Prerequisites

- A relational database is created to generate test data. The relational database may be a self-managed MySQL, ApsaraDB RDS for MySQL, AnalyticDB for MySQL, or PolarDB-X database.
- A table is created. You can use the Schema Design feature to create a table. For more information, see Design a schema.

Context

Functional tests or performance tests often require test data. In general, you may use the following methods to generate test data:

- Write test data. This method has low efficiency and is inapplicable to scenarios where a large amount of test data is required.
- Maintain existing scripts. This method incurs high costs. In addition, the data that is generated by using this method is not discrete enough.
- Use the data that is exported from an online environment as test data. This method is not secure and may cause data leak.

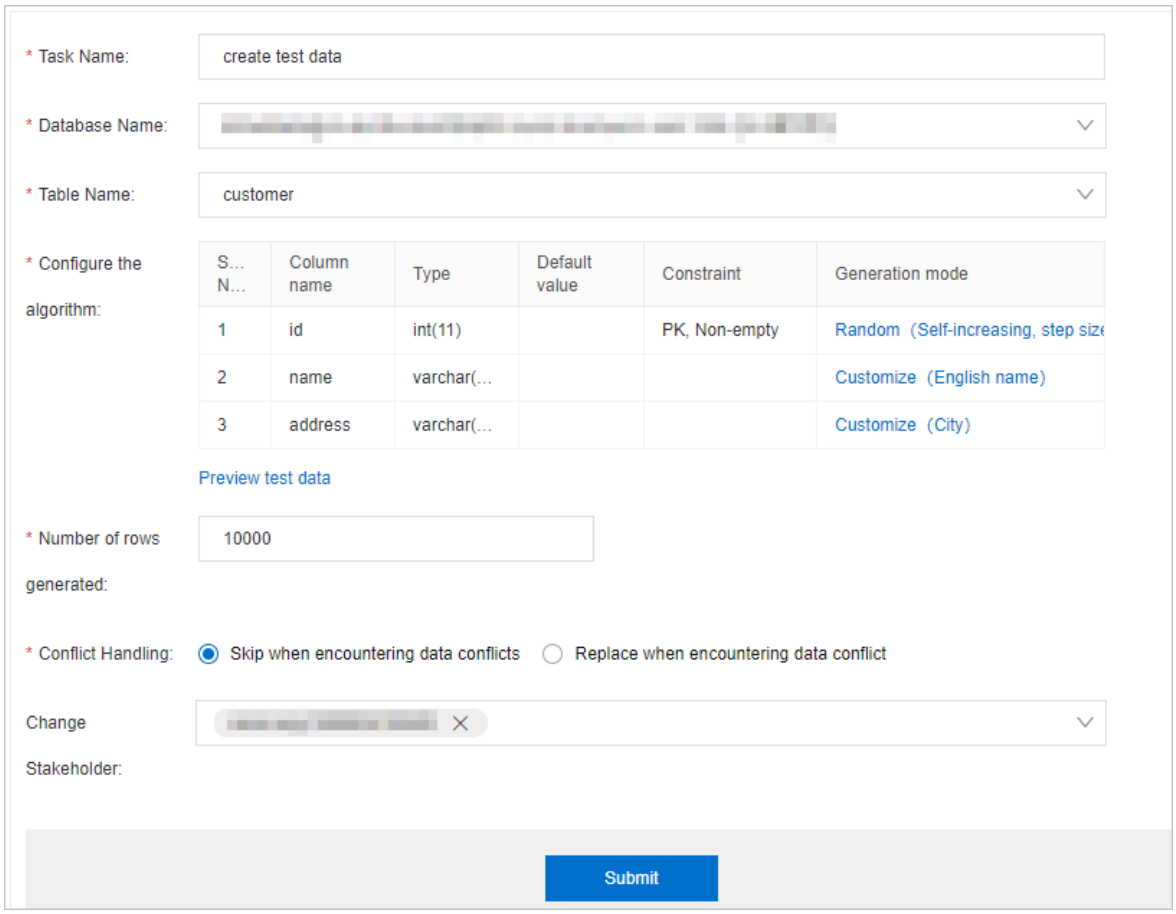
In view of this, DMS provides the Test Data Generate feature that allows you to generate test data in a quick, efficient, and secure manner. In addition, the discreteness of the data that is generated by using this feature is controllable.

Usage notes

- You can use this feature to generate test data for one table at a time. To generate test data for multiple tables, you must submit a ticket to generate test data for each table.
- To prevent database overload that is caused by instantaneous generation of excessive data, DMS allows you to perform traffic throttling. You can generate test data based on the following performance metrics:
  - One million rows of data with four fields can be generated in about 1 minute.
  - One million rows of data with 40 fields can be generated in about 2 to 3 minutes.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Plans > Test Data Generate**.
3. In the upper-right corner, click **Test Data Generate**.
4. In the Test data build ticket application dialog box, set the parameters as required.



Parameter	Description
Task Name	The name of the task. This facilitates management in subsequent operations.
Database Name	The database where the table for which you want to generate test data resides.
Table Name	The table for which you want to generate test data. Enter a keyword and select a table from the matched results. After you select the table, the **Configure the algorithm** parameter that contains the field information of the table is displayed. **Note** You can use this feature to generate test data for one table at a time. To generate test data for multiple tables, you must submit a ticket to generate test data for each table.

Parameter	Description
Configure the algorithm	The algorithms that you use to generate test data. Find the field for which you want to configure the algorithms, click the value of the Generation mode parameter, and then set the parameters in the Generation mode dialog box based on your business requirements. **Note** For example, you can use the Random, Customize, and Enumeration algorithms to generate test data of the STRING type. The Customize algorithm can be used to generate standard types of data for multiple industries.
Number of rows generated	The number of rows that you want to generate for the test data.
Conflict Handling	Specifies how DMS handles conflicts based on your business requirements.
Change Stakeholder	The stakeholders of the ticket. All specified stakeholders can view the ticket details and assist in the approval process. Irrelevant users other than DMS administrators and DBAs are not allowed to view the ticket details.

5. After you configure the settings, click **Submit**.
6. After the ticket is approved, DMS automatically starts to generate test data.

19.1.6.5. Clone databases

DMS provides the Database Clone feature that allows you to clone databases. This topic describes how to use this feature to clone databases.

Prerequisites

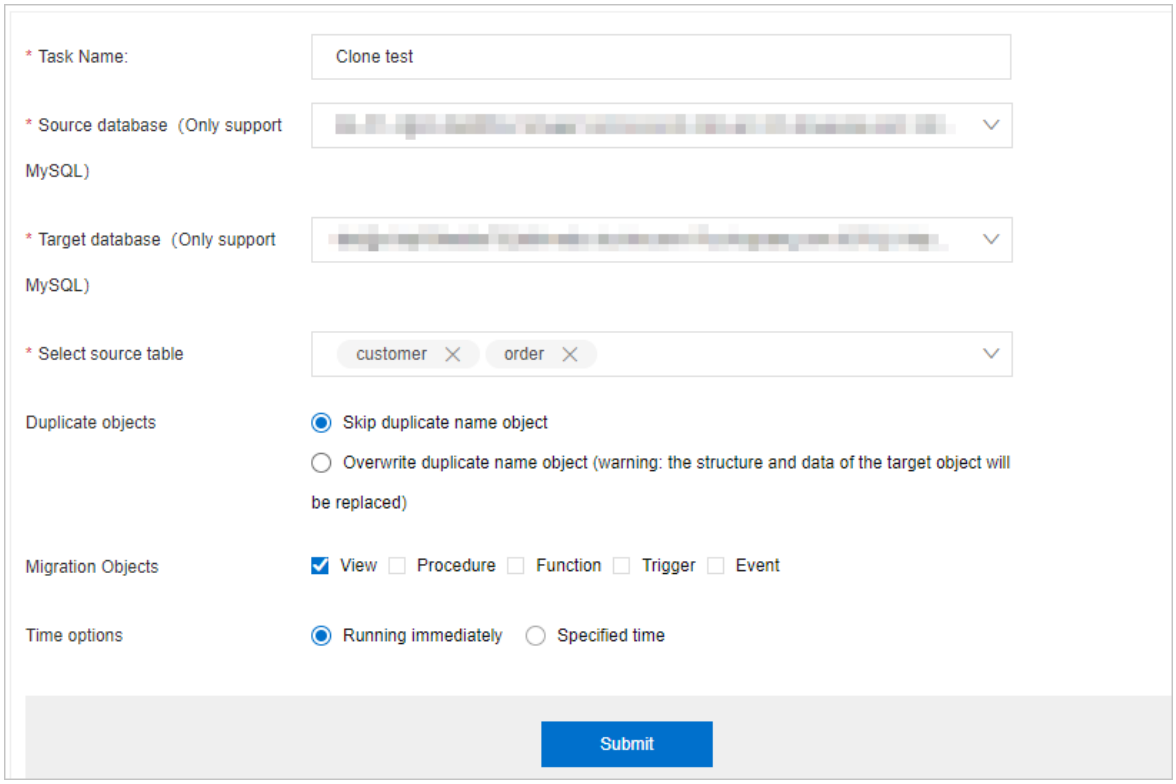
- A MySQL database is used.
- A database instance is managed in Flexible Management mode. You have logged on to the database instance in the DMS console.

Scenarios

- Create a full database backup.
- Initialize databases that are deployed across multiple environments, such as online and offline environments.
- Copy data from a database in an online environment to a database in an offline environment for data processing and analysis.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Plans > Database Clone**.
3. In the upper-right corner, click **Database Clone**.
4. In the Database clone order apply dialog box, set the parameters as required.



Parameter	Description
Task Name	The name of the task. This facilitates management in subsequent operations.
Source database (Only support MySQL)	The source database that you want to clone. You can enter a keyword to search for databases and select a database from the matched results.
Target database (Only support MySQL)	The destination database to which you want to write the data that is cloned from the source database. You can enter a keyword to search for databases and select a database from the matched results. **Note** The destination database and source database cannot be the same database.
Select source table	The one or more tables that you want to clone from the source database. You can enter a keyword to search for tables and select a table from the matched results. **Note** To clone all tables, set this parameter to All Tables.
Duplicate objects	The method that is used to handle object conflicts based on your business requirements. ◦ **Skip duplicate name object**: Skip the object that has a duplicate name. ◦ **Overwrite duplicate name object (warning: the structure and data of the target object will be replaced)**: Overwrite the schema and data of the object in the destination database with those in the source database.
Migration Objects	The objects that you want to clone. In addition to tables, you can synchronously clone objects such as views, stored procedures, functions, triggers, and events from the source database to the destination database.

Parameter	Description
Time options	Valid values: **Running immediately** and **Specified time**. If you set the Time options parameter to **Specified time**, you must specify the specific date and time for running the task. ○ **Running immediately**: The task is immediately run after the ticket is approved. ○ **Specified time**: DMS automatically runs the task to clone data at the specified time.

5. After you configure the settings, click **Submit**.
6. After the ticket is approved, the task is automatically run based on the specified time.

19.1.7. Data factory

19.1.7.1. Task orchestration

The task orchestration feature is powered by a distributed scheduling engine that is developed by Alibaba Cloud. You can use this feature to create task flows and schedule task flows to be run as needed. In addition, a variety of task nodes are provided. This way, you can use this feature to perform data archiving, data integration, and data processing as needed.

Scenarios

- Periodically archive and analyze business data.
- Synchronize online data to data warehouses for complex analysis.
- Periodically clean and process offline data.
- Orchestrate and periodically schedule tasks by performing database DDL or data manipulation language (DML) operations.

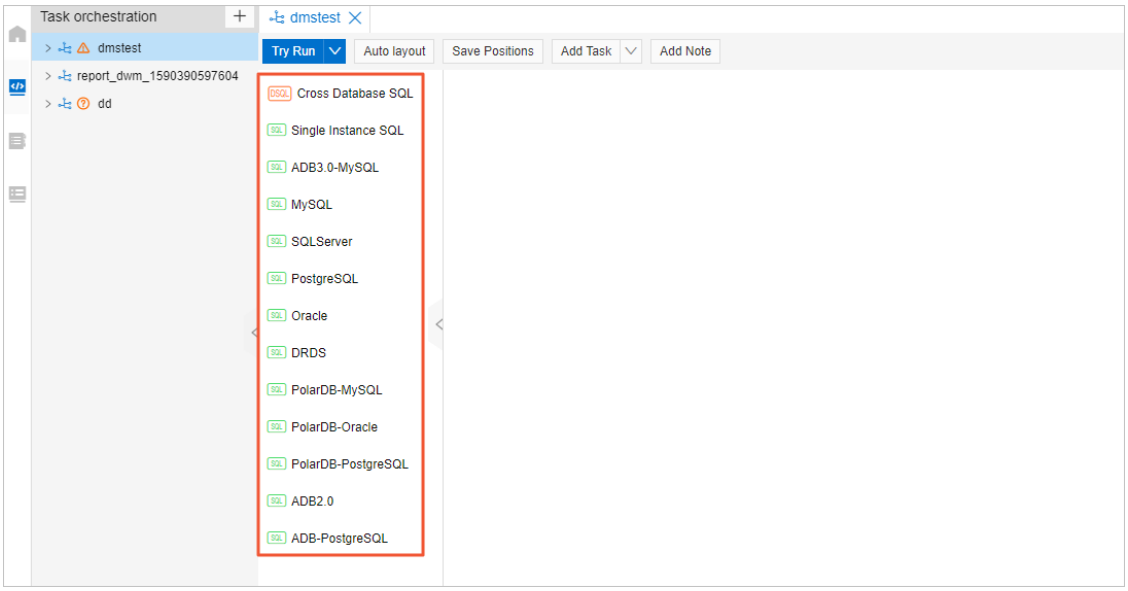
Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Factory > Task Orchestration**.
3. Click the  icon on the left-side navigation submenu.
4. Configure a task flow.
   i. Click the  icon next to **Task Orchestration**.
   ii. In the dialog box that appears, set the Task Flow Name and Description parameters.
   iii. Click **OK**.
5. Configure a specific task in the task flow.

   Note You can repeat this step to configure multiple tasks for the task flow.

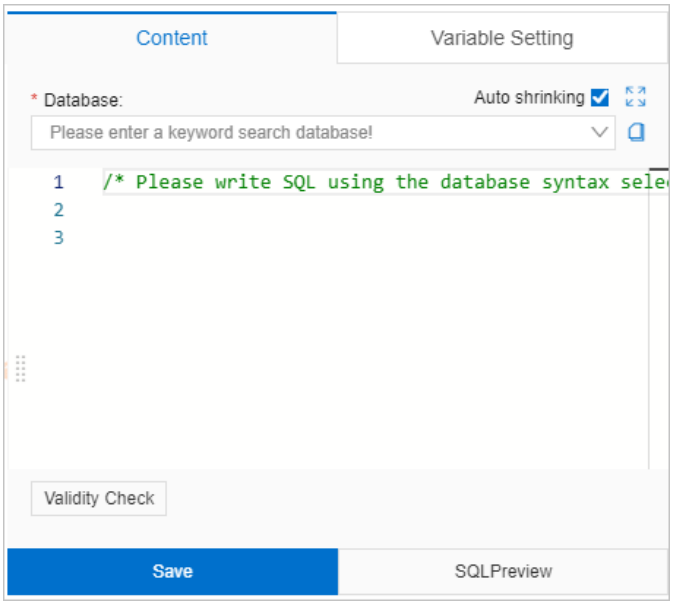
   i. In the left-side navigation pane of the Task Orchestration tab, find the task flow that you create and double-click the task flow name.

ii. On the Task Orchestration tab, drag a specific type of node from the task node list to the canvas where you can create a directed acyclic graph (DAG) based on your business requirements.



iii. In the DAG, click the task node that you want to configure.

iv. In the right-side pane, click a tab and set the parameters as required.

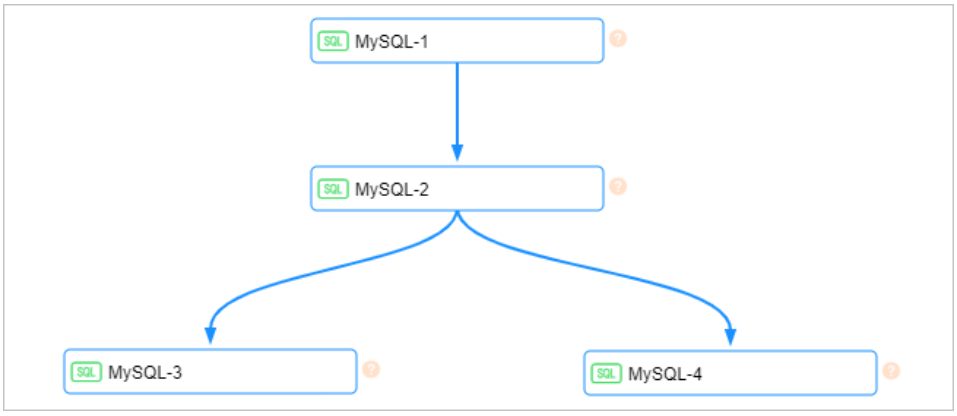


Tab	Parameter	Description

Tab	Parameter	Description
Content	**Database**	a. Select the database that you want to manage from the drop-down list. b. Enter the SQL statements to be executed in the field. c. Click **Save**. d. In the dialog box that appears, select **Existed table** or **New table** to store the query results. **Note** If you select **Existed table**, you must select a table name where you want to store the query results from the drop-down list. If you select **New table**, you need to enter a table name. e. Click **OK**.
Variable Setting	**Variable Name**	`bizdate` is the only default system variable, which indicates the previous day of the day when a task is run. The value of bizdate is in the yyyy-MM-dd format. If the default system variable cannot meet your business requirements, you can create a custom variable and enter the variable name in the Variable Name field. **Note** To delete a configured variable, click the icon.
	Variable Rule	To configure a variable rule, set the Time Format parameter and specify the operator, integer value, and time unit. Then, click **Save**. You can click **Increase Variable** to create more variables. **Note** After you configure a variable, you can reference the variable in the `${Variable name}` format in SQL statements on the **Content** tab. You can also click **SQLPreview** to check whether the variable is configured.

6. Configure node dependencies in the task flow.
   i. In the DAG, move the pointer over a task node and click and hold the circle, as shown in the following figure. Then, draw a line from the circle to the next node.

ii. Repeat the previous step to configure dependencies between task nodes based on your business requirements. This way, the sequence for running each task is established.



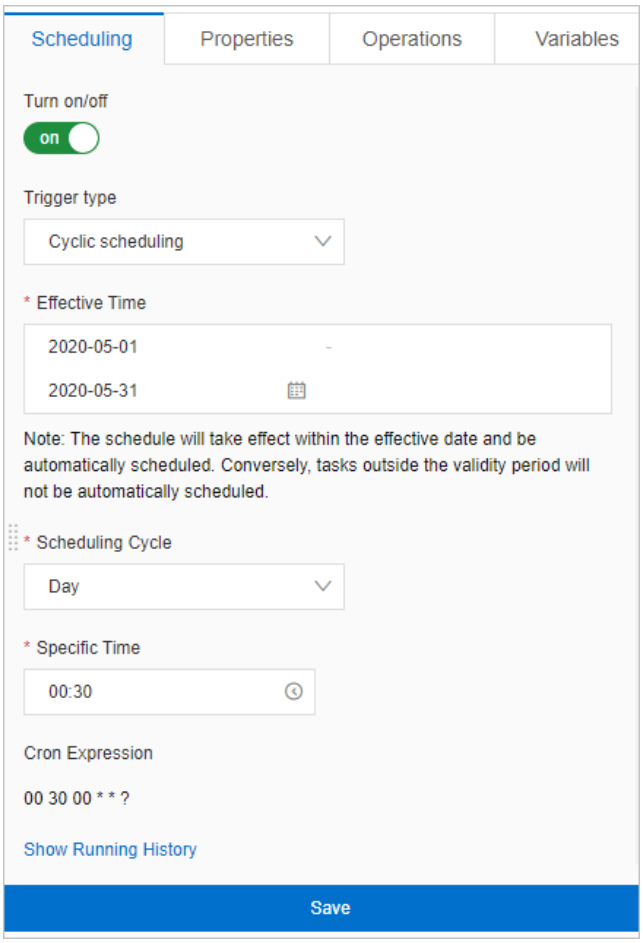
Note In the preceding figure, the MySQL-1 node is the first task to be run and the MySQL-2 node is the second. After that, the MySQL-3 and MySQL-4 nodes are run at the same time.

7. Configure scheduling information for the task flow.

i. Click the blank area on the canvas. In the right-side pane, click the **Scheduling** tab.

Note You can also click the **Properties** tab to configure the basic information of the task flow or click the **Operations** tab to view the operations that have been performed on the task flow.

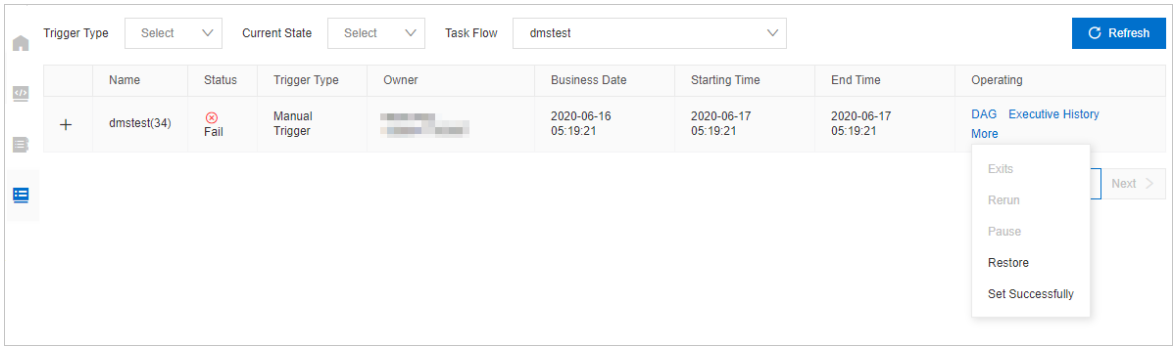
ii. Configure the scheduling information.



Parameter	Description
Turn on/off	Turn on **Turn on/off** to enable scheduling.
Trigger type	Set this parameter based on your business requirements. ■ When you set this parameter to **Cyclic scheduling**, you must set the **Effective Time**, **Scheduling cycle**, and **Specific Time** parameters. ■ When you set this parameter to **Schedule once**, you need only to set the **Specific Time** parameter.

iii. Click **Save**.

8. After you complete the configurations, click **Try Run** in the upper-left corner to check whether the task flow can be run as required.
9. Click the icon on the left-side navigation submenu, specify filter conditions, and then view the status of the task flow.



> **Note** Click the + icon before the task flow name to view the status of each task.

You can perform the following operations on the task flow:

- **DAG**: View the DAG of the task flow.
- **Executive History**: View the details of the operations that have been performed on the task flow.
- **More > Exits**: Stop running the task flow.
- **More > Rerun**: Rerun the task flow that is run or fails to be run.
- **More > Pause**: Pause the running of the task flow.
- **More > Restore**: Resume running the paused task flow.
- **More > Set Successfully** : Set the status of the task flow that fails to be run to Success.

19.1.7.2. Data warehouse development

19.1.7.2.1. Overview

Data Management (DMS) provides the data warehouse development feature. This feature uses databases as the computing engine and integrates a variety of tools and services in the database ecosystem. This allows you to develop and manage data warehouses with ease. This feature is designed to provide you with a one-stop development platform for data integration, processing, visualization, and value mining.

Benefits

- A variety of data warehouse engine types

  You can choose a data warehouse engine type based on your enterprise scale, data volume, and requirement for real-time performance. For example, you can choose AnalyticDB for MySQL or ApsaraDB RDS for MySQL as the data warehouse engine type.

- Two development modes

  The data warehouse development feature of DMS provides two development modes: task orchestration and professional development. The two modes meet different business requirements.

  - Task orchestration: This development mode allows you to develop a data warehouse by creating task flows and writing SQL scripts for task nodes. You do not need expertise in data warehouse development. You need only to focus on your business logic.
  - Professional development: This development mode meets the requirements of professional warehouse developers. It provides capabilities such as theme management, hierarchical management, production, release, multi-person collaboration, and data quality control. These capabilities empower professional warehouse development solutions for your enterprise.

> **Note** Some of the capabilities are planned to be supported soon.

- Support for offline and real-time data warehouses

  The data warehouse development feature supports offline data synchronization and task scheduling. This allows you to develop offline data warehouses with ease in DMS. In addition, DMS is integrated with Data Transmission Service (DTS) and cloud-native data warehouses. This allows you to build a real-time data warehouse system based on the real-time synchronization feature of DTS and cloud-native data warehouse engines. Then, you can develop data and consume data in real time in DMS.

- Unified management of online and offline data

  DMS supports unified database management and permission management. You can manage your online transaction processing (OLTP) databases and online analytical processing (OLAP) databases in a centralized manner in DMS. This avoids security issues that are caused by the isolation between offline and online systems.

19.1.7.2.2. Create a data warehouse project

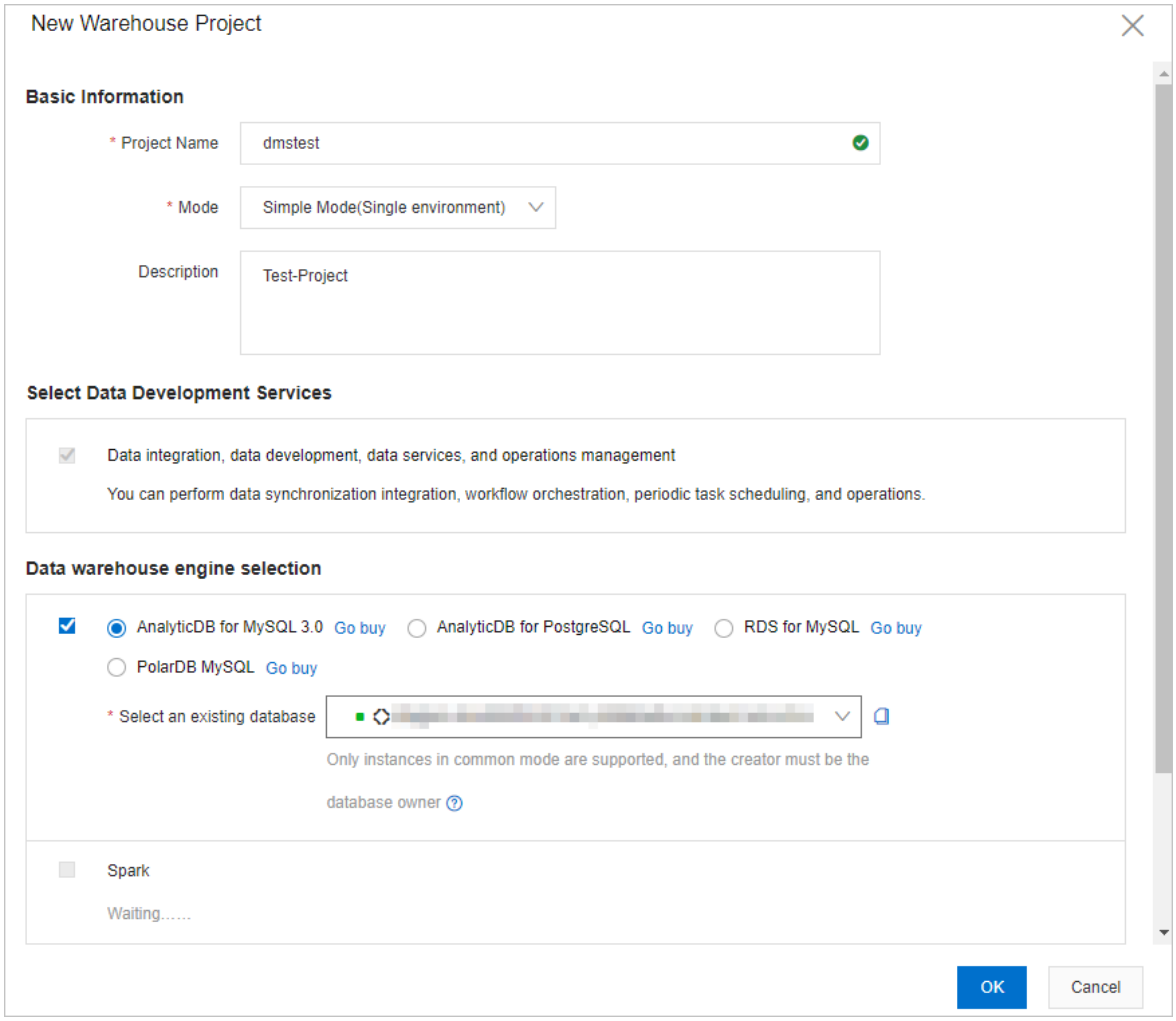
Before you can use the data warehouse development feature of Data Management (DMS), you must create a data warehouse project and select a data source for data warehouse development. This topic describes how to create a data warehouse project.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Factory > Data Warehouse Development**.
3. On the left-side navigation submenu, click the  icon.
4. Click the

   icon to the right of **Data warehouse**.
5. In the New Warehouse Project dialog box, set the parameters as required.



Section	Parameter or operation	Description
Basic Information	Project Name	The name of the project. Specify an informative name for easy identification.
	Mode	The mode of the project. Set this parameter to **Simple Mode(Single environment)**, which means that you can use the same database in a development environment and a production environment.
	Description	The description of the project.
Select Data Development Services	N/A	DMS automatically completes the configuration in this section.

Section	Parameter or operation	Description
Data warehouse engine selection	Select a data warehouse engine type by selecting the corresponding check box.	After you select a data warehouse engine type, such as **AnalyticDB for MySQL 3.0**, select a database from the **Select an existing database** drop-down list. **Note** Only databases of the instances that are managed in Security Collaboration mode are available in the drop-down list. You must be the owner of the selected database.

6. Click **OK**.

What's next

Create or import an internal table

19.1.7.2.3. Create or import an internal table

After you create a data warehouse project in Data Management (DMS), you must create or import an internal table for the project. An internal table refers to a table that exists in the data warehouse engine. This topic describes how to create or import an internal table.

Prerequisites

You have the change permissions on the database for which you want to create or import an internal table. For information about how to apply for permissions, see Apply for permissions.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Factory > Data Warehouse Development**.
3. On the left-side navigation submenu, click the icon.
4. In the left-side navigation pane, expand a data warehouse project and then expand Warehouse table. Move the pointer over **Internal table** and then the More icon that appears. Then, select an option from the menu to perform one of the following operations.

   Note You cannot configure external tables in DMS.

   
   - Create an internal table:

a. Select **Add internal table**.
b. On the tab that appears, enter an SQL statement to create a table.
c. Click **Execute**.

- Import an internal table:

> **Note** The data warehouse development feature does not support real-time synchronization of tables that are created by using other means such as a command-line tool. You can import such tables to data warehouse projects in DMS.

a. Select **Import internal tables**.
b. In the Import internal tables dialog box, select the table that you want to import from the **Choose table** drop-down list and enter a description in the Remarks field.
c. Click **OK**.

- Create a folder:

> **Note** If you have a large number of tables, you can use folders to organize and classify the tables.

a. Select **New folder**.
b. In the New folder dialog box, enter a folder name.
c. Click **OK**.

What's next

Manage task flows

19.1.7.2.4. Manage task flows

Data Management (DMS) supports task flows and timed scheduling. You can configure a variety of task nodes in task flows. This can meet your requirements for data archiving, integration, and processing.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Factory > Data Warehouse Development**.
3. On the left-side navigation submenu, click the  icon.
4. In the left-side navigation pane, expand a data warehouse project. Move the pointer over **Task Flow** and then the
   
   icon that appears.
5. In the New Task Flow dialog box, enter a name and the description for the task flow.
6. Click **OK**.
7. On the tab that appears, configure task nodes for the task flow.

> **Note** The configurations of a task flow in professional development mode are basically the same as the configurations of a task flow in task orchestration mode. For more information, see Step 5 in the *Task orchestration* topic.

19.1.7.2.5. Use the data service feature

In Data Management (DMS), the data warehouse development feature is integrated with the data service feature. The data service feature allows you to export the data that is managed by DMS. This feature is applicable to scenarios where you need to export data at the column or row level, display data in a visualized manner, or perform complex analysis.

Limits

When you use the data service feature to create an API for a data warehouse, the data source of the API must be a table in the data warehouse project.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Factory > Data Warehouse Development**.

   > **Note** You can also choose **Data Factory > Data Service** in the top navigation bar.

3. On the left-side navigation submenu, click the icon.
4. In the left-side navigation pane, expand a data warehouse project and double-click **Data Service**.

Configure an API

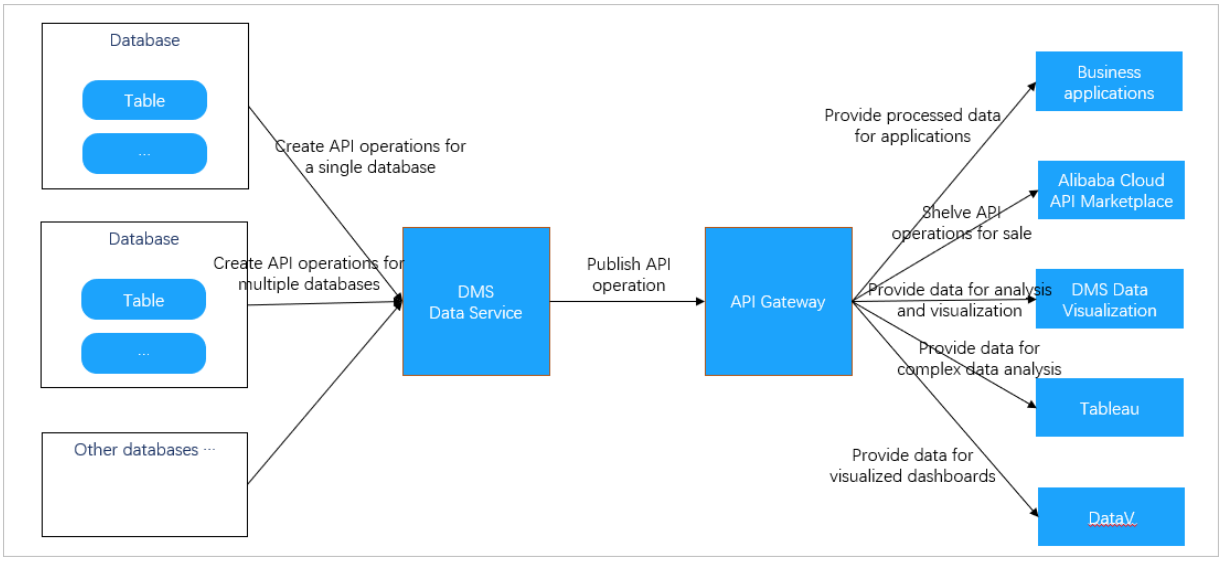
For information about how to configure an API, see Develop an API, Unpublish or test an API, Test an API, and Call an API.

19.1.7.3. Data service

19.1.7.3.1. Overview

Data Management (DMS) provides the data service feature, which allows you to export the data that is managed by DMS. This feature is applicable to scenarios where you need to export data at the column or row level, display data in a visualized manner, or perform complex analysis.

Features



- You can use the data service feature to create APIs that can be called to access the data that is managed by DMS. When you create the APIs, you can apply the security control features that are used for SQL execution in the SQLConsole, such as permission control and data de-identification.
- The data service feature works based on a serverless architecture. This feature frees you from the concern about the infrastructure of the runtime environment, such as servers and networks. You need to focus only on how to create APIs and design data query logic. This avoids operations and maintenance (O&M) overheads that are generated by using traditional architectures.
- The data service feature is fully integrated with API Gateway. You can use this feature to publish APIs to API Gateway. This way, you can use all the features that are provided by API Gateway, such as API permission control, IP address-based access control, throttling, metering and billing, and SDKs.

Scenarios

Scenario	Description
Minimize data exposure	Assume that you need to export the data that is managed by DMS to an external environment. In this case, APIs can be called to export the data of specific rows or columns to the external environment. To export the data of specific rows, specify a filter condition in the SQL statement. To export the data of specific columns, specify the columns in the SQL statement. Compared with data export of a whole table, this minimizes data exposure and ensures data security.
Connect visualization tools to databases	Most visualization tools can connect to databases by calling APIs. You can connect a visualization tool to your database by calling an API, instead of by using a username and a password. This method is easy to implement and avoids account exposure.
Sell APIs in the Alibaba Cloud Marketplace	If you want to provide paid or free data for other users, publish an API to the Alibaba Cloud Marketplace.
Provide processed data for applications	After data is processed and summarized by using the data warehouse development feature of DMS, APIs can be created and provided for applications to read the processed data from DMS to meet business needs. To modify the logic of data reading, you need only to modify the query logic of the required API without the need to republish the application.

19.1.7.3.2. Develop an API

The data service feature of Data Management (DMS) provides comprehensive capabilities to help you develop APIs with ease. This topic describes how to create and manage APIs.

Prerequisites

API Gateway is activated. For more information, see the documentation of *API Gateway*.

Context

The data service feature allows you to export the data that is managed by DMS. This feature is applicable to scenarios where you need to export data at the column or row level, display data in a visualized manner, or perform complex analysis. For more information, see Overview.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Factory > Data Service**.
3. Click the **API Development** tab on the left side.
4. On the APIManagement tab, click **New API** in the upper-right corner.
5. On the tab that appears, set the parameters as required.

i. Set the parameters on the AttributeConfiguration tab.

Parameter	Description
APIName	The name of the API. The name must be 4 to 100 characters in length and can contain letters, digits, and underscores (_). The name must start with a letter.
Description	Optional. The description of the API. Enter an informative description such as a description of the data to be returned by the API or the scenarios in which the API can be called.
Path	The path of the API. The path must start with a forward slash (/) and can contain letters, digits, underscores (-), and hyphens (-). The specified path forms a part of the URL that is used to call the API. A URL that is used to call an API must be in the `https://{Domain name}{Path}` format. For example, if the domain name is `xxxx-cn-hangzhou.alicloudapi.com` and the path is specified as `/item/monthly_data`, the URL that is used to call the API is `https://xxxx-cn-hangzhou.alicloudapi.com/item/monthly_data`.
ReturnFormat	The format of the data to be returned by the API. Set the value to **JSON**.
RequestMode	The method to be used to call the API. Valid values: **POST** and **GET**.
TimeOut (MS)	The maximum length of time during which a response to an API request must be received from the backend service of the called API. Unit: milliseconds. If the response time exceeds the specified time, API Gateway returns a timeout error. The maximum response time is 30,000 milliseconds, which equals 30 seconds.
Returns the maximum number of records	The maximum number of entries that can be returned for an API request. This parameter limits the number of entries that can be returned for each query that is performed after the API is called. **Note** If the database instance is managed in Security Collaboration mode, the value of this parameter must be smaller than the maximum number of entries that is specified in the security rules.

ii. Click the **ExecuteConfiguration** tab and set the parameters on this tab.

Parameter	Description
Instance query type	The type of instance query. Valid values: ■ **Single InstanceQuery**: The API can be called to read data from only one database instance. ■ **Cross-instanceQuery**: You can write dynamic SQL statements for the API to query data across multiple database instances. **Note** After you set this parameter to **Cross-instanceQuery**, you need only to enter dynamic SQL statements in the **QuerySQL** field.
Data source	The database to be queried when the API is called. You can enter a keyword to search for the databases on which you have query permissions and then select a database.

Parameter	Description
ConfigurationMode	The method that is used to configure data query. Valid values: ■ **Table boot mode**: You can configure data query by selecting a table and fields. ■ **Script mode**: You must configure data query by defining variables and writing SQL statements. **Note** After you set this parameter to **Script mode**, you need only to enter SQL statements in the **QuerySQL** field.
SelectTable	The table to be queried. You can enter a keyword to search for a table.
FieldList	The fields in the selected table. You can specify the fields as request parameters or response parameters as needed.
Script mode	The mode in which an SQL script is written to define the data query logic. **Note** You can set the **ConfigurationMode** parameter to **Table boot mode** or Script mode.
QuerySQL	The SQL statement that is used to query the data in the table. After you enter the SQL statement, click **ParsingScript** to verify whether the syntax is valid and parse the request parameters and response parameters. **Note** ■ Custom variables are supported. Custom variables can be mapped as request parameters in API requests. The variables in the SQL statement must be defined in the `${Variable name}` format. For example, you can define the `${category}` variable and use it in the following SQL statement: `select item_id, item_name from ex_item where category=${category}` . ■ If you set the **Instance query type** parameter to **Cross-instanceQuery**, you must use the syntax of cross-database query SQL statements. For more information, see Cross-database query.

iii. Click the **Request Parameters** tab and set the parameters on this tab.

Parameter	Description
ParametersName	The name of the request parameter. ■ The name can contain letters, digits, hyphens (-), and underscores (_). ■ The name must start with a letter or an underscore (_). ■ The name must be 1 to 50 characters in length.
FieldName	The name of the field referenced by the request parameter. The field name is specified on the **ExecuteConfiguration** tab and cannot be changed.
Cannot be empty	Specifies whether the request parameter is required.
Description	The description of the request parameter.
Data type	The data type of the request parameter. The data type is used to verify whether the value of the request parameter in an API request is valid. Valid values: String, Integer, and Floating point. Default value: String. **Note** This parameter affects the SQL statement to be executed when the API is called.
Example value	The sample value of the request parameter. Sample values that are provided in SDKs and documentation can help users call APIs.
Default value	The default value of the request parameter. If the request parameter is optional and not specified in the API request, the default value is used.

iv. Click the **Return parameter** tab and set the parameters on this tab.

Parameter	Description
ParametersName	The name of the response parameter. ■ The name can contain letters, digits, hyphens (-), and underscores (_). ■ The name must start with a letter or an underscore (_). ■ The name must be 1 to 50 characters in length.
FieldName	The name of the field referenced by the response parameter. The field name cannot be changed.
Description	The description of the response parameter.
Data type	The data type of the response parameter. Valid values: String, Integer, and Floating point. Default value: String. This parameter is used by DMS to convert the type of the data in API responses. This parameter affects the JSON data that is returned after the API is called.
Example value	The sample value of the response parameter. Sample values that are provided in SDKs and documentation can help users understand API responses.

6. Click **Save**.
7. Click the **API Development** tab on the left side.
8. Perform the following operations to manage the API based on your business requirements:

- Publish the API:

  On the APIManagement tab, find the API and click **Publish** in the **Operation** column. In the message that appears, click **OK**.

- Modify the API:

  On the APIManagement tab, find the API and click **Modify** in the **Operation** column. Modify the configurations of the API based on the description in Step 5 and click **Save**.

- Delete the API:

  On the APIManagement tab, find the API and click **Delete** in the **Operation** column. In the message that appears, click **OK**.

19.1.7.3.3. Unpublish or test an API

This topic describes how to unpublish or test an API that has been published.

Prerequisites

An API is created. For more information, see Develop an API.

Procedure

1. Log on to the DMS console.
2.
3. Click the **API Publish** tab on the left side.
   The APIPublishList tab displays all the published APIs.
4. Find the API that you want to manage and perform the following operations based on your business requirements:
   - Unpublish the API:

     Click **Offline** in the **Operation** column. In the message that appears, click **OK**.

   - Test the API:

     Click **Test** in the **Operation** column. For more information, see Test an API.

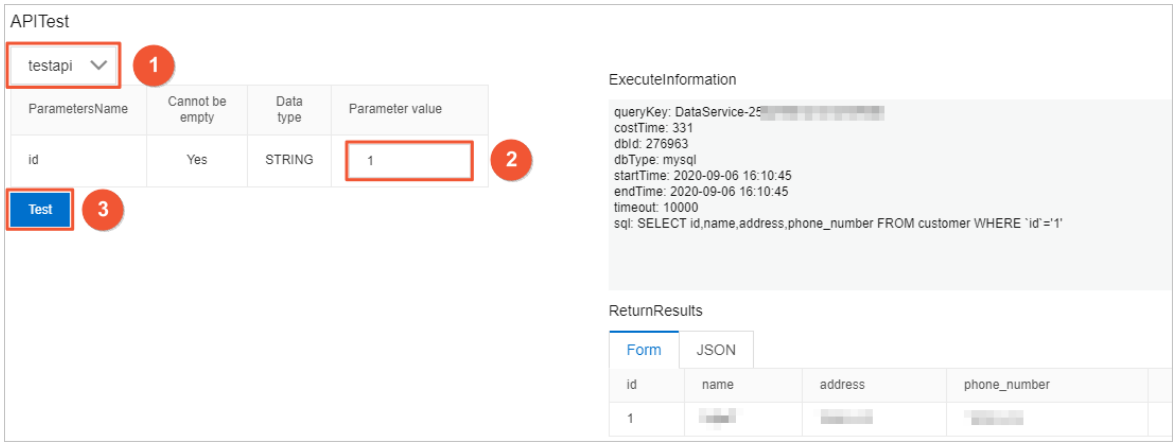
19.1.7.3.4. Test an API

After you create an API, you can test the API to verify whether the API meets your business requirements.

Prerequisites

Procedure

1. Log on to the DMS console.
2.
3. Click the **API Test** tab on the left side.
4. On the APITest tab, test an API.



i. Select the API that you want to test from the drop-down list.

ii. Enter values in the Parameter value column.

iii. Click **Test**.
After the test is complete, the execution information and return results appear on the right side. You can evaluate whether the API meets your business requirements based on the information.

> **Note** You can click the **JSON** tab in the **ReturnResults** section so that the return results are displayed in the JSON format.

19.1.7.3.5. Call an API

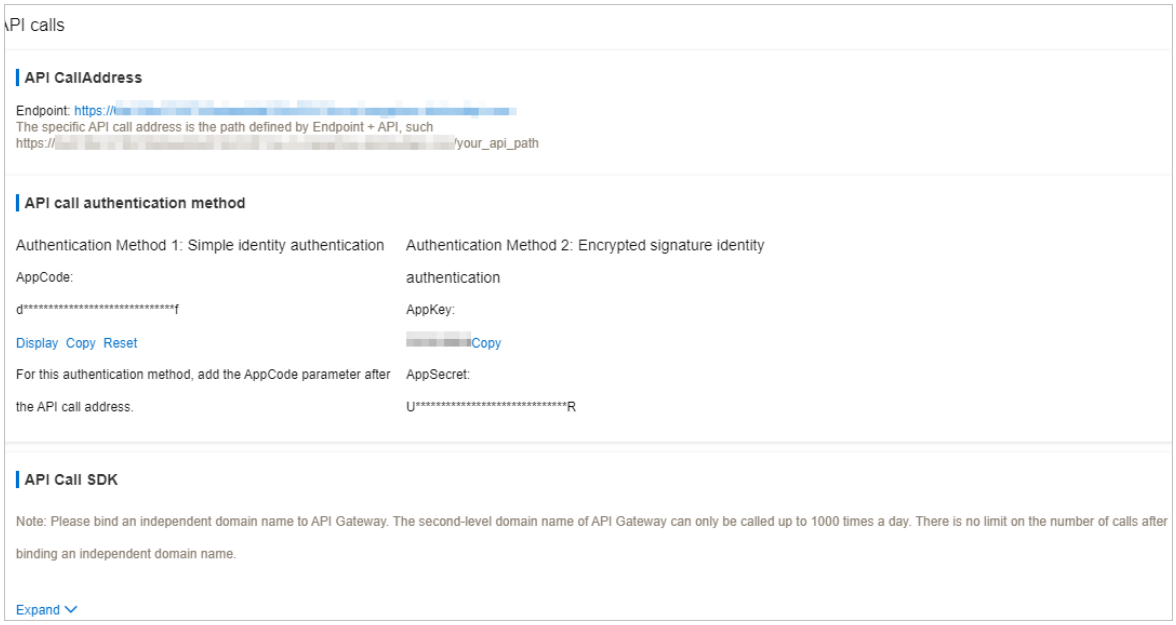
After you create, publish, and test an API, you can call the API in an application by using an SDK.

Prerequisites

- An API is created and published. For more information, see Develop an API.
- API Gateway is activated. For more information, see the documentation of *API Gateway*.

Procedure

1. Log on to the DMS console.
2.
3. Click the **API Call** tab on the left side.
4. View the API call address and the authentication information.



- **Simple identity authentication**: requires only an AppCode. This authentication method is suitable for calling APIs by using URLs. This authentication method has a low security level and is generally used in scenarios in which data visualization is involved, such as calling APIs in DataV.
- **Encrypted signature identity authentication**: requires an AppKey and an AppSecret, which are used to dynamically generate an encrypted signature for calling an API. This authentication method has a high security level.

5. Call the API in an application by using an SDK.

> **Note** For more information about how to call an API in an application by using an SDK, see the documentation of *API Gateway*.

19.1.8. Schemas

19.1.8.1. Design a schema

Data Management (DMS) provides the schema design feature. This feature allows you to change schemas with ease. This topic describes how to use this feature.

Prerequisites

A MySQL, a PolarDB-X, or an ApsaraDB for OceanBase database is available.

Context

When you create projects, process new business requirements, or optimize business operations, you may need to create tables or change schemas. For example, you may need to add or delete fields or indexes, adjust field attributes, or adjust the index composition. In these scenarios, you can use the schema design feature of DMS.

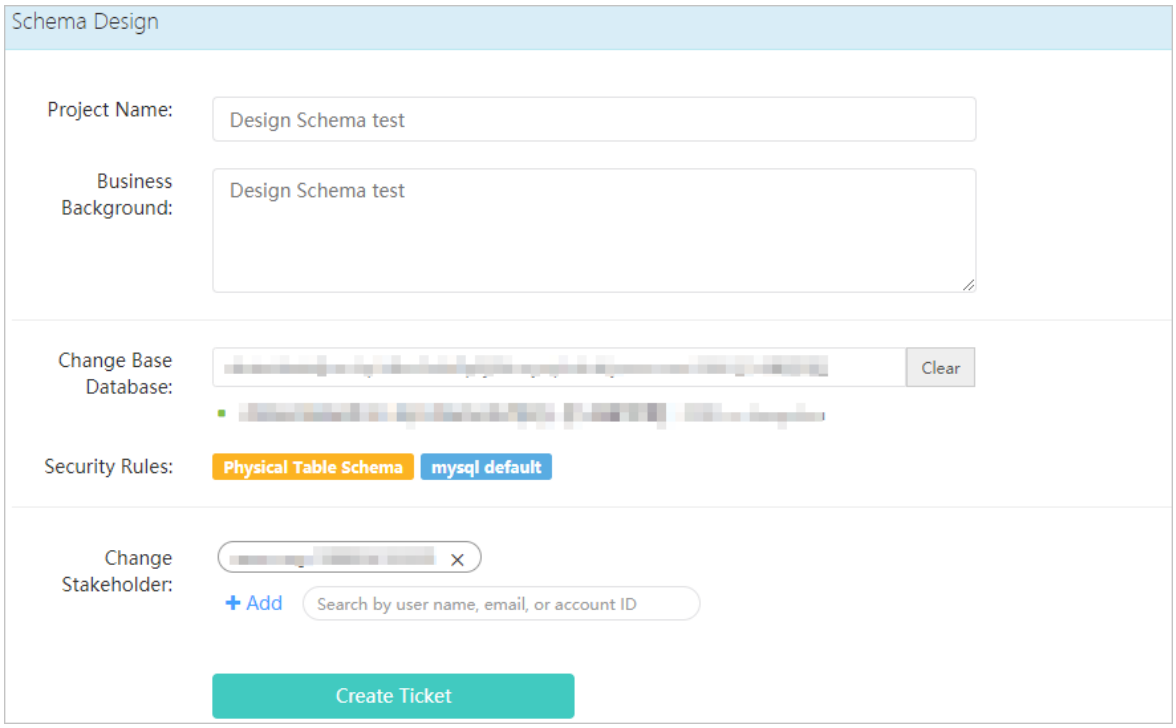
- This feature allows multiple users to collaboratively design schemas on web pages.
- This feature allows you to send verified scripts to other environments with ease. This ensures consistency between schemas in different environments.

Usage notes

When you submit a schema design ticket to delete a table, make sure that the table was created by submitting a schema design ticket.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Schemas > Schema Design**.
3. On the Schema Design tab, click **Schema Design** in the upper-right corner.
4. On the Schema Design tab, set the parameters for a schema design ticket.



Parameter	Description
Project Name	The name of the project. Set an informative name for easy identification.
Business Background	The purpose or objective of the project, which accelerates the approval process.
Change Base Database	The database whose schema you want to change. You can enter a prefix to search for a database. Only databases on which you have permissions in test or development environments are available. **Note** You must have at least one of the query, export, and change permissions on the selected database.
Security Rules	The security rules that you want to apply. DMS automatically selects security rules based on the selected database.
Change Stakeholder	The stakeholders of the changes. The specified stakeholders can view the ticket details and assist in the approval process. Irrelevant users other than DMS administrators and database administrators (DBAs) are not allowed to view the ticket details.

5. Click **Create Ticket**.
6. Design a schema based on your business requirements.
   - Create a table:

a. Click **Create Physical Table**.

> **Note** If the selected database is a logical database, click **Create Logical Table**.

b. On the Create Physical Table tab, configure information such as the table name, character set, fields, and indexes.

c. Click **Save**.

> **Note** After you click Save, DMS prechecks the configured information based on design specifications. If the information does not conform to the design specifications, a prompt appears.

d. After the configured information passes the precheck, click **Confirm Changes and Submit to Save**.

- Modify the schema of a table:

a. In the left-side pane, click the table whose schema you want to modify.

b. On the menu that appears, select **Design Table**.

c. Modify the schema as needed and click **Save**.

> **Note** After you click Save, DMS prechecks the configured information based on design specifications. If the information does not conform to the design specifications, a prompt appears.

d. After the configured information passes the precheck, click **Confirm Changes and Submit to Save**.

7. After you complete the schema design, click **Perform Changes to Base Database**.
8. In the Perform Changes to Base Database dialog box, set the Execution Strategy parameter to **Execute Now** or **Schedule**.
9. Click **Submit for Execution** and wait until the ticket is approved.
10. After the ticket is approved, click **Go to Next Node**.

> **Note**
> - After the ticket is approved, DMS performs the changes at the specified time. If you do not specify the execution time, the changes are automatically performed after the ticket passes the last approval node. You can view the execution status and operations logs. After all changes are performed, you can repeat the preceding procedure to modify the design. If you are sure that the design is complete, click Go to Next Node.
> - The preset design specifications determine whether you can go back to the previous node and modify the design after the ticket is submitted to the next node.

11. In the Go to Next Node message, click **Go to Next Node**.
12. On the Project Homepage tab, click **Perform Changes to Target Database**.
13. In the Perform Changes to Target Database dialog box, set the Target Database and Execution Strategy parameters and click **Submit for Execution**.

> **Note** The database to which changes are performed must be in a production environment.

14. Wait until the ticket is approved and the changes are performed.
15. Click **Go to Next Node**.
    The schema design process ends and the ticket is closed.

19.1.8.2. Synchronize schemas

Data Management (DMS) provides the schema synchronization feature. You can use this feature to compare the schemas of two databases, generate a script for schema synchronization, and then run the script to synchronize schemas for the destination database. This topic describes the schema synchronization feature and shows you how to synchronize schemas.

Prerequisites

ApsaraDB for OceanBase or MySQL databases are available.

Usage notes

- You cannot synchronize schemas for databases in production environments.
- You can initialize an empty database based on part or all of the tables in a physical or logical database.

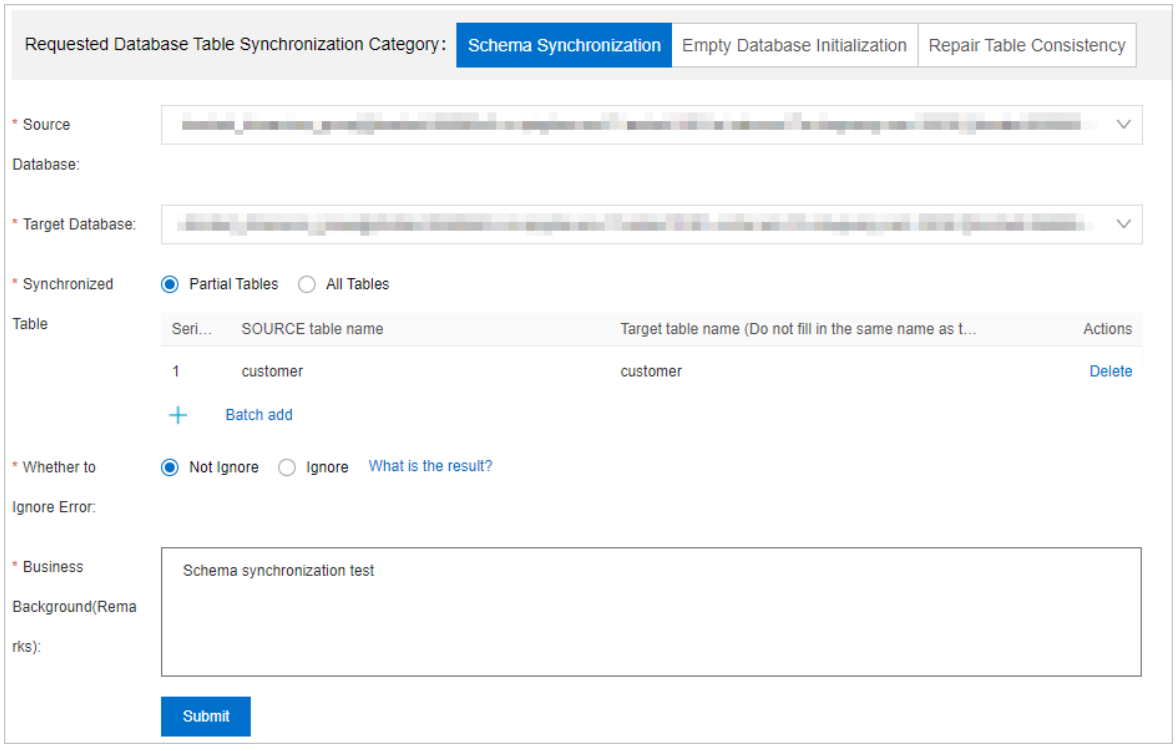
Scenarios

The schema synchronization feature can be used to synchronize schemas in the following scenarios to ensure schema consistency:

- Between a database in a production environment and a database in a test environment.
- Between databases in a test environment.
- Between databases in a production environment.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Schemas > Table Sync > Schema Synchronization**.
3. On the Schema Synchronization tab, set the parameters for a schema synchronization ticket.



Parameter	Description
Source Database	The name of the source database for schema synchronization. You must have query permissions on the source database.

Parameter	Description
Target Database	The name of the destination database for schema synchronization. You must have change permissions on the destination database.
Synchronized Table	The tables that you want to synchronize. Valid values: ○ **Partial Tables**: Synchronize some of the tables in the source database. You can click the plus icon to add tables one by one. Note If you do not specify the names of destination tables, DMS assumes that the destination table names are the same as the source table names. ○ **All Tables**: Synchronize all tables in the source database.
Whether to Ignore Error	Specifies whether to skip errors when SQL statements are being executed. Valid values: ○ **Not Ignore**: If an error occurs when SQL statements are being executed, DMS stops executing the current and subsequent SQL statements. ○ **Ignore**: If an error occurs when SQL statements are being executed, DMS skips the error and continues to execute subsequent SQL statements until all remaining statements are executed.

4. Click **Submit**. DMS starts to analyze the schemas.
5. Check the comparison results.

   Note If the schemas are changed during schema analysis, click Re-analyze in the Schema Analysis step.

6. Verify the script for schema synchronization and click **Submit and Synchronize to Target Database**.

   Note If the schemas of the source database and destination database are the same, you do not need to submit the script. The schema synchronization ticket is closed.

19.1.8.3. Initialize empty databases

DMS provides the empty database initialization feature. This feature allows you to compare the schemas of two databases, generate statements for synchronizing data from the source database to the destination database, and execute these statements against the destination database. The destination databases must be empty databases. This topic describes how to initialize empty databases.

Prerequisites

- The source databases and destination databases are MySQL or ApsaraDB for OceanBase databases.
- The destination databases are empty databases that contain no table.

Usage notes

The empty database initialization feature allows you to synchronize specific or all of the tables from a database, regardless of whether the database is a physical or logical database.

Scenarios

The empty database initialization feature is used to synchronize data between databases that are deployed in different regions or units. For example, this feature is applicable to the following scenarios:

- Synchronize data between one database that is deployed in the online environment and another in the offline environment.
- Synchronize data between different databases that are deployed in the offline environment.
- Synchronize data between different databases that are deployed in the online environment.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Schemas > Table Sync > Empty Database Initialization**.
3. On the Table/Database Synchronization Application tab, set the parameters as required to configure an Empty Database Initialization ticket.

Parameter	Description
Source Database	The name of the source database from which data is to be synchronized. You must have the read permissions on the source database.
Target Database	The name of the destination database to which data is to be synchronized. You must have the write permissions on the destination database. **Note** The type of the destination database must be the same as that of the source database.
Initialized Table	The tables that you want to synchronize. Valid values: ○ **Partial Tables**: Synchronize one or more tables in the source database. To add a table, click the **+** icon and specify a source table name. ○ **All Tables**: Synchronize all tables in the source database.
Whether to Ignore Error	○ **Not Ignore**: If an error occurs when SQL statements are being executed in serial mode, DMS immediately stops executing the current SQL statement and the remaining SQL statements. ○ **Ignore**: If an error occurs when DMS is executing an SQL statement, DMS stops executing the current SQL statement and continue to execute the next statement until all remaining SQL statements are executed.

4.
5.
6.

19.1.8.4. Repair table consistency

DMS provides the table consistency repair feature. This feature allows you to compare the schemas of tables in databases that are deployed in different environments, identify schema differences with efficiency, and execute SQL statements in the environment in which you want to modify the schemas. This ensures schema consistency in different environments.

Prerequisites

The source databases and destination databases are MySQL or ApsaraDB for OceanBase databases.

Scenarios

- Ensure the schema consistency between physical tables that are deployed in the offline environment and the online environment.

- Ensure the schema consistency between physical tables in a physical database and logical tables in a logical database.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Schemas > Table Sync > Repair Table Consistency**.
3. On the Table/Database Synchronization Application tab, set the parameters as required to configure a Repair Table Consistency ticket.

Parameter	Description
Base Database(Physical Database)	The source database based on which schema consistency is to be repaired. You must have the read permissions on the source database.
Target Database	The destination database whose data is to be modified. You must have the write permissions on the destination database.
Repaired Table	The pair of tables between which schema consistency is to be repaired. To add a pair of tables, click the **+** icon and specify the table names. **Note** If you do not specify the destination table name, DMS names the destination table after the name of the specified source table.
Whether to Ignore Error	○ **Not Ignore**: If an error occurs when SQL statements are being executed in serial mode, DMS immediately stops executing the current SQL statement and the remaining SQL statements. ○ **Ignore**: If an error occurs when DMS is executing an SQL statement, DMS stops executing the current SQL statement and continue to execute the next statement until all remaining SQL statements are executed.
Business Background(Remarks)	The business background of the ticket. This reduces unnecessary communication.

4.
5.
6.

19.1.9. SQL review

DMS provides the SQL review feature to help you prevent SQL statements that do not use indexes or do not conform to database development standards. This reduces the risk of SQL injection attacks.

Prerequisites

The environment type of the database instance in which you want to use the SQL review feature is **Test** in the DMS console. This is because SQL review is performed before DMS publishes SQL statements to an online environment.

Context

When you develop a project, you need to execute SQL statements on databases to add, delete, modify, and query data so that you can implement business logic and display data. Before the project is published, you must review all SQL statements that are used. This prevents SQL statements that do not conform to database development standards from being published to an online environment and accordingly impeding the business.

If DBAs manually review all SQL statements one by one, excessive human resources are consumed and the R&D efficiency is low. The SQL review feature helps you review SQL statements and also provides optimization suggestions.

Usage notes

- Only XML or TXT files can be uploaded.
- Tables that are involved in SQL statements must exist in the database that you select. Otherwise, DMS cannot review these SQL statements.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Optimization > SQL Review**.
3. On the tab that appears, click **New** in the upper-right corner.
4. Configure information about an SQL review ticket.

Parameter	Description
Project name	Enter a project name based on your business requirements so that the ticket can be distinguished from others in subsequent processing.
Data source	Select the database in the test environment that is used in your project. You must have the change permission on the database.
Business Description	Enter detailed information about the business scope of the project as required to help relevant users know about the project.
Relevant personnel	Enter an at sign (@) and select a user. **Note** You can repeat this operation to select multiple users.
Upload a file	Click **Add**, select files, and then click **Upload**. **Note** ◦ The iBATIS and MyBatis files are in the XML format. ◦ SQL statements are saved as TXT files. Multiple SQL statements are separated by semicolons (;). ◦ To remove an added file, you can select the check box before the file name and click **Delete**.

5. Click **Submit application**.
6. View SQL review results.

> **Note**
>
> - If SQL statements in a file conform to database development standards and use indexes, DMS determines that these SQL statements pass the SQL review and offers no suggestion about indexes.
> - If SQL statements in a file conform to database development standards but do not use indexes, DMS determines that these SQL statements pass the SQL review and offers suggestions about indexes.
> - If SQL statements in a file do not conform to database development standards, DMS determines that these SQL statements fail the SQL review.

7. Find a failed SQL review result and click **View reason** to check the reason. You can also click **Details**, **Adjust SQL**, or **More** in the **Operation** column to perform other operations.

   > **Note** After you optimize SQL statements in a file and click **Confirm**, DMS reviews the SQL statements again. For dynamic SQL statements in XML files, you must optimize each SQL statement combination.

8. When all SQL statements pass the SQL review, click **Inspection results**.
9. In the dialog box that appears, click **Submit for approval** and wait for approval.

   > **Note** The approval process of the ticket is based on the security rules that are configured for the current database instance.

19.1.10. SQLConsole

19.1.10.1. Single database query

DMS provides the single database query feature that allows you to write SQL statements to query data. This feature is applicable to scenarios where you need to verify business code before it is published, analyze product effects, or identify issues in an online environment.

Prerequisites

You have the query permission on the database or table that you want to query.

Usage notes

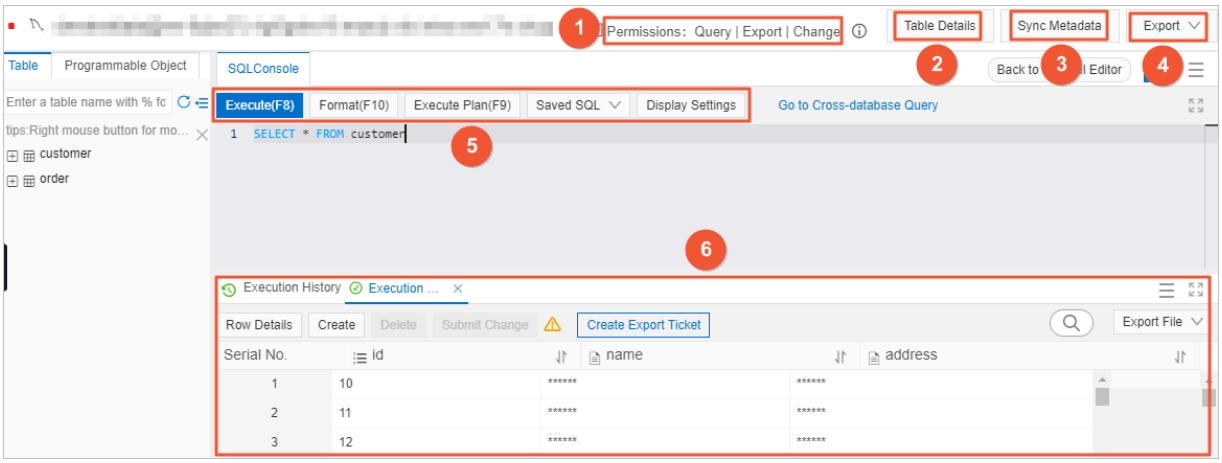
- If a table contains sensitive or confidential fields and you do not have permissions on the fields, you cannot use the fields in a WHERE clause to construct query conditions.
- If a table contains sensitive or confidential fields and you do not have permissions on the fields, the values of the fields are displayed as `******` in query results.
- In the left-side pane of the SQLConsole, you can search for tables in the current database. You can also view information about each table, such as the schema, fields, and indexes of the table. The pane can display 1,000 tables at most.
- By default, a maximum of 200 data rows can be returned for each query. If you are a DMS administrator, you can choose **System Management** > **Security** > **Security Rules** in the DMS console and modify this default number as needed.
- By default, a maximum of 10 GB of data can be queried each time. If you are a DMS administrator, you can choose **System Management** > **Security** > **Security Rules** in the DMS console and modify this default volume as needed.
- By default, the timeout period for executing each SQL statement is 60 seconds. If you are a DMS administrator,

you can find the database instance that you want to edit in the DMS console, open the **Edit instance** dialog box, and then modify the default timeout period as needed in the **Advanced information** section.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **SQLConsole > Single Database query**.
3. In the dialog box that appears, select a database from the drop-down list, or enter the keyword of a database name to search for databases and select the database that you want to query. Then, click **Confirm**.
4. In the SQLConsole, write an SQL statement and click **Execute**.
   After the SQL statement is executed, the execution results are displayed in the execution result section in the lower part.

Overview of the Single Database query tab



No.	Description
①	You can view the permissions that you have on the current database. You can move the pointer over the icon to view information about the database, such as the owner and the DBA of the database.
②	You can click the **Tables** icon to switch to the **Table List** tab, and click the **Query** icon to return to the SQLConsole.
③	You can click the **Sync Metadata** icon, and then click **OK** in the message that appears. DMS starts to collect the up-to-date metadata of the current database. The metadata includes the information about tables, fields, indexes, and programmable objects. The collected metadata is used to manage permissions on the tables, fields, and programmable objects in a fine-grained manner.
④	You can use the export feature to export data or schemas in the current database to a Word, Excel, or PDF file. You can also export the SQL statements that are used to create tables in the database.
⑤	You can write and execute SQL statements in the SQLConsole to query data in the current database. DMS also provides other features, such as Format, Execute Plan, Saved SQL, and Display Settings.

No.	Description
⑥	After SQL statements are executed, you can view the execution results. You can also perform operations on the result data. For example, you can view row details, or add, delete, or modify data. **Note** You can click the **Execution History** tab. On this tab, you can view the execution history of SQL statements. Each record includes information such as the start time, database, and executed SQL statement. You can also export the result data.

19.1.10.2. Cross-database query

DMS provides the cross-database query feature that allows you to perform join queries across online heterogeneous data sources that are deployed in different environments. Based on the cross-database query feature, you can perform join queries with ease across databases and tables in database instances that are registered in DMS.

Prerequisites

- The type of each database instance that you want to query is MySQL, SQL Server, PostgreSQL, PolarDB-X, or Redis.
- The cross-database query feature is enabled for each database instance.

  Note If the cross-database query feature is not enabled for a database instance, you can open the Edit instance dialog box in the DMS console, and then enable the feature and customize a database link name in the Advanced information section. The name of a database link must be unique.

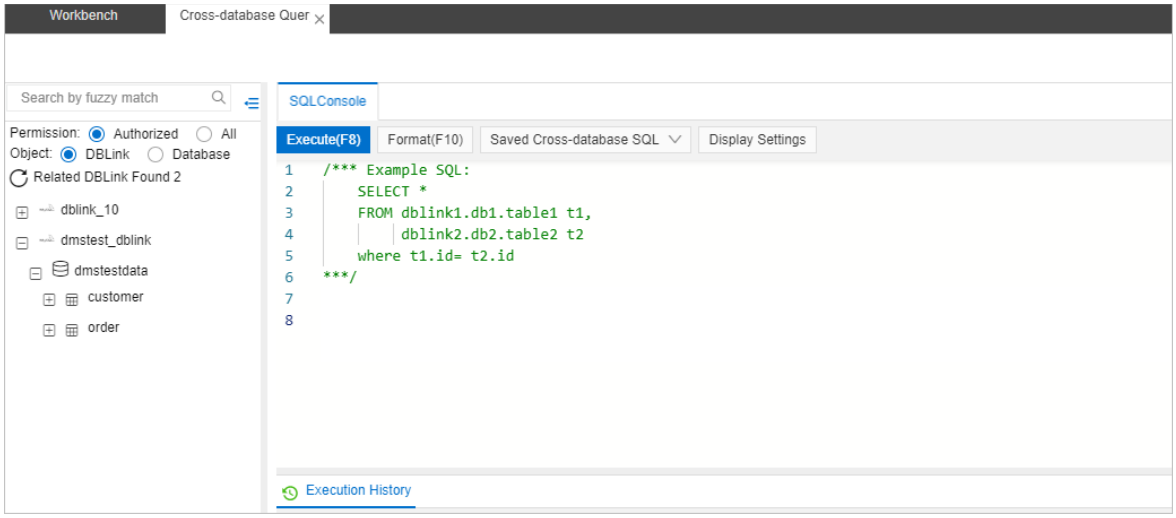
- You have the query permission on each database or table that you want to query.

Limits

You can perform join queries only across physical databases, but not across logical databases.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **SQLConsole > Cross-database Query**.
3. In the left-side pane of the **Cross-database Query** tab, view the databases on which you have the query permission or all the databases.
4. In the right-side SQLConsole, enter an SQL statement. You can perform join queries across databases and tables on which you have the query permission in database instances.



> **Note**
> - You must specify the table that you want to query in the format of `<DBLinkName>.<databaseName>.<tableName>`, such as `dmstest_dblink.dmstestdata.customer`.
> - In the left-side list, you can double-click a table on which you have the query permission or drag the table to the SQLConsole. An SQL statement that you can use to query data in the table is automatically generated.

5. Click **Execute(F8)**. You can view the execution results and execution history in the lower part.

> **Note** DMS also provides the Format, Saved Cross-database SQL, and Display Settings features. You can use these features based on your business requirements.

19.1.11. System management

19.1.11.1. Instance management

DMS allows you to manage database instances. For example, you can export the information about instance configurations or configure a whitelist.

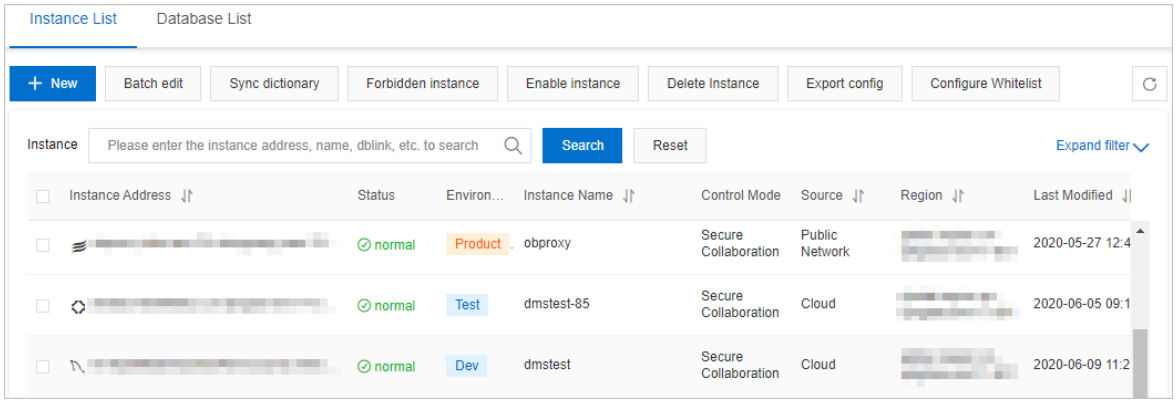
Prerequisites

You are a DBA or a DMS administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **System Management > Instance**.
3. On the **Instance List** tab, select the check box for one or more database instances that you want to manage. Then, you can perform the following operations based on your business requirements:

> **Note** You can click **Expand filter** to show more filter conditions.



- Add an instance

  Click **New** and register a database instance with DMS. For more information, see Register database instances with DMS.

- Edit one or more instances

  Click **Batch edit**. In the dialog box that appears, modify the instance information and click **OK**.

  > **Note** The database instances that you select must be of the same database type, such as MySQL.

- Synchronize the data dictionary

  Click **Sync dictionary**. In the message that appears, click **OK**.

  > **Note**
  > - If you change schemas for a database instance by using DMS, DMS automatically synchronizes the data dictionary of the instance.
  > - If you change schemas for a database instance by using a service other than DMS, you must manually synchronize the data dictionary of the instance.

- Disable or enable one or more instances

  Click **Forbidden instance** or **Enable instance**. In the message that appears, click **OK**.

  > **Note**
  > - After you disable a database instance, the instance is removed from the left-side instance list. DMS users can no longer find databases or tables in this instance in the DMS console.
  > - After you enable a database instance, the instance appears in the left-side instance list. Databases in this instance become available. Relevant permissions that have been granted to DMS users on this instance also become valid.

- Remove one or more instances

  Click **Delete Instance**. In the message that appears, click **OK**. After you remove a database instance, the instance is removed from the left-side instance list. DMS users can no longer use databases in this instance in the DMS console. Relevant permissions that have been granted to DMS users on this instance also become invalid and are revoked.

  > **Note** On the **Instance List** tab, you can find database instances in the Delete state and enable these instances to recover them.

- Export configuration information

  Click **Export config**. The browser automatically downloads a CSV file named *instances*. You can use Excel or a text editor to view this file.

- Configure a whitelist

  Click **Configure Whitelist**. In the message that appears, click **OK**. The IP addresses of DMS are automatically added to the whitelists of the selected database instances.

  > **Note** The database instances that you select must be ApsaraDB instances.

- Other operations

  You can find a database instance and click Details in the Actions column to view the details about databases and tables in this instance. You can also move the pointer over More and perform other operations. For example, you can log on to the instance or edit the instance.

19.1.11.2. Database management

On the Database List tab, you can manage databases. For example, you can set the database owner, transfer the ownership, revoke the owner permission, grant and revoke user permissions, and export the information about database configurations or permissions.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **System Management > Instance**.
3. Click the **Database List** tab.
4. Set conditions to filter databases and select the check box for one or more databases that you want to manage. Then, you can perform the following operations based on your business requirements:

   > **Note** You can click **Expand filter** to show more filter conditions.

   - Set the owner

     Set the owner for the selected databases. You can set multiple owners for multiple databases at a time.

   - Transfer the ownership

     Transfer the ownership of the selected databases to a specific user. If you transfer the ownership of multiple databases at a time, you can select only the common owner of these databases as the original owner.

   - Revoke the owner permission

     Revoke the owner permission from the owners of the selected databases.

- Grant permissions

  Grant the query, export, or change permission on the selected databases to one or more users. In addition, you can set the expiration time for the permissions.

- Revoke permissions

  Revoke the query, export, or change permission on the selected databases from one or more users. If a user does not have the corresponding permissions, the message `No corresponding permissions. You do not need to recycle or release permissions` appears.

- Export configuration information

  Export the configuration information of the selected databases in an Excel file. The configuration information includes the instance status, environment, DBA, and owner.

- Export permission information

  Export the permission information of the selected databases in an Excel file. The permission information includes the database information, users, permissions, and users who grant the permissions.

- Other operations

  You can find a database and click Tables in the Actions column to view the details about tables in this database. You can also move the pointer over More and perform other operations. For example, you can query data in the database, manage permissions, view the details about the database instance to which the database belongs, and find the instance on the Instance List tab.

19.1.11.3. User management

You can use the user management feature to maintain users in DMS. For example, you can adjust the permissions and roles of users.

Prerequisites

You are a DMS administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **System Management > User**.
3. Select the check box for one or more users that you want to manage. Then, you can perform the following operations based on your business requirements:
   - Add a user

     Click **New**. In the dialog box that appears, enter the configuration information of a user. For more information, see Add a user.

   - Edit a user

     Click **Edit User**. In the dialog box that appears, modify the configuration information of the selected user and click **Confirm Change**.

   - Disable or enable one or more users

     Click Operation user and select **Disable User** or **Enable User**. In the message that appears, click **OK**.

   - Remove one or more users

     Click Operation user and select **Delete User**. In the message that appears, click **OK**.

   - Grant permissions

     Click Authorize user and select **Authorize instance**, **Authorize database**, or **Authorize table** in the upper-left corner. In the dialog box that appears, enter a keyword to search for instances, databases, or tables, select the permissions to be granted and the expiration time, and then click **OK**.

- Manage permissions

  Find a user and click **Permission** in the **Actions** column. Set conditions to filter the permissions that are granted to the user. Select the permission that you want to manage and click **Release Permission** to revoke the permission.

19.1.11.4. Task management

The task management feature allows you to manage various tasks that are created by using tickets. You can also directly create or manage tasks.

Prerequisites

You are a DBA or a DMS administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **System Management > Task**.
3. On the **Task** tab, view and manage various tasks that are created by using tickets.
4. Find a task and perform operations based on your business requirements. For example, you can click **Pause**, **Retry**, and **Delete** to perform operations.
   - Pause a task

     Click **Pause** to stop the task.
   - Retry a task

     If the task is in the **Failure** state, click **Retry** to run the task again.
   - Delete a task

     Click **Delete**. The task enters the **Delete** state and is no longer run.
   - Create a task

     Click **Add SQL task**. In the dialog box that appears, enter the task description, database that you want to manage, and SQL statements to be executed. Then, click **Submit Task**.

19.1.11.5. Security management

19.1.11.5.1. Manage security rules

Security rules are defined, by using a domain-specific language (DSL), to control user operations on different types of databases in various aspects, such as syntax and the number of affected rows. You can use security rules to standardize database operations, development processes, and approval processes as needed. This topic describes how to manage security rules.

Prerequisites

You are a DBA or a DMS administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **System Management > Security > Security Rules**.
3. Perform the following operations based on your business requirements:
   - Create a rule set

Click **Create Rule Set**. In the dialog box that appears, set the engine type, enter the name and description of a rule set, and then click **Submit**.

- Edit a rule set
  a. Find a rule set and click **Edit** in the **Actions** column.
  b. Click a rule subset in the left-side pane, such as **SQLConsole**. In the right-side pane, select a checkpoint.
  c. Find a rule, click **Edit**, and then modify the rule. For more information about the syntax, see DSL syntax for security rules.

  > **Note** You can also disable or delete a rule.

- Create a similar rule set
  a. Find a rule set and click **Create As** in the **Actions** column.
  b. In the dialog box that appears, enter the name and description of a new rule set.
  c. Click **Submit**. DMS clones the configurations of the original rule set to the new rule set.

- Delete a rule set

  Find a rule set and click **Delete** in the **Actions** column. In the message that appears, click **OK**.

  > **Note**
  > - A deleted rule set cannot be recovered. We recommend that you proceed with caution.
  > - You can delete only custom rule sets, but not built-in rule sets.

- Set as the default rule set

  Find a rule set and click **Set as Default**. In the message that appears, click **OK**. The rule set is used as the default rule set for the corresponding database engine.

19.1.11.5.2. DSL syntax for security rules

DMS provides a DSL to describe security rules. You can use the DSL syntax to define security rules as needed. This allows you to define database development standards based on your business requirements.

Overview

The DSL syntax is an IF-THEN or IF-THEN-ELSE statement that consists of one or more conditions and actions.

> **Note** When you define a security rule, you must specify an IF condition. You can specify one or more ELSEIF conditions or an ELSE clause as needed.

Example 1: If Condition 1 is met, DMS performs Action 1.

```
if
    Condition 1
then
    Action 1
end
```

Example 2: If Condition 1 is met, DMS performs Action 1. If Condition 2 is met, DMS performs Action 2. If neither Condition 1 nor Condition 2 is met, DMS performs Action 3.

Note If the `else Action 3` clause is omitted, DMS performs no action when neither Condition 1 nor Condition 2 is met.

```
if
    Condition 1
then
    Action 1
elseif
    Condition 2
then
    Action 2
[else Action 3]
end
```

DSL syntax

- Conditional clauses

  DMS uses conditional clauses to evaluate whether to perform actions. The result of a conditional clause is true or false. A conditional clause consists of one or more connectors, operators, and factors. Connectors are AND and OR. Factors are built-in system variables. The following examples are valid conditional clauses:

```
1. true                    // This is the simplest conditional clause. The result is true.
2. 1 > 0
3. 1 > 0 and 2 > 1
4. 1 <= 0 or 1 == 1
```

- Connectors

  Connectors are AND and OR. The AND connector has higher priority than the OR connector. Both the connectors have lower priority than operators. For example, a conditional clause is `1 <= 0 or 1 == 1`. DMS evaluates the result of the `1 <= 0` expression and then the result of the `1 == 1` expression. After that, DMS checks whether at least one of the results of the two expressions is true to evaluate the result of the conditional clause.

- Operators

  Operators are used to connect factors and constants to perform logical operations. The following table describes the operators that are supported by DMS.

Operator	Description	Example
==	Evaluates whether a value is equal to another value.	1 == 1
!=	Evaluates whether a value is not equal to another value.	1 != 2
>	Evaluates whether a value is greater than another value.	1 > 2
>=	Evaluates whether a value is greater than or equal to another value.	1 >= 2
<	Evaluates whether a value is less than another value.	1 < 2
<=	Evaluates whether a value is less than or equal to another value.	1 <= 2

Operator	Description	Example
in	Evaluates whether a value belongs to an array of values.	'a' in ['a', 'b', 'c']
not in	Evaluates whether a value does not belong to an array of values.	'a' not in ['a', 'b', 'c']
matchs	Evaluates whether a string matches a regular expression.	'idxaa' matchs 'idx\w+'
not matchs	Evaluates whether a string does not match a regular expression.	'idxaa' not matchs 'idx\w+'
isBlank	Evaluates whether a value is empty.	'' isBlank
isNotBlank	Evaluates whether a value is not empty.	'' isNotBlank

Note

- If you need to use a backslash (\) in a regular expression, you must use another backslash (\) as an escape character before the backslash. For example, to write the `idx_\w+` expression, you must enter `idx_\\w+`.
- We recommend that you use parentheses () for expressions that you want DMS to evaluate first. For example, a conditional clause is `1 <= 2 == true`. To make the priority clearer, you can change the clause to `(1 <= 2) == true`. DMS first evaluates the result of the `1 <= 2` expression in the parentheses.

- Factors

  A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name is prefixed with `@fac.`. Each tab of the Security Rules tab provides different factors for different checkpoints. The following table describes the factors that are supported by DMS.

Factor	Description
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.sql_type	The type of the SQL statement. The value is the subcategory of the SQL statement, such as UPDATE or INSERT. For more information, see the SQL subcategories that are described in the "SQLConsole for relational databases" topic.
@fac.detail_type	The type of the data change. Valid values: ○ COMMON: a Normal Data Modify ticket ○ CHUNK_DML: a Lock-Free Data Modify ticket ○ PROCEDURE: a Programmable Object ticket ○ CRON_CLEAR_DATA: a History Data Clean ticket ○ BIG_FILE: a Large Data Import ticket
@fac.is_logic	A Boolean value that indicates whether the database to be affected is a logical database.

Factor	Description
@fac.extra_info	Other information about the ticket. This factor is not in use.
@fac.is_ignore_affect_rows	A Boolean value that indicates whether to skip the validation.
@fac.insert_rows	The number of rows of data to be inserted.
@fac.update_delete_rows	The number of rows of data to be updated.
@fac.max_alter_table_size	The size of the largest tablespace where the table to be modified is stored.
@fac.is_has_security_column	A Boolean value that indicates whether the SQL statement to be executed involves sensitive fields.
@fac.security_column_list	A list of sensitive fields that the SQL statement to be executed involves.
@fac.risk_level	The risk level of the operation that is to be performed by the SQL statement.
@fac.risk_reason	The reason for identifying the operation to be performed as at the risk level.

Note You can use factors in conditional clauses. For example, you can write `@fac.sql_type == 'DML'` to evaluate whether an SQL statement is a DML statement.

- Action clauses

  An action in a security rule is an operation that DMS performs when the IF condition in the rule is met. For example, DMS can forbid the submission of a ticket, select an approval process, approve a ticket, or reject a ticket. An action in a security rule shows the purpose of the security rule. An action name is prefixed with `@act.` .Each tab of the Security Rules tab provides different actions for different checkpoints. The following table describes the actions that are supported by DMS.

Action	Description
@act.allow_submit	Requires the submission of SQL statements to be executed in a ticket.
@act.allow_execute_direct	Allows the execution of SQL statements in the SQLConsole.
@act.forbid_execute	Forbids the execution of SQL statements.
@act.mark_risk	Marks the risk level of an operation. Example: `@act.mark_risk 'Medium risk level: online environment'`.
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	
@act.choose_approve_template_with_reason	

- Built-in functions

  DMS provides built-in functions that can be used in both conditional clauses and action clauses. A function name is prefixed with `@fun.`.

Function	Description	Example
@fun.concat	Connects strings to form a single string. Output: a string. Input: multiple strings.	@fun.concat('d', 'm', 's') // The output is the string 'dms'. @fun.concat('[Development standards] The [', @fac.column_name, '] field cannot be left empty.') // The output is a message that reminds the user who submits the ticket to enter a value in the field.
@fun.char_length	Calculates the length of a string. Output: an integer. Input: a string.	@fun.char_length('dms') // The output is 3. @fun.char_length(@fac.table_name) // The output is the length of the table name.
@fun.is_char_lower	Evaluates whether all the letters in a string are lowercase. Output: true or false. Input: a string.	@fun.is_char_lower('dms') // The output is true. @fun.is_char_lower(@fac.table_name) // If all the letters in the table name are lowercase, the output is true.
@fun.is_char_upper	Evaluates whether all the letters in a string are uppercase. Output: true or false. Input: a string.	@fun.is_char_upper('dms') // The output is false. @fun.is_char_upper(@fac.table_name) // If all the letters in the table name are uppercase, the output is true.
@fun.array_size	Counts the number of values in an array. Output: an integer. Input: an array of values.	@fun.array_size([1, 2, 3]) // The output is 3. @fun.array_size(@fac.table_index_array) // The output is the number of indexes of the table.
@fun.add	Adds multiple numeric values. Output: a numeric value. Input: multiple numeric values.	@fun.add(1, 2, 3) // The output is 6.
@fun.sub	Deducts a numeric value from another numeric value. Output: a numeric value. Input: two numeric values.	@fun.sub(6, 1) // The output is 5.

Function	Description	Example

@fun.between	Evaluates whether a value belongs to a specific closed range. The supported data types are numeric values, dates, and time. Output: true or false. Input: three values. The first value is the value to be evaluated. The second value indicates the lower limit. The third value indicates the upper limit.	@fun.between(1, 1, 3) // The output is true because the value 1 belongs to [1, 3].
		@fun.between(2, 1, 3) // The output is true because the value 2 belongs to [1, 3].
		@fun.between(7, 1, 3) // The output is false because the value 7 does not belong to [1, 3].
		@fun.between(@fac.export_rows, 2001, 100000) // If the number of exported rows belongs to [2001, 100000], the output is true.
		@fun.between(@fun.current_datetime(), '2019-10-31 00:00:00', '2019-11-04 00:00:00') // If the current date and time belong to [2019-10-31 00:00:00, 2019-11-04 00:00:00], the output is true.
		@fun.between(@fun.current_date(), '2019-10-31', '2019-11-04') // If the current date belongs to [2019-10-31, 2019-11-04], the output is true.
		@fun.between(@fun.current_time(), '13:30:00', '23:59:59') // If the current time belongs to [13:30:00, 23:59:59], the output is true.

@fun.current_datetime	Obtains the current date and time, in the format of yyyy-MM-dd HH:mm:ss. Output: a string. Input: none.	@fun.current_datetime() // For example, the output is 2019-10-31 00:00:00.
@fun.current_date	Obtains the current date, in the format of yyyy-MM-dd. Output: a string. Input: none.	@fun.current_date() // For example, the output is 2020-01-13.
@fun.current_time	Obtains the current time, in the format of HH:mm:ss. Output: a string. Input: none.	@fun.current_time() // For example, the output is 19:43:20.

DSL configuration examples

Limit the number of SQL statements in a ticket: If the number of SQL statements in a ticket exceeds 1,000, DMS rejects the ticket and displays the specified message.

```
if
    @fac.sql_count > 1000
then
    @act.reject_execute 'The number of SQL statements in a ticket cannot exceed 1,000.'
else
    @act.allow_execute
end
```

Allow the submission of only DML statements: If the SQL statements in a ticket are DML statements such as the UPDATE, DELETE, and INSERT statements, DMS allows the execution of these statements.

```
if
    @fac.sql_type in [ 'UPDATE','DELETE','INSERT','INSERT_SELECT']
then
    @act.allow_submit
end
```

19.1.11.5.3. Set security rules for an instance

This topic describes how to set security rules for a database instance.

Prerequisites

- You are a DBA or a DMS administrator.
- The control mode of a database instance is **Security Collaboration**.

Procedure

1. Log on to the DMS console.
2. In the left-side navigation pane, right-click the database instance that you want to manage.
3. In the shortcut menu that appears, choose **Control Mode > Security Collaboration** and select the security rule set that you want to use.

> **Note** You can also edit the database instance on the Instance tab and change the security rule set for the instance. For more information, see Instance management.

19.1.11.5.4. Customize approval processes

DMS allows you to configure instance-level security rules so that you can customize different approval processes for different database instances or database operations. However, instance-level security rules may have specific limits in the production environment. This topic describes how to customize an approval process.

Prerequisites

You are a DBA or a DMS administrator.

Context

- Each database instance has only one DBA, who is responsible for approving tickets. The entire approval process may get stuck when the DBA is not able to respond as expected. To avoid this issue, you may need to allow multiple DBA roles to participate in an approval process.
- If multiple business parties share the same database in a database instance, each business party may need to approve tickets for their respective business operations in an approval process.

To resolve the issues in the preceding scenarios, you can customize approval processes.

Usage notes

- Do not assign only one approver to an approval node. We recommend that you assign at least two approvers to each approval node and assign at least two data owners for a database.
- You can assign a maximum of three data owners for a database. If multiple business parties share the same database, you can allow all business parties to participate in an approval process by following the procedure in this topic: Create an approval node and add the data owners of multiple business parties as approvers. Then, add the new node instead of the system node Owner to an approval template.

Procedure

This topic describes the procedure for customizing an approval process by allowing multiple DBA roles to participate in an approval process. You can follow this procedure to customize an approval process in other scenarios.

1. Log on to the DMS console.
2. In the top navigation bar, choose **System Management > Security > Approval Processes**.
3. Create an approval node.

i. Click the **Approval Node** tab on the left. Then, click **Create Approval Node**.

ii. Configure the approval node.

Parameter	Description
Node Name	The name of the approval node. The name must be globally unique.
Remarks	The description of the approval node, which helps distinguish the node from the others.
Approver	The approvers on the current node. Select the Apsara Stack tenant accounts or RAM users of relevant approvers. You can enter a keyword to select an account from the auto-completion list. **Note** In this example, three approvers are selected.

iii. Click **Submit**.

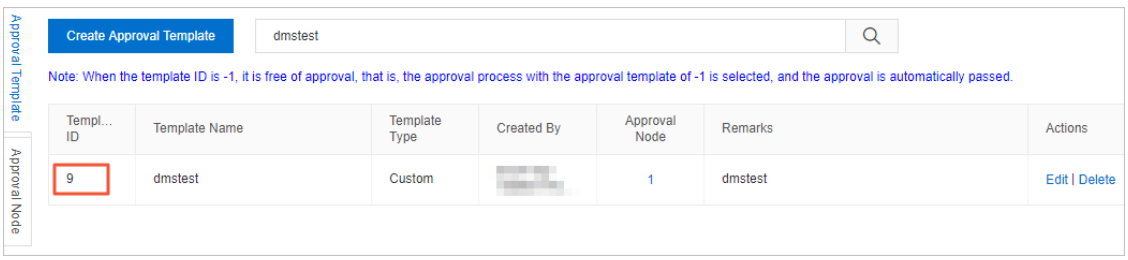
4. Create an approval template.

i. Click the **Approval Template** tab on the left. Then, click **Create Approval Template**.

ii. Configure the approval template.

Parameter	Description
Template Name	The name of the approval template. The name must be globally unique.
Remarks	The description of the approval template, which helps distinguish the template from the others.
Approval Node	Click Add Node and select the required approval nodes. In this example, the system node Owner and the approval node that is created in Step 3 are selected so that multiple DBA roles can participate in the approval process. **Note** The approval process is implemented based on the value of the Approval Order parameter in ascending order.

iii. Click **Submit**.
After the approval template is created, you can view the ID of the approval template. In this example, the ID is 9.



5. Apply the new approval process.

This example shows you how to edit the rule of the medium-level risk approval process for the **Risk Approval Rules** checkpoint in the data change approval process. You can follow this procedure to apply an approval process in other scenarios.

i. In the top navigation bar, choose **System Management > Security > Security Rules**.

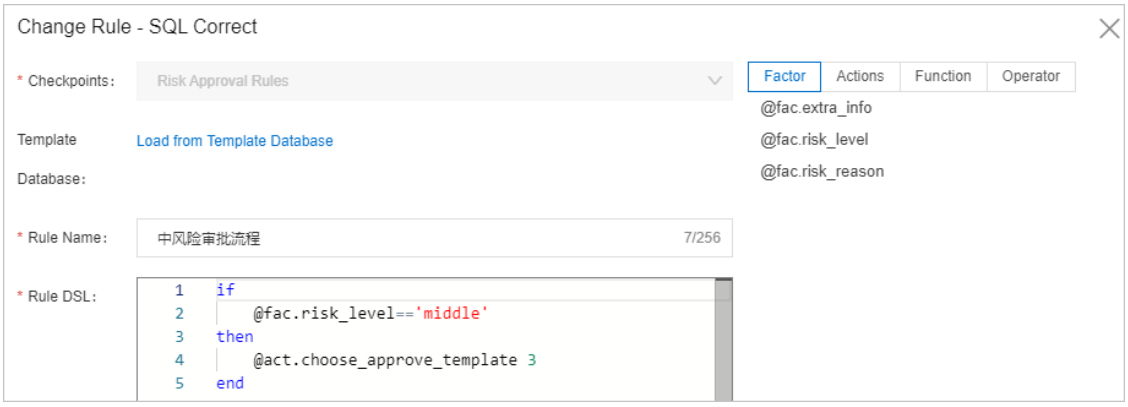
ii. Find the rule set that you want to edit and click **Edit** in the **Actions** column.

iii. In the left-side pane, click the **SQL Correct** tab.

iv. Select **Risk Approval Rules** as the checkpoint.

v. Find the rule of the medium-level risk approval process and click **Edit**.

vi. In the **Rule DSL** field, change the template ID.



> **Note** In this example, change `3` in the preceding figure to `9`, which is the ID of the approval template that is created in Step 4.

vii. Click **Submit**.

Result

If the data change tickets that are subsequently submitted match the corresponding rule, all of the specified DBA roles will receive ticket approval notifications and can participate in the approval process.

19.1.11.5.5. View operations logs

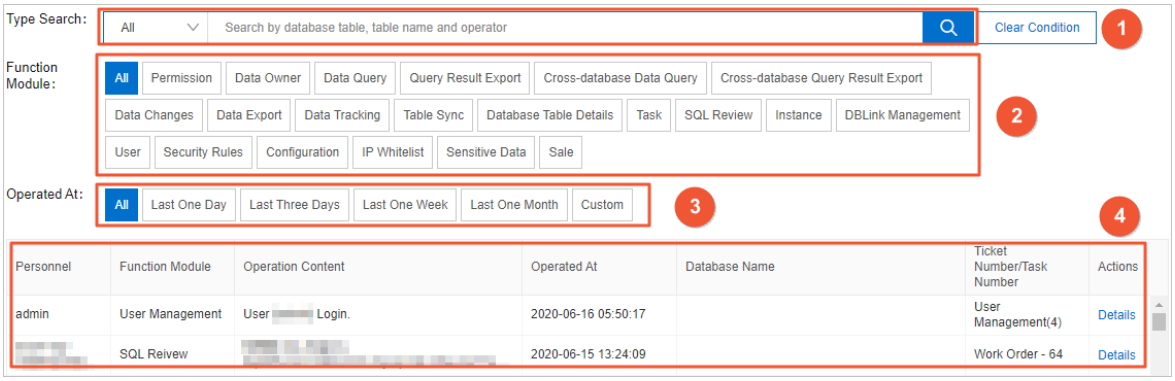
Operations logs in DMS record data changes. Each record contains information such as the user, specific operation, and time at which the operation was complete. You can trace historical user operations at any time.

Prerequisites

You are a security administrator, a DBA, or a DMS administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **System Management > Security > Operation Logs**.
3. On the **Operation Logs** tab, set conditions to filter logs and view the logs.



No.	Section	Description
①	**Type Search**	Allows you to search for logs by keyword, such as the database name, table name, or operator.
②	**Function Module**	Allows you to search for logs by feature.
③	**Operated At**	Allows you to search for logs by time period based on the time when an operation was complete.
④	Log list	Displays the logs that are found based on the specified filter conditions. By default, the logs are listed in reverse order of the recorded time. You can find a log and click **Details** in the **Actions** column to view the details about the log.

19.1.11.5.6. Configure access IP address whitelists

DMS allows you to configure access IP address whitelists to effectively control the service scope of DMS. You can allow user access to DMS only from specific trusted network environments.

Prerequisites

You are a DMS administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **System Management > Security > Access IP Whitelists**.
3. Perform the following operations based on your business requirements:
   - Enable or disable the whitelist control feature

     Click **Click to Open** or **Click to Close** to enable or disable the whitelist control feature.
   - Create a whitelist
     a. Click **Create Whitelist**.
     b. In the dialog box that appears, enter the IP addresses and description.

     > **Note**
     > - Separate IP addresses with semicolons (;). Ensure that each IP address is unique in a whitelist.
     > - Supported formats are IP addresses such as 10.23.12.24, or CIDR blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix in the CIDR block. An IP address prefix can contain 1 to 32 bits.
     > - 0.0.0.0/0 indicates that all IP addresses are allowed.

     c. Click **Submit**.
   - Edit a whitelist
     a. Find an IP address whitelist and click **Edit** in the **Actions** column.
     b. In the dialog box that appears, modify the IP address information.
     c. Click **Submit**.
   - Delete a whitelist
     a. Find an IP address whitelist and click **Delete** in the **Actions** column.

b. In the message that appears, click **OK**.

> **Note** You cannot delete all IP address whitelists. At least one IP address whitelist must be retained.

19.1.11.5.7. Configure row-level control

In specific scenarios, different users have access to different rows of data in the same table. Traditional solutions address this need by using views. DMS provides the row-level control feature to control permissions at the row level.

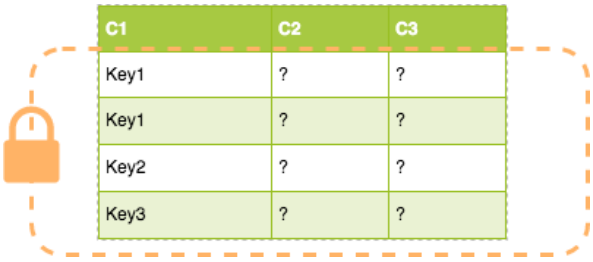
Prerequisites

You are a security administrator, a DBA, or a DMS administrator.

Context

Row-level control is used to provide horizontal data protection for tables. All the rows of a table are distinguished by one or more specified values. These values are called control values. To have access to a row that corresponds to a control value in the DMS console, users must have permissions on the row.

> **Note** A control value may correspond to multiple rows. If a user has permissions on a control value that corresponds to multiple rows, the user has permissions on all the rows that correspond to this control value.



Limits

- The sensitive data management feature applies only to relational databases such as MySQL, but not to NoSQL databases.
- The database instance to which you want to apply this feature must be managed in Security Collaboration mode.
- This feature applies only to physical databases, but not to logical databases.
- If you want to query, modify, or delete data in row-level control tables, the following limits are imposed on SQL statements:
  i. The control field must be specified in SQL statements.
  ii. All the rows of a row-level control table require access permissions. Users who do not have permissions on all rows can use only the `=` and `IN` operators to specify the control field. The control value that is specified in an SQL statement must belong to the set of control values of the table.
  iii. Users who do not have permissions on all rows cannot use specific operators such as OR, XOR, and logical NOT.

Terms

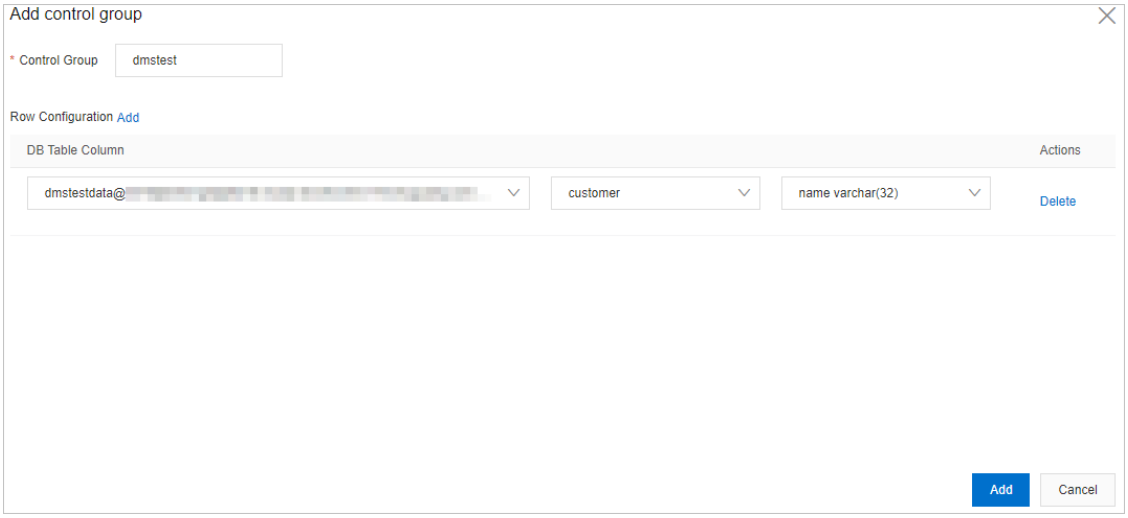
Term	Description

Term	Description
row permission	Users can apply for permissions on a control value to have access to rows that correspond to the control value. Permissions on the rows of a table are defined as row permissions and incorporated into the existing permissions of DMS. Permissions that can be controlled in Security Collaboration mode include database, table, column or field, and row permissions.
Single control value	When a user applies for permissions on the rows of a row-level control table, the user can select **Single** to apply for permissions on a single control value. **Note** A control value may correspond to multiple rows. If a user has permissions on a control value that corresponds to multiple rows, the user has permissions on all the rows that correspond to this control value.
All control values	When a user applies for permissions on the rows of a row-level control table, the user can select **ALL** to apply for permissions on all control values. Then, the user can have permissions on all the rows of the table. In addition, the user can have access to the entire row-level control table without limits. Even if the control values are changed or more control values are added, the user still has permissions on all the rows of the table.
row-level control table	A table that requires row-level control is called a row-level control table.
control field	The control values of a row-level control table are added to a field and this field is called a control field.
control group	If multiple row-level control tables have the same control values, these tables can be put in a control group. For example, if Table A and Table B have the same control values, the two tables can be put in a control group and managed at the same time by using only one set of control values.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **System Management > Security > Sensitive Data**.
3. Click the **Row Level Security** tab on the left.
4. Create a control group.
    i. Click **Add control group**.

ii. In the dialog box that appears, configure the control group.



Parameter	Description
Control Group	Enter the name of the control group.
Row Configuration	Click **Add** to add a row configuration where you can specify the database, table, and field. **Note** You can repeat this operation to add multiple row configurations.
DB Table Column	Enter the keyword of a database name in the database field to search for databases and select a database. Then, select a table and a field from the respective drop-down lists. **Note** The selected field is the control field.

iii. Click **Add**.

5. Add control values.
   i. Find the control group that is created and click **Details** in the **Actions** column.
   ii. Click **Add Row Value**.
   iii. In the dialog box that appears, specify whether to append row values and enter the row values.

   Note Separate multiple row values with commas (,).

   iv. Click **Import**.

Related operations

After you configure row-level control for a table, if a user does not have permissions on a control value that corresponds to one or more rows in the table, the user has no permission to query data in the rows. The user can apply for permissions on the control value to obtain access to the rows. For more information, see Apply for permissions.

19.1.11.5.8. Manage sensitive data

DMS allows you to manage all sensitive and confidential fields in a uniform manner. You can configure redaction algorithms for sensitive and confidential fields. This enhances the data de-identification feature.

Prerequisites

You are a security administrator, a DBA, or a DMS administrator.

Context

When you query a table and the table contains sensitive or confidential fields on which you do not have permissions, the values of the fields are displayed as `******` in query results. In this case, sensitive data is fully redacted. In specific scenarios, developers or testers may need to view a part of sensitive data for troubleshooting. To meet this requirement, you can configure redaction algorithms for fields.

Limits

- The sensitive data management feature applies only to relational databases such as MySQL, but not to NoSQL databases.
- The database instance to which you want to apply this feature must be managed in Security Collaboration mode.

Procedure

1. Log on to the DMS console.
2. Set the security levels of fields in the table that you want to manage.

   > **Note** If you have set the security levels of fields, you can skip this step.

   i. In the left-side database instance list, find the database instance that you want to manage and click the icon to show the list of databases in this instance.

   ii. Find the database that you want to manage, right-click the database, and then select **Tables**.

   iii. Find the table that you want to manage and click the + icon before the table name to show the table details.

   iv. Click **Adjust**.

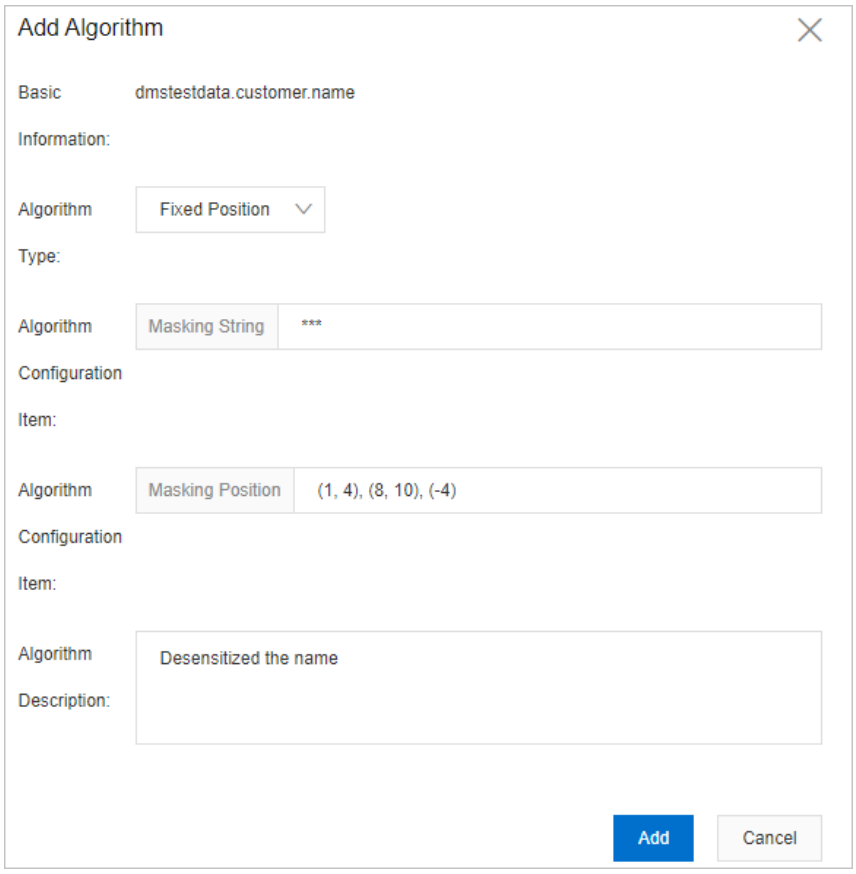
   v. In the dialog box that appears, adjust the security levels of fields.

   
   vi. Click **Submit for Security Department Approval**.

   > **Note** DMS automatically approves applications for raising the security level of a field. Applications for lowering the security level of a field must be approved based on the approval process that is specified by the DMS administrator or DBA.

   vii. In the message that appears, click **OK**.

3. In the top navigation bar, choose **System Management > Security > Sensitive Data**.
4. Find a field and click **Add Algorithm** in the **Actions** column.
5. In the dialog box that appears, configure a redaction algorithm.



Parameter	Description
Algorithm Type	Select an algorithm type based on your business requirements.

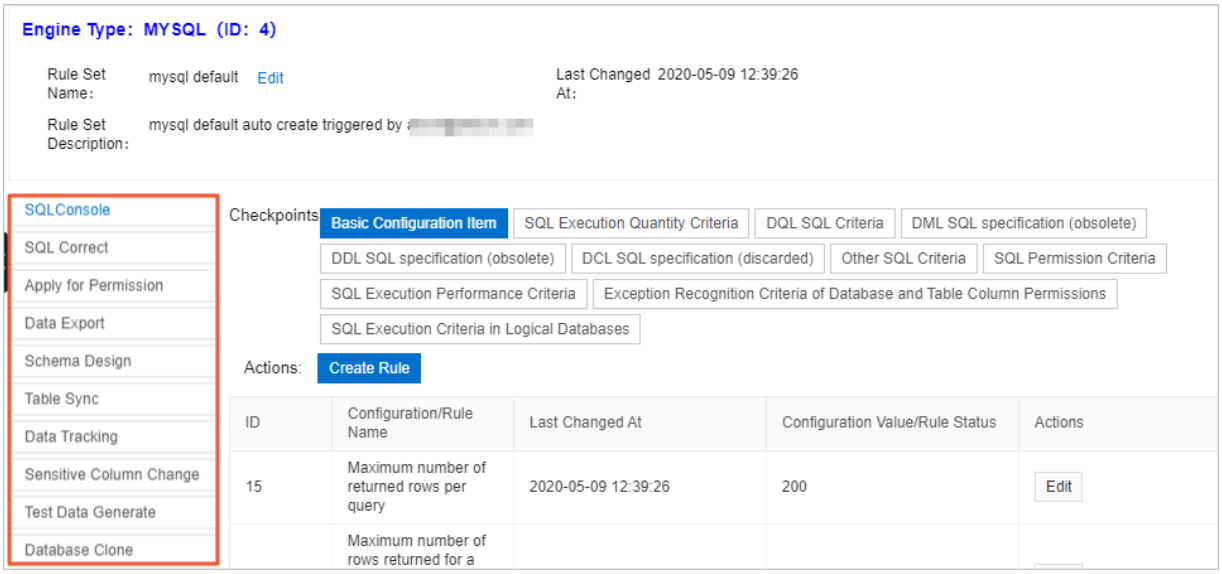
Parameter	Description
Algorithm Configuration Item	The algorithm configuration items vary based on the algorithm type that you select: ○ Select **Fixed Position** as the algorithm type You must set the Masking String and Masking Position parameters. For example, you can set the Masking String parameter to ***. The Masking Position parameter specifies the positions of the characters to be redacted in the field values. The positions are in the format of coordinates. Examples: ■ (1, 4): redacts the first four characters, which are the first to fourth characters. You can also enter (4) for short. ■ (-4): redacts the last four characters. **Note** You can specify a maximum of three positions. For example, `(1, 4), (8, 10), (-4)` indicates to redact the first four characters, the eighth to tenth characters, and the last four characters. ○ Select **Fixed Character** as the algorithm type You must set the Masking String and Character to Be Replaced parameters. **Note** The Character to Be Replaced parameter specifies the characters to be redacted, in the format of a string. You can specify a maximum of three strings. ○ Select **Full Masking** as the algorithm type You need to set only the Masking String parameter.
Algorithm Description	Enter an informative description, which helps distinguish the algorithm from the others.

6. Click **Add**.

19.1.11.6. Security rules

19.1.11.6.1. Overview of security rule sets

Security rule sets are sets of rules that use a DSL to achieve the fine-grained management of databases. These rules apply to different database types, different database management statements, and different scopes of data changes in databases. By configuring these rules, you can formulate operation guidelines and define development and approval processes based on your business requirements.



The following section lists the topics that describe the security rules that are provided on different tabs of the Security Rules tab. You can click a link to view the information about the security rules on the corresponding tab, including the basic configuration items, checkpoints, factors, actions, and supported statements or commands.

- SQLConsole for relational databases
- SQLConsole for MongoDB
- SQLConsole for Redis
- Data change
- Permission application
- Data export
- Schema design
- Database and table synchronization
- Schema design
- Sensitive field change
- Test data generation
- Database cloning

19.1.11.6.2. Manage the security rules under checkpoints

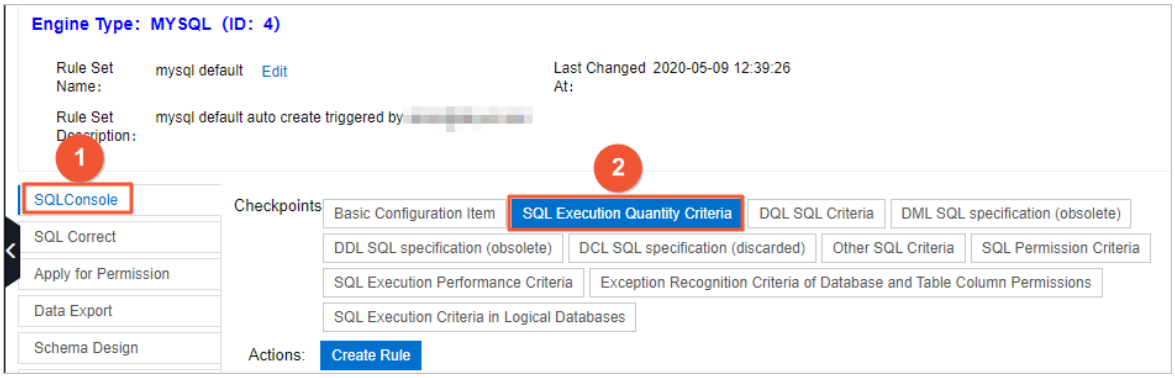
This topic describes how to configure a security rule under the SQL Execution Quantity Criteria checkpoint on the SQLConsole tab. The methods to configure the security rules under other checkpoints are similar to the method that is described in this topic.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **System Management > Security > Security Rules**.
3. Find the security rule set that you want to manage and click **Edit** in the **Actions** column.

   > **Note** In this example, the security rule set for MySQL databases is used.

4. Click a tab and then a checkpoint based on your business requirements. In this example, click the **SQLConsole** tab and then the **SQL Execution Quantity Criteria** checkpoint.



> **Note**
> - For more information about the tabs and the corresponding checkpoints, see Overview of security rule sets.
> - You can click **Create Rule** to create a security rule. For more information about the supported syntax, see DSL syntax for security rules.

5. Find the security rule that you want to manage and click **Edit** in the **Actions** column.

> **Note** You can also click **Disable** to disable a security rule or **Delete** to delete a security rule.

6. In the Change Rule - SQLConsole dialog box, modify the DSL statements of the security rule. For more information, see DSL syntax for security rules. In this example, adjust the maximum number of SQL statements that can be executed at a time from 1,000 to 500.

> **Note**
> - Various security rule templates are provided for each checkpoint. You can click **Load from Template Database** to use a template.
> - For more information about factors and actions, see Overview of security rule sets.

7. Click **Submit**.

19.1.11.6.3. SQLConsole for relational databases

DMS allows you to manage relational and non-relational databases on the SQLConsole tab. The definition and classification of security rules are different for relational and non-relational databases. This topic describes the security rules for relational databases on the SQLConsole tab, such as MySQL databases.

Default security rules

- Constraints on SQL statement categories: No constraints are imposed on data query language (DQL) statements. By default, DML statements, DDL statements, data control language (DCL) statements, and SQL statements that cannot be identified by DMS are all blocked. To execute DML, DDL, or DCL statements on the SQLConsole tab, you must configure and enable corresponding security rules.
- Constraints on permissions on databases, tables, and fields: By default, users can perform operations on databases, tables, and fields without permission validation. To enable permission validation, you must configure and enable security rules under the **SQL Permission Criteria** checkpoint. For more information, see Supported checkpoints.

Basic configuration items

Configuration item	Description
Maximum number of returned rows per query	The maximum number of rows that can be returned for a query.
Maximum number of rows returned for a single query with sensitive column conditions	The maximum number of rows that can be returned for a query that contains query conditions for sensitive fields.
Limit the maximum allowed SQL full table scan (MB)	The maximum size of data that can be scanned. Before an SQL statement is executed, DMS checks the execution plan. If the size of the data to be scanned exceeds the specified threshold, the SQL statement fails to be executed. **Note** This item can be configured only for MySQL and Oracle databases.
Turn off the execution of change SQL validation affects the number of rows and prompts	Specifies whether to check the number of rows to be affected and display a prompt before DMS executes an SQL statement to change data. By default, this item is disabled.
How many rows does result set page support	The maximum number of rows that can be returned in the query result set on the SQLConsole tab.
Does the result set support paging	Specifies whether the query result set can be displayed on multiple pages on the SQLConsole tab.
Does the result set support editing	Specifies whether the query result set can be edited on the SQLConsole tab.

Supported checkpoints

Note Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description
SQL Execution Quantity Criteria	Allows you to limit the number of SQL statements that can be submitted at a time.
DQL SQL Criteria	Allows you to set constraints on DQL statements.
Other SQL Criteria	Allows you to set constraints on multiple categories of SQL statements. Different enterprises may define different high-risk SQL statements, which may include specific subcategories of DML, DCL, and DDL statements. **Note** You can also set constraints on SQL statements that cannot be identified by DMS.
SQL Permission Criteria	Allows you to set constraints on the execution of SQL statements from the aspect of permissions. For example, DMS checks whether a user has the required permissions on the corresponding databases, tables, and fields.

Checkpoint	Description
SQL Execution Performance Criteria	Allows you to set constraints on the execution of SQL statements from the aspect of performance. For example, you can specify that a DML statement is not executed if the number of rows to be affected by the statement exceeds the specified threshold, or that a DDL statement is not executed if the size of the table involved exceeds the specified threshold.
Exception Recognition Criteria of Database and Table Column Permissions	After a user submits SQL statements on the SQLConsole tab, DMS parses the SQL statements and checks whether the user has the required permissions on the corresponding databases, tables, and fields. You can configure security rules under this checkpoint to ensure that if exceptions occur when DMS parses complex SQL statements, these statements can be executed. **Note** If you configure and enable security rules under the **Exception Recognition Criteria of Database and Table Column Permissions** checkpoint, security rules under the SQL Permission Criteria, DQL SQL Criteria, Other SQL Criteria, and SQL Execution Performance Criteria checkpoints are automatically disabled.
SQL Execution Criteria in Logical Databases	This checkpoint is reserved for logical databases and not suitable for physical databases.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`.The following table describes the supported factors for relational databases on the SQLConsole tab.

Factor	Description
@fac.sql_count	The number of SQL statements that are submitted at a time.
@fac.select_sql_count	The number of DQL statements among the SQL statements that are submitted at a time.
@fac.dml_sql_count	The number of DML statements among the SQL statements that are submitted at a time.
@fac.sql_type	The category and subcategory of the SQL statement. For more information, see Supported SQL statements.
@fac.sql_sub_type	
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.fulltable_delete	A Boolean value that indicates whether the current SQL statement deletes a full table. Valid values: *true* and *false*.
@fac.fulltable_update	A Boolean value that indicates whether the current SQL statement updates a full table. Valid values: *true* and *false*.
@fac.current_sql	The current SQL statement.
@fac.user_is_admin	A Boolean value that indicates whether the current user is a DMS administrator. Valid values: *true* and *false*.
@fac.user_is_dba	A Boolean value that indicates whether the current user is a DBA. Valid values: *true* and *false*.

Factor	Description
@fac.user_is_inst_dba	A Boolean value that indicates whether the current user is the DBA of the current instance. Valid values: *true* and *false*.
@fac.user_is_sec_admin	A Boolean value that indicates whether the current user is a security administrator. Valid values: *true* and *false*.
@fac.sql_affected_rows	The number of rows to be affected by the current SQL statement. **Warning** This factor triggers COUNT operations, which may affect the database performance. Use this factor with caution.
@fac.sql_relate_table_store_size	The estimated total size of the table to be accessed by the current SQL statement. Unit: MB. **Note** This value is estimated based on the metadata that is obtained by DMS. It is not an actual value.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`.The following table describes the supported actions for relational databases on the SQLConsole tab.

Action	Description
@act.reject_execute	Rejects the request to execute the current SQL statement.
@act.allow_execute	Allows the current SQL statement to be executed.
@act.reject_sql_type_execute	Rejects the request to execute a specific subcategory of SQL statements. You must specify an SQL statement subcategory after the action name. Example: `@act.reject_sql_type_execute 'UPDATE'`.
@act.allow_sql_type_execute	Allows a specific subcategory of SQL statements to be executed. You must specify an SQL statement subcategory after the action name. Example: `@act.allow_sql_type_execute 'UPDATE'`.
@act.check_dml_sec_column_permission	Checks whether a user has the required permissions on sensitive fields. If the user does not have the permissions, the DML statement for data change is not executed.
@act.uncheck_dml_sec_column_permission	Does not check whether a user has the required permissions on sensitive fields.
@act.check_sql_access_permission	Checks whether a user has the required permissions, such as query and change permissions, on the databases, tables, and fields that are involved in the SQL statements to be executed.
@act.uncheck_sql_access_permission	Does not check whether a user has the required permissions on the objects that are involved in the SQL statements to be executed.

Action	Description
@act.enable_sec_column_mask	De-identifies sensitive fields in query result sets that are returned for SQL statements that are submitted by users who do not have permissions on the sensitive fields.
@act.disable_sec_column_mask	Does not de-identify sensitive fields in query result sets that are returned for SQL statements that are submitted by users who do not have permissions on the sensitive fields.

Supported SQL statements

Category	Subcategory
DQL	• SELECT • DESC • EXPLAIN • SHOW
DML	• INSERT • INSERT_SELECT • REPLACE • REPLACE_INTO • UPDATE • DELETE • MERGE

Category	Subcategory
DDL	• DATABASE_OP • CREATE • CREATE_INDEX • CREATE_VIEW • CREATE_SEQUENCE • CREATE_TABLE • CREATE_SELECT • TRUNCATE • DROP_INDEX • DROP_VIEW • DROP_TABLE • RENAME • ALTER • ALTER_INDEX • ALTER_VIEW • ALTER_TABLE • ALTER_SEQUENCE • CREATE_FUNCTION • CREATE_PROCEDURE • ALTER_FUNCTION • ALTER_PROCEDURE • DROP_FUNCTION • DROP_PROCEDURE
DCL	• GRANT • DECLARE • SET • ANALYZE • FLUSH • OPTIMIZE • KILL

19.1.11.6.4. SQLConsole for MongoDB

DMS allows you to manage relational and non-relational databases on the SQLConsole tab. The definition and classification of security rules are different for relational and non-relational databases. This topic describes the security rules for MongoDB databases on the SQLConsole tab.

Basic configuration items

Maximum number of returned rows per query: the maximum number of rows that can be returned for a query.

Supported checkpoints

Note Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description
User Permission Validation	Allows you to specify whether to check the permissions of specific users when they submit commands.
Collection Statement Criteria	Allows you to specify whether to allow DMS to run a specific category of commands.
DB Statement Criteria	
Cache Query Statement Criteria	
User Management Statement Criteria	
Role Management Statement Criteria	
Replication Set Statement Criteria	
Sharding Statement Criteria	

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as command categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`.The following table describes the supported factors for MongoDB databases on the SQLConsole tab.

Factor	Description
@fac.sql_sub_type	The subcategory of the current command. For more information about the supported commands, see Supported MongoDB commands.
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as `DEV` or `PRODUCT`.
@fac.current_sql	The current command.
@fac.user_is_admin	A Boolean value that indicates whether the current user is a DMS administrator. Valid values: *true* and *false*.
@fac.user_is_dba	A Boolean value that indicates whether the current user is a DBA. Valid values: *true* and *false*.
@fac.user_is_inst_dba	A Boolean value that indicates whether the current user is the DBA of the current instance. Valid values: *true* and *false*.
@fac.user_is_sec_admin	A Boolean value that indicates whether the current user is a security administrator. Valid values: *true* and *false*.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`.The following table describes the supported actions for MongoDB databases on the SQLConsole tab.

Action	Description
@act.reject_execute	Rejects the request to run the current command.
@act.allow_execute	Allows the current command to be run.
@act.reject_sql_type_execute	Rejects the request to run a specific subcategory of commands. You must specify a subcategory after the action name. Example: `@act.reject_sql_type_execute 'UPDATE'`.
@act.allow_sql_type_execute	Allows a specific subcategory of commands to be run. You must specify a subcategory after the action name.

Supported MongoDB commands

Category	Subcategory	Command
Collection commands	Query commands	• aggregate • find • findOne • count • distinct • getIndexes • getShardDistribution • isCapped • stats • dataSize • storageSize • totalIndexSize • totalSize
	Data update commands	• insert • save • findAndModify • remove • update
	Collection modification commands	• drop • renameCollection
	Index modification commands	• createIndex • createIndexes • dropIndexes • reIndex
	Other commands	validate

Category	Subcategory	Command
Database commands	Database query commands	• commandHelp • currentOp • getCollectionInfos • getCollectionNames • getLastError • getLastErrorObj • getLogComponents • getPrevError • getProfilingStatus • getReplicationInfo • getSiblingDB • help • isMaster • listCommands • printCollectionStats • printReplicationInfo • version • serverBuildInfo • serverStatus,stats
	Collection creation commands	createCollection
	High-risk commands	• dropDatabase • fsyncLock • fsyncUnlock • killOp • repairDatabase • resetError • runCommand
Commands related to the query plan cache	Read commands	• getPlanCache • getPlansByQuery • listQueryShapes
	Write commands	clearPlansByQuery
User management commands	User query commands	• getUser • getUsers

Category	Subcategory	Command
	User modification commands	• createUser • changeUserPassword • dropUser • dropAllUsers • grantRolesToUser • revokeRolesFromUser • updateUser
Role management commands	Role query commands	• getRole • getRoles
	Role modification commands	• createRole • dropRole • dropAllRoles • grantPrivilegesToRole • revokePrivilegesFromRole • revokeRolesFromRole • updateRole
Replica set commands	N/A	• help • printReplicationInfo • status • conf
Sharding commands	N/A	• getBalancerState • isBalancerRunning

19.1.11.6.5. SQLConsole for Redis

DMS allows you to manage relational and non-relational databases on the SQLConsole tab. The definition and classification of security rules are different for relational and non-relational databases. This topic describes the security rules for Redis databases on the SQLConsole tab.

Supported checkpoints

Note Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description
Permission Execution Statement Criteria	Allows you to set constraints on the permissions for command execution.
Statement Criteria: Keys	Allows you to specify whether to check the permissions of specific users when they submit commands.

Checkpoint	Description
Statement Criteria: String	Allows you to specify whether to allow the execution of various Redis commands.
Statement Criteria: List	
Statement Criteria: SET	
Statement Criteria: SortedSet	
Statement Criteria: Hash	
Statement Criteria: Other	

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`.The following table describes the supported factors for Redis databases on the SQLConsole tab.

Factor	Description
@fac.cmd_type	The type of the Redis command. For more information about valid values, see Supported Redis commands.
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as `DEV` or `PRODUCT`.
@fac.is_read	A Boolean value that indicates whether the current command is a read command. Valid values: *true* and *false*.
@fac.is_write	A Boolean value that indicates whether the current command is a write command. Valid values: *true* and *false*.
@fac.current_sql	The current command.
@fac.user_is_admin	A Boolean value that indicates whether the current user is a DMS administrator. Valid values: *true* and *false*.
@fac.user_is_dba	A Boolean value that indicates whether the current user is a DBA. Valid values: *true* and *false*.
@fac.user_is_inst_dba	A Boolean value that indicates whether the current user is the DBA of the current instance. Valid values: *true* and *false*.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`.The following table describes the supported actions for Redis databases on the SQLConsole tab.

Action	Description
@act.reject_execute	Rejects the request to run the current command.
@act.allow_execute	Allows the current command to be run.

Supported Redis commands

Category	Subcategory	Command
Key-related commands	Key-related read commands	• EXISTS • TTL • PTTL • RANDOMKEY • TYPE • SCAN • OBJECTS
	Key-related write commands	• DEL • DUMP • EXPIRE • EXPIREART • MOVE • PERSIST • PEXPIRE • PEXPIREAT • RENAME • RENAMENX • RESTORE • SORT • TOUCH • UNLIMK • WAIT • MIGRATE
	String-related read commands	• GET • GETRANGE • BITCOUNT • GETBIT • MGET • STRLEN • BITOPS

Category	Subcategory	Command
String-related commands	String-related write commands	• APPEND • BITFIELD • BITOP • DECR • DECRBY • GETSET • INCR • INCRBY • INCRBYFLOAT • MSET • MSETNX • PSETEX • SET • SETNX
List-related commands	List-related read commands	• LINDEX • LLEN • LRANGE
	List-related write commands	• BLPOP • BRPOP • BRPOPLPUSH • LINSERT • LPOP • LPUSH • LPUSHX • LREM • LSET • LTRIM • RTOP • RPOPLPUSH • RPUSH • RPUSHX
Set-related commands	Set-related read commands	• SCARD • SISMEMBER • SRANDMEMBER • SSCAN
	Set-related write commands	• SADD • SMOVE • SPOP • SREM

Category	Subcategory	Command
Sorted set-related commands	Sorted set-related read commands	• ZCARD • ZCOUNT • ZLEXCOUNT • ZRANGE • ZRANGEBYLEX • ZRANGEBYSCORE • ZRANK • ZREVRNGE • ZREVRANGEBYLEX • ZREVRANGEBYSCORE • ZREVRANK • ZSCAN • ZSCORE
	Sorted set-related write commands	• ZADD • ZINCRBY • ZINTERSTORE • ZPOPMAX • ZPOPMIN • ZREM • ZUNIONSTORE • BZPOPMIN • BZPOPMAX
Hash-related commands	Hash-related read commands	• HEXISTS • HGET • HLEN • HMGET • HSCAN • HSTRLEN
	Hash-related write commands	• HDEL • HINCRBY • HINCRBYFLOAT • HMESET • HSET • HSETNX

19.1.11.6.6. Data change

In DMS, you can execute SQL statements for data changes. However, the execution requires a high level of security. DMS allows you to configure security rules on the SQL Correct tab to validate the submission and approval of tickets for data changes. Only the SQL statements that are validated by the security rules can be executed.

Background information

Based on a DSL, new security rules are flexible to use. You can apply new security rules to define risk levels for tickets so that a ticket can be submitted to the approval process that is designed for the specified risk level. For more information, see DSL syntax for security rules.

Basic configuration items

Configuration item	Description
Data change default approval Template	By default, this approval template takes effect if you do not configure different approval rules for data changes at different risk levels under the Risk Approval Rules checkpoint. In the Switch Approval Template dialog box, you can change the approval process of the default approval template. For more information, see Customize approval processes.
Data Change risk level list	This risk level list defines risk levels that are used in the **Risk Identification Rules** and **Risk Approval Rules** checkpoints to identify and classify risks in data changes. You can set risk levels based on the type and scenario of data changes. Data changes at different risk levels are submitted to different approval processes. DMS allows you to set the following four risk levels: • *low*: a low risk level. • *middle*: a medium risk level. • *high*: a high risk level. • *highest*: a critical risk level.

Supported checkpoints

Note Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description

SQL execution rules	SQL execution rules are used to limit the SQL statements that can be submitted for execution. If you do not enable SQL execution rules, all SQL statements that are used for data changes cannot be executed. Assume that you want to use DML statements to change the data of a database in an online environment. You can create the following SQL execution rule:
	Example:
	`if`
	`  @fac.env_type not in ['product']`
	`  and`
	`  @fac.sql_type in [ 'UPDATE','DELETE','INSERT']`
	`then`
	`  @act.allow_submit`
	`end`
	Note:
	The preceding rule specifies that you can only submit data change tickets to execute UPDATE, DELETE, and INSERT statements on a database that is deployed in an online environment.

Checkpoint	Description
Risk Identification Rules	If a ticket conforms to the preset SQL execution rules, DMS continues to validate the ticket based on the risk identification rules. Risk identification rules are used to identify and classify risks in data changes. You can create risk identification rules based on your database environment, the number of rows in which data is affected, and the categories and subcategories of SQL statements. **Note** Different risk identification rules apply to different check items. DMS automatically identifies the highest risk level for a data change. For example, if the risk level of a data change is identified as high, medium, and low by one, three, and five risk identification rules, DMS assumes that the data change is at high risk. Example: `if @fac.env_type not in ['product','pre'] then @act.mark_risk 'low 'Low risk level: offline environment' end` Note: The preceding rule specifies that if the destination database is deployed in an offline environment, data changes are at low risk.
Risk Approval Rules	After the risk level of a data change is identified by the risk identification rules, DMS processes the ticket based on the risk approval rules. You can customize risk approval rules under the **Risk Approval Rules** checkpoint. **Note** • If a data change does not hit risk approval rules, DMS uses the default approval template that is specified under the Basic Configuration Item checkpoint to process the ticket. • By default, an offline environment is identified as a factor at low risk and requires no approval.
Batch Data import rules	These rules apply only to the validation of data import tickets. You can use the default rules that are provided in templates, or configure rules based on your actual needs.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`.The following table describes the supported factors on the SQL Correct tab.

Factor	Description
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.sql_type	The type of the SQL statement. The value is the subcategory of the SQL statement, such as UPDATE or INSERT. For more information, see Supported SQL statements.

Factor	Description
@fac.detail_type	The type of the data change. Valid values: • *COMMON*: a Normal Data Modify ticket. • *CHUNK_DML*: a Lock-Free Data Modify ticket. • *PROCEDURE*: a Programmable Object ticket. • *CRON_CLEAR_DATA*: a History Data Clean ticket. • *BIG_FILE*: a Large Data Import ticket.
@fac.is_logic	A Boolean value that indicates whether the database to be affected is a logical database.
@fac.extra_info	The additional information about the data change. This factor is not in use.
@fac.is_ignore_affect_rows	A Boolean value that indicates whether to skip the validation.
@fac.insert_rows	The number of rows of data to be inserted.
@fac.update_delete_rows	The number of rows of data to be updated.
@fac.max_alter_table_size	The size of the largest tablespace where the table to be modified is stored.
@fac.is_has_security_column	A Boolean value that indicates whether the SQL statement to be executed involves sensitive fields.
@fac.security_column_list	A list of sensitive fields that the SQL statement to be executed involves.
@fac.risk_level	The risk level of the operation that is to be performed by the SQL statement.
@fac.risk_reason	The reason for identifying the operation to be performed as at the risk level.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`.The following table describes the supported action on the SQL Correct tab.

Action	Description
@act.allow_submit	Requires the submission of SQL statements to be executed in a ticket.
@act.allow_execute_direct	Allows the execution of SQL statements in the SQLConsole.
@act.forbid_execute	Forbids the execution of SQL statements.
@act.mark_risk	Marks the risk level of a data change. Example: `@act.mark_risk 'Medium risk level: online environment'`.
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	

Action	Description
@act.choose_approve_template_with_reason	

19.1.11.6.7. Permission application

DMS allows you to configure security rules on the Access apply tab to validate applications for permissions, including permissions on instances, databases, and tables.

Background information

In DMS, security rules are flexible to use. You can apply security rules to define risk levels for tickets so that a ticket can be submitted to the approval process that is designed for the specified risk level. For more information about the DSL syntax, see DSL syntax for security rules.

Basic configuration items

The following table describes the basic configuration items that are supported on the Access apply tab.

Configuration item	Description
[Instance-permission application] default approval Template	By default, this approval template takes effect if you do not set different approval processes for instance permission applications at different risk levels under the **Validation for Instance Permission Application** checkpoint. **Note** In the Switch Approval Template dialog box, you can change the approval process of the default approval template.
[DB-permission application] default approval Template	By default, this approval template takes effect if you do not set different approval processes for database permission applications at different risk levels under the **Database Permission Application Validation** checkpoint.
Table-permission request default approval Template	By default, this approval template takes effect if you do not set different approval processes for table permission applications at different risk levels under the **Table Permission Application Validation** checkpoint.
[Programmable object-permission application] default approval Template	By default, this approval template takes effect if you do not set different approval processes for programmable object permission applications at different risk levels under the **Programmable object verification** checkpoint.
[Field-permission application] default approval Template	By default, this approval template takes effect if you do not set different approval processes for sensitive field permission applications at different risk levels under the **Sensitive Field Application Validation** checkpoint.
Line-permission application default approval Template	By default, this approval template takes effect if you do not set different approval processes for row permission applications at different risk levels under the **Line permission application verification** checkpoint.
[Owner-application] default approval template (when the resource has no Owner)	By default, this approval template takes effect if you do not set different approval processes for data ownership applications at different risk levels under the **Owner Application Validation** checkpoint and the data that is involved in the application has no owner.

Configuration item	Description
[Owner-application] default approval template (when the resource has an Owner)	By default, this approval template takes effect if you do not set different approval processes for data ownership applications at different risk levels under the **Owner Application Validation** checkpoint and the data that is involved in the application has one or more owners.

Supported checkpoints

When a user submits a ticket to apply for permissions, DMS checks whether the ticket conforms to rules that are specified under checkpoints. The ticket can be submitted only after DMS determines that the ticket conforms to all rules that are specified under checkpoints.

> **Note** Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description
Owner Application Validation	Allows you to set approval processes or constraints for **Instance-OWNER**, **Table-OWNER**, and **Database-OWNER** tickets.
Validation for Instance Permission Application	Allows you to set approval processes or constraints for **Instance-Performance** and **Instance-Login** tickets.
Database Permission Application Validation	Allows you to set approval processes or constraints for **Database-Permission** tickets.
Table Permission Application Validation	Allows you to set approval processes or constraints for **Table-Permission** tickets.
Programmable object verification	Allows you to set approval processes or constraints for **Programmable Object** tickets.
Sensitive Field Application Validation	Allows you to set approval processes or constraints for **Sensitive Column-Permission** tickets.
Line permission application verification	Allows you to set approval processes or constraints for **Row-Permission** tickets.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and database names. A factor name starts with the prefix `@fac.` .The following table describes the supported factors on the Access apply tab.

Factor	Description
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.schema_name	The name of the database.
@fac.perm_apply_duration	The period of time during which the applicant needs the permission. Unit: hours.

Factor	Description
@fac.column_security_level	The security level of the field. Valid values: • *sensitive* • *confidential* • *inner*

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`.The following table describes the supported action on the Access apply tab.

Action	Description
@act.forbid_submit_order	Forbids a ticket from being submitted.
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	
@act.choose_approve_template_with_reason	

19.1.11.6.8. Data export

DMS allows you to manage security rules on the Data Export tab to validate the permissions of applicants on involved databases, tables, sensitive fields, and rows during the submission and approval of data export tickets. This helps ensure data security.

Basic configuration items

Data export default approval Template: the default approval template that takes effect if you do not set different approval processes for data export tickets at different risk levels under the Approval Rule Validation checkpoint. In the Switch Approval Template dialog box, you can change the approval process of the default approval template. For more information, see Customize approval processes.

Supported checkpoints

Note Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description
Pre-check Validation	Allows you to specify whether to validate the permissions of applicants on involved databases, tables, sensitive fields, and rows by configuring security rules.
Approval Rule Validation	Allows you to submit data export tickets to different approval processes by configuring security rules. For example, you can submit tickets for exporting more than a specific number of rows to an approval process and other tickets to another approval process.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`. The following table describes the supported factors on the Data Export tab.

Factor	Description
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.is_ignore_export_rows_check	A Boolean value that indicates whether to skip the check on the number of rows to be affected.
@fac.export_rows	The number of rows to be exported.
@fac.include_sec_columns	A Boolean value that indicates whether the data to be exported contains sensitive fields.
@fac.sec_columns_list	The sensitive fields that require or do not require approval before data is exported. The sensitive fields are displayed in the format of `Table name.Field name, [Table name.Field name, ...]`.
@fac.user_is_admin	A Boolean value that indicates whether the applicant is a DMS administrator.
@fac.user_is_dba	A Boolean value that indicates whether the applicant is a DBA.
@fac.user_is_inst_dba	A Boolean value that indicates whether the applicant is the DBA of the current instance.
@fac.user_is_sec_admin	A Boolean value that indicates whether the applicant is a security administrator.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`. The following table describes the supported actions on the Data Export tab.

Action	Description
@act.do_not_approve	Allows a ticket to be processed without approval.
@act.choose_approve_template	Specifies an approval template.
@act.choose_approve_template_with_reason	Specifies an approval template with a reason provided.
@act.forbid_submit_order	Forbids a ticket from being submitted.
@act.enable_check_permission	Validates the permissions of an applicant on involved databases and tables.
@act.disable_check_permission	Does not validate the permissions of an applicant on involved databases and tables.
@act.enable_check_sec_column	Validates the permissions of an applicant on involved sensitive fields.

Action	Description
@act.disable_check_sec_column	Does not validate the permissions of an applicant on involved sensitive fields.

19.1.11.6.9. Schema design

DMS allows you to configure security rules on the Schema Design tab to check the design rules and risk identification rules that apply to schema design tickets. This helps ensure data security.

Basic configuration items

Configuration item	Description
Enable non-peer Publishing	Specifies whether to enable non-peer publishing. By default, data changes to a table can be published only to a table with the same name in another database. After you enable non-peer publishing, you can perform data changes on all tables. **Warning** This feature may bring high risks. We recommend that you proceed with caution and enable this feature only for special requirements.
R & D process	The whole process of a schema design ticket. It is the most important configuration item on the Schema Design tab. For more information about the parameters of the configuration item, see Parameters involved in the R&D process.
Field type configuration	The supported data types of fields to be added.
Index type configuration	The supported data types of indexes to be added.
It is forbidden to modify the original field data type	Specifies whether to prohibit the data types of the original fields from being modified when the original table is to be modified.
Prohibit deleting original fields	Specifies whether to prohibit the existing fields from being deleted when the original table is to be modified. **Note** We recommend that you enable this feature because deleting existing fields may bring high risks.
Prohibit renaming original fields	Specifies whether to prohibit the existing fields from being renamed when the original table is to be modified. **Note** We recommend that you enable this feature because reaming existing fields may bring high risks.
Table character set license configuration	The range of character sets that are allowed to be used when you create a table. For example, you can specify utf8 and utf8mb4.
Default approval template for Structural design	The default approval template that is used for a schema design ticket if you do not configure the Approval Rule Validation checkpoint. In the Switch Approval Template dialog box, you can change the approval process of the default approval template.

Configuration item	Description
When published, the ticket will automatically advance to the end state	The point that is used to stop the schema change process. If you enable this feature, after the node that is set as the anchor in the R&D process is run, DMS automatically turns the ticket to the Finished state. **Note** To use this feature, you must set the last node in the R&D process as the anchor.

Supported checkpoints

Note Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

The Schema Design tab contains the following two processes:

- Process of saving changes: DMS provides the following three checkpoints for this process. The checkpoints validate the table headings, fields, and indexes.
  - **Save Changes and Validate Header**
  - **Save Changes and Validate Field**
  - **Save Changes and Validate Index**
- Process of applying changes: DMS provides the following five checkpoints for this process. The first four checkpoints identify the risks that arise from changing schemas without locking tables, and the last checkpoint assigns an approval process to each type of risk.
  - **Table Creation Risk Control**
  - **Field Change Risk Control**
  - **Index Change Risk Control**
  - **SQL Execution Risk Control**
  - **Approval Rule Validation**

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`. The following table describes the supported factors on the Schema Design tab.

Factor	Description
@fac.table_kind	The type of the table whose schema is to be changed. Valid values: • *new*: a newly created table. • *old*: an existing table.
@fac.column_kind	The type of the field to be changed. Valid values: • *new*: a newly created field. • *old*: an existing field.
@fac.xxxx_old	The value of an existing field or index that is used for comparison.
@fac.column_is_primary	A Boolean value that indicates whether the current field serves as a primary key. Valid values: *true* and *false*.

Factor	Description
@fac.column_type_support_default	A Boolean value that indicates whether the data type of the current field supports a default value. Valid values: *true* and *false*. **Note** For example, a field of the CHAR type supports a default value, whereas a field of the TEXT type does not.
@fac.index_kind	The type of the index to be changed. Valid values: • *new*: a newly created index. • *old*: an existing index.
@fac.index_column_count	The number of fields in the index.
@fac.change_type	The type of the schema change to be performed by DDL statements. Valid values: • *add*: adds one or more fields or indexes. • *modify*: modifies one or more fields or indexes. • *delete*: deletes one or more fields or indexes.
@fac.altered_table_size	The size of the table whose schema is to be changed. Unit: MB.
@fac.online_execute	A Boolean value that indicates whether the schema change can be performed in an online environment. Valid values: *true* and *false*.
@fac.change_risk_level	The risk level of the schema change. Valid values: • *high*: a high risk level. • *middle*: a medium risk level. • *low*: a low risk level.
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`.The following table describes the supported actions on the Schema Design tab.

Action	Description	Format
@act.block_submit	Blocks the submission of the schema change and displays the error message. This action can be used in the process of saving changes.	@act.block_submit 'Reason for blocking the submission'
@act.show_warning	Displays the error message without blocking the submission of the schema change. This action can be used in the process of saving changes.	@act.show_warning 'Error message'

Action	Description	Format
@act.mark_middle_risk	Specifies that the schema change is at medium risk. This action can be used in the process of identifying the risk level.	@act.mark_middle_risk 'Reason for the identification'
@act.mark_high_risk	Specifies that the schema change is at high risk. This action can be used in the process of identifying the risk level.	@act.mark_high_risk 'Reason for the identification'
@act.forbid_submit_publish	Rejects the ticket. This action can be used in the process of setting the approval process.	@act.forbid_submit_publish 'Reason for the rejection'
@act.do_not_approve	Specifies the ID of an approval template.	N/A
@act.choose_approve_template		
@act.choose_approve_template_with_reason		

Parameters involved in the R&D process

Parameter	Description
Step	• The type of the node. Valid values: • **Design**: The design node in the R&D process is generated by default and cannot be removed. It determines the environment where the schema change is designed. • **Publish**: A publish node in the R&D process is used to publish the schema change after the change is designed. You can set multiple publish nodes.
Node Name	The name of the node. The node name can be up to 10 characters in length.
Database Environment	The environment where the node is run.
Execution Strategy	• The way in which the node is run. Valid values: • **Immediately**: The node is run immediately after it is approved. • **Periodically**: The node is run at the time that you specify. **Note** If a node is approved before the specified point in time, it is run as scheduled. Otherwise, the node is interrupted and not run.
Can Go Back	Specifies whether a publish node can be rolled back to the design node.
Can Skip	Specifies whether the current node can be skipped.
Anchor	The point that is used to stop the schema change process. If you set a node as the anchor, after the node is published, the nodes that follow the anchor cannot be run and the schema change process ends. At this time, the ticket enters the Published state.
Actions	The operation that you can perform on a publish node. You can remove a publish node as required.

19.1.11.6.10. Database and table synchronization

DMS allows you to configure security rules on the Table Sync tab to validate operations that are related to schema synchronization, empty database initialization, and table consistency repair.

Basic configuration items

Configuration item	Description
Enable execution capability	Specifies whether to enable SQL-based synchronization. If this configuration item is set to OFF, applicants can compare table schemas but cannot execute SQL statements to synchronize databases and tables. Other configuration items and security rules you set under checkpoints on the Table Sync tab also become invalid.
Database table synchronization default approval Template	The default approval template for database and table synchronization applications. You can use the default approval template or click Switch Approval Template and select another template. For more information, see Customize approval processes.
Analysis phase script Expiration Time (unit: hours)	The timeout period of the analysis phase. You can set an appropriate timeout period in which synchronization can be canceled if schemas are changed in the destination database.

Supported checkpoints

The Table Sync tab contains three checkpoints that are corresponding to the three features that are supported by the tab. The three checkpoints are unrelated to each other. For example, when you submit a Schema Synchronization ticket, only the basic configuration items and the security rules that are specified under the Schema Synchronization Validation checkpoint are used to validate the ticket.

> **Note** Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description
Schema Synchronization Validation	Allows you to set approval processes or constraints for Schema Synchronization tickets.
Empty Database Initialization Validation	Allows you to set approval processes or constraints for Empty Database Initialization tickets.
Table Consistency Repair Validation	Allows you to set approval processes or constraints for Repair Table Consistency tickets.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`.The following table describes the supported factors on the Table Sync tab.

Factor	Description
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.schema_name	The name of the schema.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`.The following table describes the supported actions on the Table Sync tab.

Action	Description
@act.forbid_submit_order	Forbids a ticket from being submitted. The statement is in the following format: `@act.forbid_submit_order 'Reason for forbidding the submission of the ticket'`.
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	
@act.choose_approve_template_with_reason	

19.1.11.6.11. Sensitive field change

The topic describes the security rules on the Sensitive Column Change tab.

Basic configuration items

Sensitive column default approval Template: the default approval template that takes effect if you do not set approval processes for tickets that apply to change the security levels of sensitive fields under the Approval Rule Validation checkpoint. In the Switch Approval Template dialog box, you can change the approval process of the default approval template.

Supported checkpoints

Approval Rule Validation: When a user submits a ticket to change the security level of a sensitive field, DMS checks whether the ticket conforms to the rules that are specified under the Approval Rule Validation checkpoint.

> **Note** Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`.The following table describes the supported factors on the Sensitive Column Change tab.

Factor	Description

@fac.column_level_change_type	The type of security level change that the applicant wants to perform on a sensitive field. Valid values:
	• *upper*: raises the current security level, including the following three cases:
	  ◦ From inner to sensitive
	  ◦ From inner to confidential
	  ◦ From sensitive to confidential
	• *sensitive_to_inner*: lowers the security level from sensitive to inner.
	• *confidential_to_sensitive*: lowers the security level from confidential to sensitive.
	• *confidential_to_inner*: lowers the security level from confidential to inner.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`.The following table describes the supported actions on the Sensitive Column Change tab.

Action	Description
@act.forbid_submit_order	Forbids a ticket from being submitted. The statement is in the following format: `@act.forbid_submit_order 'Reason for forbidding the submission of the ticket'`.
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	
@act.choose_approve_template_with_reason	

19.1.11.6.12. Test data generation

This topic describes the security rules on the Test Data Generate tab.

Supported checkpoints

Approval rule validation: When a user submits a ticket to generate test data, DMS checks whether the ticket conforms to the rules that are specified under the Approval rule validation checkpoint.

> **Note** Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`.The following table describes the supported factors on the Test Data Generate tab.

Factor	Description
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.schema_name	The name of the schema.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`.The following table describes the supported actions on the Test Data Generate tab.

Action	Description

Action	Description
@act.forbid_submit_order	Forbids a ticket from being submitted. The statement is in the following format: `@act.forbid_submit_order 'Reason for forbidding the submission of the ticket'` .
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	
@act.choose_approve_template_with_reason	

19.1.11.6.13. Database cloning

This topic describes the security rules on the Database Clone tab.

Basic configuration items

Database clone default approval Template: the default approval template that takes effect if you do not set approval processes for database clone tickets under the Approval rule validation checkpoint. In the Switch Approval Template dialog box, you can change the approval process of the default approval template.

Supported checkpoints

Approval rule validation: When a user submits a database clone ticket, DMS checks whether the ticket conforms to the rules that are specified under the Approval rule validation checkpoint.

> **Note** Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.` .The following table describes the supported actions on the Database Clone tab.

Action	Description
@act.forbid_submit_order	Forbids a ticket from being submitted. The statement is in the following format: `@act.forbid_submit_order 'Reason for forbidding the submission of the ticket'` .
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	
@act.choose_approve_template_with_reason	

19.1.11.7. Configuration management

DMS allows DMS administrators to manage system configurations. If you are a DMS administrator, you can modify the system configuration items to flexibly meet your business requirements.

Prerequisites

You are a DMS administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **System Management > Configuration**.
3. Find the parameter that you want to modify and click **Change** in the **Actions** column.

   > **Note** You can also click **Change History** to view the change history of the parameter.

4. In the Change Parameter Configuration dialog box, enter a specific value.
5. Click **Confirm Change**.

Types of data changes

key	value	Description
config_correct	Modify Config	To modify configurations.
project_init_data	Init Project Data	To initialize the data for a project.
program_bug	Program Bug	To fix a bug.
require_deal_without_backend_function	Requirements Without Backend Function	To manage the data of an application that does not support backend management.
history_data_clear	History Data Clean	To clear historical data.
test	Test	To run a test.
mis_operation	Mis Operation	To restore data after a misoperation.
others	Others	To change data for other reasons.

20.Server Load Balancer (SLB)

20.1. User Guide

20.1.1. What is SLB?

This topic provides an overview of Server Load Balancer (SLB). SLB distributes inbound network traffic across multiple Elastic Compute Service (ECS) instances that act as backend servers based on forwarding rules. You can use SLB to improve the responsiveness and availability of your applications.

Overview

After you add ECS instances that are deployed in the same region to a SLB instance, SLB uses virtual IP addresses (VIPs) to virtualize these ECS instances into backend servers in a high-performance server pool that ensures high availability. Client requests are distributed to the ECS instances based on forwarding rules.

SLB checks the health status of the ECS instances and automatically removes unhealthy ones from the server pool to eliminate single points of failure (SPOFs). This enhances the resilience of your applications.

Components

SLB consists of three components:

- SLB instances

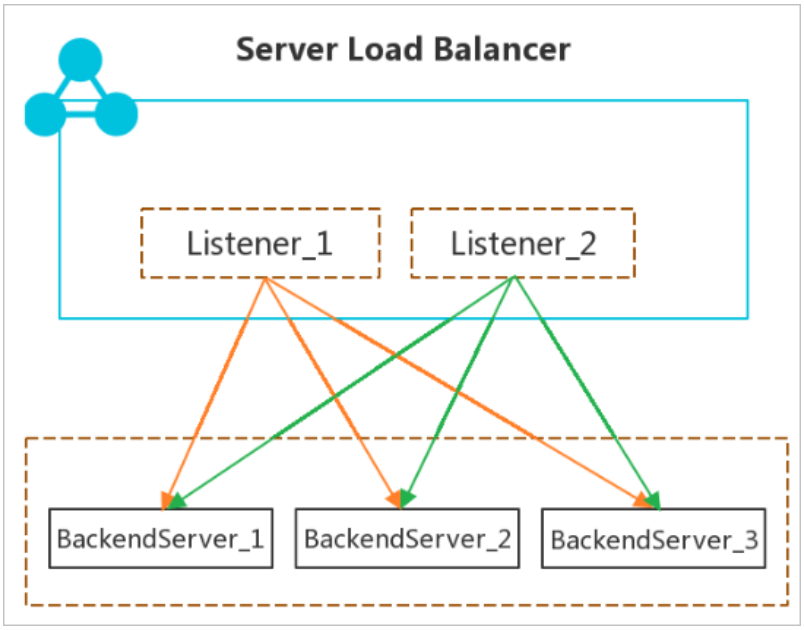
  A SLB instance is a running SLB service entity that receives traffic and distributes traffic to backend servers. To get started with SLB, you must create a SLB instance and add at least one listener and two ECS instances to the SLB instance.

- Listeners

  A listener checks client requests and forwards them to backend servers. It also performs health checks on backend servers.

- Backend servers

  ECS instances are used as backend servers to receive distributed requests. You can separately add ECS instances to the server pool, or use vServer groups or primary/secondary server groups to add and manage ECS instances in batches.



Benefits

- High availability

  SLB is designed with full redundancy that avoids SPOFs and supports zone-disaster recovery.

  SLB can be scaled based on application loads and can provide continuous service during traffic fluctuations.

- High scalability

  You can increase or decrease the number of backend servers to adjust the load balancing capability of your applications.

- Cost-effectiveness

  SLB can save 60% of load balancing costs compared with using traditional hardware solutions.

- Security

  You can use SLB with Apsara Stack Security to defend your applications against up to 5 Gbit/s DDoS attacks.

- High concurrency

  A SLB cluster supports hundreds of millions of concurrent connections and a single SLB instance supports tens of millions of concurrent connections.

20.1.2. Log on to the SLB console

This topic describes how to go to the Server Load Balancer (SLB) console after you log on to the Apsara Uni-manager Management Console by using the Chrome browser.

Prerequisites

- The domain name of the Apsara Uni-manager Management Console is obtained from the engineer that deploys the service before you log on to the Apsara Uni-manager Management Console.
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. If your account has multi-factor authentication (MFA) enabled, perform corresponding operations in the following scenarios:
   - It is the first time that you log on to the console after MFA is forcibly enabled by the administrator.
     a. On the Bind Virtual MFA Device page, bind an MFA device.
     b. Enter the account and password again as in Step 2 and click **Log On**.

c. Enter a six-digit MFA verification code and click **Authenticate**.

- You have enabled MFA and bound an MFA device.

  Enter a six-digit MFA authentication code and click **Authenticate**.

  > **Note** For more information, see the *Bind a virtual MFA device to enable MFA* topic in *Apsara Uni-manager Operations Console User Guide*.

5. In the top navigation bar, choose **Products > Networking > Server Load Balancer**.

20.1.3. Quick start

20.1.3.1. Overview

This quick start tutotial describes how to create a public-facing Server Load Balancer (SLB) instance and how to forward requests to two backend servers.

> **Note** Before creating an SLB instance, you must determine the region, type, and billing method of the SLB instance. For more information, see Preparations.

This tutotial includes the following content:

1. Create a CLB instance

   Create an SLB instance. An SLB instance is a running entity of the SLB service.

2. Add listeners and backend servers.

   Configure listening rules and backend servers for the SLB instance.

3. Release an SLB instance

   If you no longer need the SLB instance, delete it to avoid extra fees.

20.1.3.2. Before you begin

This article presents the essential considerations for configuring an SLB instance. Before you create an SLB instance, you must determine the types of listeners and the network traffic you want to balance.

Instance region

When you select a region, note the following points:

- To reduce latency and increase the download speed, we recommend that you select a region closest to your end-users.
- SLB offers stable and reliable load balancing services by providing support for primary/secondary failovers in most regions. This implements disaster recovery across different zones within the same region. We recommend that you select a region that supports the primary/secondary SLB deployment.
- SLB instances cannot span across regions. Therefore, you must make sure that the SLB instance and its backend Elastic Compute Service (ECS) instances are located in the same region.

Network traffic

SLB provides load balancing services for both Internet and internal network traffic:

- If you need to use SLB to distribute requests from the Internet, you can create an Internet-facing SLB instance.

  An Internet-facing SLB instance comes with a public IP address to receive requests from the Internet.

- If you need to use SLB to distribute requests from the internal network, you can create an internal SLB instance.

Internal SLB instances only have private IP addresses and are only accessible from the internal network and not from the Internet.

Listener protocol

SLB supports Layer-4 load balancing of Transmission Control Protocol (TCP) and User Datagram Protocol (UDP) traffic, and Layer-7 load balancing of HTTP and HTTPS traffic.

- A Layer-4 listener directly distributes requests to backend servers without modifying packet headers. After a client request reaches a Layer-4 listener, SLB uses the backend port configured for the listener to establish a TCP connection with an Elastic Compute Service (ECS) instance (backend server).
- A Layer-7 listener is implemented as a reverse proxy. After a client request reaches a Layer-7 listener, SLB establishes a new TCP connection over HTTP to a backend server, instead of directly forwarding the request to the backend server (ECS instance).

  Compared with Layer-4 listeners, Layer-7 listeners require an additional step of Tengine processing. Therefore, Layer-4 listeners provide better performance than Layer-7 listeners. In addition, the performance of Layer-7 listeners can also be affected by factors such as insufficient client ports or excessive backend server connections. Therefore, we recommend that you use Layer-4 listeners for high-performance load-balancing services.

Backend servers

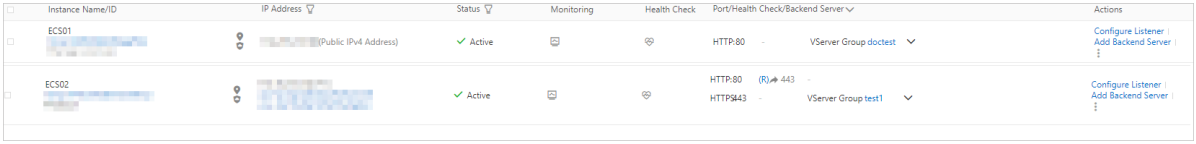
Before you use the SLB service, you must create ECS instances, deploy applications on them, and add the ECS instances to your SLB instance to process client requests.

When you create and configure an ECS instance, note the following points:

- Select a region and zone for the ECS instance

  Make sure that the ECS instance resides in the same region and Virtual Private Cloud (VPC) as the SLB instance. We recommend that you deploy ECS instances in different zones to improve availability.

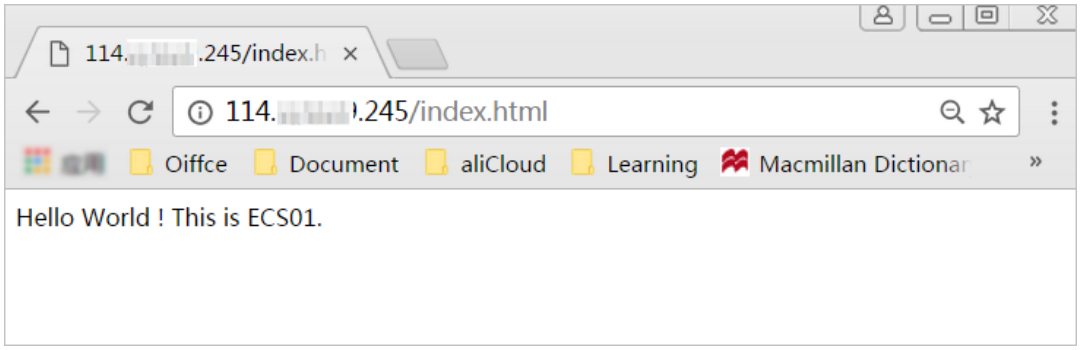
  In this example, two ECS instances named ECS01 and ECS02 are created in the **China (Hangzhou)** region. The following figure shows their basic configurations.



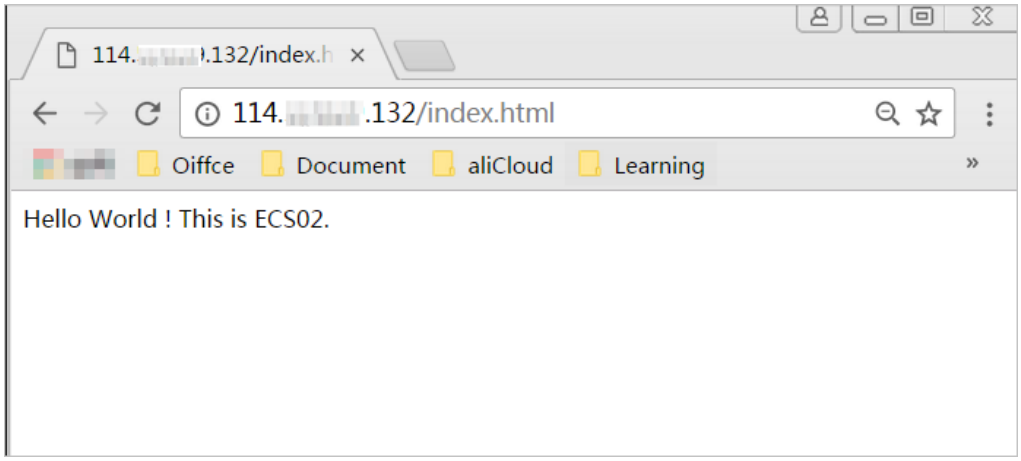
- Configure applications

  In this example, two static web pages are built on ECS01 and ECS02 by using Apache.

  - Enter the Elastic IP address (EIP) associated with ECS01 in the address box of your browser.



- Enter the EIP associated with ECS02 in the address box.



No additional configuration is required after you deploy applications on the ECS instances. However, if you need to use a Layer-4 (TCP or UDP) listener and the ECS instances run on Linux, make sure that the following parameters in the *net.ipv4.conf* file under */etc/sysctl.conf* are set to 0:

```
net.ipv4.conf.default.rp_filter = 0
net.ipv4.conf.all.rp_filter = 0
net.ipv4.conf.eth0.rp_filter = 0
```

20.1.3.3. Create an SLB instance

This topic describes how to create a Server Load Balancer (SLB) instance. An SLB instance is a running entity of the SLB service. You can add multiple listeners and backend servers to an SLB instance.

Prerequisites

- Elastic Compute Service (ECS) instances are created and applications are deployed on the ECS instances.
- The ECS instances and the SLB instance belong to the same organization. In addition, the security group rules of the ECS instances allow access from port 80 (HTTP) and port 443 (HTTPS).

Procedure

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Instances**.
3. On the **Instances** page, click **Create Instance**.
4. Configure the SLB instance and click **Submit**.

Parameter	Description
Organization	Select an organization for the SLB instance from the drop-down list. **Note** Make sure that the organization of the SLB instance is the same as that of its backend servers.
Resource Set	Select the region where you want to deploy the SLB instance.
Region	Select the region where you want to deploy the SLB instance.

Parameter	Description
Zone	Select a zone for the SLB instance from the drop-down list.
Instance Name	Enter a name for the SLB instance in the Instance Name field. The name must be 2 to 128 characters in length, and can contain letters, digits, full-width characters, underscores (_), hyphens (-), periods (.), and colons (:). Line breaks and spaces are supported. The name must start with a letter and cannot start with `http://` or `https://`.
Instance Edition	Select one of the following options: ○ Shared-performance: Shared-performance SLB instances share resources with each other. The performance of shared-performance SLB instances is not guaranteed. ○ Guaranteed-performance: Guaranteed-performance SLB instances use exclusive resources. The performance of guaranteed-performance SLB instances varies by type.
Instance Type	Select the type of network traffic that you want to distribute. Valid values: Internal Network and Internet. Internal Network is selected in this example.
Network Type	Select the network type of the SLB instance. Valid values: Classic Network and VPC. VPC is selected in this example.
VPC	Select a virtual private cloud (VPC).
vSwitch	Select a vSwitch.
IP Version	Select an IP version.
IP Address	Enter a service IP address. Make sure that the service IP address is valid. Otherwise, the SLB instance cannot be created. If you do not set this parameter, the system automatically allocates an IP address to the SLB instance. **Note** The private IP address that you specify must belong to the destination CIDR block of the vSwitch.

What's next

Configure a CLB instance

20.1.3.4. Configure an SLB instance

This topic describes how to configure a Server Load Balancer (SLB) instance. After you create an SLB instance, you must add at least one listener and one group of backend servers to the SLB instance so that it can forward traffic. The following example describes how to add a TCP listener and two Elastic Compute Service (ECS) instances to an SLB instance as backend servers. The ECS instances are ECS01 and ECS02 that host static web pages.

Procedure

1. Log on to the SLB console
2. On the **Instances** page, find the SLB instance that you want to manage and click **Configure Listener** in the Actions column.

3. On the **Protocol and Listener** wizard page, set the required parameters based on the following information. Use the default settings for other parameters.
   - **Select Listener Protocol**: Select a listener protocol. **TCP** is selected in this example.
   - **Listening Port**: Specify a frontend port to receive and forward requests to backend servers.

     The SLB instance uses this port to provide external services. In most cases, port 80 is set for HTTP listeners and port 443 is set for HTTPS listeners.

     This parameter is set to **80** in this example.

   Advanced:

   - **Enable Peak Bandwidth Limit**: Applications running on backend ECS instances provide external services. You can set bandwidth caps to limit service capabilities of applications.
   - **Scheduling Algorithm**: SLB supports the following three scheduling algorithms. **Round-Robin (RR)** is selected in this example.
     - Weighted Round-Robin (WRR): Requests are sequentially distributed to backend servers. Backend servers with higher weights receive more requests.
     - Weighted Least Connections (WLC): In addition to the weight of each backend server, the number of connections of each backend server also affects request distribution. If multiple backend servers have the same weight, requests are routed to the backend server with the least connections.
     - Round-Robin (RR): Requests are evenly and sequentially distributed to backend servers.
4. Click **Next**. On the **Backend Servers** wizard page, select **Default Server Group** and click **Add More** to add backend servers.
   i. In the **My Servers** panel, select the created ECS instances, ECS01 and ECS02, and click **Next**.
   ii. A backend server with a higher weight receives more requests. The default value is 100. We recommend that you use the default value.
   iii. Click **Add**.
   iv. On the **Default Server Group** tab, specify backend ports. The ports are used by backend ECS instances to receive requests. You can specify the same port for multiple backend servers that are added to the same SLB instance. The port is set to 80 in this example.
5. Click **Next** to configure the health check feature. The default health check settings are used in this example.

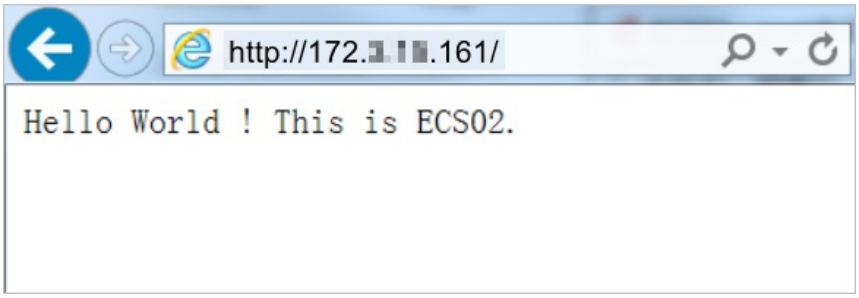
   After you enable the health check feature, when an ECS instance is considered unhealthy, SLB sends new requests to other healthy ECS instances. SLB only sends requests to this ECS instance after it is recovered and considered healthy.
6. Click **Next**. On the **Confirm** wizard page, check the configurations and click **Submit**.
7. Click **OK** to go back to the **Instances** page and click to refresh the page.

   If the health check state of a backend ECS instance is **Active**, the backend server is working as expected and can process requests.
8. Enter the service address of the SLB instance into the address bar of the browser to test load balancing services of the instance.

   ECS01

   
   ECS02

ECS02



20.1.3.5. Release an SLB instance

If an SLB instance is no longer needed, you can release the instance to save costs. The backend ECS instances will not be deleted or affected after you delete an SLB instance.

Procedure

1. Log on to the SLB console.
2. On the **Instances** page, find the instance and click > **Release** in the Actions column, or select the instance and click **Release** at the lower part of the page.
3. In the **Release** dialog box, select **Release Now**.

   > **Note** The system performs release operations at 30-minute and hour marks. However, billing for the SLB instance is stopped at the specified release time.

4. Click **Next**.
5. Click **OK** to release the SLB instance.

   > **Note** Pay-as-you-go SLB instances cannot be restored once deleted. We recommend that you exercise caution when you release SLB instances.

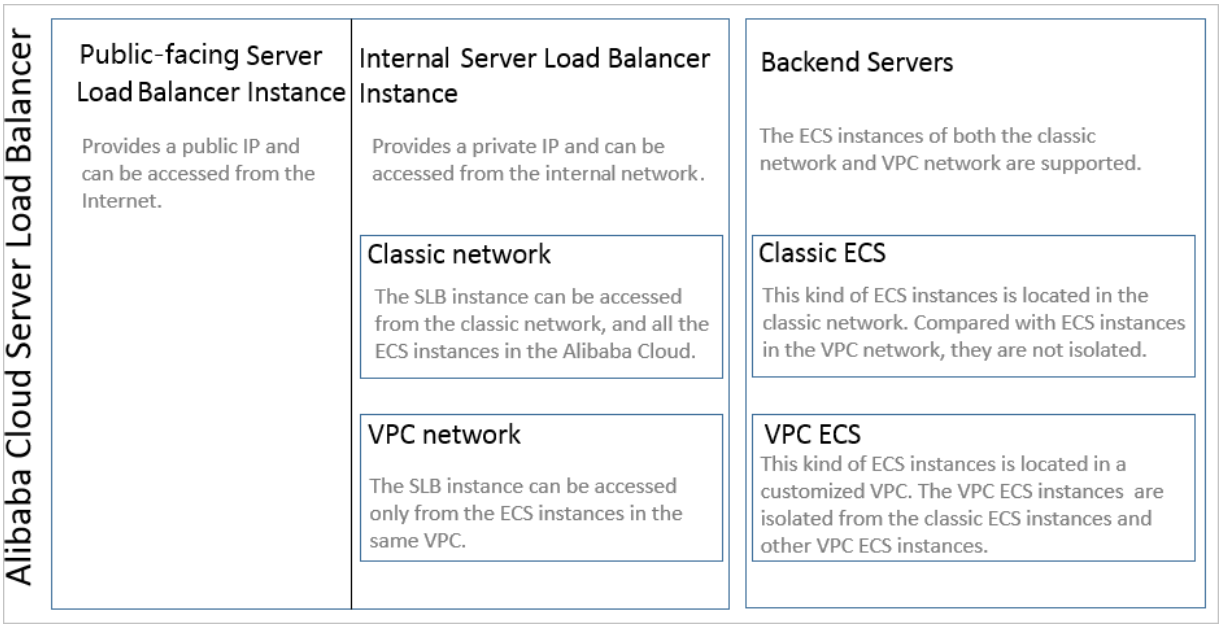
20.1.4. SLB instances

20.1.4.1. SLB instance overview

A Server Load Balancer (SLB) instance is a running entity of the SLB service. To use the SLB service, you must create an SLB instance and add listeners and backend servers to the instance.

Instance network types

Apsara Stack provides Internet-facing and internal-facing SLB instances. You can create Internet-facing SLB instances or internal-facing SLB instances based on your business requirements. If you create an Internet-facing SLB instance, a public IP address is allocated. If you create an internal-facing SLB instance, a private IP address is allocated.



- Internet-facing SLB instances

  An Internet-facing SLB instance distributes client requests over the Internet to backend servers based on configured forwarding rules. An internal-facing SLB instance in a virtual private cloud (VPC) can process requests sent over the Internet only when the instance is associated with an elastic IP address (EIP). The following table provides more detailed information.

Type	Feature
Internet-facing SLB instances After you create an Internet-facing SLB instance, the system allocates a public IP address to the instance. You can bind a domain name to the public IP address to provide external services.	○ The public IP address is allocated to the SLB instance and cannot be unbound from the instance. ○ Internet-facing SLB instances support only pay-by-data-transfer and pay-by-bandwidth billing methods.
Internal-facing SLB instances that are associated with EIPs An internal-facing SLB instance that is associated with an EIP can process requests sent over the Internet.	○ A public IP address is allocated to the EIP. You can associate the EIP with the SLB instance and disassociate the EIP from the SLB instance based on your requirements. ○ An EIP that is associated with an EIP bandwidth plan supports the 95th percentile bandwidth billing method.

- Internal-facing SLB instances

  Internal-facing SLB instances can be used only inside Apsara Stack and can forward only requests from clients that can access SLB instances over the internal network.

  You can select one of the following network types for an internal-facing SLB instance:

- Classic network

  If you choose classic network for an internal-facing SLB instance, the IP address of the SLB instance is allocated and maintained by Apsara Stack. This instance can be accessed only by Elastic Compute Service (ECS) instances in the classic network.

- VPC

  If you choose VPC for an internal-facing SLB instance, the IP address of the SLB instance is allocated from the CIDR block of the vSwitch that is attached to the VPC. This SLB instance can be accessed only by ECS instances in the VPC.

Instance types and specifications

Alibaba Cloud provides shared-performance SLB instances and guaranteed-performance SLB instances. Guaranteed-performance SLB instances provide reliable performance metrics.

- Shared-performance SLB instances

  All shared-performance SLB instances share SLB resources. This indicates that the instance performance cannot be guaranteed.

- Guaranteed-performance SLB instances

  The following content describes three key metrics of guaranteed-performance SLB instances:

Apsara Stack provides four types of guaranteed-performance SLB instances.

Type	Specification	Max connection	CPS	QPS	Purchase method
Type 1	Small I (slb.s1.small)	5,000	3,000	1,000	Available for purchase from the official website of Apsara Stack.
Type 2	Standard I (slb.s2.small)	50,000	5,000	5,000	Available for purchase from the official website of Apsara Stack.
Type 3	Standard II (slb.s2.medium)	100,000	10,000	10,000	Available for purchase from the official website of Apsara Stack.
Type 4	Higher I (slb.s3.small)	200,000	20,000	20,000	Available for purchase from the official website of Apsara Stack.

The following table describes the differences between shared-performance SLB instances and guaranteed-performance SLB instances.

Feature	Shared-performance SLB instance	Guaranteed-performance SLB instance
Resource allocation	Shared resources	Exclusive resources

Feature	Shared-performance SLB instance	Guaranteed-performance SLB instance
Service level agreement for guaranteed availability	Not supported	99.95%
IPv6	×	√
Server Name Indication (SNI) certificates	×	√
Support for blacklists and whitelists	×	√
Elastic network interface (ENI) mounting	×	√
Assignment of secondary IP addresses to ENIs that are bound to ECS instances	×	√
HTTP-to-HTTPS redirection	×	√
Consistent hashing	×	√
TLS security policies	×	√
HTTP2	×	√
Websocket(S)	×	√

20.1.4.2. Create an SLB instance

This topic describes how to create a Server Load Balancer (SLB) instance. An SLB instance is a running entity of the SLB service. You can add multiple listeners and backend servers to an SLB instance.

Prerequisites

- Elastic Compute Service (ECS) instances are created and applications are deployed on the ECS instances.
- The ECS instances and the SLB instance belong to the same organization. In addition, the security group rules of the ECS instances allow access from port 80 (HTTP) and port 443 (HTTPS).

Procedure

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Instances**.
3. On the **Instances** page, click **Create Instance**.
   - **Organization**: Select an organization for the SLB instance from the drop-down list.

     > **Note** Make sure that the organization of the SLB instance is the same as the organization of its backend servers.

   - **Resource Set**: Select a resource set for the SLB instance from the drop-down list.
   - **Region**: Select the region where you want to deploy the SLB instance.
   - **Zone**: Select a zone for the SLB instance from the drop-down list.
   - **Instance Name**: Enter a name for the SLB instance in the Instance Name field.

The name must be 2 to 128 characters in length, and can contain letters, digits, full-width characters, hyphens (-), colons (:), periods (.), and underscores (_). Line breaks and spaces are supported. It must start with a letter and cannot start with `http://` or `https://`.

- **Instance Edition**: Select one of the following options: shared-performance and guaranteed-performance. Shared-performance SLB instances share resources with each other. The performance of shared-performance SLB instances is not guaranteed. The performance of guaranteed-performance SLB instances varies by type.
- **Instance Type**: Select the type of network traffic that you want to distribute. Valid values: Internal Network and Internet.
- **Network Type**: Select the network type of the SLB instance. Valid values: Classic Network and VPC.
- **IP Version**: Select an IP version.
- **IP Address**: Enter a service IP address for the SLB instance. Make sure that the service IP address is valid. Otherwise, the SLB instance cannot be created. If you do not set this parameter, the system automatically allocates an IP address to the SLB instance.

  > **Note** The private IP address that you specify must belong to the destination CIDR block of the vSwitch.

4. Click **Submit**.

What's next

Configure a CLB instance

20.1.4.3. Start and stop an SLB instance

This topic describes how to start and stop an SLB instance. SLB instances can be started or stopped at any time. A stopped SLB instance does not receive or forward client traffic.

Procedure

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. Find the target SLB instance. In the **Actions** column, choose  **> Start** or  **> Stop**.
4. To start or stop multiple instances at a time, select the instances and click **Start** or **Stop** at the bottom of the page.

20.1.4.4. Tags

20.1.4.4.1. Tag overview

This topic provides an overview of tags in SLB. SLB provides the tag management feature that allows you to classify SLB instances by using tags.

Each tag consists of a key and a value. Before you use tags, note the following limits:

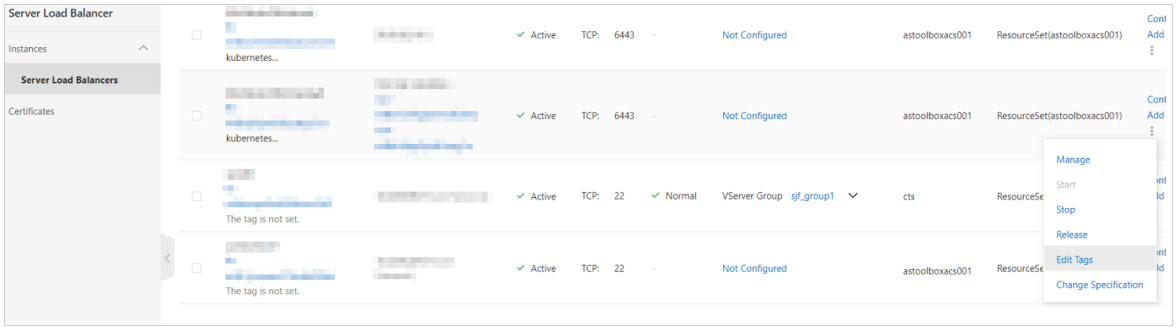
- Tags must be added to SLB instances.
- Each SLB instance can have a maximum of ten tags. You can add or remove a maximum of 5 tags at a time.
- The key of each tag added to an SLB instance must be unique. If a tag with the same key already exists, the tag is overwritten with the new value.

20.1.4.4.2. Add tags

This topic describes how to add tags to an SLB instance.

Procedure

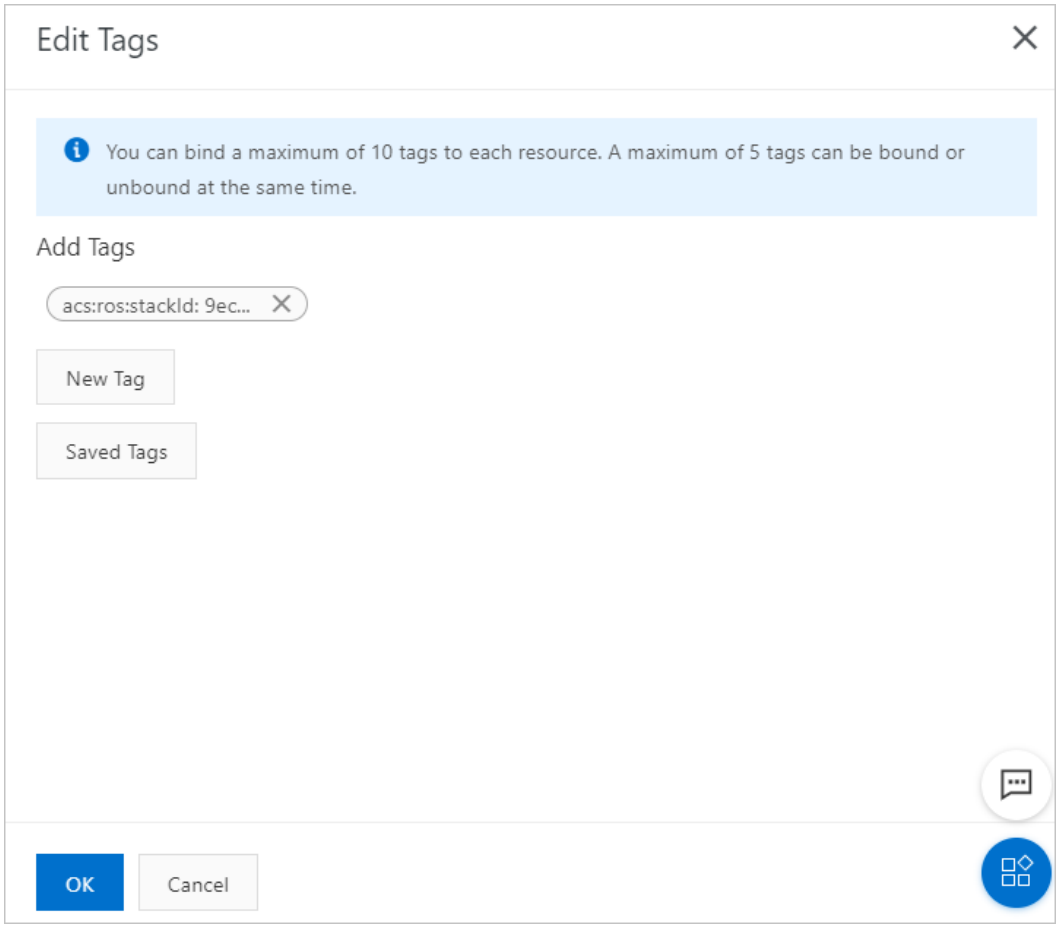
1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. In the **Actions** column, choose > **Edit Tags**.



4. Edit tags in the **Edit Tags** dialog box.

   To add a tag, perform the following operations:

   - To add an existing tag, click **Saved Tags** and then select a tag.
   - To create and add a new tag, click **New Tag** in the **Edit Tags** dialog box, enter the key and value of the new tag, and then click **OK** next to the value.



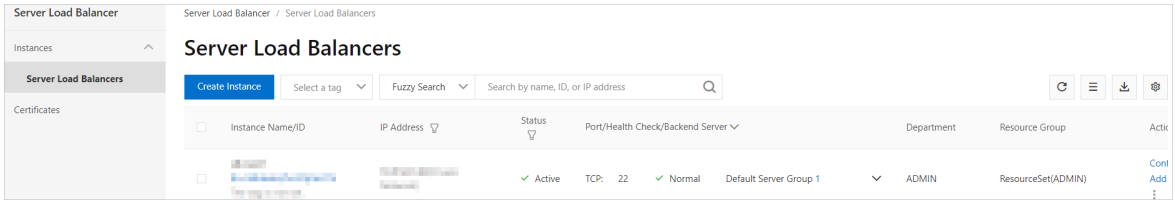
5. Click **OK**.

20.1.4.4.3. Query SLB instances by tag

This topic describes how to use tags to query SLB instances.

Procedure

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. Select a data from the **Select a tag** drip-down list to filter instances.



> **Note** To clear the search condition, move the pointer over the selected tag and click the displayed deletion icon next to it.

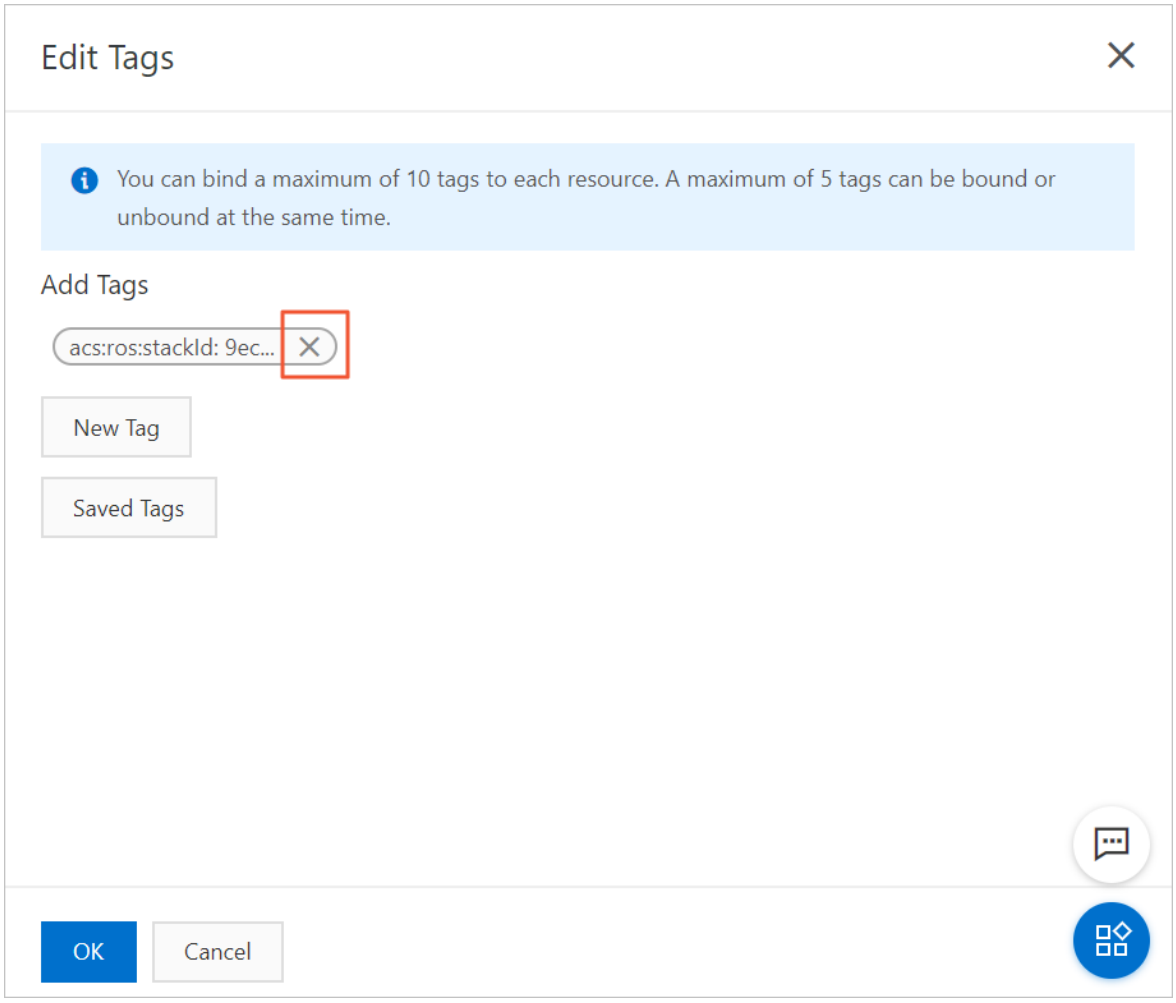
20.1.4.4.4. Remove tags

This topic describes how to remove tags from an SLB instance. You can only remove tags for one SLB instance at a time.

Procedure

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. In the **Actions** column, choose > **Edit Tags**.
4. In the **Edit Tags** dialog box, click the deletion icon next to the tags to be removed, and then click **OK**.

> **Note** If a tag is removed from an SLB instance and is not added to any other instances, the tag is deleted from the system.



20.1.4.5. Release an SLB instance

This topic describes how to release a Server Load Balancer (SLB) instance. You can immediately release SLB instances .

Procedure

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Instances**.
3. Find the SLB instance that you want to release and choose ⋮ **> Release** in the Actions column.
4. In the **Release** panel, **click Release Now**.
5. Click **Next**.
6. Confirm the displayed information and click **OK** to release the instance.

20.1.5. Listeners

20.1.5.1. Listener overview

This topic provides an overview of listeners. After you create a Server Load Balancer (SLB) instance, you must configure one or more listeners for it. A listener checks for connection requests and then distributes the requests to backend servers based on the forwarding rules that are defined by a specified scheduling algorithm.

SLB provides Layer 4 (TCP and UDP) and Layer 7 (HTTP and HTTPS) listeners. The following table lists the features and use cases of these listeners.

Protocol	Feature	Use case
TCP	• A connection-oriented protocol. A logical connection must be established before data can be sent and received. • Source IP address-based session persistence. • Source IP addresses readable at the network layer. • Fast data transmission	• Applicable to scenarios that require high reliability and data accuracy but can tolerate low speeds, such as file transmission, sending or receiving emails, and remote logons. • Web applications that do not have special requirements. For more information, see Add a TCP listener.
UDP	• A connectionless protocol. UDP transmits data packets directly instead of making a three-way handshake with the other party before UDP sends data. UDP does not provide error recovery or data re-transmission. • Fast data transmission but relatively low reliability.	Applicable to scenarios where real-time transmission is more important than reliability, such as video chats and real-time financial market pushes. For more information, see Add a UDP listener.
HTTP	• An application-layer protocol that is used to package data. • Cookie-based session persistence. • Use X-Forward-For to obtain source IP addresses.	Applicable to scenarios that require data content to be identified, such as web applications and small mobile games. For more information, see Add an HTTP listener.
HTTPS	• Encrypted data transmission that prevents unauthorized access. • Centralized certificate management service. You can upload certificates to SLB. The decryption operations are directly completed on SLB.	Applicable to scenarios that require encrypted transmission. For more information, see Add an HTTPS listener.

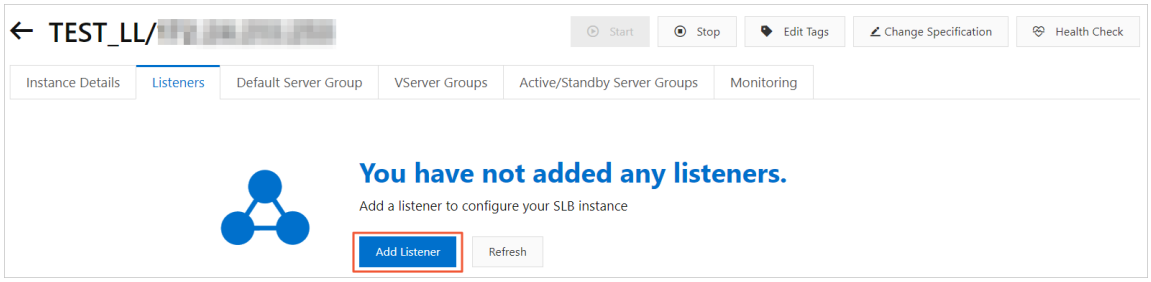
20.1.5.2. Add a TCP listener

This topic describes how to add a TCP listener to an SLB instance. TCP provides reliable and accurate data delivery at relatively low connection speeds and therefore is applicable to services such as file transmission, email sending or receiving, and remote logon. You can add a TCP listener to forward TCP requests.

Step 1: Start the listener configuration wizard

To start the listener configuration wizard, perform the following operations:

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Instances**.
3. Use one of the following methods to start the listener configuration wizard:
   - On the **Instances** page, find the SLB instance to which you want to add a TCP listener and then click **Configure Listener** in the Actions column.
   - On the **Instances** page, click the ID of the SLB instance. On the **Listener** tab, click **Add Listener**.



Step 2: Configure the TCP listener

To configure the TCP listener, perform the following operations:

1. Configure the following parameters.

Parameter	Description
Select Listener Protocol	Select the protocol of the listener. In this example, select **TCP**.
Listening Port	Set the listening port used to receive requests and forward them to backend servers. Valid values: 1 to 65535.
Advanced	
Scheduling Algorithm	SLB supports the following scheduling algorithms: RR, WRR, WLC. ○ **Weighted Round-Robin (WRR)**: Backend servers with a higher weight receive more requests than those with a lower weight. ○ **Round-Robin (RR)**: Requests are sequentially distributed to backend servers. ○ **Weighted Least Connections (WLC)**: Requests are distributed based on the combination of the weights and active connections of backend servers. If two backend servers have the same weight, requests are forwarded to the backend server with fewer connections.
Enable Session Persistence	Specify whether to enable session persistence. After session persistence is enabled, the listener forwards all requests from the same client to a specific backend server for the duration of a session. For TCP listeners, session persistence is implemented based on IP addresses. Requests from the same IP address are forwarded to the same backend server.
Enable Connection Draining	When connection draining is enabled, connections to the backend server that was removed or that is unhealthy are kept alive. **Note** The connection draining feature can be enabled only in the Australia (Sydney) and the UK (London) regions.

Parameter	Description
Connection Draining Timeout	After you enable connection draining, you can specify the maximum timeout period to keep connections alive before a backend server is removed from an SLB server group. After the backend server is removed or remains unhealthy for the specified period of time, SLB forcefully closes the connections to the server. Value values: 10 to 900. Unit: seconds.
Enable Peak Bandwidth Limit	Specify whether to set the bandwidth limit for the listener. If an SLB instance incurs fees based on the bandwidth, you can set different peak bandwidth values for different listeners to limit the amount of traffic that flows in each listener. The sum of the peak bandwidth values of all listeners added to an SLB instance cannot exceed the bandwidth of this SLB instance. By default, this feature is disabled and all listeners share the bandwidth of the SLB instance.
Idle Timeout	Specify the idle timeout period of TCP connections. Unit: seconds. Valid values: 10 to 900.
Obtain Client Source IP Address	For Layer 4 listeners, backend servers can directly obtain the actual IP addresses of clients.
Automatically Enable Listener After Creation	Specify whether to start the listener immediately after the listener is configured. By default, the listener is started after configuration.

2. Click **Next**.

Step 3: Add backend servers

After you configure the listener, you must add backend servers to process client requests. You can add backend servers to the default server group, or create VServer groups or primary/secondary server groups and then add servers to them. For more information, see Backend server overview.

The default server group is used in the example.

1. Select **Default Server Group** and click **Add More**.
2. On the **My Servers** panel, select ECS instances as the backend servers that you want to add and click **Next**.
3. In the **Configure Ports and Weights** step, configure weights for the added backend servers. A backend server that has a higher weight receives more requests.

   > **Note** If the weight of a backend server is set to 0, the backend server does not receive new requests.

4. Click **Add**. On the Default Server Group tab, configure ports for the backend servers. Valid values: 1 to 65535.

   You can specify the same port for multiple backend servers of an SLB instance.

5. Click **Next**.

Step 4: Configure health checks

SLB checks the availability of backend servers by performing health checks. The health check feature improves the overall availability of frontend services and avoid impacts on the service caused by exceptions of backend servers. Click **Modify** to configure advanced health check settings and click Next. For more information, see Health check overview.

Step 5: Submit the configurations

Perform the following operations to submit the configurations:

1. In the **Confirm** step, check the configurations. You can click **Modify** to modify the configurations.
2. Click **Submit**.
3. In the **Configuration Successful** message, click **OK**.

   You can check the created listener on the Listener tab.

20.1.5.3. Add a UDP listener

This topic describes how to add a UDP listener to an SLB instance. UDP is applicable to services that prioritize real-time content delivery over reliability, such as video chats and real-time quotes. You can add a UDP listener to forward UDP requests.

Context

Before you configure a UDP listener, take note of the following items:

- Ports 250, 4789, and 4790 of a UDP listener are reserved and therefore are unavailable for your configuration.
- Fragmented packets are not supported.
- The UDP listeners of an SLB instance in the classic network do not allow you to view source IP addresses.
- The following operations take five minutes to take effect if they are performed for a UDP listener:
  - Remove backend servers
  - Set the weight of a backend server to 0 after it is detected unhealthy

Step 1: Configure the UDP listener

To configure the UDP listener, perform the following operations:

1. In the **Protocol and Listener** step, configure the following parameters.

Parameter	Description
Select Listener Protocol	Select the protocol of the listener. In this example, select **UDP**.
Listening Port	Set the listening port that is used to receive requests and forward them to backend servers. Valid values: 1 to 65535.
Advanced	
Scheduling Algorithm	SLB supports three scheduling algorithms: RR and WRR. ○ **Weighted Round-Robin (WRR)**: Backend servers with a higher weight receive more requests than those with a lower weight. ○ **Round-Robin (RR)**: Requests are sequentially distributed to backend servers.

Parameter	Description
Enable Peak Bandwidth Limit	You can switch on this option and then set a bandwidth limit for the listener. If an SLB instance incurs fees based on the bandwidth, you can set different peak bandwidth values for different listeners to limit the amount of traffic that flows in each listener. The sum of the peak bandwidth values of all listeners added to an SLB instance cannot exceed the bandwidth of this SLB instance. By default, this feature is disabled and all listeners share the bandwidth of the SLB instance.
Obtain Client Source IP Address	Backend servers of a UDP listener can directly obtain the actual IP addresses of clients. **Note** UDP listeners of an SLB instance in the classic network do not allow you to view source IP addresses.
Automatically Enable Listener After Creation	Specify whether to start the listener after the listener is configured. By default, the listener is started after configuration.

2. Click **Next**.

Step 2: Add backend servers

After you configure the listener, you must add backend servers to process client requests. You can add backend servers to the default server group, or create VServer groups or primary/secondary server groups and then add servers to them. For more information, see Backend server overview.

Backend servers are added to the default server group in this example.

1. Select **Default Server Group** and click **Add More**.
2. Select ECS instances (backend servers) that you want to add, and then click **Next**.
3. Configure weights for the added backend servers.

   A backend server with a higher weight receives more requests.

   Note If the weight of a backend server is set to 0, the backend server does not receive new requests.

4. Click **Add**. On the **Default Server Group** tab, configure ports for the backend servers.

   Set a port for each backend server to receive requests. Valid values: 1 to 65535. You can specify the same port for multiple backend servers of an SLB instance.

5. Click **Next**.

Step 3: Configure health checks

CLB performs health checks to check the availability of the ECS instances that serve as backend servers. The health check feature improves overall service availability and reduces the impact of backend server failures.

On the **Health Check** wizard page, click **Modify** to modify the health check configurations. For more information, see Configure health checks.

Step 4: Submit the configurations

1. On the **Confirm** wizard page, check the configurations. You can click **Modify** to modify the configurations.
2. After you confirm the configurations, click **Submit**.
3. When Configuration Successful appears, click **OK**.

   After you configure the listener, you can view the listener on the Listener tab.

20.1.5.4. Add an HTTP listener

This topic describes how to add an HTTP listener to a Server Load Balancer (SLB) instance. HTTP is applicable to applications that need to identify data from different users, such as web applications and mini mobile games. You can add an HTTP listener to forward HTTP requests.

Step 2: Configure an HTTP listener

To configure an HTTP listener, perform the following operations:

1. On the **Protocol and Listener** wizard page, set the following parameters.

Parameter	Description
Select Listener Protocol	Select a protocol for the listener. **HTTP** is selected in this example.
Listening Port	Specify the listening port that is used to receive requests and forward them to backend servers. Valid values: 1 to 65535. **Note** You must not specify the same listening port for listeners that are associated with the same SLB instance.
Advanced	
Scheduling Algorithm	SLB supports three scheduling algorithms: round robin (RR) and weighted round robin (WRR). ○ **Weighted Round-Robin (WRR)**: Backend servers with higher weights receive more requests. ○ **Round-Robin (RR)**: Requests are sequentially distributed to backend servers.
Redirection	Specify whether to redirect traffic from the HTTP listener to an HTTPS listener. **Note** Before you enable redirection, make sure that you have created an HTTPS listener.

Parameter	Description
Enable Session Persistence	Specify whether to enable session persistence. After session persistence is enabled, SLB forwards all requests from a client to the same backend server. SLB maintains the persistence of HTTP sessions based on cookies. SLB allows you to use the following methods to process cookies: ◦ **Insert cookie**: You only need to specify the timeout period of the cookie. SLB inserts a cookie (SERVERID) into the first HTTP or HTTPS response packet that is sent to a client. The next request from the client contains this cookie and the listener distributes this request to the recorded backend server. ◦ **Rewrite cookie**: You can specify the cookie to be inserted into an HTTP or HTTPS response. You must specify the timeout period and lifecycle of this cookie on the backend server. After you specify a cookie, SLB overwrites the original cookie with the specified cookie. The next time SLB receives a client request that carries the specified cookie, the listener distributes the request to the recorded backend server.
Enable Peak Bandwidth Limit	Specify whether to enable bandwidth capping for the listener. If an SLB instance is billed based on bandwidth, you can set different maximum bandwidth values for different listeners to limit the amount of traffic that flows through each listener. The sum of the maximum bandwidth values of all listeners that are added to an SLB instance cannot exceed the bandwidth of the SLB instance. By default, this feature is disabled and all listeners share the bandwidth of the SLB instance.
Idle Timeout	Specify the timeout period of idle connections. Unit: seconds. Valid values: 1 to 60. If no request is received within the timeout period, SLB closes the connection. SLB recreates the connection after it receives a new connection request. This feature is available in all regions. **Note** This feature is unavailable for HTTP/2 requests.
Request Timeout	Specify the request timeout period. Unit: seconds. Valid values: 1 to 180. If no response is received from the backend server within the request timeout period, SLB returns an HTTP 504 error to the client. This feature is available in all regions.
Enable Gzip Compression	Specify whether to enable compression for a specified file type. Gzip supports the following file types: text/xml, text/plain, text/css, application/javascript, application/x-javascript, application/rss+xml, application/atom+xml, and application/xml.

Parameter	Description
Add HTTP Header Fields	You can add the following HTTP header fields: ○ Use the `X-Forwarded-For` header field to retrieve the IP addresses of clients. ○ Use the `X-Forwarded-Proto` header field to retrieve the listener protocol used by the SLB instance. ○ Use the `SLB-IP` header field to retrieve the public IP address of the SLB instance. ○ Use the `SLB-ID` header field to retrieve the ID of the SLB instance.
Obtain Client Source IP Address	HTTP listeners use the X-Forwarded-For header field to obtain the real IP addresses of clients.
Automatically Enable Listener After Creation	Specify whether to immediately enable the listener after the listener is created. By default, the listener is enabled after it is created.

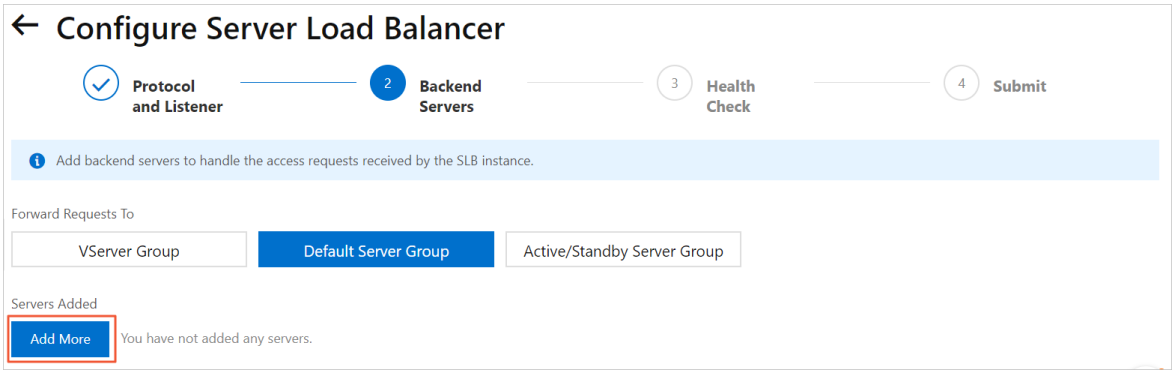
2. Click **Next**.

Step 3: Add backend servers

After you configure the listener, you must add backend servers to process client requests. You can use the default server group that is configured for the SLB instance, or create a vServer group or a primary/secondary server group. For more information, see Backend server overview.

Backend servers are added to the default server group in this example.

1. Select **Default Server Group** and click **Add More**.



2. In the **My Servers** panel, select the Elastic Compute Service (ECS) instances that you want to add as backend servers and click **Next**.
3. On the **Configure Ports and Weights** wizard page, specify the weights of the backend servers that you want to add. A backend server with a higher weight receives more requests.

> **Note** If the weight of a backend server is set to 0, no request is distributed to the backend server.

4. Click **Add**. On the Default Server Group tab, specify the ports that you want to open on the backend servers (ECS instances) to receive requests. Valid values: 1 to 65535.

   You can specify the same port on different backend servers that are connected to an SLB instance.
5. Click **Next**.

Step 3: Configure health checks

CLB performs health checks to check the availability of the ECS instances that serve as backend servers. The health check feature improves overall service availability and reduces the impact of backend server failures.

On the **Health Check** wizard page, click **Modify** to modify the health check configurations. For more information, see Configure health checks.

Step 4: Submit the configurations

1. On the **Confirm** wizard page, check the configurations. You can click **Modify** to modify the configurations.
2. After you confirm the configurations, click **Submit**.
3. When Configuration Successful appears, click **OK**.

   After you configure the listener, you can view the listener on the Listener tab.

20.1.5.5. Add an HTTPS listener

This topic describes how to add an HTTPS listener to a Server Load Balancer (SLB) instance. HTTPS is intended for applications that require encrypted data transmission. You can add an HTTPS listener to forward HTTPS requests.

Step 1: Configure a TCP listener

1.
2. Use one of the following methods to open the listener configuration wizard:
   - On the **Instances** page, find the CLB instance and click **Configure Listener** in the **Actions** column.
   - On the **Instances** page, find the CLB instance that you want to manage and click the ID of the instance. On the **Listener** tab, click **Add Listener**.
3. Set the following parameters and click **Next**.

Parameter	Description
Select Listener Protocol	Select **TCP**.
Listening Port	Set the listening port that is used to receive requests and forward them to backend servers. Valid values: 1 to 65535. You can set a TCP or UDP listener to listen on all ports within a specified port range.
Listener Name	Specify a name for the listener.
Advanced	Click **Modify** to configure advanced settings.

Parameter	Description
Scheduling Algorithm	Select a scheduling algorithm. ○ **Weighted Round-Robin (WRR)**: Backend servers that have higher weights receive more requests than backend servers that have lower weights. ○ **Round-Robin (RR)**: Requests are distributed to backend servers in sequence. ○ **Consistent Hash (CH)**: ■ **Tuple**: specifies consistent hashing that is based on four factors: source IP address, destination IP address, source port, and destination port. Requests that contain the same information based on the four factors are distributed to the same backend server. ■ **Source IP**: specifies consistent hashing that is based on source IP addresses. Requests from the same source IP address are distributed to the same backend server. **Note** Only high-performance CLB instances support the CH algorithm.
Enable Session Persistence	Specify whether to enable session persistence. After session persistence is enabled, CLB forwards all requests from a client to the same backend server. For TCP listeners, session persistence is implemented based on IP addresses. Requests from the same IP address are forwarded to the same backend server.
Enable Peak Bandwidth Limit	Specify whether to set the bandwidth limit of the listener. If a CLB instance is billed based on bandwidth usage, you can set different maximum bandwidth values for different listeners. This limits the amount of traffic that flows through each listener. The sum of the maximum bandwidth values of all listeners that are added to a CLB instance cannot exceed the maximum bandwidth value of the CLB instance. By default, this feature is disabled and all listeners share the bandwidth of the CLB instance.
Idle Timeout	Specify the timeout period of idle TCP connections. Unit: seconds. Valid values: 10 to 900.
Proxy Protocol	Use the proxy protocol to pass client IP addresses to backend servers. **Note** You cannot enable this feature in scenarios where PrivateLink is used.
Obtain Client Source IP Address	Specify whether to retrieve the real IP addresses of clients. Only Layer 4 listeners support this feature. By default, this feature is enabled.
Automatically Enable Listener After Creation	Specify whether to immediately enable the listener after it is created. By default, listeners are enabled after they are created.

Step 2: Configure an HTTPS listener

To configure an HTTPS listener, perform the following operations:

1. On the **Protocol and Listener** wizard page, set the following parameters.

Parameter	Description
Select Listener Protocol	Select a protocol for the listener. **HTTPS** is selected in this example.
Listening Port	Specify the listening port that is used to receive requests and forward them to backend servers. Valid values: 1 to 65535. **Note** You must not specify the same listening port for listeners that are associated with the same SLB instance.
Advanced	
Scheduling Algorithm	SLB supports three scheduling algorithms: round robin (RR), weighted round robin (WRR), and weighted least connections (WLC). ○ **Weighted Round-Robin (WRR)**: Backend servers with higher weights receive more requests. ○ **Round-Robin (RR)**: Requests are sequentially distributed to backend servers. ○ **Weighted Least Connections (WLC)**: Requests are distributed based on the weights and active connections of backend servers. Requests are distributed to the backend server with the least number of active connections. If two backend servers have the same number of active connections, the backend server with a higher weight receives more requests.
Enable Session Persistence	Specify whether to enable session persistence. After session persistence is enabled, SLB forwards all requests from a client to the same backend server. The timeout period for session persistence is 1 to 86,400 seconds. SLB maintains the persistence of HTTP sessions based on cookies. SLB allows you to use the following methods to process cookies: ○ **Insert cookie**: If you select this option, you only need to specify the timeout period of the cookie. SLB inserts a cookie (SERVERID) into the first HTTP or HTTPS response packet that is sent to a client. The next request from the client contains this cookie and the listener distributes this request to the recorded backend server. ○ **Rewrite cookie**: If you select this option, you can specify the cookie to be inserted into an HTTP or HTTPS response. You must specify the timeout period and lifecycle of the cookie on the backend server. After you specify a cookie, SLB overwrites the original cookie with the specified cookie. The next time SLB receives a client request that carries the specified cookie, the listener distributes the request to the recorded backend server.
Enable HTTP/2	Specify whether to enable HTTP/2.

Parameter	Description
Enable Peak Bandwidth Limit	Specify whether to enable bandwidth capping for the listener. If an SLB instance is billed based on bandwidth, you can set different maximum bandwidth values for different listeners to limit the amount of traffic that flows through each listener. The sum of the maximum bandwidth values of all listeners that are added to an SLB instance cannot exceed the bandwidth of this SLB instance. By default, this feature is disabled and all listeners share the bandwidth of the SLB instance.
Idle Timeout	Specify the timeout period of idle connections. Unit: seconds. Valid values: 1 to 60. If no request is received within the timeout period, SLB closes the connection. SLB recreates the connection after it receives a new connection request. This feature is available in all regions.
Request Timeout	Specify the request timeout period. Unit: seconds. Valid values: 1 to 180. If no response is received from the backend server within the request timeout period, SLB returns an HTTP 504 error to the client. This feature is available in all regions.
Enable Gzip Compression	Specify whether to enable Gzip compression for a specified file type. Gzip supports the following file types: text/xml, text/plain, text/css, application/javascript, application/x-javascript, application/rss+xml, application/atom+xml, and application/xml.
Add HTTP Header Fields	You can add the following HTTP header fields: ◦ Use the `X-Forwarded-For` header field to retrieve the IP addresses of clients. ◦ Use the `X-Forwarded-Proto` header field to retrieve the listener protocol used by the SLB instance. ◦ Use the `SLB-IP` header field to retrieve the public IP address of the SLB instance. ◦ Use the `SLB-ID` header field to retrieve the ID of the SLB instance.
Obtain Client Source IP Address	HTTP listeners use the X-Forwarded-For header field to retrieve the IP addresses of clients.
Automatically Enable Listener After Creation	Specify whether to immediately enable the listener after the listener is created. By default, the listener is enabled after it is created.

2. Click **Next**.

Step 3: Configure an SSL certificate

When you add an HTTPS listener, you must upload a server certificate or CA certificate, as shown in the following table.

Notice SLB supports the following public key algorithms:

- RSA 1024
- RSA 2048
- RSA 4096
- ECDSA P-256
- ECDSA P-384
- ECDSA P-521

Certificate	Description	Required for one-way authentication	Required for mutual authentication
Server certificate	The certificate that is used to identify the server. Your browser uses the server certificate to verify whether the certificate sent by the server is signed and issued by a trusted certification authority (CA).	Yes. You must upload the server certificate to the certificate management system of SLB.	Yes. You must upload the server certificate to the certificate management system of SLB.
Client certificate	The certificate that is used to identify the client. The server identifies the client by checking the certificate sent by the client. You can sign a client certificate with a self-signed CA certificate.	No.	Yes. You must install the client certificate on the client.
CA certificate	The server uses a CA certificate to verify the signature on the client certificate. If the signature is invalid, the connection request is denied.	No.	Yes. You must upload the CA certificate to the certificate management system of SLB.

Before you upload a certificate, take note of the following items:

- The certificate that you want to upload must be in the PEM format.
- After you upload a certificate to SLB, SLB can manage the certificate and you do not need to bind the certificate to backend servers.
- Time is needed to upload, load, and verify the certificate. Therefore, an HTTPS listener is not enabled immediately after it is created. It takes one to three minutes to enable an HTTPS listener.
- The ECDHE cipher suite used by HTTPS listeners supports forward secrecy. It does not support the security enhancement parameters that are required by the DHE cipher suite. Therefore, you cannot upload certificates (PEM files) that contain the `BEGIN DH PARAMETERS` field. For more information, see Certificate requirements.
- HTTPS listeners do not support Server Name Indication (SNI). You can choose TCP listeners and configure SNI on backend servers.
- The session ticket timeout period of HTTPS listeners is 300 seconds.
- The actual amount of data transfer on an HTTPS listener is larger than the billed amount because a portion of data is used for handshaking.
- The amount of data used for handshaking is large when a great number of connections are established.

The following section describes how to configure an SSL certificate. The international standard certificate and national standard certificate are taken as examples.

1. On the **SSL Certificates** wizard page, click **Switch Certificate Type** next to **International Standard Certificate Configuration**, select **International and National Standard Certificates**, and then click **OK**.
2. Select an uploaded server certificate from the **Select Server Certificate** drop-down list, a national standard encryption certificate from the **Select Server Encryption Certificate (National Standard Certificate)** drop-down list, and a national standard signature certificate from the **Select Server Signature Certificate (National Standard Certificate)** drop-down list. You can also click **Create Server Certificate** to upload a server certificate, national standard encryption certificate, and signature certificate.

   For more information, see Upload certificates.
3. To enable HTTPS mutual authentication, click **Modify** next to **Advanced**.
4. Turn on **Enable Mutual Authentication** and select an uploaded CA certificate, or click **Create CA Certificate** and upload a CA certificate.

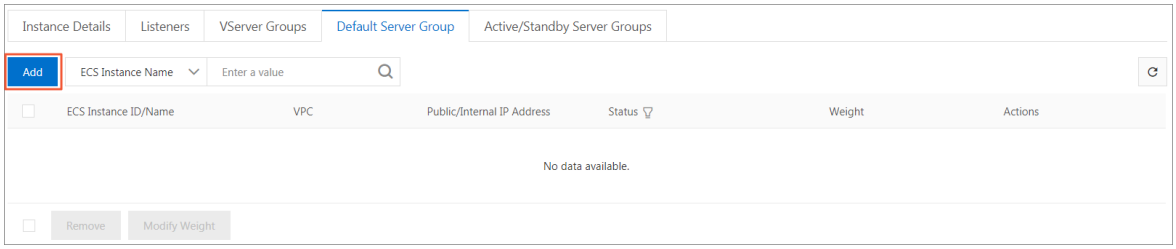
   You can use a self-signed CA certificate. For more information, see Overview.

Step 4: Add backend servers

After you configure the listener, you must add backend servers to process client requests. You can use the default server group that is configured for the SLB instance, or create a vServer group or a primary/secondary server group. For more information, see Backend server overview.

Backend servers are added to the default server group in this example.

1. Log on to the SLB console.
2. Find the SLB instance and click its instance ID.
3. Click the **Default Server Group** tab.
4. Click **Add**.



5. In the **My Servers** panel, select the Elastic Compute Service (ECS) instances that you want to add.
6. Click **Next**.
7. On the **Configure Ports and Weights** wizard page, specify the weight of each ECS instance.

   An ECS instance with a higher weight receives more requests.

   You can change the weight of a server and then move the pointer over  to change the weights of other servers:

   - Click **Replicate to Below**: The weights of all servers below the current server are set to the weight of the current server.
   - Click **Replicate to Above**: The weights of all servers above the current server are set to the weight of the current server.
   - Click **Replicate to All**: The weights of all servers in the default server group are set to the weight of the current server.
   - Click **Reset**: When you clear the weight of the current server, the weights of all servers in the default server group are cleared.

   > **Notice** After you set the weight of a server to 0, no request is distributed to the server.

8. Click **Add**.
9. Click **OK**.

Step 5: Configure health checks

CLB performs health checks to check the availability of the ECS instances that serve as backend servers. The health check feature improves overall service availability and reduces the impact of backend server failures.

Step 6: Confirm the configurations

To submit the configurations, perform the following operations:

1. On the **Confirm** wizard page, check the configurations. You can click **Modify** to modify the configurations.
2. After you confirm the configurations, click **Submit**.
3. When Configuration Successful appears, click **OK**.

   After you configure the listener, you can view the listener on the Listener tab.

20.1.5.6. Configure forwarding rules

This topic describes how to configure forwarding rules for a Server Load Balancer (SLB) instance. You can configure domain name-based or URL-based forwarding rules for an SLB instance that uses Layer 7 listeners. Layer 7 listeners distribute requests destined for different domain names or URLs to different Elastic Compute Service (ECS) instances.

Context

You can add multiple forwarding rules for a listener. Each forwarding rule is associated with a unique server group. Each server group contains multiple ECS instances. For example, you can configure a listener to forward read requests to one server group and write requests to another server group. This allows you to optimize load balancing among your server resources.

SLB forwards requests based on the following rules:

- If a request matches a domain name-based or URL-based forwarding rule of a listener, the request is forward to the corresponding server group based on the forwarding rule.
- If a request does not match any domain name-based or URL-based forwarding rules of a listener but the listener is associated with a server group, the request is forwarded to the server group.
- If none of the preceding conditions are met, requests are forwarded to backend ECS instances of the SLB instance based on the listener configuration.

Procedure

1. Log on to the SLB console.
2. Find the SLB instance that you want to manage and click the instance ID.
3. On the page that appears, click the **Listener** tab.
4. On the **Listeners** tab, find the listener that you want to manage.

   You can configure domain name-based or URL-based forwarding rules only for HTTP and HTTPS listeners.
5. In the **Actions** column, click the icon and select **Set Forwarding Rule** from the shortcut menu.
6. In the **Add Forwarding Rules** panel, click **Add Forwarding Rules**.
7. Configure forwarding rules based on the following information:
   - Configure a domain name-based forwarding rule
     - When you configure a domain name-based forwarding rule, leave the URL field empty. You do not need to enter a forward slash (/) in this field. The domain name can contain only letters, digits, hyphens (-), and periods (.).

- Domain-based forwarding rules support both exact match and wildcard match. For example, www.aliyun.com is an exact domain name while *.aliyun.com and *.market.aliyun.com are wildcard domain names. When a request matches multiple domain name-based forwarding rules, an exact match prevails over wildcard matches, as described in the following table. Domain name matching rule

Mode	Request URL	Domain name matching rule (√ indicates that the domain name is matched whereas x indicates that the domain name is not matched.)		
		www.aliyun.com	*.aliyun.com	*.market.aliyun.com
Exact match	www.aliyun.com	√	x	x
Wildcard match	market.aliyun.com	x	x	x
	info.market.aliyun.com	x	x	√

- Configure a URL-based forwarding rule
  - When you configure a URL-based forwarding rule, leave the Domain Name field empty.
  - The URL can contain only letters, digits, and hyphens `(-). /%? #&`
  - The URL must start with a forward slash (/).

    > **Note** If you enter only a forward slash (/) in the URL field, the URL-based forwarding rule is invalid.

  - URL-based forwarding rules support string matching and adopt sequential matching. Examples: `/admin`, `/bbs_`, and `/ino_test`.
- Configure both domain name-based and URL-based forwarding rules

  You can configure both domain name-based and URL-based forwarding rules when you need to forward traffic destined for different URLs of the same domain name. We recommend that you configure a default forwarding rule with the URL field left empty in case errors are returned when the URLs of requests are not matched.

  For example, the domain name of a website is `www.aaa.com`. You are required to forward requests destined for `www.aaa.com/index.html` to server group 1 and forward requests destined for other URLs of the domain name to server group 2. To meet the preceding requirements, you must configure two forwarding rules, as shown in the following figure. Otherwise, a 404 error code is returned when a request destined for the `www.aaa.com` domain name does not match any forwarding rules.

8. Click **Save**.

20.1.5.7. Enable access control

This topic describes how to enable access control for a listener. SLB provides listener-based access control. You can configure different whitelists for different listeners.

Procedure

1. Log on to the SLB console.
2. Find an SLB instance and click its instance ID.
3. On the page that appears, click the **Listener** tab.

4. Find the listener for which you want to enable access control, and choose > Set

Access Control in the Actions column.

5. In the **Access Control Settings** panel, turn on Enable Access Control and specify an ACL as a whitelist, and then click **OK**.

   Whitelist: Only the requests from the IP addresses or CIDR blocks in the specified ACL are forwarded. You can use the whitelist feature when you want to allow access from specified IP addresses.

   Risks may arise if you specify an ACL as a whitelist. After a whitelist is enabled, only IP addresses contained in the whitelist can access the SLB listener. If a whitelist is enabled without any IP addresses specified, the SLB listener forwards all requests.

   Separate multiple IP addresses with commas (,). Each IP address must be unique. You can add a maximum of 300 IP addresses.

   - IP addresses such as 10.23.12.24 and CIDR blocks such as 10.23.12.0/24 are supported.
   - 0.0.0.0 and x.x.x.x/0 are not supported.

   > **Note** The access control feature works only for new connection requests and does not affect existing connections.

20.1.5.8. Disable access control

This topic describes how to disable access control for a listener.

Procedure

1. Log on to the SLB console.
2. Find an SLB instance and click its instance ID.
3. Click the **Listener** tab next to the **Instance Details** tab.
4. Find the listener for which you want to disable access control, and choose > **Set Access Control** in the Actions column.
5. In the **Access Control Settings** panel, disable access control and then click **OK**.

20.1.6. Backend servers

20.1.6.1. Backend server overview

Before you use the Server Load Balancer (SLB) service, you must add Elastic Compute Service (ECS) instances as backend servers to an SLB instance to process client requests.

Backend server overview

You can set virtual IP addresses for an SLB instance. This way, the added ECS instances in the same region can be virtualized into an application service pool that provides high performance and availability. You can manage backend servers by using vServer groups. A listener of an SLB instance can be associated with a specific vServer group so that different listeners can forward requests to their associated backend servers that use different ports.

> **Note** If you associate a vServer group with a listener, the listener distributes requests to backend servers in the associated vServer group instead of those in the default server group.

Limits

You can increase or decrease the number of backend ECS instances at any time and switch ECS instances to receive client requests. When you perform the operations, make sure that the health check feature is enabled and at least one ECS instance is running as expected to maintain service stability.

When you add backend ECS instances, take note of the following items:

- You can add ECS instances of different operating systems to an SLB instance. However, the applications deployed on the ECS instances must be the same and have consistent data. We recommend that you use ECS instances of the same operating system to facilitate management and maintenance.
- Up to 50 listeners can be added to a single SLB instance. Each listener corresponds to an application deployed on backend ECS instances. Listening ports of an SLB instance correspond to application service ports that are opened on backend ECS instances.
- You can specify a weight for each ECS instance in the application service pool. An ECS instance with a higher weight receives more requests.
- If session persistence is enabled, requests may not be evenly distributed to backend ECS instances. To solve this problem, we recommend that you disable session persistence and check whether the problem persists.

  If requests are not evenly distributed, troubleshoot the issue in the following way:

  i. Collect statistics on the access logs of the web service on backend ECS instances for a specified period.
  ii. Check whether the numbers of access logs of backend ECS instances match SLB configurations. If session persistence is enabled, you must differentiate the access logs for the same IP address. If different weights are configured for backend ECS instances, you must check whether the percentage of access logs is normal based on the percentage of weights.
- When an ECS instance is undergoing hot migration, persistent connections to SLB may be interrupted. You can solve this problem by reestablishing the connections.

Default server groups

A default server group contains ECS instances that are used to receive requests. If a listener is not associated with a vServer group or a primary/secondary server group, the listener forwards requests to ECS instances in the default server group.

Before you use the SLB service, you must add at least one default backend server to receive client requests forwarded by SLB. For more information, see Add a default backend server.

vServer groups

You can use a vServer group if you want to distribute different requests to different backend servers or configure forwarding rules based on domain names and URLs. For more information, see Create a vServer group.

Primary/secondary server groups

A primary/secondary server group contains only two ECS instances. One ECS instance acts as the primary server and the other acts as the secondary server. Health checks are not performed on the secondary server. If the primary server is detected unhealthy, traffic is redirected to the secondary server. After the primary server recovers and is considered healthy, traffic is switched back to the primary server. For more information, see Create a primary/secondary server group.

> **Note** You can add primary/secondary server groups only for TCP and UDP listeners.

Related information

- Add a default backend server
- Create a vServer group
- Create a primary/secondary server group

20.1.6.2. Default server groups

20.1.6.2.1. Add ECS instances to the default server group

This topic describes how to add ECS instances as default backend servers to the default server group of an SLB instance. Before you use the SLB service, you must add at least one default backend server to receive client requests forwarded by SLB.

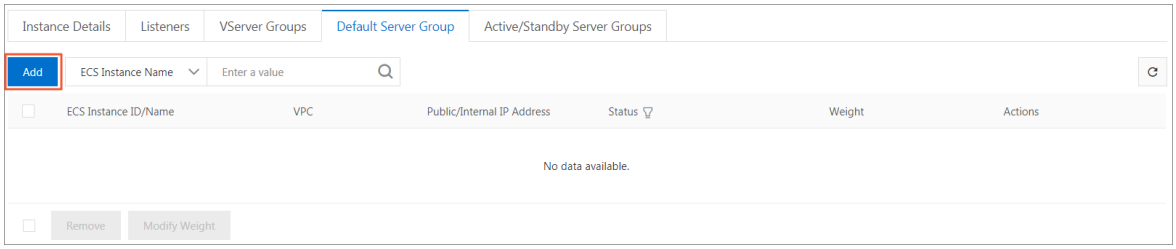
Prerequisites

Before you add ECS instances to the default server group, make sure that the following conditions are met:

- An SLB instance is created. For more information, see Create an SLB instance.
- You have created ECS instances and deployed applications on these ECS instances to process requests.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **Default Server Group** tab.
4. Click **Add**.



5. In the **My Servers** dialog box, select ECS instances that you want to add.
6. Click **Next**.
7. In the **Configure Ports and Weights** dialog box, specify the weight of each added ECS instance.

   An ECS instance with a higher weight receives more requests.

   You can change the weight of a server and then move the pointer over to change the weights of multiple servers:

   - Click **Replicate to Below**: The weights of all servers below the current server are set to the weight of the current server.
   - Click **Replicate to Above**: The weights of all servers above the current server are set to the weight of the current server.
   - Click **Replicate to All**: The weights of all servers in the default server group are set to the weight of the current server.
   - Click **Reset**: The weight fields of all servers in the default server group are cleared.

> **Notice** If the weight of a backend server is set to 0, this backend server no longer receives new requests.

8. Click **Add**.
9. Click **OK**.

20.1.6.2.2. Add IDC servers to the default server group

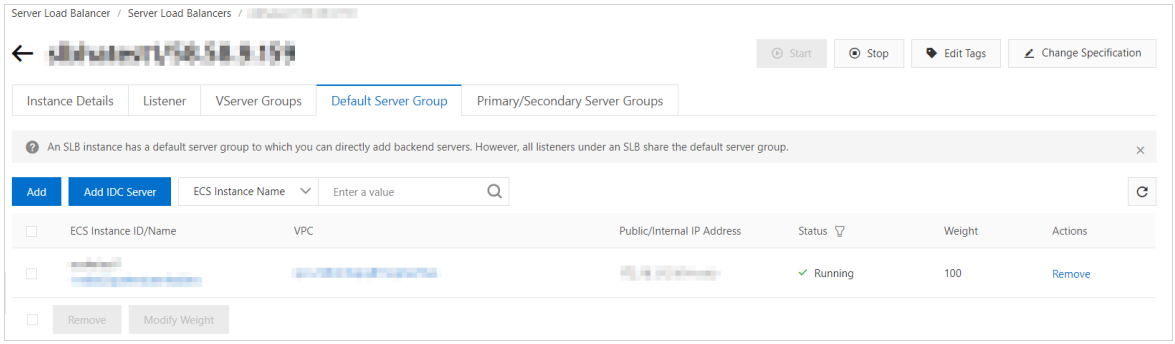
This topic describes how to add servers in on-premises Internet Data Centers (IDCs) as default backend servers to the default server group of an SLB instance. Before you use the SLB service, you must add at least one default backend server to receive client requests forwarded by SLB.

Prerequisites

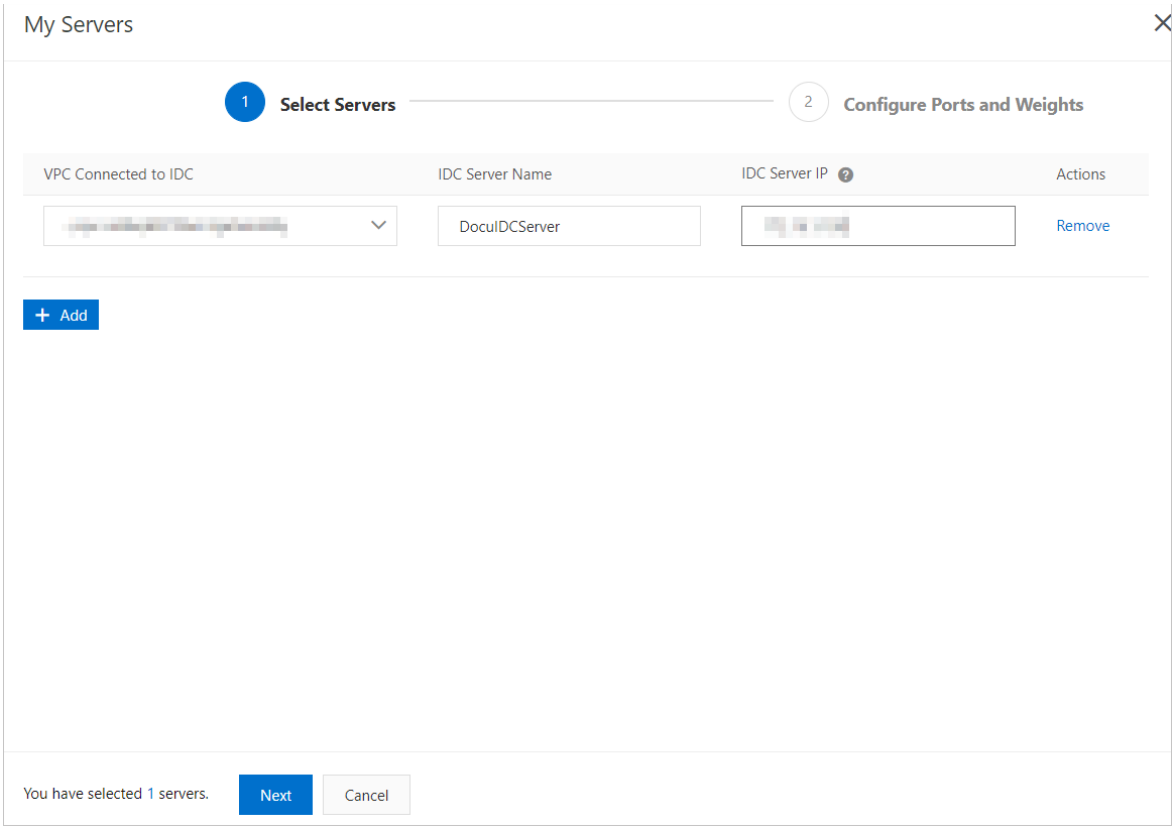
Applications are deployed on the IDC servers, and the IDC servers are ready to receive distributed requests.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **Default Server Group** tab.
4. Click **Add IDC Server**.



5. In the **My Servers** dialog box, click **Add**.
6. Select a VPC from the VPC Connected to IDC drop-down list, enter a name for the IDC server, and specify the IP address of the IDC server.



7. Click **Next**.
8. In the **Configure Ports and Weights** step, specify the weight of each added IDC server.

   An IDC server with a higher weight receives more requests.

   You can change the weight of a server and then move the pointer over to change the weights of multiple servers:

   - Click **Replicate to Below**: The weights of all servers below the current server are set to the weight of the current server.
   - Click **Replicate to Above**: The weights of all servers above the current server are set to the weight of the current server.
   - Click **Replicate to All**: The weights of all servers in the default server group are set to the weight of the current server.
   - Click **Reset**: The weight fields of all servers in the default server group are cleared.

   > **Notice** If the weight of a backend server is set to 0, this backend server no longer receives new requests.

9. Click **Add**.
10. Click **OK**.

20.1.6.2.3. Change the weight of a backend server

This topic describes how to change the weight of a backend server to adjust the proportion of requests sent to the backend server.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **Default Server Group** tab.
4. Move the pointer over the weight value of the target backend server and click the  icon.
5. Change the weight and then click **OK**.

   A backend server (ECS instance or IDC server) with a higher weight receives more requests.

   > **Notice** The weight value ranges from 0 to 100. If the weight of a backend server is set to 0, no requests are sent to the backend server.

20.1.6.2.4. Remove a backend server

This topic describes how to remove a backend server that is no longer needed.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **Default Server Group** tab.
4. Find the target backend server and click **Remove** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

20.1.6.3. VServer groups

20.1.6.3.1. Create a vServer group

This topic describes how to create a vServer group for a Server Load Balancer (SLB) instance. A vServer group contains Elastic Compute Service (ECS) instances that function as backend servers. If you associate a vServer group with a listener, the listener distributes requests only to backend servers in the vServer group.

Prerequisites

Before you create a vServer group, make sure that the following conditions are met:

- An SLB instance is created. For more information, see Create an SLB instance.
- ECS instances are created and applications are deployed on the ECS instances to process requests.

Context

Take note of the following items before you create a vServer group for an SLB instance:

- ECS instances are added to a vServer group and the corresponding SLB instance must be deployed in the same region.
- An ECS instance can be added to multiple vServer groups.
- A vServer group can be associated with multiple listeners of an SLB instance.
- A vServer group consists of ECS instances and application ports.

Procedure

1. Log on to the SLB console.
2. Find the SLB instance and click its instance ID.

3. Click the **VServer Groups** tab.
4. On the **VServer Groups** tab, click **Create VServer Group**.
5. On the **Create VServer Group** page, set the parameters.
   i. In the **VServer Group Name** field, enter a name for the vServer group.
   ii. Click **Add**. On the **My Servers** wizard page, select the ECS instances that you want to add.
   iii. Click **Next**.
   iv. Set the Port and Weight parameters for each ECS instance, and then click **Add**.

   Set the Port and Weight parameters based on the following information:

   - **Port**: The backend port opened on an ECS instance to receive requests.

     You can set the same port number for multiple backend servers of an SLB instance.
   - **Weight**: An ECS instance with a higher weight receives more requests.

     > **Notice** If the weight of an ECS instance is set to 0, the ECS instance no longer receives new requests.

   You can click  to specify the ports and weights of the added ECS instances in batches.

   - **Replicate to Below**: The ports or weights of all servers below the current server are set to the port or weight of the current server.
   - **Replicate to Above**: The ports or weights of all servers above the current server are set to the port or weight of the current server.
   - **Replicate to All**: The ports or weights of all servers in the vServer group are set to the port or weight of the current server.
   - **Reset**: If the port or weight of the current server is cleared, the ports or weights of all servers in the vServer group are also cleared.
6. Click **Create**.

20.1.6.3.2. Add IDC servers to a VServer group

This topic describes how to create a VServer group and then add IDC servers to the VServer group. You can add ECS instances and IDC servers as backend servers to a VServer group. If you associate a VServer group with a listener, the listener distributes requests only to the backend servers in the VServer group instead of other backend servers.

Prerequisites

Before you create a VServer group, make sure that applications are deployed on the IDC servers and the IDC servers are ready to receive distributed requests.

Context

Note the following items before you create a VServer group:

- An IDC server can be added to multiple VServer groups.
- A VServer group can be associated with multiple listeners of an SLB instance.
- The settings of the VServer group include the settings of IDC servers and application ports.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.

3. Click the **VServer Groups** tab.
4. On the **VServer Groups** tab, click **Create VServer Group**.
5. On the **Create VServer Group** page, configure the VServer group.
   i. In the **VServer Group Name** field, enter a name for the VServer group.
   ii. Click **Add IDC Server**.
   iii. In the **My Servers** dialog box, click **Add**.
   iv. Select a VPC from the VPC Connected to IDC drop-down list, enter a name for the IDC server, and specify the IP address of the IDC server.

   The IP address of the IDC server must be accessible to the VPC.
   v. Click **Next**.
   vi. Specify a port and weight for each IDC server, and then click **Add**.

   Set the ports and weights based on the following information:

   - **Port**: The backend port opened on an IDC server to receive requests. Multiple ports can be added to an IDC server.

     You can set the same port number for multiple backend servers of the same SLB instance.
   - **Weight**: An IDC server with a higher weight receives more requests.

     > **Notice** If the weight of an IDC server is set to 0, the IDC server no longer receives new requests.

   You can change the weight of a server and then move the pointer over  to change the weights of multiple servers:

   - Click **Replicate to Below**: The weights of all servers below the current server are set to the weight of the current server.
   - Click **Replicate to Above**: The weights of all servers above the current server are set to the weight of the current server.
   - Click **Replicate to All**: The weights of all servers in the VServer group are set to the weight of the current server.
   - Click **Reset**: The weight fields of all servers in the VServer group are cleared.

     > **Notice** If the weight of a backend server is set to 0, this backend server no longer receives new requests.

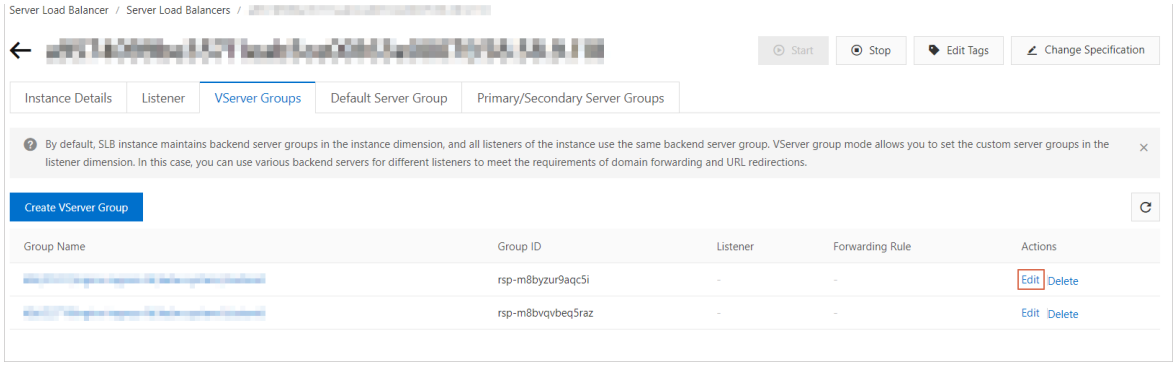
   vii. Click **Add**.
6. Click **Create**.

20.1.6.3.3. Modify a VServer group

This topic describes how to modify the settings of ECS instances or IDC servers in a VServer group.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **VServer Groups** tab.
4. Find the target VServer group and then click **Edit** in the Actions column.



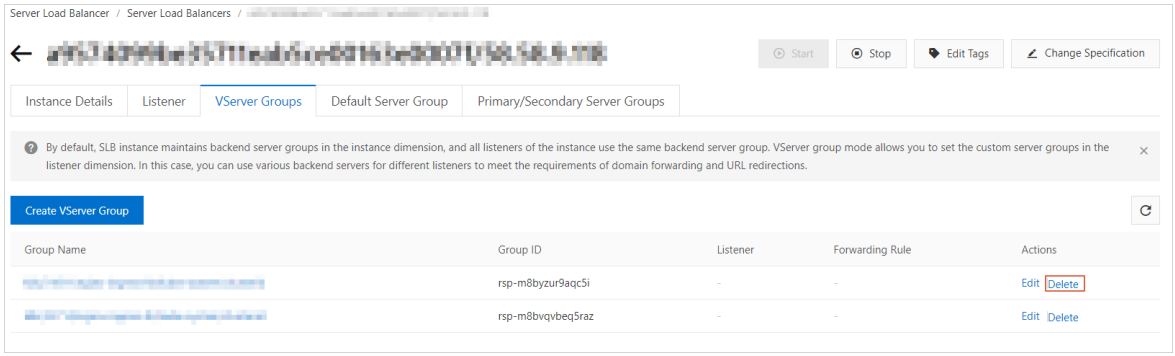
5. Modify the ports and weights of ECS instances or IDC servers, and then click **Save**.

20.1.6.3.4. Delete a VServer group

This topic describes how to delete a VServer group that is no longer needed for traffic distribution.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **VServer Groups** tab.
4. Find the target VServer group, and then click **Delete** in the Actions column.



5. In the dialog box that appears, click **OK**.

20.1.6.4. Active/standby server groups

20.1.6.4.1. Create a primary/secondary server group

This topic describes how to create a primary/secondary server group and then add Elastic Compute Service (ECS) instances to the primary/secondary server group. A primary/secondary server group contains a primary server and a secondary server that can fail over to prevent service interruption. By default, the primary server handles all requests that are distributed by the SLB instance. When the primary server fails, requests are redirected to the secondary server.

Prerequisites

Before you create a primary/secondary server group, make sure that the following requirements are met:

- A Server Load Balancer (SLB) instance is created. For more information, see Create an SLB instance.
- ECS instances are created and applications are deployed on the ECS instances to process requests.

> **Note** Only TCP and UDP listeners support primary/secondary server groups.

Procedure

1. Log on to the SLB console.
2. Find the SLB instance and click its instance ID.
3. Click the **Primary/Secondary Server Groups** tab.
4. On the **Primary/Secondary Server Groups** tab, click **Create Primary/Secondary Server Group**.
5. On the **Create Primary/Secondary Server Group** page, configure the primary/secondary server group.
   i. In the **Primary/Secondary Server Group Name** field, enter a name for the primary/secondary server group.
   ii. Click **Add**. In the **My Servers** panel, select the ECS instances that you want to add.

   You can add only two ECS instances to a primary/secondary server group.
   iii. Click **Next**.
   iv. On the **Configure Ports and Weights** wizard page, specify the backend ports that you want to open on the ECS instances to receive requests. If you want to open more than one port on an ECS instance, click **Add Port** in the **Actions** column.

   You can open the same port on different backend servers that are connected to the same SLB instance.
   v. Click **Add**.
6. On the **Create Primary/Secondary Server Group** page, select an ECS instance in the **Type** column as the primary server.
7. Click **Create**.

20.1.6.4.2. Add IDC servers to a primary/secondary server group

This topic describes how to create a primary/secondary server group and then add IDC servers to the primary/secondary server group. You can use a primary/secondary server group to implement failover between a primary server and a secondary server. By default, the primary server handles all distributed requests. When the primary server fails, traffic is redirected to the secondary server.

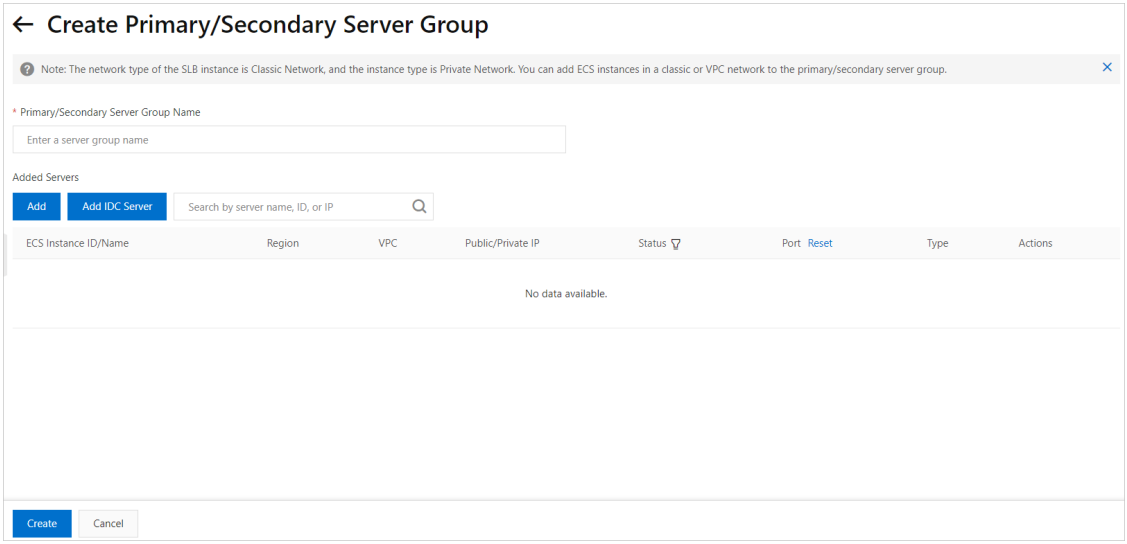
Prerequisites

The IDC servers are created, configured to deploy applications, and ready to receive distributed requests.

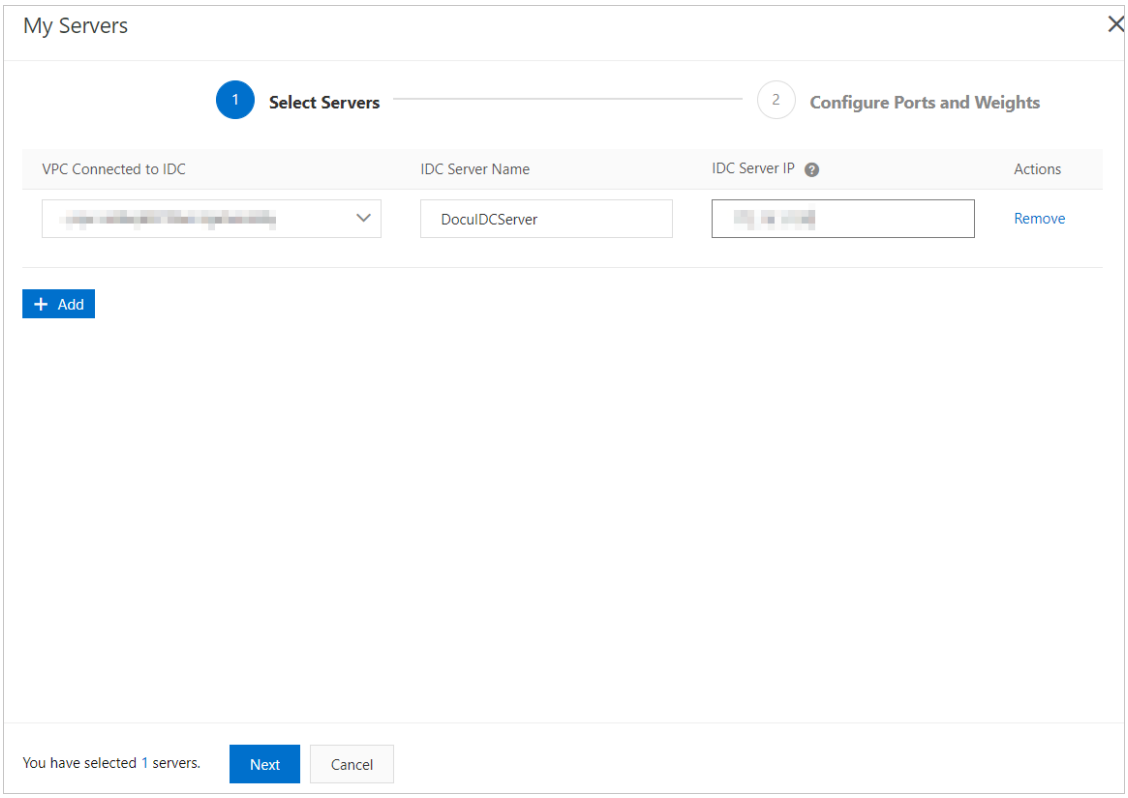
Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **Primary/Secondary Server Groups** tab.
4. On the **Primary/Secondary Server Groups** tab, click **Create Primary/Secondary Server Group**.
5. On the **Create Primary/Secondary Server Group** page, configure the primary/secondary server group.

i. In the **Primary/Secondary Server Group Name** field, enter a name for the primary/secondary server group, and then click **Add IDC Server**.



ii. In the **My Servers** dialog box, click **Add**.

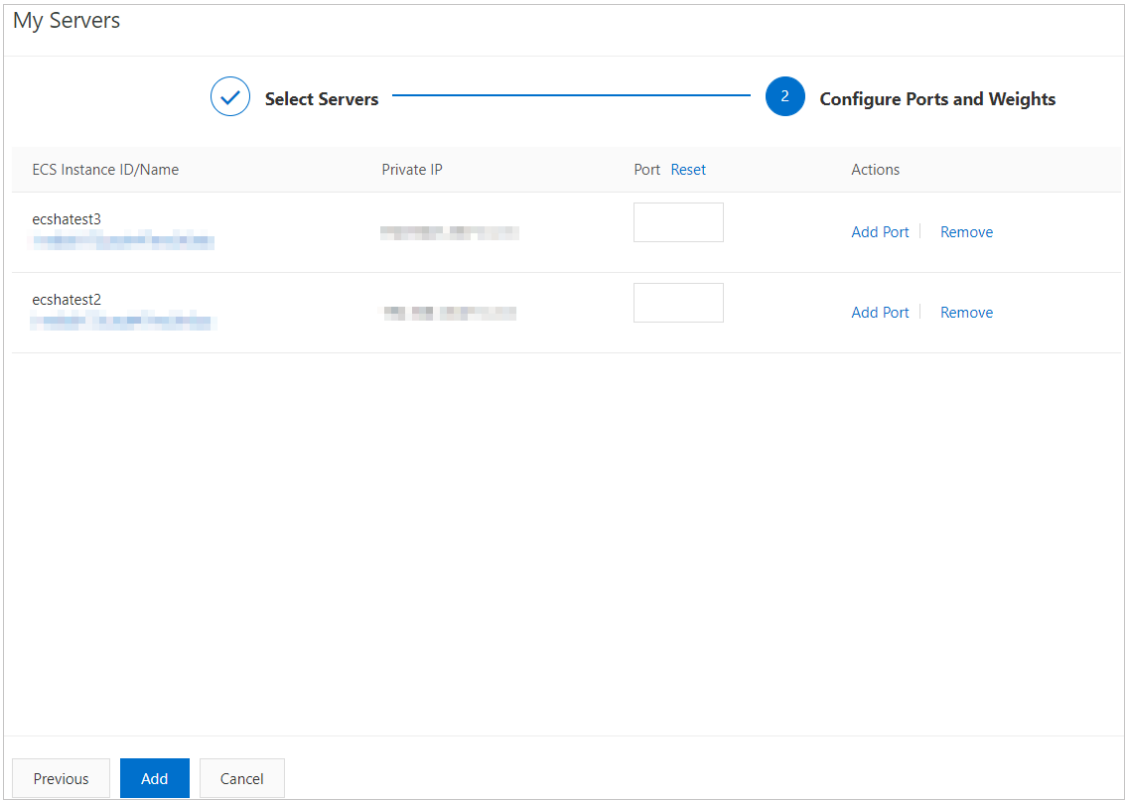


iii. Select a VPC from the VPC Connected to IDC drop-down list, enter a name for the IDC server, and specify the IP address of the IDC server.

The IP address of the IDC server must be accessible to the VPC.

iv. Click **Next**.

v. Configure the backend ports opened on ECS instances to receive requests, and then click **Add**.



You can set multiple ports for an IDC server.

vi. Set a backend server as the primary server.

vii. Click **Create**.

20.1.6.4.3. Delete a primary/secondary server group

This topic describes how to delete a primary/secondary server group of a Server Load Balancer (SLB) instance. If a primary/secondary server group is no longer needed to forward traffic, you can delete the primary/secondary server group.

Procedure

1. Log on to the SLB console.
2. Find the SLB instance and click its instance ID.
3. Click the **Primary/Secondary Server Groups** tab.
4. On the **Primary/Secondary Server Groups** tab, find the primary/secondary server group that you want to delete and click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

20.1.7. Health check

20.1.7.1. Health check overview

This topic describes the health check feature of Server Load Balancer (SLB). SLB checks the availability of Elastic Compute Service (ECS) instances that act as backend servers by performing health checks. The health check feature improves the overall availability of your frontend business and mitigates the impacts of exceptions that occur on backend ECS instances.

After you enable the health check feature, SLB stops distributing requests to ECS instances that are declared unhealthy and distributes new requests to healthy ECS instances. When the unhealthy ECS instances have recovered, SLB starts forwarding requests to these ECS instances again.

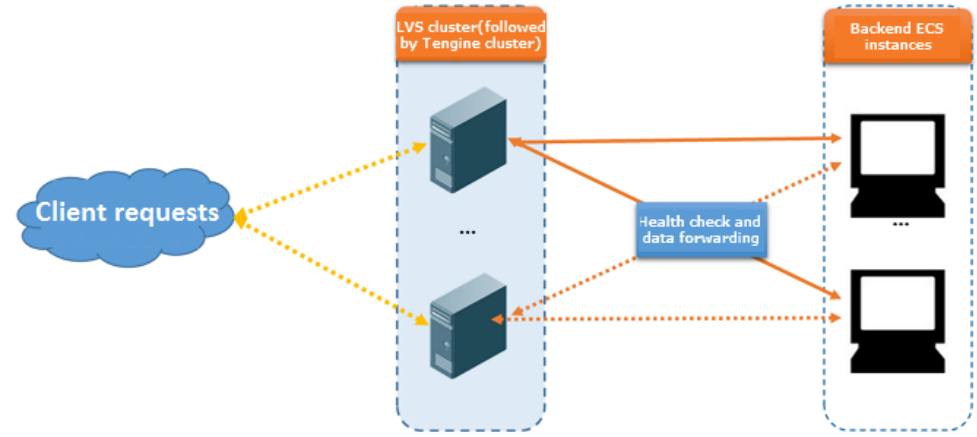
If your business is highly sensitive to traffic loads, frequent health checks may impact the availability of normal business. To reduce the impacts of health checks on your business, you can reduce the health check frequency, increase the health check interval, or change Layer 7 health checks to Layer 4 health checks. We recommend that you do not disable the health check feature to ensure business continuity.

Health check process

SLB is deployed in clusters. Node servers in the LVS or Tengine cluster forward data and perform health checks.

The node servers in the LVS cluster forward data and perform health checks independently and in parallel based on configured load balancing policies. If an LVS node server detects that a backend ECS instance is unhealthy, this node server no longer sends new client requests to this ECS instance. This operation is synchronized among all node servers in the LVS cluster.

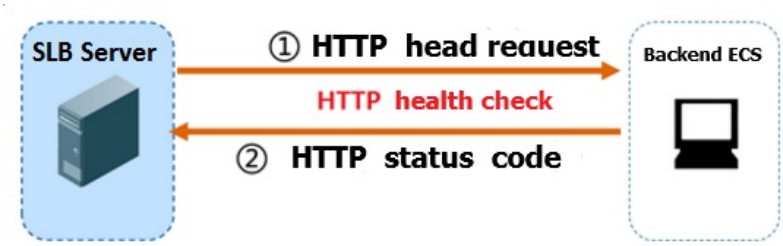
SLB uses the CIDR block of 100.64.0.0/10 for health checks. Make sure that backend ECS instances do not block this CIDR block. You do not need to configure a security group rule to allow access from this CIDR block. However, if you have configured security rules such as iptables, you must allow access from this CIDR block. 100.64.0.0/10 is reserved by Alibaba Cloud. Other users cannot use any IP addresses within this CIDR block, and therefore no relevant security risks exist.



Health checks of HTTP or HTTPS listeners

For Layer 7 (HTTP or HTTPS) listeners, SLB checks the status of backend ECS instances by sending HTTP HEAD requests. The following figure shows the process.

For HTTPS listeners, certificates are managed in SLB. To improve system performance, HTTPS is not used for data exchange (including health check data and business interaction data) between SLB and backend ECS instances.



The following section describes the health check process of a Layer 7 listener:

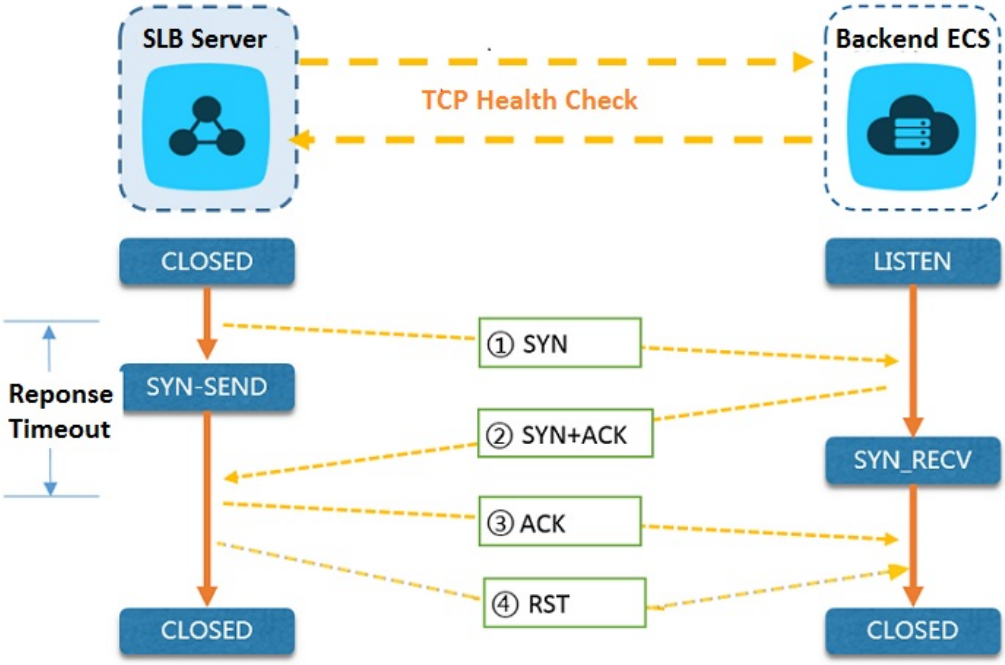
1. A Tengine node server sends an HTTP HEAD request that contains the configured domain name to the internal IP address, health check port, and health check path of a backend ECS instance based on health check settings.
2. After the backend ECS instance receives the request, the ECS instance returns an HTTP status code based on

the running status.

3. If the Tengine node server does not receive a response from the backend ECS instance within the specified response timeout period, the backend server is declared unhealthy.
4. If the Tengine node server receives a response from the backend ECS instance within the specified response timeout period, the node server compares the response with the configured status code. If the response contains the status code that indicates a healthy server, the backend server is declared healthy. Otherwise, the backend server is declared unhealthy.

Health checks of TCP listeners

For TCP listeners, SLB checks the status of backend servers by establishing TCP connections to improve health check efficiency. The following figure shows the process.



The following section describes the health check process of a TCP listener:

1. An LVS node server sends a TCP SYN packet to the internal IP address and health check port of a backend ECS instance.
2. After the backend ECS instance receives the request, the ECS instance returns an SYN-ACK packet if the corresponding port is listening normally.
3. If the LVS node server does not receive a packet from the backend ECS instance within the specified response timeout period, the backend ECS instance is declared unhealthy. Then, the node server sends an RST packet to the backend ECS instance to terminate the TCP connection.
4. If the LVS node server receives a packet from the backend ECS instance within the specified response timeout period, the node server determines that the service runs properly and the health check succeeds. Then, the node server sends an RST packet to the backend ECS instance to terminate the TCP connection.

Note A TCP three-way handshake is conducted to establish a TCP connection. After the LVS node server receives the SYN+ACK packet from the backend ECS instance, the node server sends an ACK packet, and then immediately sends an RST packet to terminate the TCP connection.

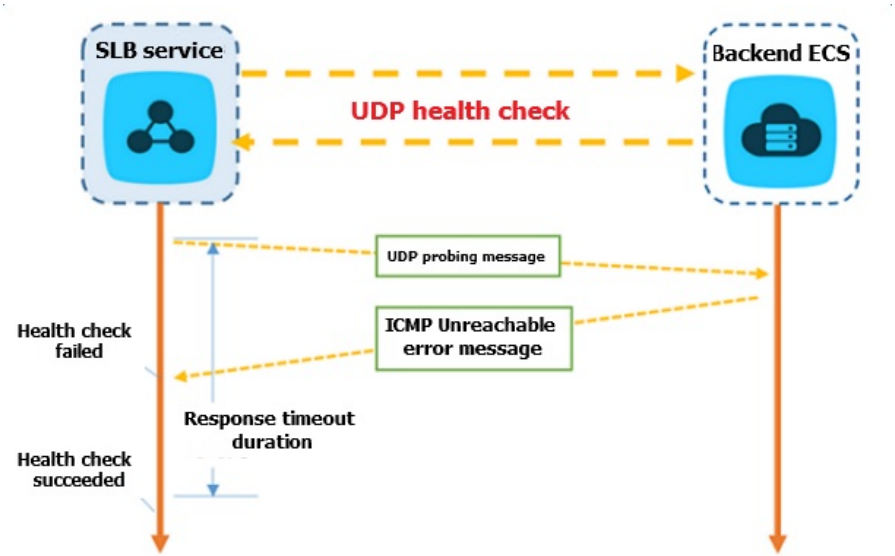
This process may cause backend ECS instances to think that an error such as an abnormal exit occurred in the TCP connection. Then, these instances may report a corresponding error message, such as `Connection reset by peer`, in logs such as Java connection pool logs.

Solution:

- You can implement HTTP health checks.
- If you have enabled the feature of obtaining actual client IP addresses on backend ECS instances, you can ignore connection errors caused by the access of the SLB CIDR block.

Health checks of UDP listeners

For UDP listeners, SLB checks the status of backend ECS instances by sending UDP packets. The following figure shows the process.



The following section describes the health check process of a UDP listener:

1. An LVS node server sends a UDP packet to the internal IP address and health check port of an ECS instance based on health check configurations.
2. If the corresponding port of the ECS instance is not listening normally, the system returns an ICMP error message, such as `port XX unreachable`. Otherwise, no message is returned.
3. If the LVS node server receives the ICMP error message within the response timeout period, the backend ECS instance is declared unhealthy.
4. If the LVS node server does not receive any messages from the backend ECS instance within the response timeout period, the ECS instance is declared healthy.

Note For UDP health checks, the health check result may not reflect the real status of a backend ECS instance in the following situation:

If the backend ECS instance uses a Linux operating system, the speed at which ICMP messages in high concurrency scenarios are sent is limited due to the ICMP attack prevention feature of Linux. In this case, even if a service exception occurs, SLB may declare the backend ECS instance healthy because the error message `port XX unreachable` is not returned. Consequently, the health check result deviates from the actual service status.

Solution:

You can specify a request and a response for UDP health checks. The ECS instance is considered healthy only when the specified response is returned. However, the client must be configured accordingly to return responses.

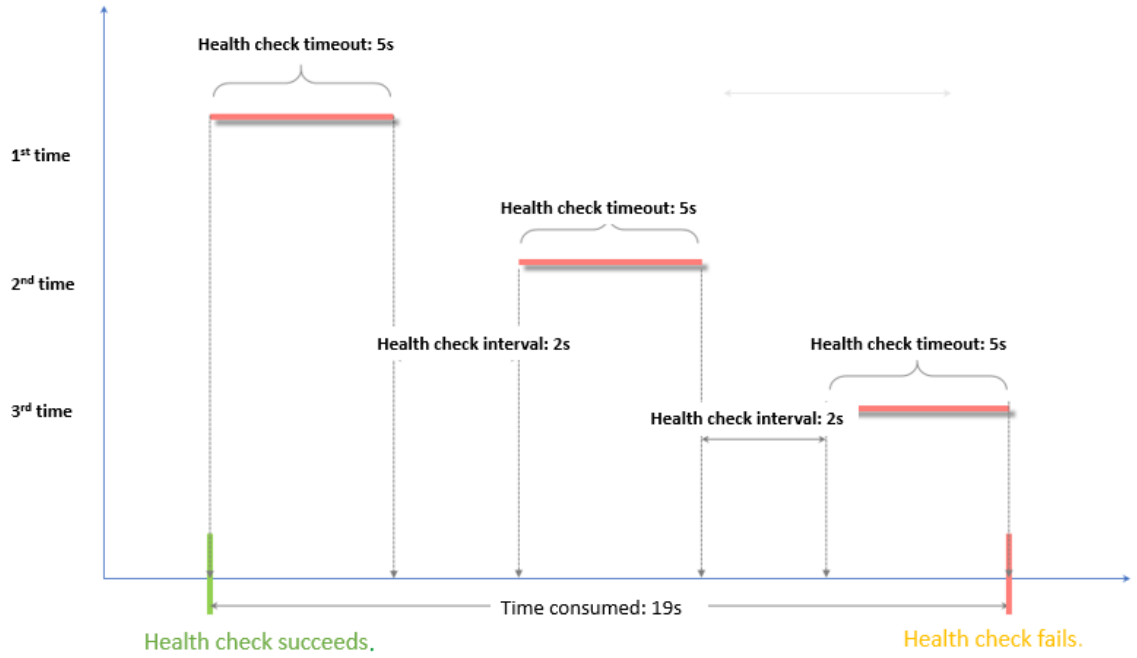
Health check time window

The health check feature effectively improves the availability of your services. However, to avoid impacts on system availability caused by frequent switching after failed health checks, the health check status switches only when health checks successively succeed or fail for a specified number of times within a certain time window. The health check time window is determined by the following factors:

- Health check interval: how often health checks are performed
- Response timeout: the length of time to wait for a response
- Health check threshold: the number of consecutive successes or failures of health checks

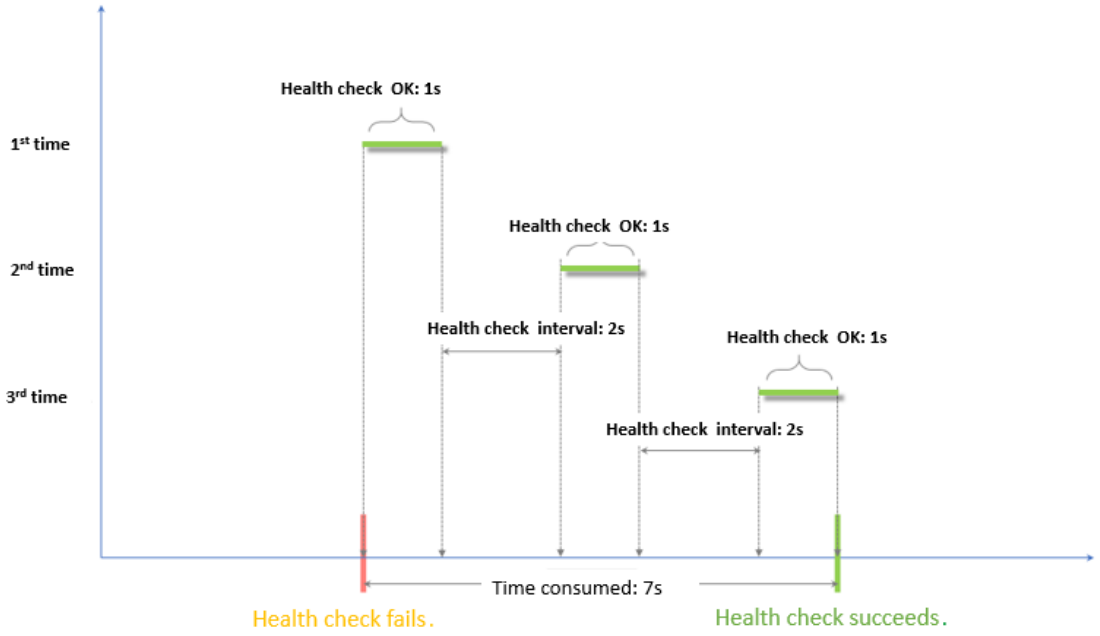
The health check time window is calculated based on the following formula:

- Time window for health check failures = Response timeout × Unhealthy threshold + Health check interval × (Unhealthy threshold - 1)



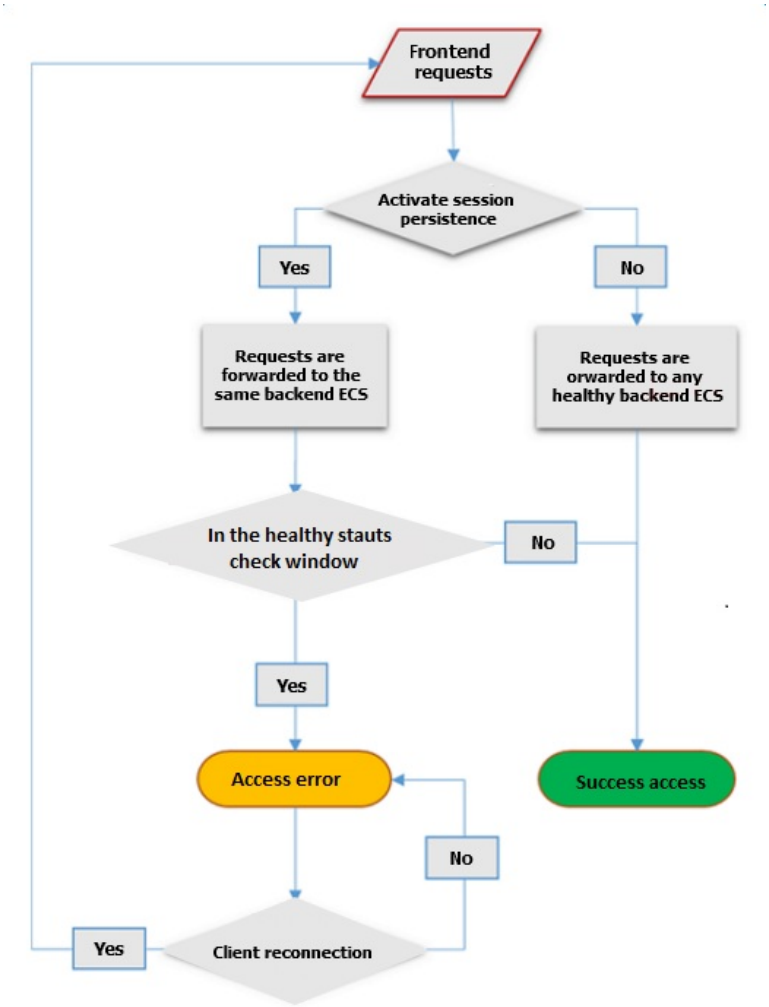
- Time window for health check successes = Response time of a successful health check × Healthy threshold + Health check interval × (Healthy threshold - 1)

> **Note** The response time of a successful health check is the duration from the time when the health check request is sent to the time when the response is received. When TCP health checks are used, the response time is short and almost negligible because only whether the specific port is alive is checked. For HTTP health checks, the response time depends on the performance and load of the application server and is typically within a few seconds.



The health check result has the following impacts on request forwarding:

- If the health check of the backend ECS instance fails, new requests are distributed to other backend ECS instances. This does not affect client access.
- If the health check of the backend ECS instance succeeds, new requests are distributed to this instance. The client access is normal.
- If an exception occurs on the backend ECS instance and a request arrives during a time window for health check failures, the request is still sent to the backend ECS instance. This is because the number of failed health checks has not reached the unhealthy threshold (3 times by default). In this case, the client access fails.



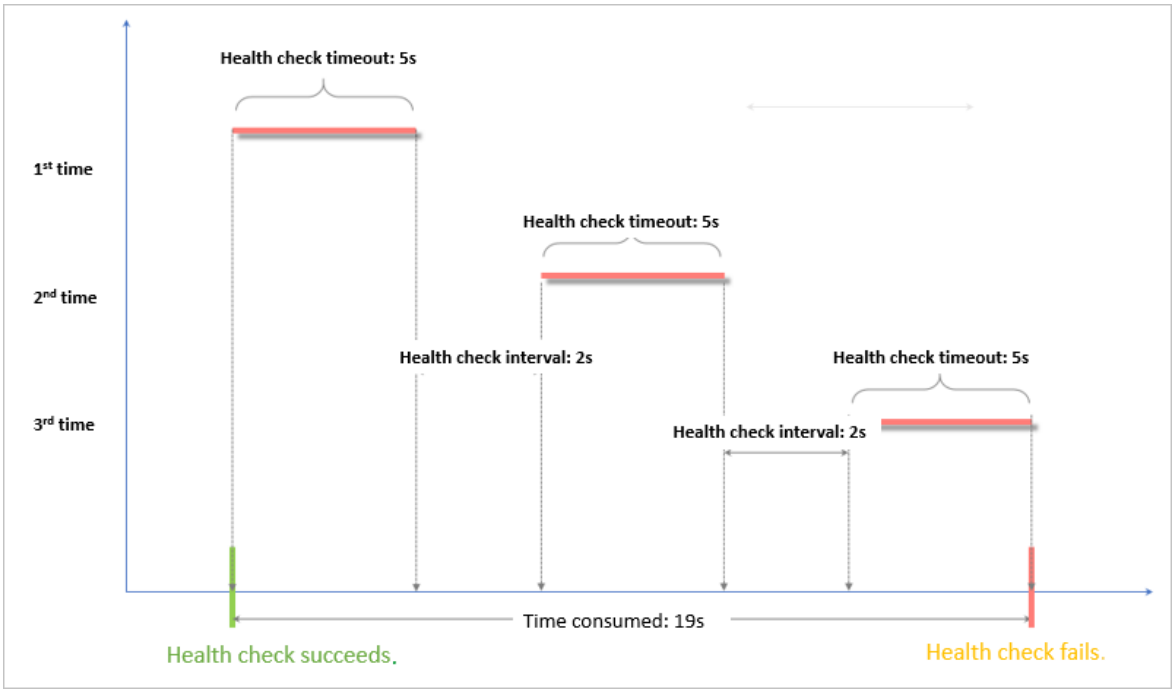
Examples of health check response timeout and health check interval

The following health check settings are used in these examples:

- **Response Timeout Period: 5 Seconds**
- **Health Check Interval: 2 Seconds**
- **Healthy Threshold: 3 Times**
- **Unhealthy Threshold: 3 Times**

Time window for health check failures = Response timeout × Unhealthy threshold + Health check interval × (Unhealthy threshold - 1). That is, 5 × 3 + 2 × (3 - 1) = 19 seconds. If the response time of a health check exceeds 19 seconds, the health check fails.

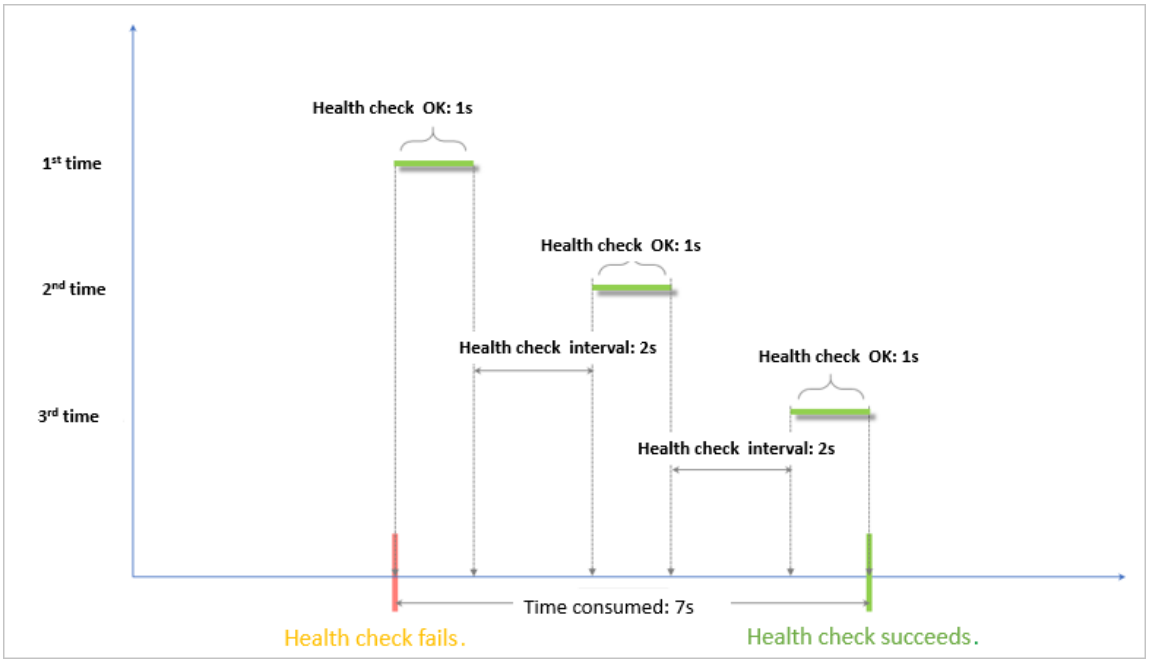
The following figure shows the time window from a healthy status to an unhealthy status.



Time window for health check successes = Response time of a successful health check × Healthy threshold + Health check interval × (Healthy threshold - 1). That is, (1 × 3) + 2 × (3 - 1) = 7 seconds. If the response time of a successful health check is less than seven seconds, the health check succeeds.

> **Note** The response time of a successful health check is the duration from the time when the health check request is sent to the time when the response is received. When TCP health checks are used, the response time is short and almost negligible because only whether the specific port is alive is checked. For HTTP health checks, the response time depends on the performance and load of the application server and is typically within a few seconds.

The following figure shows the time window from an unhealthy status to a healthy status (assume that it takes 1 second for the server to respond to a health check request).



Domain name setting in HTTP health checks

When HTTP health checks are used, you can set a domain name for health checks. The setting is optional. Some application servers verify the host field in requests. In this case, the request header must contain the host field. If a domain name is configured in health check setting, SLB adds the domain name to the host field when SLB forwards a request to an application server. If no domain name is configured, the health check request is denied by the application server because it does not contain a host field and the health check may fail. If your application server verifies the host field in requests, you must configure a domain name to make sure that the health check feature works.

20.1.7.2. Configure health checks

This topic describes how to configure health checks. You can configure health checks when you create a listener or for an existing listener. The default health check settings can meet your requirements in most cases.

Procedure

1. Log on to the SLB console.
2. Find an SLB instance and click the instance ID.
3. On the page that appears, click the **Listener** tab.
4. Click **Add Listener**, or find an existing listener and click **Modify Listener** in the **Actions** column.
5. Click **Next** to go to the **Health Check** step and configure the health check.

   We recommend that you use the default settings when you configure health checks.

   Health check parameters

Parameter	Description
Health Check Protocol	Select the protocol that the SLB instance uses when it performs health checks. For TCP listeners, both TCP health checks and HTTP health checks are supported. ○ A TCP health check implements detection at the network layer by sending SYN packets to check whether a port is open. ○ An HTTP health check verifies the health of a backend server by sending HEAD or GET requests to simulate browser access.
Health Check Method (for the HTTP and HTTPS health checks only)	Health checks of Layer 7 (HTTP or HTTPS) listeners support both the HEAD and GET methods. The HEAD method is used by default. If your backend application server does not support the HEAD method or if the HEAD method is disabled, the health check may fail. To solve this issue, you can use the GET method instead. If the GET method is used and the response size exceeds 8 KB, the response is truncated. However, the health check result is not affected.

Parameter	Description
Health Check Path and **Health Check Domain Name (Optional)** (for the HTTP health checks only)	By default, SLB sends HTTP HEAD requests to the default homepage configured on the application server through the internal IP address of the backend ECS instance to perform health checks. If you do not use the default homepage of the application server for health checks, you must specify the path for health checks. Some application servers verify the host field in requests. In this case, the request header must contain the host field. If a domain name is configured in health check settings, SLB adds this domain name to the host field when SLB forwards a health check request to one of the preceding application servers. If no domain name is configured, SLB does not include the host field in requests and the requests are rejected by the application server, which may cause health checks to fail. If your application server verifies the host field in requests, you must configure a domain name in health check settings to ensure that the health check feature functions properly.
Normal Status Code (for the HTTP health checks only)	Select the HTTP status code that indicates successful health checks. Default values: http_2xx and http_3xx.
Health Check Port	The detection port used by the health check feature to access backend servers. By default, the backend port configured for the listener is used. **Note** If a VServer group or a primary/secondary server group is configured for the listener, and the ECS instances in the group use different ports, leave this parameter empty. SLB uses the backend port of each ECS instance to perform health checks.
Response Timeout	The length of time to wait for a health check response. If the backend ECS instance does not send an expected response within the specified period of time, the health check fails. Valid values: 1 to 300. Unit: seconds. Default value for UDP listeners: 10. Default value for HTTP, HTTPS, and TCP listeners: 5.
Health Check Interval	The interval between two consecutive health checks. All nodes in the LVS cluster perform health checks independently and in parallel on backend ECS instances at the specified interval. The health check statistics of a single ECS instance cannot reflect the health check interval because the nodes perform health checks at different times. Valid values: 1 to 50. Unit: seconds. Default value for UDP listeners: 5. Default value for HTTP, HTTPS, and TCP listeners: 2.
Unhealthy Threshold	The number of consecutive failed health checks that must occur on a backend ECS instance before this ECS instance is declared unhealthy. Valid values: 2 to 10. Default value: 3.

6. Click **Next**.

20.1.7.3. Disable the health check feature

This topic describes how to disable the health check feature for a Server Load Balancer (SLB) instance. If you disable the health check feature, requests may be distributed to unhealthy backend Elastic Compute Service (ECS) instances. This causes service disruptions. We recommend that you enable the health check feature.

Procedure

1. Log on to the SLB console.
2. On the **Instances** page, find the SLB instance that you want to manage and click its instance ID.
3. On the **Listener** tab, find the listener for which you want to disable the health check feature and click **Modify Listener** in the **Actions** column.
4. On the **Configure Listener** page, click **Next** to proceed to the **Health Check** wizard page.
5. Turn off the Enable Health Check switch and click **Next**.
6. Click **Submit** and click **OK**.

20.1.8. Certificate management

20.1.8.1. Certificate overview

This topic provides an overview of the certificates that can be deployed on SLB instances. To use an HTTPS listener, you must upload the required third-party server certificate and digital identification issued by a certificate authority (CA) to SLB. You do not need to configure certificates on backend servers after uploading the certificates to SLB.

To upload a third-party certificate, you must have the files that contain the public key and private key of the certificate.

HTTPS server certificates and client CA certificates are supported.

You can create a maximum of 100 certificates per account.

20.1.8.2. Certificate requirements

Server Load Balancer (SLB) supports only certificates in the PEM format. Before you upload a certificate, make sure that the certificate content, certificate chain, and private key meet the corresponding format requirements.

Certificates issued by a root CA

If the certificate was issued by a root certification authority (CA), the received certificate is the only one that needs to be uploaded to SLB. In this case, the website that is configured with this certificate is regarded as a trusted website and does not require additional certificates.

The certificate must meet the following format requirements:

- The certificate must start with `-----BEGIN CERTIFICATE-----` and end with -----END CERTIFICATE-----.
- Each line (except the last line) must contain 64 characters. The last line can contain 64 or fewer characters.
- The certificate content cannot contain spaces.

Certificates issued by an intermediate CA

If the certificate was issued by an intermediate CA, the received certificate file contains multiple certificates. You must upload both the server certificate and the required intermediate certificates to SLB.

The format of the certificate chain must meet the following requirements:

- The server certificate must be put first and the content of the one or more required intermediate certificates must be put underneath without blank lines between the certificates.
- The certificate content cannot contain spaces.
- Blank lines are not allowed between the certificates. Each line must contain 64 characters. For more information, see RFC1421.
- Certificates must meet the corresponding format requirements. In most cases, the intermediate CA provides instructions about the certificate format when certificates are issued. The certificates must meet the format requirements.

The following section provides a sample certificate chain:

```
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
```

Public keys of certificates

SLB supports the following public key algorithms:

- RSA 1024
- RSA 2048
- RSA 4096
- ECDSA P-256
- ECDSA P-384
- ECDSA P-521

RSA private keys

When you upload a server certificate, you must upload the private key of the certificate.

An RSA private key must meet the following format requirements:

- The private key must start with `-----BEGIN RSA PRIVATE KEY-----` and end with -----END RSA PRIVATE KEY-----, and these parts must also be uploaded.
- Blank lines are not allowed in the content. Each line (except the last line) must contain 64 characters. The last line can contain 64 or fewer characters. For more information, see RFC1421.

You may use an encrypted private key. For example, the private key starts with `----BEGIN PRIVATE KEY-----` and ends with -----END PRIVATE KEY-----, or starts with `-----BEGIN ENCRYPTED PRIVATE KEY-----` and ends with -----END ENCRYPTED PRIVATE KEY-----. The private key may also contain `Proc-Type: 4,ENCRYPTED`. In this case, you must first run the following command to convert the private key:

```
openssl rsa -in old_server_key.pem -out new_server_key.pem
```

20.1.8.3. Upload certificates

This topic describes how to create and upload certificates to Server Load Balancer (SLB). Before you create an HTTPS listener, you must upload the required server certificate and CA certificate to SLB. You do not need to configure certificates on backend servers after you upload the certificates to SLB.

Prerequisites

- A server certificate is purchased.

- A CA certificate and a client certificate are generated.

Context

Note that you can create up to 100 certificates with each account.

Procedure

1. In the left-side navigation pane, click **Certificates**.
2. On the Certificates page, click **Create Certificate**.
3. In the **Create Certificate** panel, set the required parameters and click **Create**.

Parameter	Description
Certificate Name	Enter a name for the certificate. The name must be 1 to 80 characters in length, and can contain only letters, digits, hyphens (-), forward slashes (/), periods (.), underscores (_), and asterisks (*).
Organization	The organization to which the certificate belongs.
Resource Group	The resource set to which the certificate belongs.
Certificate Standard	Select the type of certificate. You can select **International Standard Certificate** or **National Standard Certificate**.
Public Key Certificate	The content of the server certificate. Paste the content into the editor. Click **Example** to view the valid certificate formats. For more information, see Certificate requirements.
Private Key	The private key of the server certificate. Paste the private key into the editor. Click **Example** to view the valid certificate formats. For more information, see Certificate requirements. **Notice** A private key is required only when you upload a server certificate.
Region	The region where you want to deploy the certificate.

4. Click **Create**.

20.1.8.4. Generate a CA certificate

When you configure an HTTPS listener, you can use a self-signed CA certificate. This topic describes how to generate a CA certificate and use the CA certificate to sign a client certificate.

Generate a CA certificate by using Open SSL

1. Run the following commands to create a *ca* folder in the */root* directory and then create four subfolders under the *ca* folder.

```
sudo mkdir ca
cd ca
sudo mkdir newcerts private conf server
```

   - *newcerts* is used to store the digital certificate signed by the CA certificate.
   - *private* is used to store the private Key of the CA certificate.

- *conf* is used to store the configuration files used for simplifying parameters.
- *server* is used to store the server certificate.

2. Create an *openssl.conf* file that contains the following information in the *conf* directory.

```
[ ca ]
default_ca = foo
[ foo ]
dir = /root/ca
database = /root/ca/index.txt
new_certs_dir = /root/ca/newcerts
certificate = /root/ca/private/ca.crt
serial = /root/ca/serial
private_key = /root/ca/private/ca.key
RANDFILE = /root/ca/private/.rand
default_days = 365
default_crl_days= 30
default_md = md5
unique_subject = no
policy = policy_any
[ policy_any ]
countryName = match
stateOrProvinceName = match
organizationName = match
organizationalUnitName = match
localityName = optional
commonName      = supplied
emailAddress    = optional
```

3. Run the following command to generate a private Key.

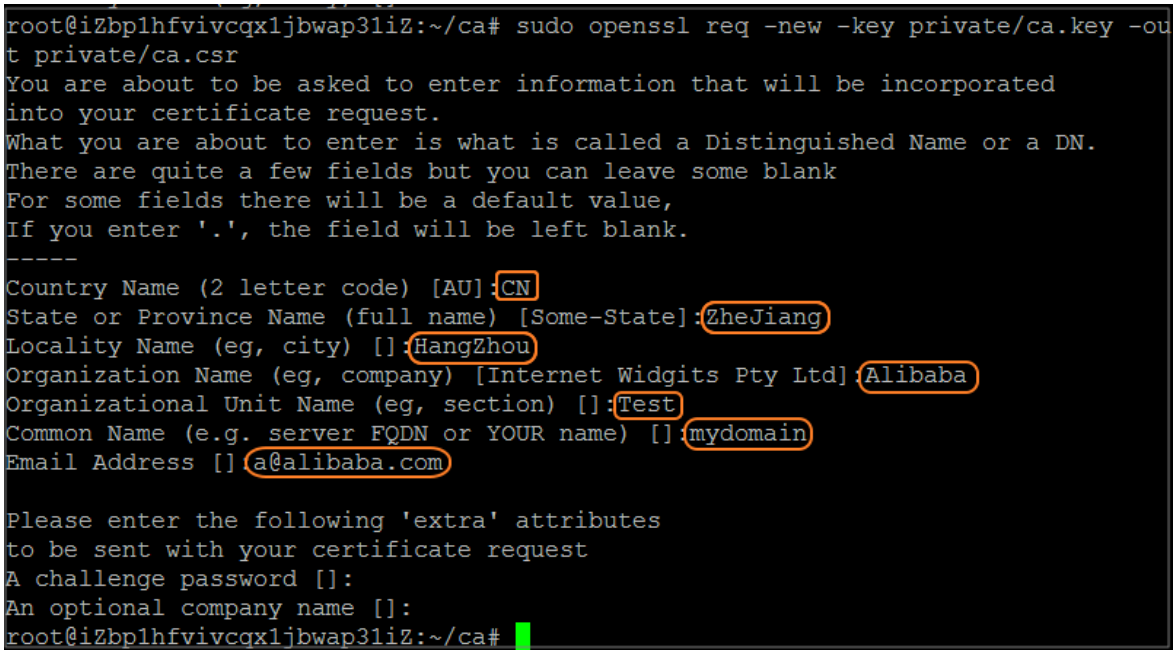
```
cd /root/ca
sudo openssl genrsa -out private/ca.key
```

The following figure is an example of the key generation.

```
root@iZbp1hfvivcqx1jbwap31iZ:~/ca/conf# cd /root/ca
root@iZbp1hfvivcqx1jbwap31iZ:~/ca# sudo openssl genrsa -out private/ca.key
Generating RSA private key, 2048 bit long modulus
.....+++
..+++
e is 65537 (0x10001)
```

4. Run the following command and input the required information according to the prompts. Press Enter to generate a *csr* file.

```
sudo openssl req -new -key private/ca.key -out private/ca.csr
```



> **Note**
>
> Common Name is the domain name of the SLB instance.

5. Run the following command to generate a *crt* file:

```
sudo openssl x509 -req -days 365 -in private/ca.csr -signkey private/ca.key -out private/ca.crt
```

6. Run the following command to set the start sequence number for the private Key, which can be any four characters.

```
sudo echo FACE > serial
```

7. Run the following command to create a CA Key library:

```
sudo touch index.txt
```

8. Run the following command to create a certificate revocation list for removing the client certificate:

```
sudo openssl ca -gencrl -out /root/ca/private/ca.crl -crldays 7 -config "/root/ca/conf/openssl.conf"
```

The output is:

```
Using configuration from /root/ca/conf/openssl.conf
```

Sign the client certificate

1. Run the following command to generate a *users* folder under the *ca* directory to store the client Key.

```
sudo mkdir users
```

2. Run the following command to create a Key for the client certificate:

```
sudo openssl genrsa -des3 -out /root/ca/users/client.key 1024
```

> **Note**
>
> Enter a pass phrase when creating the Key. It is the password to protect the private Key from unauthorized access. Enter the same password twice.

3. Run the following command to create a *csr* file for the client Key.

```
sudo openssl req -new -key /root/ca/users/client.key -out /root/ca/users/client.csr
```

Enter the pass phrase set in the previous step and other required information when prompted.

> **Note**
>
> A challenge password is the password of the client certificate. Note that it is not the password of the client Key.

4. Run the following command to sign the client Key.

```
sudo openssl ca -in /root/ca/users/client.csr -cert /root/ca/private/ca.crt -keyfile /root/ca/private/ca.key -out /root/ca/users/client.crt -config "/root/ca/conf/openssl.conf"
```

Enter *y* twice when prompted to confirm the operation.

```
root@iZbp1hfvivcqx1jbwap31iZ:~/ca# sudo openssl ca -in /root/ca/users/client.csr
 -cert /root/ca/private/ca.crt -keyfile /root/ca/private/ca.key -out /root/ca/us
ers/client.crt -config "/root/ca/conf/openssl.conf"
Using configuration from /root/ca/conf/openssl.conf
Check that the request matches the signature
Signature ok
The Subject's Distinguished Name is as follows
countryName           :PRINTABLE:'CN'
stateOrProvinceName   :ASN.1 12:'ZheJiang'
localityName          :ASN.1 12:'HangZhou'
organizationName      :ASN.1 12:'Alibaba'
organizationalUnitName:ASN.1 12:'Test'
commonName            :ASN.1 12:'mydomain'
emailAddress          :IA5STRING:'a@alibaba.com'
Certificate is to be certified until Jun  4 15:28:55 2018 GMT (365 days)
Sign the certificate? [y/n]:y

1 out of 1 certificate requests certified, commit? [y/n]y
Write out database with 1 new entries
Data Base Updated
root@iZbp1hfvivcqx1jbwap31iZ:~/ca#
```

5. Run the following command to convert the certificate to a *PKCS12* file.

```
sudo openssl pkcs12 -export -clcerts -in /root/ca/users/client.crt -inkey /root/ca/users/client.key -out /root/ca/users/client.p12
```

Follow the prompts to enter the pass phrase of client Key. Then enter the password used for exporting the client certificate. This password is used to protect the client certificate, which is required when you install the client certificate.

6. Run the following commands to view the generated client certificate:

```
cd users
ls
```

20.1.8.5. Convert the certificate format

Server Load Balancer (SLB) supports PEM certificates only. Certificates in other formats must be converted to the PEM format before they can be uploaded to SLB. We recommend that you use Open SSL for conversion.

Convert DER to PEM

DER: This format is usually used on a Java platform. The certificate file suffix is generally *. der*, *. cer*, or *. crt*.

- Run the following command to convert the certificate format:

```
openssl x509 -inform der -in certificate.cer -out certificate.pem
```

- Run the following command to convert the private key:

```
openssl rsa -inform DER -outform PEM -in privatekey.der -out privatekey.pem
```

Convert P7B to PEM

P7B: This format is usually used in a Windows server and Tomcat.

Run the following command to convert the certificate format:

```
openssl pkcs7 -print_certs -in incertificate.p7b -out outcertificate.cer
```

Convert PFX to PEM

PFX: This format is usually used in a Windows server.

- Run the following command to extract the certificate:

```
openssl pkcs12 -in certname.pfx -nokeys -out cert.pem
```

- Run the following command to extract the private key:

```
openssl pkcs12 -in certname.pfx -nocerts -out key.pem -nodes
```

20.1.8.6. Replace a certificate

This topic describes how to replace a certificate with a new certificate. We recommend that you replace certificates before they expire to avoid impacts on your service.

Procedure

1. Create and upload a new certificate.

   For more information, see Overview.
2. Configure the certificate for the target HTTPS listener.

   For more information, see Add an HTTPS listener.
3. On the **Certificates** page, find the certificate to be replaced and click **Delete** in the Actions column.
4. In the dialog box that appears, click **OK**.

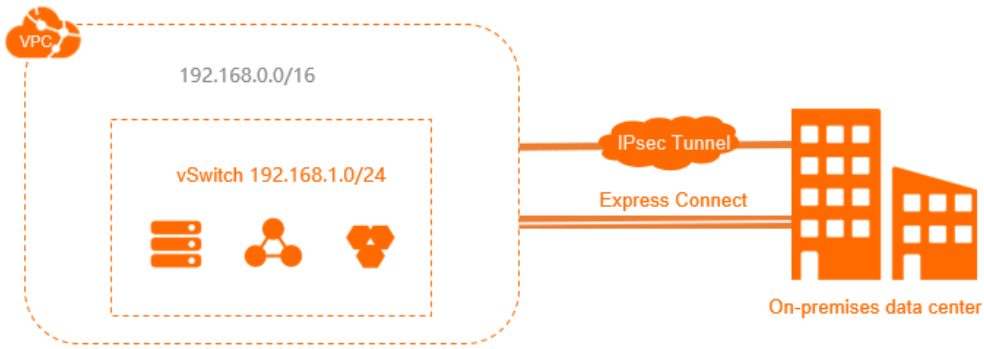
21.Virtual Private Cloud (VPC)

21.1. User Guide

21.1.1. What is a VPC?

A virtual private cloud (VPC) is a private network dedicated for your use. You have full control over your VPC. For example, you can specify the CIDR block and configure route tables and gateways. In a VPC, you can deploy Apsara Stack resources, such as Elastic Compute Service (ECS) instances, ApsaraDB RDS instances, and Server Load Balancer (SLB) instances.

Furthermore, you can connect your VPC to other VPCs or on-premises networks to create a custom network environment. This way, you can migrate applications to the cloud and extend data centers.



Components

Each VPC consists of one vRouter, at least one private CIDR block, and at least one vSwitch.

- Private CIDR blocks

  When you create a VPC and a vSwitch, you must specify the private IP address range for the VPC in CIDR notation.

  You can use the standard private CIDR blocks listed in the following table and their subsets as CIDR blocks for your VPCs. For more information, see the Plan and design a VPC topic in *User Guide*.

CIDR blocks	Number of available private IP addresses (system reserved ones excluded)
192.168.0.0/16	65,532
172.16.0.0/12	1,048,572
10.0.0.0/8	16,777,212

- vRouters

  A vRouter is the hub of a VPC and serves as a gateway between the VPC and other networks. After a VPC is created, a vRouter is automatically created for the VPC. Each vRouter is associated with a route table.

  For more information, see the Route table overview topic in *User Guide*.

- vSwitches

A vSwitch is a basic network component that connects different cloud resources in a VPC. After you create a VPC, you can create a vSwitch to divide your VPC into multiple subnets. vSwitches deployed in a VPC can communicate with each other over the private network. You can deploy your applications in vSwitches that belong to different zones to improve service availability.

For more information, see the Create a vSwitch topic in *User Guide*.

21.1.2. Log on to the VPC console

This topic describes how to log on to the Virtual Private Cloud (VPC) console of Apsara Uni-manager by using the Google Chrome browser.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, choose **Products > Networking > Virtual Private Cloud**.

21.1.3. Quick start

21.1.3.1. Plan and design a VPC

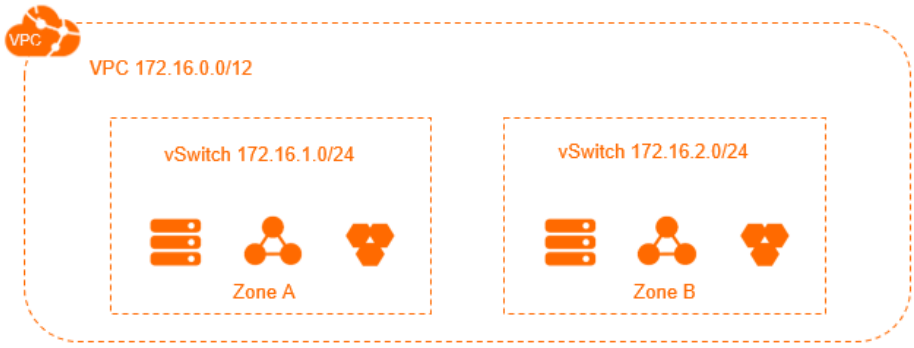
Before you create virtual private clouds (VPCs) and VSwitches, you need to plan the quantity and Classless Inter-domain Routing (CIDR) blocks of VPCs and VSwitches.

- How many VPCs are required?
- How many VSwitches are required?
- How do I specify CIDR blocks?
- How do I specify CIDR blocks if I want to connect a VPC to other VPCs or on-premises data centers?

How many VPCs are required?

- One VPC

  We recommend that you create one VPC if you do not need to deploy systems in multiple regions or separate VPCs.



- Multiple VPCs

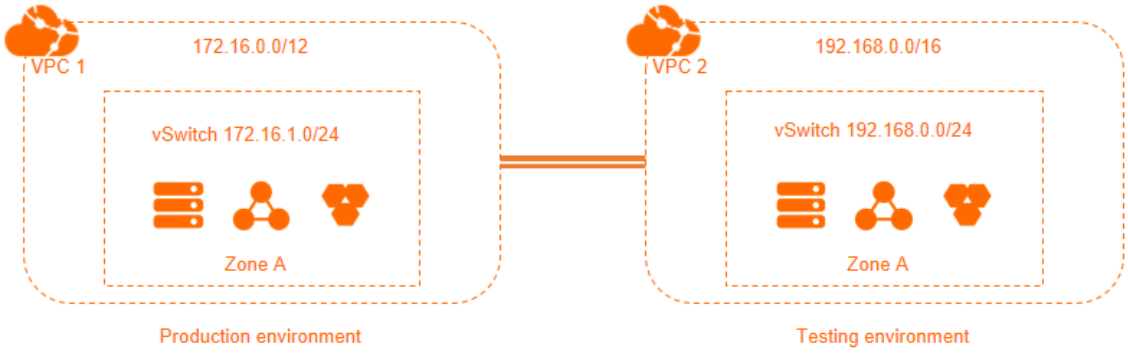
  We recommend that you create multiple VPCs if you need to:

  - Deploy application systems across regions.

    A VPC cannot be deployed across regions. If you want to deploy your application systems in different regions, you must create multiple VPCs. You can use Express Connect and VPN Gateway to connect VPCs.

  - Separate IT systems

    To separate IT systems, you must create multiple VPCs. The following figure shows an example of isolating a production environment from a test environment by deploying them in separate VPCs.



How many VSwitches are required?

We recommend that you create at least two VSwitches for each VPC and deploy these VSwitches in different zones to achieve zone-disaster recovery.

After you deploy your applications in different zones within a region, you must measure the network latency between these applications. This is because the cross-zone network latency may be higher than expected due to complex data processing or cross-zone calls. An ideal approach is to optimize and adjust your systems to strike a balance between availability and latency.

In addition, the sizes and designs of your IT systems must also be taken into consideration when you create VSwitches. If you allow traffic from the Internet to be routed to and from the frontend systems, you can deploy the front-end systems in different VSwitches and the backend systems in other VSwitches to create a robust disaster recovery strategy.

How do I specify CIDR blocks?

When you create VPCs and VSwitches, you must specify their private IP address ranges in the form of CIDR blocks.

- VPC CIDR blocks

  You can use 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or their subsets as the CIDR blocks of your VPCs. To specify CIDR blocks for VPCs, follow these rules:

  - If you have only one VPC and this VPC does not need to communicate with any on-premises data center, you can use one of the preceding CIDR blocks or one of their subsets as the CIDR block of the VPC.
  - If you have multiple VPCs, or you need to build a hybrid cloud to integrate VPCs and on-premises data centers, we recommend that you use the subsets of the preceding CIDR blocks for your VPCs. In this case, the mask cannot be longer than 16 bits.

- VSwitch CIDR blocks

  The CIDR block of a VSwitch must be a subset of the CIDR block of the VPC this VSwitch resides in. For example, if the CIDR block of a VPC is 192.168.0.0/16, the CIDR block of a VSwitch in the VPC must be a segment from 192.168.0.0/17 to 192.168.0.0/29.

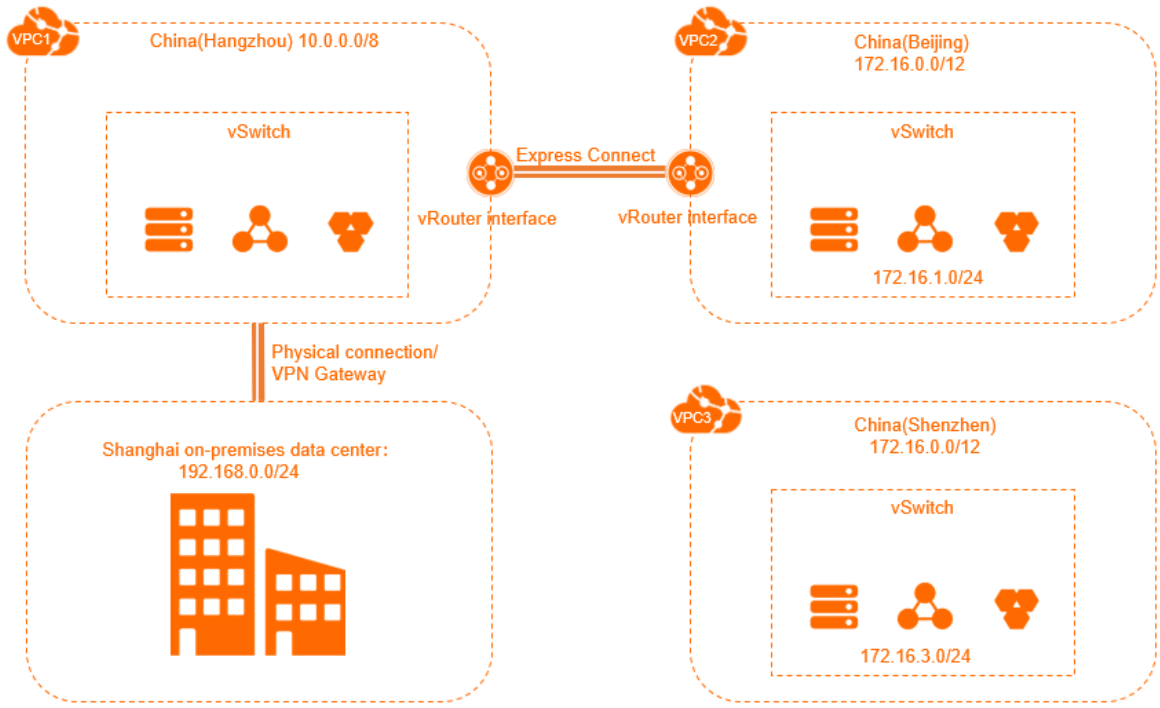
  To specify CIDR blocks for VSwitches, follow these rules:

  - The CIDR block size for a VSwitch is between a 16-bit mask and a 29-bit mask. It means that 8 to 65,536 IP addresses can be provided. This range is set because a 16-bit host address space provides addressing for 65,534 ECS instances, which can meet your needs in most cases, while a mask smaller than 29 bits can only allow very few usable host addresses.
  - The first and the last three IP addresses in each VSwitch CIDR block are reserved by the system. For example, if the CIDR block of a VSwitch is 192.168.1.0/24, the IP addresses 192.168.1.0, 192.168.1.253, 192.168.1.254, and 192.168.1.255 are reserved.
  - You must check the number of ECS instances in the VSwitch before you specify the CIDR block of a VSwitch.

How do I specify CIDR blocks if I want to connect a VPC to other VPCs or on-premises data centers?

Before you connect your VPC to another VPC or an on-premises data center, you must make sure that the CIDR block of your VPC does not conflict with that of the peer network.

For example, assume you have three VPCs: VPC1 in China (Hangzhou), VPC2 in China (Beijing), and VPC3 in China (Shenzhen), as shown in the following figure. Express Connect circuit is used for VPC1 and VPC2 to communicate with each other. VPC3 does not communicate with other VPCs, but may need to communicate with VPC2 in the future. Additionally, you have an on-premises data center in Shanghai, and you need to connect it to VPC1 by using an Express Connect circuit.



In this example, the CIDR block of VPC2 is different from the CIDR block of VPC1, but is the same with the CIDR block of VPC3. However, considering that VPC2 and VPC3 may need to communicate with each other later in the private network, the VSwitches in these VPCs are assigned with different CIDR blocks. This example demonstrates that VPCs communicating with each other can have identical CIDR blocks, but their VSwitches must have different CIDR blocks.

When you specify CIDR blocks for multiple VPCs that need to communicate with each other, follow these rules:

- The preferred practice is to specify different CIDR blocks for different VPCs. You can use the subsets of the standard CIDR blocks to increase the number of available CIDR blocks.
- If you cannot assign different CIDR blocks for VPCs, try to specify different CIDR blocks for the VSwitches in these VPCs.
- If you cannot assign different CIDR blocks for all VSwitches in these VPCs, make sure that different CIDR blocks are configured for the VSwitches communicating with each other.

21.1.3.2. Create an IPv4 VPC

This topic describes how to create a virtual private cloud (VPC) with an IPv4 CIDR block and create an Elastic Compute Service (ECS) instance in the VPC.

Prerequisites

To deploy cloud resources in a VPC, you must have network subnetting prepared first. For more information, see Plan networks.

Step 1: Create a VPC

Perform the following steps to create a VPC:

1. Log on to the VPC console.
2. On the **VPCs** page, click **Create VPC**.
3. On the **Create VPC** page, set the following parameters and click **Submit**.

Parameter	Description
Organization	Select the organization to which the VPC belongs.
Resource Set	Select the resource set to which the VPC belongs.
Region	Select the region where you want to deploy the VPC.
Sharing Scope	Select the participants who can use the VPC to create resources. ○ **Current Resource Set**: Only the administrator of the current resource set can use the VPC to create resources. ○ **Current Organization and Subordinate Organization**: Only the administrators of the current organization and its subordinate organization can use the VPC to create resources. ○ **Current Organization**: Only the administrator of the current organization can use the VPC to create resources. **Current Resource Set** is selected in this example.
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length, and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`. **VPCtest** is used in this example.
IPv4 CIDR Block	Select an IPv4 CIDR block for the VPC. The following setting methods are supported: ○ **Recommended CIDR Block**: You can use one of the following standard IPv4 CIDR blocks: 192.168.0.0/16, 172.16.0.0/12, and 10.0.0.0/8. ○ **Custom CIDR Block**: You can use 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or a subset of these CIDR blocks. The subnet mask must be 8 to 28 bits in length. For example, enter 192.168.0.0/16. In this example, 192.168.0.0/16 is used as the IPv4 CIDR block of the VPC. **Note** After you create a VPC, you cannot change its IPv4 CIDR block.
IPv6 CIDR Block	Specify whether to assign an IPv6 CIDR block. ○ **Do Not Assign**: No IPv6 CIDR block will be assigned to the VPC. ○ **Assign**: An IPv6 CIDR block will be automatically assigned to the VPC. **Do Not Assign** is selected in this example.
Description	Enter a description for the VPC. The description must be 2 to 256 characters in length, and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

4. Click **Back to Console**. On the **VPCs** page, you can view the VPCs that are created.

Step 2: Create a vSwitch

Perform the following steps to create a vSwitch in a VPC:

1. In the left-side navigation pane, click **vSwitches**.
2. On the **vSwitches** page, click **Create vSwitch**.
3. On the **Create vSwitch** page, set the following parameters and click **Submit**.

Parameter	Description
Organization	Select the organization to which the vSwitch belongs.
Resource Set	Select the resource set to which the vSwitch belongs.
Region	Select the region where the vSwitch is deployed.
Zone	Select the zone to which the vSwitch belongs. In a VPC, a vSwitch can belong to only one zone. However, you can deploy cloud resources in vSwitches that reside in different zones to achieve cross-zone disaster recovery. **Note** A cloud instance can be deployed in only one vSwitch.
Sharing Scope	Select the participants that can use the vSwitch to create resources. ○ **Current Resource Set**: Only the administrator of the current resource set can use the vSwitch to create resources. ○ **Current Organization and Subordinate Organization**: Only the administrators of the current organization and its subordinate organization can use the vSwitch to create resources. ○ **Current Organization**: Only the administrator of the current organization can use the vSwitch to create resources. **Current Resource Set** is selected in this example.
VPC	The VPC in which you want to create the vSwitch. VPCtest is selected in this example.
Dedicated for Out-of-cloud Physical Machines	Specify whether the vSwitch to be created is dedicated for bare-metal servers. For more information about bare-metal servers, see the **VPC bare-metal server features** topic in *BMS user guide*. **No** is selected in this example.
vSwitch Name	Enter a name for the vSwitch. The name must be 2 to 128 characters in length, and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.
IPv4 CIDR Block	Specify an IPv4 CIDR block for the vSwitch. The default IPv4 CIDR block is used in this example.

Parameter	Description
IPv6 CIDR Block	Specify an IPv6 CIDR block for the vSwitch. **Do Not Assign** is selected in this example.
Description	Enter a description for the vSwitch. The name must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

Step 3: Create a security group

Perform the following steps to create a security group:

1. In the top navigation bar, choose **Products > Elastic Computing > Elastic Compute Service**.
2. Choose **Networks and Security > Security Groups**.
3. On the **Security Groups** page, click **Create Security Group**.
4. On the **Create Security Group** page, set the following parameters and click **Submit**.

Parameter	Description
Organization	Select the organization to which the security group belongs.
Resource Set	Select the resource set to which the security group belongs.
Region	Select the region to which the security group belongs. Make sure that the security group and the VPC belong to the same region.
Zone	Select the zone to which the security group belongs.
VPC	The VPC to which the security group belongs.
Security Group Name	Enter a name for the security group. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.
Description	Enter a description for the security group. The description must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

Step 4: Create an ECS instance

Perform the following steps to create an ECS instance in the VPC:

1. In the top navigation bar, choose **Products > Networking > Virtual Private Cloud**.
2. In the left-side navigation pane, click **vSwitches**.
3. In the top navigation bar, select the region where the vSwitch is deployed.
4. On the **vSwitches** page, find the vSwitch and choose **Create > ECS Instance** in the **Actions** column.
5. On the **Create ECS Instance** page, set the parameters and click **Submit**.

   For more information about how to configure ECS instances, see **Create an instance** in **Quick start** of *ECS u*

ser guide.

21.1.3.3. Create an IPv6 VPC

This topic describes how to create a virtual private cloud (VPC) that supports IPv6 CIDR blocks and then create an Elastic Compute Service (ECS) instance that is assigned an IPv6 address in the VPC to access IPv6 services.

Step 1: Create a VPC and a vSwitch

Before you deploy cloud resources in a VPC, you must create a VPC and a vSwitch.

Perform the following steps to create a VPC and a vSwitch:

1. Log on to the VPC console.
2. On the **VPCs** page, click **Create VPC**.
3. On the **Create VPC** page, set the following parameters to configure the VPC and click **OK**.

Parameter	Description
Organization	Select the organization to which the VPC belongs.
Resource Set	Select the resource set to which the VPC belongs.
Region	Select the region where you want to deploy the VPC.
Sharing Scope	Specify the scope of entities that are allowed to use the VPC. ○ **Current Resource Set**: If you select this option, the administrator of the current resource set can create resources in the VPC. ○ **Current Organization and Subordinate Organizations**: If you select this option, administrators that belong to the current organization and subordinate organizations can create resources in the VPC. ○ **Current Organization**: If you select this option, administrators that belong to the current organization can create resources in the VPC. In this example, **Current Resource Set** is selected.
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character and cannot start with `http://` or `https://`. In this example, **VPCtest** is entered.
IPv4 CIDR Block	Specify the IPv4 CIDR block of the VPC. You can specify an IPv4 CIDR block in one of the following ways: ○ **Recommended CIDR Block**: You can use one of the following standard IPv4 CIDR blocks: 192.168.0.0/16, 172.16.0.0/12, and 10.0.0.0/8. ○ **Custom CIDR Block**: Enter 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or a subset of these CIDR blocks. The subnet mask must be 8 to 28 bits in length. For example, you can enter 192.168.0.0/16. In this example, Recommended CIDR Block is selected and 192.168.0.0/16 is selected as the IPv4 CIDR block of the VPC. **Note** After you create a VPC, you cannot change its IPv4 CIDR block.

Parameter	Description
IPv6 CIDR Block	Specify whether to assign an IPv6 CIDR block. ○ **Do Not Assign**: If you select this option, the system does not assign an IPv6 CIDR block to the VPC. ○ **Assign**: If you select this option, the system automatically assigns an IPv6 CIDR block to the VPC. In this example, **Assign** is selected.
Description	Enter a description for the VPC. The description must be 2 to 256 characters in length and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.

4. Click **Back to Console**. In the left-side navigation pane, click **VSwitches**.
5. On the **VSwitches** page, click **Create VSwitch**.
6. On the **vSwitch** page, set the following parameter to configure the vSwitch and click **Submit**.

Parameter	Description
Organization	Select the organization to which the vSwitch belongs.
Resource Set	Select the resource set to which the vSwitch belongs.
Region	Select the region where you want to deploy the vSwitch.
Zone	Select the zone where you want to deploy the vSwitch. In a VPC, each vSwitch can be deployed in only one zone. You cannot deploy a vSwitch across zones. However, you can deploy cloud resources in vSwitches that belong to different zones to achieve zone-disaster recovery. **Note** Each cloud resource can be added to only one vSwitch.

Parameter	Description
Sharing Scope	Specify the scope of entities that are allowed to use the vSwitch. ○ **Current Resource Set**: If you select this option, the administrator of the current resource set can create resources in the vSwitch. ○ **Current Organization and Subordinate Organizations**: If you select this option, administrators that belong to the current organization and subordinate organizations can create resources in the vSwitch. ○ **Current Organization**: If you select this option, administrators that belong to the current organization can can create resources in the vSwitch. In this example, **Current Resource Set** is selected.
VPC	Select the VPC where you want to deploy the vSwitch. In this example, VPCtest is selected.
Dedicated for Out-of-cloud Physical Machines	Specify whether the vSwitch to be created is dedicated to bare-metal servers. For more information about bare-metal servers, see the **Bare-metal servers in VPCs** topic in *Bare-metal Server Management Service User Guide*. In this example, **No** is selected.
vSwitch Name	Enter a name for the vSwitch. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.
IPv4 CIDR Block	Enter an IPv4 CIDR block for the vSwitch. In this example, the default IPv4 CIDR block is used.
IPv6 CIDR Block	Enter an IPv6 CIDR block for the vSwitch. In this example, the default IPv6 CIDR block is used.
Description	Enter a description for the vSwitch. The description must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.

Step 2: Create a security group

Perform the following steps to create a security group:

1. In the top navigation bar, choose **Products > Elastic Computing > Elastic Compute Service**.
2. Choose **Networks and Security > Security Groups**.
3. On the **Security Groups** page, click **Create Security Group**.
4. On the **Create Security Group** page, set the following parameters to configure the security group and click **Submit**.

Parameter	Description
Organization	Select the organization to which the security group belongs.

Parameter	Description
Resource Set	Select the resource set to which the security group belongs.
Region	Select the region to which the security group belongs. Make sure that the security group and the VPC belong to the same region.
Zone	Select the zone to which the security group belongs.
VPC	Select the VPC to which the security group belongs.
Security Group Name	Enter a name for the security group. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.
Description	Enter a description for the security group. The description must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.

Step 3: Create and configure an ECS instance

After you create a VPC and a vSwitch, you must create an ECS instance and assign an IPv6 address to the ECS instance. You must associate this IPv6 address with the network interface controller (NIC) of the ECS instance.

Perform the following steps to create and configure an ECS instance:

1. In the top navigation bar, choose **Products > Networking > Virtual Private Cloud**.
2. In the left-side navigation pane, click **VSwitches**.
3. Select the region where the vSwitch is created.
4. On the **VSwitches** page, find the vSwitch that you want to manage and choose **Create > ECS Instance** in the **Actions** column.
5. On the **Create ECS Instance** page, configure the ECS instance and click **Submit**.

   In this example, **Assign** is selected. Therefore, an IPv6 IP address is assigned to the ECS instance. For more information about other parameters that you are required to specify when you create an ECS instance, see **Create an ECS instance** in **Quick Start** of *Elastic Compute Service User Guide*.
6. Return to the **Instances** page and click the instance ID to view the IPv6 address that is assigned to the ECS instance.
7. Configure a static IPv6 address.
   - If the image of your ECS instance supports DHCPv6, you do not need to manually configure a static IPv6 address. DHCPv6 enables automatic configuration of IPv6 addresses. Therefore, if your ECS instance image supports DHCPv6, the ECS instance can use the assigned IPv6 address to communicate within the private network.

     The following images support DHCPv6:

     - Linux images:
       - CentOS 7.6 IPV6 64Bit
       - CentOS 6.10 64Bit
       - SUSE Linux Enterprise Server 12 SP4 64Bit

- Windows Server images

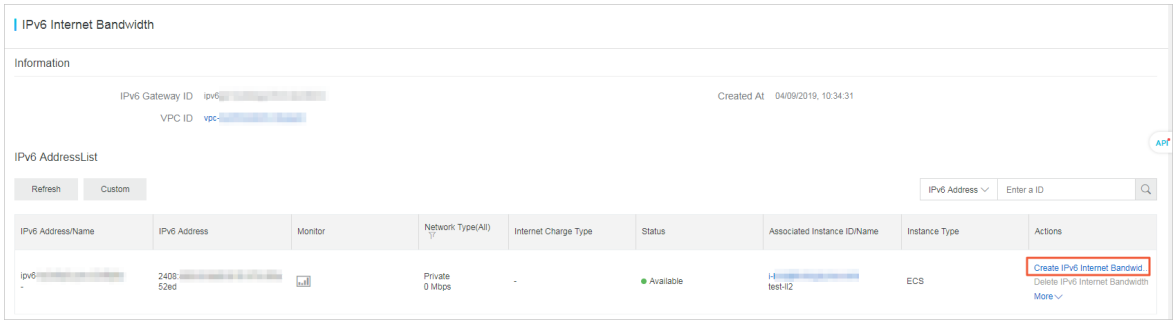
- If the image of your ECS instance does not support DHCPv6, you must manually configure an IPv6 address for the ECS instance. We recommend that you refer to the related documentation for each image for configuration guidance.

Step 4: Purchase an IPv6 Internet bandwidth plan

By default, IPv6 addresses are only used for communication within private networks. If you want to allow an instance that is assigned an IPv6 address to access the Internet or receive requests from IPv6 clients over the Internet, you must purchase an Internet bandwidth plan for the IPv6 address.

Perform the following steps to purchase an Internet bandwidth plan for the IPv6 address:

1. In the top navigation bar, choose **Products > Networking > IPv6 Gateway**.
2. Select the region where the IPv6 gateway is created.
3. On the **IPv6 Gateway** page, find the IPv6 gateway that you want to manage and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **IPv6 Internet Bandwidth**.
5. On the **IPv6 Internet Bandwidth** page, find the IPv6 address that you want to manage and click **Enable IPv6 Internet Bandwidth** in the **Actions** column.



6. Select a bandwidth plan and click **OK**.

   The maximum IPv6 Internet bandwidth for an IPv6 gateway of the Free, Enterprise, or Enhanced Edition is 2 Gbit/s.

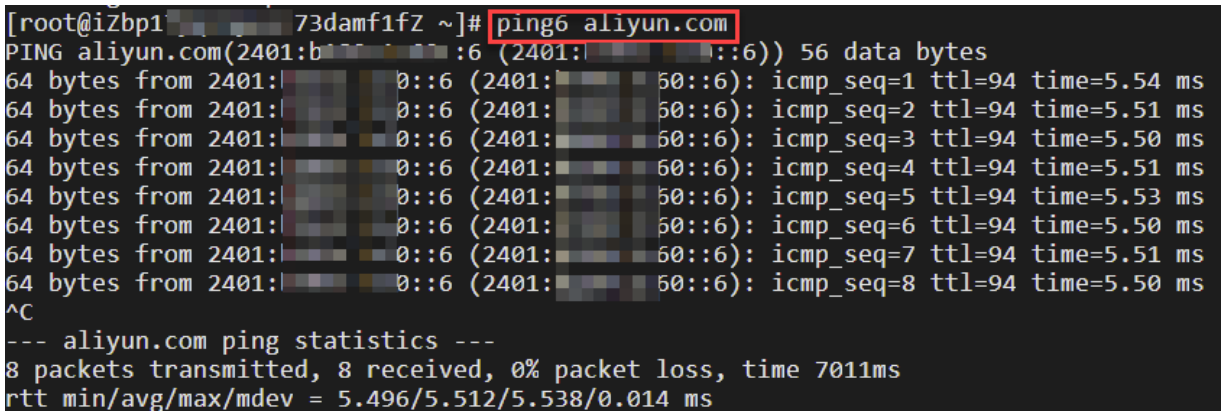
Step 5: Configure security group rules

IPv4 and IPv6 addresses are independent of each other. If the current security group rules do not apply to your IPv6 services, you must configure security group rules for the ECS instances to regulate communication with IPv6 addresses.

For more information about how to configure security rules, see the **Add security group rules** chapter in **Security Groups** of *Elastic Compute Service User Guide*.

Step 6: Test the network connectivity

Log on to an ECS instance and **ping** an IPv6 service to test the network connectivity.



21.1.4. VPCs and VSwitches

21.1.4.1. Overview

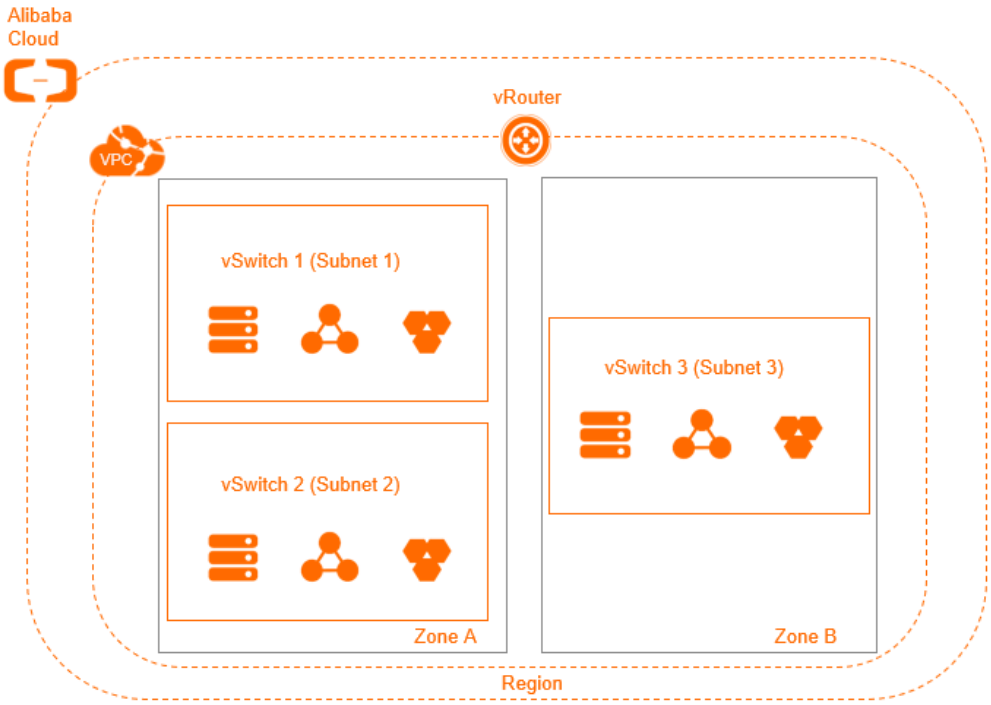
To get started with Virtual Private Cloud, you need to create at least one virtual private cloud (VPC) and one VSwitch. You can create VSwitches in a VPC to partition a VPC into multiple subnets. By default, subnets (VSwitches) within a VPC can communicate with each other over the private network.

VPCs and VSwitches

A VPC is a virtual network dedicated for your use. You can deploy cloud resources in VPCs that you define.

> **Note** A cloud resource cannot be directly deployed in a VPC, but can be deployed in a VSwitch of the VPC.

A VSwitch is a basic network component in a VPC and is used to connect cloud resources. Each VPC must reside entirely within one region and cannot span multiple regions. However, a VPC spans all of the zones in a region, which means you can create one or more VSwitches in each zone to partition a VPC into subnets.



CIDR blocks and IP addresses

VPCs support both IPv4 and IPv6 addressing protocols. By default, VPCs use the IPv4 addressing protocol. You can enable the IPv6 addressing protocol as needed.

VPCs can operate in a dual-stack mode, which allows your resources to communicate over IPv4, or IPv6, or both. IPv4 and IPv6 addresses are independent of each other. Therefore, you must configure routing and security groups in your VPC separately for IPv4 and IPv6.

The following table summarizes the differences between IPv4 and IPv6 in Apsara Stack VPC.

IPv4 VPC	IPv6 VPC
The format is 32-bit, 4 groups of up to 3 decimal digits.	The format is 128-bit, 8 groups of 4 hexadecimal digits.
The IPv4 addressing protocol is enabled for all VPCs by default.	The IPv6 addressing protocol is optional for a VPC.
The VPC Classless Inter-domain Routing (CIDR) block size can be from /8 to /24.	The VPC CIDR block size is fixed at /61.
The VSwitch CIDR block size can be from /16 to /29.	The VSwitch CIDR block size is fixed at /64.
You can choose the private IPv4 CIDR block for your VPC.	Apsara Stack automatically assigns an IPv6 CIDR block for your VPC from its IPv6 address pool.You cannot select your own range.

IPv4 VPC	IPv6 VPC
Supported on all instance types.	Not supported on certain instance types. For more information, see **Instance types** under **What is ECS** in the *Apsara Stack Elastic Compute Service User Guide*.
Elastic IPv4 addresses are supported.	Elastic IPv6 addresses are not supported.
VPN gateways and NAT gateways are supported.	VPN gateways and NAT gateways are supported.

By default, the IPv4 and IPv6 addresses provided for VPCs can only be used for communication within the private network. Resources in different VSwitches within a VPC communicate with one another over private network connections. To connect a VPC to another VPC or an on-premises data center, you need to configure Express Connect or VPN Gateway. .

To enable cloud resources in a VPC to access the Internet, set the following configurations:

- IPv4 communication

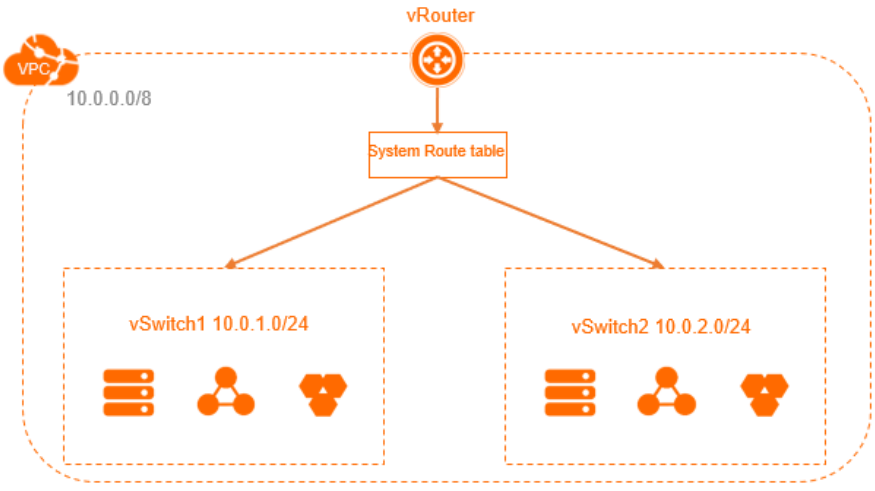
  You can configure a NAT gateway or associate elastic IP addresses (EIPs) to the Elastic Compute Service (ECS) instances in a VPC to allow these ECS instances to access the Internet by using IPv4 addresses.

- IPv6 communication

  To enable cloud resources in a VPC to access the Internet by using an IPv6 address, you must purchase public bandwidth for the IPv6 address. You can also configure an egress-only rule for an IPv6 address to allow outbound communication over IPv6 from instances in your VPC to the Internet, and prevent clients on the Internet from initiating IPv6 connections with your instances.

Routing

After a VPC is created, the system automatically creates a system route table and adds system routes to the route table for traffic management. Each VPC has only one system route table, which is generated automatically upon the creation of the VPC. You cannot create or delete system route tables.



If one destination address matches more than one route entry in a route table, the system selects an entry by implementing the longest prefix match algorithm, whereby the most specific of the matching entries, the one with the longest subnet mask, is used to route traffic. You can add a custom route entry to route traffic destined for a specific destination. For more information, see Add a custom route entry.

21.1.4.2. VPC management

21.1.4.2.1. Create a VPC

A virtual private cloud (VPC) is a private network dedicated for your use. You have full control over your VPC. For example, you can specify CIDR blocks, configure route tables and gateways for your VPC. You can deploy cloud resources in your own VPC, such as Elastic Compute Service (ECS) instances, ApsaraDB RDS instances, and Server Load Balancer (SLB) instances. This topic describes how to create a VPC.

Prerequisites

Before you create a VPC, you must plan your networks. For more information, see Plan networks.

Procedure

1. Log on to the VPC console.
2. In the top navigation bar, select the region where you want to deploy the VPC.

   > **Note** The VPC must be deployed in the same region as that of the cloud resources that you want to deploy in this VPC.

3. On the **VPC** page, click **Create VPC**.
4. On the **Create VPC** page, configure the VPC and click **OK**. The following table describes the parameters.

Parameter	Description
Organization	Select the organization to which the VPC belongs.
Resource Set	Select the resource set to which the VPC belongs.
Region	Select the region where your VPC is deployed.
Sharing Scope	Select the participants who can use the VPC to create resources. ○ **Current Resource Set**: Only the administrator of the current resource set can use the VPC to create resources. ○ **Current Organization and Subordinate Organization**: Only the administrators of the current organization and its subordinate organization can use the VPC to create resources. ○ **Current Organization**: Only the administrator of the current organization can use the VPC to create resources.
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

Parameter	Description
IPv4 CIDR Block	Select an IPv4 CIDR block for the VPC. The following setting are supported: ○ **Recommended CIDR Block**: You can use one of the following standard IPv4 CIDR blocks: 192.168.0.0/16, 172.16.0.0/12, and 10.0.0.0/8. ○ **Custom CIDR Block**: You can use 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or a subset of these CIDR blocks. The subnet mask must be 8 to 28 bits in length. For example, enter 192.168.0.0/24. **Note** After you create a VPC, you cannot change its IPv4 CIDR block.
IPv6 CIDR Block	Specify whether to assign an IPv6 CIDR block. ○ **Do Not Assign**: No IPv6 CIDR block will be assigned to the VPC. ○ **Assign**: An IPv6 CIDR block will be automatically assigned to the VPC. If you set this parameter to Assign, the system automatically creates a free IPv6 gateway for this VPC, and assigns an IPv6 CIDR block with the subnet mask /56, such as 2xx1: db8::/56. By default, IPv6 addresses can only be used to communicate within private networks. If you want to allow an instance assigned with an IPv6 address to access the Internet or be accessed by IPv6 clients over the Internet, you must purchase an Internet bandwidth plan for the IPv6 address. For more information, see the **Activate IPv6 Internet bandwidth** section of the **Manage IPv6 Internet bandwidth** topic of the *IPv6 gateway user guide*.
Description	Enter a description for the VPC. The description must be 2 to 256 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

21.1.4.2.2. Add a secondary IPv4 CIDR block

This topic describes how to expand a virtual private cloud (VPC) by adding a secondary IPv4 CIDR block to the VPC.

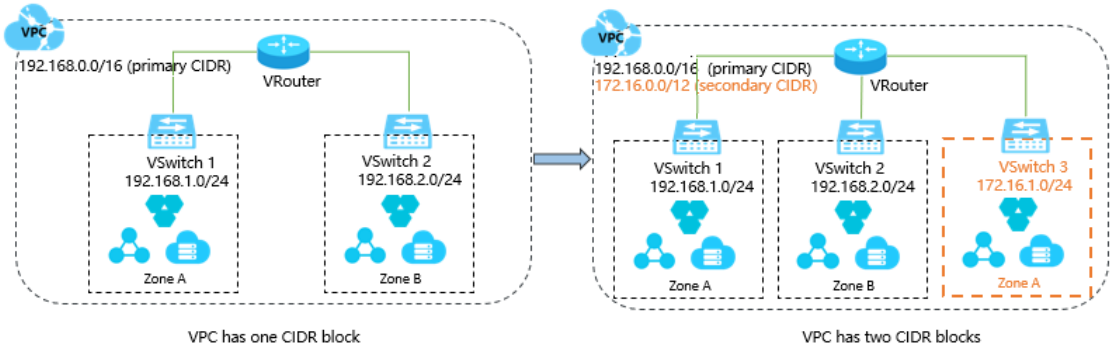
Prerequisites

A VPC is created. For more information, see Create a VPC.

Context

When you create a VPC, the IPv4 CIDR block you specified is the primary CIDR block. After the VPC is created, the primary IPv4 CIDR block of the VPC cannot be modified. However, you can add a secondary IPv4 CIDR block to expand the VPC. After you add the secondary IPv4 CIDR block, both the primary and secondary IPv4 CIDR blocks are in effect. You can create a vSwitch with the primary or a secondary IPv4 CIDR block. However, each vSwitch belongs to only one VPC CIDR block.

The system automatically adds a vSwitch route to the VPC route table when you create a vSwitch with the primary or a secondary IPv4 CIDR block. The destination CIDR block of a vSwitch route is the CIDR block with which the vSwitch is created. The CIDR block range cannot be the same as or larger than those of other routes in the route table of the VPC.



Note You can add only one secondary IPv4 CIDR block to a VPC and you cannot increase the quota.

Procedure

1. Log on to the VPC console.
2. In the top navigation bar, select the region where the VPC is deployed.
3. On the **VPC** page, find the VPC and click **Manage** in the **Actions** column.
4. On the **CIDRs** tab, click **Add IPv4 CIDR**.
5. In the **Add Secondary CIDR** panel, set the following parameters and click **OK**.

Parameter	Description
VPC	The VPC to which you want to add the secondary IPv4 CIDR block.
Secondary CIDR	Select a method to configure the secondary IPv4 CIDR block: ○ **Default CIDR Block**: You can specify one of the following standard IPv4 CIDR blocks as the secondary IPv4 CIDR block: 192.168.0.0/16, 172.16.0.0/12, and 10.0.0.0/8. ○ **Custom CIDR Block**: You can specify one of the following standard IPv4 CIDR blocks and their subnets as the secondary IPv4 CIDR block: 192.168.0.0/16, 172.16.0.0/12, and 10.0.0.0/8. When you add a secondary IPv4 CIDR block, take note of the following items: ○ The CIDR block cannot start with 0. The subnet mask must be 8 to 24 bits in length. ○ The secondary IPv4 CIDR block cannot overlap with the primary IPv4 CIDR block or or an existing secondary IPv4 CIDR block? For example, if the primary IPv4 CIDR block of a VPC is 192.168.0.0/16, you cannot specify one of the following CIDR blocks as a secondary IPv4 CIDR block: ■ A larger CIDR block that overlaps with 192.168.0.0/16, such as 192.168.0.0/8. ■ 192.168.0.0/16. ■ A smaller CIDR block that overlaps with 192.168.0.0/16, such as 192.168.0.0/24.

What's next

Work with vSwitches

21.1.4.2.3. Delete a secondary IPv4 CIDR block

This topic describes how to delete a secondary IPv4 CIDR block of a virtual private cloud (VPC). You cannot delete the primary IPv4 CIDR block of a VPC.

Prerequisites

Make sure that you have deleted the vSwitch that is created with the secondary IPv4 CIDR block. For more information, see Delete a vSwitch.

Procedure

1. Log on to the VPC console.
2. In the top navigation bar, select the region where the VPC is deployed.
3. On the **VPCs** page, find the VPC and click **Manage** in the **Actions** column.
4. On the **CIDRs** tab, find the secondary IPv4 CIDR block and click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

21.1.4.2.4. Modify the name and description of a VPC

This topic describes how to modify the name and description of a virtual private cloud (VPC).

Procedure

1. Log on to the VPC console.
2. In the top navigation bar, select the region where your VPC is deployed.
3. On the **VPCs** page, find the target VPC network and click **Manage** in the **Actions** column.
4. In the **VPC Details** section, click **Edit** next to **Name**. In the dialog box that appears, enter a new name for the VPC and click **OK**.

   The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), and hyphens (-). It must start with a letter or a Chinese character.
5. Click **Edit** next to **Description**. In the dialog box that appears, enter a new description, and click **OK**.

   The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.

21.1.4.2.5. Delete a VPC

This topic describes how to delete a virtual private cloud (VPC). After you delete a VPC, the VRouter and route tables associated with this VPC are also deleted.

Prerequisites

Before you delete a VPC, make sure that the following requirements are met:

- No VSwitch exists in the VPC. If the VPC has one or more VSwitches, we recommend that you delete the VSwitches first before deleting the VPC. For more information, see Delete a vSwitch.
- No IPv6 gateway is associated with the VPC. If the VPC is associated with an IPv6 gateway, we recommend that you delete the IPv6 gateway first before deleting the VPC.

Procedure

1. Log on to the VPC console.
2. In the top navigation bar, select the region where your VPC is deployed.
3. On the **VPCs** page, find the target VPC and click **Delete** in the **Actions** column.
4. In the **Delete VPC** dialog box, click **OK**.

21.1.4.3. VSwitch management

21.1.4.3.1. Create a vSwitch

A vSwitch is a basic network component in a virtual private cloud (VPC) and is used to connect cloud resources.

Context

After you create a VPC, you can create vSwitches to divide the VPC into one or more subnets. vSwitches within the same VPC can communicate with each other. Cloud resources must be deployed within the CIDR blocks of vSwitches. You can deploy applications in zones that are managed by different vSwitches to improve service availability.

> **Note** vSwitches do not support multicasting or broadcasting.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **vSwitches**.
3. Select the region of the VPC in which you want to create a vSwitch.
4. On the **vSwitches** page, click **Create vSwitch**.
5. On the **vSwitch** page, configure the vSwitch and click **OK**. The following table describes the parameters.

Parameter	Description
Organization	Select the organization to which the vSwitch belongs.
Resource Set	Select the resource set to which the vSwitch belongs.
Region	Select the region where you want to deploy the vSwitch.
Zone	Select the zone to which the vSwitch belongs. In a VPC, a vSwitch can belong to only one zone. However, you can deploy cloud resources in vSwitches that reside in different zones to achieve cross-zone disaster recovery. **Note** A cloud instance can be deployed in only one vSwitch.
Sharing Scope	Select the participants that can use the vSwitch to create resources. ○ **Current Resource Set**: Only the administrator of the current resource set can use the vSwitch to create resources. ○ **Current Organization and Subordinate Organization**: Only the administrators of the current organization and its subordinate organization can use the vSwitch to create resources. ○ **Current Organization**: Only the administrator of the current organization can use the vSwitch to create resources.
VPC	Select the VPC for which you want to create the vSwitch.
Dedicated for Out-of-cloud Physical Machines	Specify whether the vSwitch to be created is dedicated for bare-metal servers. For more information about bare-metal servers, see the **VPC bare-metal server features** topic in *BMS user guide*.

Parameter	Description
vSwitch Name	Enter a name for the vSwitch. The name must be 2 to 128 characters in length and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.
IPv4 CIDR Block	Enter an IPv4 CIDR block for the vSwitch. ○ You must specify the IP address range for the vSwitch in CIDR form. The CIDR block size for a vSwitch is between a 16-bit mask and a 29-bit mask. It means that 8 to 65,536 IP addresses can be provided. ○ The CIDR block of a vSwitch must be a subset of the CIDR block of the VPC network to which the vSwitch belongs. ○ The first and last three IP addresses of a vSwitch are reserved. For example, if the CIDR block of a vSwitch is 192.168.1.0/24, the IP addresses 192.168.1.0, 192.168.1.253, 192.168.1.254, and 192.168.1.255 are reserved. ○ The CIDR block of a vSwitch cannot be the same as the destination CIDR block in a route entry of the VPC to which the vSwitch belongs. However, the CIDR block of the vSwitch can be a subset of the destination CIDR block of the route entry. ○ After a vSwitch is created, you cannot modify its CIDR block.
IPv6 CIDR Block	Specify an IPv6 CIDR block for the vSwitch. ○ You must check whether IPv6 is enabled for the specified VPC. If not, you cannot assign an IPv6 CIDR block to the vSwitch. ○ If yes, you can enter a decimal number ranging from 0 to 255 to define the last 8 bits of the IPv6 CIDR block of the vSwitch. For example, if the IPv6 CIDR block of the VPC that contains the vSwitch is 2xx1:db8::/64, you can enter 255 (FF in the hexadecimal system) in this field to define the IPv6 CIDR block of the vSwitch as 2xx1:db8:ff::/64.
Description	Enter a description for the vSwitch. The description must be 2 to 256 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

21.1.4.3.2. Create cloud resources in a vSwitch

You cannot directly deploy cloud resources in a virtual private cloud (VPC). You can deploy cloud resources only in a vSwitch that belongs to a VPC. This topic describes how to create cloud resources in a vSwitch.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **vSwitches**.
3. Select the region of the VPC to which the vSwitch belongs.
4. On the **vSwitches** page, find the vSwitch, click **Create** in the **Actions** column, and select the cloud resource that you want to create.

   You can create Elastic Compute Service (ECS) instances, ApsaraDB RDS instances, and Server Load Balancer (SLB) instances in a vSwitch.
5. On the page that appears, set the parameters.

21.1.4.3.3. Modify the name and description of a VSwitch

This topic describes how to modify the name and description of a VSwitch.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **vSwitches**.
3. Select the region of the VPC in which you want to create a vSwitch.
4. On the **VSwitches** page, find the target VSwitch and click **Manage** in the **Actions** column.
5. In the **VSwitch Basic Information** section, click **Edit** next to **Name**. In the dialog box that appears, enter a new name for the VSwitch and click **OK**.

   The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), and hyphens (-). It must start with a letter or a Chinese character.
6. Click **Edit** next to **Description**. In the dialog box that appears, enter a new description for the VSwitch and click OK.

   The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.

21.1.4.3.4. Delete a vSwitch

This topic describes how to delete a vSwitch. After you delete a vSwitch, you cannot deploy cloud resources in it.

Prerequisites

Before you delete a vSwitch, make sure that the following conditions are met:

- You have deleted all the resources deployed in the vSwitch, such as Elastic Compute Service (ECS) instances, Server Load Balancer (SLB) instances, and ApsaraDB RDS instances.
- You have deleted all the resources associated with the vSwitch, such as high-availability virtual IP addresses (HAVIPs) and Source Network Address Translation (SNAT) entries.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **vSwitches**.
3. Select the region of the VPC in which you want to create a vSwitch.
4. On the **vSwitch** page, find the vSwitch and click **Delete** in the **Actions** column.
5. In the **Delete vSwitch** dialog box, click **OK**.

21.1.5. Route tables

21.1.5.1. Overview

Routes and route tables

Each virtual private cloud (VPC) comes with a default route table pre-configured with system route entries that direct traffic flowing in and out of the VPC. You cannot create or delete system route entries. However, you can create custom route entries to route traffic destined for specific Classless Inter-domain Routing (CIDR) blocks to the destinations that you define.

Route tables

When you create a VPC, it automatically has a system route table that controls the routing for all VSwitches (subnets) within the VPC by default. You cannot create or delete the system route table of a VPC.

Each *route entry* in the route table defines a route that is used to direct traffic, and consists of multiple fields, including the destination CIDR block, the next hop for the traffic, and the type of the next hop. Route entries are classified into system route entries and custom route entries.

System routes

After you create a VPC, the system automatically adds the following system routes to the route table:

- A route entry with a destination CIDR block of 100.64.0.0/10. This route is used for communication among cloud resources within the VPC.
- Route entries with destination CIDR blocks same as the CIDR blocks of the VSwitches in this VPC. Such routes are used for communication among cloud resources within VSwitches.

For example, if you create a VPC and specify 192.168.0.0/16 as its CIDR block, and then create two VSwitches whose CIDR blocks are 192.168.1.0/24 and 192.168.0.0/24, three system routes listed in the following table are automatically added to the route table of the VPC.

Destination CIDR block	Next hop	Route entry type
100.64.0.0/10	-	System route
192.168.1.0/24	-	System route
192.168.0.0/24	-	System route

Custom routes

You can add custom routes to replace system routes or route traffic to specified destinations. You can specify the following next hop types when you create a custom route:

- ECS instance: Traffic destined for the destination CIDR block is forwarded to a specified Elastic Compute Service (ECS) instance in the VPC.

  You can select this type if you want to access the Internet or other applications through the applications deployed on an ECS instance.
- VPN gateway: Traffic destined for the destination CIDR block is forwarded to a specified VPN gateway.

  You can select this type if you want to connect a VPC to another VPC or a local network through a VPN connection.
- NAT gateway: Traffic destined for the destination CIDR block is forwarded to a specified NAT gateway.

  You can select this type if you want to connect a VPC to the Internet by using a NAT gateway.
- Router interface (to VPC): Traffic destined for the destination CIDR block is forwarded to a specified VPC.

  You can select this type if you want to connect two VPCs by using Express Connect.
- Router interface (to VBR): Traffic destined for the destination CIDR block is forwarded to a specified Virtual Border Router (VBR).

  You can select this type if you want to connect a VPC to an on-premises network by using Express Connect.
- Secondary ENI: Traffic destined for the destination CIDR block is forwarded to a specified secondary Elastic Network Interface (ENI).

IPv6 routes

If IPv6 is enabled for your VPC, the following route entries are automatically added to the system route table of the VPC:

- A custom route entry with a destination CIDR block of ::/0 and whose next hop is the IPv6 gateway. This route is used to direct traffic between the cloud resources deployed in the VPC and the Internet by using IPv6 addresses.

- System route entries whose destination CIDR blocks are the IPv6 CIDR blocks of the VSwitches in the VPC. Such routes are used for communication within the VSwitches.

Routing rules

If one destination address matches more than one route entry in a route table, the system selects an entry by implementing the longest prefix match algorithm, whereby the most specific of the matching entries, the one with the longest subnet mask, is used to route traffic.

The following table describes a route table of a VPC.

Destination CIDR block	Next hop type	Next hop	Route entry type
100.64.0.0/10	-	-	System route
192.168.0.0/24	-	-	System route
0.0.0.0/0	Instance	i-12345678	Custom route
10.0.0.0/24	Instance	i-87654321	Custom route

As shown in the preceding table, the route entries destined for `100.64.0.0/10` and `192.168.0.0/24` are system route entries, and the two destined for `0.0.0.0/0` and `10.0.0.0/24` are custom route entries. Traffic destined for `0.0.0.0/0` is forwarded to the ECS instance `i-12345678`, and traffic destined for `10.0.0.0/24` is forwarded to the ECS instance `i-87654321`. According to the longest prefix match algorithm, traffic destined for `10.0.0.1` is forwarded to the ECS instance `i-87654321`, and traffic destined for `10.0.1.1` is forwarded to the ECS instance `i-12345678`.

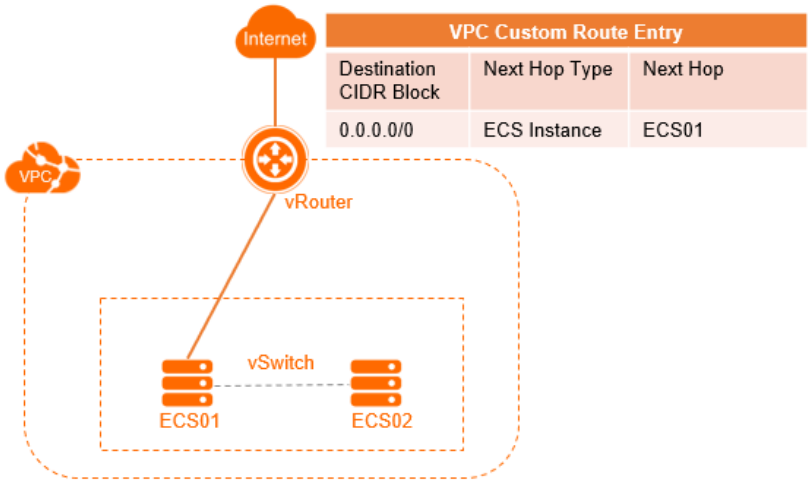
Routing examples

You can add custom route entries to a route table to control inbound and outbound traffic for a VPC.

- Routing within a VPC

  As shown in the following figure, a NAT gateway is deployed on an ECS instance (ECS01) in a VPC. To enable the cloud resources in this VPC to access the Internet by this ECS instance, you can add the following route entry to the route table.

Destination CIDR block	Next hop type	Next hop
0.0.0.0/0	ECS instance	ECS01



- Connect two VPCs by using Express Connect

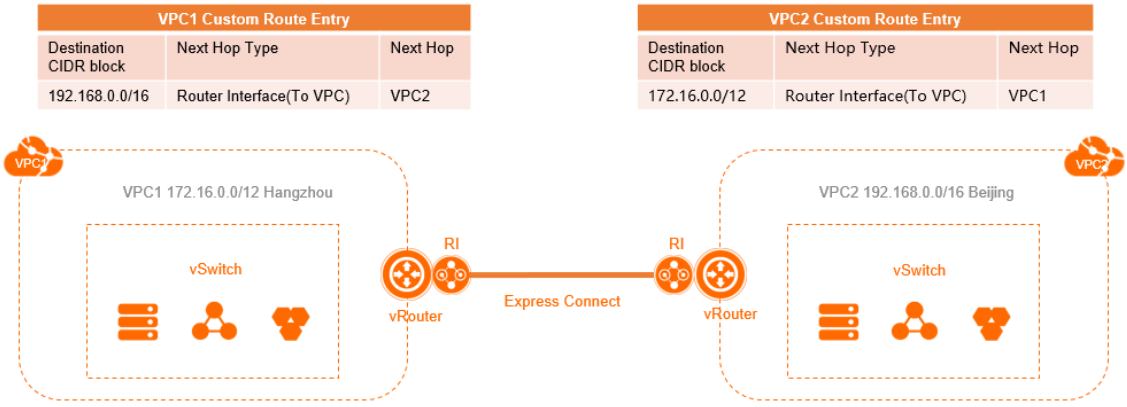
  As shown in the following figure, VPC1 (172.16.0.0/12) needs to be connected to VPC2 (192.168.0.0/16) by using Express Connect. After you create router interfaces for interconnection, you must add the following route entries in the route table of each VPC respectively.

  - VPC1

Destination CIDR block	Next hop type	Next hop
192.168.0.0/16	Router interface (to VPC)	VPC2

  - VPC2

Destination CIDR block	Next hop type	Next hop
172.16.0.0/12	Router interface (to VPC)	VPC1



- Connect two VPCs by using VPN gateways

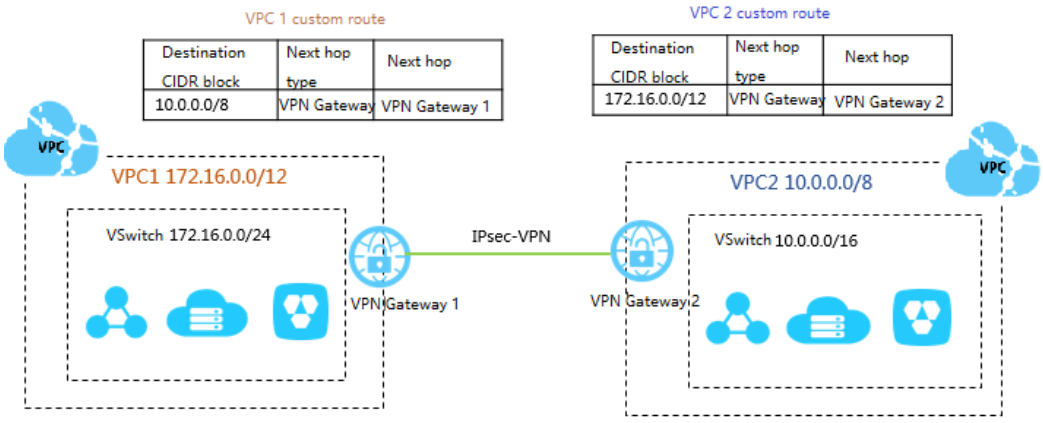
  As shown in the following figure, VPC1 (172.16.0.0/12) needs to be connected to VPC2 (10.0.0.0/8) with VPN gateways. After you configure the VPN gateways, you must add the following route entries in the route table of each VPC respectively.

- VPC1

Destination CIDR block	Next hop type	Next hop
10.0.0.0/8	VPN gateway	VPN gateway 1

- VPC2

Destination CIDR block	Next hop type	Next hop
172.16.0.0/12	VPN gateway	VPN gateway 2



- Connect a VPC to an on-premises data center by using Express Connect

  As shown in the following figure, a VPC needs to be connected to an on-premises data center by using Express Connect. After you configure an Express Connect circuit and a VBR, you must add the following route entries for related networks and devices:

  - VPC

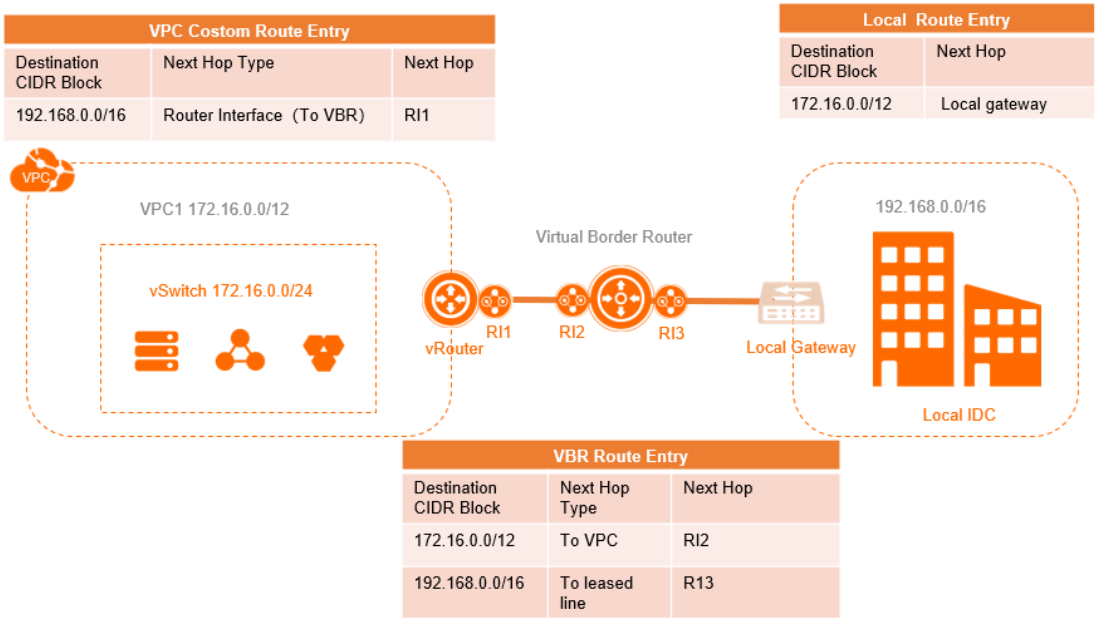
Destination CIDR block	Next hop type	Next hop
192.168.0.0/16	Router interface (general routing)	Router interface RI1

  - VBR

Destination CIDR block	Next hop type	Next hop
192.168.0.0/16	To the Express Connect circuit	Router interface RI3
172.16.0.0/12	To VPC	Router interface RI2

- On-premises network

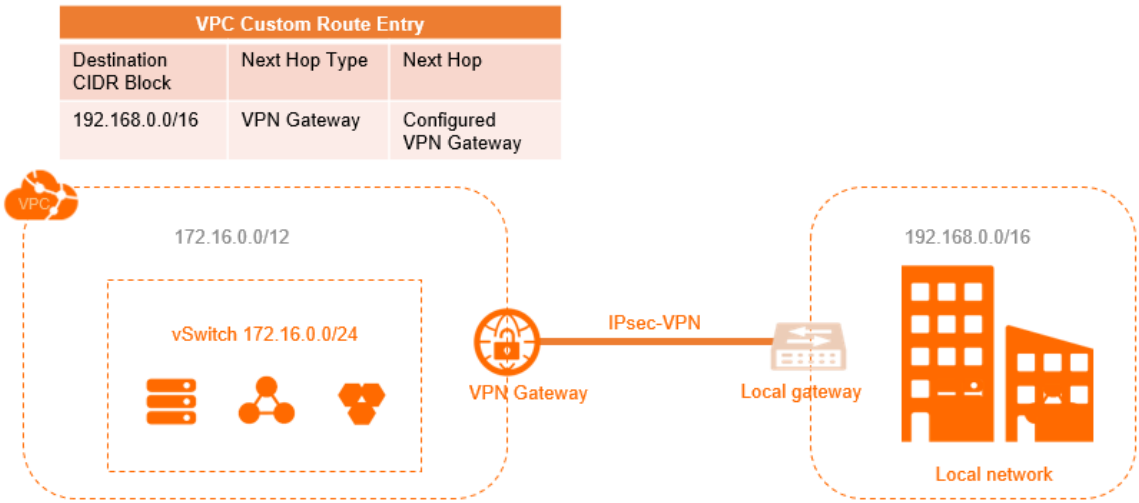
Destination CIDR block	Next hop type	Next hop
172.16.0.0/12	-	A specified local gateway device



- Connect a VPC to an on-premises data center by using VPN gateways

  As shown in the following figure, a VPC (172.16.0.0/12) needs to be connected to an on-premises data center (192.168.0.0/16). After you configure the VPN gateway, you must add the following route entry to the route table of the VPC.

Destination CIDR block	Next hop type	Next hop
192.168.0.0/16	VPN gateway	A specified VPN gateway



21.1.5.2. Add a custom route entry

This topic describes how to add a custom route entry. After you create a virtual private cloud (VPC), the system creates a default route table and adds system route entries to the route table for traffic management. You cannot create or delete system route entries. However, you can create custom route entries to route traffic from source CIDR blocks to specific destinations.

Context

Each item in the route table is a route entry. A route entry, which specifies the destination for network traffic, consists of the destination CIDR block, next hop type, and next hop. Route entries are classified into system route entries and custom route entries.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route table belongs.
4. On the **Route Tables** page, find the route table and click **Manage** in the **Actions** column.
5. In the **Route Table Details** section, click **Add Route Entry**.
6. In the **Add Route Entry** panel, set the following parameters and click **OK**.

Parameter	Description
Name	Enter a name for the route entry. The name must be 2 to 128 characters and can contain digits, underscores (_), and hyphens (-). The name must start with a letter.
Destination CIDR Block	Enter a destination CIDR block for the route entry.

Parameter	Description
Next Hop Type	Select the next hop type. Valid values: ○ **ECS Instance**: Traffic destined for the specified CIDR block is routed to the specified Elastic Compute Service (ECS) instance. Select this type if you want to route traffic to an ECS instance for centralized traffic forwarding and management. For example, when an ECS instance is configured as the public-facing gateway to manage the traffic from other ECS instances to the Internet. ○ **HaVip Address**: Traffic destined for the specified CIDR block is routed to the specified high-availability virtual IP address (HAVIP). ○ **VPN Gateway**: Traffic destined for the specified CIDR block is routed to the specified VPN gateway. ○ **NAT Gateway**: Traffic destined for the specified CIDR block is routed to the specified NAT gateway. ○ **Secondary ENI**: Traffic destined for the specified CIDR block is routed to the specified secondary elastic network interface (ENI). ○ **Router Interface (To VPC)**: Traffic destined for the specified CIDR block is routed to the specified VPC. Select this type if you want to connect VPCs through Express Connect. ○ **Router Interface (To VBR)**: Traffic destined for the specified CIDR block is routed to the router interface that is associated with a virtual border router (VBR). Select this type if you want to connect the VPC to a data center through Express Connect. If you select Router Interface (To VBR), you must also select a routing mode: ■ **General Routing**: Select an associated router interface. ■ **Active/Standby Routing**: Select two instances as the next hop. The active route has a weight of 100 and the standby route has a weight of 0. The standby route takes over when the active route fails the health check. ■ **Load Balancing**: Select two to four router interfaces as the next hop. The peer router of each router interface must be a VBR. Valid values of the instance weight: 1 to 255. The value must be an integer and the default value is 100. The weights of the selected instances must be the same. This way, traffic can be evenly distributed to the next-hop instances.
ECS Instance/VPN Gateway/NAT Gateway/Secondary ENI/HAVIP/VPC	Select the next hop instance.

21.1.5.3. Export route entries

This topic describes how to export route entries from a route table for backup.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route table belongs.
4. On the **Route Tables** page, find the route table and click **Manage** in the **Actions** column.

5. In the **Route Table Details** section, click the **Route Entry List** tab, and then click **Export**.

   The route entries are exported to a *.csv* file in your local computer.

21.1.5.4. Modify a route table

This topic describes how to modify the name and description of a route table.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route table belongs.
4. On the **Route Tables** page, find the route table and click its ID.
5. In the **Route Table Details** section, click **Edit** next to **Name**. In the dialog box that appears, enter a new name for the route table and click **OK**.

   The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), and hyphens (-). It must start with a letter or a Chinese character.
6. Click **Edit** next to **Description**. In the dialog box that appears, enter a new description of the route table, and click **OK**.

   The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.

21.1.5.5. Delete a custom route entry

This topic describes how to delete a custom route entry. A route table consists of one or more route entries that determine which way to forward traffic. Note that system route entries cannot be deleted.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route table belongs.
4. On the **Route Tables** page, find the route table and click its ID.
5. On the **Route Entry List** tab, find the target route entry and then click **Delete** in the **Actions** column.
6. In the **Delete Route Entry** dialog box, click **OK**.

21.1.6. HAVIPs

21.1.6.1. Overview

High-availability virtual IP addresses (HAVIPs) are private IP addresses that can be created and released as independent resources. You can use HAVIPs with high-availability (HA) software such as Keepalived to provide active/standby services. This improves the availability of your services.

Features

Each Elastic Compute Service (ECS) instance is assigned a private IP address as the primary IP address. If you want the ECS instance to use more than one private IP address, you can associate HAVIPs with the ECS instance. Both the primary IP address and HAVIPs of an ECS instance can be used to access networks. In addition, you can use HAVIPs with HA software such as Keepalived to provide active/standby services. This improves the availability of your services. You can associate an HAVIP with ECS instances in the following ways:

- Directly associate an HAVIP with ECS instances.

Each HAVIP can be associated with two ECS instances. After an HAVIP is associated with ECS instances, the ECS instances can send Address Resolution Protocol (ARP) messages to advertise the HAVIP. After the ECS instances advertise the HAVIP, one of the ECS instances serves as the primary instance, and the other ECS instance serves as the secondary instance. If the primary ECS instance is down, the secondary ECS instance takes over to provide services.

- Attach a secondary elastic network interface (ENI) to each ECS instance. Then, associate an HAVIP with the secondary ENIs.

  Each HAVIP can be associated with two ECS instances. After an HAVIP is associated with ECS instances, the ECS instances can send ARP messages to advertise the HAVIP. After the ECS instances advertise the HAVIP, one of the ECS instances serves as the primary instance, and the other ECS instance serves as the secondary instance. If the primary ECS instance is down, the secondary ECS instance takes over to provide services.

  > **Note** Before you associate an HAVIP with secondary ENIs, make sure that the secondary ENIs are attached to different ECS instances.

HAVIPs have the following features:

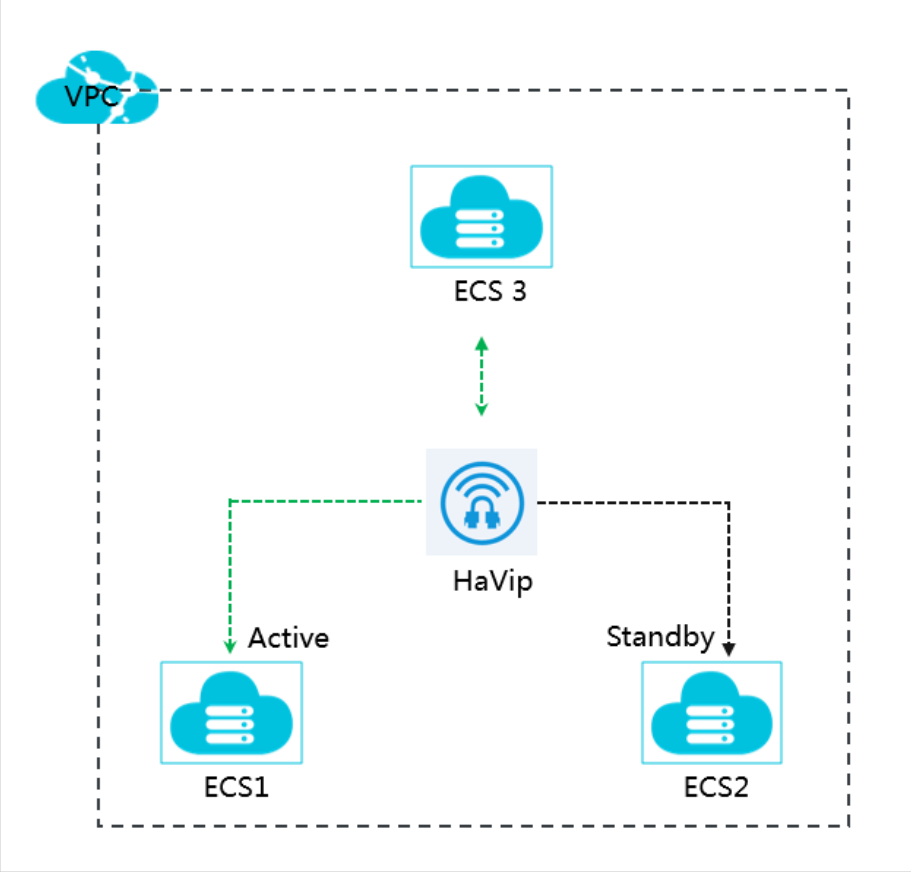
- HAVIPs are floating private IP addresses and are not statically assigned to ECS instances. HAVIPs can be associated with or disassociated from ECS instances through ARP announcements.
- You must associate HAVIPs with ECS instances or secondary ENIs within the same vSwitch. This means that the ECS instances or secondary ENIs must belong to the same subnet.
- You can associate each HAVIP with two ECS instances or two secondary ENIs. However, you cannot associate an HAVIP with an ECS instance and a secondary ENI.

Scenarios

HAVIPs can be used in different ways to meet the requirements of diverse scenarios:

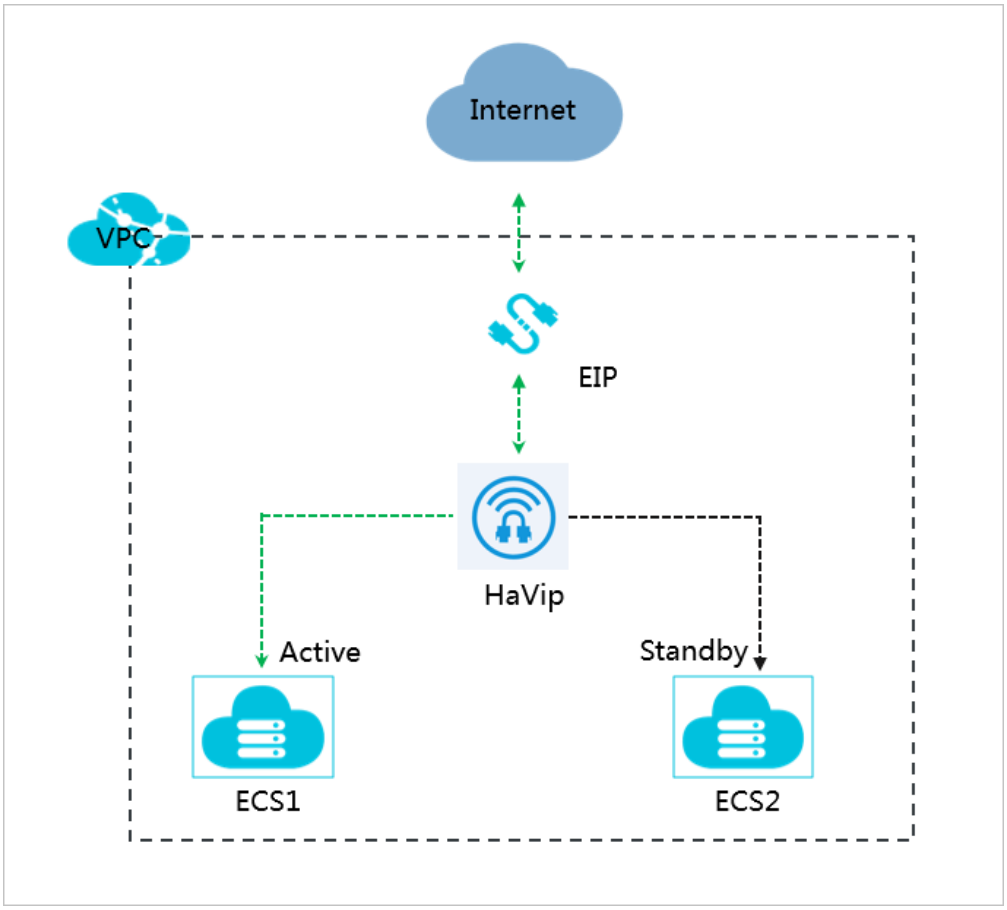
- Scenario 1: Private network-facing HA services

  In the following figure, two ECS instances are assigned the same HAVIP. Keepalived is configured for the ECS instances to provide a private network-facing HA service. Other instances in the same virtual private cloud (VPC) can access this service over the private network. The HAVIP functions as the service address. If the primary ECS instance is down, the secondary ECS instance takes over. This improves the availability of your services.



- Scenario 2: Internet-facing HA services

  In the following figure, two ECS instances are assigned the same HAVIP. Keepalived is configured and the HAVIP is associated with an elastic IP address (EIP) for the ECS instances to provide an Internet-facing HA service. The EIP that is associated with the HAVIP functions as the service address. If the primary ECS instance is down, the secondary ECS instance takes over. This improves the availability of your services.



Limits

Before you use HAVIPs, take note of the following limits:

Item	Default limit
Number of HAVIPs that can be created in each VPC	5
Number of HAVIPs that can be associated with each ECS instance	5
Number of HAVIPs that can be associated with each ENI	5
Number of ECS instances that can be associated with each HAVIP	2
Number of ENIs that can be associated with each HAVIP	2
Number of route entries destined for an HAVIP in each VPC	5

Item	Default limit
Whether HAVIPs support broadcast or multicast communication	Not supported **Note** HAVIPs support only unicast. To implement high availability through third-party software such keepalived, you must modify the configuration file to change the communication method to unicast.

21.1.6.2. Create HAVIPs

High-availability virtual IP addresses (HAVIPs) are private IP addresses that can be created and released as independent resources. This topic describes how to create HAVIPs in the console.

Prerequisites

A VPC and vSwitches are created. For more information, see Create a VPC and Work with vSwitches.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top menu bar, select the region where you want to create the HAVIP.
4. On the **HaVip** page, click **Create HaVip**.
5. On the **Create a high-availability virtual IP address** page, set the following parameters and click **Submitted** to create an HAVIP.

Parameter	Description
Tissue	Select the organization to which the HAVIP belongs.
Resource Set	Select the resource set to which the HAVIP belongs.
Region	Select the region where you want to create the HAVIP.
Proprietary Network vpc	Select the VPC to which the HAVIP that you want to create belongs.
vswitch	Select the vSwitch to which the HAVIP that you want to create belongs.
Private IP Address	Specify a private IP address for the HAVIP. **Note** You must specify an idle private IP address that falls within the CIDR block of the vSwitch.

21.1.6.3. Associate HAVIPs with backend cloud resources

21.1.6.3.1. Associate HAVIPs with ECS instances

This topic describes how to associate high-availability virtual IP addresses (HAVIPs) with Elastic Compute Service (ECS) instances that are deployed in virtual private clouds (VPCs). After you associate an HAVIP with an ECS instance, the ECS instance can send Address Resolution Protocol (ARP) messages to advertise the HAVIP. This way, the ECS instance can use more than one private IP address. Each HAVIP can be associated with at most two ECS instances.

Prerequisites

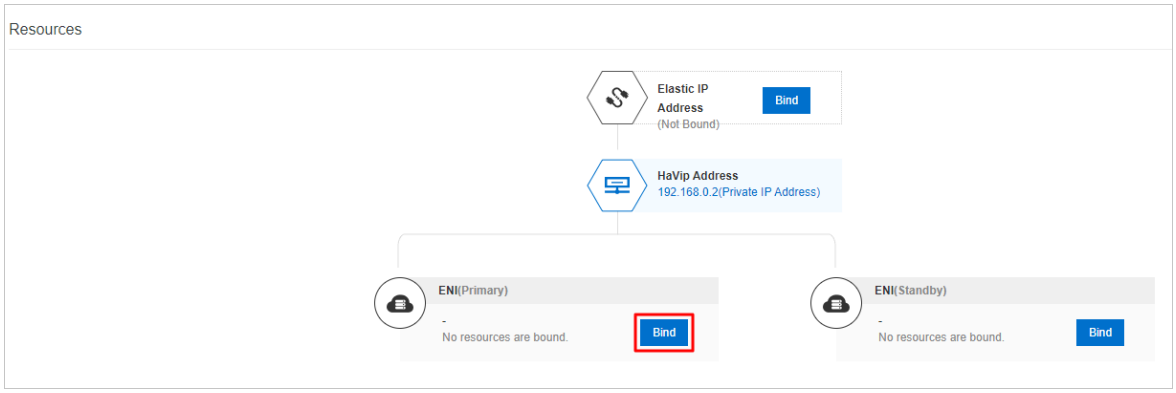
An ECS instance is created. For more information, see in the **Create an ECS instance** topic in **Quick Start** of *Elastic Compute Service User Guide*.

Context

You can associate an HAVIP with two ECS instances or two secondary ENIs. However, you cannot associate an HAVIP with an ECS instance and a secondary ENI.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top menu bar, select the region where the HAVIP is created.
4. On the **HaVip Addresses** page, find the HAVIP that you want to manage and click **Manage** in the **Actions** column.
5. In the **Resources** section, find **ENI (Primary)** or **ENI (Standby)** and click **Bind**.



6. In the dialog box that appears, set the following parameters to associate the HAVIP with an ECS instance.

Parameter	Description
Resource Type	Select the type of resource with which you want to associate the HAVIP. Supported resource types are: ○ **ECS Instance** ○ **Secondary ENI** In this example, **ECS Instance** is selected.
Bind Resource	Select the ECS instance with which you want to associate the HAVIP. The ECS instance that you select must meet the following requirements: ○ The ECS instance is deployed in a VPC. ○ The ECS instance and the HAVIP belong to the same vSwitch.

7. Click **OK**.

21.1.6.3.2. Associate an HAVIP with a secondary ENI

This topic describes how to associate a high-availability virtual IP address (HAVIP) with secondary ENIs that are attached to Elastic Compute Service (ECS) instances. Then, the ECS instances can send Address Resolution Protocol (ARP) messages to advertise the HAVIP. This way, the ECS instances can use more than one private IP address.

Prerequisites

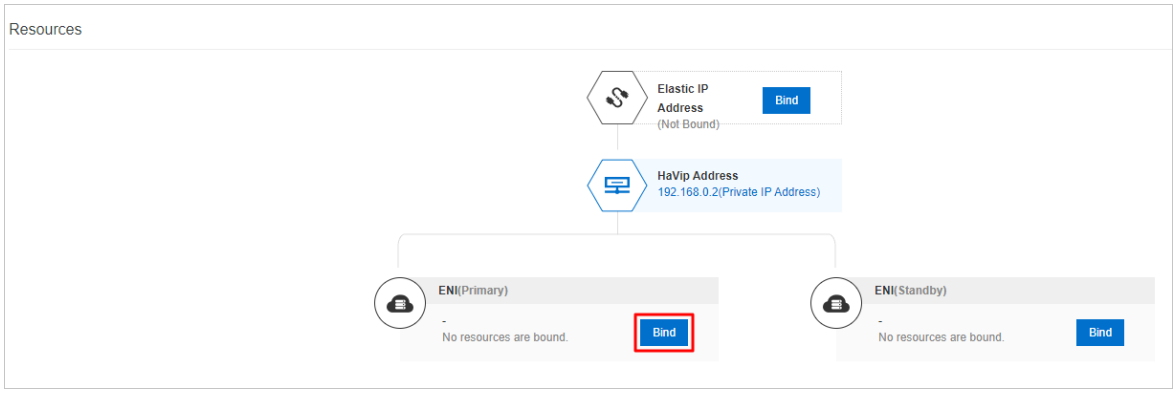
Secondary ENIs are created. For more information, see the **Create an Elastic Network Interface** topic in the **Elastic Network Interface** chapter of *Elastic Compute Service User Guide*.

Context

You can associate each HAVIP with two ECS instances or two secondary ENIs. However, you cannot associate an HAVIP with an ECS instance and a secondary ENI.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top navigation bar, select the region where the HAVIP is created.
4. On the **HaVip Details** page, find the HAVIP that you want to manage and click **Manage** in the **Actions** column.
5. In the **Resources** section, find **ENI (Primary)** or **ENI (Standby)** and click **Bind**.



6. In the dialog box that appears, set the following parameters to associate an HAVIP with a secondary ENI.

Parameter	Description
Resource Type	Select the type of resource with which you want to associate the HAVIP. Supported types of resources are: ○ **ECS Instances** ○ **Secondary ENI** In this example, **Secondary ENI** is selected.
Bind Resource	Select the secondary ENI with which you want to associate the HAVIP. The secondary ENI and the HAVIP must belong to the same vSwitch.

7. Click **OK**.

21.1.6.4. Associate HAVIPs with EIPs

This topic describes how to associate high-availability virtual IP addresses (HAVIPs) with elastic IP addresses (EIPs). After you associate an HAVIP with an EIP, the HAVIP can use the EIP to provide services over the Internet.

Prerequisites

An EIP is created. For more information, see **Create an EIP** in **Quick Start** of the *Elastic IP Address User Guide*.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top menu bar, select the region where the HAVIP is created.
4. On the **HaVip Addresses** page, find the HAVIP that you want to manage, and choose **More > Bind EIP Address** in the **Actions** column.
5. In the dialog box that appears, select the EIP with which you want to associate the HAVIP and click **OK**.

   The EIP with which you want to associate the HAVIP must meet the following requirements:

   - The EIP and HAVIP are created in the same region.
   - The EIP must be in the Available state.

21.1.6.5. Disassociate HAVIPs from backend cloud resources

21.1.6.5.1. Disassociate HAVIPs from ECS instances

This topic describes how to disassociate high-availability virtual private IP addresses (HAVIPs) from Elastic Compute Service (ECS) instances. After you disassociate an HAVIP from an ECS instance, the ECS instance cannot send Address Resolution Protocol (ARP) messages to advertise the HAVIP.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top menu bar, select the region where the HAVIP is created.
4. On the **HaVip** page, find the HAVIP that you want to manage and click **Manage** in the **Actions** column.
5. In the **Resources** section, find the ECS instance that you want to manage and click **Unbind**.
6. In the message that appears, click **OK**.

21.1.6.5.2. Disassociate HAVIPs from secondary ENIs

This topic describes how to disassociate high-availability IP addresses (HAVIPs) from secondary elastic network interfaces (ENIs). After you disassociate an HAVIP from a secondary ENI, the Elastic Compute Service (ECS) instance with which the secondary ENI is attached cannot send Address Resolution Protocol (ARP) messages to advertise the HAVIP.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top menu bar, select the region where the HAVIP is created.
4. On the **HaVip** page, find the HAVIP that you want to manage and click **Manage** in the **Actions** column.

5. In the **Resources** section, find the secondary ENI that you want to manage and click **Unbind**.
6. In the message that appears, click **OK**.

21.1.6.6. Disassociate an EIP from an HAVIP

This topic describes how to disassociate a high-availability virtual IP address (HAVIP) from an elastic IP address (EIP). After the disassociation, you can no longer use the HAVIP to provide your instances with Internet access.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip Addresses**.
3. Select the region of the HAVIP.
4. On the **HaVip Addresses** page, find the target HAVIP and then choose **More > Unbind with EIP** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

21.1.6.7. Delete HAVIPs

This topic describes how to delete a high-availability virtual IP address (HAVIP) that you no longer need.

Prerequisites

- The HAVIP that you want to delete is not associated with an elastic IP address (EIP). If the HAVIP that you want to delete is associated with an EIP, disassociate the HAVIP from the EIP first. For more information, see Disassociate HAVIPs from EIPs.
- The HAVIP that you want to delete is not associated with an Elastic Compute Service (ECS) instance. If the HAVIP that you want to delete is associated with an ECS instance, disassociate the HAVIP from the ECS instance. For more information, see Disassociate an HAVIP from an ECS instance.
- The HAVIP that you want to delete is not associated with a secondary elastic network interface (ENI). If the HAVIP that you want to delete is associated with a secondary ENI, disassociate the HAVIP from the secondary ENI first. For more information, see Disassociate HAVIPs from secondary ENIs.

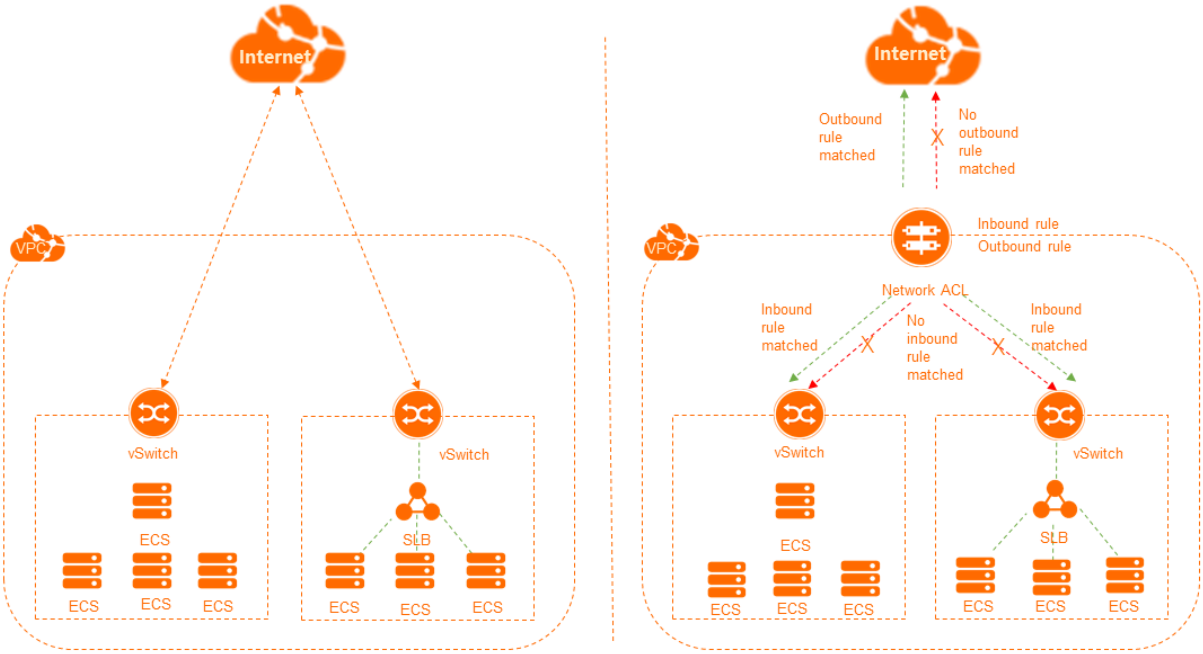
Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top navigation bar, select the region where the HAVIP is created.
4. On the **HaVip** page, find the HAVIP that you want to manage and choose **More > Delete** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

21.1.7. Network ACLs

21.1.7.1. Overview

Network access control lists (ACLs) provided by Virtual Private Cloud (VPC) allow you to manage network access permissions. You can create network ACL rules and associate a network ACL with a vSwitch. This allows you to control inbound and outbound traffic of Elastic Compute Service (ECS) instances that are associated with the vSwitch.



Features

Network ACLs have the following features:

- A network ACL is used to filter inbound and outbound network traffic of ECS instances that are associated with a vSwitch in a VPC. The network traffic forwarded to ECS instances by Server Load Balancer (SLB) instances is also filtered.
- Network ACLs are stateless. You must set both inbound and outbound rules. Otherwise, the system may fail to respond to requests.
- If you create a network ACL that does not contain any rule, all inbound and outbound access are rejected.
- If a network ACL is associated with a vSwitch, the network ACL does not filter the traffic forwarded between ECS instances that are associated with the vSwitch.

Rule descriptions

You can add rules to or delete rules from a network ACL. Changes to the rules are automatically synchronized to the associated vSwitch. By default, an inbound and outbound rule are automatically added to a newly created network ACL. These rules allow all inbound and outbound network traffic transmitted through the associated vSwitch. You can delete the default rules. The following table lists the default inbound and outbound rules.

- Default inbound rule

Priority	Protocol type	Source CIDR block	Destination port range	Action	Type
1	all	0.0.0.0/0	-1/-1	Allow	Custom

- Default outbound rule

Priority	Protocol type	Destination CIDR block	Destination port range	Action	Type
1	all	0.0.0.0/0	-1/-1	Allow	Custom

A network ACL contains the following parameters:

- Priority: A smaller value indicates a higher priority. The system compares traffic requests with rules in

descending order of priority starting from the rule whose priority is 1. If a request meets a rule, the system applies the rule to the request and ignores the other rules.

For example, the following rules are added and requests destined for IP address 172.16.0.1 are sent from an ECS instance. In the following table, the requests meet Rules 2 and 3. Rule 2 has a higher priority than Rule 3. Therefore, the system applies Rule 2. Based on the action of Rule 2, the requests are denied.

Priority	Protocol type	Destination CIDR block	Destination port range	Action	Type
1	all	10.0.0.0/8	-1/-1	Allow	Custom
2	all	172.16.0.0/12	-1/-1	Deny	Custom
3	all	172.16.0.0/12	-1/-1	Allow	Custom

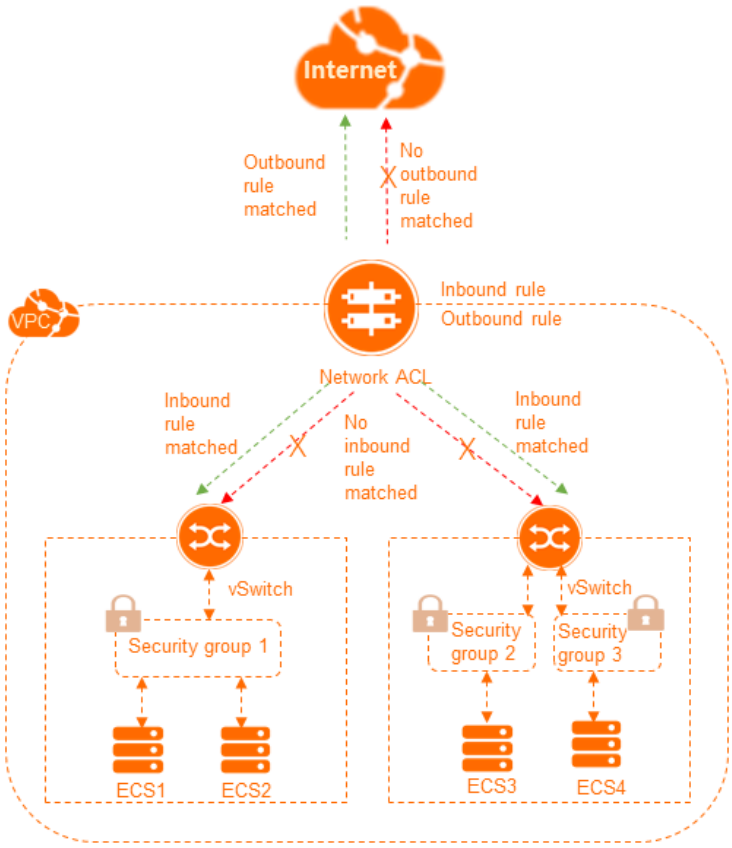
- Policy: indicates whether to allow or deny specific traffic.
- Protocol: the protocol type. Valid values: All, ICMP, GRE, TCP, and UDP.
- Source CIDR block: the source CIDR block from which inbound traffic is transmitted.
- Destination CIDR block: the destination CIDR block to which outbound traffic is transmitted.
- Destination port range: the range of destination ports to which the inbound rule applies.
- Destination port range: the range of destination ports to which the outbound rule applies.

Comparison between network ACLs and security groups

Network ACLs control data transmitted through associated vSwitches while security groups control data transmitted through associated ECS instances. The following table lists the differences between network ACLs and security groups.

Network ACL	Security group
Applied to vSwitches.	Applied to instances.
Stateless: Returned traffic must be allowed by rules.	Stateful: Returned traffic is automatically allowed and not affected by any rule.
The system compares traffic requests with rules in descending order of priority. Not all rules are compared.	All rules are compared before a rule is applied.
Each vSwitch can be associated with only one network ACL.	Each ECS instance can be added to more than one security group.

The following figure shows how network ACLs and security groups are applied to ensure network security.



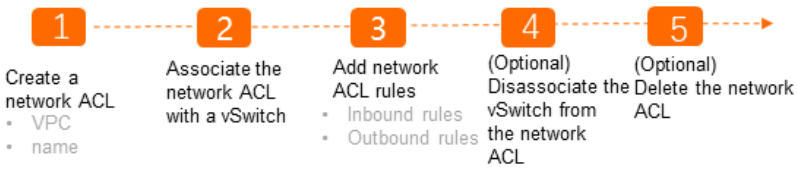
Limits

Before you use network ACLs, take note of the following limits.

Item	Default limit
Number of network ACLs that can be created in each VPC	200
Number of network ACLs that can be associated with each vSwitch	1
Number of rules that can be added to a network ACL	• Inbound rules: 20 • Outbound rules: 20

Procedure

The following flowchart shows how to use a network ACL.



21.1.7.2. Scenarios

If you are familiar with the ports that are commonly used by ECS instances, you can specify them in access control list (ACL) rules to facilitate precise network traffic filtering. This topic describes the ports that are commonly used by ECS instances and the application scenarios of these ports.

Ports

The following table lists the ports and the services that use these ports.

Port	Service	Description
21	FTP	The FTP port. It is used to upload and download files.
22	SSH	The SSH port. It is used to log on to Linux instances in the command line method by using username and password pairs.
23	Telnet	The Telnet port. It is used to remotely log on to ECS instances.
25	SMTP	The SMTP port. It is used to send emails.
80	HTTP	The HTTP port. It is used to access services such as IIS, Apache, and NGINX.
110	POP3	The POP3 port. It is used to send and receive emails.
143	IMAP	The Internet Message Access Protocol (IMAP) port. It is used to receive emails.
443	HTTPS	The HTTPS port. It is used to access services. The HTTPS protocol can implement encrypted and secure data transmission.
1433	SQL Server	The TCP port of SQL Server. It is used for SQL Server to provide external services.
1434	SQL Server	The UDP port of SQL Server. It is used to return the TCP/IP port occupied by SQL Server.
1521	Oracle	The Oracle communication port. ECS instances that run Oracle SQL must have this port open.
3306	MySQL	The MySQL port. It is used for MySQL databases to provide external services.
3389	Windows Server Remote Desktop Services	The Windows Server Remote Desktop Services port. It is used to log on to a Windows instance.
8080	Proxy port	An alternative to port 80. It is commonly used for WWW proxy services.

Custom network ACLs

Inbound rules and Outbound rules describe a network ACL example for VPCs that support IPv4 addresses only.

- The inbound rules in effective order 1, 2, 3, and 4 respectively allow HTTP, HTTPS, SSH, and RDP traffic to the vSwitch. Outbound response rules are those in effective order 3.
- The outbound rules in effective order 1 and 2 respectively allow HTTP and HTTPS traffic from the vSwitch. Outbound response rules are those in effective order 5.
- The inbound rule in effective order 6 denies all inbound IPv4 traffic. This rule ensures that packets that do not match any other rules are denied.
- The outbound rule in effective order 4 denies all outbound IPv4 traffic. This rule ensures that packets that do

not match any other rules are denied.

> **Note** An inbound or outbound rule must correspond to an inbound or outbound rule that allows response traffic.

Inbound rules

Effective order	Protocol	Source IP addresses	Destination port range	Action	Description
1	TCP	0.0.0.0/0	80/80	Accept	Allows inbound HTTP traffic from any IPv4 addresses.
2	TCP	0.0.0.0/0	443/443	Accept	Allows inbound HTTPS traffic from any IPv4 addresses.
3	TCP	0.0.0.0/0	22/22	Accept	Allows inbound SSH traffic from any IPv4 addresses.
4	TCP	0.0.0.0/0	3389/3389	Accept	Allows inbound RDP traffic from any IPv4 addresses.
5	TCP	0.0.0.0/0	32768/65535	Accept	Allows inbound IPv4 traffic from the Internet. This port range is for reference only. For more information on how to select appropriate ephemeral ports, see Ephemeral ports.
6	All	0.0.0.0/0	-1/-1	Drop	Denies all inbound IPv4 traffic.

Outbound rules

Effective order	Protocol	Destination IP addresses	Destination port range	Action	Description
1	TCP	0.0.0.0/0	80/80	Accept	Allows outbound IPv4 HTTP traffic from the vSwitch to the Internet.
2	TCP	0.0.0.0/0	443/443	Accept	Allows outbound IPv4 HTTPS traffic from the vSwitch to the Internet.
3	TCP	0.0.0.0/0	32768/65535	Accept	Allows outbound IPv4 traffic from the vSwitch to the Internet. This port range is for reference only. For more information on how to select appropriate ephemeral ports, see Ephemeral ports.
4	All	0.0.0.0/0	-1/-1	Drop	Denies all outbound IPv4 traffic.

Network ACLs for SLB

If the ECS instance in the vSwitch acts as the backend server of an SLB instance, you must add the following network ACL rules.

- Inbound rules

Effective order	Protocol	Source IP addresses	Destination port range	Action	Description
1	SLB listener protocol	Client IP addresses allowed to access the SLB instance	SLB listener port	Accept	Allows inbound traffic from specified client IP addresses.
2	Health check protocol	100.64.0.0/10	Health check port	Accept	Allows inbound traffic from health check IP addresses.

- Outbound rules

Effective order	Protocol	Destination IP addresses	Destination port range	Action	Description
1	All	Client IP addresses allowed to access the SLB instance	-1/-1	Accept	Allows all outbound traffic to specified client IP addresses.
2	All	100.64.0.0/10	-1/-1	Accept	Allows outbound traffic to health check IP addresses.

Ephemeral ports

Clients use different ports to initiate requests. You can select different port ranges for network ACL rules based on the client type. The following table lists ephemeral port ranges for common clients.

Client	Port range
Linux	32768/61000
Windows Server 2003	1025/5000
Windows Server 2008 and later	49152/65535
NAT gateway	1024/65535

21.1.7.3. Create a network ACL

A network access control list (ACL) allows you to manage network access in a virtual private cloud (VPC). This topic describes how to create a network ACL in a VPC.

Prerequisites

A VPC is created. For more information, see Create a VPC.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where you want to create the network ACL.
4. On the **Network ACL** page, click **Create Network ACL**.
5. In the **Create Network ACL** dialog box, set the following parameters, and click **OK**.

Parameter	Description
Organization	Select the organization to which the network ACL belongs.
Resource Set	Select the resource set to which the network ACL belongs.
Region	Select the region where you want to deploy the network ACL.
Name	Enter a name for the network ACL. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter.
Description	Enter a description for the network ACL. The description must be 2 to 256 characters in length, and can contain letters, digits, underscores (_), colons (:), and hyphens (-). It must start with a letter and cannot start with `http://` or `https://`.
VPC	Select the VPC for which you want to create the network ACL. **Note** The VPC and network ACL must be deployed in the same region.

What's next

- Associate a network ACL with a VSwitch
- Add an inbound rule
- Add an outbound rule

21.1.7.4. Associate a network ACL with a vSwitch

After you create a network access control list (ACL), you can associate the network ACL with a vSwitch. This way, you can use the network ACL to manage the traffic of the Elastic Compute Service (ECS) instances in the vSwitch.

Prerequisites

Before you associate a network ACL with a vSwitch, make sure that the following requirements are met:

- A network ACL is created. For more information, see Work with network ACLs.
- A vSwitch is created. The vSwitch and network ACL belong to the same virtual private cloud (VPC). For more information, see Work with vSwitches.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.

4. On the **Network ACL** page, find the network ACL that you want to manage and click **Manage** in the **Actions** column.
5. On the **Resources** tab, click **Bind Resource**.
6. In the **Associate vSwitch** panel, select the vSwitch and click **OK**.

> **Note** The network ACL and vSwitch must belong to the same VPC. A vSwitch can be associated with only one network ACL.

What's next

- Add an inbound rule
- Add an outbound rule

21.1.7.5. Add network ACL rules

21.1.7.5.1. Add an inbound rule

This topic describes how to add an inbound rule to a network access control list (ACL). You can use inbound rules to manage whether Elastic Compute Service (ECS) instances in a vSwitch can be accessed over the Internet or private networks.

Prerequisites

A network ACL is created. For more information, see Work with network ACLs.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL and click **Inbound Rule** in the **Actions** column.
5. On the **Inbound Rule** tab, click **Create Inbound Rule**.
6. In the **Create Inbound Rule** panel, set the following parameters and click **OK**.

Parameter	Description
Name	Enter a name for the inbound rule. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). The name must start with a letter and cannot start with `http://` or `https://`.
Effective order	The order in which the inbound rule takes effect. Valid values: 1 to 20. A smaller number indicates a higher priority. For more information, see Rule descriptions.
Action	Select an action for the inbound rule. Valid values: ○ **Accept**: ECS instances in the vSwitch can be accessed. ○ **Drop**: ECS instances in the vSwitch cannot be accessed.

Parameter	Description
Protocol	Select a Layer 4 protocol. Valid values: ○ **ALL**: all protocols. ○ **ICMP**: Internet Control Message Protocol (ICMP). ○ **GRE**: Generic Routing Encapsulation (GRE). ○ **TCP**: Transmission Control Protocol (TCP). ○ **UDP**: User Datagram Protocol (UDP).
Source IP Address	The destination CIDR block to which data is transmitted. Default value: 0.0.0.0/32.
Destination Port Range	Enter the destination port range. Valid values: 1 to 65535. Separate the first port and last port with a forward slash (/), such as 1/200 or 80/80. A value of -1/-1 indicates that all ports are available. Therefore, do not set the value to -1/-1.

21.1.7.5.2. Add an outbound rule

This topic describes how to add an outbound rule to a network access control list (ACL). You can use outbound rules to manage whether Elastic Compute Service (ECS) instances in a vSwitch can access the Internet or private networks.

Prerequisites

A network ACL is created. For more information, see Work with network ACLs.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL and click **Outbound Rule** in the **Actions** column.
5. On the **Outbound Rule** tab, click **Create Outbound Rule**.
6. In the **Create Outbound Rule** pane, set the following parameters and click **OK**.

Parameter	Description
Name	Enter a name for the outbound rule. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). The name must start with a letter and cannot start with `http://` or `https://`.
Effective order	The order in which the outbound rule takes effect. Valid values: 1 to 20. A smaller number indicates a higher priority. For more information, see Rule descriptions.

Parameter	Description
Action	Select an action for the outbound rule. Valid values: ○ **Accept**: ECS instances in the vSwitch are allowed to access the Internet or private networks. ○ **Drop**: ECS instances in the vSwitch are not allowed to access the Internet or private networks.
Protocol	Select a Layer 4 protocol. Valid values: ○ **ALL**: all protocols. ○ **ICMP**: Internet Control Message Protocol (ICMP). ○ **GRE**: Generic Routing Encapsulation (GRE). ○ **TCP**: Transmission Control Protocol (TCP). ○ **UDP**: User Datagram Protocol (UDP).
Destination IP Addresses	The destination CIDR block to which data is transmitted. Default value: 0.0.0.0/32.
Destination Port Range	Enter the destination port range. Valid values: 1 to 65535. Separate the first port and last port with a forward slash (/), such as 1/200 or 80/80. -1/-1 indicates that all ports are available. Therefore, do not set the value to -1/-1.

21.1.7.5.3. Modify the priority of a network ACL rule

Network access control list (ACL) rules take effect in descending order of priority. A smaller number indicates a higher priority. This topic describes how to modify the priority of a network ACL rule.

Modify the priority of an inbound rule

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL and click **Manage** in the **Actions** column.
5. Click the **Inbound Rule** tab and click **Sort**.
6. In the **Sort** panel, drag rules up or down and click **OK**.

> **Note** An upper rule has a higher priority.

Adjust the priority of an outbound rule

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL and click **Manage** in the **Actions** column.
5. Click the **Outbound Rule** tab and click **Sort**.
6. In the **Sort** panel, drag rules up or down and click **OK**.

> **Note** An upper rule has a higher priority.

Related information

- Add an inbound rule
- Add an outbound rule

21.1.7.6. Disassociate a network ACL from a vSwitch

This topic describes how to disassociate a network access control list (ACL) from a vSwitch. After you disassociate a network ACL from a vSwitch, the network ACL no longer controls the traffic of Elastic Compute Service (ECS) instances that belong to the vSwitch.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL and click **Manage** in the **Actions** column.
5. On the **Resources** tab, find the vSwitch and click **Unbind** in the **Actions column**.
6. In the **Unbind Network ACL** message, click **OK**.

21.1.7.7. Delete a network ACL

This topic describes how to delete a network access control list (ACL).

Prerequisites

Make sure that the network ACL is not associated with a vSwitch. If the network ACL is associated with a vSwitch, disassociate the network ACL from the vSwitch first. For more information, see Disassociate a VSwitch from a network ACL.

Procedure

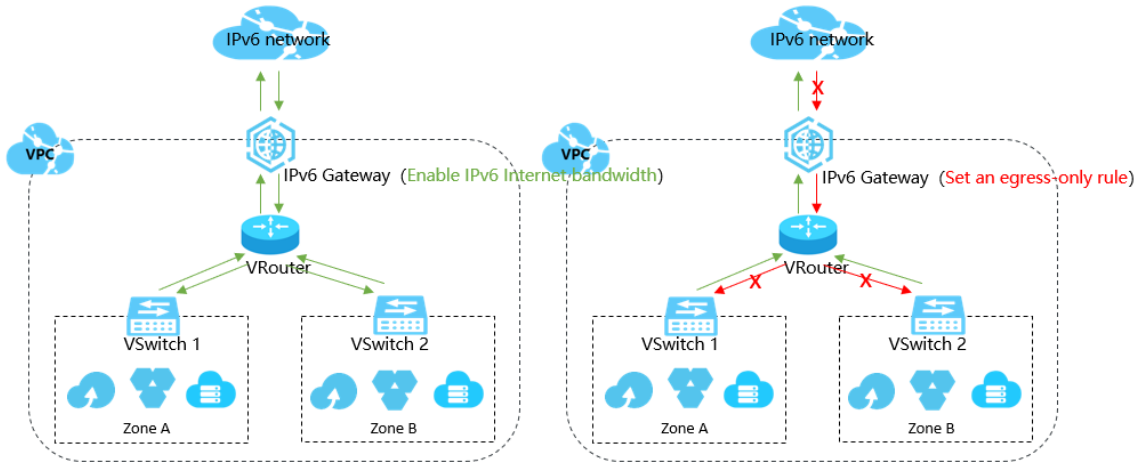
1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL and click **Delete** in the **Actions** column.
5. In the **Delete Network ACL** message, click **OK**.

22.IPv6 Gateway

22.1. User Guide

22.1.1. What is an IPv6 Gateway?

This topic provides an overview of the IPv6 Gateways of Virtual Private Cloud (VPC). An IPv6 Gateway functions as an IPv6 traffic gateway for a VPC. You can configure the IPv6 Internet bandwidth and egress-only rules to manage the inbound and outbound IPv6 traffic.



Functions

The functions of an IPv6 gateway are as follows:

- **IPv6 internal network communication**

  By default, an IPv6 address in a VPC is allocated with an Internet bandwidth of 0 Mbit/s and only supports communication over the internal network. Specifically, the cloud instances in a VPC can only access other IPv6 addresses in the same VPC through the IPv6 address. The resources cannot access the Internet with these IPv6 addresses or be accessed by IPv6 clients over the Internet.

- **IPv6 public network communication**

  You can purchase an Internet bandwidth for the IPv6 address for which you have applied. In this way, the resources in the VPC can access the Internet through the IPv6 address and be accessed by IPv6 clients over the Internet.

  You can set the Internet bandwidth to 0 Mbit/s at any time to deny the IPv6 address Internet access. After this configuration, the IPv6 address can only communicate over the internal network.

- **IPv6 public network communication with an egress-only rule**

  You can set an egress-only rule for an IPv6 Gateway. In this way, the IPv6 address can access the Internet, but IPv6 clients are denied access to your cloud resources in the VPC over the Internet.

  You can delete the egress-only rule at any time. After the rule is deleted, your resources in the VPC can access the Internet through the IPv6 address for which you have purchased Internet bandwidth, and IPv6 clients can access the resources in the VPC over the Internet.

The network access capability of IPv6 addresses is dependent on the settings of the network type, Internet bandwidth, and egress-only rule, as shown in the following table.

IPv6 network type	Enable IPv6 Internet bandwidth?	Set an egress-only rule?	IPv6 network access capability
Internal network	No	No	Internal network communication
Public network	Yes	No	Internal network communication Public network communication
		Yes	Internal network communication Public network communication when access is initiated by VPCs

Benefits

IPv6 Gateway provides the following benefits:

- **High availability**

  IPv6 Gateways provide cross-zone high availability and stable IPv6 Internet gateway services.
- **High performance**

  A single IPv6 Gateway provides a 10-gigabit level throughput.
- **Flexible management of public network communication**

  You can manage the Internet communication capability of an IPv6 Gateway by adjusting its Internet bandwidth and setting an egress-only rule.

22.1.2. Log on to the IPv6 Gateway console

This topic describes how to log on to the Apsara Uni-manager Management Console to manage your IPv6 gateways. The Google Chrome browser is used as an example.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

> **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
>
> - Uppercase or lowercase letters
> - Digits
> - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, choose **Products > Networking > Virtual Private Cloud**.
5. In the left-side navigation pane, choose **Internet Access > IPv6 Gateway**.

22.1.3. Quick start

22.1.3.1. Create an IPv6 VPC

This topic describes how to create a virtual private cloud (VPC) that supports IPv6 CIDR blocks and then create an Elastic Compute Service (ECS) instance that is assigned an IPv6 address in the VPC to access IPv6 services.

Step 1: Create a VPC and a vSwitch

Before you deploy cloud resources in a VPC, you must create a VPC and a vSwitch.

Perform the following steps to create a VPC and a vSwitch:

1. Log on to the VPC console.
2. On the **VPCs** page, click **Create VPC**.
3. On the **Create VPC** page, set the following parameters to configure the VPC and click **OK**.

Parameter	Description
Organization	Select the organization to which the VPC belongs.
Resource Set	Select the resource set to which the VPC belongs.
Region	Select the region where you want to deploy the VPC.
Sharing Scope	Specify the scope of entities that are allowed to use the VPC. ○ **Current Resource Set**: If you select this option, the administrator of the current resource set can create resources in the VPC. ○ **Current Organization and Subordinate Organizations**: If you select this option, administrators that belong to the current organization and subordinate organizations can create resources in the VPC. ○ **Current Organization**: If you select this option, administrators that belong to the current organization can create resources in the VPC. In this example, **Current Resource Set** is selected.

Parameter	Description
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character and cannot start with `http://` or `https://`. In this example, **VPCtest** is entered.
IPv4 CIDR Block	Specify the IPv4 CIDR block of the VPC. You can specify an IPv4 CIDR block in one of the following ways: ○ **Recommended CIDR Block**: You can use one of the following standard IPv4 CIDR blocks: 192.168.0.0/16, 172.16.0.0/12, and 10.0.0.0/8. ○ **Custom CIDR Block**: Enter 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or a subset of these CIDR blocks. The subnet mask must be 8 to 28 bits in length. For example, you can enter 192.168.0.0/16. In this example, Recommended CIDR Block is selected and 192.168.0.0/16 is selected as the IPv4 CIDR block of the VPC. **Note** After you create a VPC, you cannot change its IPv4 CIDR block.
IPv6 CIDR Block	Specify whether to assign an IPv6 CIDR block. ○ **Do Not Assign**: If you select this option, the system does not assign an IPv6 CIDR block to the VPC. ○ **Assign**: If you select this option, the system automatically assigns an IPv6 CIDR block to the VPC. In this example, **Assign** is selected.
Description	Enter a description for the VPC. The description must be 2 to 256 characters in length and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.

4. Click **Back to Console**. In the left-side navigation pane, click **VSwitches**.
5. On the **VSwitches** page, click **Create VSwitch**.
6. On the **vSwitch** page, set the following parameter to configure the vSwitch and click **Submit**.

Parameter	Description
Organization	Select the organization to which the vSwitch belongs.
Resource Set	Select the resource set to which the vSwitch belongs.
Region	Select the region where you want to deploy the vSwitch.
Zone	Select the zone where you want to deploy the vSwitch. In a VPC, each vSwitch can be deployed in only one zone. You cannot deploy a vSwitch across zones. However, you can deploy cloud resources in vSwitches that belong to different zones to achieve zone-disaster recovery. **Note** Each cloud resource can be added to only one vSwitch.

Parameter	Description
Sharing Scope	Specify the scope of entities that are allowed to use the vSwitch. ○ **Current Resource Set**: If you select this option, the administrator of the current resource set can create resources in the vSwitch. ○ **Current Organization and Subordinate Organizations**: If you select this option, administrators that belong to the current organization and subordinate organizations can create resources in the vSwitch. ○ **Current Organization**: If you select this option, administrators that belong to the current organization can can create resources in the vSwitch. In this example, **Current Resource Set** is selected.
VPC	Select the VPC where you want to deploy the vSwitch. In this example, VPCtest is selected.
Dedicated for Out-of-cloud Physical Machines	Specify whether the vSwitch to be created is dedicated to bare-metal servers. For more information about bare-metal servers, see the **Bare-metal servers in VPCs** topic in *Bare-metal Server Management Service User Guide*. In this example, **No** is selected.
vSwitch Name	Enter a name for the vSwitch. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.
IPv4 CIDR Block	Enter an IPv4 CIDR block for the vSwitch. In this example, the default IPv4 CIDR block is used.
IPv6 CIDR Block	Enter an IPv6 CIDR block for the vSwitch. In this example, the default IPv6 CIDR block is used.
Description	Enter a description for the vSwitch. The description must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.

Step 2: Create a security group

Perform the following steps to create a security group:

1. In the top navigation bar, choose **Products > Elastic Computing > Elastic Compute Service**.
2. Choose **Networks and Security > Security Groups**.
3. On the **Security Groups** page, click **Create Security Group**.
4. On the **Create Security Group** page, set the following parameters to configure the security group and click **Submit**.

Parameter	Description
Organization	Select the organization to which the security group belongs.

Parameter	Description
Resource Set	Select the resource set to which the security group belongs.
Region	Select the region to which the security group belongs. Make sure that the security group and the VPC belong to the same region.
Zone	Select the zone to which the security group belongs.
VPC	Select the VPC to which the security group belongs.
Security Group Name	Enter a name for the security group. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.
Description	Enter a description for the security group. The description must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.

Step 3: Create and configure an ECS instance

After you create a VPC and a vSwitch, you must create an ECS instance and assign an IPv6 address to the ECS instance. You must associate this IPv6 address with the network interface controller (NIC) of the ECS instance.

Perform the following steps to create and configure an ECS instance:

1. In the top navigation bar, choose **Products > Networking > Virtual Private Cloud**.
2. In the left-side navigation pane, click **VSwitches**.
3. Select the region where the vSwitch is created.
4. On the **VSwitches** page, find the vSwitch that you want to manage and choose **Create > ECS Instance** in the **Actions** column.
5. On the **Create ECS Instance** page, configure the ECS instance and click **Submit**.

   In this example, **Assign** is selected. Therefore, an IPv6 IP address is assigned to the ECS instance. For more information about other parameters that you are required to specify when you create an ECS instance, see **Create an ECS instance** in **Quick Start** of *Elastic Compute Service User Guide*.
6. Return to the **Instances** page and click the instance ID to view the IPv6 address that is assigned to the ECS instance.
7. Configure a static IPv6 address.
   - If the image of your ECS instance supports DHCPv6, you do not need to manually configure a static IPv6 address. DHCPv6 enables automatic configuration of IPv6 addresses. Therefore, if your ECS instance image supports DHCPv6, the ECS instance can use the assigned IPv6 address to communicate within the private network.

     The following images support DHCPv6:

     - Linux images:
       - CentOS 7.6 IPV6 64Bit
       - CentOS 6.10 64Bit
       - SUSE Linux Enterprise Server 12 SP4 64Bit

- Windows Server images

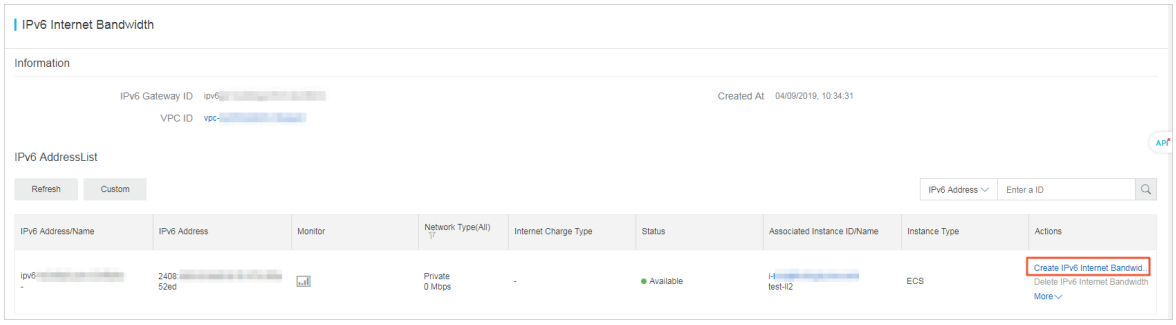
- If the image of your ECS instance does not support DHCPv6, you must manually configure an IPv6 address for the ECS instance. We recommend that you refer to the related documentation for each image for configuration guidance.

Step 4: Purchase an IPv6 Internet bandwidth plan

By default, IPv6 addresses are only used for communication within private networks. If you want to allow an instance that is assigned an IPv6 address to access the Internet or receive requests from IPv6 clients over the Internet, you must purchase an Internet bandwidth plan for the IPv6 address.

Perform the following steps to purchase an Internet bandwidth plan for the IPv6 address:

1. In the top navigation bar, choose **Products > Networking > IPv6 Gateway**.
2. Select the region where the IPv6 gateway is created.
3. On the **IPv6 Gateway** page, find the IPv6 gateway that you want to manage and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **IPv6 Internet Bandwidth**.
5. On the **IPv6 Internet Bandwidth** page, find the IPv6 address that you want to manage and click **Enable IPv6 Internet Bandwidth** in the **Actions** column.



6. Select a bandwidth plan and click **OK**.

   The maximum IPv6 Internet bandwidth for an IPv6 gateway of the Free, Enterprise, or Enhanced Edition is 2 Gbit/s.

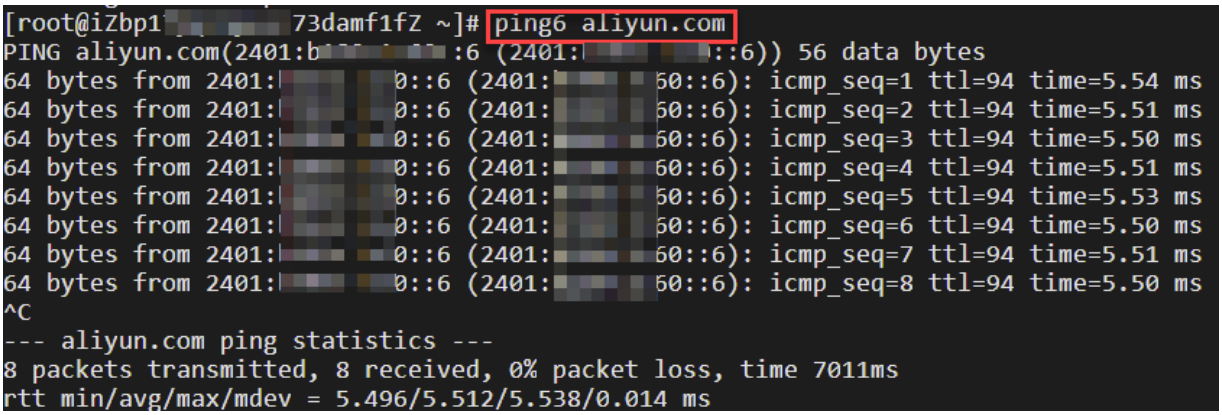
Step 5: Configure security group rules

IPv4 and IPv6 addresses are independent of each other. If the current security group rules do not apply to your IPv6 services, you must configure security group rules for the ECS instances to regulate communication with IPv6 addresses.

For more information about how to configure security rules, see the **Add security group rules** chapter in **Security Groups** of *Elastic Compute Service User Guide*.

Step 6: Test the network connectivity

Log on to an ECS instance and **ping** an IPv6 service to test the network connectivity.



22.1.4. Enable IPv6 for VPCs

22.1.4.1. Create an IPv4 and IPv6 dual-stack VPC

This topic describes how to configure both IPv4 and IPv6 CIDR blocks for a VPC when you create the VPC. By default, all VPCs are associated with IPv4 CIDR blocks which cannot be deleted. However, you can choose whether to allocate an IPv6 CIDR blocks to a VPC. After you choose to allocate an IPv6 CIDR block to a VPC, the system creates an IPv6 gateway of the Free Edition for the VPC for you to provision IPv6 bandwidth and manage IPv6 traffic.

Procedure

1. Log on to the VPC console.
2. On the top of the page, select a region to deploy your VPC.
3. On the **VPCs** page, click **Create VPC**.
4. On the **Create VPC** page, configure the VPC network and click **Submit**. The following table describes the configuration parameters.

Parameter	Description
Organization	Select the organization to which the VPC belongs.
Resource Set	Select the resource set to which the VPC belongs.
Region	Select a region to deploy the VPC.
Share with Sub-organizations	Specify whether to share the VPC. If you select Yes, administrators of sub-organizations can create resources in the VPC network.
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

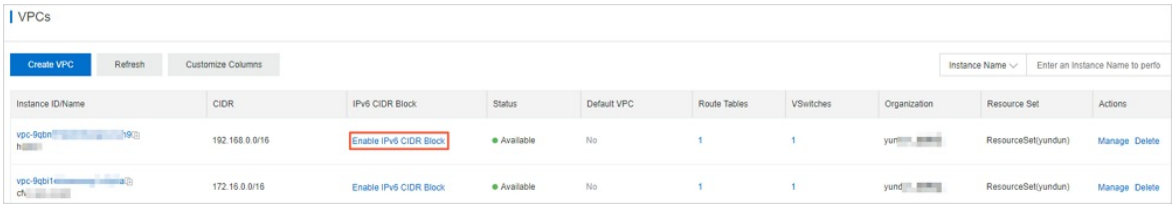
Parameter	Description
IPv4 CIDR Block	Specify an IPv4 CIDR block for the VPC. The following setting methods are supported: ○ **Recommended CIDR Block**: Use 192.168.0.0/16, 172.16.0.0/12, or 10.0.0.0/8 as the IPv4 CIDR block of the VPC. ○ **Custom CIDR Block**: Use 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or one of their subnets as the IPv4 CIDR block of the VPC. The subnet mask must be 8 to 24 bits in length. For example, enter 192.168.0.0/16. **Note** After you create a VPC, you cannot modify its IPv4 CIDR block.
IPv6 CIDR Block	Specify whether to assign an IPv6 CIDR block to the VPC. In this example, select **Assign**. If you set this parameter to Assign, the system automatically creates an IPv6 gateway of the Free Edition for your VPC and assigns an IPv6 CIDR block with the subnet mask /61, such as 2xx1:db8::/61. By default, IPv6 addresses can only be used for communication within private networks. If you need to enable an IPv6 address to access and be accessed over the Internet, you must purchase IPv6 Internet bandwidth for the IPv6 address. For more information, see Enable Internet connectivity for an IPv6 address. **Note** After you create a VPC, you cannot modify its IPv6 CIDR block.
Description	Enter a description for the VPC. The description must be 2 to 256 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

22.1.4.2. Enable an IPv6 CIDR block for a VPC network

This topic describes how to enable an IPv6 CIDR block for a Virtual Private Cloud (VPC) network. After the IPv6 CIDR block is enabled, the system automatically creates an IPv6 gateway free of charge for the VPC network. You can use the IPv6 Gateway to manage the IPv6 Internet bandwidth and set egress-only rules.

Procedure

1. Log on to the VPC console.
2. Select the region where your VPC network is deployed.
3. On the **VPCs** page, find the target VPC network and click **Enable IPv6 CIDR Block** in the **IPv6 CIDR Block** column.



4. In the **Enable IPv6 CIDR Block** dialog box, select **Enable IPv6 CIDR Block of all VSwitches in VPC**, and then click **OK**.

   If you do not select **Enable IPv6 CIDR Block of all VSwitches in VPC**, you must enable IPv6 CIDR Block for each VSwitch. For more information, see Enable IPv6 for a vSwitch.

22.1.5. Enable IPv6 for vSwitches

22.1.5.1. Create an IPv4 and IPv6 dual-stack VSwitch

This topic describes how to assign an IPv6 CIDR block to a VSwitch when you create the VSwitch.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **VSwitches**.
3. Select the region where you want to deploy the VSwitch.
4. On the **VSwitches** page, click **Create VSwitch**.
5. On the **VSwitch** page, configure the VSwitch and click **Submit**. The following table describes the configuration parameters.

Parameter	Description
Organization	Select the organization to which the VSwitch belongs.
Resource Set	Select the resource set to which the VSwitch belongs.
Region	Select a region to deploy the VSwitch.
Zone	Select a zone to deploy the VSwitch. Each VSwitch must reside entirely within one zone and cannot span multiple zones. However, you can deploy cloud resources in VSwitches of different zones to achieve cross-zone disaster recovery. **Note** Each cloud resource can be deployed in only one VSwitch.
VPC	Select the VPC for which you want to create the VSwitch.
Dedicated for Off-Cloud Servers	Specify whether the VSwitch is dedicated for off-cloud servers. For more information, see *the* **Features of off-cloud servers for VPC** topic in the Apsara Stack Bare Metal Server User Guide.
VSwitch Name	Enter a name for the VSwitch. The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

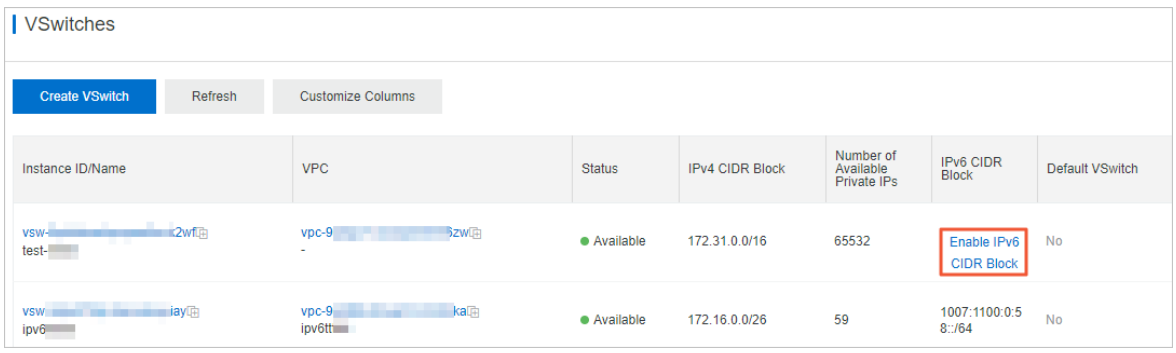
Parameter	Description
IPv4 CIDR Block	Specify an IPv4 CIDR block for the VSwitch. ○ You must specify the IP address range for the VSwitch in the form of a CIDR block. The IPv4 CIDR block size for a VSwitch is between a 16-bit mask and a 29-bit mask. It means that 8 to 65,536 IP addresses can be provided. ○ The IPv4 CIDR block of a VSwitch must be a subset of the IPv4 CIDR block of the VPC this VSwitch resides in. ○ The first and the last three IP addresses of each VSwitch IPv4 CIDR block are reserved. For example, if the VSwitch IPv4 CIDR block is 192.168.1.0/24, the IP addresses 192.168.1.0, 192.168.1.253, 192.168.1.254, and 192.168.1.255 are reserved. ○ The IPv4 CIDR block of a VSwitch must be more specific than the CIDR range of a route in any of the VPC route tables. ○ After you create a VSwitch, you cannot modify its IPv4 CIDR block.
IPv6 CIDR Block	Specify an IPv6 CIDR block for the VSwitch. The default subnet mask for the IPv6 CIDR block of a VSwitch is /64. You can enter a decimal number ranging from 0 to 255 to define the last 8 bits of the IPv6 CIDR block. For example, if the IPv6 CIDR block of the VPC that contains the VSwitch is 2xx1:db8::/64, you can enter 255 (FF in hexadecimal notation) in this field to define the IPv6 CIDR block of the VSwitch as 2xx1:db8:ff::/64.
Description	Enter a description for the VSwitch. The description must be 2 to 256 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

22.1.5.2. Enable IPv6 for a vSwitch

This topic describes how to allocate an IPv6 CIDR block to a vSwitch.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **vSwitches**.
3. Select the region where your vSwitch resides.
4. On the **vSwitches** page, find the target vSwitch, and click **Enable IPv6 CIDR Block** in the **IPv6 CIDR Block** column.



5. (Optional)In the **Enable IPv6 CIDR Block** dialog box, click **OK**.

> **Note** This operation is required only when IPv6 is not enabled for the VPC to which the vSwitch belongs.

6. Specify an IPv6 CIDR block and click **OK**.

   The default subnet mask for the IPv6 CIDR block of a vSwitch is /64. You can enter a decimal number ranging from 0 to 255 to define the last 8 bits of the IPv6 CIDR block.

   For example, if the IPv6 CIDR block of the VPC that contains the vSwitch is 2xx1:db8::/64, you can enter 255 (FF in hexadecimal notation) in this field to define the IPv6 CIDR block of the vSwitch as 2xx1:db8::ff/64.

22.1.6. Manage IPv6 Gateways

22.1.6.1. Editions of IPv6 gateways

This topic describes the different editions of IPv6 gateways. Different quotas and limits apply to IPv6 gateways of different editions, such as the maximum forwarding bandwidth, maximum IPv6 bandwidth per IPv6 address, and maximum number of egress-only rules.

IPv6 gateway edition	Maximum forwarding bandwidth	Maximum IPv6 bandwidth per IPv6 address	Maximum number of egress-only rules
Free Edition	10 Gbit/s	2 Gbit/s	0
Enterprise Edition	20 Gbit/s	2 Gbit/s	50
Enhanced Enterprise Edition	50 Gbit/s	2 Gbit/s	200

22.1.6.2. Create an IPv6 gateway

This topic describes how to create an IPv6 gateway for a VPC. After you create an IPv6 gateway, you can purchase IPv6 Internet bandwidth and set egress-only rules for the IPv6 gateway.

Prerequisites

Make sure that IPv6 is enabled for the VPC before you create an IPv6 gateway for the VPC. For more information, see Allocate an IPv6 CIDR block when you create a VPC and Enable an IPv6 CIDR block for a VPC network.

Procedure

1. Log on to the IPv6 Gateway console.
2. On the **IPv6 Gateway** page, click **Create IPv6 Gateway**.
3. Configure the IPv6 gateway and click **Submit**. The following table describes the configuration parameters.

Parameter	Description
Organization	Select the organization to which the IPv6 gateway belongs.
Resource Set	Select the resource set to which the IPv6 gateway belongs.
Region	Select a region to deploy the IPv6 gateway. The IPv6 gateway must belong to the same region as the VPC for which you want to create the IPv6 gateway.

Parameter	Description
VPC	Select the VPC for which you want to create an IPv6 gateway. The target VPC may not be available due to the following reasons: ○ Only one IPv6 gateway can be created for each VPC. The VPC already has an IPv6 gateway. ○ The VPC has a custom route with the destination CIDR block set to ::/0. If this happens, you must delete this custom route before you can create an IPv6 gateway for the VPC. **Note** After an IPv6 gateway is created, you cannot change the VPC that is associated with the IPv6 gateway.
Edition	Select the edition of the IPv6 gateway. IPv6 gateways are available in the following editions: ○ Free Edition ○ Enterprise Edition ○ Enhanced Enterprise Edition Different quotas and limits apply to IPv6 gateways of different editions, such as the maximum forwarding bandwidth, maximum IPv6 bandwidth per IPv6 address, and maximum number of egress-only rules. For more information, see Editions of IPv6 gateways.

22.1.6.3. Modify an IPv6 gateway

This topic describes how to modify the name and description of an IPv6 gateway.

Procedure

1. Log on to the IPv6 Gateway console.
2. Select the region where the IPv6 gateway resides.
3. On the **IPv6 Gateway** page, find the target IPv6 gateway, and click **Manage** in the **Actions** column.
4. On the **IPv6 Gateway Details** page, click **Edit** next to **Name**. In the dialog box that appears, enter a new name for the IPv6 gateway, and click **OK**.

   The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter.
5. Click **Edit** next to **Description**. In the dialog box that appears, enter a new description for the IPv6 gateway and click **OK**.

   The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.

22.1.6.4. Delete an IPv6 gateway

This topic describes how to delete an IPv6 gateway. If a VPC no longer needs to access or be accessed by IPv6 clients, you can delete the IPv6 gateway associated with the VPC.

Prerequisites

Before you delete an IPv6 gateway of the enterprise edition or enhanced enterprise edition, you must delete the egress-only rules of the IPv6 gateway. For more information, see Delete an egress-only rule.

Procedure

1. Log on to the IPv6 Gateway console.
2. Select the region where the IPv6 gateway resides.
3. On the **IPv6 Gateway** page, find the target IPv6 gateway, and click **Delete** in the **Actions** column.
4. In the dialog box that appears, click **OK**.

22.1.7. Manage IPv6 Internet bandwidth

22.1.7.1. Enable Internet connectivity for an IPv6 address

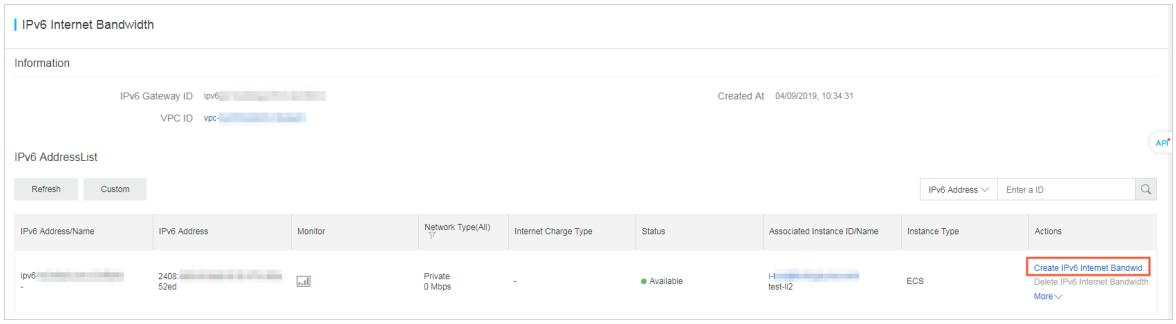
This topic describes how to enable Internet bandwidth for an IPv6 address. After Internet bandwidth is enabled for an IPv6 address, the IPv6 address can be used to communicate over the Internet.

Prerequisites

An ECS instance is created in the VPC associated with the corresponding IPv6 gateway and is configured with an IPv6 address.

Procedure

1. Log on to the IPv6 Gateway console.
2. Select the region where the IPv6 gateway resides.
3. On the **IPv6 Gateway** page, find the target IPv6 gateway, and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **IPv6 Internet Bandwidth**.
5. On the **IPv6 Internet Bandwidth** page, find the target IPv6 address, and click **Enable IPv6 Internet Bandwidth** in the **Actions** column.



6. Specify a bandwidth and click **Submit**.

   An IPv6 gateway of the Free Edition, Enterprise Edition, or Enhanced Enterprise Edition supports a 2 Gbit/s maximum bandwidth per IPv6 address.

22.1.7.2. Modify the maximum bandwidth of an IPv6 address

This topic describes how to modify the maximum bandwidth of an IPv6 address. The modification takes effect immediately.

Procedure

1. Log on to the IPv6 Gateway console.
2. Select the region where the IPv6 gateway resides.
3. On the **IPv6 Gateway** page, find the target IPv6 gateway, and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **IPv6 Internet Bandwidth**.
5. In the **IPv6 AddressList** section, find the target IPv6 address, and choose **More > Modify IPv6 Internet Bandwidth** in the **Actions** column.

6. Specify a bandwidth and click **Submit**.

22.1.7.3. Disable Internet connectivity for an IPv6 address

This topic describes how to delete the Internet bandwidth of an IPv6 address that is no longer needed for Internet communication.

Procedure

1. Log on to the IPv6 Gateway console.
2. Select the region where the IPv6 gateway resides.
3. On the **IPv6 Gateway** page, find the target IPv6 gateway, and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **IPv6 Internet Bandwidth**.
5. In the **IPv6 AddressList** section, find the target IPv6 address, and click **Delete IPv6 Internet Bandwidth** in the **Actions** column.
6. In the dialog box that appears, click **OK**.

22.1.8. Manage egress-only rules

22.1.8.1. Create an egress-only rule

This topic describes how to create an egress-only rule. If you want an instance in the VPC associated with an IPv6 gateway to be able to access the Internet with an IPv6 address, while resources on the Internet cannot initiate communication with this instance, you can create an egress-only rule for the instance.

Prerequisites

IPv6 Internet bandwidth is enabled for the IPv6 address configured for the instance. For more information, see Enable and manage IPv6 Internet bandwidth.

Context

IPv6 gateways of the Free Edition do not support egress-only rules. IPv6 gateways of the enterprise edition and enterprise enhanced edition support a maximum of 50 and 200 egress-only rules respectively.

Procedure

1. Log on to the IPv6 Gateway console.
2. Select the region where the IPv6 gateway resides.
3. On the **IPv6 Gateway** page, find the target IPv6 gateway, and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **Egress-only Rule**.
5. On the **Egress-only Rule** page, click **Create Egress-only Rule**.
6. In the **Create Egress-only Rule** dialog box, select the ECS instance that uses the IPv6 address to communicate with the Internet, and click **OK**.

22.1.8.2. Delete an egress-only rule

This topic describes how to delete an egress-only rule. After the rule is deleted, the IPv6 address with Internet bandwidth can access the Internet, and the instance associated with the IPv6 address can be accessed over the Internet.

Procedure

1. Log on to the IPv6 Gateway console.

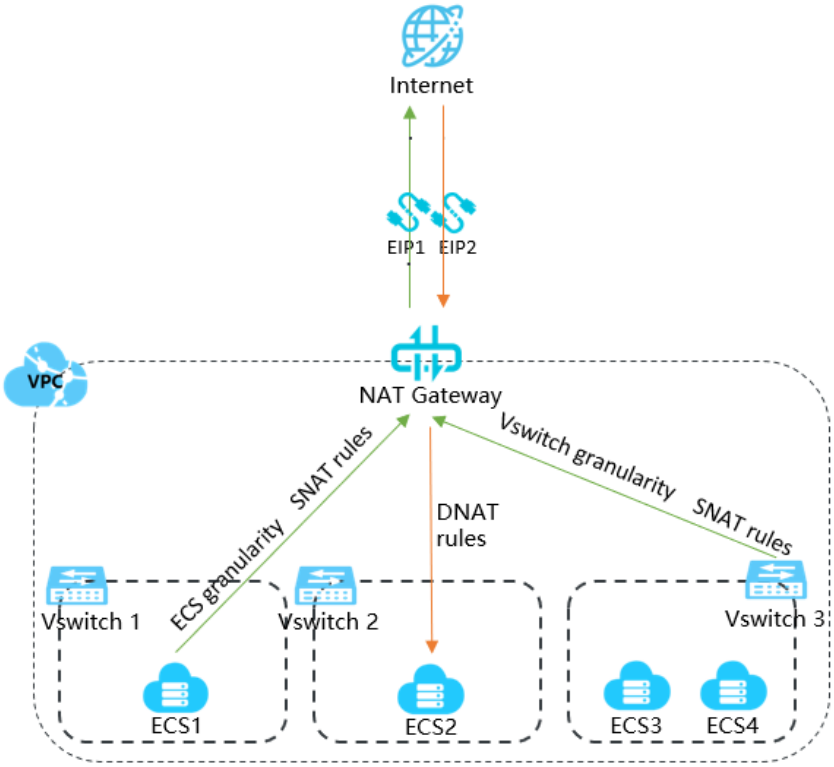
2. Select the region where the IPv6 gateway resides.
3. On the **IPv6 Gateway** page, find the target IPv6 gateway, and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **Egress-only Rule**.
5. On the **Egress-only Rule** page, find the egress-only rule that you want to delete, and click **Delete** in the **Actions** column.
6. In the dialog box that appears, click **OK**.

23.NAT Gateway

23.1. User Guide

23.1.1. What is NAT Gateway?

A NAT gateway is an enterprise-grade Internet gateway. NAT Gateway provides source network address translation (SNAT) and destination network address translation (DNAT) features, a maximum forwarding capacity of 10 Gbit/s, and support for cross-zone disaster recovery.



Features

NAT gateways must be associated with public IP addresses. After you create a NAT gateway, you can associate it with one or more elastic IP addresses (EIPs).

NAT Gateway supports SNAT and DNAT.

- SNAT allows Elastic Compute Service (ECS) instances that are deployed in a virtual private cloud (VPC) and not associated with public IP addresses to access the Internet.
- DNAT maps public IP addresses of a NAT gateway to ECS instances so that the ECS instances can be accessible from the Internet.

23.1.2. Log on to the NAT Gateway console

This topic describes how to log on to the Apsara Uni-manager Management Console to manage your NAT gateways. The Google Chrome browser is used as an example.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top menu bar, choose **Products > Networking > Virtual Private Cloud**.
5. In the left-side navigation pane, choose **Internet Access > NAT Gateway**.

23.1.3. Quick Start

23.1.3.1. Overview

This topic describes how to configure Source Network Address Translation (SNAT) and Destination Network Address Translation (DNAT). You can configure SNAT and DNAT to enable ECS instances in a Virtual Private Cloud (VPC) network to communicate with the Internet through a NAT gateway.

Prerequisites

Before you start, make sure that the following conditions are met:

- A VPC network is created. For more information, see *VPC User Guide* **Create a VPC network** in the **Quick Start** chapter in the VPC User Guide.
- An ECS instance is created in the VPC network. For more information, see *ECS User Guide* **Create an instance** in the **Quick Start** chapter in the ECS User Guide.
- An elastic IP address (EIP) is created. For more information, see *EIP User Guide* **Create an EIP** in the **Quick Start** chapter in the EIP User Guide.

Procedure

In this topic, an ECS instance that is not associated with any public IP addresses in a VPC network is used as an example. The following flowchart shows how to associate an EIP with a NAT gateway:

1. Create a NAT gateway

   A NAT gateway is an enterprise-class gateway that provides NAT proxy services. Before you configure SNAT and DNAT entries, you must create a NAT gateway.

   For more information, see Create a NAT gateway.

2. Associate an EIP to a NAT gateway

   A NAT gateway functions as expected only after it is associated with a public IP address. After you create a NAT gateway, you can associate it with an EIP.

   For more information, see Associate an EIP with a NAT Gateway.

3. Create a DNAT entry

   This topic describes how to create a Destination Network Address Translation (DNAT) entry. DNAT maps public IP addresses to Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network. This way, the ECS instances can receive requests sent over the Internet. DNAT supports port mapping and IP mapping.

   For more information, see Create a DNAT entry.

4. Create an SNAT entry

   This topic describes how to create a Source Network Address Translation (SNAT) entry. SNAT allows Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network to access the Internet without using public IP addresses.

   For more information, see Create a SNAT entry.

23.1.3.2. Create a NAT gateway

A NAT gateway is an enterprise-class gateway that provides NAT proxy services. Before you configure SNAT and DNAT entries, you must create a NAT gateway.

Prerequisites

A VPC network is created. For more information, see *VPC User Guide*Create a VPC network in the Quick Start chapter in the VPC User Guide.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateway** page, click **Create NAT Gateway**.
3. Set the parameters for the NAT gateway based on the following information, and then click **Submit**.

Parameter	Description
Organization	The organization to which the NAT gateway belongs.
Resource set	The resource set to which the NAT gateway belongs.
Region	The region where the NAT gateway is deployed.

Parameter	Description
VPC	The VPC network to which the NAT gateway belongs. If you cannot find the target VPC network in the list, perform the following operations: ○ Check whether the VPC network is already associated with a NAT gateway. Each VPC network can be associated with only one NAT gateway. ○ Check whether the VPC network has a custom route entry with the destination CIDR block set to 0.0.0.0/0. If such a custom route entry exists, delete it. ○ Check whether the RAM user is authorized to access the VPC network. If the RAM user is not authorized, contact your Alibaba Cloud account owner to grant permissions.
Specification	Select the size of the NAT gateway. Valid values: ○ **Small**: supports up to 10,000 SNAT connections. ○ **Medium**: supports up to 50,000 SNAT connections. ○ **Large**: supports up to 200,000 SNAT connections. ○ **Super Large**: supports up to 1,000,000 SNAT connections. **Note** The size of a NAT gateway determines the maximum number of SNAT connections, but it does not affect the maximum number of DNAT connections.
Parameter	Enter a name for the NAT gateway. The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character but cannot start with `http://` or `https://`.

23.1.3.3. Associate an EIP with the a NAT gateway

A NAT gateway functions as expected only after it is associated with a public IP address. After you create a NAT gateway, you can associate it with an elastic IP address (EIP).

Context

You can associate an EIP or a NAT service plan with a NAT gateway. However, you can choose only one of them for the NAT gateway. If you want to associate a NAT service plan with a NAT gateway, you must purchase a NAT service plan first. Then, you can configure the SNAT or DNAT feature for the NAT gateway. For more information, see Create a NAT service plan.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateways** page, find the NAT gateway, and choose ⋮ > **Bind Elastic IP Address** in the **Actions** column.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters, and then click **OK**.

Parameter	Description
Usable EIP list	Select the EIP that is used to access the Internet.
VSwitch	Select the VSwitch for which you want to add SNAT entries. After a VSwitch is selected, the system automatically adds an SNAT entry so that Alibaba cloud services in the VSwitch can access the Internet. You can also skip this step and manually add SNAT entries after you associate an EIP with the NAT gateway. For more information, see Create a SNAT entry.

23.1.3.4. Create a DNAT entry

This topic describes how to create a Destination Network Address Translation (DNAT) entry. DNAT maps public IP addresses to Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network. This way, the ECS instances can receive requests sent over the Internet. DNAT supports port mapping and IP mapping.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateways** page, find the target NAT gateway, and click **Configure DNAT** in the **Actions** column.
4. On the **DNAT Table** page, click **Create DNAT Entry**.
5. On the **Create DNAT Entry** page, set the following parameters, and then click **OK**.

Parameter	Description
Public IP address	Select an available public IP address. **Note** If a public IP address is already used in a SNAT entry, it cannot be used to create a DNAT entry.
Private IP address	Select the ECS instance that uses the DNAT entry to receive requests from the Internet. You can specify the private IP address of the target ECS instance in the following ways: ○ **Auto Fill**: select an ECS instance from the ECS instance or Elastic Network Interface (ENI) list. ○ **Manually Input**: enter the private IP address of the target ECS instance. **Note** The private IP address that you enter must fall in the range of the CIDR block or belong to an in-use ECS instance.

Parameter	Description
Port Settings	Select a DNAT mapping method: ○ **All**: This method uses IP mapping. All requests destined for the public IP address are forwarded to the target ECS instance. ○ **Specific Port**: This method uses port mapping. The NAT gateway forwards requests from the specified protocol and port to the specified port of the target ECS instance. After you select a specific port, specify **Public Port** (the external port for port mapping), **Private Port** (the internal port for port mapping), and **IP Protocol** (the protocol of the ports).
Entry Name	Enter a name for the DNAT entry. The name must be 2 to 128 characters in length and can contain digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.

23.1.3.5. Create an SNAT entry

This topic describes how to create a Source Network Address Translation (SNAT) entry. You can create SNAT entries on the NAT gateway of a Virtual Private Cloud (VPC) network. Then, the Elastic Compute Service (ECS) instances without public IP addresses assigned in the VPC network can use the SNAT entries to access the Internet.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateways** page, find the target NAT gateway and click **Configure SNAT** in the **Actions** column.
4. On the **SNAT Table** page, click **Create SNAT Entry**.
5. In the **Create SNAT Entry** dialog box, set the following parameters, and then click **OK**.

Parameter	Description
VSwitch Granularity	
VSwitch	Select the VSwitch for which you want to create the SNAT entry in the associated VPC network. All ECS instances attached to the specified VSwitch can access the Internet by using the SNAT entry. **Note** SNAT entries do not take effect on ECS instances that are assigned public IP addresses. For example, an ECS instance may be assigned static public IP address, associated with an elastic IP address (EIP) or has a Destination Network Address Translation (DNAT) IP mapping configured. These ECS instances use the public IP addresses instead of the SNAT entries to access the Internet.
VSwitch CIDR block	The CIDR block of the selected VSwitch.

Parameter	Description
Public IP address	Select the public IP address that is used to access the Internet. You can select multiple public IP addresses to create an SNAT IP address pool. **Note** A public IP address that is already used in a DNAT entry cannot be used to create an SNAT entry.
Entry name	Enter a name for the SNAT entry. The name must be 2 to 128 characters in length and can contain digits, underscores (_), and hyphens (-). It must start with a letter or a Chinese character.
ECS Granularity	
Available ECS Instances	Select the ECS instance for which you want to create the SNAT entry in the associated VPC network. The selected ECS instance can access the Internet by using the specified public IP address. Make sure that the following conditions are met: ○ The ECS instance is in the running state. ○ The ECS instance is not associated with an EIP or assigned a static public IP address.
ECS CIDR Block	Displays the CIDR block of the ECS instance.
Public IP address	Select the public IP address that is used to access the Internet. You can select multiple public IP addresses to create an SNAT IP address pool. The maximum bandwidth for each public IP address in an SNAT IP address pool is 200 Mbit/s. To fully utilize the EIP bandwidth plan and avoid port conflicts caused by insufficient public IP addresses, note the following limits when you add public IP addresses to an SNAT entry: ○ If the maximum bandwidth of the EIP bandwidth plan is 1024 Mbit/s, add at least five public IP addresses to the SNAT entry. ○ For each additional 200 Mbit/s of the peak bandwidth to the EIP bandwidth plan, at least one public IP address must be added to the SNAT entry. **Note** A public IP address that is used in a DNAT entry cannot be used to create an SNAT entry.
Entry Name	Enter a name for the SNAT entry. The name must be 2 to 128 characters in length and can contain numbers, underscores (_), and hyphens (-). The name must start with a letter or Chinese character.

23.1.4. Manage a NAT gateway

23.1.4.1. Sizes of NAT gateways

This topic describes the available sizes of Network Address Translation (NAT) gateways.The available sizes are Small, Middle, Large, and Super Large. The maximum number of SNAT connections and the number of SNAT connections per second (CPS) supported by a NAT gateway are determined by the size of NAT gateway. However, the size of a NAT gateway does not affect the performance of Destination Network Address Translation (DNAT).

Compare NAT gateway sizes

The following table lists different sizes of NAT gateways.

Size	Maximum number of SNAT connections	Number of SNAT CPS
Small	10,000	1,000
Middle	50,000	5,000
Large	200,000	10,000
Super Large	1,000,000	30,000

Limits

When you select a size for a NAT gateway, note the following limits:

- Cloud Monitor monitors only the maximum number of SNAT connections for NAT gateways. It does not monitor the number of new SNAT connections per second.
- The timeout of SNAT connections in a NAT gateway is 900 seconds.
- To avoid the timeout of SNAT connections caused by network congestion and Internet instability, make sure that your applications support automatic reconnection. This ensures higher availability.
- NAT gateways do not support packet fragmentation.
- For the same destination public IP address and port, the number of EIPs associated with a NAT gateway determines the maximum number of connections. Each EIP associated with a NAT gateway supports up to 55,000 connections. If N EIPs are associated with the NAT gateway, the maximum number of connections that the NAT gateway supports is N × 55,000.

23.1.4.2. Create a NAT gateway

A NAT gateway is an enterprise-class gateway that provides NAT proxy services. Before you configure SNAT and DNAT entries, you must create a NAT gateway.

Prerequisites

A VPC network is created. For more information, see *VPC User Guide*Create a VPC network in the Quick Start chapter in the VPC User Guide.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateway** page, click **Create NAT Gateway**.
3. Set the following parameters and click **submit**.

Parameter	Description
Organization	Select the organization to which the NAT gateway belongs.
Resource Set	Select the resource group to which the NAT gateway belongs.

Parameter	Description
Region	Select the region where you want to deploy the NAT gateway.
VPC	Select the VPC where you want to deploy the NAT gateway. If you cannot find the VPC in the list, perform the following operations: ○ Check whether the VPC is already associated with a NAT gateway. Each VPC can be associated with only one NAT gateway. ○ Check whether the VPC has a custom route entry whose destination CIDR block is 0.0.0.0/0. If the custom route entry exists, delete it. ○ Check whether the Resource Access Management (RAM) user is authorized to access the VPC. If the RAM user is unauthorized, contact the owner of the Apsara Stack account that created the RAM user to grant permissions.
Sharing Scope	Select the participants who can use the VPC to create resources. ○ **Current Resource Set**: Only the administrator of the current resource set can create resources for the shared VPC. ○ **Current Organization and Subordinate Organization**: Only the administrators of the current organization and its subordinate organization can create resources for the shared VPC. ○ **Current Organization**: Only the administrator of the current organization can create resources for the shared VPC.
Specification	Select the size of the NAT gateway. Valid values: ○ **Small**: supports up to 10,000 SNAT connections. ○ **Medium**: supports up to 50,000 SNAT connections. ○ **Large**: supports up to 200,000 SNAT connections. ○ **Super Large-1**: supports up to 1,000,000 SNAT connections. **Note** The maximum number of SNAT connections is limited by the size of a NAT gateway. However, the gateway size does not affect the maximum number of DNAT connections.
Name	Enter a name for the NAT gateway. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

23.1.4.3. Modify a NAT gateway

This topic describes how to modify the name and description of a NAT gateway.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway that you want to manage, and then click **Manage** in the **Actions** column.
4. On the **NAT Gateway Details** tab, click **Edit** next to the name. In the dialog box that appears, enter a new name for the NAT gateway, and then click **OK**.

The name must be 2 to128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.

5. Click **Edit** next to the description. In the dialog box that appears, enter a new description, and then click **OK**.

   The description must be 2 to 256 characters in length. It cannot start with `http://` or `https://`.

23.1.4.4. Delete a NAT gateway

You can delete NAT gateways that are billed on a pay-as-you-go basis. You cannot delete subscription NAT gateways.

Prerequisites

Before you delete a NAT gateway, make sure that the following conditions are met:

- The NAT gateway is not associated with an EIP. If the NAT gateway is associated with an EIP, disassociate the EIP first. For more information, see Disassociate EIPs from a NAT gateway.
- The DNAT table is empty. If the DNAT table contains DNAT entries, delete these entries first. For more information, see Delete a DNAT entry.
- The SNAT table is empty. If the DNAT table contains SNAT entries, delete these entries first. For more information, see Delete a SNAT entry.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateways** page, find the target NAT gateway, and click ⋮ > **Delete** in the **Actions** column.
4. In the dialog box that appears, click **OK**.

> **Note** If you select **Delete (Delete NAT gateway and resources)**, the DNAT and SNAT entries of the NAT gateway are deleted automatically. The EIP associated with the NAT gateway is also disassociated.

23.1.5. Manage EIPs

23.1.5.1. Associate an EIP with a NAT gateway

This topic describes how to associate an EIP with a NAT gateway. NAT gateways must be associated with EIPs so that they can work as expected. After you create a NAT gateway, you can associate it with an EIP.

Prerequisites

Before you associate an EIP with a NAT gateway, make sure that the following conditions are met:

- A NAT gateway is created. For more information, see Create a NAT Gateway.
- An EIP is purchased. For more information, see the **Create an Elastic IP address** topic of the **Quick start** document in the *EIP user guide*.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway with which you want to associate an EIP, and choose ⋮ > **Bind Elastic IP Address** in the **Actions** column.

4. In the **Associate EIP** dialog box, set the following parameters, and click **OK**.

Parameter	Description
Usable EIP List	Select the EIP that is used to communicate with the Internet.
vSwitch	Select the vSwitch to which you want to add SNAT entries. After you select a vSwitch, the system automatically adds SNAT entries to the vSwitch. Then, cloud services in the vSwitch can access the Internet. You can skip this step and manually add SNAT entries after you associate an EIP with the NAT gateway. For more information, see Create a SNAT entry.

23.1.5.2. Disassociate an EIP from a NAT gateway

If your NAT gateway does not need to communicate with the Internet, you can disassociate the EIP from the NAT gateway.

Prerequisites

The EIP that you want to disassociate is not used in any SNAT or DNAT entries.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateways** page, find the NAT gateway, and choose ⋮ > **Unbind Elastic IP Address** in the **Actions** column.
4. In the **Unbind Elastic IP Address** dialog box, select the EIP that you want to disassociate, and click **OK**.

23.1.6. Manage a DNAT table

23.1.6.1. DNAT table overview

NAT Gateway supports the Destination Network Address Translation (DNAT) feature. You can create DNAT entries to map public IP addresses to ECS instances in a Virtual Private Cloud (VPC) network. This way, the ECS instances can receive requests from the Internet.

DNAT entries

You can configure port mapping when you create a DNAT entry. After the DNAT entry is created, requests destined for the specified public IP address are forwarded to the ECS instances within a VPC network based on the port mapping rule.

Each DNAT entry consists of the following elements:

- **Public IP address**: the EIP associated with the NAT gateway.
- **Private IP address**: the private IP address assigned to the ECS instance in the VPC network.
- **Public Port**: the external port where requests from the Internet are received.
- **Private Port**: the internal port to which the requests received on the external port are forwarded.
- **Protocol Type**: the protocol used by the ports.

Port mapping and IP mapping

The DNAT feature supports port mapping and IP mapping:

- Port mapping

After port mapping is configured, a NAT gateway forwards requests destined for a public IP address to the specified ECS instance based on the specified protocol and ports.

DNAT entry	Public IP address	Public port	Private IP address	Private port	Protocol type
Entry 1	139.224.xx.xx	80	192.168.x.x	80	TCP
Entry 2	139.224.xx.xx	8080	192.168.x.x	8000	UDP

Entry 1: The NAT gateway forwards requests destined for TCP port 80 of ECS instance 139.244.xx.xx to TCP port 80 of ECS instance 192.168.x.x.

Entry 2: The NAT gateway forwards requests destined for UDP port 8080 of ECS instance 139.224.xx.xx to UDP port 8000 of ECS instance 192.168.x.x.

- IP mapping

  After IP mapping is configured, a NAT gateway forwards all requests destined for a public IP address to the specified ECS instance.

DNAT entry	Public IP address	Public port	Private IP address	Private port	Protocol type
Entry 3	139.224.xx.xx	Any	192.168.x.x	Any	Any

Entry 3: The NAT gateway forwards requests destined for ECS instance 139.224.xx.xx to ECS instance 192.168.x.x.

23.1.6.2. Create a DNAT entry

This topic describes how to create a Destination Network Address Translation (DNAT) entry. DNAT maps a public IP address to an Elastic Compute Service (ECS) instance in a Virtual Private Cloud (VPC) network. This allows the ECS instance to receive requests sent over the Internet. DNAT supports port mapping and IP mapping.

Prerequisites

A NAT gateway is created and associated with an elastic IP address (EIP). For more information, see Create a NAT gateway and Associate an EIP with a NAT Gateway.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway that you want to manage, and click **Configure DNAT** in the **Actions** column.
4. On the **DNAT Table** page, click **Create DNAT Entry**.
5. In the **Create DNAT Entry** panel, set the following parameters and click **OK**.

Parameter	Description
Public IP Address	Select an available public IP address. **Note** If a public IP address is already used to create an SNAT entry, the public IP address cannot be used to create a DNAT entry.

Parameter	Description
Private IP Address	Specify the ECS instance that uses the DNAT entry to communicate with the Internet. You can specify the private IP address of the ECS instance in the following ways: ○ **Auto Fill**: Select the ECS instance from the drop-down list. ○ **Manually Input**: Enter the private IP address of the ECS instance. **Note** This private IP address must fall within the CIDR block of the virtual private cloud (VPC). You can also enter the private IP address of an existing ECS instance.
Port Settings	Select a DNAT mapping method: ○ **All**: This method uses IP mapping. All requests destined for the elastic IP address (EIP) are forwarded to the ECS instance. ○ **Specific Port**: This method uses port mapping. The NAT gateway forwards requests that use the specified protocol and port to the specified port of the ECS instance. After you select Specific Port, specify the **Public Port** (the external port), **Private Port** (the internal port), and **IP Protocol** (the protocol over which data is transferred).
Entry Name	Enter a name for the DNAT entry. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter.

23.1.6.3. Modify a DNAT entry

This topic describes how to modify a Destination Network Address Translation (DNAT) entry. After you create a DNAT entry, you can modify the public IP address, private IP address, ports, and name of the DNAT entry.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway that you want to manage, and click **Configure DNAT** in the **Actions** column.
4. On the **DNAT table** page, find the target DNAT entry, and click **Edit** in the **Actions** column.
5. In the **Edit DNAT Entry** dialog box, change the public IP address, private IP address, ports, and name of the DNAT entry, and then click **OK**.

23.1.6.4. Delete a DNAT entry

This topic describes how to delete a Destination Network Address Translation (DNAT) entry. If you no longer need an Elastic Compute Service (ECS) instance to receive requests sent over the Internet, you can delete the DNAT entry of the ECS instance.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.

3. On the **NAT Gateway** page, find the NAT gateway that you want to manage, and click **Configure DNAT** in the **Actions** column.
4. On the **DNAT table** page, find the target DNAT entry, and click **Remove** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

23.1.7. Manage an SNAT table

23.1.7.1. SNAT table overview

NAT Gateway supports Source Network Address Translation (SNAT). SNAT allows Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network to access the Internet without using public IP addresses.

SNAT entries

You can create SNAT entries in an SNAT table to allow ECS instances to access the Internet.

An SNAT entry consists of the following elements:

- **VSwitch or ECS instance**: the VSwitch or ECS instance that requires the SNAT proxy service.
- **Public IP address**: the public IP address used to access the Internet.

VSwitch granularity and ECS granularity

SNAT entries can be created based on the following granularity to enable ECS instances in a VPC network to access the Internet.

- VSwitch granularity

  You can select the VSwitch granularity to create an SNAT entry. The NAT gateway provides proxy service for an ECS instance attached to the specified VSwitch by using a specified public IP address when the instance sends requests to the Internet. By default, all ECS instances attached to the VSwitch can use the specified public IP address to access the Internet.

  > **Note** SNAT entries do not take effect on ECS instances that are assigned public IP addresses. For example, an ECS instance may be assigned static public IP address, associated with an elastic IP address (EIP) or has a Destination Network Address Translation (DNAT) IP mapping configured. These ECS instances use the public IP addresses instead of the SNAT entries to access the Internet.

- ECS granularity

  If you select the ECS granularity to create an SNAT entry, the specified ECS instance uses the specified public IP address to access the Internet. The NAT gateway provides proxy service (SNAT) for a specified ECS instance by using a specified public IP address when the instance sends requests to the Internet.

23.1.7.2. Create an SNAT entry

This topic describes how to create a Source Network Address Translation (SNAT) entry. SNAT allows Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network to access the Internet without using public IP addresses.

Prerequisites

Before you create an SNAT entry, make sure that the following requirements are met:

- A NAT gateway is created and associated with an elastic IP address (EIP). For more information, see Create a NAT gateway and Associate an EIP with a NAT Gateway.
- To create an SNAT entry with VSwitch granularity, make sure that the VSwitch is created and associated with the NAT gateway in a VPC network.
- To create an SNAT entry with ECS granularity, make sure that the ECS instance is created and associated with

the NAT gateway in a VPC network.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway and click **Configure SNAT** in the **Actions** column.
4. On the **SNAT Table** page, click **Create SNAT Entry**.
5. In the **Create SNAT Entry** panel, set the following parameters and click **OK**.

Parameter	Description
VSwitch Granularity	
VSwitch	Select a vSwitch in the VPC. All ECS instances in the vSwitch can access the Internet by using SNAT. **Note** SNAT entries do not take effect on ECS instances that are assigned public IP addresses. For example, an ECS instance may be assigned a static public IP address, associated with an elastic IP address (EIP), or configured with DNAT IP mapping. Such an ECS instance uses the public IP address instead of the SNAT entry to access the Internet.
VSwitch CIDR Block	The CIDR block of the selected vSwitch.
Public IP Address	Select the EIP that is used to access the Internet. You can select one or more EIPs. You can use multiple EIPs to create an SNAT IP address pool. **Note** An EIP that is already used in a DNAT entry cannot be used in an SNAT entry.
ECS Granularity	
Available ECS Instances	Select an ECS instance in the VPC. The ECS instance can access the Internet by using the specified EIP. Make sure that the following requirements are met: ○ The ECS instance is in the Running state. ○ The ECS instance is not assigned an EIP or a static public IP address.
ECS CIDR Block	The CIDR block of the ECS instance.
Public IP Address	Select the EIP that is used to access the Internet. You can select one or more EIPs. You can use multiple EIPs to create an SNAT IP address pool. **Note** An EIP that is already used in a DNAT entry cannot be used in an SNAT entry.

23.1.7.3. Modify an SNAT entry

This topic describes how to modify a Source Network Address Translation (SNAT) entry. After you create an SNAT entry, you can modify the public IP address and name of the SNAT entry.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway and click **Configure SNAT** in the **Actions** column.
4. On the **SNAT table** page, find the target SNAT entry, and click **Edit** in the **Actions** column.
5. In the **Edit SNAT Entry** dialog box, change the public IP address and name of the SNAT entry, and then click **OK**.

23.1.7.4. Delete a SNAT entry

This topic describes how to delete a Source Network Address Translation (SNAT) entry. You can delete the SNAT entry if the Elastic Compute Service (ECS) instances without public IP addresses in a Virtual Private Cloud (VPC) network no longer need the SNAT service to access the Internet.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway and click **Configure SNAT** in the **Actions** column.
4. On the **SNAT table** page, find the target SNAT entry, and click **Remove** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

23.1.8. NAT service plan

23.1.8.1. Create a NAT service plan

You can associate an elastic IP address (EIP) or a NAT service plan to a NAT gateway. However, you can choose only one of them for the NAT gateway. If you want to associate a NAT service plan with the NAT gateway, you must create a NAT service plan first. Then, you can configure SNAT or DNAT for the NAT gateway. A NAT service plan consists of public IP addresses and Internet bandwidth.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateways** page, find the target NAT gateway and choose **Purchase NAT Bandwidth Package** in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, click **Purchase**.
4. On the **NAT Bandwidth Package** page, set the following parameters, and click **Submit**.

Parameter	Description
Region	Indicates the region for which the NAT service plan is purchased.
Billing methods	Select the billing method of the NAT service plan. Only **By Bandwidth** is supported.

Parameter	Description
Bandwidth (Mbit/s)	Enter a bandwidth value for the NAT service plan that you want to purchase. The maximum value is 5000 Mbit/s.
Name	Enter a name for the NAT service plan. The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.
Description	Enter a description for the NAT service plan. The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.
Quantity	Enter the number of NAT bandwidth plans that you want to purchase.

23.1.8.2. Modify the bandwidth of a NAT service plan

This topic describes how to modify the bandwidth of a NAT bandwidth plan. The modification takes effect immediately.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateways** page, find the target NAT gateway and click the ID of the NAT service plan in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, click the target NAT service plan, and then choose **Modify Bandwidth**.
4. On the **Modify Bandwidth** page, modify the bandwidth, and then click **Submit**.

   Each NAT bandwidth plan supports a maximum of 5,000 Mbit/s in bandwidth.

23.1.8.3. Add an IP address

This topic describes how to add IP addresses to a NAT service plan. The added IP addresses can be used to create Source Network Address Translation (SNAT) and Destination Network Address Translation (DNAT) rules.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateways** page, find the target NAT gateway and click the ID of the NAT service plan in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, click the target NAT service plan, and then choose **Add IP Address**.
4. On the **Modify IP Addresses** page, enter the number of IP addresses to be added, and then click **Submit**.

23.1.8.4. Release an IP address

This topic describes how to release IP addresses in a NAT service plan. The NAT service plan must contain at least one IP address.

Prerequisites

Before you release an IP address in the NAT service plan, make sure that the IP address is not used in Source

Network Address Translation (SNAT) and Destination Network Address Translation (DNAT) entries. If the IP address is used in an SNAT or DNAT entry, delete the SNAT or DNAT entry first. For more information, see Delete a DNAT entry and Delete a SNAT entry.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateways** page, find the target NAT gateway and click the ID of the NAT service plan in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, click the target NAT service plan.
4. In the **Public IP List** section, find the target IP address, and click **Release** in the **Actions** column.
5. In the **Release IP** dialog box, click **OK**.

23.1.8.5. Delete a NAT service plan

This topic describes how to delete a service plan.

Prerequisites

Before you start, make sure that the following requirements are met:

- Delete the IP addresses that are used in Destination Network Address Translation (DNAT) entries. For more information, see Delete a DNAT entry.
- Delete the IP addresses that are used for Source Network Address Translation (SNAT) entries. For more information, see Delete a SNAT entry.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateways** page, find the target NAT gateway and click the ID of the NAT service plan in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, find the target NAT service plan and click **Delete**.
4. In the **Delete Shared Internet Shared Bandwidth** dialog box, click **OK**.

23.1.9. Anti-DDoS Basic

Distributed Denial of Service (DDoS) attack is a malicious network attack against the target system, which can make the attacked network inaccessible. Alibaba Cloud provides up to 5 Gbit/s of basic anti-DDoS protection for NAT Gateway, which can efficiently prevent DDoS attack.

How Anti-DDoS Basic works

After you enable Anti-DDos Basic, all traffic from the Internet must first pass through Alibaba Cloud Security before arriving at NAT Gateway. Anti-DDoS Basic scrubs and filters common DDoS attacks at Alibaba Cloud Security. Anti-DDos Basic protects your services against attacks such as SYN flood, UDP flood, ACK flood, ICMP flood, and DNS Query flood.

Anti-DDoS Basic sets the scrubbing threshold and black hole triggering threshold based on the EIP bandwidth of NAT Gateway. When the inbound traffic reaches the threshold, scrubbing or blackholing is triggered:

- Scrubbing: When the attack traffic from the Internet exceeds the scrubbing threshold or matches certain attack traffic pattern, Alibaba Cloud Security starts scrubbing the attack traffic. The scrubbing includes packet filtering, bandwidth capping, and traffic throttling.
- Blackholing: When the attack traffic from the Internet exceeds the black hole triggering threshold, blackholing is triggered and all inbound traffic is dropped.

Scrubbing threshold

The thresholds for triggering traffic scrubbing and blackholing on NAT Gateway are calculated as described in the following table:

EIP bandwidth	Traffic scrubbing threshold (bits/s)	Traffic scrubbing threshold (packets/s)	Default black hole triggering threshold
Lower than or equal to 800 Mbit/s	800Mbps	120,000	1.5 Gbps
Higher than 800 Mbit/s	Predefined bandwidth	Predefined bandwidth × 150	Predefined bandwidth × 2

If the EIP bandwidth is 1,000 Mbit/s, the traffic scrubbing threshold (bits/s) is 1,000 Mbit/s, the traffic scrubbing threshold (packets/s) is 150,000 and the default blackholing threshold is 2 Gbit/s.

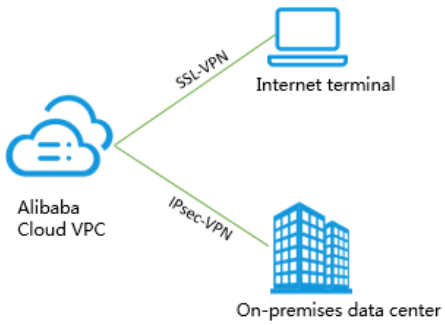
24.VPN Gateway

24.1. User Guide

24.1.1. What is VPN Gateway?

VPN Gateway is an Internet-based service that allows you to connect enterprise data centers, office networks, or Internet-facing terminals to Alibaba Cloud Virtual Private Cloud (VPC) networks through secure and reliable connections. VPN Gateway supports both IPsec-VPN connections and SSL-VPN connections.

> **Note** The Alibaba Cloud VPN Gateway service complies with the local regulations and policies. VPN Gateway does not provide Internet access services.



Features

VPN Gateway supports the following features:

- IPsec-VPN

  Route-based IPsec-VPN allows you to route network traffic in multiple ways, and also facilitates the configuration and maintenance of VPN policies.

  You can use IPsec-VPN to connect an on-premises data center to a VPC network or connect two VPC networks. IPsec-VPN supports the IKEv1 and IKEv2 protocols. Any devices that support these two protocols can connect to Alibaba Cloud VPN Gateway, such as devices manufactured by Huawei, H3C, Hillstone, Sangfor, Cisco ASA, Juniper, SonicWall, Nokia, IBM, and Ixia.

- SSL-VPN

  SSL-VPN is implemented based on the OpenVPN framework. You can create an SSL-VPN connection to connect a remote client to applications and services deployed in a VPC network. After you deploy your applications or services, you only need to import the certificate to the client to initiate a connection.

Benefits

VPN Gateway offers the following benefits:

- High security: You can use the IKE and IPsec protocols to encrypt data for secure and reliable data transmission.
- High availability: VPN Gateway adopts the hot-standby architecture to achieve failover within a few seconds, session persistence, and zero service downtime.
- Cost-effectiveness: The encrypted Internet connections provided by VPN Gateway are more cost-effective than leased lines.
- Ease of use: VPN Gateway is a ready-to-use service. VPN gateways start to work immediately after they are deployed.

24.1.2. Log on to the VPN Gateway console

This topic describes how to log on to the Apsara Uni-manager Management Console. You can manage your VPN gateways in the console. The Google Chrome browser is used as an example.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top menu bar, choose **Products > Networking > Virtual Private Cloud**.
5. In the left-side navigation pane, choose **Interconnections > VPN**.

24.1.3. Get started with IPsec-VPN

24.1.3.1. Connect on-premises data centers to VPC networks

This topic describes how to create IPsec-VPN connections on VPN gateways to connect an on-premises data center to a Virtual Private Cloud (VPC) network.

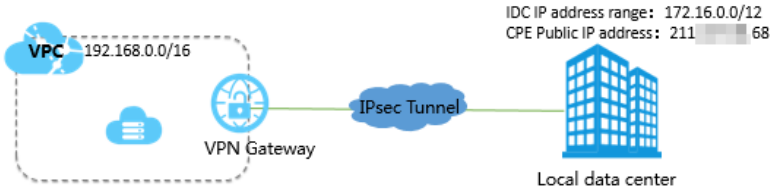
Prerequisites

Before you start, make sure that the following requirements are met:

- Check the gateway device in the on-premises data center. Alibaba Cloud VPN gateways support the standard IKEv1 and IKEv2 protocols. Any gateway device that supports these two protocols can connect to Alibaba Cloud VPN gateways, such as gateway devices manufactured by H3C,Huawei, Hillstone, Sangfor, Cisco ASA, Juniper, SonicWall, Nokia, IBM, and Ixia.
- Make sure that you have set a static public IP address for the gateway device in the on-premises data center.
- The CIDR block of the on-premises data center must not overlap with that of the VPC network.

Context

For example, a company creates a VPC network on Alibaba Cloud. The CIDR block of the VPC network is 192.168.0.0/16. The CIDR block of the on-premises data center is 172.16.0.0/12. The static public IP address for the gateway device in the on-premises data center is 211.xx.xx.68. To meet business requirements, the company needs to connect the on-premises data center to the VPC network.



The preceding figure displays that the on-premises data center is connected to the VPC network through IPsec-VPN. Cloud resources can be shared with on-premises data centers.

Step 1: Create a VPN gateway

Take the following steps to create a VPN gateway:

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN Gateway** page, set the following parameters for the VPN gateway, and then click **Submit**.
   - **Organization**: Select the organization to which the VPN gateway belongs.
   - **Resource Set**: Select the resource set to which the VPN gateway belongs.
   - **Region**: Select the region where you want to deploy the VPN gateway.

     > **Note** Make sure that the VPC network and the VPN gateway associated with the VPC network are deployed in the same region.

   - **Name**: Enter a name for the VPN gateway.

     The name must be 2 to 128 characters in length, and can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter or Chinese character and cannot start with `http://` or `https://`.
   - **VPC**: Select the VPC network to be associated with the VPN gateway.
   - **Bandwidth**: Specify the maximum bandwidth of the VPN gateway. The bandwidth is provided for data transfer over the Internet.
   - **IPsec-VPN**: Specify whether to enable IPsec-VPN for the VPN gateway. In this example, select **Enable**.

     After IPsec-VPN is enabled, you can create IPsec-VPN connections between an on-premises data center and a VPC network, or between two VPC networks.
   - **SSL-VPN**: Specify whether to enable SSL-VPN. In this example, select **Disable**.

     SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without configuring a customer gateway.
   - **SSL Connections**: Specify the maximum number of concurrent SSL connections that the VPN gateway supports.

     > **Note** This parameter is available only after SSL-VPN is enabled.

5. Go to the VPN Gateways page to view the newly created VPN gateway.

   The newly created VPN gateway is in the Preparing state. Its status changes to Normal after about two

minutes. The Normal state indicates that the VPN gateway is initialized and ready for use.

> **Note** It takes about one to five minutes to create a VPN gateway.

Step 2: Create a customer gateway

Take the following steps to create a customer gateway.

1. In the left-side navigation pane, choose **VPN > Customer Gateways**.
2. Select the region where you want to deploy the customer gateway
3. On the **Customer Gateways** page, click **Create Customer Gateway**.
4. On the **Create Customer Gateway** page, set the following parameters, and click **Submit**.
   - **Organization**: Select the organization to which the customer gateway belongs.
   - **Resource Set**: Select the resource set to which the customer gateway belongs.
   - **Region**: Select the region where you want to deploy the customer gateway.

     > **Note** Make sure that the customer gateway and the VPN gateway to be connected are deployed in the same region.

   - **Zone**: Select the zone where you want to deploy the customer gateway.
   - **Name**: Enter a name for the customer gateway.

     The name must be 2 to 128 characters in length, and can contain letters, digits, hyphens (-), and underscores (_). It must start with a letter or Chinese character and cannot start with `http://` or `https://`.
   - **IP Address**: Enter the public IP address of the gateway device in the on-premises data center that is to be connected to the VPC network. In this example, enter **211.xx.xx.68**.
   - **Description**: Enter a description for the customer gateway.

     The description must be 2 to 256 characters in length, and cannot start with `http://` or `https://`.

Step 3: Create an IPsec-VPN connection

Take the following steps to create an IPsec-VPN connection:

1. In the left-side navigation pane, choose **VPN > IPsec Connections**.
2. Select the region where you want to create an IPsec-VPN connection.
3. On the **IPsec Connections** page, click **Create IPsec Connection**.
4. On the **Create IPsec Connection** page, set the following parameters for the IPsec-VPN connection, and click **Submit**.
   - **Organization**: Select the organization to which the IPsec-VPN connection belongs.
   - **Resource Set**: Select the resource set to which the IPsec-VPN connection belongs.
   - **Region**: Select the region where the IPsec-VPN connection is established.
   - **Zone**: Select the zone where the IPsec-VPN connection is established.
   - **Name**: Enter a name for the IPsec-VPN connection.
   - **VPN Gateway**: Select a VPN gateway.
   - **Customer Gateway**: Select the customer gateway to be connected through the IPsec-VPN connection.
   - **Source CIDR Block**: Enter the CIDR block of the VPC network with which the selected VPN gateway is associated. In this example, enter **192.168.0.0/16**.
   - **Destination CIDR Block**: Enter the CIDR block of the on-premises data center. In this example, enter

172.16.0.0/12.

- **Immediate Effect**: Specify whether to start connection negotiations immediately.
  - **Yes**: negotiate immediately after the configuration is complete.
  - **No**: negotiate when traffic is detected in the IPsec-VPN connection.
- **Pre-shared Key**: Enter the pre-shared key. The pre-shared key must be the same as that of the gateway device deployed in the on-premises data center.

  Use the default settings for other parameters.

Step 4: Load the configurations of the IPsec-VPN connection to the customer gateway device

Take the following steps to load the configurations of the IPsec-VPN connection to the customer gateway device:

1. In the left-side navigation pane, choose **VPN > IPsec Connections**.
2. Select the region where the IPsec-VPN connection is established.
3. On the **IPsec Connections** page, find the target IPsec-VPN connection, and then choose **More > Download Configuration** in the **Actions** column.
4. Load the configurations of the IPsec-VPN connection to the customer gateway device by following the instructions described in . For more information about how to configure customer gateways, consult the manufacturers of the gateway devices.

   RemotSubnet and LocalSubnet in the downloaded configurations are opposite to RemotSubnet and LocalSubnet that you specify when you create an IPsec-VPN connection. For a VPN gateway, RemotSubnet refers to the CIDR block of the on-premises data center and LocalSubnet refers to the CIDR block of the VPC network. For a customer gateway, LocalSubnet refers to the CIDR block of the on-premises data center and RemoteSubnet refers to the CIDR block of the VPC network.

Step 5: Configure routes for the VPN gateway

Take the following steps to configure routes for the VPN gateway:

1. In the left-side navigation pane, choose **VPN > VPN Gateways**.
2. Select the region where the VPN gateway is deployed.
3. On the **VPN Gateways** page, find the target VPN gateway, and then click the instance ID in the **Instance ID/Name** column.
4. In the **Destination-based routing** tab, click **Add Route Entry**.
5. In the **Add Route Entry** dialog box, set the following parameters and click **OK**.
   - **Destination CIDR Block**: Enter the CIDR block of the on-premises data center. In this example, enter **172.16.0.0/12**.
   - **Next Hop Type**: Select IPsec Connection.
   - **Next Hop**: Select an IPsec instance.
   - **Publish to VPC**: Specify whether to automatically publish new route entries to the VPC route table. In this example, select **Yes**.
   - **Weight**: Select a weight. In this example, select **100**.

Step 6: Verify the settings

Log on to an Elastic Compute Service (ECS) instance that is not assigned a public IP address in the VPC network. Run the **ping** command to **ping** the private IP address of a server that resides in the on-premises data center, and test the connectivity.

24.1.4. Get started with SSL-VPN

24.1.4.1. Initiate a connection from a Linux client

This topic describes how to use SSL-VPN to connect a Linux client to a Virtual Private Cloud (VPC) network.

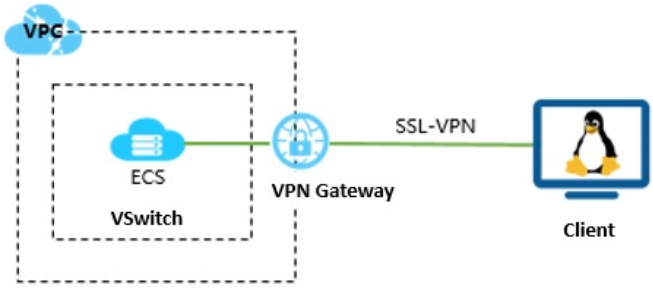
Prerequisites

Before you start, make sure that the following requirements are met:

- The CIDR block of the VPC network must not overlap with that of the client. Otherwise, the client cannot communicate with the VPC network.
- The client must be able to access the Internet.

Context

The following scenario is used as an example.



Step 1: Create a VPN gateway

Take the following steps to create a VPN gateway.

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN Gateway** page, specify the following parameters for the VPN gateway, and then click **Submit**.
   - **Organization**: Select the organization to which the VPN gateway belongs.
   - **Resource Set**: Select the resource set to which the VPN gateway belongs.
   - **Region**: Select the region where the VPN gateway is deployed.

     > **Note** Make sure that the VPC network and the VPN gateway associated with the VPC network are deployed in the same region.

   - **Instance Name**: Enter a name for the VPN gateway.

     The name must be 2 to 128 characters in length, and can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter or Chinese character, and cannot start with `http://` or `https://`.
   - **VPC**: Select the VPC network to be associated with the VPN gateway.
   - **Bandwidth**: Specify the maximum bandwidth of the VPN gateway. The bandwidth is provided for data transfer over the Internet.

- **IPsec-VPN**: Specify whether to enable IPsec-VPN for the VPN gateway. In this example, select **Disable**.
- **SSL-VPN**: Specify whether to enable SSL-VPN for the VPN gateway. In this example, select **Enable**.

  SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without configuring a gateway for the client.
- **SSL Connections**: Specify the maximum number of concurrent SSL connections that the VPN gateway supports.

5. Go to the VPN Gateways page to view the newly created VPN gateway.

   The newly created VPN gateway is in the Preparing state. Its status changes to Normal after about two minutes. The Normal status indicates that the VPN gateway is initialized and ready for use.

   > **Note** It takes about one to five minutes to create a VPN gateway.

Step 2: Create an SSL server

Take the following steps to create an SSL server.

1. In the left-side navigation pane, choose **VPN > SSL Servers**.
2. Select the region where you want to create the SSL server.
3. On the **SSL Servers** page, click **Create SSL Server**.
4. On the **Create SSL Server** page, set the following parameters for the SSL server, and then click **Submit**.
   - **Organization**: Select the organization to which the SSL server belongs.
   - **Resource Set**: Select the resource set to which the SSL server belongs.
   - **Region**: Select the region where you want to deploy the SSL server.
   - **Zone**: Select the zone where you want to deploy the SSL server.
   - **Name**: Enter a name for the SSL server.
   - **VPN Gateway**: Select a VPN gateway from the drop-down list.
   - **Source CIDR Block**: Enter the CIDR block of the VPC network. Click **+Add Local Network** to add more CIDR blocks. You can add the CIDR block of a VPC network, a VSwitch, and a local network.
   - **Client CIDR Block**: Enter the CIDR block of the client. The client connects to the SSL server from the specified CIDR block.
   - **Advanced Settings**: Specify whether to customize the advanced settings. In this topic, the default settings are used.

Step 3: Create and download an SSL client certificate

Take the following steps to create and download an SSL client certificate.

1. In the left-side navigation pane, choose **VPN > SSL Clients**.
2. Select the region where the client is created.
3. On the **SSL Clients** page, click **Create Client Certificate**.
4. On the **Create SSL Client Certificate** page, set the following parameters for the SSL client, and then click **Submit**.
   - **Organization**: Select the organization to which the SSL client certificate belongs.
   - **Resource Set**: Select the resource set to which the SSL client certificate belongs.
   - **Region**: Select the region where you want to create the SSL client certificate.
   - **Zone**: Select the zone where you want to create the SSL client certificate.
   - **Name**: Enter a name for the SSL client certificate.
   - **VPN Gateway**: Select the VPN gateway to be associated with the SSL client certificate.

- **SSL Server**: Select the SSL server to which you want to import the SSL client certificate.

5. On the **SSL Clients** page, find the target SSL client certificate, and then click **Download** in the **Actions** column.

Step 4: Configure the client

Take the following steps to configure the Linux client:

1. Run the following command to install the OpenVPN:

```
yum install -y openvpn
```

2. Decompress the client certificate package that you downloaded in Step 3 and copy the client certificate file to the */etc/openvpn/conf/* folder where OpenVPN is installed.
3. Run the following command to launch OpenVPN:

```
openvpn --config /etc/openvpn/conf/config.ovpn --daemon
```

Step 5: Test the connectivity

To test the connectivity, run the **ping** command to ping the connected ECS instance in the VPC network.

> **Note** Make sure that the security group rules of the ECS instance allow remote access from Linux clients.

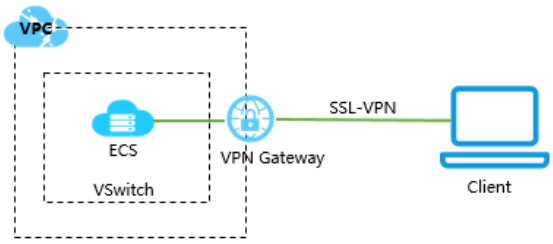
24.1.4.2. Initiate a connection from a Windows client

This topic describes how to use SSL-VPN to connect a Windows client to a Virtual Private Cloud (VPC) network.

Prerequisites

Context

The following scenario is used as an example.

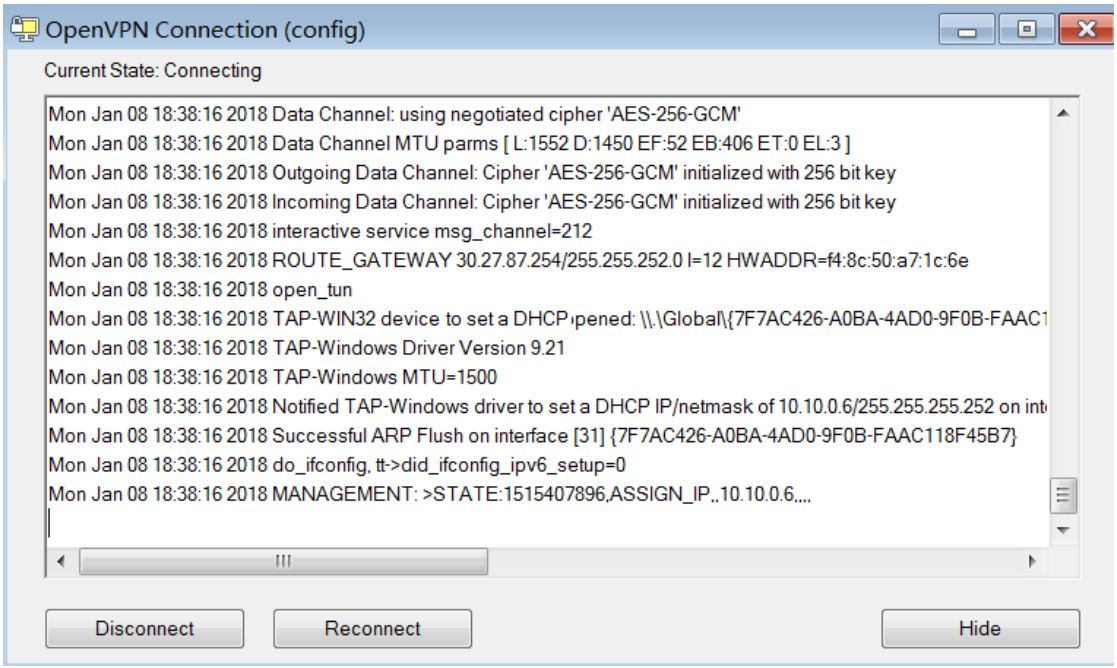


Step 4: Configure the client

Take the following steps to configure the Windows client:

> **Notice** You must run the client as an administrator.

1. Download and install OpenVPN.
2. Decompress the client certificate package that you downloaded in Step 3 and copy the client certificate file to the *config* folder where OpenVPN is installed.
3. Click **Connect** to initiate a connection.



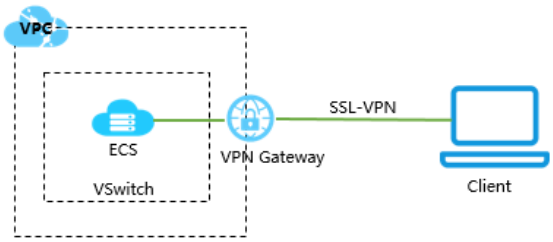
24.1.4.3. Initiate a connection from a macOS client

This topic describes how to use SSL-VPN to connect a macOS client to a Virtual Private Cloud (VPC) network.

Prerequisites

Context

The following scenario is used as an example.



Step 4: Configure the client

Take the following steps to configure the macOS client:

1. Run the following command to install OpenVPN:

   ```
   brew install openvpn
   ```

   > **Note** If Homebrew is not installed, install Homebrew first.

2. Decompress the client certificate package that you downloaded in Step 3, copy the client certificate file to the folder where OpenVPN is installed, and initiate a connection.
   i. Back up the default configuration file.
   ii. Run the following command to delete the default configuration file:

   ```
   rm /usr/local/etc/openvpn/*
   ```

iii. Run the following command to copy the file to the configuration directory:

```
cp cert_location /usr/local/etc/openvpn/
```

In the preceding command, `cert_location` represents the path that stores the certificate downloaded in Step 3, for example, */Users/example/Downloads/certs6.zip*.

iv. Run the following command to decompress the client certificate package:

```
cd  /usr/local/certificates
unzip /usr/local/etc/openvpn/certs6.zip
```

v. Run the following command to initiate a connection:

```
sudo /usr/local/opt/openvpn/sbin/openvpn --config /usr/local/etc/openvpn/config.ovpn
```

24.1.5. Manage a VPN Gateway

24.1.5.1. Create a VPN gateway

This topic describes how to create a VPN gateway. You must create a VPN gateway before you can use the IPsec-VPN and SSL-VPN services. After the VPN gateway is created, a public IP address is assigned to the VPN gateway.

Procedure

1. Log on to the VPN Gateway console.
2.
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN** page, specify the following parameters for the VPN gateway, and then click **Submit**.

Parameter	Description
Organization	Select the organization to which the VPN gateway belongs.
Resource Set	Select the resource set to which the VPN gateway belongs.
Region	Select the region where the VPN gateway is deployed. You can use IPsec-VPN to connect an on-premises data center to a VPC network or connect two VPC networks. Make sure that the VPC network and the VPN gateway associated with the VPC network are deployed in the same region.
Instance Name	Enter a name for the VPN gateway. The name must be 2 to 128 characters in length, and can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter or Chinese character and cannot start with `http://` or `https://`.
VPC	Select the VPC network to be associated with the VPN gateway.
Bandwidth	Specify the maximum bandwidth of the VPN gateway. The bandwidth is provided for data transfer over the Internet.
IPsec-VPN	Specify whether to enable IPsec-VPN for the VPN gateway. After IPsec-VPN is enabled, you can create IPsec-VPN connections between an on-premises data center and a VPC network, or between two VPC networks.

Parameter	Description
SSL-VPN	Specify whether to enable SSL-VPN for the VPN gateway. SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without configuring a customer gateway.
SSL Connections	Specify the maximum number of concurrent SSL connections that the VPN gateway supports. **Note** This parameter is available only after SSL-VPN is enabled.

24.1.5.2. Modify a VPN gateway

This topic describes how to modify the name and description of a VPN gateway.

Prerequisites

A VPN gateway is created. For more information, see Create and manage a VPN gateway.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the target VPN gateway, and click the icon in the **Instance ID/Name** column. In the dialog box that appears, enter a new name and click **OK**.

   The name must be 2 to 100 characters in length, and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.
5. Click the icon in the **Description** column. In the dialog box that appears, enter a new description and click **OK**.

   The description must be 2 to 256 characters in length, and cannot start with http:// or https://.

24.1.5.3. Configure routes of a VPN Gateway

24.1.5.3.1. VPN Gateway route overview

After you create an IPsec-VPN connection, you must manually add a VPN Gateway route.

The route-based IPsec-VPN enables you to easily configure and maintain VPN policies, and provides flexible ways for routing traffic.

You can add the following two types of routes for a VPN Gateway:

- Policy-based routes.
- Destination-based routes.

Policy-based route

If a policy-based route is used, traffic is forwarded based on both the source IP address and the destination IP address.

For more information, see Add a policy-based route entry.

> **Note** Policy-based routes take precedence over destination-based routes.

Destination-based route

If a destination-based route is used, traffic is forwarded based only on the destination IP address.

For more information, see Add a destination-based route entry.

24.1.5.3.2. Add a policy-based route entry

This topic describes how to add a policy-based route entry after an IPsec-VPN connection is created. Policy-based routing (PBR) is a technique that routes packets based on source and destination IP addresses.

Procedure

1. Log on to the VPN Gateway console.
2.
3.
4. On the **VPN Gateways** page, find the target VPN gateway and click the instance ID in the **Instance ID/Name** column.
5. Click the **Policy-based Routing** tab, and then click **Add Route Entry**.
6. In the **Add Route Entry** dialog box, set the following parameters and click **OK**.

Parameter	Description
Destination CIDR Block	The CIDR block that you want to access.
Source CIDR Block	The CIDR block of the VPC network.
Next Hop Type	Select IPsec Connection.
Next Hop	Select an IPsec instance to create an IPsec-VPN connection.
Publish to VPC	Specify whether to automatically publish new route entries to the VPC route table. ○ Yes (Recommended): automatically publishes new route entries to the VPC route table. ○ No: does not automatically publish new route entries to the VPC route table. **Note** If you select No, you must manually publish new route entries to the VPC route table.
Weight	Select a weight. Valid values: ○ 100: indicates that the priority of the route entry is high. ○ 0: indicates that the priority of the route entry is low. **Note** If two policy-based route entries are configured with the same destination CIDR block, you cannot set the weights of both route entries to 100.

24.1.5.3.3. Add a destination-based route entry

This topic describes how to manually add a destination-based route entry after an IPsec-VPN connection is created. Destination-based routing is a technique that routes packets to specified destination IP addresses.

Procedure

1. Log on to the VPN Gateway console.
2.
3.
4.
5. In the **Destination-based routing** tab, click **Add Route Entry**.
6. In the **Add Route Entry** dialog box, set the following parameters and click **OK**.

Parameter	Description
Destination CIDR Block	The CIDR block that you want to access.
Next Hop Type	Select IPsec Connection.
Next Hop	Select an IPsec instance to create an IPsec-VPN connection.
Publish to VPC	Specify whether to automatically publish new route entries to the VPC route table. ○ Yes (Recommended): automatically publishes new route entries to the VPC route table. ○ No: does not automatically publish new route entries to the VPC route table. **Note** If you select No, you must manually publish new route entries to the VPC route table.
Weight	Select a weight. Valid values: ○ 100: indicates that the priority of the route entry is high. ○ 0: indicates that the priority of the route entry is low. **Note** If two destination-based route entries are configure with the same destination CIDR block, you cannot set the weights of both route entries to 100.

24.1.5.4. Delete a VPN gateway

This topic describes how to delete a VPN gateway. After you delete a VPN gateway, you can no longer use the VPN gateway to establish IPsec-VPN or SSL-VPN connections.

Context

Before you delete a VPN gateway, make sure that the following conditions are met:

- The IPsec-VPN connections on the VPN gateway are deleted. For more information, see and Delete an IPsec-VPN connection.
- The SSL server associated with the VPN gateway is deleted. For more information, see and Delete an SSL server.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the target VPN gateway, and then click **Delete** in the **Actions** column.
5. In the **Delete VPN Gateway** dialog box, click **OK**.

24.1.6. Manage a customer gateway

24.1.6.1. Create a customer gateway

This topic describes how to create a customer gateway when you use IPsec-VPN to connect a Virtual Private Cloud (VPC) network to an on-premises data center or connect two VPC networks. You can register and update the information of an on-premises gateway to Alibaba Cloud by creating a customer gateway, and then connect the customer gateway to the VPN gateway. A customer gateway can be connected to multiple VPN gateways.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, click **VPN > Customer Gateways**.
3. Select the region where you want to deploy the customer gateway.

   > **Note** Make sure that the customer gateway and the VPN gateway to be connected are deployed in the same region.

4. On the **Customer Gateways** page, click **Create Customer Gateway**.
5. On the **Create Customer Gateway** page, set the following parameters, and click **Submit**.

Parameter	Description
Organization	Select the organization to which the customer gateway belongs.
Resource Set	Select the resource set to which the customer gateway belongs.
Region	Select the region where you want to deploy the customer gateway. **Note** Make sure that the customer gateway and the VPN gateway to be connected are deployed in the same region.
Zone	Select the zone where you want to deploy the customer gateway
Name	Enter a name for the customer gateway. The name must be 2 to 128 characters in length, and can contain letters, digits, hyphens (-), and underscores (_). It must start with a letter or Chinese character and cannot start with `http://` or `https://`.
IP Address	Enter the static public IP address of the gateway device that is deployed in the on-premises data center.
Description	Enter a description for the customer gateway. The description must be 2 to 256 characters in length, and cannot start with `http://` or `https://`.

24.1.6.2. Modify a customer gateway

This topic describes how to modify the name and description of a customer gateway.

Prerequisites

A customer gateway is created. For more information, see Create a customer gateway.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > Customer Gateways**.
3. Select the region where the customer gateway is deployed.
4. On the **Customer Gateways** page, find the target customer gateway, click the icon in the **Instance ID** column. In the dialog box that appears, enter a name and click **OK**.

   The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.
5. Click the icon in the **Description** column. In the dialog box that appears, enter a new description and click **OK**.

   The description must be 2 to 256 characters in length, and cannot start with http:// or https://.

24.1.6.3. Delete a customer gateway

This topic describes how to delete a customer gateway.

Procedure

1. Log on to the VPN Gateway console.
2.
3.
4. On the **Customer Gateways** page, find the target customer gateway, and then click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

24.1.7. Configure SSL-VPN

24.1.7.1. Configuration overview

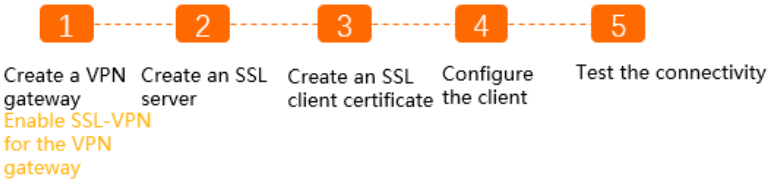
This topic describes how to use the SSL-VPN function to connect a remote client to a VPC.

Prerequisites

Before you use SSL-VPN to establish a connection between a client and a VPC, make sure that the following requirements are met:

- The private CIDR block of the client does not overlap with the private CIDR block of the VPC. Otherwise, the client and the VPC cannot communicate with each other.
- The client can access the Internet.
- You have read and understand the security group rules that apply to the Elastic Compute Service (ECS) instances in the VPC, and make sure that the security rules allow the client to access the ECS instances.

Procedure



1. Create a VPN gateway.

   Create a VPN gateway and enable the SSL-VPN feature.

2. Create an SSL server.

   On the SSL server, specify the private CIDR block that the client needs to access and the CIDR block that is used by the client.

3. Create an SSL client certificate.

   Create and download a client certificate based on the SSL server configuration.

4. Configure the client.

   Download and install VPN software on the client, load the SSL client certificate, and then initiate an SSL-VPN connection.

5. Verify the connectivity.

   Open the CLI on the client, and run the **ping** command to ping an ECS instance in the VPC.

24.1.7.2. Manage an SSL server

24.1.7.2.1. Create an SSL server

This topic describes how to create an SSL server. Before you use SSL-VPN to establish a point-to-site connection, you must create an SSL server.

Prerequisites

A VPN gateway is created and SSL-VPN is enabled for the VPN gateway. For more information, see Create a VPN gateway.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **Cross-Network Connections > SSL Servers**.
3. In the top navigation bar, select the region where you want to create the SSL server.
4. On the **SSL Servers** page, click **Create SSL Server**.
5. On the **Create SSL Server** page, configure the SSL server based on the following information and click **Submit**.

Parameter	Description
Organization	Select the organization to which the SSL server belongs.
Resource Set	Select the resource set to which the SSL server belongs.
Region	Select the region where the SSL server is to be deployed.
Zone	Select the zone where the SSL server is to be deployed.

Parameter	Description
Name	Enter a name for the SSL server. The name must be 2 to 128 characters in length, and can contain letters, digits, hyphens (-), and underscores (_). It must start with a letter or Chinese character and cannot start with `http://` or `https://`.
VPN Gateway	Select the VPN gateway that you want to associate with the SSL server. Make sure that SSL-VPN is enabled for the VPN gateway.
Source CIDR Block	Enter the CIDR block of the network to be connected to the client through an SSL-VPN connection. It can be the CIDR block of a VPC, a vSwitch, a data center connected to a VPC through a leased line, or a cloud service such as ApsaraDB RDS or Object Storage Service (OSS). Click **+** to add more CIDR blocks. **Note** The subnet mask of the specified server CIDR block must be 16 to 29 bits in length.
Client CIDR Block	Enter the CIDR block to be allocated to the virtual network interface of the client. Do not enter the CIDR block where the client resides. When a client accesses the server through an SSL-VPN connection, the VPN gateway assigns an IP address from the specified client CIDR block to the client. **Note** Make sure that the server CIDR block and the client CIDR block do not overlap with each other.
Advanced Settings	Specify whether to customize the advanced settings. ○ **Default**: Use the default advanced settings. ○ **Custom**: Use custom settings. You can customize the following settings: ■ **Protocol**: Select the protocol over which the SSL-VPN connection is established. Supported protocols are UDP and TCP. ■ **Port**: Specify the port to which the SSL-VPN connection is established. The following ports are not supported: 22, 2222, 22222, 9000, 9001, 9002, 7505, 80, 443, 53, 68, 123, 4510, 4560, 500, and 4500. ■ **Encryption Algorithm**: Select the encryption algorithm used by the SSL connection. Valid values: AES-128-CBC, AES-192-CBC, AES-256-CBC, and none. ■ **Compressed**: Specify whether to enable data compression.

24.1.7.2.2. Modify an SSL server

This topic describes how to modify the name, server CIDR block, client CIDR block, and advanced settings of an SSL server.

Prerequisites

An SSL server is created. For more information, see Create an SSL server.

Procedure

1. Log on to the VPN Gateway console.
2.
3.
4. On the **SSL Servers** page, find the target SSL server, and then click **Edit** in the **Actions** column.
5. On the **Edit SSL Server** page, modify the name, server CIDR block, client CIDR block, and advanced settings of the SSL server, and then click **OK**.

24.1.7.2.3. Configure a routing group

This topic describes how to configure a routing group to control the inbound and outbound traffic of an Elastic Compute Service (ECS) instance after you create an IPsec-VPN connection.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > SSL Servers**.
3. Select the region where the SSL server is deployed.
4. On the **SSL Servers** page, find the target SSL server, and then click **Configure Routing Group** in the **Actions** column.
5. In the **Configure Routing Group** panel, set the following parameters and click **OK**.

Parameter	Description
Security Group	Select the security group to which you want to add the security group rule.
Rule Direction	Select the direction of data transfer that the rule controls. ○ **Outbound**: controls data transfer from the ECS instances in the security group to the Internet or other ECS instances. ○ **Inbound**: controls data transfer from the Internet or other ECS instances to the ECS instances in the security group.
Action	Specify the action to be performed on the matching requests. ○ **Allow**: accepts requests. ○ **Deny**: drops requests without returning messages. If two security group rules use the same settings except for different actions, the **Deny** rule prevails over the **Allow** rule.
Protocol Type	The protocol of the security group rule.
Port Range	Enter a port range for the security group rule. Valid values: -1 and 1 to 65535. You cannot enter only -1. Examples: ○ 1/200 specifies ports 1 to 200. ○ 80/80 specifies port 80. ○ -1/-1 specifies all ports.
Priority	Set the priority of the rule. Valid values: 1 to 100. The default value is 1, which indicates the highest priority.

Parameter	Description
Authorization Mode	Specify the type of addresses that the security group rule permits or blocks. You can select only **Address**, which indicates CIDR blocks.
ENI Type	Specify the type of data transfer that the security group rule controls. ○ **Internal**: controls data transfer within Alibaba Cloud. ○ **External**: controls data transfer over the Internet.
Authorization IP Addresses	Specify the CIDR blocks that you want the security group rule to accept or block. You can specify at most 10 CIDR blocks.
Enable Automatically Configure Routers	Specify whether to automatically propagate routes. The feature is enabled by default.
Description	Enter a description for the security group rule. The description must be 2 to 256 characters in length, and cannot start with `http://` or `https://`. You can leave this parameter empty.

24.1.7.2.4. Delete an SSL server

This topic describes how to delete an SSL server.

Procedure

1. Log on to the VPN Gateway console.
2.
3.
4. On the **SSL Servers** page, find the target SSL server, and then click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

24.1.7.3. Manage an SSL client certificate

24.1.7.3.1. Create an SSL client certificate

After you create an SSL server, you must create an SSL client certificate based on the configuration of the SSL server before you can establish an SSL-VPN connection.

Prerequisites

An SSL server is created. For more information, see Create an SSL server.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > SSL Clients**.
3. Select the region where the SSL client is deployed.
4. On the **SSL Clients** page, click **Create Client Certificate**.
5. On the **Create SSL Client Certificate** page, configure the client certificate based on the following

information, and then click **Submit**.

Parameter	Description
Organization	Select the organization to which the SSL client belongs.
Resource Set	Select the resource set to which the SSL client belongs.
Region	Select the region where the SSL client is deployed.
Zone	Select the zone where the SSL client is deployed.
Name	Enter a name for the SSL client certificate. The name must be 2 to 128 characters in length, and can contain letters, digits, hyphens (-), and underscores (_). It must start with a letter or Chinese character and cannot start with `http://` or `https://`.
VPN Gateway	Select the VPN gateway that is used to establish the SSL-VPN connection.
SSL Server	Select the SSL server to be associated with the SSL client.

24.1.7.3.2. Download an SSL client certificate

This topic describes how to download an SSL client certificate. Before you use an SSL client to initiate an SSL-VPN connection, you must import the SSL client certificate to the SSL client.

Prerequisites

An SSL client certificate is created. For information, see Create an SSL client certificate.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > SSL Clients**.
3. Select the region where the SSL client is deployed.
4. On the **SSL Clients** page, find the target SSL client certificate, and then click **Download** in the **Actions** column.

24.1.7.3.3. Delete an SSL client certificate

This topic describes how to delete an SSL client certificate.

Procedure

1. Log on to the VPN Gateway console.
2.
3.
4. On the **SSL Clients** page, find the target SSL client certificate, and then click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

24.1.8. Configure IPsec-VPN connections

24.1.8.1. Configuration overview

This topic describes how to connect a VPC to an on-premises data center through IPsec-VPN.

Prerequisites

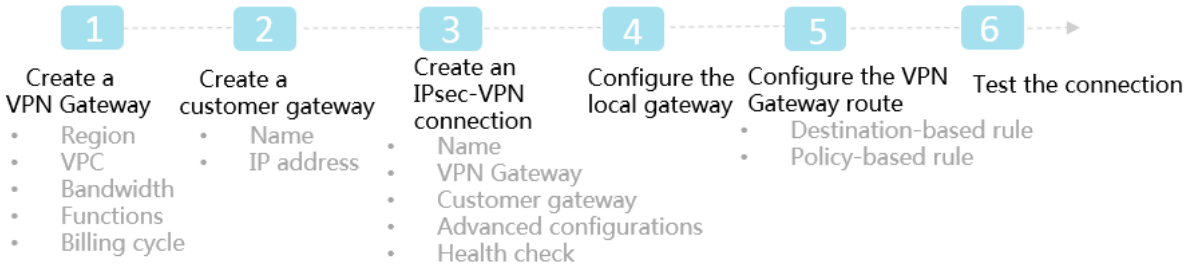
Before creating a site-to-site VPN connection, make sure the following conditions are met:

- The protocols IKEv1 and IKEv2 are supported by the gateway device of the on-premises data center.

  IPsec-VPN supports IKEv1 and IKEv2 protocols. Devices that support these two protocols can connect to Alibaba Cloud VPN Gateway, including devices of Huawei, H3C, Hillstone, SANGFOR, Cisco ASA, Juniper, SonicWall, Nokia, IBM, and Ixia.
- A static public IP address is configured for the local gateway.
- The IP address ranges of the VPC and on-premises data center to be connected do not conflict with each other.

Procedure

The following figure shows the procedure of connecting a VPC to an on-premises data center through IPsec-VPN.



1. Create a VPN Gateway

   Enable the IPsec-VPN function. Up to 10 IPsec-VPN connections can be established in a VPN Gateway.
2. Create a customer gateway

   By creating a customer gateway, you can register the local gateway to Alibaba Cloud and connect the customer gateway to the VPN Gateway. A customer gateway can be connected to multiple VPN Gateways.
3. Create an IPsec connection

   An IPsec connection is a VPN channel established between a VPN Gateway and a customer gateway. The encrypted communication between the VPN Gateway and the on-premises data center can be achieved only after the IPsec connection is established.
4. Configure the local gateway

   You need to load the VPN Gateway configurations to the local gateway device.
5. Configure the VPN Gateway route

   You need to configure a route in the VPN Gateway and publish it to the VPC route table.
6. Test the connection

   Log on to an ECS instance (without a public IP address) in the connected VPC. **ping** the private IP address of a server in the on-premises data center to check whether the connection is established.

24.1.8.2. Manage an IPsec-VPN connection

24.1.8.2.1. Create an IPsec-VPN connection

This topic describes how to create an IPsec-VPN connection. After you create a VPN gateway and a customer gateway, you can create an IPsec-VPN connection between the two gateways for encrypted data transmission.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. Select the region where you want to create the IPsec-VPN connection.
4. On the **IPsec Connections** page, click **Create IPsec Connection**.
5. On the **Create IPsec Connection** page, configure the IPsec-VPN connection based on the following information and click **Submit**.

Parameter	Description
Organization	Select the organization to which the IPsec-VPN connection belongs.
Resource Set	Select the resource set to which the IPsec-VPN connection belongs.
Region	Select the region where the IPsec-VPN connection is established.
Zone	Select the zone where the IPsec-VPN connection is established.
Name	Enter a name for the IPsec-VPN connection. The name must be 2 to 128 characters in length, and can contain letters, digits, hyphens (-), and underscores (_). It must start with a letter or Chinese character and cannot start with `http://` or `https://`.
VPN Gateway	Select the VPN gateway to be connected through the IPsec-VPN connection.
Customer Gateway	Select the customer gateway to be connected through the IPsec-VPN connection.
Source CIDR Block	Enter the CIDR block of the VPC network to be connected to the on-premises data center. The CIDR block is used during phase 2 negotiation. You can add more than one CIDR blocks only if IKEv2 is used.
Destination CIDR Block	Enter the CIDR block of the on-premises data center to be connected to the VPC network. This CIDR block is used during phase 2 negotiation. You can add more than one CIDR blocks only if IKEv2 is used.
Immediate Effect	Specify whether to start connection negotiations immediately. ○ **Yes**: Negotiate immediately after the configuration is complete. ○ **No**: Negotiate when traffic is detected in the IPsec-VPN tunnel.
Advanced Settings	Specify whether to customize the advanced settings. ○ **Default**: Use default settings. ○ **Configure**: Use custom settings.
Advanced configuration: IKE configuration	
Pre-shared Key	Enter the pre-shared key used for authentication between the VPN gateway and customer gateway. You can specify a key, or use the default key that is randomly generated by the system.

Parameter	Description
Version	The version of the IKE protocol. Select an IKE version. Compared with IKEv1, IKEv2 simplifies the process of Security Association (SA) negotiation and provides better support for scenarios where an SSL-VPN connection is established with multiple subnets. We recommend that you select IKEv2.
Negotiation Mode	The negotiation mode of IKEv1. ○ Main: This mode offers higher security. ○ Aggressive: This mode is faster than the main mode. Negotiations are more likely to succeed in this mode. Connections negotiated in both modes ensure the same security level of data transmission.
Encryption Algorithm	Select the encryption algorithm used during phase 1 negotiation. Supported algorithms are aes, aes192, aes256, des, and 3des.
Authentication Algorithm	Select the authentication algorithm used during phase 1 negotiation. Supported algorithms are sha1, and md5.
DH Group	Select the Diffie-Hellman key exchange algorithm used during phase 1 negotiation.
SA Life Cycle (Seconds)	Specify the lifecycle of the SA after phase 1 negotiation succeeds. Default value: 86,400.
LocalId	The ID of the VPN gateway used during phase 1 negotiation. The default value is the public IP address of the VPN gateway. If you set LocalId to a FQDN, we recommend that you set Negotiation Mode to Aggressive.
RemoteId	The ID of the customer gateway used during phase 1 negotiation. The default value is the public IP address of the customer gateway. If you set RemoteId to a FQDN, we recommend that you select set Negotiation Mode to Aggressive.
Advanced configuration: IPSec configuration	
Encryption Algorithm	Select the encryption algorithm used during phase 2 negotiation. Supported algorithms are aes, aes192, aes256, des, and 3des.
Authentication Algorithm	Select the authentication algorithm used during phase 2 negotiation. Supported algorithms are sha1, and md5.
DH Group	Select the Diffie-Hellman key exchange algorithm for phase 2 negotiations. ○ If you select a Diffie-Hellman group, the perfect forward secrecy (PFS) feature is enabled and each negotiation requires a new key. Therefore, you must also enable PFS for the client. ○ For clients that do not support PFS, select disabled.
SA Life Cycle (Seconds)	Specify the lifecycle of the SA after phase 2 negotiation succeeds. Default value: 86,400.

24.1.8.2.2. Modify an IPsec-VPN connection

This topic describes how to modify the name, advanced settings, and health check for an IPsec-VPN connection.

Prerequisites

An IPsec-VPN connection is created. For more information, see Create an IPsec-VPN connection.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. In the top navigation bar, select the region where the IPsec-VPN connection is created.
4. On the **IPsec Connections** page, find the target IPsec-VPN connection and then click **Edit** in the **Actions** column.
5. In the **Modify IPsec Connections** dialog box, modify the name, advanced settings, and health check, and click **Submit**.

24.1.8.2.3. Download the configuration file of an IPsec-VPN connection

This topic describes how to download the configurations of an IPsec-VPN connection, and load the configurations to the customer gateway device after an IPsec-VPN connection is configured.

Prerequisites

An IPsec-VPN connection is created. For more information, see Create an IPsec-VPN connection.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. In the top navigation bar, select the region where the IPsec-VPN connection is created.
4. On the **IPsec Connections** page, find the target IPsec-VPN connection, and then choose **More > Download Configuration** in the **Actions** column.

> **Note** RemoteSubnet and LocalSubnet in the downloaded configurations are opposite to RemoteSubnet and LocalSubnet that you specify when you create an IPsec-VPN connection. For a VPN gateway, RemotSubnet refers to the CIDR block of the on-premises data center and LocalSubnet refers to the CIDR block of the VPC network. For a customer gateway, LocalSubnet refers to the CIDR block of the on-premises data center and RemoteSubnet refers to the CIDR block of the VPC network.

24.1.8.2.4. Configure a routing group

This topic describes how to configure routing groups to control the inbound and outbound traffic of ECS instances in a routing group after an IPsec-VPN connection is created.

Procedure

1. Log on to the VPN Gateway console.
2.
3.
4. On the **IPsec Connections** page, find the target IPsec-VPN connection, and then choose **More > Configure Routing Group** in the **Actions** column.
5. In the **Configure Routing Group** dialog box, set the following parameters, and then click **Submit**.

Parameter	Description
Routing Group	Select the routing group to which you want to add the routing group rule.

Parameter	Description
Rule Direction	Select the direction in which the rule is applied. ◦ **Outbound**: from the ECS instances in the current routing group to other ECS instances on Alibaba Cloud or resources on the Internet. ◦ **Inbound**: from other ECS instances on Alibaba Cloud or resources on the Internet to the ECS instances in the current routing group.
Authorization Policy	Select an authorization policy. ◦ **Allow**: accept requests received on the specified ports. ◦ **Deny**: discard requests received on the specified ports without returning messages. If you specify different authorization policies for two routing group rules but the other settings are the same, the **Deny** rule prevails over the **Allow** rule.
Protocol Type	Select a protocol type.
Port Range	Select a port range for the routing group rule. The port range depends on the protocol type: ◦ When you set Protocol to **All**, this parameter displays **-1/-1**, which indicates all ports. You cannot specify a port range if you select this protocol type. ◦ When you set Protocol to **TCP**, you can specify a port range in the <start port number>/<end port number> format. Valid port numbers: 1 to 65535. To specify a single port, set the start and end port numbers to the same value. For example, use 22/22 to indicate port 22. ◦ When Protocol is set to **UDP**, specify a port range in the <start port number>/<end port number> format. Valid port numbers: 1 to 65535. To specify a single port, set the start and end port numbers to the same value. For example, use 3389/3389 to indicate port 3389. ◦ When Protocol is set to **ICMP**, this parameter displays **-1/-1**, which indicates all ports. You cannot set a port range if you select this protocol type. ◦ When Protocol is set to **GRE**, this parameter displays **-1/-1**, which indicates all ports. You cannot set a port range if you select this protocol type.
Priority	Set the priority of the rule. Valid values: 1 to 100. The default value is 1, which indicates the highest priority.
Authorization Type	Select the authorization type of the routing group rule. You can select only **Address**.
NIC type	Select a NIC type. ◦ **Internal**: Control inbound and outbound traffic within Alibaba Cloud. ◦ **External**: Control inbound and outbound traffic over the Internet.
Authorized IP Addresses	Select the CIDR blocks to be authorized. You can specify up to 10 CIDR blocks at a time.
Automatically Configure Routers	Specify whether to automatically configure routers.

Parameter	Description
Description	The description of the routing group rule. The description must be 2 to 256 characters in length, and cannot start with `http://` or `https://`. You can left this parameter empty.

24.1.8.2.5. View IPsec-VPN connection logs

This topic describes how to view IPsec-VPN connection logs that are generated within the last 30 days to troubleshoot connection errors. You can query log data generated within 10 minutes.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. In the top navigation bar, select the region where the IPsec-VPN connection is created.
4. On the **IPsec Connections** page, find the target IPsec-VPN connection, and then choose **More > View Logs** in the **Actions** column.
5. In the **IPsec Connection Logs** dialog box, set the time range and query the logs.

24.1.8.2.6. Delete an IPsec-VPN connection

This topic describes how to delete an IPsec-VPN connection.

Procedure

1. Log on to the VPN Gateway console.
2.
3.
4. On the **IPsec Connections** page, find the target IPsec-VPN connection, and then click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

24.1.8.3. MTU notes

The maximum transmission unit (MTU) is the size (in bytes) of the largest packet supported by the network layer protocol (such as TCP), with headers and data included.

Network packets sent over IPsec tunnels are encrypted and then encapsulated in external packets for routing. Because an encapsulated internal packet itself must fit the MTU of the corresponding external packet, the MTU of the internal packet must be smaller.

Gateway MTU and system MTU

You must configure the MTU limit of the local VPN Gateway to not more than 1,400 bytes. We recommend that you set the MTU to 1,400 bytes.

For TCP traffic, the maximum length of data that can be carried by each packet segment can be negotiated by the sender and receiver when they communicate based on the maximum segment size (MSS).

25.Elastic IP Address

25.1. User Guide

25.1.1. What is an EIP?

This topic provides an overview of Elastic IP Address. An elastic IP address (EIP) is a public IP address that you can purchase and hold as an independent resource. You can associate an EIP with an Elastic Compute Service (ECS) instance deployed in a virtual private cloud (VPC), an internal Server Load Balancer (SLB) instance deployed in a VPC, or a secondary elastic network interface (ENI) attached to a VPC. You can also associate an EIP with a NAT gateway, or a High-Availability Virtual IP Address (HAVIP).

An EIP is also a NAT IP address that is provisioned in a public-facing gateway of Alibaba Cloud and is mapped to the associated cloud resource with NAT. After an EIP is associated with a cloud resource, the cloud resource can connect to the Internet by using this EIP.

Line types

EIPs support BGP (Multi-ISP) lines and BGP (Multi-ISP) Pro lines. The following table describes the differences between BGP (Multi-ISP) and BGP (Multi-ISP) Pro.

Item	BGP (Multi-ISP)	BGP (Multi-ISP) Pro
Advantages	BGP (Multi-ISP) provides high-quality and high-bandwidth BGP lines. • Up to 89 high-quality BGP lines are available worldwide. • Direct connections can be established in all regions of the Chinese mainland through lines of the following Internet Service Providers (ISPs): China Telecom, China Unicom, China Mobile, China Mobile Tietong, China Netcom, China Education and Research Network (CERNET), National Radio and Television Administration, Dr. Peng Telecom & Media Group, and Founder Broadband Network. • You can use BGP (Multi-ISP) with EIP bandwidth plans to obtain bandwidth of 100 Gbit/s and higher.	BGP (Multi-ISP) Pro lines optimize data transmission to the Chinese mainland and improve connection quality for international services. Compared with BGP (Multi-ISP), when BGP (Multi-ISP) Pro lines provide services to users in the Chinese mainland (excluding data centers), cross-border connections are established by using Chinese mainland ISP services. This reduces network latency.
Region	All regions	China (Hong Kong)

Benefits

EIPs have the following benefits:

- Independent purchase and possession

  You can purchase and hold an EIP as an independent resource. EIPs are not bundled with other computing or storage resources.

- Flexible association

  You can dissociate an EIP from a cloud resource and then release the EIP if the EIP is no longer needed.

- Configurable network capabilities

  You can adjust the peak bandwidth of an EIP at any time. The bandwidth changes take effect immediately.

25.1.2. Log on to the EIP console

This topic describes how to log on to the Apsara Uni-manager Management Console to manage your elastic IP addresses (EIPs). The Google Chrome browser is used as an example.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top menu bar, choose **Products > Networking > Elastic IP Address**.

25.1.3. Quick start

25.1.3.1. Tutorial overview

This topic provides an overview of the tutorial that guides you in creating an EIP and associating an EIP with an ECS instance to allow the ECS instance to access the Internet.

This tutorial walks you through the following tasks:

1. Apply for new EIPs

   An EIP is a public IP address that you can purchase and hold as an independent resource. To get started, you must create an EIP.

2. Associate an EIP with an ECS instance

   You can associate an EIP with an ECS instance deployed in a VPC to enable the ECS instance to connect to the Internet.

3. Disassociate an EIP from a cloud resource

   You can disassociate an ECS instance from an EIP when the ECS instance no longer requires access to the Internet.

4. Release an EIP

   You can release an EIP if it is no longer needed.

25.1.3.2. Apply for EIPs

This topic describes how to apply for elastic IP addresses (EIPs). An EIP is a public IP address that you can purchase and hold as an independent resource.

Procedure

1. Log on to the EIP console.
2. On the **Elastic IP Addresses** page, click **Create EIP**.
3. On the **Create Elastic IP Address** page, set the following parameters and click **Submit**.

Parameter	Description
Organization	Select the organization to which the EIP belongs.
Resource Set	Select the resource group to which the EIP belongs.
Region	Select a region for the EIP. Make sure that the EIP and the cloud resources to be associated with the EIP are deployed in the same region.
Zone	Select a zone for the EIP.
Internet Connection Type	Select a line type for the EIP.
Network Type	Select a network type for the EIP. ◦ **Public Network**: The EIP is used to enable communication on the Internet. ◦ **Hybrid Cloud**: The EIP is used to enable communication within a hybrid cloud. For example, you must select an EIP of this type to allow your server in the on-premises data center to access the Internet by using Source Network Address Translation (SNAT) and Destination Network Address Translation (DNAT).
Service IP	Enter the IP address that you want to request. Make sure that the specified IP address is an IPv4 address and the IP address is not used by another account. Otherwise, the EIP cannot be allocated. **Note** If you do not specify an EIP, the system automatically assigns one.
Max Bandwidth	Specify the maximum bandwidth of the EIP. Unit: Mbit/s.

25.1.3.3. Associate an EIP with an ECS instance

This topic describes how to associate an EIP with an ECS instance deployed in a VPC. ECS instances that are associated with EIPs can communicate with the Internet.

Prerequisites

You have created an ECS instance. For more information, see the **Create an instance** topic of **Quick start** in the *Apsara Stack Elastic Compute Service User Guide*.

Procedure

1. Log on to the EIP console.

2. In the top navigation bar, select the region where the EIP is deployed.
3. On the **Elastic IP Addresses** page, find the target EIP, and then click **Bind** in the **Actions** column.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select **ECS Instance**.
ECS Instance	Select the ECS instance to be associated with the EIP. When you select an ECS instance, note the following points: ○ The ECS instance must be deployed in a VPC. ○ The ECS instance must be running or stopped. ○ An ECS instance can be associated with only one EIP. ○ The ECS instance and the EIP must reside in the same region. ○ The ECS instance is not associated with a public IP address or another EIP.

25.1.3.4. Disassociate an EIP from a cloud resource

This topic describes how to dissociate an EIP from a cloud resource when this cloud resource no longer needs to communicate with the Internet.

Procedure

1. Log on to the EIP console.
2.
3. On the **Elastic IP Addresses** page, find the target EIP, and click **Unbind** in the **Actions** column.
4. In the **Unbind Elastic IP Address** dialog box, click **OK**.

25.1.3.5. Release an EIP

This topic describes how to release an Elastic IP address (EIP).

Prerequisites

The EIP is disassociated from all instances. For more information, see Disassociate an EIP from a cloud resource.

Procedure

1. Log on to the EIP console.
2.
3. On the **Elastic IP Addresses** page, find the target EIP, move the mouse pointer over **More operations** in the **Actions** column, and then click **Release**.
4. In the **Release an EIP** dialog box, click **OK**.

25.1.4. Manage EIPs

25.1.4.1. Create a EIP

This topic describes how to create a EIP. An EIP is a public IP address that you can purchase and hold as an independent resource.

Procedure

1. Log on to the EIP console.
2. On the **Elastic IP Addresses** page, click **Create EIP**.
3. On the **Create Elastic IP Address** page, set the parameters and click **Submit**. The following table describes the configuration parameters.

Parameter	Description
Organization	Select the organization to which the EIP belongs.
Resource Set	Select the resource set to which the EIP belongs.
Region	Select a region for the EIP. Make sure that the EIP and the cloud resource to be associated with the EIP are located in the same region.
Zone	Select the zone to which the EIP belongs.
Line Type	Select the line type of the EIP.
Network Type	Select the network type of communication for which the EIP will be used. ○ **Public Network**: Use the EIP to enable communication with the Internet. ○ **Hybrid Cloud**: Use the EIP to enable communication within a hybrid cloud. For example, if you need to establish network connections from an on-premises data center to the Internet by using source network address translation (SNAT) and destination network address translation (DNAT), you must select this type for your EIP.
Service IP	Specify a specific EIP. Make sure that the specified IP address is an IPv4 address and is not taken by another account. Otherwise, the EIP cannot be allocated. **Note** If you do not specify a service IP, a random EIP will be assigned to you by the system.
Peak Bandwidth	Specify the maximum bandwidth for the EIP. Unit: Mbit/s.

25.1.4.2. Bind an EIP to a cloud instance

25.1.4.2.1. Associate an EIP with an ECS instance

This topic describes how to associate an EIP with an ECS instance deployed in a VPC. ECS instances that are associated with EIPs can communicate with the Internet.

Prerequisites

You have created an ECS instance. For more information, see the **Create an instance** topic of **Quick start** in the *Apsara Stack Elastic Compute Service User Guide*.

Procedure

1. Log on to the EIP console.
2. In the top navigation bar, select the region where the EIP is deployed.

3. On the **Elastic IP Addresses** page, find the target EIP, and then click **Bind** in the **Actions** column.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select **ECS Instance**.
ECS Instance	Select the ECS instance to be associated with the EIP. When you select an ECS instance, note the following points: ○ The ECS instance must be deployed in a VPC. ○ The ECS instance must be running or stopped. ○ An ECS instance can be associated with only one EIP. ○ The ECS instance and the EIP must reside in the same region. ○ The ECS instance is not associated with a public IP address or another EIP.

25.1.4.2.2. Associate an EIP with an SLB instance

This topic describes how to associate an EIP with an SLB instance. After the association, the SLB instance can distribute requests from the Internet.

Prerequisites

You have created an SLB instance. For more information, see the **Create an SLB instance** topic of **Quick start** in the *Apsara Stack Server Load Balancer User Guide*.

Procedure

1.
2. Log on to the EIP console.
3.
4.
5. In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select **SLB Instance**.
SLB Instance	Select the SLB instance to be associated with the EIP. When you select an SLB instance, note the following points: ○ The SLB instance must be deployed in a VPC. ○ The SLB instance and the EIP must reside in the same region. ○ An SLB instance can be associated with only one EIP.

25.1.4.2.3. Associate an EIP with an HAVIP

This topic describes how to associate an EIP with an HAVIP. After the association, the HAVIP can be used to connect to the Internet.

Prerequisites

You have created an HAVIP. For more information, see the **Create an HAVIP** topic of **HAVIPs** in the *Apsara Stack*

Virtual Private Cloud User Guide.

Procedure

1. Log on to the EIP console.
2.
3.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select **HaVip Address**.
HaVip Address	Select the HAVIP to be associated with the EIP. When you select an HAVIP, note the following points: ○ The HAVIP and the EIP must reside in the same region. ○ The HAVIP must be available or allocated. ○ An HAVIP can be associated with only one EIP.

25.1.4.2.4. Associate an EIP with a NAT gateway

This topic describes how to associate an EIP with a NAT gateway. After the association, you can use the EIP to configure DNAT and SNAT entries.

Prerequisites

You have created a NAT gateway. For more information, see the **Create a NAT gateway** topic of **Quick start** in the *Apsara Stack NAT Gateway User Guide*.

Procedure

1. Log on to the EIP console.
2.
3.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

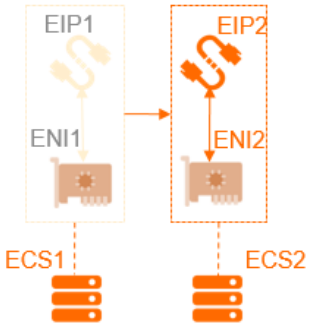
Parameter	Description
Instance Type	Select **NAT Gateway**.
NAT Gateway	Select the NAT gateway to be associated with the EIP. When you select a NAT gateway, note the following points: ○ The NAT gateway and the EIP must reside in the same region. ○ A NAT gateway can be associated with a maximum of 20 EIPs.

25.1.4.2.5. Bind an EIP to a secondary ENI

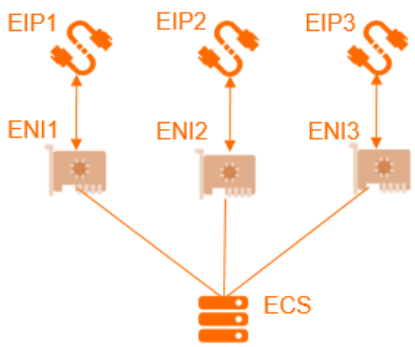
25.1.4.2.5.1. Overview

This topic provides an overview of EIP associations with ENIs. You can associate EIPs with ENIs to build a highly robust, flexible, and scalable IT solution. This also allows a cloud server to use multiple public IP addresses.

An ENI is assigned with a private IP address. After you associate an EIP with an ENI, the ENI has both a private IP address and a public IP address. When you migrate an ENI that is associated with an EIP from an ECS instance to another ECS instance, the public and private IP addresses are also migrated. This provides a highly reliable and available IP migration solution for cloud servers that use both public and private IP addresses.



To enable an ECS instance to use multiple public IP addresses, you can associate the ECS instance with multiple ENIs, and then associate each ENI with an EIP. You can use these public IP addresses along with security group rules to provide external services.



Association modes

You can associate an EIP with an ENI in one of the following two modes:

- NAT mode
- Cut-through mode

The following table lists the distinguishing features of each mode.

Feature	NAT mode	Cut-through mode
Support for displaying the associated EIPs in the ENI information	No	Yes **Note** You can run the **ifconfig** or **ipconfig** command to query the EIP associated with the corresponding ENI.
Supported ENIs that can be associated with EIPs	Primary and secondary ENIs	Secondary ENIs
The maximum number of EIPs that can be associated with a primary ENI	1	EIP associations with primary ENIs are not supported.

Feature	NAT mode	Cut-through mode
The maximum number of EIPs that can be associated with a secondary ENI	Depends on the number of private IP addresses of the secondary ENI. **Note** A one-to-one relationship is implemented between EIPs and the private IP addresses of a secondary ENI. For example, if a secondary ENI has 10 private IP addresses, a maximum of 10 EIPs can be associated with this ENI.	1 **Note** In the cut-through mode, an EIP can only be associated with the primary private IP address of a secondary ENI.
Support for the secondary ENI to deliver networking connectivity within the private network after the ENI is associated with an EIP	Yes	No
Supported protocols	EIPs that are associated in the NAT mode do not support the protocols that require connection management from NAT application-level gateway (ALG), such as H.323, Session Initiation Protocol (SIP), Domain Network System (DNS), and Real Time Streaming Protocol (RTSP).	All IP protocols, such as H.323, SIP, DNS, RTSP, File Transfer Protocol (FTP), and Trivial File Transfer Protocol (TFTP).

25.1.4.2.5.2. Associate an EIP with an ENI in the NAT mode

This topic describes how to associate an EIP with an ENI in the NAT mode. With this association, both the public and private IP addresses of the ENI can be used to provide networking connectivity. EIPs associated in the NAT mode cannot be displayed in the ENI information.

Prerequisites

Before you associate an EIP with an ENI in the NAT mode, make sure that the following conditions are met:

- You have created a secondary ENI that is attached to a VPC. The secondary ENI and the EIP to be associated reside in the same region. For more information, see the **Create an ENI** topic of **Elastic Network Interfaces** in the *Apsara Stack Elastic Compute Service User Guide*.
- The secondary ENI is not associated with an ECS instance.

  If the secondary ENI is associated with an ECS instance, you must disassociate it from the ECS instance. You can re-associate the ENI with the ECS instance after you have associated the ENI with the intended EIP in the NAT mode. For more information, see the **Unbind a secondary ENI from an instance** topic of **Elastic Network Interfaces** in the *Apsara Stack Elastic Compute Service User Guide*.

Context

The NAT mode has the following characteristics:

- The number of EIPs with which a secondary ENI can be associated depends on the number of private IP addresses of this secondary ENI.
- When an EIP is associated with an ENI in the NAT mode, both the private and public IP addresses of this ENI are available.
- The EIP associated with an ENI cannot be viewed in the operating system. To query the EIP associated with an ENI, call the DescribeEipAddresses operation.

- EIPs that are associated in the NAT mode do not support the protocols that require connection management from NAT ALG, such as H.323, SIP, DNS, RTSP, and TFTP.

Procedure

1. Log on to the EIP console.
2. In the top navigation bar, select the region of the EIP.
3. On the **Elastic IP Addresses** page, find the target EIP and click **Bind** in the **Actions** column.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

Parameter	Description
IP Address	Displays the target EIP.
Instance Type	Select **Secondary ENI**.
Mode	Select **NAT Mode**.
Secondary ENI	Select the secondary ENI to be associated with the EIP.

25.1.4.2.5.3. Associate an EIP with an ENI in the cut-through mode

This topic describes how to associate an EIP with an ENI in the cut-through mode. After the association, the EIP replaces the private IP address of the secondary ENI, which changes the secondary ENI to an Internet interface. You can view the EIP in the ENI information.

Prerequisites

Before you associate an EIP with an ENI in the cut-through mode, make sure that the following conditions are met:

- The secondary ENI is attached to a VPC.
- The secondary ENI and the EIP reside in the same region.
- The secondary ENI is not associated with an ECS instance.

  If the secondary ENI is associated with an ECS instance, you must disassociate it from the ECS instance. You can re-associate the ENI with the ECS instance after you have associated the ENI with the intended EIP in the cut-through mode. For more information, see the **Unbind a secondary ENI from an instance** topic of **Elastic Network Interfaces** in the *Apsara Stack Elastic Compute Service User Guide*.
- A secondary ENI can be associated with only one EIP.

Context

An EIP is essentially a NAT IP address. After you associate an EIP with an ENI in the NAT mode, the public IP address of the ENI is provisioned in a gateway rather than the ENI of the associated ECS instance. Therefore, the public IP address cannot be displayed in the operating system of the ECS instance, which only shows the private IP address in the ENI information. This complicates operations and maintenance because you must keep track of the mappings between network interfaces or servers and public IP addresses. In addition, EIPs that are associated with ENIs in the NAT mode do not support protocols such as H.323, SIP, DNS, or RTSP.

To solve the preceding problems, you can associate an EIP with an ENI in **cut-through mode**. In the cut-through mode:

- The EIP replaces the private IP address of the secondary ENI. This changes the secondary ENI to an Internet interface which can no longer deliver networking connectivity within the private network.

- You can view the EIP in the ENI information. To query the EIP associated with the corresponding ENI, you can call the **ifconfig** or **ipconfig** operation.
- EIPs that are associated in the cut-through mode support all Internet protocols, such as H.323, SIP, DNS, RTSP, FTP, and TFTP.

Procedure

1. Log on to the EIP console.
2. Select the region of the EIP.
3.
4. In the **Bind Elastic IP Address** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select **Secondary ENI**.
Binding mode	Select **Cut-Through Mode**.
Secondary ENI	Select the secondary ENI to be associated with the EIP.

> **Notice** Make sure that the selected secondary ENI is not associated with an ECS instance.

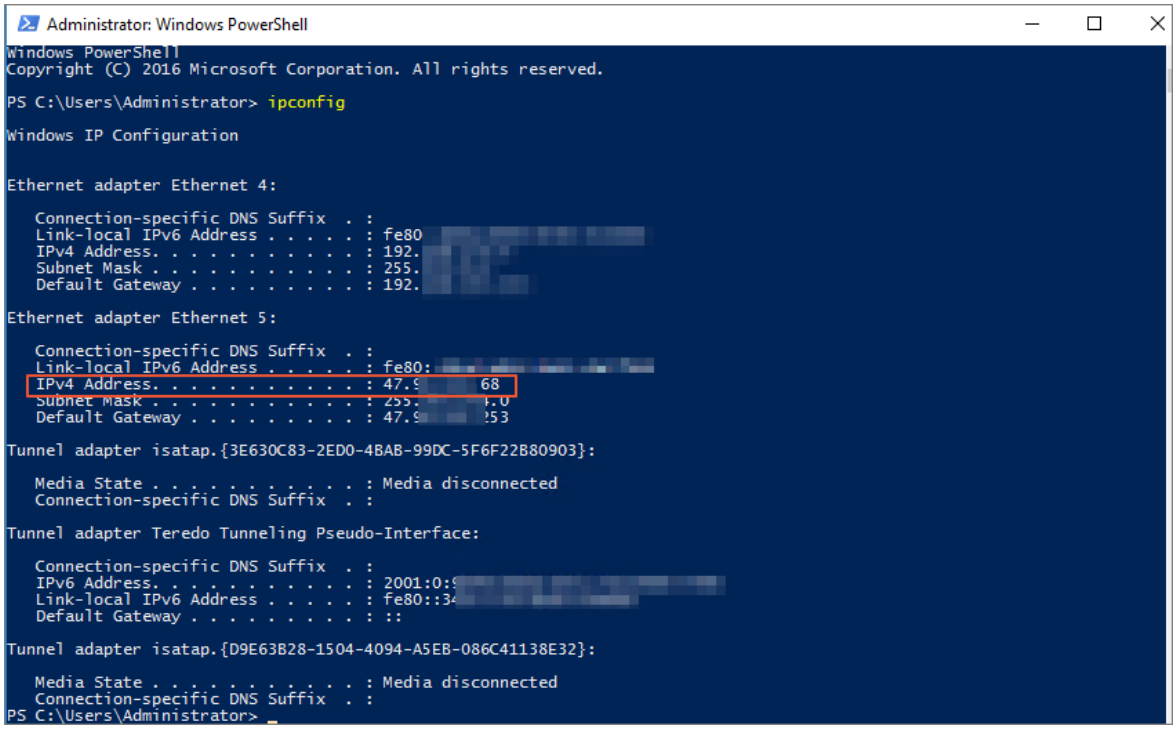
5. Return to the Elastic IP Addresses page and click the ID of the associated ENI.
6. Find the target ENI from the list of ENIs. In the **Actions** column, click **Bind** to associate the ENI with an ECS instance.

> **Note**
> - The maximum number of ENIs that can be associated with an ECS instance depends on the specification of the ECS instance. For more information, see the **Instance types** topic of **What is ECS** in the *Apsara Stack Elastic Compute Service User Guide*.
> - After you associate a secondary ENI with an ECS instance, you must enable Dynamic Host Configuration Protocol (DHCP) for the secondary ENI and then restart the ENI. Otherwise, the configuration made for the cut-through mode will not take effect.
> - After the configuration is complete, a route entry is automatically created for the ECS instance with the secondary ENI as the egress interface. The priority of this route entry is lower than that of the route with the primary ENI as the egress interface. Therefore, you can adjust the priority of these entries based on your service requirements.

7. Log on to the ECS instance by using the associated EIP to check the network configuration of the ECS instance.

> **Note** Make sure that the security group rules of the ECS instance allow remote access.

As shown in the following figure, the IPv4 address of the ECS instance is changed to the associated EIP.



25.1.4.3. Upgrade a subscription EIP

This topic describes how to upgrade the bandwidth of EIP. Bandwidth upgrades take effect immediately.

Procedure

1. Log on to the EIP console.
2.
3. On the **Elastic IP Addresses** page, find the target EIP and choose **More > Upgrade** in the **Actions** column.
4. On the **Change Specifications** page, set a new peak bandwidth for the EIP, and then click **Submit**.

25.1.4.4. Disassociate an EIP from a cloud resource

This topic describes how to dissociate an EIP from a cloud resource when this cloud resource no longer needs to communicate with the Internet.

Procedure

1. Log on to the EIP console.
2.
3. On the **Elastic IP Addresses** page, find the target EIP, and click **Unbind** in the **Actions** column.
4. In the **Unbind Elastic IP Address** dialog box, click **OK**.

25.1.4.5. Release an EIP

This topic describes how to release an Elastic IP address (EIP).

Prerequisites

The EIP is disassociated from all instances. For more information, see Disassociate an EIP from a cloud resource.

Procedure

1. Log on to the EIP console.
2.
3. On the **Elastic IP Addresses** page, find the target EIP, move the mouse pointer over **More operations** in the **Actions** column, and then click **Release**.
4. In the **Release an EIP** dialog box, click **OK**.

26.Express Connect

26.1. User Guide

26.1.1. What is Express Connect?

This topic provides an overview of Express Connect. Express Connect allows you to establish private connections to enable fast, stable, and secure communication between different networking environments. You can use Express Connect to ensure network stability and prevent data breaches.

Features

You can use a leased line provided by an Internet Service Provider (ISP) to establish a physical connection between your data center and an Alibaba Cloud access point. After the physical connection is established, you can create a virtual border router (VBR) to connect your data center with Alibaba Cloud to build a hybrid cloud.

The physical connections of Express Connect do not traverse the Internet, and therefore feature faster speeds, lower latency, greater security, and higher reliability compared with Internet connections.

Express Connect enables you to create a peering connection between two Virtual Private Clouds (VPCs) as a channel for private communication.

Benefits

Express Connect provides the following benefits:

- High-speed interconnections

  Powered by the network virtualization technology of Alibaba Cloud, Express Connect allows networks to connect and exchange traffic at high speeds within internal networks without carrying traffic across the Internet. The impact of distance on network performance is minimized to ensure low-latency and high-bandwidth communication.

- Stability and reliability

  Built on the state-of-the-art infrastructure of Alibaba Cloud, Express Connect guarantees stable and reliable communication between networks.

- Security

  Express Connect implements cross-network communication at the network virtualization layer, where data is transmitted over separate and private channels within the infrastructure of Alibaba Cloud, mitigating the risks of data breaches.

- Buy-as-you-need service

  Express Connect delivers connectivity with a wide range of bandwidth options. You can choose based on the needs of your business to get the best value for your purchase.

26.1.2. Log on to the Express Connect console

This topic describes how to log on to the Apsara Uni-manager Management Console to manage your Express Connect services. The Google Chrome browser is used as an example.

Prerequisites

- Before you log on to the Apsara Uni-manager Management Console, you must obtain the URL of the console from the engineer that deploys the service.
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar of the browser, enter the URL of the Apsara Uni-manager Management Console and press the Enter key.
2. Enter your username and password.

   Obtain the username and password that are used to log on to the console from the operations administrator.

   > **Note** If this is the first time you log on to the Apsara Uni-manager Management Console, you must change your password as prompted. For higher security, the password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters.
   > - Digits.
   > - Special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Log On**.
4. In the top navigation bar, choose **Products > Networking > Express Connect**.

26.1.3. VPC peering connections

26.1.3.1. What is a peering connection

You can create a peering connection to connect two virtual private clouds (VPCs). In addition, you can create a peering connection to connect a VPC and a virtual border router (VBR).

Initiator and acceptor

When you establish a peering connection between two VPCs or between a VPC and a VBR, one end of the peering connection functions as the initiator. The other end of the peering connection functions as the acceptor. Only the initiator can initiate the peering connection. The acceptor must wait for the initiator to initiate the peering connection. The concepts of initiator and acceptor are only used to control how a peering connection is established. Data transmission between the initiator and acceptor is bidirectional. Therefore, after the peering connection is established, both the initiator and acceptor can send and receive data.

When you connect two VPCs under the same account, you can specify the initiator and acceptor in the Express Connect console. After you specify the initiator and acceptor, the system automatically initiates a connection request and then establishes a peering connection. You do not need to manually send a connection request. To connect two VPCs under different accounts, you must manually send a request to establish a peering connection.

The following table describes the differences between the initiator and acceptor.

Item	Initiator	Acceptor
Whether the configuration of the peer is required before a peering connection is initiated	Yes	Yes
Initiate connection requests	Yes	No
Send messages to the peer after the peering connection is established	Yes	Yes

Connection stages and states

The initiator sends a connection request to the acceptor to establish a peering connection. After the acceptor accepts the request, the peering connection is established.

The following table describes the states of a peering connection at different stages.

> **Note** If you specify the initiator and acceptor when you create a peering connection, the system automatically sends a connection request and establishes the peering connection. The peering connection is activated on both the initiator and acceptor after the peering connection is established.

Stage	State of the peering connection on the initiator	State of the peering connection on the acceptor
Send a connection request from the initiator	Connecting	Accepting
Successfully establish a peering connection	Active	Active
Deactivate a peering connection	Deactivating	Deactivating
Close a peering connection	Inactive	Inactive
Resend a connection request	Activating	Activating

26.1.3.2. Connect two VPCs

This topic describes how to create a peering connection to connect two virtual private clouds (VPCs).

Procedure

1. Log on to the Express Connect console.
2. In the left-side navigation pane, choose **VPC Peering Connections > VPC-to-VPC**.
3. On the **VPC-to-VPC** page, click **Create Peering Connection**.
4. Set the following parameters to configure the peering connection.

Parameter	Description
Scenarios	Select **VPC-to-VPC** to create a peering connection between two VPCs.
Local Configurations	
Organization	Select the organization to which the source VPC belongs.
Resource Set	Select the resource group to which the source VPC belongs.
Region	Select the region where the source VPC is created.
Router Type	Use the default setting **vRouter** for this parameter.
Local VPC ID	Select the ID of the source VPC.
Peer Configurations	
Organization	Select the organization to which the destination VPC belongs.
Resource Set	Select the resource group to which the destination VPC belongs.
Peer Region	Select the region where the destination VPC is created.

Parameter	Description
Peer Router Type	Use the default setting **vRouter** for this parameter.
Peer VPC ID	Select the ID of the destination VPC.
Basic Settings	
Bandwidth	Specify the bandwidth of the peering connection.

5. Click **Submit**.

26.1.3.3. Connect a VBR to a VPC

This topic describes how to create a peering connection between a virtual border router (VBR) and a virtual private cloud (VPC).

Procedure

1. Log on to the Express Connect console.
2. In the left-side navigation pane, choose **VPC Peering Connections > VBR-to-VPC**.
3. On the **VBR-to-VPC** page, click **Create Peering Connection**.
4. On the **Create Peering Connection** page, set the following parameters to configure the peering connection.

Parameter	Description
Scenarios	Use the default setting **VBR-to-VPC** for this parameter.
Common Settings	
Organization	Select the organization to which the VBR belongs.
Resource Sets	Select the resource group to which the VBR belongs.
VBR-side Configurations	
Router Type	Use the default setting **VBR** for this parameter.
Region	Select the region where the VBR is created.
Endpoint	Select an access point.
VBR ID	Select the ID of the VBR.
Router Interface Specifications	Select the interface specification of the router. In this example, 1,000 Mbit/s is selected.
Router Interface Name	Enter a name for the router interface.
Description	Enter a description for the router.
VPC-side Configurations	
Router Type	Use the default setting **vRouter** for this parameter.

Parameter	Description
Region	Select the region where the VPC is created.
VPC ID	Select the ID of the VPC.
Router Interface Name	Enter a name for the router interface.
Health Check Source IP Address	Enter the source IP address of health checks. **Note** The source IP address of health checks must be an idle IP address that belongs to the CIDR block of a vSwitch in the VPC.
Health Check Destination IP Address	Enter the destination IP address of health checks. **Note** The destination IP address is the IP address of the customer-premises device that is connected to the VBR to which the physical connection is established.
Description	Enter a description for the VPC.

5. Click **Submit**.

26.1.3.4. Delete a peering connection

This topic describes how to delete a peering connection.

Procedure

1. Log on to the Express Connect console.
2. In the left-side navigation pane, choose **VPC Peering Connections > VPC-to-VPC**.
3. Find the target peering connection and choose > **Suspend Initiator** in the **Actions** column.
4. Find the target peering connection and choose > **Suspend Acceptor** in the **Actions** column.
5. Find the target peering connection and choose > **Delete** in the **Actions** column.
6. In the **Delete Peering Connection** dialog box, click **Confirm**.

26.1.4. Physical connections

26.1.4.1. What is a physical connection?

Express Connect provides a secure and convenient method to connect a data center to Alibaba Cloud. You can use a leased line provided by an Internet service provider (ISP) to establish a physical connection between your data center and an Alibaba Cloud access point. Physical connections do not pass through the Internet. Compared with Internet connections, physical connections are safer, faster, more reliable, and have lower latency.

You can use a point-to-point Ethernet connection or MPLS VPN connection. Only 10 Gbit/s single-mode fiber ports can be used to establish physical connections.

Connection methods

You can apply for a physical connection port to establish a physical connection.

Then, you can use the physical connection port to connect a data center to an Alibaba Cloud access point. The physical connection port is dedicated to the physical connection. You can apply for a dedicated physical connection port in the Express Connect console. For more information, see Create a physical connection.

26.1.4.2. Create a physical connection

This topic describes how to create a physical connection. To establish a physical connection, you must first confirm the access point of the data center. Then, apply for and activate a physical connection port and create a virtual border router (VBR) in the Express Connect console.

Step 1: Confirm the access point of the data center

An access point indicates where network services are provided. You can use multiple types of connection to connect a data center to Alibaba Cloud. When you select an access point, take note of the elements such as the region, service provider, and port type. When you select an access point, you must confirm the region of Apsara Stack that you want to access.

Step 2: Apply for a physical connection port in the console

To apply for a physical connection port, perform the following operations:

1. Log on to the Express Connect console.
2. In the left-side navigation pane, click **Exclusive Physical Connection**.
3. On the **Exclusive Physical Connection** page, click **Apply for New Interface**.
4. Set the following parameters and click **Submit** to configure the physical connection port.

Parameter	Description
Region	
Organization	Select the organization to which the physical connection belongs.
Resource Set	Select the resource group to which the physical connection belongs.
Region	Select the region where you want to establish the physical connection.
Basic Settings	
Physical Connection Name	Enter a name for the physical connection. The name must be 2 to 128 characters in length and can contain digits, periods (.), underscores (_), and hyphens (-). It must start with a letter or Chinese character but cannot start with `http:// or https://` .
Description	Enter a description for the physical connection. The description must be 2 to 256 characters in length. It must start with a letter or Chinese character but cannot start with `http://` or `https://` .
Peer Address	Enter the address of the data center to which you want to establish the physical connection.
Physical Connection Configurations	

Parameter	Description
Endpoint	Select the access point to which you want to connect the data center. Access points are Alibaba Cloud data centers located in different regions. Each region contains one or more access points. Different access points allow you to connect to Alibaba Cloud from different geolocations and support different connection types.
Port Type	Select 10 GE Single-mode Optical Port for this parameter.
Access Device	Select the device to be connected to the physical connection.
Physical Connection Bandwidth	Enter a value as the maximum bandwidth of the physical connection port. Unit: Mbit/s. Minimum value: 2.

5. Return to the **Exclusive Physical Connection** page, confirm that the physical connection is in the **Allocating** state.

Step 3: Enable the physical connection

To enable a physical connection, perform the following operations:

1. After resources are allocated for the physical connection, the physical connection changes to the Pending state. Click **Confirm** in the Actions column.
2. Refresh the **Exclusive Physical Connection** page. The state of the physical connection changes to **Enabled**.

Step 4: Create a VBR

After a physical connection is enabled, you must create a VBR to connect the data center to Alibaba Cloud.

To create a VBR, perform the following operations:

1. Log on to the Express Connect console.
2. In the left-side navigation pane, click **Virtual Border Routers (VBRs)**.
3. On the **Virtual Border Routers (VBRs)** page, click **Create VBR**.
4. Set the following parameters and click **OK** to create a VBR.

Parameter	Description
Account	◦ **Current account**: Create a VBR for the account that you use to log on to the console. ◦ **For others account create**: Create a VBR for another account. In this example, **Current account** is selected.
Account	This parameter is displayed only when the account type is set to **For others account create**. Enter the ID of the account for which you want to create the VBR.

Parameter	Description
Name	Enter a name for the VBR. The name must be 2 to 128 characters in length and can contain digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with `http:// or` `https://`. This parameter is displayed only when the account type is set to **Current account**.
Physical Connection Interface	Select a physical connection port that you want to associate with the VBR. The physical connection port must be in the Installed and Running state.
VLAN ID	Enter the VLAN ID of the VBR. Valid values: 0 to 2999. ○ If the VLAN ID is set to 0, the switch port of the VBR uses the Layer 3 router interface mode instead of the VLAN mode. In Layer 3 router interface mode, each physical connection is associated with a VBR. ○ If the VLAN ID is set to a value from 1 to 2999, the switch port of the VBR uses VLAN Layer 3 subinterface mode. In Layer 3 subinterface mode, each VLAN ID corresponds to a VBR. In this mode, the physical connection to which the VBR is established can connect to virtual private clouds (VPCs) that are created by different accounts. VBRs that correspond to different VLANs are isolated from each other at Layer 2. **Notice** The VLAN ID that you specify for the VBR and that of the customer-premises device must be the same.
Gateway IP Address on Alibaba Cloud Side	Enter the IPv4 address of the gateway that is deployed on Alibaba Cloud. In this example, `192.168.101.5` is entered.
Gateway IP Address on Customer Side	Enter the IPv4 address of the gateway that is deployed in the data center. In this example, `192.168.101.6` is entered.
Subnet Mask	Enter the subnet mask of the IPv4 addresses on the Alibaba Cloud and the data center sides. In this example, `255.255.255.252` is entered. You can enter a longer subnet mask because only two IP addresses are required.

5. When the VBR is in the **Active** state, **ping** the IP address of the gateway that is deployed on Alibaba Cloud from the gateway that is deployed in the data center to test the connectivity.

Step 5: Create a peering connection between the VBR and a VPC

After you associate the physical connection with the VBR, you must create a peering connection between the VBR and a VPC. This way, the VPC and the data center can communicate with each other through private connections.

To create a peering connection between the VBR and a VPC, perform the following operations:

1. Log on to the Express Connect console.
2. In the left-side navigation pane, choose **VPC Peering Connections > VBR-to-VPC**.
3. On the **VBR-to-VPC** page, click **Create Peering Connection**.
4. Set the following parameters and click **Submit** to configure the peering connection.

Parameter	Description
Scenarios	Use the default setting **VBR-to-VPC** for this parameter.
Common Settings	
Organization	Select the organization to which the VBR belongs.
Resource Set	Select the resource group to which the VBR belongs.
VBR-side Configurations	
Router Type	Use the default setting **VBR** for this parameter.
Region	Select the region where the VBR is created.
Endpoint	Select an access point.
VBR ID	Select the ID of the VBR.
Router Interface Specifications	Select the interface specification of the router. In this example, 1,000 Mbit/s is selected.
Router Interface Name	Enter a name for the router interface. The name must be 2 to 128 characters in length and can contain digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with `http:// or https://`.
Description	Enter a description for the router. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with `http:// or https://`.
VPC-side Configurations	
Router Type	Use the default setting **vRouter** for this parameter.
Region	Select the region where the VPC is created.
VPC ID	Select the ID of the VPC.
Router Interface Name	Enter a name for the router interface. The name must be 2 to 128 characters in length and can contain digits, periods (.), underscores (_), and hyphens (-). It must start with a letter but cannot start with `http:// or https://`.
Health Check Source IP Address	Enter the source IP address of health checks. **Note** The source IP address must be an idle IP address that belongs to the CIDR block of a vSwitch in the VPC.

Parameter	Description
Health Check Destination IP Address	Enter the destination IP address of health checks. **Note** The destination IP address is the IP address of the customer-premises device that is connected to the VBR to which the physical connection is established.
Description	Enter a description for the VPC. The description must be 2 to 256 characters in length. It must start with a letter or Chinese character but cannot start with `http://` or `https://`.

5. Click **Submit**.

26.1.4.3. Delete a physical connection

This topic describes how to delete a physical connection that you no longer need.

To delete a physical connection that is established to a virtual private cloud (VPC) and a virtual border router (VBR), perform the following operations:

1. Delete routes on the router of the VPC and routes on the VBR.
2. If Border Gateway Protocol (BGP) routing is configured, you must delete the BGP peers and BGP groups.
3. Delete the connection between the VPC and the VBR.
4. Delete all VBRs that are associated with the physical connection.
5. Delete the physical connection.

Step 1: Delete routes

To delete routes on the router of a VPC and routes on a VBR, perform the following operations:

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route table belongs.
4. On the **Route Tables** page, find the route table that you want to manage and click **Manage** in the **Actions** column.
5. On the **Route Entry List** tab, find the custom route that you want to delete and click **Delete** in the **Actions** column.
6. In the **Delete Route Entry** message, click **OK**.
7. Log on to the Express Connect console.
8. In the left-side navigation pane, click **Virtual Border Routers (VBRs)**.
9. On the **Virtual Border Routers (VBRs)** page, select the region where the VBR that you want to manage is created and click the ID of the VBR.
10. On the **Routes** tab, find the route that you added and click **Delete** in the **Actions** column.
11. In the **Delete Route** message, click **OK**.

Step 2: Delete BGP peers and BGP groups

If BGP is configured, you must perform the following operations to delete the VBR-related BGP settings:

1. Log on to the Express Connect console.
2. In the left-side navigation pane, click **Virtual Border Routers (VBRs)**.

3. On the **Virtual Border Routers (VBRs)** page, select the region where the VBR that you want to manage is created and click the ID of the VBR.
4. On the **BGP Peers** tab, delete the BGP peers that you added.
5. On the **BGP Groups** tab, delete the BGP groups that you created.
6. On the **Advertised BGP Subnets** tab, delete the BGP CIDR blocks that are advertised.

Step 3: Delete the connection between the VBR and the VPC

To delete the connection between the VPC and the VBR, perform the following operations:

1. Log on to the CEN console.
2. On the **Instances** page, find the target CEN instance, and then click **Manage** in the **Actions** column.
3. On the **Networks** tab page, find the target network instance, and then click **Detach** in the **Actions** column.
4. In the **Detach Network** dialog box, click **OK**.

Step 4: Delete a VBR

To delete a VBR, perform the following operations:

1. Log on to the Express Connect console.
2. In the left-side navigation pane, click **Virtual Border Routers (VBRs)**.
3. On the **Virtual Border Routers (VBRs)** page, find the VBR that you want to delete and click **Delete** in the **Actions** column.
4. In the **Delete VBR** message, click **Confirm**.

Step 5: Delete a physical connection

To delete a physical connection, perform the following operations:

1. Log on to the Express Connect console.
2. In the left-side navigation pane, click **Exclusive Physical Connection**.
3. On the **Exclusive Physical Connection** page, find the physical connection that you want to delete and click **Terminate Connection**.
4. In the **Terminate Connection** message, click **Confirm**.
5. On the **Exclusive Physical Connection** page, find the physical connection that you want to delete and click **Delete** in the Actions column.
6. In the **Delete Physical Connection** message, click **Confirm**.

26.1.5. VBRs

26.1.5.1. What is a VBR?

Virtual border routers (VBRs) are virtualization of physical connection ports that are isolated by Alibaba Cloud. VBRs are defined on top of the Layer 3 overlay and switch virtualization technologies in the Software Defined Network (SDN) architecture. A VBR functions as a router between a customer-premises device and a virtual private cloud (VPC). VBRs route traffic between VPCs and data centers.

Each VBR is associated with a route table, which is similar to the vRouter of a VPC. You can add routes to the route table of a VBR to control traffic forwarding on the VBR.

Features

VBRs provide the following features:

- Exchange data between a VPC and a data center.

- Add or identify VLAN tags in Layer 3 subinterface mode.
- Determine the mode of a physical connection port: Layer 3 router interface or VLAN Layer 3 subinterface.
- Support Border Gateway Protocol (BGP).

  BGP is a dynamic routing protocol based on Transmission Control Protocol (TCP). BGP is used to exchange routing information and network accessibility information among autonomous systems. When you create physical connections to connect a data center to a VBR, you can configure BGP settings. BGP helps you build hybrid clouds in a more efficient, flexible, and reliable way.

Limits

- Source address-specific policy-based routes are not supported.
- Each VBR can be associated with only one route table.
- VBRs support only BGP4.
- VBRs support IPv4 BGP. IPv6 BGP is not supported.
- You can create up to eight BGP peers for each VBR.
- Each BGP peer supports up to 100 dynamic routes. If the number of dynamic routes that a BGP peer learns reaches the upper limit, the system generates an alert. However, the dynamic routes are not denied.
- To configure BGP when you connect to a VPC, you must specify an Autonomous System Number (ASN) for the VPC. The ASN that you specify must not be the same as the ASNs of the vSwitches in the VPC.

26.1.5.2. Create a VBR

After a physical connection is enabled, you must create a virtual border router (VBR) for the physical connection. The VBR is used to route traffic between the virtual private cloud (VPC) and data center that are connected through the physical connection.

Context

A VBR is a router deployed between a VPC and a customer-premises equipment (CPE) in a data center. Each VBR is associated with a route table. To manage traffic forwarding on a VBR, you can add routes to the route table that is associated with the VBR.

A VBR provides the following features:

- Exchanges data as a router between a VPC and a data center.
- Determines the port mode of the physical connection: Layer 3 router interface mode or VLAN Layer 3 subinterface mode.
- Adds or identifies VLAN tags in Layer 3 subinterface mode.
- Supports Border Gateway Protocol (BGP) dynamic routing.

Procedure

1. Log on to the Express Connect console.
2. In the left-side navigation pane, click **Virtual Border Routers (VBRs)**.
3. On the **Virtual Border Routers (VBRs)** page, click **Create VBR**.
4. Configure the VBR based on the following information and click **OK**.

Parameter	Description
Account	Select the type of account to which the VBR that you want to create belongs: **Current account** or **For others account create**.

Parameter	Description
Account	Enter the primary key of the account. This parameter is displayed only when you select **For others account create**. **Note** To obtain the primary key of the account, log on to the Apsara Uni-manager Management Console. In the top navigation bar, choose **Enterprise > Organizations > Obtain an accesskey**.
Name	Enter a name for the VBR. The name must be 2 to 128 characters in length, and start with a letter or Chinese character. It can contain digits, periods (.), underscores (_), and hyphens (-). It cannot start with `http://` or `https://`. This parameter is displayed only when the account type is set to **Current account**.
Physical Connection Interface	Select a physical connection port to associate with the VBR. The physical connection port must be installed and function as expected.
VLAN ID	The VLAN ID of the VBR. Valid values: 0 to 2999. ◦ If the VLAN ID is set to 0, the switch port of the VBR uses the Layer 3 router interface mode instead of the VLAN mode. In Layer 3 router interface mode, each physical connection is associated with a VBR. ◦ If the VLAN ID is set to a value from 1 to 2999, the switch port on the VBR uses VLAN Layer 3 subinterface mode. In Layer 3 subinterface mode, each VLAN ID corresponds to a VBR. In this mode, the physical connection that is established to the VBR can connect to VPCs created by different accounts. VBRs that correspond to different VLANs are isolated from each other at Layer 2. For example, assume that a company has multiple subdivisions or subsidiaries. Each subdivision or subsidiary has a separate Alibaba Cloud account. Each account has a separate VPC. If the company applies for a physical connection, they must assign a VLAN ID for each subdivision or subsidiary. When the company creates router interfaces, they use VLAN IDs to identify the subsidiaries or subdivisions that use the physical connection. This way, the subsidiaries or subdivisions are isolated at Layer 2.
Gateway IP Address on Alibaba Cloud Side	Enter the IP address of the gateway that routes traffic from the VPC to the data center.
Gateway IP Address on Customer Side	Enter the IP address of the gateway that routes traffic from the data center to the VPC.
Subnet Mask	Enter the subnet mask of the gateway IPv4 address on the Alibaba Cloud side and the gateway IPv4 address on the customer side. You can enter a longer subnet mask because only two IP addresses are required.

26.1.5.3. Configure BGP

This topic describes how to establish Border Gateway Protocol (BGP) peering relationships between a data center and a virtual border router (VBR). To perform this task, you must add the BGP peer that communicates with the VBR to a BGP group, and then advertise the BGP CIDR block on the VBR.

> **Note** Express Connect allows you to establish BGP peering relationships only between a VBR and a data center. However, when you establish a physical connection, you still need to add two routes on the VBR. You must add a route that points to the physical connection and a route that points to the virtual private cloud (VPC). For more information, see Add routes.

What is BGP?

BGP is a dynamic routing protocol based on Transmission Control Protocol (TCP). BGP is used to exchange routing information and network accessibility information in different autonomous systems. When you create a physical connection to connect a data center to a VBR, you can configure BGP routing to enable private communication. BGP can help you build hybrid clouds in a more efficient, flexible, and reliable manner.

Before you configure BGP, you must create a BGP group. BGP groups are used to simplify BGP configurations. You can save time and effort by adding BGP peers that use the same configurations to one BGP group. This way, you only need to create a BGP group with an Autonomous System Numbers (ASN) and add BGP peers that meet your requirements to the BGP group. After you add the BGP peers to the BGP group, the BGP peers share the configurations of the BGP group. This saves you the need to configure each BGP peer separately.

Limits

BGP has the following limits:

- VBRs can establish peering relationships only with data centers that are connected to the VBRs through physical connections. Static routing is still required between the VBRs and VPCs.
- VBRs support only BGP 4.
- You can create up to eight BGP peers with each VBR.
- Each BGP peer supports at most 110 dynamic routes. If the number of dynamic routes that a BGP peer learns reaches the upper limit, the system generates an alert. However, the dynamic routes are not denied.
- To configure BGP when you connect to a VPC, you must specify an ASN for the VPC. The ASN that you specify must not be the same as the ASNs of the vSwitches in the VPC.

Step 1: Create a BGP group

Before you configure BGP routing, you must create a BGP group with the requested ASN.

To create a BGP group, perform the following operations:

1. Log on to the Express Connect console.
2. In the left-side navigation pane, select **Virtual Border Routers (VBRs)**.
3. On the **Virtual Border Routers (VBRs)** page, click the ID of the VBR that you want to manage.
4. Click the **BGP Groups** tab and click **Create BGP Group**.
5. Set the following parameters to configure the BGP group and click **OK**.

Parameter	Description
Name	Enter a name for the BGP group. The name must be 2 to 128 characters in length, and can contain digits, periods (.), underscores (_), and hyphens (-). The name must start with a letter or Chinese character. It cannot start with `http://` or `https://`.
Peer ASN	Enter the ASN of the data center network.
BGP Key	Enter the key of the BGP group.
Description	Enter a description for the BGP group. The description must be 2 to 256 characters in length. It must start with a letter but cannot start with `http://` or `https://`.

Parameter	Description
Local AS	Enter the ASN of the VPC.

Step 2: Add a BGP peer

To add a BGP peer, perform the following operations:

1. Log on to the Express Connect console.
2. In the left-side navigation pane, click **Virtual Border Routers (VBRs)**.
3. On the **Virtual Border Routers (VBRs)** page, click the ID of the VBR that you want to manage.
4. Click the **BGP Peers** tab and click **Create BGP Peer**.
5. Configure the BGP peer and click **OK**.

Parameter	Description
BGP Group	Select the BGP group to which you want to add the BGP peer.
BGP Peer IP Address	Enter the IP address of the BGP peer.

6. Return to the **Virtual Border Routers (VBRs)** page and click the **BGP Peers** tab to check the state of the BGP peer.

   A BGP peer can be in the following states:

   - **Idle**: indicates that the BGP peer is idle. Idle is the initial state of a BGP peering relationship. In this state, BGP waits for a start event. After the start event occurs, BGP initializes all resources and resets the ConnectRetry timer. Then, BGP initiates a TCP connection while the BGP peer changes to the Connect state.
   - **Connect**: indicates that a connection is being established to the BGP peer. In the Connect state, BGP initiates the first TCP connection request. If the ConnectRetry timer depletes before the TCP connection is established, a new TCP connection request is initiated and the BGP peer remains in the Connect state.
     - If the TCP connection is established, the BGP peer changes to the OpenSent state.
     - If the TCP connection attempt fails, the BGP peer changes to the Active state.
   - **Active**: indicates that the BGP peer is active. In the Active state, BGP attempts to establish the TCP connection again. If the ConnectRetry timer depletes, the BGP peer switches back to the Connect state.
     - If the TCP connection is established, the BGP peer changes to the OpenSent state.
     - If the TCP connection attempt fails, the BGP peer remains in the Active state and BGP continues to initiate TCP connection requests.
   - **OpenSent**: indicates that an OPEN message is sent. The OpenSent state indicates that the TCP connection is established. The first OPEN message has been sent to the BGP peer. BGP is waiting for an OPEN message from the BGP peer. After BGP receives the OPEN message, it checks the message for errors.
     - If the message contains errors, the system returns an error message to the BGP peer and the BGP peer switches back to the Idle state.
     - If the OPEN message does not contain any errors, BGP sends a Keepalive message and resets the Keepalive timer. In this case, the BGP peer changes to the OpenConfirm state.
   - **OpenConfirm**: indicates that BGP has confirmed the OPEN message. In the OpenConfirm state, BGP sends a Keepalive message and resets the timer.
     - If the Keepalive message is received before the timer expires, the BGP peer changes to the Established state. This state indicates that the BGP peering relationship is established.
     - If the TCP connection is interrupted, the BGP peer switches back to the Idle state.

- **Established**: indicates that the BGP peering relationship is established. In this state, the VBR and the BGP peer send Update messages to each other and the timer is reset.
- **UnEstablished**: indicates that the BGP peering relationship is not established.

Step 3: Advertise the BGP CIDR block

After you configure BGP peers, you must advertise the CIDR block of the VPC to complete the BGP configuration. After the BGP peering relationship is established, the VBR automatically learns the CIDR block of the data center.

To advertise the CIDR block of the VPC, perform the following operations:

1. Log on to the Express Connect console.
2. In the left-side navigation pane, click **Virtual Border Routers (VBRs)**.
3. On the **Virtual Border Routers (VBRs)** page, click the ID of the VBR that you want to manage.
4. Click the **Advertised BGP Subnets** tab and click **Advertise BGP Subnet**.
5. Enter the CIDR block that you want to advertise and click **OK**.

Step 4: Configure BGP for the data center

The preceding steps describe how to configure BGP on Alibaba Cloud. After you configure BGP on Alibaba Cloud, you must configure BGP for the data center and advertise routes of the network device in the data center. For more information about the command, consult the manufacturer of the network device.

26.1.5.4. Add routes

This topic describes how to add routes to the route table of a virtual border router (VBR). You can configure routes to manage where traffic is routed on a VBR.

Context

To forward network traffic between a virtual private cloud (VPC) and a data center, you must add two routes to the route table of the VBR that is used to connect the data center to the VPC. One of the routes points to the physical connection and the other route points to the VPC. You can configure BGP routing for a data center on a VBR. For more information, see Configure BGP.

Take note of the following items when you manage routes in the route table of a VBR:

> Notice
> - You can query routes by type. Fuzzy match is supported.
> - Each route table supports up to 48 custom routes.
> - Source address-specific policy-based routes are not supported.

Procedure

1. Log on to the Express Connect console.
2. In the left-side navigation pane, click **Virtual Border Routers (VBRs)**.
3. On the **Virtual Border Routers (VBRs)** page, click the ID of the VBR that you want to manage.
4. Click the **Routes** tab and click **Add Route**.
5. Configure the route and click **OK**.

Parameter	Description

Parameter	Description
Next Hop Type	The type of next hop. You can select the following types: ○ **VPC**: The VBR routes traffic to a VPC based on the destination CIDR block. ○ **Physical Connection Interface**: The VBR routes traffic to a physical connection port based on the destination CIDR block.
Destination CIDR block	Enter the destination CIDR block.
Next Hop	Select the next hop based on the specified type.

26.1.5.5. Create a peering connection

This topic describes how to create a peering connection. After you create a virtual border router (VBR), you must create a peering connection between the VBR and a virtual private cloud (VPC). This way, the VBR can route traffic between the VPC and the data center that is connected to the VBR.

For more information about how to create a peering connection, see Connect two VPCs.

27.Apsara Stack Security

27.1. User Guide

27.1.1. What is Apsara Stack Security

Apsara Stack Security is a solution that protects Apsara Stack assets with a full suite of security features, such as network, server, application, data, and security management.

Background information

Traditional security solutions for IT services detect attacks on network perimeters. These solutions use hardware products such as firewalls and intrusion prevention systems (IPSs) to protect networks against attacks.

With the development of cloud computing, an increasing number of enterprises and organizations use cloud computing services instead of traditional IT services. Cloud computing features low costs, on-demand flexible configuration, and high resource utilization. Cloud computing environments do not have definite network perimeters. As a result, traditional security solutions cannot effectively safeguard cloud assets.

With the powerful data analysis capabilities and professional security operations team of Alibaba Cloud, Apsara Stack Security provides integrated security protection services for networks, applications, and servers.

Complete security solution

Apsara Stack Security consists of Apsara Stack Security Standard Edition and optional security services to provide a comprehensive security solution.

Security domain	Service name	Description
Security management	Threat Detection Service (TDS)	Monitors traffic and overall security status to audit and centrally manage assets.
Server security	Server Guard	Protects Elastic Compute Service (ECS) instances against intrusions and malicious code.
	Server Security	Protects physical servers against intrusions.
Application security	Web Application Firewall (WAF)	Protects web applications against attacks and ensures that mobile and PC users can securely access web applications over the Internet.
Network security	Anti-DDoS	Ensures the availability of network links and improves business continuity.
Data security	Sensitive Data Discovery and Protection (SDDP)	Prevents data leaks and helps your business system meet compliance requirements.
Security O&M service	On-premises security service	Helps you establish and optimize the cloud security system to protect your business system against attacks by using security features of Apsara Stack Security and other Apsara Stack services.

27.1.2. Precautions

Before you log on to the Apsara Stack Security console, you must verify that your local PC meets the configuration requirements.

The configuration requirements for the local PC are listed in Configuration requirements.

Configuration requirements

Item	Requirement
Browser	• Internet Explorer: V11 or later • Chrome (recommended): V42.0.0 or later • Firefox: V30 or later • Safari: V9.0.2 or later
Operating system	• Windows XP, Windows 7, or later • macOS

27.1.3. Quick start

27.1.3.1. User roles and permissions

This topic describes the user roles involved in Apsara Stack Security.

All roles in Apsara Stack Security Center are provided by default. You cannot add custom roles. Before you log on to Apsara Stack Security Center, make sure that your account is assigned the required role. For more information, see Default roles in Apsara Stack Security.

Default roles in Apsara Stack Security

Role	Permission
System administrator of Apsara Stack Security Center	Manages and configures system settings for Apsara Stack Security Center. The system administrator has permissions to manage Apsara Stack accounts, synchronize data, configure alerts, and configure global settings.
Security administrator of Apsara Stack Security Center	Monitors the security status across Apsara Stack and configures security policies for each functional module of Apsara Stack Security. The security administrator has permissions on all features under Threat Detection, Network Security, Application Security, Server Security, PM Security, and Asset Management. **Note** The permissions on Web Application Firewall (WAF) and Cloud Firewall must be separately assigned.
Department security administrator	Monitors the security status of cloud resources in a specific department and configures security policies for each functional module of Apsara Stack Security for this department. The department security administrator has permissions on all features under Threat Detection, Network Security, Application Security, Server Security, PM Security, and Asset Management. In addition, the department security administrator can specify alert notification methods and alert recipients in the department. **Note** The permissions on WAF and Cloud Firewall must be separately assigned.
Auditor of Apsara Stack Security Center	Conducts security audits across Apsara Stack. The auditor can view audit events and original logs, configure audit policies, and access all features under Security Audit.

If you do not have an account that assumes the required role, contact the administrator to create an account and assign the role to the account. For more information, see the **Create a user** topic in the *Apsara Uni-manager Management Console User Guide*.

27.1.3.2. Log on to Apsara Stack Security Center

This topic describes how to log on to Apsara Stack Security Center.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 10 to 32 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Log On**.
4. In the top navigation bar, choose **Security > Apsara Stack Security**.
5. On the **Apsara Stack Security Center** page, select **Region**.
6. Click **YD** to go to Apsara Stack Security Center.

27.1.4. Threat Detection Service

27.1.4.1. Threat Detection Service overview

This topic describes the basic concepts of Threat Detection Service (TDS).

TDS provides comprehensive protection for enterprises. It can monitor vulnerabilities, intrusions, web attacks, DDoS attacks, threat intelligence, and public opinions. TDS uses modeling and analysis to obtain key information based on traffic characteristics, host processes, and host operations logs. In addition, TDS identifies intrusions that cannot be detected by traffic inspection or file scan. You can use the input of cloud analysis models and intelligence data to discover sources and behavior of attacks and assess threats.

TDS provides the following features:

- Overview: provides a security situation overview and information about security screens.
- Security Alerts: displays security alerts that occur in the business system.
- Attack Analysis: displays application attacks and brute-force attacks that occur in the system.
- Cloud Service Check: checks whether the security configuration for cloud services has risks.
- Application Whitelist: provides information about application processes on servers that require protection

based on intelligent learning. The application processes are identified as trusted, suspicious, or malicious. This prevents unauthorized processes.

- Assets: manages servers and cloud services on Apsara Stack.
- Security Reports: allows you to configure security report tasks on Apsara Stack.

27.1.4.2. Security overview

27.1.4.2.1. View security overview information

This topic describes how to view security statistics, attack trends, and network traffic information on the Apsara Stack platform.

Context

The **Security Overview** tab provides an overview of detected security events, the latest threats, and inherent vulnerabilities of the system. A security administrator can view information on the **Security Overview** tab to better understand the security posture of the system.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Overview**. By default, the **Security Overview** tab appears.
3. View the security posture of the Apsara Stack platform.

   Sections on the Security Overview tab

Section	Description
Secure Score	The security score of assets and the number of detected security risks.
Asset Status	The total number of assets and the numbers of servers that are not protected, servers that are stopped, and servers that are at risk.
Security Detection And Defense Capabilities	The numbers of precise defense events and anti-tampering events over the last 15 days, the time when the antivirus database was last updated, and the time when vulnerability scanning was last performed. This allows you to obtain the defense situation and security status of your assets in real time.
Threat statistics	The numbers of alerts that are not handled, vulnerabilities that are not fixed, baseline risks, and attacks.
Config Assessment Risks	Risks in the baseline configurations of cloud services.
Issue Resolved	Statistics on alerts, vulnerabilities, and baseline risks that have been processed over the last 15 days. The statistics are displayed in a bar and trend chart.

27.1.4.3. Security alerts

27.1.4.3.1. View security alerts

This topic describes how to view security alerts on the Security Alerts page.

Procedure

1.

2. In the left-side navigation pane, choose **Threat Detection > Security Alerts**.
3. (Optional)Set filter conditions for security alerts.

> **Note** If you want to view all alerts, do not set the conditions.

Filter condition	Description
Severity	The severity level. You can select one or more levels. Valid values: ○ Urgent ○ Warning ○ Notice
Alert status	The status of alerts. Valid values: ○ Unhandled Alerts ○ Handled
Alert type	The type of alerts. Select **All** or a specific type.
Affected asset group	The affected asset group. Select **Asset Group** or a specific group.
Search for alerts by name or asset	Enter an alert name or a keyword of affected assets to search for alerts.

4. View security alerts and their details in the list.

27.1.4.3.2. Manage quarantined files

This topic describes how to manage threat files that are quarantined by the system. The system deletes a quarantined file 30 days after the file is quarantined. You can restore the file before it is deleted.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Security Alerts**.
3. In the upper-right corner of the **Alerts** page, click **Quarantine**.
4. In the **Quarantine** panel, view the information about a quarantined file, such as the host, path, status, and operation time.
5. (Optional)If a file is incorrectly quarantined, click **Restore** in the **Actions** column to restore the file.

> **Notice** Before you can restore a quarantined file, make sure that the file is normal and does not bring risks.

The restored file is removed from the quarantine and is displayed in the security alert list again.

27.1.4.3.3. Configure security alerts

This topic describes how to configure logon settings and web directories that are scanned.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Security Alerts**.
3. In the upper-right corner of the page, click **Settings**.

   You can perform the following operations:

   - **Manage a common logon location.**
     a. On the right side of **Login Location**, click **Add**.

     b. Select a logon location and the servers that are allowed to be logged on to from the location.

     c. Click **OK**.

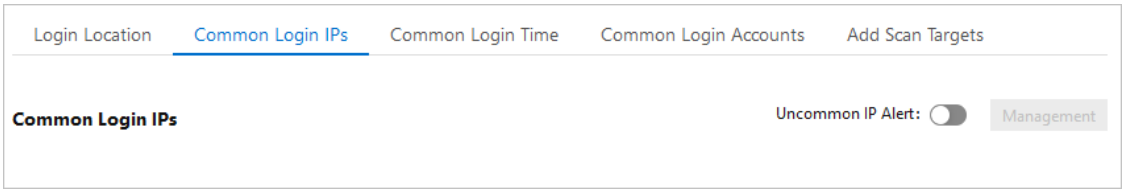
   Threat Detection Service (TDS) allows you to **edit** and **delete** added logon locations.

   - Find the target logon location and click **Edit** on the right side to change the servers that are allowed to be logged on to from this location.
   - Find the target logon location and click **Delete** on the right side to delete the logon location.

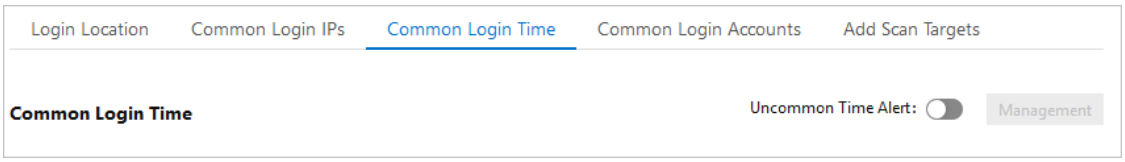
   - **Configure advanced logon settings.**

> **Note** You can specify the IP addresses, accounts, and time periods that are allowed to log on to your assets. After you configure these settings, alerts are triggered if your assets receive logon requests that do not meet the requirements. The procedure to configure advanced logon settings is similar to that to configure **common logon locations**. You can follow the preceding procedure to **add**, **edit**, and **delete** advanced logon settings.

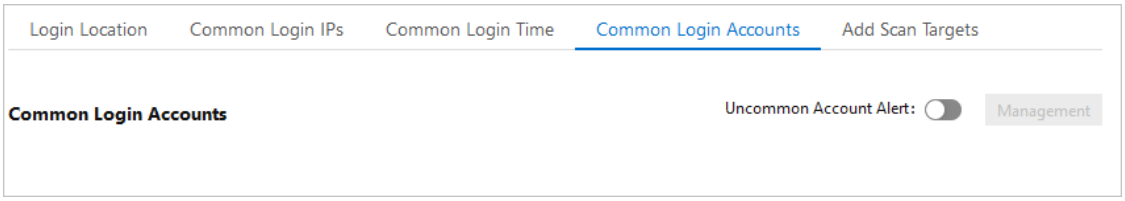
- On the right side of **Common Login IPs**, enable or disable Uncommon IP Alert. After this function is enabled, alerts are triggered if your assets receive logon requests from unauthorized IP addresses.



- On the right side of **Common Logon Time**, enable or disable Uncommon Time Alert. After this function is enabled, alerts are triggered if your assets receive logon requests at unauthorized time.



- On the right side of **Common Login Accounts**, enable or disable Uncommon Account Alert. After this function is enabled, alerts are triggered if your assets receive logon requests from unauthorized accounts.



- **Add a web directory as the scan target.**

  TDS automatically detects web directories on your servers.

  It performs dynamic and static scans on these directories. You can also manually add web directories for scanning.

  a. On the right side of **Add Scan Targets**, click **Add**.

  b. Enter a valid web directory and select the servers on which the directory is scanned. The web directory is added to the scan list.

  > **Note** To ensure performance and efficiency, do not enter a root directory.

  c. Click **OK**.

27.1.4.4. Attack analysis

This topic describes the statistics provided by the attack analysis feature. The statistics include the total number of attacks, distribution of attack types, top five attack sources, top five assets attacked, and an attack list.

Background information

The attack analysis feature provides basic attack detection and prevention capabilities in Apsara Stack Security Center. We recommend that you optimize firewalls and enhance business security to develop a more fine-grained and in-depth defense system.

On the **Attack Awareness** page, you can specify a time range to view these attack details. You can view the attack analysis statistics of the current day, last 7 days, or last 30 days. You can also set Time Range to **Custom** to view the statistics of a time range within the last 30 days.

- **Attacks**: the total number of attacks detected in your assets within a specific time range.
- **Attack Type Distribution**: the attack types and the number of attacks for each type.
- **Top 5 Attack Sources**: the top five IP addresses from which the most attacks are launched.
- **Top 5 Attacked Assets**: the top five assets that are attacked the most frequently.
- **Attack list**: the details about each attack. The details include the attack time, source IP address, attacked asset, attack type, and attack status.

  > **Note** The attack list displays a maximum of 10,000 attacks. You can specify **Time Range** to view details about the attacks that occur over the specified time range.

  Parameters in the attack list

Parameter	Description
Attacked At	The time at which an attack occurs.
Attack Source	The source IP address of an attack.
Attacked Asset	The name, public IP address, and private IP address of an attacked asset.
Attack Method	The HTTP request method used to initiate an attack. Valid values: POST and GET.
Attack Type	The type of an attack. The types of attacks that can be detected include SSH brute-force attacks and remote code execution attacks.

- Search for an attack.

  To view the details about a specific attack, specify search conditions in the search box above the attack list. Search conditions include the attack type, attacked asset, and source IP address.

- View the details of an attacked asset.

  To view the details about an attacked asset, move the pointer over the name of the attacked asset.

- Export the attack list.

  To export and save the attack list to your computer, you can click the  icon in the upper-left corner above the attack list. The attack list is exported to an Excel file.

27.1.4.5. Cloud service check

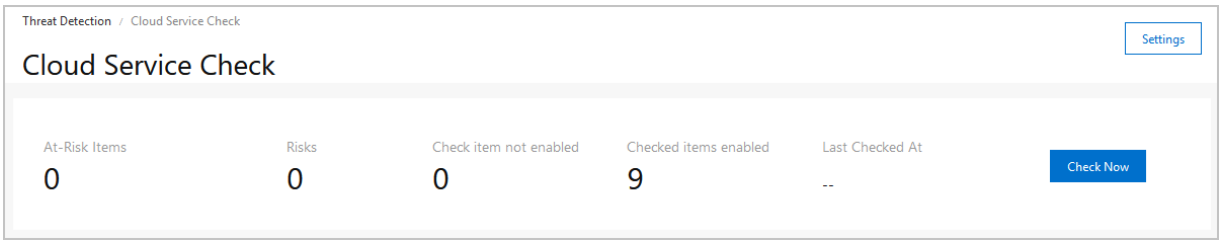
27.1.4.5.1. Overview

Threat Detection Service (TDS) provides the cloud service check feature. This feature allows you to check for security risks in the configurations of your Apsara Stack services. This topic describes the features and check items that are supported by the cloud service check feature.

Background information

The cloud service check feature allows you to perform network access control and data security checks. The checks help you detect configuration risks of your Apsara Stack services and provide repair solutions.

You can view the number of **Checked items enabled** on the **Cloud Service Check** page.



Cloud service check list

The following table describes the check items.

Type	Supported item	Description
	PolarDB - Backup configurations	Checks whether the automatic backup feature is enabled for PolarDB. Regular backups help you improve database security. If an error occurs in your database after backup is performed, you can restore data. PolarDB supports automatic backup. We recommend that you enable automatic backup to create a backup on a daily basis.
	Container Registry - Repository permission configurations	Checks whether the status of Container Registry repositories is set to private. Container Registry repositories include public repositories and private repositories. Public repositories allow Internet users to anonymously download information. If an image contains sensitive information, we recommend that you set the status of Container Registry repositories to private. Otherwise, ignore related alerts.
	OSS - Server-side encryption	Checks whether the data encryption feature is enabled for Object Storage Service (OSS) buckets. OSS supports server-side encryption to ensure the security of data that is persistently stored in OSS. We recommend that you enable server-side encryption to protect sensitive data.
	OSS - Sensitive information leakage scans	Checks whether OSS sensitive files require access permissions.
	ApsaraDB RDS - Cross-region backup configurations	Checks whether cross-region backup is enabled for ApsaraDB RDS instances. ApsaraDB RDS for MySQL provides the cross-region backup feature that automatically synchronizes local backup files to OSS in another region. We recommend that you enable the cross-region backup feature.
	KVStore for Redis - Backup configurations	Checks whether the data backup feature is enabled for KVStore for Redis instances.

Type	Supported item	Description
Data security	ApsaraDB for MongoDB - SSL encryption	Checks whether SSL encryption is enabled for ApsaraDB for MongoDB databases. We recommend that you enable the SSL encryption feature to improve the security of data links in ApsaraDB for MongoDB databases.
	ApsaraDB for MongoDB - Backup configurations	Checks whether the automatic backup feature is enabled for ApsaraDB for MongoDB databases. Regular backups help you improve database security. If an error occurs in your database after backup is performed, you can restore data. ApsaraDB for MongoDB provides automatic backup policies. We recommend that you enable automatic backup to create a backup on a daily basis.
	ECS - Disk encryption	Checks whether encryption is enabled for disks on Elastic Compute Service (ECS) instances.
	ECS - Automatic snapshot policies	Checks whether the automatic snapshot feature is enabled for the disks on ECS instances. The automatic snapshot feature improves the security of ECS data and supports disaster recovery.
	OSS - Bucket permissions	Checks whether the OSS bucket ACL is set to *private*.
	OSS - Logging	Checks whether the logging feature is enabled for OSS.
	OSS - Cross-region replication configurations	Checks whether the cross-region replication feature is enabled for OSS.
	ApsaraDB RDS - Database security policies	Checks whether the SQL audit, SSL encryption, and transparent database encryption features are enabled for ApsaraDB RDS databases.
	ApsaraDB RDS - Backup configurations	Checks whether the data backup feature is enabled for ApsaraDB RDS instances.
	SSL Certificates Service - Expiration check	Checks whether your SSL certificate is expired. If your SSL certificate is expired, you are not allowed to use SSL Certificates Service.
	ECS - Security group policies	Checks ECS security group policies. We recommend that you grant minimum permissions to users. We also recommend that you specify 0.0.0.0/0 only for public-facing ports, such as port 80, 443, 22, or 3389.
	OSS - Bucket hotlink protection	Checks whether hotlink protection is enabled for OSS buckets. The OSS hotlink protection feature checks the Referer header to deny access from unauthorized users. We recommend that you enable this feature.
	VPC - DNAT rules	Checks whether a port is open to the Internet. When you create a Destination Network Address Translation (DNAT) rule for a NAT Gateway that is deployed in a virtual private cloud (VPC), we recommend that you do not open internal management ports to the Internet. Do not open all ports or an important port, for example, ports 22, 3389, 1433, or 3306, to the Internet.

Type	Supported item	Description
Network access control	Apsara Stack Security - Back-to-origin configuration checks	Checks whether Anti-DDoS Pro or Anti-DDoS Premium is configured to allow only Web Application Firewall (WAF) back-to-origin IP addresses. After you set up Anti-DDoS Pro, Anti-DDoS Premium, or WAF, you must hide the IP addresses of the backend servers to prevent attacks on the cloud assets.
	Apsara Stack Security - WAF back-to-origin configurations	Checks whether WAF allows requests only from WAF back-to-origin IP addresses. After you set up Anti-DDoS Pro, Anti-DDoS Premium, or WAF, you must hide the IP addresses of the backend servers to prevent attacks on the cloud assets.
	SLB - IP address whitelist configurations	Checks the access control configurations of Server Load Balancer (SLB) instances. Checks whether access control is enabled for HTTP and HTTPS services and checks whether 0.0.0.0/0 is added to the IP address whitelist.
	SLB - Open ports	Checks whether ports of SLB instances are unnecessarily open to the Internet.
	ApsaraDB RDS - IP address whitelist configurations	Checks whether a whitelist is configured for ApsaraDB RDS and whether the whitelist contains 0.0.0.0/0. If the whitelist contains 0.0.0.0/0, requests from all IP addresses are allowed. We recommend that you configure the whitelist to allow requests only from specific IP addresses.
	KVStore for Redis - IP address whitelist configurations	Checks whether a whitelist is configured for KVStore for Redis and whether the whitelist contains 0.0.0.0/0. If the whitelist contains 0.0.0.0/0, requests from all IP addresses are allowed. We recommend that you configure the whitelist to allow requests only from specific IP addresses.
	AnalyticDB for PostgreSQL - IP address whitelist configurations	Checks whether a whitelist is configured for AnalyticDB for PostgreSQL and whether the whitelist contains 0.0.0.0/0. If the whitelist contains 0.0.0.0/0, requests from all IP addresses are allowed. We recommend that you configure the whitelist to allow requests only from specific IP addresses.
	PolarDB - IP address whitelist configurations	Checks whether a whitelist is configured for PolarDB to allow access from the Internet and whether the whitelist contains `0.0.0.0/0`. If the whitelist contains 0.0.0.0/0, requests from all IP addresses are allowed. We recommend that you configure the whitelist to allow requests only from specific IP addresses.
	ApsaraDB for MongoDB - IP address whitelist configurations	Checks whether a whitelist is configured for ApsaraDB for MongoDB and whether the whitelist contains `0.0.0.0/0`. If the whitelist contains 0.0.0.0/0, requests from all IP addresses are allowed. We recommend that you configure the whitelist to allow requests only from specific IP addresses.

27.1.4.5.2. Run cloud service checks

Threat Detection Service (TDS) provides the cloud service check feature. This feature allows you to check for security risks in the configurations of your cloud services. This topic describes how to manually run cloud service checks on your cloud services. This topic also describes how to specify a detection interval for automated periodic checks.

Context

Apsara Stack Security supports manual checks and automated periodic checks to scan for configuration risks in cloud services.

- Manual checks: On the **Cloud Service Check** page, you can click **Check Now** to check for security risks in the configurations of your cloud services.
- Automated periodic checks: By default, Apsara Stack Security automatically runs checks during the time range `00:00:00-06:00:00` every other day. You can also customize a time range for automated periodic checks. This way, you can detect and handle configuration risks at the earliest opportunity.

Manual checks

1.
2. In the left-side navigation pane, choose **Threat Detection > Cloud Service Check**.
3. On the **Cloud Service Check** page, click **Check Now** to check whether the configurations of all your cloud services contain risks and the number of affected assets.

   > **Note** Do not perform other operations until the check is complete.

   After the check is complete, the detected risks are listed based on their severities in descending order.

Automated checks

1.
2. In the left-side navigation pane, choose **Threat Detection > Cloud Service Check**.
3.
4. In the **Settings** dialog box, configure the **Detection Cycle** and **Detection Time** parameters.

   
   - **Detection Cycle**: supports Monday to Sunday. You can select multiple days of the week.
   - **Detection Time**: supports `24:00:00-06:00:00`, `06:00:00-12:00:00`, `12:00:00-18:00:00`, and `18:00:00-24:00:00`. You can select only one time range.
5. Click **OK**.
   During the selected time range, Apsara Stack Security automatically runs checks based on all check items.

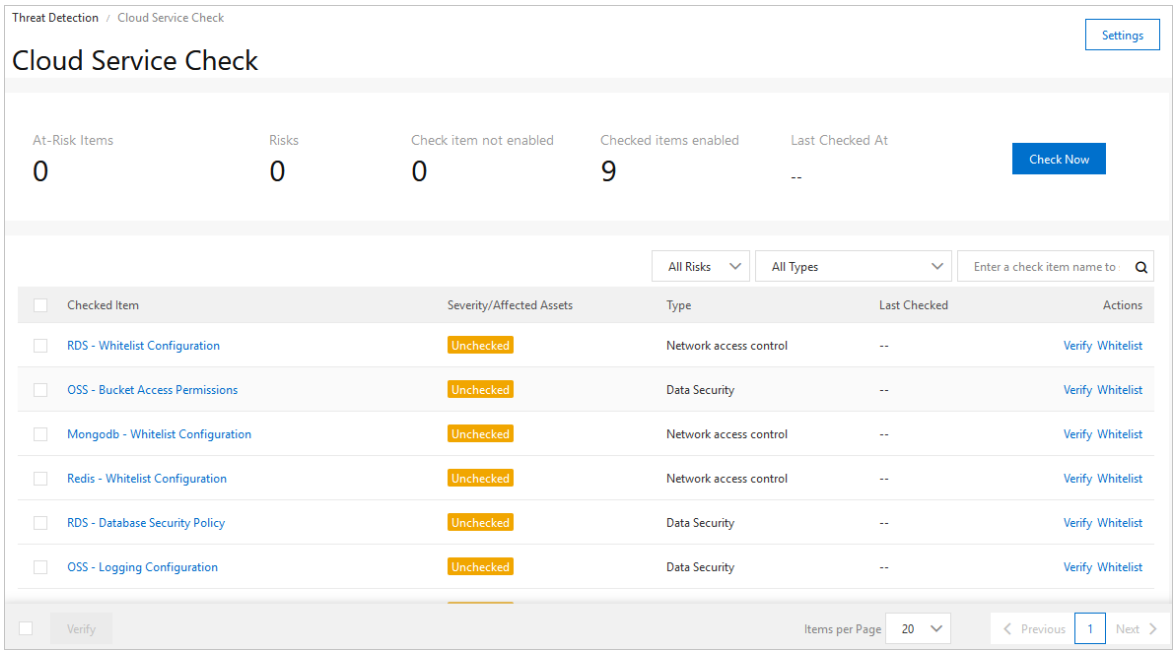
27.1.4.5.3. View and manage check results of Alibaba Cloud services

This topic describes how to view check results and manage configuration risks in Apsara Stack Security Center. Check results include check items, details of check items, potential impacts, and suggestions on how to manage configuration risks. You can manage configuration risks on the Cloud Service Check page.

View check results

1.
2.
3. On the **Cloud Service Check** page, you can view the check results and details of the last configuration

check.



- **View statistics on the result of the last check.**

  Above the check item list, you can view the number of **At-Risk Items** (including the total number of items and the number of items at each risk level), the number of assets with risks (**Risks**), the number of enabled check items, the number of disabled check items, and the last check time.

- **View the check items.**

  In the check item list, you can view information about the check items. The check items include the risk level, the type and number of assets affected by each check item, the type of each check item, and the time of the last check.

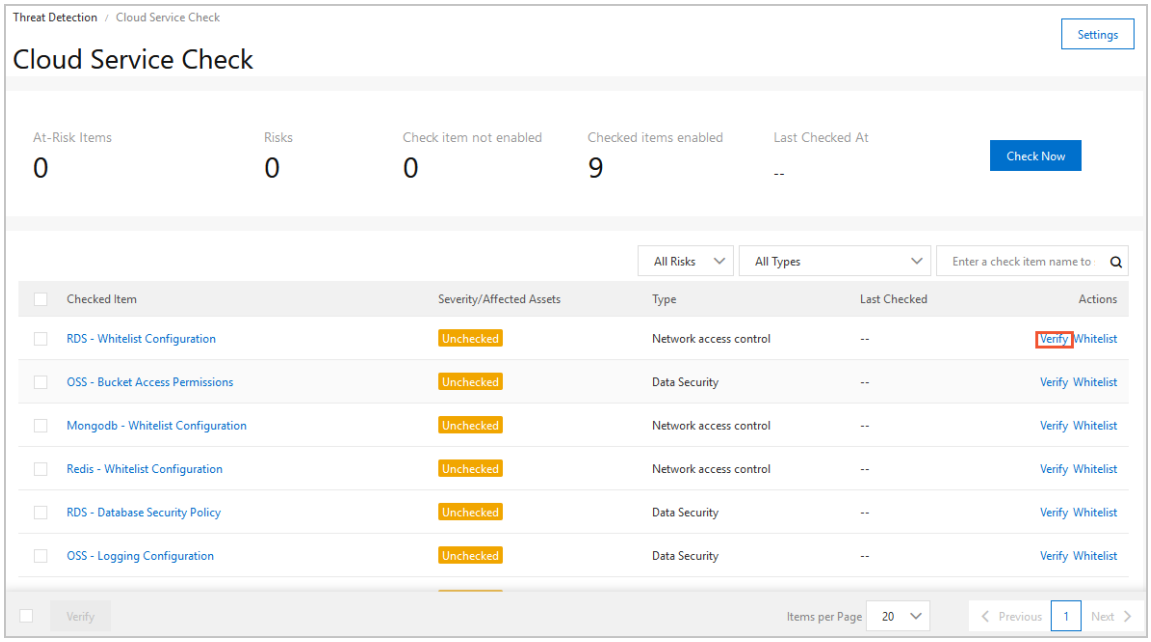
- **View the check result details of a check item.**

  Click the name of the target checked item in the **Checked Item** column to go to the details page. You can view the check description, potential risks, and suggestions on how to manage the risks on this page.

Manage configuration risks

1.
2.
3. On the **Cloud Service Check** page, manage the configuration risks.
   - **Check whether the new settings contain risks.**

If you have changed the configuration settings of an item, find the item on the check item list on the Cloud Service Check page and click **Verify** in the Actions column to check whether the new settings contain risks.



- **Add a check item to the whitelist.**

  If you want to ignore the detected risks of a checked item, find the item on the check item list and click **Whitelist** to add the item to the whitelist. The status of the item will change to **Ignored**. **Ignored** items are not counted as **At-Risk Items**.

  In the check item list, you can also click **Remove** to remove the **Ignored** items from the whitelist.

  > **Note** After you click **Whitelist**, the risk is ignored for this time only. If the risk is detected in the future, Apsara Stack Security Center will continue to report it.

27.1.4.6. Application whitelist

Application whitelists can prevent unauthorized programs from running on your servers and provide a trusted running environment for your assets.

Context

The application whitelist feature allows you to add servers and trusted applications to a whitelist. Applications that are not specified in the whitelist cannot run on your servers. This feature protects your servers from untrusted or malicious programs and improves resource utilization.

After you apply a whitelist policy to a server, Apsara Stack Security Center detects suspicious or malicious processes and generates alerts on the processes that are not specified in the whitelist.

> **Note** An alert is triggered if a process that is not specified in the whitelist is detected. The detected process may be a normal process or a malicious process. If you trust the process that triggers an alert, we recommend that you add the process to the whitelist. A process that is added to the whitelist no longer triggers alerts when it restarts. If the process is malicious, we recommend that you remove this process immediately and check whether configuration files of scheduled tasks have been modified.

Step 1: Create an application whitelist policy

1.

2. In the left-side navigation pane, choose **Threat Detection > Application Whitelists**.
3.
4. On the App Control page, click the **Policies** tab. Then click **Create Policy** in the upper-left corner.
5. In the Create Policy step of the **Create Whitelist Policy** pane, configure the following parameters:
   - **Policy Name**: Enter a whitelist policy name.
   - **Intelligent Learning Duration**: Select a duration for intelligent learning. Valid values: 1 Day, 3 Days, 7 Days, and 15 Days. The intelligent learning feature uses machine learning to automatically collect and categorize large amounts of alert data. Apsara Stack Security Center can identify suspicious or malicious processes based on the collected data.
   - **Servers for Intelligent Learning**: Select the servers that you want to add to the whitelist.
6. Click **Next** to create the whitelist policy.
   After the whitelist policy is created, its details are automatically displayed in the policy list on the Policies tab.

   The following table lists the parameters in the policy list.

Parameter	Description
Policy Name	The name of the created whitelist policy.
Servers	The number of servers to which the whitelist policy is applied.
Status	The status of the policy. Valid values: ○ **Applied**: Intelligent learning is completed. The policy is applied to servers. ○ **Pending Confirmation**: Intelligent learning is completed. The policy must be confirmed and enabled. After intelligent learning is completed, you also need to turn on the switch in the **Policy Status** column to enable this policy. The policy takes effect only after it is enabled. Apsara Stack Security Center automatically identifies the processes on your servers as trusted, suspicious, or malicious processes. ○ **Paused**: Intelligent learning is manually paused. You can click **Continue** in the Actions column to resume intelligent learning. ○ **Progress**: Intelligent learning is in progress. After a whitelist policy is created, Apsara Stack Security Center automatically performs intelligent learning based on the policy. The status of a newly created policy is **Progress**.
Applications	The numbers of processes, including **Trusted**, **Suspicious**, and **Malicious** processes, on all servers to which the policy is applied.

Parameter	Description
Actions	The operations that you can perform on a policy. Valid values: ○ **Apply**: Add or remove servers to which the policy is applied on the **Apply Whitelist Policy** pane. ○ **Modify**: Modify the policy on the **Modify Whitelist Policy** pane. You can change the values of **Policy Name** and **Intelligent Learning Duration**, and modify the servers that need to automatically perform intelligent learning. ○ **Pause Learning**: Pause intelligent learning. ○ **Continue**: Resume intelligent learning. After you click **Continue**, the status of the policy changes to **Progress**. You can view the learning progress of the policy in the **Status** column. ○ **Delete**: Delete the policy. After the policy is deleted, the corresponding servers and processes are no longer protected by the policy.

Step 2: Add servers to the application whitelist

1.
2. In the left-side navigation pane, choose **Threat Detection > Application Whitelists**.
3. On the **Servers** tab of the App Control page, click **Add Server** in the upper-left corner.
4. In the **Add Server** pane, configure the following parameters:
   - **Whitelist Policy**: Select an existing whitelist policy from the drop-down list.
   - **Event Handling**: The default value is **Alert**, which indicates that Apsara Stack Security Center generates alerts when a suspicious process is detected.

     When an unauthorized process starts on a server protected by the whitelist, an alert is automatically triggered. You can click the number in the **Suspicious Events** column to go to the **Alerts** tab and view the alert details.
   - **Servers**: Select the servers that you want to add to the whitelist. You can select multiple servers.

     To search for a server, enter the server name in the search box of **Servers** and click the search icon. Fuzzy match is supported.
5. Click **OK**.
   After you create an application whitelist, you can view the protected servers and the name of the whitelist policy applied to the servers in the server list on the **Servers** tab.

   The following information of the added servers is displayed on the **Servers** tab:
   - **Server Name/IP**: the name and IP address of the server to which the whitelist policy is applied.
   - **Whitelist Policy**: the whitelist policy that is applied to the server.
   - **Suspicious Events**: the number of unauthorized processes that are detected on the server. Apsara Stack Security Center generates alerts immediately when a suspicious process is detected.
   - **Event Handling**: The default value is **Alert**, which indicates that Apsara Stack Security Center generates alerts when a suspicious process is detected.

     When an unauthorized process starts on a server protected by the whitelist, an alert is automatically triggered. You can click the number in the **Suspicious Events** column to go to the **Alerts** tab and view the alert details.
   - **Actions**: You can click **Delete** in the **Actions** column to remove a server from the application whitelist.

     After the server is removed from the whitelist, the application whitelist policy no longer protects the server. Apsara Stack Security Center generates alerts when a process starts on that server.

Add or remove a process to or from an application whitelist

After an application whitelist is configured for your servers, you can view the protected servers and the names of the whitelist policies applied to the servers in the server list on the **Servers** tab. You can click a policy name in the **Whitelist Policy** column to view the processes running on the required server. You can also view the trusted, suspicious, and malicious processes and their detailed information.

The following information about each process on the server is displayed:

- **Type**: the type of the process. Processes are classified as trusted, suspicious, or malicious processes.
- **Process Name**: the name of the process.
- **Hash**: the Hash function of the process. The Hash function is used to ensure that the process is unique and has not been forged.
- **Path**: the file path of the process on the server.
- **Degree of Trustability**: the degree of trustability for the process determined by Apsara Stack Security Center. Valid values: 0% (malicious process), 60% (suspicious process), and 100% (trusted process).

  > **Note** We recommend that you focus on the processes of 0% trustability.

- **Actions**: the operations that can be performed on the process. You can determine whether to add the process to the whitelist based on the services deployed on your server. You can perform the following operations:
  - **Add to Whitelist**: If a process is trusted, add it to the whitelist.
  - **Remove from Whitelist**: After a process is removed from the whitelist, Apsara Stack Security Center identifies the process as untrusted and generates an alert when this process starts.

27.1.4.7. Assets

27.1.4.7.1. View the security status of a server

The Assets page displays security information about each protected server. The information includes the virtual private could (VPC) where each server resides, server status, and risk status. This topic describes how to view the security status of a server. You can specify filter conditions to search for servers and select the items that you want to display on the Assets page.

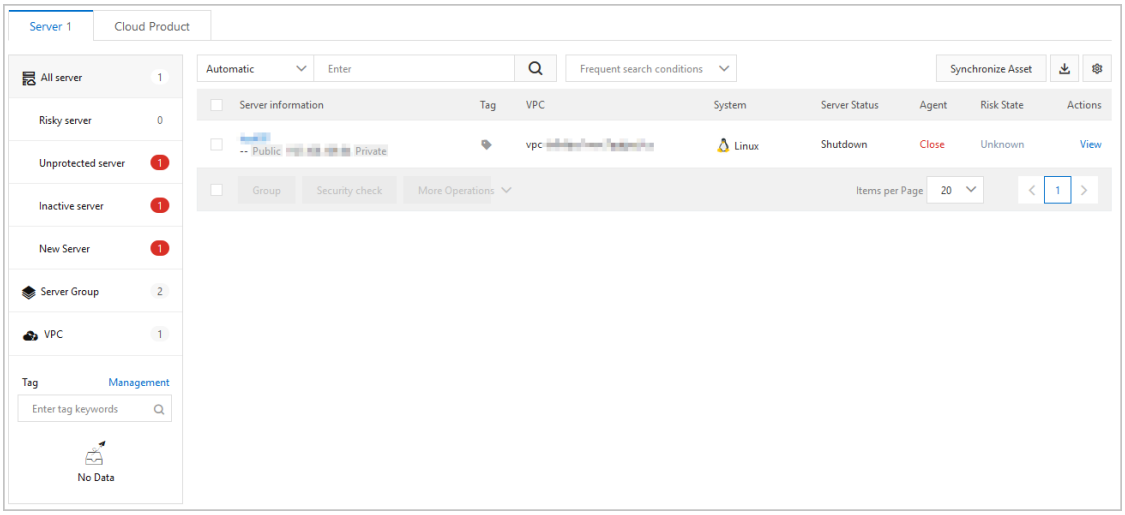
Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server** tab, view the security status of each server.

   You can perform the following operations:

   - **Filter servers by status**

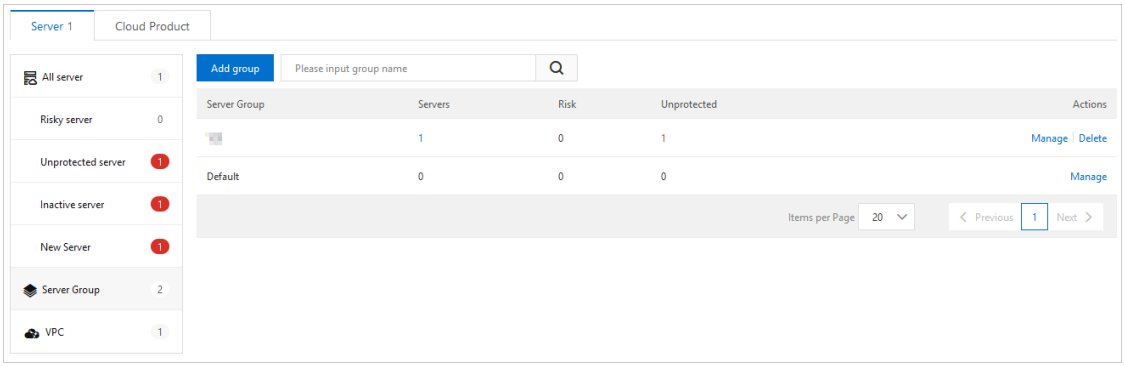
- In **All server**, you can view the numbers of all servers, risky servers, unprotected servers, inactive servers, and new servers.



To view the security information about a server, you can click the name of the server or click **Fix** in the **Actions** column. For more information, see View the details of a single asset.

- You can click **Risky server**, **Unprotected server**, **Inactive server**, or **New Server** to view security information about specific servers.

- **Filter servers by group**
  - You can click **Server Group** to view the numbers of all servers, servers that are at risk, and unprotected servers in each server group. You can also view the total number of server groups.

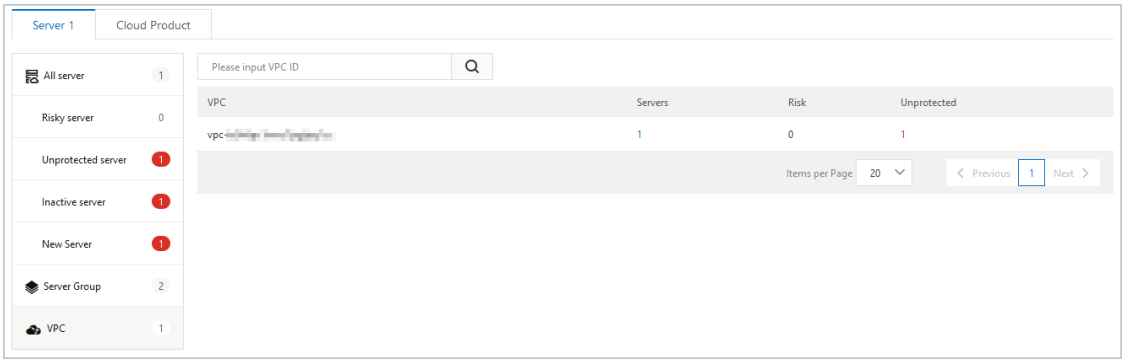


To manage server groups, you can click **Manage** or **Delete** in the Actions column. For more information, see Manage asset groups.

- You can select a server group and click the number in the **Servers**, **Risk**, or **Unprotected** column to view the security information about specific servers in this group.

- **Filter servers by VPC ID**

- You can click **VPC** to view the numbers of all servers, servers that are at risk, and unprotected servers in each VPC. You can also view the total number of VPCs.



- You can select a VPC and click the number in the **Servers**, **Risk**, or **Unprotected** column to view the security information about specific servers in this VPC.

- **Filter servers by tag**

  In the navigation tree, you can click a tag to view the security information about servers to which the tag is added.

- **Filter servers by condition**

  If you click **All server**, **Server Group**, **VPC**, or a tag in the navigation tree, you can specify filter conditions above the right-side list to search for specific servers.

  - Use one filter condition to search for specific servers:

    Above the right-side list, you can select a filter condition and select or enter keywords to search for specific servers. The filter conditions include **Internet IP**, **Private IP**, **Instance name**, **System**, **Baseline problems**, **Vul problems**, **Alert problems**, **Risk Status**, **Online or Offline**, **Tag**, **Group name**, and **OS**.

    > **Note**
    >
    > You can specify multiple filter conditions at a time and specify a Boolean operator for the conditions. The following list describes the Boolean operators:
    >
    > - Boolean operators:
    >   - **AND**: specifies the **AND** logical relation for the conditions.
    >   - **OR**: specifies the **OR** logical relation for the conditions.
    > - If you want to search for servers that meet at least one of the filter conditions, you must set the Boolean operator to **OR**.
    > - If a filter condition requires you to enter a keyword, you must enter the keyword and click the **Search** icon. Results are displayed only after you click the Search icon.

  - Use multiple filter conditions to search for specific servers:

    If you select multiple filter conditions, they are all applied to search for specific servers.

    You can also select **Server Group**, **VPC**, or a tag in the navigation tree and specify filter conditions above the right-side lists to search for specific servers.

- **Save frequently used filter conditions**

  You can save the filter conditions that are applied as frequently used search conditions. To save the conditions, click **Save** above the right-side list, and enter a name in the **Save condition** dialog box. Then, you can select the saved conditions from the **Frequent search conditions** drop-down list to the right of the Search icon.

- **Customize displayed items**

  On the **Assets** page, you can click the icon in the upper-right corner. Then, you can select the items that you want to display on the Assets page.

27.1.4.7.2. View the security status of cloud services

The Assets page displays the security information about each protected cloud service. The information includes the at-risk services and the types of services, for example, SLB and NAT Gateway. This topic describes how to configure search conditions to view the security status of cloud services.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. Click the **Cloud Product** tab to view the security status of cloud services.

   You can perform the following operations based on your business requirements:

   - **Search by asset status**
     - In the left-side pane on the **Cloud Product** tab, you can view the numbers of **All cloud product** and **Risky cloud product**. You can also view the security status of all cloud services.

       
     - You can click **Risky cloud product** to view the cloud services that are at risk.

     You can click the name of the target cloud service or click **View** in the Actions column that corresponds to a service to view detailed information. For more information, see View the details of a single asset.

   - **Search by asset type**

     Cloud services are classified into two asset types:

     - **SLB**
     - **NAT Gateway**

     In the left-side pane on the Cloud Product tab, you can view the number of cloud services of each asset type. You can click **SLB** or **NAT** to view the security status of the target cloud service.

   - **Search by tag**

     In the **Tag** section in the left-side pane of the Cloud Product tab, you can view the number of assets bound to each tag. You can click a tag on the left of the asset list to view the security status of the cloud services to which this tag is bound.

   - **Filter by search condition**

     You can click **All cloud product**, **SLB**, or **NAT** in the left-side pane of the **Cloud Product** tab and configure search conditions in the search box to search for specific assets.

     For example, you can click **All cloud product** and configure search conditions to search for specific assets.

- Use multiple subconditions to search for specific assets:

  Select a condition from the drop-down list of the search box on the **Cloud Product** tab, and select a subcondition or enter a keyword into the search box to search for specific assets. Supported search conditions are **Internet IP**, **Instance name**, **Alert problems**, **Risk Status**, **Tag**, and **Group name**.

  > Note

- Use multiple search conditions to search for specific assets:

  Apply multiple search conditions.

  - You can click **SLB**, **NAT**, or a tag specified in the **Tag** section and configure conditions in the search box on the **Cloud Product** tab to search for specific assets.
  - You can also click **All cloud product**, **SLB**, or **NAT** and select a tag specified in the **Tag** section to search for specific assets.

- **Set frequently used search conditions**

  You can save applied search conditions as frequently used search conditions. Click **Save** below the search box and enter a name in the **Save condition** dialog box. Then, you can select the saved search condition from the Frequent search conditions drop-down list on the right of the search box.

27.1.4.7.3. View the details of a single asset

The Assets page provides details about all assets. These details include basic information, alert management status, baseline check analysis, and asset fingerprints. This topic describes how to view details of a single server or Alibaba Cloud service.

Context

The basic information about assets is displayed on the **Assets** page. Based on the types of assets, servers or Alibaba Cloud services can be managed in different ways.

The following table lists the features that are supported by servers and Alibaba Cloud services on the **Assets** page. The following content describes the marks that are used to indicate whether a feature is supported by servers or Alibaba Cloud services:

- ×: not supported by this edition.
- √: supported by this edition.

Feature	Description	Server	Cloud service
Basic information	Risk state: displays the number of risks of an asset. Risks can be divided into the following types: • **Vulnerability** • **Alert** • **Baseline risk**	√	√ (Only alerts can be processed.)
	Detail: displays the configuration and protection status of an asset. You can specify a group and a tag for the asset.	√	√ (You cannot specify a group for the asset.)
	Asset investigation: displays asset fingerprints, including ports, software, processes, and accounts.	√	×

Feature	Description	Server	Cloud service
	Vulnerability check: displays the supported types of vulnerability checks. You can enable or disable different types of vulnerability checks for an asset.	√	X
	Logon security setting: displays the common logon locations, IP addresses, time, and accounts of an asset. You can also enable or disable alerts for the asset.	√	X
Vulnerabilities	Displays the vulnerability check results of an asset.	√	X
Alerts	Displays the security alerts of an asset.	√	√
Baseline Risks	Displays the baseline check results of an asset.	√	X
Asset Fingerprints	Displays the fingerprints of an asset.	√	X

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Assets** page, click the **Server** or the **Cloud Product** tab.
4. On the **Server** or **Cloud Product** tab, find the target asset and click its name.
5. View the details of the target asset.

   On the asset details page, click the **Basic Information**, **Vulnerabilities**, **Alerts**, **Baseline Risks**, or **Asset Fingerprints** tab to view relevant details.

   The following content displays the details of the target asset:

   - **Basic Information**: This tab consists of sections where you can view asset details and manage an asset.
     - **Risk State**: This section displays information about vulnerabilities, alerts, and baseline risks of an asset. You can click the number under Vulnerabilities, Alerts, or Baseline Risks to view the details.

- **Detail**: This section displays information about the asset configuration and security protection settings, and allows you to manage asset tags and groups.
  - **Change asset groups**

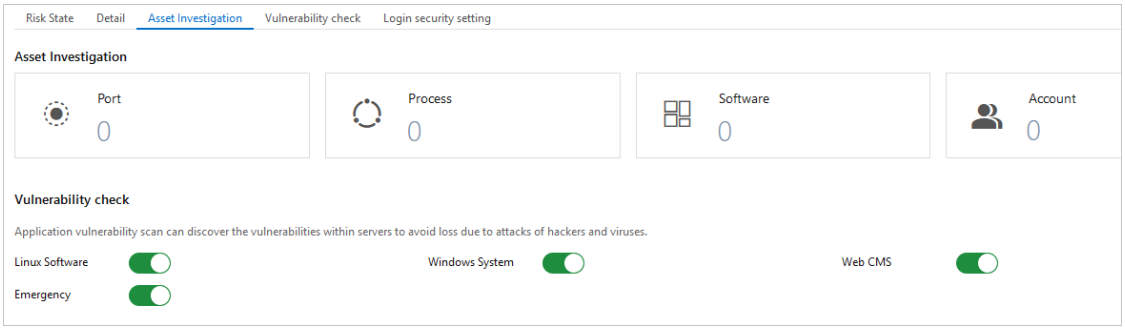
    Click **Group**. In the **Group** dialog box, select a new group and click **OK**.

    
  - **Modify tags**

    Click the icon. In the **Add tag** dialog box, select a tag and click **OK**.

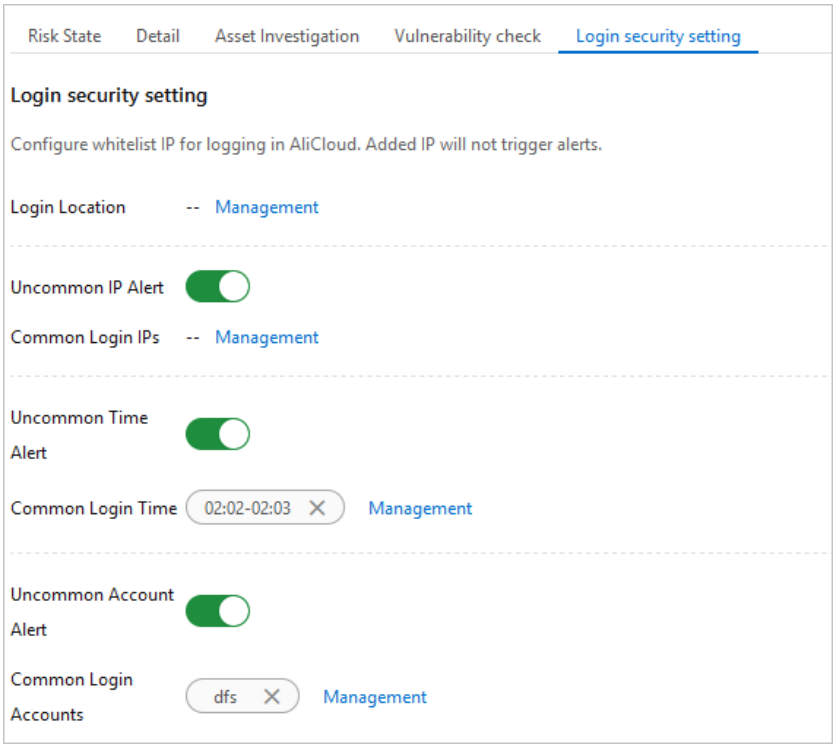
    
    To remove the tag of an asset, click the icon to the right of the tag.

- **Asset Investigation**: This section displays the fingerprints of an asset. You can click the number under an item to go to the **Asset Fingerprints** tab to view the details.

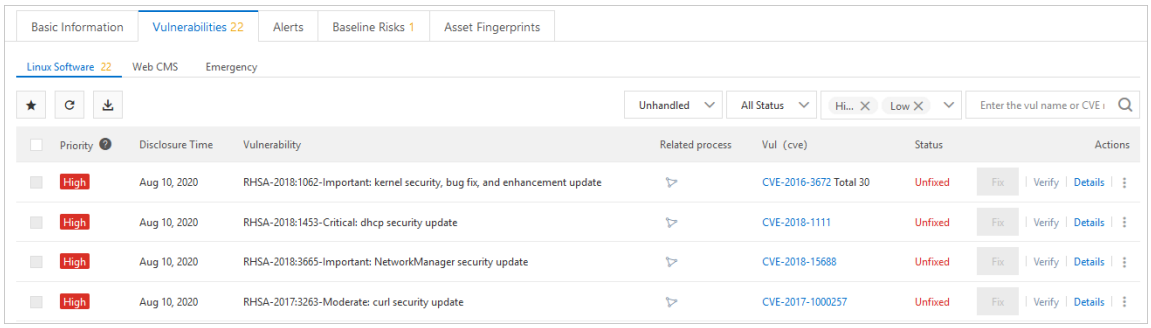
  


- **Vulnerability check**: This section displays vulnerability check items that are enabled or disabled for an asset. You can enable or disable different types of vulnerability checks for the asset. The vulnerabilities include Linux software vulnerabilities, Windows system vulnerabilities, Web CMS vulnerabilities, and emergency vulnerabilities.

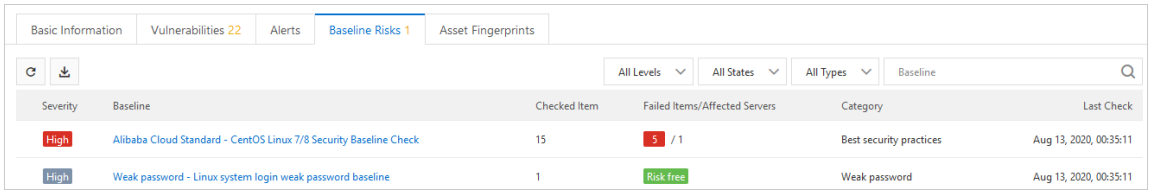
- **Login security setting**: This section allows you to **add approved logon locations**, configure advanced logon settings, **turn on or turn off** the unapproved IP address, time, and account alert function. The advanced logon settings include approved IP addresses or Classless Inter-Domain Routing (CIDR) blocks, time periods, and accounts. You can also add approved IP addresses, time periods, and accounts that are allowed to log on to a specific asset.



- **Vulnerabilities**: This tab displays vulnerabilities of an asset.



- **Alerts**: This tab displays security alerts of an asset.
- **Baseline Risks**: This tab displays baseline risks of an asset.

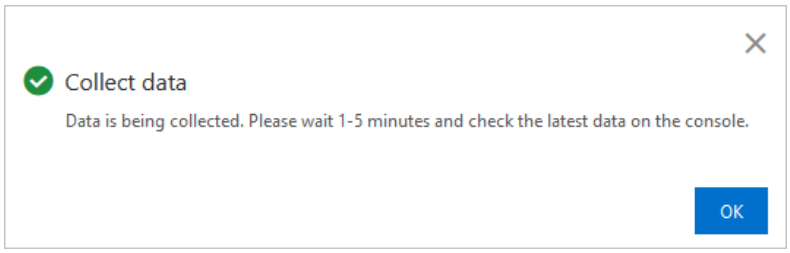


- **Asset Fingerprints**: This tab displays the fingerprints, including ports, processes, software, and accounts of an asset.

  You can manually collect the latest fingerprints of an asset.

  a. You can click the **Port**, **Software**, **Process**, **Account**, or **Scheduled Tasks** tab. In the upper-right corner, click **Collect data now**.

b. In the **Collect data** dialog box, click **OK**.



After the data collection task is submitted, it takes one to five minutes to collect the fingerprints of the target asset. After the data collection task is complete, you can view the latest fingerprints of the target asset.

27.1.4.7.4. Enable and disable server protection

This topic describes how to enable and disable server protection.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server** tab, enable or disable server protection for specified servers.
   - **Enable server protection**

     Select one or more servers where the agent is in the **Close** state, and choose **More operations > Turn on protection**.

     After server protection is enabled, the status of the agent on the servers changes to **Enable**.
   - **Disable server protection**

     You can disable server protection for specified servers. Select one or more servers where the **agent** is in the **Enable** state, and choose **More operations > Suspend Protection**.

     > **Note** After server protection is disabled, Apsara Stack Security Center stops providing protection for your servers. The protection mechanisms that are stopped include vulnerability detection and security event alerting. We recommend that you proceed with caution.

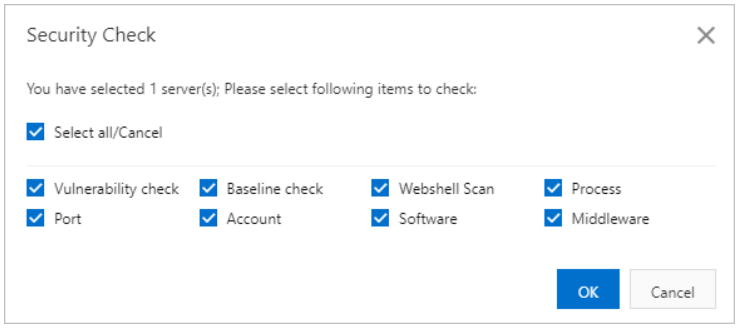
     After server protection is disabled, the status of the **agent** on your servers changes to **Close**.

27.1.4.7.5. Perform a quick security check

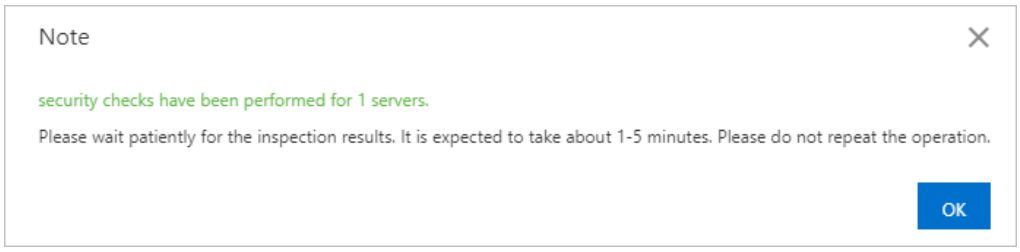
The Server tab of the Assets page allows you to run security checks. You can dispatch security check tasks to scan for vulnerabilities, baseline risks, or webshells, and collect asset fingerprints on a specific server. The asset fingerprints are ports, software, processes, and accounts. This topic describes how to perform a security check on servers.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server** tab, select one or more servers on which you want to perform a security check.
4. In the lower part of the page, click **Security check**.
5. In the **Security Check** dialog box, select check items.



6. Click **OK** to start the check.
7. In the message that appears, click **OK**.



After the security check is complete, the check results are automatically displayed on the details pages of the selected servers.

27.1.4.7.6. Manage server groups

This topic describes how to create, modify, delete, and replace server groups.

Create a server group

1.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server** tab, click **Server Group** in the navigation tree.

   > **Note** Ungrouped servers are in the **Default** group.

4. Click **Add group**.
5. In the **Add group** dialog box, configure parameters for the new group.

   To configure the parameters, perform the following steps:

   i. Enter a name for the new group in the **Group name** field.

   ii. Add servers to the new group.

   You can add servers in the Default group to the new group. You can also move servers from another group to the new group. To add or move servers, select **Default** or other groups from the **Select Group** drop-down list, select servers in the groups, and then click the > icon to add the selected servers to the new group.

6. Click **OK**.
   In the server group list, you can view the new group.

Modify or delete a server group

The following procedure describes how to modify or delete a server group. When you modify a server group, you can rename the group or adjust the servers in the group.

1.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server** tab, click **Server Group** in the navigation tree.
4. Find the server group that you want to modify or delete. In the Actions column, click **Manage** or **Delete**.

   You can perform the following operations based on your business requirements:

   - **Modify the group**
     a. In the Actions column, click **Manage**. The Group dialog box appears.
     b. In the **Group** dialog box, select a group from the **Select Group** drop-down list, select servers in the current group on the right, and then click the icon to move the selected servers to the selected group on the left. You can also select servers in the group on the left and click the icon to move the selected servers to the current group on the right.
     c. Click **OK**.
   - **Delete the group**

     In the Actions column, click **Delete**. In the message that appears, click **OK**.

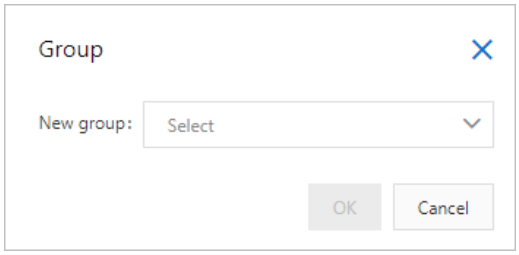
     > **Note** After you delete a group, servers in this group are moved to the **Default** group.

Replace a server group

You can add servers to a server group to manage multiple servers at a time. We recommend that you add the same types of servers to a server group. For example, if you configure a baseline check template, you can specify a server group and apply the template to all servers in the group. You can also filter and view servers based on server groups.

To move servers to a specific server group, perform the following steps:

1.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the Server tab, select one or more servers and click **Group** in the lower part of the page.
4. In the **Group** dialog box, select a new server group.



5. Click **OK**.

27.1.4.7.7. Manage asset tags

This topic describes how to add asset importance tags to your assets and how to create, modify, and delete custom tags.

Context

Apsara Stack Security provides the asset importance tags described in the following table to classify assets. You can select appropriate importance tags for your assets.

An asset importance tag is transformed to an **asset importance score**. An **asset importance score** is used to calculate a vulnerability priority score. You can determine whether to preferentially fix a vulnerability based on the vulnerability priority score. We recommend that you add importance asset tags to core assets. Apsara Stack Security prompts you to fix vulnerabilities based on the importance of each asset. The following table describes the relationships between asset importance tags and asset importance scores.

Asset importance tag	Asset importance score	Recommendation
Important Assets	1.5	Assets that are related to crucial business or store core business data. Virus intrusion into the assets adversely affects the system and causes major loss.
General Assets	1	Assets that are related to non-crucial business and are highly replaceable. Virus intrusion into the assets causes less impact on the system.
Test Assets	0.5	Assets for functional or performance tests, or assets that can cause less impact on the system.

Note If you do not add asset importance tags, the **General Assets** tag is automatically added to each asset. This tag indicates that the asset importance score is 1.

Create a custom tag

1.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. Click the **Server** or **Cloud Product** tab.
4. In the navigation tree of the **Server** or **Cloud Product** tab, click **Management** to the right of **Tag**.
5. In the **Add tag** dialog box, enter the tag name. In the left-side server list, select servers and click the icon to add the new tag to the selected servers.
6. Click **OK**.

   In the asset list of the Server or Cloud Product tab, you can click the icon in the **Tag** column to add the new tag to an asset.

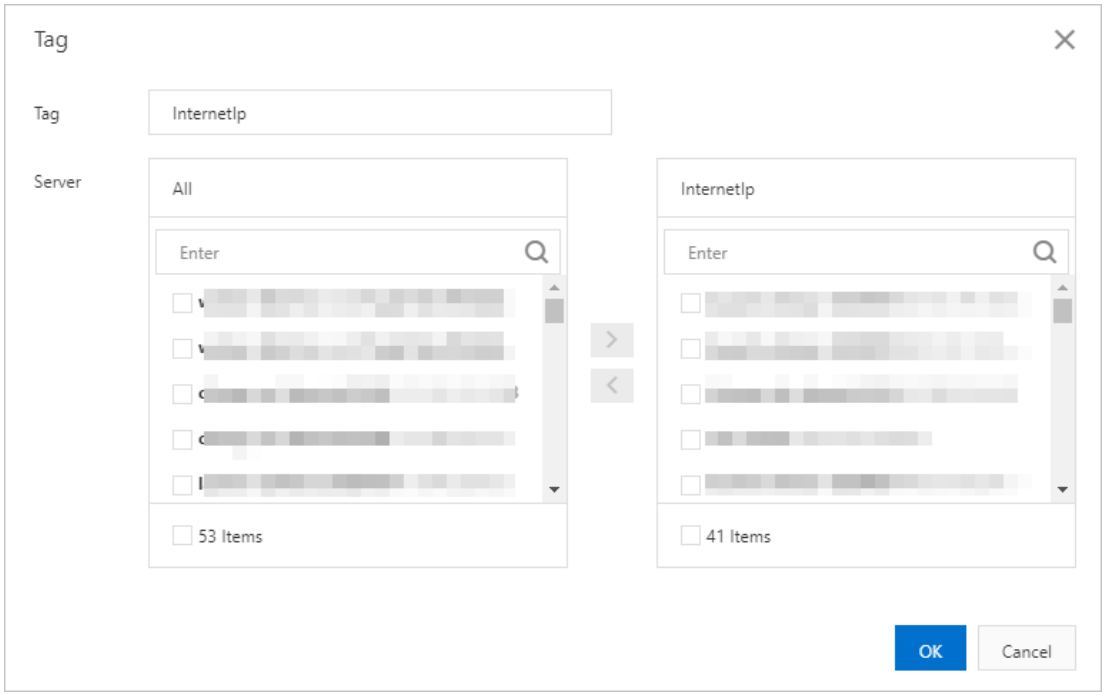
   Note You can add multiple tags to one asset. All tags of an asset are displayed in the **Tag** column.

Modify or delete a custom tag

The following procedure describes how to modify or delete a custom tag. When you modify a tag, you can rename the tag or adjust the servers to which the tag is added.

1.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. Click the **Server** or **Cloud Product** tab.
4. On the **Server** or **Cloud Product** tab, modify or delete a tag.
   - **Modify a tag**
     a. Find the tag that you want to modify and move the pointer over the icon to the right of the tag.

b. In the **Tag** dialog box, enter a new name in the **Tag** field, add the tag to more servers, or remove the tag from specific servers.



c. Click **OK**.

- **Delete a tag**

  Find the tag that you want to delete and click the × icon in the Tag column. In the message that appears, click **OK**.

27.1.4.8. Vulnerability scan

27.1.4.8.1. Quick start

This topic describes how to get started with the vulnerability scan feature.

The following procedure shows how to use the vulnerability scan feature:

1. Configure the following detection items and the required cycles based on your environment requirements:
   - Overall Monitoring: Configure detection features and the monitoring cycle of each detection feature. For more information, see Configure overall monitoring.
   - Basic Monitoring: Configure Weak Password Vulnerability Monitoring, Operation Security Vulnerability Monitoring, CMS Application Vulnerability Monitoring, and Baseline Monitoring. For more information, see Configure basic monitoring.
   - Web Monitoring: Configure the monitoring cycle and the types of web vulnerabilities that you want to monitor. For more information, see Configure web monitoring.
   - Whitelist: Add the assets that do not need detection to the whitelist. For more information, see Configure a whitelist.
2. Import assets that require vulnerability scans.
   - Import internal assets: Configure a scan engine to import your internal assets in virtual private clouds (VPCs). For more information, see Configure a scan engine for internal assets.
   - Import Internet assets: Directly import Internet assets. For more information, see Import assets.

> **Note** The number of imported assets cannot exceed the specified upper limit.

3. View and confirm the results of vulnerability scans.
   - View the overview information to obtain the general results of vulnerability scans. For more information, see View the information on the Overview page.
   - View and confirm security vulnerability risks. For more information, see .
   - View and confirm host compliance risks. For more information, see Manage security vulnerabilities.
   - View and confirm external risks, such as code leak risks. For more information, see Manage host compliance risks.
4. Generate vulnerability scan reports.

   Generate reports to audit the vulnerabilities and baselines of assets at a regular basis. For more information, see Manage external risks.

27.1.4.8.2. View the information on the Overview page

This topic describes the overall results of vulnerability scans. Security administrators can understand the vulnerability situation based on the overall results.

Context

The vulnerability scan feature can identify the following vulnerabilities: web security vulnerabilities, content management system (CMS) application vulnerabilities, weak password vulnerabilities, operations and maintenance (O&M) security vulnerabilities, and baseline security vulnerabilities.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Overview**.
3. View the overall result of vulnerability scans.

Section	Description
Today's attention	View Asset Overview, Disclosured Risk, and Resolved Risk of the current day. ○ **Asset Overview**: displays the numbers of hosts, websites, and domain names for the current day and provides a security score for the current assets. The radar chart on the right shows the distribution of web security vulnerabilities, CMS application vulnerabilities, weak password vulnerabilities, O&M security vulnerabilities, and baseline security vulnerabilities. ○ **Disclosured Risk**: displays the numbers of high-risk vulnerabilities, medium-risk vulnerabilities, and low-risk vulnerabilities, and the total number of these vulnerabilities for the current day. These vulnerabilities are not fixed. The **Disclosured Risk Distribution** section on the right displays the distribution of unfixed vulnerabilities. ○ **Resolved Risk**: displays the numbers of high-risk vulnerabilities, medium-risk vulnerabilities, and low-risk vulnerabilities, and the total number of these vulnerabilities for the current day. These vulnerabilities are fixed. The **Resolved Risk Distribution** section on the right displays the distribution of fixed vulnerabilities.

Section	Description
Asset Risk Top 5	View the top 5 assets that are at risk on the **Security Vulnerabilities** and **Host Compliance** tabs. These assets are displayed by asset or group.
Risk Monitoring Trend	View the trend charts of vulnerabilities on the **Security Vulnerabilities** and **Host Compliance** tabs. Fixed and unfixed vulnerabilities are identified by lines in different colors. You can move the pointer over a line to view the numbers of unfixed vulnerabilities and fixed vulnerabilities for the specific day.
Asset Monitoring Trend	View the trends in the numbers of protected hosts and websites. Hosts and websites are identified by lines in different colors. You can move the pointer over a line to view the number of protected hosts and websites for the specific day.
Risk Asset Ranking List	View the rankings of assets that are at risk on the **Latest Risk** and **High Risk** tabs.
Port Service Statistics	View the statistics on the **Port** and **Host Service** tabs.

27.1.4.8.3. Asset management

27.1.4.8.3.1. View the results of asset analysis

This topic describes how to view the analysis results of websites and hosts.

Context

The asset analysis feature allows you to view the analysis results of websites and hosts. For the websites, you can view Web Service, Open Source Framework, and Device Type. For the hosts, you can view Host Port, Host Service, and Operation System.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Asset > Asset Analysis**.
3. View websites.
4. View hosts.

27.1.4.8.3.2. Import assets

This topic describes how to import Internet assets.

Context

The vulnerability scan feature works only on imported assets. If you want to scan the vulnerabilities of your assets, you must import your assets.

The assets that the feature supports include Internet assets and internal assets. The internal assets refer to the assets in a virtual private cloud (VPC).

- To import internal assets, you must add a scan engine. For more information, see Configure a scan engine for internal assets.

- To import Internet assets, see this topic.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Asset > Asset Import**.
3. View imported assets.
4. Click **Asset Import** to create an asset import task.
   - To import internal assets, you must add a scan engine. For more information, see Configure a scan engine for internal assets.
   - To import Internet assets, perform the following steps. Elastic IP Address (EIP) assets and Server Load Balancer (SLB) assets are automatically imported, and monitored.
     i. Choose **Internet Assets > Internet Assets**.
     ii. In the **Import Asset** section, select **Manual Import** and enter the required assets in the field. Then, read and select the disclaimer.
     - You can enter domain names, URLs, IP addresses, and CIDR blocks.
     - You can enter multiple assets at a time. Press Enter each time you enter an asset.
     - You cannot enter the assets in VPCs.
     - The number of imported assets must be less than the number of remaining assets supported by the platform.

     > **Note** For example, if the number of remaining assets supported by the platform is 100 and 90 assets are entered, all the assets can be scanned. If 110 assets are entered, only 100 assets can be scanned, and the 10 assets that remain cannot be scanned.

     iii. In the **Asset Info** section, select a group for the imported assets and configure an owner and a tag for the assets.
     - **Asset Group**: Select a group from the drop-down list. You can click the icon to create, edit, or delete a group.
     - **Person in charge**: Select an owner from the drop-down list. You can click the icon to create, edit, or delete an owner.
     - **Asset Tag**: Click **Add Tag** to add a tag to the imported assets.

iv. In the **Import Set** section, select the operations that you want to perform after the assets are imported.

Operation		Description
Asset Discovery	*Auto Import Subdomains*	Automatically queries the subdomain assets of the imported domain names.
	Auto import associated IP	Automatically adds IP addresses that are mapped to the domain names.
	Auto synchronize tags and groups	Applies the group and tag of the imported assets to the assets that are discovered by the system.
Web Asset	*Open WEB Monitoring*	Allows you to enable the web monitoring feature on the imported website assets. If you want to select the web monitoring rules to use, click the icon. In the dialog box that appears, select the required web monitoring rules. For more information about how to configure web monitoring rules, see Configure web monitoring.

v. In the **Whitelist** section, add the assets that do not need to be scanned.

You can enter IP addresses and URLs. If you add more than one asset, you must press Enter each time you enter an asset.

vi. Click **Save**.

5. Manage the new asset import task.

After the asset import task is created, you can view the task in the task list. You can also perform the following operations on the new asset import task.

Icon	Description
	Allows you to view the details, results, and import process of the asset import task.
 or 	Allows you to enable or disable the asset import task.
	Allows you to delete the asset import task.

27.1.4.8.3.3. Manage assets

This topic describes how to view and manage assets.

Context

You can view the information about assets in the asset list. If the purpose or owner of an asset changes, security administrators can move the asset to another group or change the owner.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Asset > Asset List**.
3. View the asset list.

4. Click the **Web Asset** tab and manage websites.
   i. Specify filter conditions to search for specific websites.

      The filter feature allows you to search for the required websites in a more efficient manner.

Filter condition	Description
VPC	The asset type, such as Internet assets or a specific virtual private cloud (VPC).
Asset Source	The source from which the asset is imported. Valid values: **Manual** and **System Find**.
Asset Group	The group to which the asset belongs.
Web Status	The status of the website.
Person in charge	The owner of the website.
Asset Change	The change status of the asset. Valid values: **All**, **New**, **Update**, **No Update**, and **Offline**.
Web Monitoring	The monitoring status of the website.
Risk Level	The risk level of the asset.
Web Service	The service type and version of the website.
WAF Recognition	Specifies whether the asset is identified by WAF.
Open Source Framework	The open source framework type of the asset.
Device Type	The type of the device.
Time Range	The time range during which assets are imported.
Key Information	The crucial information of the asset. The crucial information includes the website, domain name, IP address, title, and tag.

   ii. Click **Export** to export the websites to an Excel file.

   iii. Select multiple websites to manage them.

Action	Description
Batch Web Monitoring	Allows you to enable or disable web monitoring for multiple websites. ■ **Batch Open Monitoring**: To enable web monitoring for multiple websites, select Batch Open Monitoring from the drop-down list of Batch Web Monitoring. ■ **Batch Stop Monitoring**: To disable web monitoring for multiple websites, select Batch Stop Monitoring from the drop-down list of Batch Web Monitoring
Change Group	Allows you to change the asset group of multiple assets at a time.
Change Person in charge	Allows you to change the owner of multiple assets at a time.
Batch Delete	Allows you to delete multiple assets at a time. After assets are deleted, Apsara Stack Security does not scan the assets.

iv. Manage a single website.

Find the website and perform operations allowed in the **Operation** column.

5. Click the **Host Asset** tab and manage the hosts.

i. Specify filter conditions to search for specific hosts.

The filter feature allows you to search for the required hosts in a more efficient manner.

Filter condition	Description
VPC	The asset type, such as Internet assets or a specific VPC.
Asset Source	The source from which the asset is imported. Valid values: **Manual** and **System Find**.
Asset Groups	The group to which the asset belongs.
Person in charge	The owner of the asset.
Asset Change	The change status of the asset. Valid values: **All**, **New**, **Update**, **No Update**, and **Offline**.
Risk Level	The risk level of the asset. Valid values: **All**, **High**, **Middle**, **Low**, and **Security**.
SurviveStatus	The status of the asset. Valid values: **Alive** and **Close**.
Operation System	The operating system of the host.
Host Port	The port of the host.
CDN Recognition	Specifies whether Content Delivery Network (CDN) is configured for the asset.
Host Service	The service of the host.
Time Range	The time range during which assets are imported.
Key Information	The crucial information of the asset. The crucial information includes the IP address, host, tag, and domain name.

ii. Click **Export** to export the hosts to an Excel file.

iii. Select multiple hosts to manage them.

Action	Description
Change Group	Allows you to change the asset group of multiple assets at a time.
Change Person in charge	Allows you to change the owner of multiple assets at a time.
Delete	Allows you to delete multiple assets at a time. After assets are deleted, Apsara Stack Security does not scan the assets.

iv. Manage a single host.

Find the host and perform operations allowed in the **Operation** column.

27.1.4.8.3.4. Manage asset availability

This topic describes how to manage the availability of assets.

Context

If hosts or websites are used for a long period of time, they may become unavailable due to errors. Availability monitoring allows security administrators to discover unavailable assets. Then, the security administrators can troubleshoot the issues that cause the assets to become unavailable.

Availability monitoring supports the following methods:

- HTTP monitoring: This method is used to monitor websites.
- PING monitoring: This method is used to monitor hosts.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Asset > Availability Monitoring**.
3. View availability monitoring tasks.
4. Create an availability monitoring task.

   Availability monitoring supports HTTP monitoring and PING monitoring.

   - To create an HTTP monitoring task, perform the following steps:
     a. Click **Add Monitoring**.
     b. Click the **HTTP Monitoring** tab.
     c. Configure the following parameters.

Parameter	Description
Monitoring Name	The name of the availability monitoring task.
Monitoring Target	The website that you want to monitor.
Monitoring Frequency	The interval at which you want to monitor the website. Valid values: **1 Minute**, **5 Minute**, **15 Minute**, and **30 Minute**.
Request Method	The request method that is used to send HTTP request packets. Valid values: **HEAD**, **GET**, **POST**, and **PUT**.
Alert Setting	The policy based on which Apsara Stack Security reports alerts. If one of the following conditions is met, the website is unavailable: ■ Response Time: If the actual response time is greater than the specified value, an exception occurs. ■ Response Status: If an unexpected status code is returned, an exception occurs.

     d. Click **Save**.
   - To create a PING monitoring task, perform the following steps:
     a. Click **Add Monitoring**.
     b. Click the **PING Monitoring** tab.

c. Configure the following parameters.

Parameter	Description
Monitoring Name	The name of the availability monitoring task.
Monitoring Target	The host that you want to monitor.
Monitoring Frequency	The interval at which you want to monitor the host. Valid values: **1 Minute**, **5 Minute**, **15 Minute**, and **30 Minute**.
Alert Setting	The policy based on which Apsara Stack Security reports alerts. If one of the following conditions is met, the host is unavailable: ■ Response Time: If the actual response time is greater than the specified value, an exception occurs. ■ Response Status: If an unexpected status code is returned, an exception occurs.

d. Click **Save**.

5. Manage multiple availability monitoring tasks at a time.

   You can manage multiple availability monitoring tasks in the monitoring task list at a time.

   - Start multiple availability monitoring tasks at a time

     Select multiple availability monitoring tasks and choose **Batch Monitoring Manage > Batch Open Monitoring**.

   - Stop multiple availability monitoring tasks at a time

     Select multiple availability monitoring tasks and choose **Batch Monitoring Manage > Batch Stop Monitoring**.

   - Delete multiple availability monitoring tasks at a time

     Select multiple availability monitoring tasks and choose **Batch Monitoring Manage > Batch Delete Monitoring**.

27.1.4.8.3.5. Manage custom update detection tasks

This topic describes how to manage custom update detection tasks.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Asset > Custom Update Detection**.
3. View custom update detection tasks.
4. Create a custom update detection task.
   i. Click **Add Detection**.
   ii. On the **Add Custom Update Detection** page, configure the following parameters.
   iii. Click **Save**.

27.1.4.8.4. Risk management

27.1.4.8.4.1. Manage security vulnerabilities

This topic describes how to view and handle security vulnerabilities detected by the vulnerability scan feature.

Context

On the **Security Vulnerability** page, security administrators can view the security vulnerabilities detected by the vulnerability scan feature.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Risk > Security Vulnerability**.
3. View security vulnerabilities.
   - Click the **Disclosured** or **Resolved** tab to view **unfixed vulnerabilities** or **fixed vulnerabilities**.
   - View risk statistics. The statistics cover **Unfixed Risks**, **Recovered Risks**, **Unconfirmed Risks**, **Confirmed Risks**, and **Ignored Risks**.
4. Specify search conditions to view specific security vulnerabilities. The conditions include the **VPC** and **Risk Level** parameters.
5. Handle security vulnerabilities.

   Security administrators can analyze and confirm whether security vulnerabilities affect the security of assets based on the vulnerability information.
   - Confirm risks

     If a vulnerability affects the security of assets, confirm the risk after the security vulnerability is fixed.

     a. Find the vulnerability and click the  icon in the **Actions** column.

     b. In the drop-down list, select **Confirm Risk**.

     c. In the dialog box that appears, click **OK**.
   - Ignore risks

     If a vulnerability is a false positive or does not affect the security of assets, ignore the risk.

     a. Find the vulnerability and click the  icon in the **Actions** column.

     b. In the drop-down list, select **Ignore Risk**.

     c. In the dialog box that appears, click **OK**.
6. Click **Export** to export the security vulnerabilities to your local computer.

27.1.4.8.4.2. Manage host compliance risks

This topic describes how to view and confirm host compliance risks.

Context

On the **Host Compliance** tab, security administrators can view the host compliance issues that are detected by the vulnerability scan feature.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Risk**. On the page that appears, click the **Host Compliance** tab.
3. View host compliance risks.

You can click the **Disclosured** and **Resolved** tabs to view **unfixed risks** and **fixed risks**.

4. Specify search conditions to search for host compliance risks. The conditions include the **VPC** and **Risk Level** parameters.
5. Handle host compliance risks.

   Security administrators can analyze and confirm whether host compliance risks affect the security of assets based on the risk information.

   - Confirm risks

     If a host compliance risk affects the security of assets, harden the security of hosts and confirm the risk.

     a. Find the vulnerability and click the icon in the **Operation** column.

     b. In the drop-down list, select **Confirm Risk**.

     c. In the dialog box that appears, click **OK**.

   - Ignore risks

     If a host compliance risk proves to be a false positive or does not affect the security of assets, ignore the risk.

     a. Find the vulnerability and click the icon in the **Operation** column.

     b. In the drop-down list, select **Ignore Risk**.

     c. In the dialog box that appears, click **OK**.
6. Click **Export** to export the host compliance risks to your local computer.

27.1.4.8.4.3. Manage external risks

This topic describes how to view and identify external risks, such as code leaks.

Prerequisites

A GitHub account is available, and the tokens of the account are obtained.

Context

On the **External Risk** page, security administrators can use the vulnerability scan feature to check whether the GitHub library has risks of code leaks.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Risk > External Risk**.
3. Click the **Code Disclosure** tab.
4. Add the assets that you want to monitor.

   i. In the **Asset Monitoring List** section, click **Token setting**.

   ii. In the **Enter GitHub Token** dialog box, enter the tokens.

   You can enter multiple tokens. Press Enter each time you enter a token.

   iii. Click **Add Asset** and select the external assets that you want to monitor.
5. View the assets that have risks of code leaks.

   You can view the unfixed and fixed risks on the **Resolved** and **Disclosured** tabs.
6. Handle the risks of code leaks.

   Security administrators can analyze and check whether the security of the assets is affected based on the risk

information.

- Confirm risks

  If the risks of code leaks affect the security of your assets, harden the hosts and confirm the risks.

- Ignore risks

  If the risks of code leaks prove to be false positives or do not affect the security of your assets, ignore the risks.

27.1.4.8.4.4. Create a custom risk detection task

This topic describes how to create a custom risk detection task.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Risk > Custom Risk Detection**.
3. Click **Add Detection**.
4. On the **Add Custom Risk Detection** page, configure the following parameters.

Parameter	Description
Detection Name	The name of the custom risk detection task.
Detection Target	The asset on which you want to perform risk detection. Valid values: **Private network asset** and **Public network asset**.
Emergency Detection	The switch that is used to enable or disable the emergency detection feature. If you enable this feature, you can select emergency detection items from the detection item list.
Basic Risk Detection	The switch that is used to enable or disable the basic risk detection feature. For more information about how to configure this feature, see Configure basic monitoring.
WEB Risk Detection	The switch that is used to enable or disable the web risk detection feature. For more information about how to configure this feature, seeConfigure web monitoring.

5. Click **Save**.

27.1.4.8.5. Report management

27.1.4.8.5.1. Create a report

This topic describes how to create a report.

Context

A security administrator can create a report to view the security statuses of specific assets during a period of time and implement security measures as required.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Report**.
3. Click **Risk Report**.
4. Click **Add Report**.
5. Configure the following parameters.
6. Click **Create**.

Result

After the report is created, it appears in the report list on the **Report** page.

27.1.4.8.5.2. Delete multiple reports at a time

This topic describes how to delete multiple reports at a time.

Context

You can delete multiple reports that are no longer required at a time to save storage space.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Report**.
3. Click **Risk Report**.
4. In the report list, select the reports that you want to delete.
5. Click **Batch Delete**.

27.1.4.8.6. Configuration management

27.1.4.8.6.1. Configure overall monitoring

This topic describes how to configure overall monitoring for the vulnerability scan feature. Overall monitoring includes Asset Monitoring Configuration, Base Risk Monitoring Configuration, External Risk Monitoring Configuration, and Scan Configuration.

Context

Overall monitoring allows you to configure detection features and the monitoring cycle for each detection feature.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Configuration > Monitoring Configuration > Overall Monitoring**.
3. In the **Monitoring Status** section, view the status of overall monitoring.
4. Configure detection features.

   Detection features include **Asset Monitoring Configuration**, **Base Risk Monitoring Configuration**, **External Risk Monitoring Configuration**, and **Scan Configuration**.

   In this step, the **Asset Monitoring Configuration** detection feature is used as an example.

i. Turn on Asset Monitoring Configuration to enable the asset monitoring feature.
   - After the switch is turned on, the switch is in the **On** state. When in the On state, the switch is blue. After the switch is turned off, the switch is in the **Off** state. When in the Off state, the switch is gray.
   - You must turn on **Asset Monitoring Configuration** and **Base Risk Monitoring Configuration** to enable the two features. External Risk Monitoring Configuration and Scan Configuration are automatically enabled.

ii. Configure the following parameters.

Asset Monitoring Configuration

Parameter	Description
Monitoring Item	The item that you want to monitor. Valid value: **Subdomain Discovery**. If you want to import assets, you can set the Import Set parameter to **Auto Import subdomains**. Then, subdomains are automatically imported. If you select **Subdomain Discovery**, Apsara Stack Security regularly discovers subdomains for assets whose Import Set parameter is set to **Auto Import subdomains**.
Monitoring Cycle	The cycle based on which you want to perform detection. Valid values: **customization**, **per week**, and **per month**. ■ **customization**: Specify the interval at which you want to perform detection. Unit: days. ■ **per week**: Specify the days of each week on which you want to perform detection. ■ **per month**: Specify the days of each month on which you want to perform detection.
Detection Time	The time when you want to perform detection. The time varies based on the value of the **Monitoring Cycle** parameter. ■ If you set the **Monitoring Cycle** parameter to **customization**, select a time range of the day in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **per week**, select the days of each week and the time range in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **per month**, select the days of each month and the time range in which you want to perform detection. **Note** For example, if you set the **Monitoring Cycle** parameter to **per week** and select **Monday** to **Sunday** and 00:00:00 to 24:00:00 for the **Detection Time** parameter, Apsara Stack Security performs detection 24 hours a day, 7 days a week.
Port Range	The ports on which you want to perform detection. Valid values: **customization**, **Full port**, **TOP100**, and **TOP1000**. ■ **customization**: Specify the ports to scan. ■ **Full port**: Scan all ports. ■ **TOP100**: Scan top 100 ports. You can click **Add** to add more ports. ■ **TOP1000**: Scan top 1,000 ports. You can click **Add** to add more ports.

Parameter	Description
Host Alive Detection Settings	The option that is used to check whether a host is running. By default, the ping feature is used to check whether a host is running. If the host has the ping feature disabled, the status of the host is detected based on top 20 ports and custom ports. To specify custom ports, click **Settings**. In the Host Alive Detection Settings dialog box, specify the ports in the **Custom Port** field.

Base Risk Monitoring Configuration

Parameter	Description
Monitoring Item	The item that you want to monitor. Valid values: **Weak Password**, **Common Vulnerabilities**, **Baseline Monitoring**, and **Host Compliance**. ■ **Weak Password**: Attackers can guess passwords or launch brute-force attacks to crack passwords. Then, the attackers can obtain relevant permissions. If you select this item, weak password vulnerabilities can be identified. ■ **Common Vulnerabilities**: Web security vulnerabilities and CMS application vulnerabilities are included. If you select this item, common vulnerabilities can be identified. Then, you can install patches at the earliest opportunity. ■ **Baseline Monitoring**: Risks in host configuration and account configuration are detected. ■ **Host Compliance**: Host compliance risks are detected.
Monitoring Cycle	The cycle based on which you want to perform detection. Valid values: **customization**, **per week**, and **per month**. ■ **customization**: Specify the interval at which you want to perform detection. Unit: days. ■ **per week**: Specify the days of each week on which you want to perform detection. ■ **per month**: Specify the days of each month on which you want to perform detection.
Detection Time	The time when you want to perform detection. The time varies based on the value of the **Monitoring Cycle** parameter. ■ If you set the **Monitoring Cycle** parameter to **customization**, select a time range of the day in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **per week**, select the days of each week and the time range in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **per month**, select the days of each month and the time range in which you want to perform detection. **Note** For example, if you set the **Monitoring Cycle** parameter to **per week** and select **Monday** to **Sunday** and 00:00:00 to 24:00:00 for the **Detection Time** parameter, Apsara Stack Security performs detection 24 hours a day, 7 days a week.

External Risk Monitoring Configuration

Parameter	Description
Monitoring Item	The item that you want to monitor. Valid value: **Code Disclosure**. If you select Code Disclosure, Apsara Stack Security detects leaked source code of your assets.
Monitoring Cycle	The cycle based on which you want to perform detection. Valid values: **customization**, **per week**, and **per month**. ■ **customization**: Specify the interval at which you want to perform detection. Unit: days. ■ **per week**: Specify the days of each week on which you want to perform detection. ■ **per month**: Specify the days of each month on which you want to perform detection.
Detection Time	The time when you want to perform detection. The time varies based on the value of the **Monitoring Cycle** parameter. ■ If you set the **Monitoring Cycle** parameter to **customization**, select a time range of the day in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **per week**, select the days of each week and the time range in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **per month**, select the days of each month and the time range in which you want to perform detection. Note For example, if you set the **Monitoring Cycle** parameter to **per week** and select **Monday** to **Sunday** and 00:00:00 to 24:00:00 for the **Detection Time** parameter, Apsara Stack Security performs detection 24 hours a day, 7 days a week.

Scan Configuration

Parameter	Description
Risk Re-detection	The time at which you want to perform detection again. If risks are detected in specific assets, Apsara Stack Security scans the assets again each day at the time you specify.
Asset Scanning Rate	The scan rate. Valid values: **Slow Mode**, **General Mode**, **Fast Mode**, and **Turbo Mode**.
Risk Scanning Rate	The scan rate. Valid values: **Slow Mode**, **General Mode**, **Fast Mode**, and **Turbo Mode**.
UserAgent Setting	The User-Agent property.

iii. Click **Save**.

27.1.4.8.6.2. Configure basic monitoring

This topic describes how to configure basic monitoring.

Context

Basic monitoring includes Weak Password Vulnerability Monitoring, Operation Security Vulnerability Monitoring, CMS Application Vulnerability Monitoring, and Baseline Monitoring.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Configuration**. On the page that appears, click the **Monitoring Configuration** tab. Then, click the **Basic Monitoring** tab.
3. Click **Weak Password Vulnerability Monitoring** and configure rules to monitor weak password vulnerabilities.
   - By default, all monitoring items use the default weak password library.
   - To disable a monitoring item, perform the following step:

     Find the monitoring item that you want to disable and click the icon in the **Operation** column.
   - To enable a monitoring item, perform the following step:

     Find the monitoring item that you want to enable and click the icon in the **Operation** column.
   - To customize weak passwords for a monitoring item, perform the following steps. In this example, **MySQL Weak Password Vulnerability** is used.
     a. In the **Default Weak Password** column, turn off the switch. The switch status changes to .
     b. In the **Operation** column, click the icon.
     c. In the **Customize MySQL Weak Password** dialog box, customize weak passwords.
     d. Click **Yes**.
   - To apply the same custom weak passwords to multiple monitoring items, perform the following steps:
     a. In the **Default Weak Password** column, turn off the switches for the monitoring items that you want to apply the same custom weak passwords. The switch status changes to .

     > **Note** If you want to apply a custom weak password to a monitoring item, you must turn off the switch in the Default Weak Password column of the monitoring item.

     b. Click **Tailored Overall Weak Password**.
     c. In the **Tailored Overall Weak Password** dialog box, customize weak passwords.
     d. Click **Yes**.
4. Click **Operation Security Vulnerability Monitoring** and configure operations and maintenance (O&M) security vulnerability monitoring.

No.	Description
1	The switch that is used to enable or disable the **Operation Security Vulnerability Monitoring** feature. We recommend that you enable this feature to improve system security.
2	The switch that is used to enable or disable a monitoring item. You can disable monitoring items based on your business requirements.

5. Click **CMS Application Vulnerability Monitoring** and configure content management system (CMS) application vulnerability monitoring.

No.	Description
1	The switch that is used to enable or disable the **CMS Application Vulnerability Monitoring** feature. We recommend that you enable this feature to improve system security.
2	The switch that is used to enable or disable a monitoring item. You can disable monitoring items based on your business requirements.

6. Click **Baseline Monitoring** and configure baseline monitoring.

   To add a baseline monitoring item, perform the following steps:

   i. Click **Add**.

   ii. In the **Add Baseline** dialog box, configure the baseline monitoring item.

   In this example, a baseline monitoring item is added to block Telnet-based access.

Parameter	Description
Baseline Name	The name of the baseline monitoring item. Example: Block Telnet-based access.
Baseline Rule	The detection rule that is used by the baseline monitoring item. This rule checks whether hosts use disabled ports or run disabled services. Valid values: ■ **Port Disabled**: ports that you want to disable. Example, 23. ■ **Service Disabled**: services that you want to disable. Example: Telnet.
Baseline Range	The scope of assets to which the baseline monitoring item can be applied. Valid values: **Private IP** and **NatIP**. You must configure this parameter and select specific assets.

   iii. Click **Yes**.

27.1.4.8.6.3. Configure web monitoring

This topic describes how to configure web monitoring.

Context

Web monitoring allows you to configure monitoring items for monitoring web vulnerabilities. You can also configure conditions to block website crawlers.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Configuration**. On the page that appears, click the **Monitoring Configuration** tab and then the **Web Monitoring** tab.
3. View existing rules.

   > **Note** **Default rules** are created by the system. You can only view details of the default rules, but cannot modify or delete them.

4. Create a web monitoring rule.

   i. Click **Add Rule**.

ii. On the **Add Web Monitoring Rule** page, configure the following parameters.

Parameter	Description
Rule Name	The name of the web monitoring rule.
Monitoring Cycle	The monitoring cycle. Valid values: **Customization**, **Per Week**, and **Per Month**. ■ **Customization**: Specify the interval at which you want to perform detection. ■ **Per Week**: Specify the days of each week on which you want to perform detection. ■ **Per Month**: Specify the days of each month on which you want to perform detection.
Detection Time	The detection time varies based on the value of the **Monitoring Cycle** parameter. ■ If you set the **Monitoring Cycle** parameter to **Customization**, select the time range of the day in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **Per Week**, select the days of each week and the time range in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **Per Month**, select the days of each month and the time range in which you want to perform detection. **Note** For example, if you set the **Monitoring Cycle** parameter to **Per Week** and select **Monday** to **Sunday** and 00:00:00 to 24:00:00 for the **Detection Time** parameter, Apsara Stack Security performs detection 24 hours a day, 7 days a week.
Monitoring Options	The type of web vulnerabilities that you want to monitor. Supported operations: **Select All**, **Inverse**, and **Clear**.
UserAgent	The User-Agent field of the HTTP request packet. The User-Agent field identifies the application type, operating system, software developer, and version number of the proxy software that initiates requests.
Cookies	The cookie parameters.
Key Page	The web directories or pages that you want to monitor.
Excluded Page	The web directories or pages that you do not want to monitor.
Crawler Depth	The capturing depth of crawlers. Valid values: **10**, **15**, and **30**.
URL Numbers	The number of URLs that are used for crawling. Valid values: **500**, **1000**, and **2000**.
Scanning Frequency	The scan frequency of web monitoring. Valid values: **Request 10 Times Per Second** and **Request 15 Times Per Second**.

iii. Click **Yes**.

5. Manage the web monitoring rule.

Icon	Description
	Modify the rule.
	Delete the rule.
Batch Delete	If you want to delete multiple rules, select the rules you want to delete and click **Batch Delete**.

27.1.4.8.6.4. Configure a whitelist

This topic describes how to configure a whitelist.

Context

Apsara Stack Security does not scan the assets that are added to a whitelist. Before you add assets to a whitelist, make sure that the assets are secure.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Configuration**. On the page that appears, click the **Monitoring Configuration** tab. Then, click the **Whitelist** tab.
3. View the whitelists.

   > **Note** By default, the whitelist feature is enabled. If you do not want to use the whitelist feature, turn off the switch in the upper-right corner.

4. Create a whitelist.
   i. Click **Add**.
   ii. In the **Add Whitelist** dialog box, configure the following parameters.
   - If you select **Asset Group** for the **Whitelist** parameter, select a group from the second drop-down list. The assets in this group are added to the whitelist.
   - If you select **Customization** for the **Whitelist** parameter, enter the IP addresses or URLs that you want to add to the whitelist in the field that appears.

   iii. Click **Yes**.
5. Manage whitelists.
   - Delete a whitelist

     Find a whitelist and click the  icon in the **Operation** column.

   - Delete multiple whitelists at a time

     Select multiple whitelists and click **Batch Delete**.

27.1.4.8.6.5. Configure a scan engine for internal assets

This topic describes how to configure a scan engine for internal assets, such as the assets of a virtual private cloud (VPC).

Context

You must add a scan engine for a VPC before you can scan for vulnerabilities on the assets of the VPC.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Configuration**. On the page that appears, click the **Scan Engine Manage** tab. Then, click the **Private-sector assets** tab.
3. Click the name of the VPC whose assets you want to scan.
4. Click **Add Scan Engine**.
5. In the **Add Scan Engine** dialog box, select a vSwitch for the VPC from the **vSwitch** drop-down list.
6. Click **OK**.

27.1.4.9. Create a security report

Security reports help monitor the security status of your assets. You can specify the content, types of statistics, and email addresses of recipients to create a security report. This topic describes how to create a security report.

Procedure

1.
2. In the left-side navigation pane, choose **Threat Detection > Security Reports**.
3. On the **Reports** page, click **Create Report**.

   > **Notice** In addition to the default security report created by Apsara Stack Security, you can create a maximum of nine security reports.

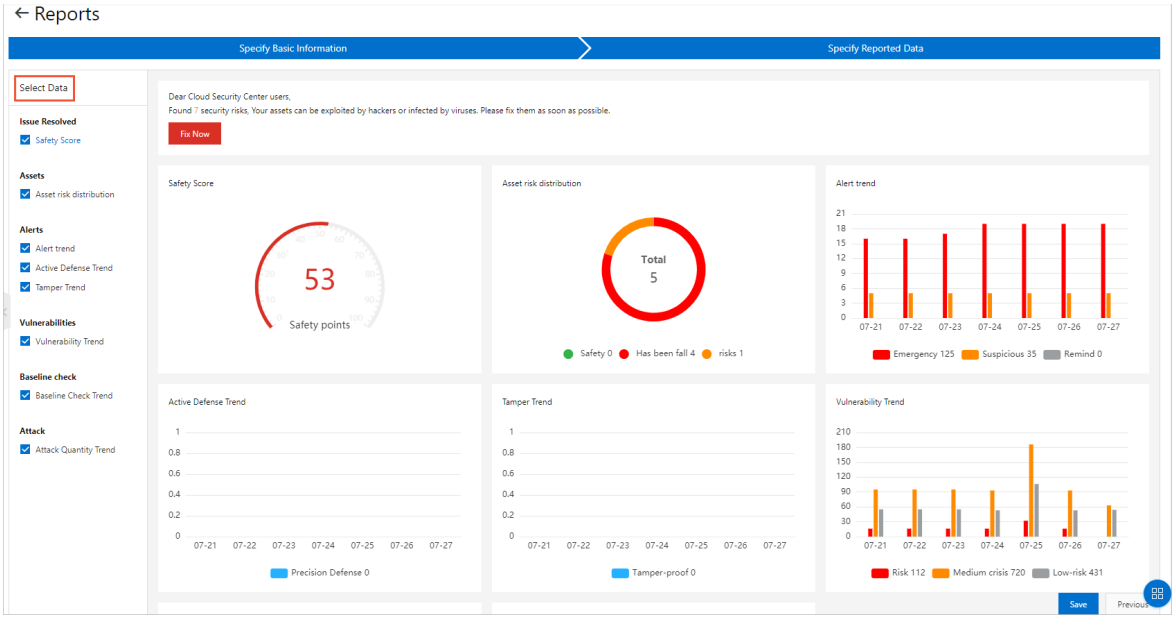
4. In the **Specify Basic Information** step, configure the parameters.

   Configure the following parameters:

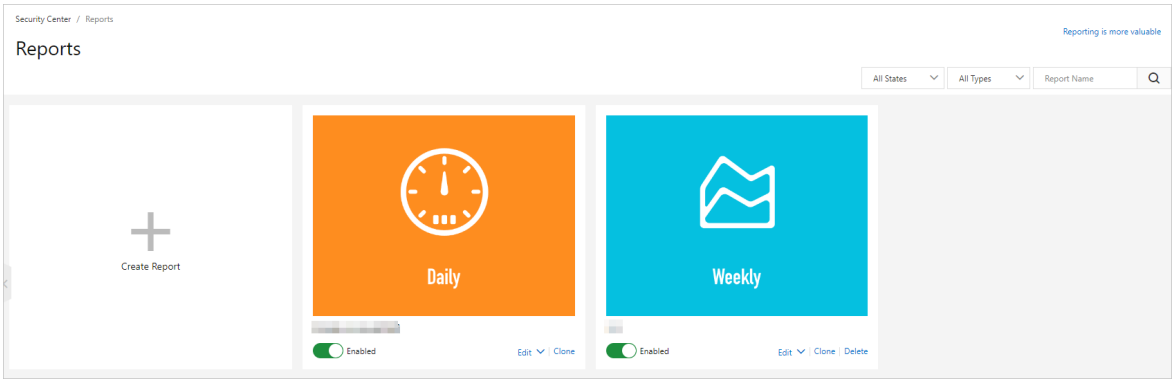
   - **Report Name**: Enter a name for the security report.
   - **Report Type**: Select a report type from the drop-down list. Valid values: *Daily*, *Weekly*, *Monthly*, and *Custom*.

     If you select *Custom*, you must also set the **Data Collection Period** parameter to specify the cycle on which data is collected.

5. Click **Next**.
6. In the **Specify Reported Data** step, select the types of data that you want to view in the security report. You can select assets, alerts, vulnerabilities, baselines, attacks, and other data related to security operations.



7. Click **Save**.
   You can view the newly created security report on the **Reports** page.



27.1.5. Network Traffic Monitoring System

27.1.5.1. View traffic trends

This topic describes how to view the network traffic trends, inbound traffic statistics, and outbound traffic statistics.

Context

By analyzing traffic trends, the security administrator can obtain the throughput and the peaks and troughs of traffic periods. In addition, the security administrator can block traffic from malicious IP addresses by viewing the top five IP addresses with the most traffic.

Procedure

1.
2. In the left-side navigation pane, choose **Network Security > Traffic Analysis > Traffic Trend**.
3. In the upper-right corner of the **Traffic Trends** page, select the time range, which can be **Last 1 Hour**, **Last 24 Hours**, or **Last 7 Days**.
4. View network traffic information.
   - Network traffic trends

View the network traffic trends from the selected time range. The network traffic trends include inbound and outbound traffic measured in bit/s.

- Inbound Traffic

  View the information of Inbound Sessions, Inbound Applications, and Destination IPs with Most Requests.

- Outbound Traffic

  View the information of Outbound Sessions, Outbound Applications, and Source IPs with Most Requests.

5. (Optional)Click the icon to export traffic trends as a PDF file.

27.1.5.2. View traffic at the Internet border

This topic describes how to view traffic at the Internet border. You can obtain up-to-date information about network security.

Prerequisites

The Network Traffic Monitoring System module is purchased and deployed at the egress (ISW) of Apsara Stack. **This module audits, analyzes, and manages both inbound and outbound traffic at Internet borders.**

Context

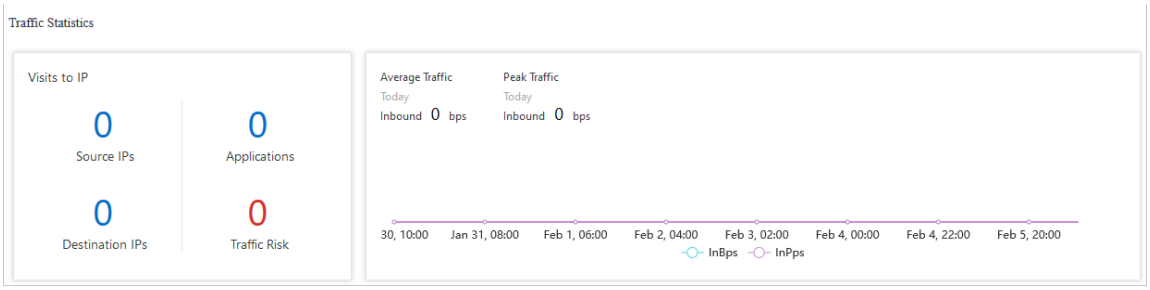
You can use traffic information to identify abnormal Internet traffic and block malicious traffic.

Procedure

1.
2. In the left-side navigation pane, choose **Network Security > Traffic Analysis > Internet Border**.
3. Specify traffic filter conditions.

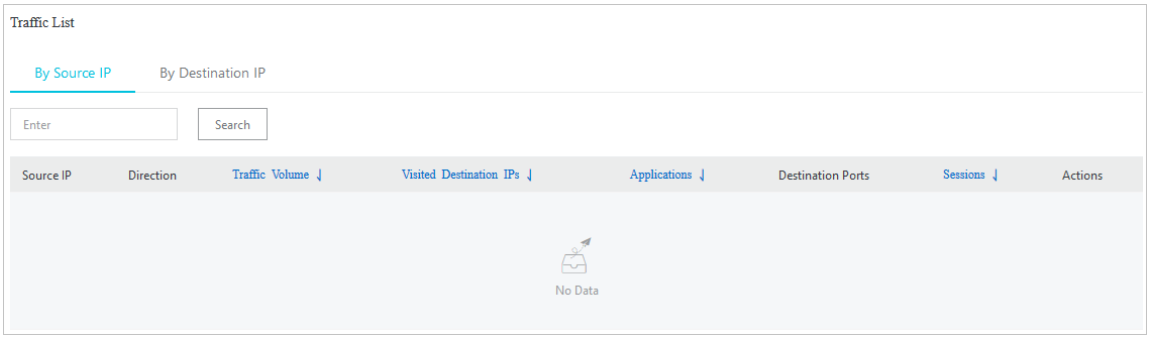
Item	Description
1	Specify the traffic direction. Valid values: *Inbound* and *Outbound*. ○ *Inbound*: The traffic flows from the Internet to the internal network. ○ *Outbound*: The traffic flows from the internal network to the Internet.
2	Specify whether you want to view the traffic from the IP address or application dimension. Valid values: *By IP* and *By Application*.
3	Specify the time range. Valid values: *Last 1 Hour*, *Last 24 Hours*, and *Last 7 Days*.

4. View details about the traffic at the Internet border.
   - **Traffic Statistics**



- The **Visits to IP** section includes **Source IPs**, **Destination IPs**, **Applications**, and **Traffic Risk**.
- In the traffic chart on the right, you can view **Average Traffic**, **Peak Traffic**, and traffic trends.

- **Traffic List**



In the **Traffic List** section, you can view traffic details.

5. In the **Traffic List** section, view abnormal traffic of the specified IP address.
   - If *Inbound* is specified, you can view abnormal traffic on the **By Destination IP** tab of the **Traffic List** section.
   - If *Outbound* is specified, you can view abnormal traffic in the **Traffic List** section.

27.1.5.3. View traffic at the internal network border

This topic describes how to view the traffic at the internal network border. You can obtain up-to-date information about network security based on the traffic.

Prerequisites

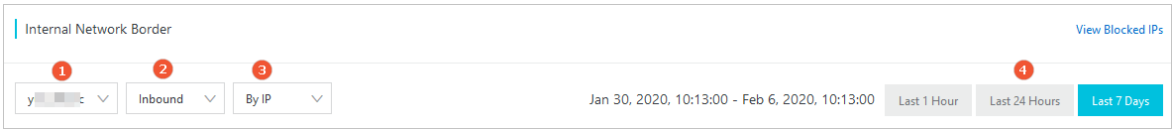
The Network Traffic Monitoring System module is purchased and deployed at the ingress (CSW) of Apsara Stack. **This module is used to audit, analyze, and control both inbound and outbound traffic routed over leased lines between on-premises data centers and virtual private clouds (VPCs).**

Context

You can use traffic information to identify suspicious traffic from the internal network and block malicious requests.

Procedure

1.
2. In the left-side navigation pane, choose **Network Security > Traffic Analysis > Internal Network Border**.
3. Specify traffic filter conditions.



Item	Description
1	Select a VPC name from the drop-down list.
2	Specify the traffic direction. Valid values: *Inbound* and *Outbound*. ○ *Inbound*: The traffic flows from the Internet to the internal network. ○ *Outbound*: The traffic flows from the internal network to the Internet.
3	Specify whether you want to view the traffic that flows through the internal network border from the IP address or application dimensions. Valid values: *By IP* and *By Application*.
4	Specify the time range. Valid values: *Last 1 Hour*, *Last 24 Hours*, and *Last 7 Days*.

4. View details about the traffic at the internal network border.
   - **Traffic Statistics**
     - The **Visits to IP** section includes **Source IPs**, **Destination IPs**, **Applications**, and **Traffic Risk**.
     - In the traffic chart on the right, you can view **Average Traffic**, **Peak Traffic**, and traffic trends.
   - **Traffic List**

     In the **Traffic List** section, you can view traffic details.

     If **By IP** is specified, you can view the suspicious traffic of the specified IP address in the **Traffic List** section.

27.1.5.4. Create packet capture tasks

This topic describes how to create a packet capture task. You can enable the packet capture feature to capture network data packets for specific IP addresses and ports and analyze the packets. This way, you can locate faults, analyze attacks, and identify security risks to network communications.

Procedure

1.
2. In the left-side navigation pane, choose **Network Security > Traffic Analysis > Packet Capture**.
3. On the **Packet Capture** page, click **Create Packet Capture Task**.
4. In the **Create Packet Capture Task** panel, configure parameters and click **OK**.

Parameter	Description
Task Name	The name of the packet capture task. We recommend that you enter an informative name, such as a name that indicates the purpose of the task.
Maximum Bytes	The maximum number of bytes in a packet that can be captured. If the number of bytes in a packet exceeds this value, the excessive bytes are discarded.
Duration (s)	The maximum duration for the packet capture task. Unit: seconds.

Parameter	Description
Protocol	The transmission protocol of packets. Valid values: ○ **All** ○ **TCP** ○ **UDP** ○ **ICMP**
IP Address Type	The IP protocol of packets. Valid values: IPV4 and IPV6.
Direction	The direction of packets. Valid values: **Bidirectional**, **In**, and **Out**.
IP	The IP address of packets.
Port	The port of packets.

Result

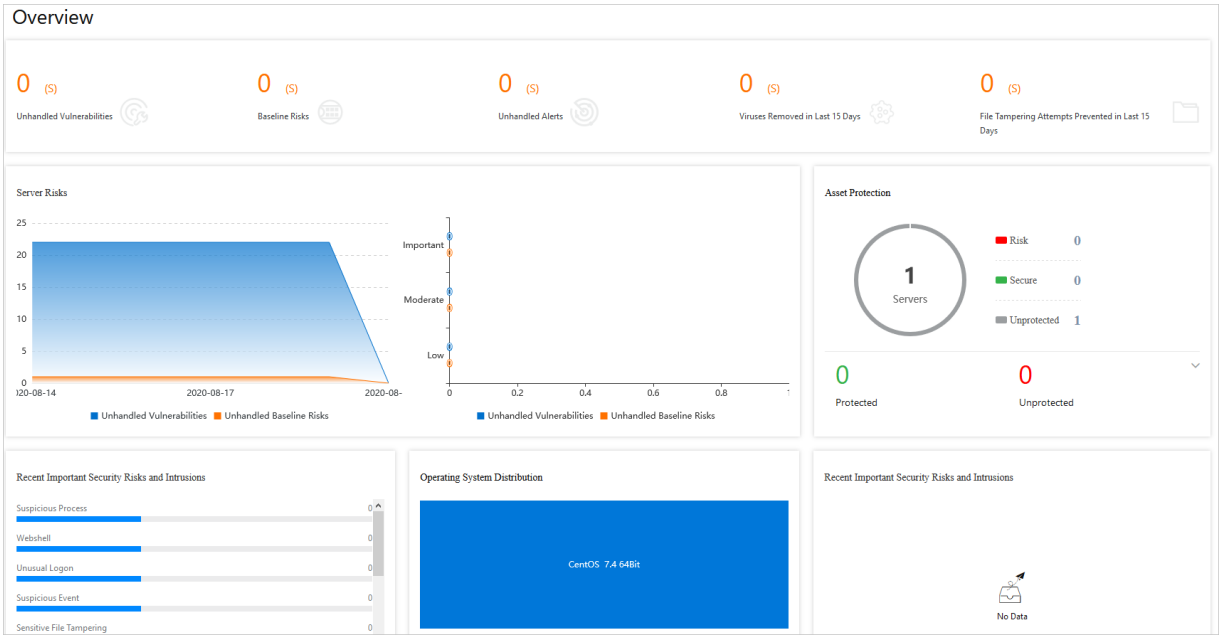
You can go to the **Packet Capture** page to view the newly created packet capture task and the task status.

27.1.6. Server security

27.1.6.1. Server security overview

The security administrator can view the current security status of all servers on the server security overview page of Apsara Stack Security Center.

In the left-side navigation pane, choose **Server Security > Overview**. On the page that appears, you can view detailed information in the Overview, Server Risks, Asset Protection, Operating System Distribution, and Recent Important Security Risks and Intrusions sections.



- **Overview**: This section displays the number of security vulnerabilities of each type (including **Unhandled Vulnerabilities** and **Baseline Risks**) and the number of security events of each type (including **Unhandled Alerts**, **Viruses Removed in Last 15 Days**, and **File Tampering Attempts Prevented in Last 15 Days**) on servers.

- **Server Risks**: This section displays the number of unhandled vulnerabilities, the number of baseline risks, and the distribution of risk levels.
- **Asset Protection**: This section displays the number of protected servers and the number of offline servers.
- **Recent Important Security Risks and Intrusions**: This section displays the recent important risks and events on your servers. You can click a risk or event to view the details.

27.1.6.2. Server fingerprints

27.1.6.2.1. Manage listener ports

This topic describes how to regularly collect information from listener ports on a server, and record and view the port changes and historical port information. This allows you to locate suspicious listening behavior.

Context

This task is suitable to the following scenarios:

- Check for servers that listen on a specific port.
- Check for ports that are open on a specific server.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Port** tab.
3. View **Port**, **Protocol**, and **Server**.

   You can search for a port by using its port number, process name, server name, or IP address.
4. Click a port number to view the details, such as the assets and protocol.

27.1.6.2.2. Manage software versions

This topic describes how to regularly collect software version information of a server and record the changes. This helps to check your software assets.

Context

This task is suitable to the following scenarios:

- Check for software assets that are installed without authorization.
- Check for software of outdated versions.
- Locate the affected assets when vulnerabilities are detected.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Software** tab.
3. View all software in use and the number of servers that use such software.

   You can search for a piece of software by using its software name, version, installation directory, server name, or IP address.
4. Click a software name to view the details, such as the assets and software version.

27.1.6.2.3. Manage processes

This topic describes how to regularly collect the process information on a server and record changes. This helps check for processes and view historical process changes.

Context

This task is suitable to the following scenarios:

- Checks for servers that run a specified process.
- Checks for processes that run on a server.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Process** tab.
3. View all running processes and the number of servers that run these processes.

   You can search for a process by using its **process name**, **running user**, **startup parameter**, or **server name or IP address**.
4. Click a process name to view the details, such as the assets, path, and startup parameters.

27.1.6.2.4. Manage account information

This topic describes how to regularly collect the account information on a server and record changes. This helps check for accounts and view historical account changes.

Context

This task is suitable to the following scenarios:

- Check for servers where the specified account is created.
- Check for accounts that are created on a server.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Account** tab.
3. View all logged-on accounts and the number of servers that use these accounts.

   You can search for an account by using its account name, root permissions, server name, or IP address.
4. Click an account name to view the details, such as the assets, root permissions, and user group.

27.1.6.2.5. Manage scheduled tasks

This topic describes how to regularly collect information of scheduled tasks on a server. This allows you to check your tasks.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Scheduled Tasks** tab.
3. View the paths of all tasks and the number of servers that run these tasks.

   You can search for a task by using its path, server name, or IP address.
4. Click a task path to view the details, such as the assets, executed command, and task cycle.

27.1.6.2.6. Set the server fingerprint collection frequency

You can set the frequency at which the data of running processes, system accounts, listening ports, and software versions is collected.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. In the upper-right corner of the page that appears, click **Settings**.
3. Select the collection frequency from each drop-down list.
4. Click **OK** to complete the configuration.

27.1.6.3. Threat protection

27.1.6.3.1. Vulnerability management

27.1.6.3.1.1. Manage Linux software vulnerabilities

This topic describes how to manage Linux software vulnerabilities.

Context

Apsara Stack Security automatically scans the software that are installed on your servers based on the vulnerabilities provided in the Common Vulnerabilities and Exposures (CVE) list. It also sends you alerts about the detected vulnerabilities. In addition, Apsara Stack Security provides commands that are used to fix vulnerabilities and allows you to verify these vulnerability fixes.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**. On the page that appears, click the **Linux Software** tab.
3. View the detected Linux vulnerabilities.

   > **Note** You can locate a vulnerability by using the search and filter functions.

4. Click a vulnerability to go to the vulnerability details page. You can view details about the vulnerability and affected assets on this page.

   > **Note** You can locate specific affected assets by using the search and filter functions.

   - **Basic Information**: the basic information of the vulnerability, including the name, Common Vulnerability Scoring System (CVSS) score, description, and resolution.
   - **Affected Assets**: the servers that are affected by the vulnerability.
5. Select an action based on the impact of the vulnerability.

   Actions on vulnerabilities

Option	Description
Generate Fix Command	Select this option to generate the commands that are used fix the vulnerability. You can then log on to the server to run these commands.

Option	Description
Fix Now	Select this option to fix the vulnerability.
Restarted and Verified	If a vulnerability fix takes effect only after a server reboot, you must reboot the server after the status of the vulnerability changes to **Fixed (To Be Restarted)**. After the reboot, click **Restarted and Verified**.
Ignore	Select this option to ignore a vulnerability. The system does not send you an alert about an ignored vulnerability.
Verify	Click **Verify** to verify the vulnerability fix. If you do not manually verify a fix, the system automatically verifies the fix within 48 hours after the vulnerability fix is complete.

You can fix a vulnerability for one or more affected assets at a time.

- To fix a vulnerability for one affected asset, select an action from the **Actions** column of the asset.
- To fix a vulnerability for one or more affected assets, select the target servers, and select an action in the lower-left corner.

27.1.6.3.1.2. Manage Windows vulnerabilities

This topic describes how to manage Window vulnerabilities.

Context

Apsara Stack Security automatically checks if your servers have the latest Microsoft updates installed, and notifies you of the detected vulnerabilities. Apsara Stack Security also automatically detects and fixes major vulnerabilities on your servers.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**. On the page that appears, click the **Window System** tab.
3. Check the detected Windows vulnerabilities.

   > **Note** You can find a vulnerability by using the search and filter functions.

4. Click a vulnerability to go to the vulnerability details page. You can view details about the vulnerability and affected assets on this page.

   > **Note** You can find specific affected assets by using the search and filter functions.

   - **Basic Information**: the basic information of the vulnerability, including the name, Common Vulnerability Scoring System (CVSS) score, description, and resolution.
   - **Affected Assets**: the servers that are affected by the vulnerability.
5. Select an action based on the impact of the vulnerability. Actions on vulnerabilities describes the actions.

   Actions on vulnerabilities

Option	Description

Option	Description
Rectify	Select this option to fix the vulnerability. The system caches an official Windows patch in the cloud for your server to download and update.
Ignore	Select this option to ignore a vulnerability. The system does not send you an alert about an ignored vulnerability.
Verify	Click **Verify** to verify the vulnerability fix.
Restarted and Verified	If a vulnerability fix takes effect only after a server reboot, you must reboot the server after the status of the vulnerability changes to **Fixed (To Be Restarted)**. After the reboot, click **Restarted and Verified**.

You can fix a vulnerability for one or more affected assets at a time.

- To fix a vulnerability for one affected asset, select an action from the **Actions** column of the asset.
- To fix a vulnerability for one or more affected assets, select the target servers, and select an action in the lower-left corner.

27.1.6.3.1.3. Manage Web CMS vulnerabilities

This topic describes how to manage Web CMS vulnerabilities.

Context

The Web CMS vulnerability detection feature obtains the information of the latest vulnerabilities and provides patches in the cloud. This helps you detect and fix vulnerabilities.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**. On the page that appears, click the **Web CMS** tab.
3. View all vulnerabilities.

   > **Note** You can find a vulnerability by using the search and filter functions.

4. Click a vulnerability to go to the vulnerability details page. You can view details about the vulnerability and affected assets on this page.

   > **Note** You can find specific affected assets by using the search and filter functions.

5. Select an action based on the impact of the vulnerability. Actions on vulnerabilities describes the actions.

   Actions on vulnerabilities

Option	Description
Rectify	Select this option to fix the Web CMS vulnerability by replacing the web files that contain the vulnerability on your server. **Note** Before you fix the vulnerability, we recommend that you back up the web files affected by this vulnerability. For more information about the paths of the web files, see the paths specified in the vulnerability remarks.

Option	Description
Ignore	Select this option to ignore a vulnerability. The system does not send you an alert about an ignored vulnerability.
Verify	Click **Verify** to verify the vulnerability fix. If you do not manually verify a fix, the system automatically verifies the fix within 48 hours after the vulnerability fix is complete.
Undo Fix	For vulnerabilities that have been fixed, click **Undo Fix** to restore the web files that have been replaced.

You can fix a vulnerability for one or more affected assets at a time.

- To fix a vulnerability for one affected asset, select an action from the **Actions** column of the asset.
- To fix a vulnerability for one or more affected assets, select the target servers, and select an action in the lower-left corner.

27.1.6.3.1.4. Manage emergency vulnerabilities

This topic describes how to manage emergency vulnerabilities.

Context

Apsara Stack Security automatically detects vulnerabilities on servers, such as the unauthorized Redis access vulnerability and Struts S2-052 vulnerability, and sends vulnerability alerts. After you fix a vulnerability, you can also check whether the fix is successful.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**. On the page that appears, click the **Emergency** tab.
3. View all vulnerabilities.

   You can quickly locate a vulnerability by using the search and filter functions.
4. Click a vulnerability to go to the vulnerability details page. You can view detailed vulnerability information and affected assets on this page.

   You can quickly locate specific affected assets by using the search and filter functions.
5. Select an action based on the impact of the vulnerability. Actions on vulnerabilities describes the actions.

   Follow the instructions to manually fix the vulnerabilities on the **Emergency** tab.

   Actions on vulnerabilities

Action	Description
Ignore	Ignore a vulnerability. The system does not alert you about an ignored vulnerability.
Verify	**Verify** the fix after you manually fix a vulnerability. If you do not manually verify a fix, the system automatically verifies the fix within 48 hours after the vulnerability fix is complete.

You can fix a vulnerability for one or more affected assets at a time.

- To fix a vulnerability for one affected asset, select an action from the **Actions** column of the asset.

- To fix a vulnerability for one or more affected assets, select the target servers, and select an action in the lower-left corner.

27.1.6.3.1.5. Configure vulnerability management policies

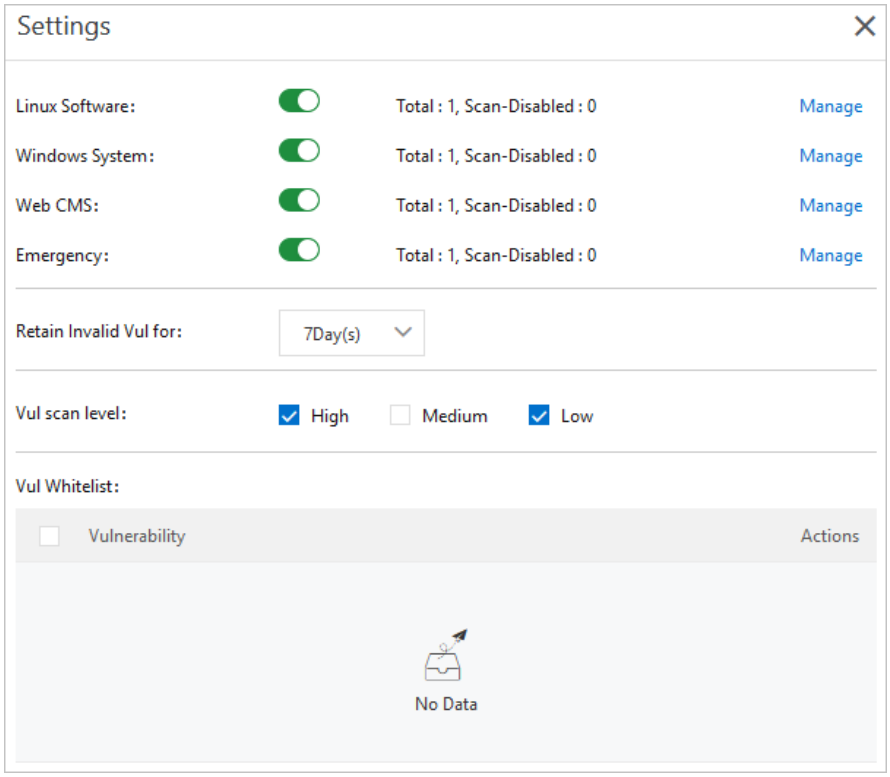
You can enable or disable automatic detection for different types of vulnerabilities, and enable vulnerability detection for specific servers. You can also set a time duration for which invalid vulnerabilities are retained, and configure a vulnerability whitelist.

Context

A vulnerability whitelist allows you to exclude vulnerabilities from the detection list. You can add multiple vulnerabilities in the vulnerability list to the whitelist. The system does not detect vulnerabilities in the whitelist. You can manage the vulnerability whitelist on the vulnerability settings page.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**.
3. In the upper-right corner, click **Settings** to configure vulnerability management policies.



- Select a vulnerability type and enable or disable detection for vulnerabilities of this type.
- Click **Manage** next to a vulnerability type and specify the servers on which vulnerabilities of this type are detected.
- Select a time duration for which invalid vulnerabilities are retained: 7 days, 30 days, or 90 days.

  > **Note** If you do not take any action on a detected vulnerability, the system determines that the alert is invalid. The system deletes the vulnerability after the specified duration.

- Select the vulnerability severities for scanning.
  - **High**: Vulnerabilities of this severity must be fixed as soon as possible.

- **Medium**: Vulnerabilities of this severity can be fixed later.
- **Low**: Vulnerabilities of this severity do not need to be fixed for now.

- Select vulnerabilities in the whitelist and click **Remove** to enable the system to detect these vulnerabilities and send alerts again.

27.1.6.3.2. Baseline check

27.1.6.3.2.1. Baseline check overview

The baseline check feature automatically checks the security configurations on servers and provides the detailed check results and suggestions for baseline reinforcement.

Description

After you enable the baseline check feature, Apsara Stack Security automatically checks for risks related to the operating systems, accounts, databases, passwords, and security compliance configurations of your servers, and provides reinforcement suggestions. For more information, see Baseline check items.

By default, a full baseline check is automatically performed from 00:00 to 06:00 every day. You can create and manage scan policies for baseline checks. When you create or modify a policy, you can customize the check items, interval, and time period of a baseline check, and select the servers to which you want to apply this policy. For more information, see Add a custom baseline check policy.

Precautions

The following check items are disabled by default. To check these items, make sure that these items do not affect your business and select them when you customize a scan policy.

- Check items related to weak passwords for specific applications such as MySQL, PostgreSQL, and SQL Server

  Note If these check items are enabled, the system attempts to log on to servers with weak passwords. The logon attempts consume server resources and generate many logon failure records.

- Check items related to China classified protection of cybersecurity
- Check items related to the Center for Internet Security (CIS) standard

Baseline check items

Category	Check item
Database	Alibaba Cloud Standard - MongoDB Security Baseline Check
	Alibaba Cloud Standard - Redis Security Baseline Check
	Alibaba Cloud Standard - Oracle 11g Security Baseline Check
	Alibaba Cloud Standard - Memcached Security Baseline Check
	Alibaba Cloud Standard - Mysql Security Baseline Check

Category	Check item
Operating system	Security baseline check against the Alibaba Cloud standard: • Alibaba Cloud Aliyun Linux 2 Benchmark • Alibaba Cloud Standard - CentOS Linux 6 Security Baseline Check • Alibaba Cloud Standard - CentOS Linux 7/8 Security Baseline Check • Alibaba Cloud Standard - Debian Linux 8 Security Baseline • Alibaba Cloud Standard - Red Hat Enterprise Linux 6 Security Baseline Check • Alibaba Cloud Standard - Red Hat Enterprise Linux 7 Security Baseline Check • Alibaba Cloud Standard - Ubuntu Security Baseline • Alibaba Cloud Standard - Windows Server 2008 R2 Security Baseline Check • Alibaba Cloud Standard - Windows 2012 R2 Security Baseline • Alibaba Cloud Standard - Windows 2016/2019 R2 Security Baseline
	Security baseline check against the CIS standard: • Alibaba Cloud Aliyun Linux 2 CIS Benchmark • CIS CentOS Linux 6 LTS Benchmark • CIS CentOS Linux 7 LTS Benchmark • CIS Debian Linux 8 Benchmark • CIS Ubuntu Linux 14 LTS Benchmark • CIS Ubuntu Linux 16/18 LTS Benchmark • CIS Microsoft Windows Server 2008 R2 Benchmark • CIS Microsoft Windows Server 2012 R2 Benchmark • CIS Microsoft Windows Server 2016/2019 R2 Benchmark
	Baseline check on compliance of China classified protection of cybersecurity level II: • Aliyun Linux 2 Baseline for China classified protection of cybersecurity-Level II • CentOS Linux 6 Baseline for China classified protection of cybersecurity-Level II • CentOS Linux 7 Baseline for China classified protection of cybersecurity-Level II • Debian Linux 8 Baseline for China classified protection of cybersecurity-Level II • Redhat Linux 7 Baseline for China classified protection of cybersecurity-Level II • Ubuntu 14 Baseline for China classified protection of cybersecurity-Level II • Linux Ubuntu 16/18 Baseline for China classified protection of cybersecurity-Level II • Windows 2008 R2 Baseline for China classified protection of cybersecurity-Level II • Windows 2012 R2 Baseline for China classified protection of cybersecurity-Level II • Windows 2016/2019 R2 Baseline for China classified protection of cybersecurity-Level II

Category	Check item
	Baseline check on compliance of China classified protection of cybersecurity level III: • Aliyun Linux 2 Baseline for China classified protection of cybersecurity-Level III • CentOS Linux 6 Baseline for China classified protection of cybersecurity-Level III • CentOS Linux 7 Baseline for China classified protection of cybersecurity-Level III • Debian Linux 8 Baseline for China classified protection of cybersecurity-Level III • Redhat Linux 6 Baseline for China classified protection of cybersecurity-Level III • China's Level 3 Protection of Cybersecurity - Red Hat Enterprise Linux 7 Compliance Baseline Check • SUSE Linux 10 Baseline for China classified protection of cybersecurity-Level III • SUSE Linux 11 Baseline for China classified protection of cybersecurity-Level III • SUSE Linux 12 Baseline for China classified protection of cybersecurity-Level III • Ubuntu 14 Baseline for China classified protection of cybersecurity-Level III • Linux Ubuntu 16 Baseline for China classified protection of cybersecurity-Level III • Windows 2008 R2 Baseline for China classified protection of cybersecurity-Level III • Windows 2012 R2 Baseline for China classified protection of cybersecurity-Level III • Windows 2016/2019 R2 Baseline for China classified protection of cybersecurity-Level III
Weak password	Weak password - Linux system login weak password baseline
	Weak password - SQL Server DB login weak password baseline
	Weak password - PostgreSQL DB login weak password baseline
	Weak password - Windows system login weak password baseline
	Weak password - Ftp login weak password baseline
	Weak password - Mysql DB login weak password baseline
Middleware	Alibaba Cloud Standard - IIS 8 Security Baseline Check
	Alibaba Cloud Standard-Apache Tomcat Security Baseline
	Alibaba Cloud Standard - Apache Security Baseline Check
	Alibaba Cloud Standard - Nginx Security Baseline Check

27.1.6.3.2.2. Configure baseline check policies

This topic describes how to add, modify, and delete baseline check policies and how to set baseline check levels.

Context

By default, the baseline check feature uses the **default policy** to check the baseline security of assets. You can also customize baseline check policies based on your business requirements, for example, to check the compliance with China classified protection of cybersecurity-Level II.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Baseline Check**.

3. In the upper-right corner of the page that appears, click **Manage Policies**. In the **Manage Policies** pane, add, modify, or delete a baseline check policy, or modify the default policy.
   - In the upper-right corner of the pane, click **Create Policy** to customize a baseline check policy. Then, click **Ok**.

Parameter	Description
Policy Name	Enter a policy name.
Schedule	Select a time interval for scheduled scan tasks from: 1 Day(s), 3 Day(s), 7 Day(s), and 30 Day(s), which represent every second day, every fourth day, every eighth day, and every thirty-first day. You can also select a time period for scheduled scan tasks from: 00:00 to 06:00, 06:00 to 12:00, 12:00 to 18:00, and 18:00 to 24:00.
Check Items	Select the baseline items that need to be checked under these categories: High risk exploit, CIS and China's Protection of Cybersecurity, Best security practices, and Weak password.
Servers	Select the asset groups to which you want to apply this policy. **Note** Newly purchased servers belong to **Default** under **Asset Groups**. To apply this policy to new servers, select **Default**.

   - Click **Edit** or **Delete** next to the target policy to modify or delete it.

     Note You cannot restore a policy after it is deleted.

   - Click **Edit** in the **Actions** column next to the **Default** policy to modify the asset groups to which the default policy is applied.

     Note You cannot delete the default policy or modify the check items of the default policy. You can only modify the asset groups to which the default policy is applied.

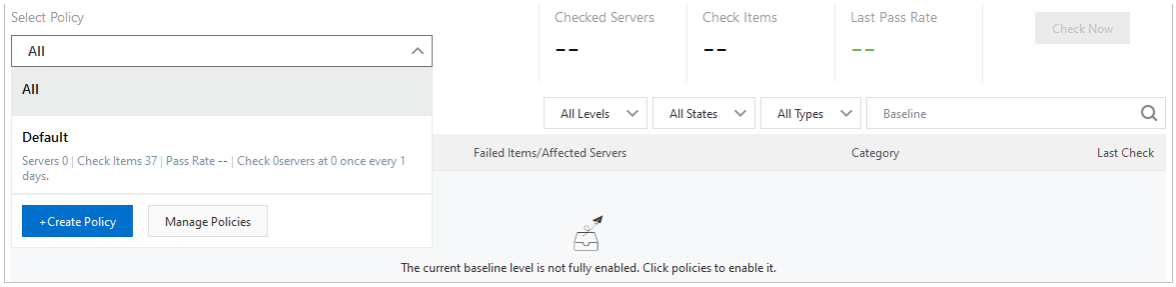
   - In the lower part of the **Manage Policies** pane, set the baseline check level to High, Medium, and Low.
4. Click **Ok**.

27.1.6.3.2.3. View baseline check results and manage failed check items

The Apsara Stack Security console provides detailed baseline check results and suggestions on how to manage failed check items. This topic describes how to view baseline check results and manage failed check items in the Apsara Stack Security console. The check results include affected assets, checked items, and the suggestions.

View the summary of baseline check results

1. Log on to Apsara Stack Security Center.
2.
3. In the upper part of the **Baseline Check** page, view the summary of baseline check results. You can filter data by policy.



You can select a policy from the **Select Policy** drop-down list to view the following information:

- **Checked Servers**: The number of servers on which the baseline check runs. These servers are specified in the selected baseline check policy.
- **Check Items**: The number of **Check Items** specified in the selected baseline check policy.
- **Last Pass Rate**: The pass rate of the last baseline check.

  If the number under **Last Pass Rate** is green, the pass rate of the checked servers is high. If this number is red, a large number of failed check items have been detected on the checked servers. We recommend that you view the check result details and manage the failed check items.

View all check items

1. Log on to Apsara Stack Security Center.
2.
3. Select **All** from the **Select Policy** drop-down list.
   The **Baseline Check** page displays check result details, including **Baseline**, **Checked Item**, **Failed Items/Affected Servers**, **Category**, and **Last Check**.

> **Note** You can also select a baseline check policy from the **Select Policy** drop-down list to view the check items specified in this policy.

View details of a check item

1. Log on to Apsara Stack Security Center.
2.
3. In the **Baseline** column, click the target check item to view its details.
4. On the details page, manage the failed check items.
   - Find the target asset and click **View** in the **Actions** column to open the **At-Risk Items** pane.
   -

View failed check items

1. Open the check item details page. Find the target asset and click **View** in the **Actions** column to view failed check items.
   You can view the check items of the asset and the statuses of the check items (**Passed** or **Failed**).
2.

> **Note** We recommend that you follow the suggestions to manage **Failed** check items at the earliest opportunity, especially the high-risk check items.

Manage failed check items

In the At-Risk Items pane, manage failed check items as required.

- **Add a check item to the whitelist**

If you want to disable alerts for a check item, click **Whitelist** to add the check item to the whitelist. Check items in the whitelist do not trigger alerts.

> **Note** You can also select multiple check items and click **Whitelist** in the lower-left corner to add the check items to the whitelist at a time.

- **Remove a check item from the whitelist**

  If you want to enable alerts for a check item in the whitelist, you can click **Remove** to remove the check item from the whitelist. You can remove one or more check items from the whitelist at a time. After a check item is removed from the whitelist, the check item triggers alerts again.

- **Verify a fixed check item**

  If you do not manually perform the verification, Apsara Stack Security automatically verifies the check item based on the detection interval specified in the policies.

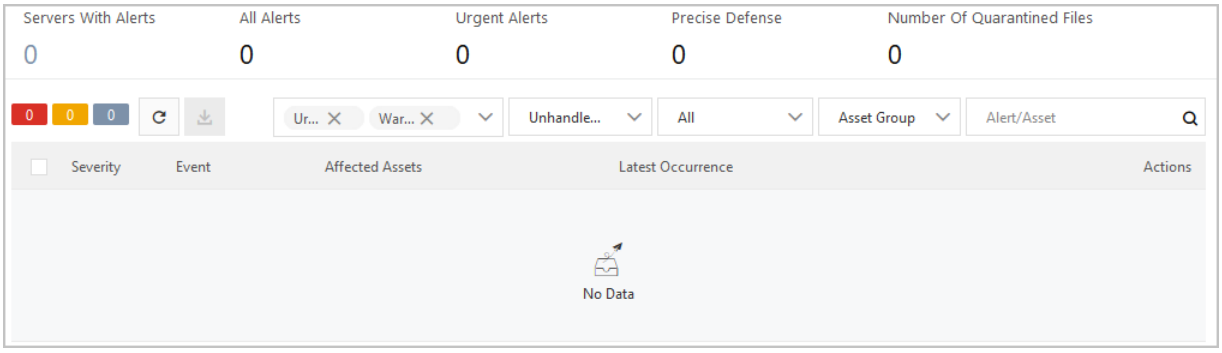
27.1.6.4. Intrusion prevention

27.1.6.4.1. Intrusion events

27.1.6.4.1.1. Intrusion event types

If the Server Security feature detects sensitive file tampering, webshells, unusual logons, suspicious processes, and malicious processes, it generates alerts. Based on these alerts, you can monitor the security status of your assets and handle potential threats at the earliest opportunity.

Apsara Stack Security Center provides statistics based on enabled alerts and defense items. This allows you to understand enabled and disabled defense items. You can view statistics on alerts and information about defense items. To achieve this purpose, choose **Server Security > Intrusion Prevention > Intrusions**.



Alert types

The following table describes the defense items.

Alert	Description
Suspicious Process	Detects whether suspicious processes exist.

Alert	Description
Webshell	Uses engines developed by Alibaba Cloud to scan common webshell files. Apsara Stack Security Center supports scheduled scan tasks, provides real-time protection, and quarantines webshell files. • Apsara Stack Security Center scans the entire web directory early in the morning on a daily basis. A change made to files under the web directory triggers dynamic detection. • You can specify the assets on which Apsara Stack Security Center scans for webshells. • You can quarantine, restore, and ignore detected Trojan files.
Unusual Logon	Detects unusual logons to your servers. You can specify approved logon IP addresses, time periods, and accounts. Logons from unapproved IP addresses, accounts, or time periods trigger alerts. You can manually add approved logon locations or configure the system to automatically update approved logon locations. You can also specify assets on which alerts are triggered when unusual logon locations are detected. Apsara Stack Security Center can detect the following logon events: • Logons to Elastic Compute Service (ECS) instances from unapproved IP addresses • Logons to ECS instances from unapproved locations • Execution of unusual commands after logons to ECS instances by using Secure Shell (SSH) • ECS instances passwords cracked due to brute-force attacks based on the SSH protocol
Sensitive File Tampering	Checks whether sensitive files on your servers are maliciously modified, such as tampering of pre-loaded configuration files in Linux shared libraries.
Malicious Process	Dynamically scans your servers based on the anti-virus mechanism of Alibaba Cloud and Apsara Stack Security Center, and generates alerts if viruses are detected. Process information is collected by Apsara Stack Security Center and uploaded to Alibaba Cloud. You can manage detected viruses in the Apsara Stack Security Center console. Apsara Stack Security Center can detect the following malicious activities and processes: • Visiting malicious IP addresses • Mining programs • Self-mutating Trojans • Malicious programs • Trojans
Unusual Network Connection	Detects disconnections or unusual network connections.
Suspicious Account	Detects logons to your assets from unapproved accounts.
Application intrusion event	Detects intrusion activities that use system application components.
Precision defense	The **Virus Removal** feature provides precise defenses against a majority of ransomware, distributed denial-of-service (DDoS) Trojans, mining programs, Trojan programs, malicious processes, webshells, and worms.
Cloud threat detection	Detects threats in other Alibaba Cloud services.

Alert	Description
Persistence	Detects suspicious scheduled tasks on servers and generates alerts when persistent threats against the servers are detected.
Web Application Threat Detection	Detects server intrusions that use web applications.
Malicious scripts	Checks whether the system services of your assets are attacked or modified by malicious scripts. Alerts are generated if potential script attacks are detected.
Other	Detects other types of attacks, such as DDoS attacks.

27.1.6.4.1.2. View and handle detected alert events

This topic describes how to view and handle detected alert events on the Intrusions page.

Background information

After alert events are detected, they are displayed on the Intrusions page. You can choose **Server Security > Intrusion Prevention > Intrusions** to go to the Intrusions page.

If the alert events are not handled, they are displayed in the **Unhandled Alerts** list on the **Intrusions** page. After the alert events are handled, the status changes from **Unhandled Alerts** to **Handled**.

> **Note** Apsara Stack Security Center retains the records of **Unhandled Alerts** and **Handled** on the **Intrusions** page. By default, the records of **Unhandled Alerts** are displayed.

View detected alert events

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions**.
3. In the intrusions list, search for or view detected intrusion events, alert events, and relevant details.

Handle alert events

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions**.
3. On the **Intrusions** page, find the specific alert event and click **Processing** in the **Actions** column. In the dialog box that appears, configure parameters and click **Process Now**.

   > **Note** If the alert event contains multiple correlated exceptions, click **Processing**. On the details page that appears, you can handle different alert events.

   - **Ignore**: If you ignore the alert event, the status of the alert event changes to **Handled**. The system no longer generates alerts for the event.
   - **Whitelist**: If the alert event is a false positive, you can add the alert event to the whitelist. After you add the alert event to the whitelist, the status of the alert event changes to **Handled**. Server Guard no longer generates alerts for the event. In the **Handled** alert list, you can click **Cancel whitelist** to remove the specific alert event from the whitelist.

     > **Note** A false positive represents that the system has generated a false alert on a normal process. Common false positives include **suspicious processes that send TCP packets**. The false positive notifies you that suspicious scans other devices have been detected on your servers.

- **Batch unhandled**: This method handles multiple alerts at a time. Before you handle multiple alert events at a time, we recommend that you view the details of the alert events.

4. (Optional)If you confirm that one or more alert events are false positives or need to be ignored, go to the **Intrusions** page, select the specific alert events, and then click **Ignore Once** or **Whitelist**.

Export alert events

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions**.
3. In the upper-left corner of the **Intrusions** page, click the icon to export the alert list.

   After the alert list is exported, the **Done** message appears in the upper-right corner.
4. In the **Done** notification of the **Alerts** page, click **Download**.
   The alert list is downloaded to your computer.

27.1.6.4.1.3. View exceptions related to an alert

Server Guide supports automatic analysis of exceptions related to an alert. You can click an alert name on the alert list to view and manage all exceptions related to this alert and view the results of automatic attack tracing.

Context

- Security Center automatically associates alerts with exceptions in real time to detect potential threats.
- Exceptions related to an alert are listed in chronological order. This allows you to analyze and handle the exceptions to improve the emergency response mechanism of your system.
- An automatically correlated alert is identified by the icon.

Procedure

1. Log on to Apsara Stack Security Center.
2.
3. On the Intrusions page, click the target **alert name**. The alert details page appears.
4. On the alert details page, view the details and related exceptions of the alert and manage the exceptions.
   - View alert details

     You can view the assets affected by this alert, the first and latest occurrence time of the alert, and the details of the related exceptions.
   - View affected assets

     Click the name of an **affected asset** to view the details of the asset. These details include alerts, vulnerabilities, baseline risks, and asset fingerprints.
   - View and manage **related exceptions**

     In the **Related Exceptions** section, you can view the details and recommended solutions of all exceptions related to this alert.
     - Click **Note** to the right of an exception name to add notes for the exception.
     - Click the icon to the right of a note to delete the note.

27.1.6.4.1.4. Use the file quarantine function

Sever Guide can quarantine malicious files. Quarantined files are listed in the quarantine box on the Intrusions page. The system automatically deletes a quarantined file 30 days after it is quarantined. You can restore a quarantined file with a few clicks before it is deleted. This topic describes how to view quarantined files and remove files from the quarantine box.

Procedure

1. Log on to Apsara Stack Security Center.
2.
3. In the upper-right corner of the **Intrusions** page, click **Quarantine**.

   You can perform the following operations in the **Quarantine** pane:

   - View information about quarantined files. The information includes server IP addresses, directories that store the files, file status, and time of the last modification.
   - Click **Restore** in the **Actions** column to remove a file from the quarantine box. The restored file appears in the alert list again.

27.1.6.4.1.5. Configure security alerts

This topic describes how to configure security alerts, which allow you to specify approved logon locations and customize web directories to scan.

Context

Server Guard supports advanced logon settings and security alerts. You can configure more fine-grained logon detection rules. For example, you can specify approved logon IP addresses, logon time, and logon accounts to block unauthorized requests sent to your assets.

Procedure

1. Log on to Apsara Stack Security Center.
2.
3. In the upper-right corner, click **Settings**.

   Configure parameters on different tabs.

   - **Add an approved logon location**
     a. Click **Management** to the right of **Login Location**.
     b. Select the logon location that you want to add, and select the servers that allow logons from the added location.
     c. Click **OK**.

     Server Guard allows you to **edit** and **delete** approved logon locations.

     - Find the specific logon location and click **Edit** on the right side to change the servers that allow logons from this location.
     - Find the specific logon location and click **Delete** on the right side to delete the logon location.

   - **Configure advanced logon settings**

     > **Note** When you configure advanced logon settings, you can specify the IP addresses, accounts, and time ranges that are allowed for logons to your assets. After the advanced logon settings are configured, Server Guard sends you alerts if your assets receive unauthorized logon requests. The procedure of configuring advanced logon settings is similar to that of configuring **Login Location**. You can **add**, **edit**, and **delete** advanced logon settings in the similar way.

- Turn on or turn off Uncommon IP Alert to the right of **Common Login IPs**. If your assets receive logon requests from unauthorized IP addresses, alerts are triggered.
- Turn on or turn off Uncommon Time Alert to the right of **Common Login Time**. If your assets receive logon requests at unauthorized time periods, alerts are triggered.
- Turn on or turn off Uncommon Account Alert to the right of **Common Login Accounts**. If your assets receive logon requests from unauthorized accounts, alerts are triggered.

- **Add web directories to scan**

  Server Guard automatically scans web directories of data assets in your servers and runs dynamic and static scan tasks. You can also manually add other web directories of your servers.

  a. On the right of **Add Scan Targets**, click **Management**.
  b. Specify a valid web directory and select the servers on which the specified web directory is scanned.

  > **Note** To ensure the performance and efficiency, do not specify a root directory.

  c. Click **OK**.

27.1.6.4.1.6. Virus removal

The virus removal feature provided by Server Guard is integrated with major antivirus engines worldwide. It detects viruses against large amounts of threat intelligence data provided by Alibaba Cloud. Virus removal also provides an exception detection module designed by Alibaba Cloud to detect viruses based on machine learning and deep learning. This way, virus removal can provide full-scale and dynamic antivirus protection to safeguard your servers.

The cloud threat detection feature scans hundreds of millions of files on a daily basis and protects millions of servers on the cloud.

Detection capabilities

The virus removal feature uses the Server Guard client to collect process information, and then scans the retrieved data for viruses in the cloud. If a malicious process is detected, you can stop the process and quarantine the related files.

- **Deep learning engine developed by Alibaba Cloud**: The deep learning engine is built on deep learning technology and a large number of attack samples. The engine detects malicious files on the cloud and automatically identifies potential threats to supplement traditional antivirus engines.
- **Cloud sandbox developed by Alibaba Cloud**: The cloud sandbox feature allows you to simulate cloud environments and monitor attacks launched by malicious samples. The cloud sandbox feature automatically detects threats and offers dynamic analysis and detection capabilities based on big data analytics and machine learning modeling techniques.
- **Integration with major antivirus engines**: The cloud threat detection feature is integrated with major antivirus engines and updates its virus library in real time.
- **Threat intelligence detection**: The cloud threat detection feature works with the exception detection module to detect malicious processes and operations based on threat intelligence data provided by Alibaba Cloud Security.

Detectable virus types

The cloud threat detection feature is developed based on the security technologies and expertise of Alibaba Cloud. The feature provides end-to-end security services, including threat intelligence collection, data masking, threat identification, threat analysis, and malicious file quarantine and restoration. You can quarantine and restore files that contain viruses in the Security Center console.

The cloud threat detection feature can detect the following types of viruses.

Virus	Description
Mining program	A mining program consumes server resources and mines cryptocurrency without authorization.
Computer worm	A computer worm uses computer networks to replicate itself and spread to a large number of computers within a short period of time.
Ransomware	Ransomware, such as WannaCry, uses encryption algorithms to encrypt files and prevent users from accessing the files.
Trojan	A trojan is a program that allows an attacker to access information about servers and users, gain control of the servers, and consume system resources.
DDoS trojan	A DDoS trojan hijacks servers and uses zombie servers to launch DDoS attacks, which interrupts your service.
Backdoor	A backdoor is a malicious program injected by an attacker. Then, the attacker can use the backdoor to control the server or launch attacks.
Computer virus	A computer virus inserts malicious code into normal programs and replicates the code to infect the whole system.
Malicious program	A malicious program may pose threats to system and data security.

Benefits

- **Self-developed and controllable**: The cloud threat detection feature is based on deep learning, machine learning, and big data analytics with a large number of attack and defense practices. The feature uses multiple detection engines to dynamically protect your assets against viruses.
- **Lightweight**: The cloud threat detection feature consumes only 1% of CPU resources and 50 MB of memory.
- **Dynamic**: The cloud threat detection feature dynamically retrieves startup logs of processes to monitor the startup of viruses.
- **Easy to manage**: You can manage all servers and view their status at any time in the Security Center console.

Threat detection limits

Apsara Stack Security Center allows you to process security alerts, scan for vulnerabilities, analyze attacks, and check security settings in the Security Center console. Apsara Stack Security Center can analyze alerts and automatically trace attacks. This allows you to protect your assets. Apsara Stack Security Center supports a wide range of protection features. We recommend that you also install the latest system patches on your server. We also recommend you to use security services, such as Cloud Firewall and Web Application Firewall (WAF), to better protect your assets against attacks.

> **Note** Attacks and viruses are evolving, and your business environments vary. Security breaches may occur. We recommend that you use the alerting, vulnerability detection, baseline check, and configuration assessment features provided by Apsara Stack Security Center to better protect your assets against attacks.

27.1.6.4.2. Website tamper-proofing

27.1.6.4.2.1. Overview

Tamper protection monitors website directories in real time, restores modified files or directories, and protects websites from trojans, hidden links, and uploads of violent and illicit content.

Background information

To make illegal profits or conduct business attacks, attackers exploit vulnerabilities in websites to insert illegal hidden links and tamper with the websites. Defaced web pages affect normal user access and may lead to serious economic losses, damaged brand reputation, or political risks.

Tamper protection allows you to add Linux and Windows processes to the whitelist and update protected files in real time.

How tamper protection works

The Security Center agent automatically collects the list of processes that attempt to modify files in the protected directories of the protected servers. It identifies unusual processes and file changes in real time and blocks unusual processes.

The alert list is displayed on the Tamper Protection page. You can view unusual file changes, the corresponding processes, and the number of attempts made by each process in the alert list. If a file is modified by a trusted process, you can add the process to the whitelist. After the process is added to the whitelist, tamper protection no longer blocks the process. In scenarios where the content of websites, such as news and education websites, is frequently modified, the whitelist saves you the effort of frequently enabling and disabling tamper protection.

Versions of operating systems and kernels supported by tamper protection

OS	Supported operating system version	Supported kernel version
Windows	Windows Server 2008 and later	All versions
CentOS	6.5, 6.6, 6.7, 6.8, 6.9, 6.10, 7.0, 7.1, 7.2, 7.3, 7.4, 7.5, and 7.6	• 2.6.32-x • 3.10.0-x
Ubuntu	14, 16, and 18	• 3.13.0-32-generic • 3.13.0-86-generic • 4.4.0-62-generic • 4.4.0-63-generic • 4.4.0-93-generic • 4.4.0-151-generic • 4.4.0-117-generic • 4.15.0-23-generic • 4.15.0-42-generic • 4.15.0-45-generic • 4.15.0-52-generic

Note

- The preceding table lists kernel versions supported by tamper protection. Servers that use an unsupported kernel version cannot use tamper protection. Make sure that your server uses a supported kernel version. If a kernel version is not supported, you must upgrade it to a supported version. Otherwise, you cannot add processes to the whitelist.
- Before you upgrade the server kernel, back up your asset data.

27.1.6.4.2.2. Configure tamper protection

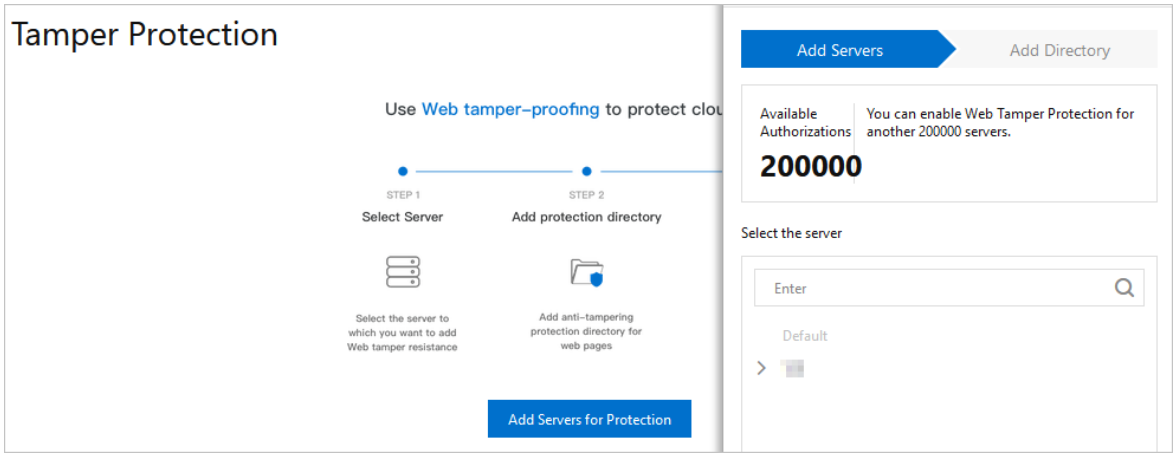
The Server Security feature allows you to configure tamper protection for web pages.

Limits

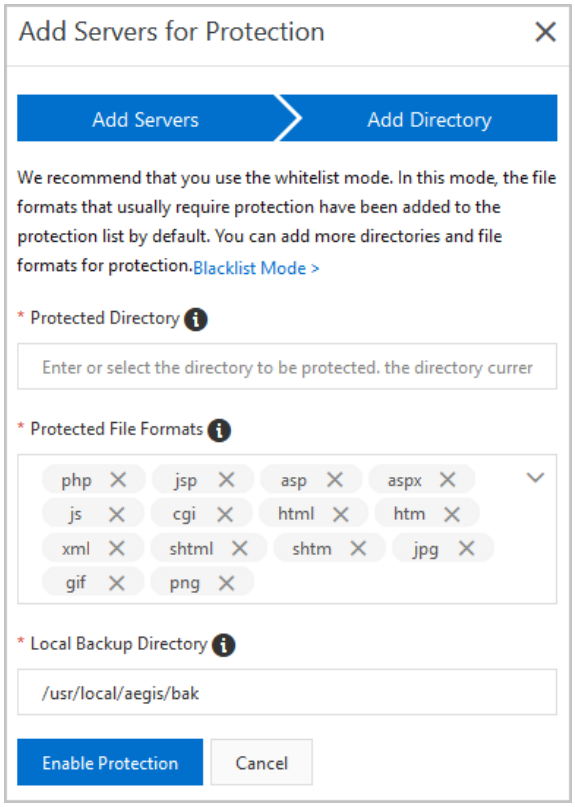
- For each server, you can add a maximum of 10 directories for protection.
- The protected directories of a Windows server must meet the following requirements: The maximum size of each directory is no more than 20 GB. Each directory contains a maximum of 2,000 folders. The maximum directory level is 20. The maximum size of each file is 3 MB.
- The protected directories of a Linux server must meet the following requirements: The maximum size of each directory is no more than 20 GB. Each directory contains a maximum of 3,000 folders. The maximum directory level is 20. The maximum size of each file is 3 MB.
- Before you add a directory for protection, make sure that the directory level, the number of folders, and the directory size meet the preceding requirements.
- We recommend that you exclude file formats that do not require protection, such as *.log*, *.png*, *.jpg*, *.mp4*, *.avi*, and *.mp3*. Separate multiple file formats with semicolons (;).

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, click **Server Security** and choose **Intrusion Prevention > File Tamper Protection**.
3.
4. On the **Tamper Protection** page, click **Add Servers for Protection**.
5. In the **Add Servers for Protection** dialog box, select a server that you want to protect.



6. Click **Next** to go to the **Add Directory** step.
7. In the **Add Directory** step, configure the following parameters:



Select the protection mode. You can select the **Whitelist Mode** or **Blacklist Mode**. In whitelist mode, tamper protection is enabled for the specified directories and file formats. In blacklist mode, tamper protection is enabled for the subdirectories, file formats, and files that are not specified. The whitelist mode is selected by default.

- In whitelist mode, configure the following parameters.

Parameter	Description
Protected Directory	Enter the path of the directory that you want to protect. **Note** Servers that run Linux and Windows operating systems use different path formats. Enter a valid directory path based on your operating system type.
Protected File Formats	Select file formats from the drop-down list, such as *.js*, *.html*, *.xml*, and *.jpg*.
Local Backup Directory	The default path where backup files of the protected directories are stored. By default, Security Center assigns */usr/local/aegis/bak* to servers that run the Linux operating system and *C:\Program Files (x86)\Alibaba\Aegis\bak* to servers that run the Windows operating system. You can change the default path as needed.

- In blacklist mode, configure the following parameters.

Parameter	Description
Protected Directory	Enter the path of the directory that you want to protect.

Parameter	Description
Excluded Sub-Directories	Enter the subdirectories that do not require tamper protection. Click **Add Sub-Directory** to enter more subdirectories. Security Center does not provide tamper protection for files under the excluded sub-directories.
Excluded File Formats	Select the formats of files that do not require tamper protection. Supported formats include **log**, **txt**, and **ldb**. Security Center does not provide tamper protection for the files in the excluded formats.
Excluded Files	Enter the path of the file that does not require tamper protection. You can click **Add File** to add more files. Security Center does not provide tamper protection for the excluded files.
Local Backup Directory	The default path where backup files of the protected directories are stored. By default, Security Center assigns */usr/local/aegis/bak* to servers that run the Linux operating system and *C:\Program Files (x86)\Alibaba\Aegis\bak* to servers that run the Windows operating system. You can change the default path as needed.

8. Click **Enable Protection**.
   After you enable tamper protection for a server, it is displayed in the server list on the **Tamper Protection** page.

   > **Note** By default, tamper protection is in the **Not Initiated** state for newly added servers. To enable tamper protection, you must turn on the **On** switch on the **Tamper Protection** page for the target server.

9. In the server list on the Tamper Protection page, find the target server and turn on the switch in the **Protection** column to enable tamper protection for the server.

   > **Note** By default, tamper protection is in the **Not Initiated** state for newly added servers. You must enable tamper protection on the **Tamper Protection** page for the target server.

   After tamper protection is enabled, the protection state changes to **Running**.

   > **Note** If the protection state of a server is **Exception**, click **Exception** in the Status column. A message that indicates the causes appears. Click **Retry** in the message.

What to do next

After you enable tamper protection for a server, you can go to the **Overview** page, and select tamper protection in the event type drop-down list to view the alerts on tampering events.

> **Note**
>
> Tamper protection does not take effect immediately after you configure the protected directory, and you can still write files to the directory. In this case, you must go to the **Management** page, disable **Protection** for the server where the directory is located, and then enable **Protection** again.

Handle abnormal protection states

Protection state	Description	Suggestion
Initializing	Web tamper protection is being initialized.	If this is your first time enabling tamper protection for a server, the protection status becomes **Initializing**. It takes a few seconds to enable tamper protection.
Running	Tamper protection is enabled and running as expected.	-
Exception	An error occurred when tamper protection was enabled.	Click **Exception** in the Status column to view the exception cause and click Retry.
Not Initiated	Tamper protection is disabled.	You must turn on the **On** switch to enable tamper protection.

27.1.6.4.2.3. View the protection status

This topic describes how to view the status of tamper protection for your assets.

Context

The tamper protection feature monitors changes of directories and files in real time and blocks suspicious file changes. To view the status and details of tamper protection in the Apsara Stack Security console, click **Server Security** and choose **Intrusion Prevention > File Tamper Protection**. The details include:

- Overview

  On the Overview page, you can view the total number of changed files, protected servers, and protected directories on the current day and during the last 15 days.

- Distribution of protected file types

  Protected file types include .txt, .png, .msi, and .zip. You can also add more types of files for protection as needed.

  > **Note** All types of files can be added for tamper protection.

- Top five files with the largest number of changes

  This module shows the names and paths of the five files with the largest number of changes in the last 15 days.

- Details of tamper protection alerts

  The tamper protection feature helps you block all suspicious changes to directories and files on your assets. On the alert details page, you can view the alerts of these changes, including the severity, alert name, affected assets, paths of files with suspicious changes, and protection status.

> Note
> - If the number of alerts exceeds 100, we recommend that you process these alerts at your earliest opportunity.
> - Only the alerts at the **Warning** level are displayed in the console.
> - Only alerts in the **Isolation successful** state are displayed. This indicates that the tamper protection feature has blocked the suspicious processes that attempted to make unauthorized file changes.

27.1.6.4.3. Configure the Virus Removal feature

The Virus Removal feature of Server Guard allows you to customize virus and webshell detection settings.

Virus detection

The Virus Removal feature can automatically quarantine common Internet viruses, such as mainstream trojans, ransomware, mining programs, and DDoS trojans. Apsara Stack Security experts test and verify all automatically quarantined viruses to ensure a minimum false positive rate.

If automatic quarantine is disabled, Server Guard generates alerts when viruses are detected. You must manually manage detected viruses in the console. We recommend that you enable automatic quarantine to better safeguard your servers.

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, click **Server Security** and choose **Intrusion Prevention > Virus Removal**.
3. In the **Anti-virus** section, click **Manage**.
4. In the **Configure Servers for Virus Detection** dialog box, select the servers for which you want to enable the Virus Removal feature.
5. Click **OK**.
6. In the **Anti-virus** section, turn on **Virus Blocking** to enable virus blocking.

   After virus blocking is enabled, Server Guard automatically quarantines detected viruses. Quarantined viruses are listed on the Overview page. You can select the **Precision Defense** type to filter quarantined viruses.

Webshell detection

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, click **Server Security** and choose **Intrusion Prevention > Virus Removal**.
3. Configure servers for webshell detection.
   i. In the **Webshell Detection** section, click **Manage**.
   ii. Select the servers for which you want to enable webshell detection.
   iii. Click **OK** to complete the configuration.

27.1.6.5. Log retrieval

27.1.6.5.1. Log retrieval overview

The log retrieval function provided by Server Security allows you to manage logs scattered in various systems of Apsara Stack in a centralized manner, so that you can easily identify the causes of issues that occur on your servers.

The log retrieval function supports storage of logs for 180 days and query of logs generated within 30 days.

Benefits

The log retrieval function provides the following benefits:

- **End-to-end log retrieval platform**: Allows you to retrieve logs of various Apsara Stack services in a centralized manner and trace issues easily.
- **Cloud-based SaaS service**: Allows you to query logs on all servers in Apsara Stack without additional installment and deployment.
- Supports TB-level data retrieval. It also allows you to add a maximum of 50 inference rules (Boolean expressions) in a search condition and obtain full-text search results within several seconds.
- Supports a wide range of log sources.
- Supports log shipping, which allows you to import security logs to Log Service for further analysis.

Scenarios

You can use log retrieval to meet the following requirements:

- **Security event analysis**: When a security event is detected on a server, you can retrieve the logs to identify the cause and assess the damage and affected assets.
- **Operation audit**: You can audit the operation logs on a server to identify high-risk operations and serious issues in a meticulous way.

Supported log types

Log types

Log type	Description
Logon history	Log entries about successful system logons
Brute-force attack	Log entries about system logon failures that are generated during brute-force attacks
Process snapshot	Log entries about processes on a server at a specific time
Listening port snapshot	Log entries about listening ports on a server at a specific time
Account snapshot	Log entries about account logon information on a server at a specific time
Process initiation	Log entries about process initiation on a server
Network connection	Log entries about active connections from a server to external networks

27.1.6.5.2. Query logs

This topic describes how to search for and view server logs.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Log Retrieval**.
3. Specify search conditions.

Search condition	Description
Log source	The supported log source. For more information, see Log sources.

Search condition	Description
Field	The field that is supported by the specified log source. For more information, see Log sources.
Keyword	The keyword of the field that you want to search for.
Logical operator	The equality operator.
+	The inference rules in a search condition for a log source.
Add conditions	The search conditions for different log sources.

4. Click **Search** and view the search result.
   - **Reset**: Click **Reset** to clear the search condition configurations.
   - **Save Search**: Click **Save Search** to save the search condition configurations for future use.
   - **Saved Searches**: Click **Saved Searches** to select and apply a search condition configuration that has been saved.

27.1.6.5.3. Supported log sources and fields

This topic describes the log sources and fields that are supported by the log retrieval feature.

The log retrieval feature allows you to query the following types of log sources. You can click a log source link to view the fields that can be retrieved.

Log source	Description
Logon history	Log entries about successful system logons.
Logs of brute-force attacks	Log entries about failed system logons during brute-force attacks.
Process snapshot logs	Log entries about processes on a server at a specific point in time .
Logs of listening port snapshots	Log entries about listening ports on a server at a specific point in time.
Account snapshot logs	Log entries about account-based logons on a server at a specific point in time.
Process startup logs	Log entries about process startups on a server.
Network connection logs	Log entries about active connections from a server to the Internet.

Logon history

You can query the logon history by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
warn_ip	string	The source IP address for the logon.
warn_port	string	The logon port.

Field	Data type	Description
warn_user	string	The username for the logon.
warn_type	string	The logon type.
warn_count	string	The number of logon attempts.

Logs of brute-force attacks

You can query logs about brute-force attacks by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
warn_ip	string	The source IP address of the attack.
warn_port	string	The target port.
warn_user	string	The target username.
warn_type	string	The type.
warn_count	string	The number of brute-force attack attempts.

Process startup logs

You can query process startup logs by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
pid	string	The ID of the process.
groupname	string	The user group.
ppid	string	The ID of the parent process.
uid	string	The ID of the user.
username	string	The username.
filename	string	The file name.
pfilename	string	The name of the parent process file.
cmdline	string	The command line.
filepath	string	The path of the process file.
pfilepath	string	The path of the parent process file.

Logs of listening port snapshots

You can query logs about listening port snapshots by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
src_port	string	The listening port.
src_ip	string	The listening IP address.
proc_path	string	The path of the process file.
pid	string	The ID of the process.
proc_name	string	The name of the process.
proto	string	The protocol.

Account snapshot logs

You can query account snapshot logs by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
perm	string	Indicates whether the user has root permissions.
home_dir	string	The home directory.
warn_time	string	The time at which a password expiration notification is sent.
groups	string	The group to which the user belongs.
login_ip	string	The IP address of the last logon.
last_chg	string	The time at which the password was last changed.
shell	string	The Linux shell command.
domain	string	The Windows domain.
tty	string	The logon terminal.
account_expire	string	The time at which the account expires.
passwd_expire	string	The time at which the password expires.
last_logon	string	The last logon time.

Field	Data type	Description
user	string	The username.
status	string	The account status. Valid values: • 0: disabled • 1: normal

Process snapshot logs

You can query process snapshot logs by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
path	string	The path of the process file.
start_time	string	The time at which the process was started.
uid	string	The ID of the user.
cmdline	string	The command line.
pname	string	The name of the parent process.
name	string	The name of the process.
pid	string	The ID of the process.
user	string	The username.
md5	string	The MD5 hash of the process file. If the size of the process file exceeds 1 MB, the system does not calculate the MD5 hash value of the process file.

Network connection logs

You can query network connection logs by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
src_ip	string	The source IP address.
src_port	string	The source port.
proc_path	string	The path of the process file.
dst_port	string	The destination port.

Field	Data type	Description
proc_name	string	The name of the process.
dst_ip	string	The destination IP address.
status	string	The status.

27.1.6.5.4. Logical operators

The log retrieval feature supports multiple search conditions. You can add multiple logical operators to one search condition for one log source, or combine multiple search conditions for several log sources by using different logical operators. This topic describes the logical operators that are supported in log retrieval. Examples are provided to help you understand these operators.

The following table describes the logical operators that are supported in log retrieval.

Logical operators

Logical operator	Description
and	Binary operator. This operator is in the format of `query 1 and query 2`, which indicates the intersection of the query results of `query 1` and `query 2`. **Note** If no logical operators are used for multiple keywords, the default operator is AND.
or	Binary operator. This operator is in the format of `query 1 or query 2`, which indicates the union of the query results of `query 1` and `query 2`.
not	Binary operator. This operator is in the format of `query 1 not query 2`, which indicates the results that match `query 1` but do not match `query 2`. This format is equivalent to `query 1 - query 2`. **Note** If you use only `not query 1`, the log data that does not contain the query results of `query 1` is returned.

27.1.6.6. Settings

27.1.6.6.1. Install the Server Guard agent

This topic describes how to install the Server Guard agent by specifying parameters.

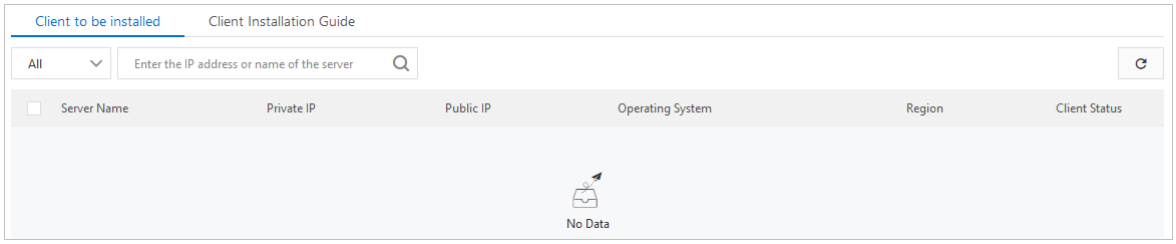
Context

To use the protection services provided by Server Guard, you must install the Server Guard agent on the operating system of your server.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Server Settings > Client Installation**.
3. (Optional)On the Client Installation page, click the **Client to be installed** tab to view the number of servers on which the Server Guard agent is not installed. On this tab, you can also view the relevant information in the server list.

   You can specify the operating system type, IP address, or server name to search for a target server.



4. Click the **Client Installation Guide** tab.
5. Obtain and install the Server Guard agent based on the operating system type of your server.
   - **Windows**
     a. In the left-side pane of the page, click **Click to download** to download the client software package to your computer.
     b. Upload the installation package to your server. For example, you can use an FTP client to upload the package to your server.
     c. Run the installation package on your server as an administrator.

     > **Note** When you install the agent on a server that is not in Alibaba Cloud, you will be prompted to enter the installation verification key. You can find the installation verification key on the Server Guard agent installation page.

   - **Linux**
     a. In the right-side pane of the page, select Alibaba Cloud Server or Non-Alibaba Server.
     b. Select the installation command for your 32-bit or 64-bit operating system and click **Copy** to copy the command.
     c. Log on to your Linux server as an administrator.
     d. Run the installation command on your Linux server to download and install the Server Guard agent.

27.1.6.6.2. Manage protection modes

This topic describes how to manage protection modes for each server to make them more efficient and secure.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Server Settings > Protection Mode**.
3. On the Protection Mode page, click **Manage**.

   Configure protection modes for each server.
   - **Business First Mode**: The peak CPU utilization is less than 10%, and the peak memory usage is less than 50 MB.
   - **Protection First Mode**: The peak CPU utilization is less than 20%, and the peak memory usage is less than 80 MB.
4. Click **OK**.

27.1.7. Physical server security

27.1.7.1. Create and grant permissions to a security administrator account

The physical server security feature is used to ensure the security of physical servers on the platform side. This feature requires you to use a dedicated security administrator account for the platform. This topic describes how to create and grant permissions to a security administrator account.

Procedure

1. Log on to the Apsara Uni-manager Management Console as a system administrator.

   For more information, see the **"Log on to the Apsara Uni-manager Management Console"** topic of *Apsara Uni-manager Management Console User Guide*.

2. Create a dedicated organization that is used to manage the security of physical servers, and obtain the primary key of the organization.

   > **Notice** Make sure that the organization is used only to manage the security of physical servers. Do not add Elastic Compute Service (ECS) instances to the organization.

   i. Create the dedicated organization.

      For more information, see **Enterprise Center > Organization Management > Create Organization** in *Apsara Uni-manager Management Console User Guide*.

   ii. Obtain the **primary key** of the newly created organization.

      For more information, see **Enterprise CenterOrganization ManagementObtain the AccessKey pair of an organization** in *Apsara Uni-manager Management Console User Guide*.

3. Create a dedicated account to manage the security of physical servers.

   For more information, see **Enterprise Center > User Management > System User Management > Create User** in *Apsara Uni-manager Management Console User Guide*.

   > **Note** When you create the account, take note of the following points for the **organization** and **role**:
   >
   > - In the **Organization** section, select the organization that is created in the previous step.
   > - In the **Role** section, select **Platform Security Configuration Administrator** and **Security System Configuration Administrator**.

4. Log on to Apsara Stack Security Center by using the newly created account.

   For more information, see Log on to Apsara Stack Security Center.

5. Add the **primary key** of the newly created organization to the protection configuration of physical servers.

   i. In the left-side navigation pane, choose **Security Management Center (SOC) > System Configuration > Global Settings**.

   ii. On the **Global Settings** page, click the **Physical Server Protection** tab.

   iii. Click **Add Account**.

   iv. In the **Add Account** dialog box, specify the **Username** and **Primary Key** parameters.

   - **Username**: Enter the account that you created in Step 3.
   - **Primary Key**: Enter the primary key that you obtained in Step 2.

v. Click **OK**.

Result

After you complete the configuration, the **Physical Server Security** feature appears in the left-side navigation pane of Apsara Stack Security. Then, you can use the account created in this topic to maintain the security of physical servers.

27.1.7.2. View the information on the Overview page

Security administrators can view the security status of all physical servers on the Overview page of Apsara Stack Security.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Overview**.
3. On the **Overview** page, view the security status of your physical servers.
   - Security event statistics: displays the numbers of security events on the physical servers. Security events include unusual logons, webshells, and server exceptions.
   - **Events**: displays the trends of security events on the physical servers. A security event is an intrusion event that is detected on a physical server.
   - **Protection Status**: displays the number of physical servers that are protected and the number of offline physical servers.
   - **Recent Important Events**: displays the recent important security events that are detected on the physical servers. You can click a security event to view its details.

27.1.7.3. Physical servers

27.1.7.3.1. Manage physical server groups

This topic describes how to manage physical server groups. To facilitate the security management of physical servers, you can add the physical servers to groups and view their security events by group.

Context

If you do not add a physical server to a server group, the physical server does not belong to a server group by default. If you delete a group, all the physical servers in the group no longer belong to a server group.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Physical Servers**.
3. In the left-side group section, manage sever groups.
   - Create a group.

     Click the Add Subgroup icon next to **All Servers** or a specific group, enter a group name, and click **OK**.

> **Note** The system supports a maximum of three levels of groups.

- Modify a group.

  Click the Modify Group Name icon next to the target group, enter a new name, and click **OK**.

- Delete a group.

  Click the Delete icon next to the target group. In the message that appears, click **OK**.

  > **Note** After you delete a group, all servers in the group are automatically moved to the **default** group.

- Sort groups.

  Click **Manage Groups** to sort groups in descending order by priority.

4. Change the server group of specific physical servers.
   i. Select servers from the list on the right.
   ii. Click **Change Group**.
   iii. In the Change Group dialog box that appears, select a group from the drop-down list.
   iv. Click **OK**.

27.1.7.3.2. Manage physical servers

This topic describes how to manage servers. On the Servers page, you can view the status of servers protected by Server Guard.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Servers**.
3. (Optional)Search for a server.

   To view the agent status of a server, enter the server IP address in the search bar, and click **Search**. Detailed server information, such as security information, is displayed.

4. View the agent status and detailed security information of the server.

   Click

   in the upper-right corner of the page to select the information columns you want to display. The following table lists the information categories.

Category	Information
Basic information	○ Server IP/Name ○ Tag ○ OS ○ Region
Agent status	Agent Status

Category	Information
Threat prevention	○ Vulnerability ○ Baseline Risk
Intrusion detection	○ Unusual Logons ○ Webshells ○ Suspicious Servers
Server fingerprints	○ Processes ○ Ports ○ Root Accounts/Total Accounts

5. Manage servers.

Action	Description
Change Group	Select servers and click **Change Group** to add the selected servers to a new group.
Modify Tag	Select servers and click **Modify Tag** to modify tags for the servers.
Security Inspection	Select servers and click **Security Inspection** to select the items to be checked.
Delete External Servers	Select **external** servers, and choose **More > Delete External Servers**.
Disable Protection	Select the servers whose agent status is **Online**, and choose **More > Disable Protection**. This temporarily disables protection for these servers to reduce server resource consumption.
Enable Protection	Select the servers whose agent status is **Disable Protection**, and choose **More > Enable Protection**. This enables protection for these servers.

27.1.7.4. Intrusion detection

27.1.7.4.1. Configure policies to identify unusual logons

This topic describes how to configure logon security. You can set approved locations, IP addresses, time periods, and accounts for logons.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Intrusion Detection**.
3. Click the **Unusual Logons** tab.
4. Click **Logon Security** in the upper-right corner of the page.
5. Set approved logon locations.

To add an approved logon location, follow these steps:

i. Click **Add**.
ii. Select a logon location from the drop-down list.
iii. Specify the servers on which the selected logon location takes effect.
   - Click **All Servers** to select specific servers.
   - Click **Server Groups** to select servers by group.
iv. Click **OK**.

> **Note** Click **Modify** or **Delete** to modify or delete an approved logon location.

6. Set approved logon IP addresses.

   Turn on the **Disapproved IP Alert** switch. The switch is turned on if it turns green.

   To add an approved logon IP address, follow these steps:

   i. Click **Add**.
   ii. In the **Specify an Approved Logon IP** section, enter an IP address.
   iii. Specify the servers on which the specified IP address takes effect.
      - Click **All Servers** to select specific servers.
      - Click **Server Groups** to select servers by group.
   iv. Click **OK**.

   Click **Modify** or **Delete** to modify or delete an approved logon IP address.

7. Set approved logon time periods.

   Turn on the **Disapproved Time Alert** switch. The switch is turned on if it turns green.

   To add an approved logon time period, follow these steps:

   i. Click **Add**.
   ii. In the **Specify an Approved Logon Duration** section, specify a time period.
   iii. Specify the servers on which the specified logon time period takes effect.
      - Click **All Servers** to select specific servers.
      - Click **Server Groups** to select servers by group.
   iv. Click **OK**.

   Click **Modify** or **Delete** to modify or delete an approved logon time period.

8. Set approved accounts.

   Turn on the **Disapproved Account Alert** switch. The switch is turned on if it turns green.

   To add an approved account, follow these steps:

   i. Click **Add**.
   ii. In the **Specify an Approved Account** section, enter an account.
   iii. Select the servers on which the specified account takes effect.
      - Click **All Servers** to select specific servers.
      - Click **Server Groups** to select servers by group.
   iv. Click **OK**.

   Click **Modify** or **Delete** to modify or delete an approved account.

What's next

After you configure policies to identify unusual logons, you can view and handle unusual logons on the **Unusual Logons** tab. For more information, see Handle unusual logons.

27.1.7.4.2. Handle unusual logons

This topic describes how to handle unusual logons. The unusual logons include logons from disapproved locations or IP addresses, logons by using brute-force attacks or disapproved accounts, and logons at a disapproved time.

Context

For more information about the policies that are configured to identify unusual logons, see Configure policies to identify unusual logons.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Intrusion Detection**.
3. Click the **Unusual Logons** tab.
4. (Optional)Specify the filter conditions to locate unusual logons. The filter conditions include **Asset**, **Alert Type**, and **Status**.

   > **Note** If you skip this step, all unusual logons appear in the event list.

5. In the event list, view and handle unusual logons.

   Check whether an unusual logon is a false positive.

   - If the unusual logon is a false positive, click **Ignore**.
   - If the unusual logon is not a false positive, harden the security of the physical server and click **Ignore**. To harden the security of the physical server, you can specify a more complex password, fix vulnerabilities, or check configuration items.

27.1.7.4.3. Handle webshell events

This topic describes how to view and handle webshell events.

Context

The webshell detection feature uses a webshell detection engine developed by Alibaba Cloud to detect and handle webshell files. The feature handles webshell files of the PHP and JSP types.

> **Note** By default, the system checks the web directories of all protected physical servers once a day. You can specify the servers that you want the system to check. For more information, see Configure security settings for physical servers.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Intrusion Detection**.
3. In the left-side navigation pane, choose **Physical Server Security > Intrusion Detection**.
4. Click the **Webshells** tab.
5. (Optional)Configure search conditions to search for webshell events. The search conditions include **Asset** and **Status**.

   > **Note** If you skip this step, all webshell events appear in the event list.

6. In the webshell event list, view and handle webshell events.

   Check whether a webshell event is a false positive based on the webshell information.

   - If the webshell event proves to be a false positive, click **Ignore**. The system no longer reports alerts for the webshell file.
   - If the webshell event is not a false positive, manually handle the webshell file.

27.1.7.4.4. Handle server exceptions

This topic describes how to view the alerts for server exceptions and handle the server exceptions.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Intrusion Detection**.
3. Click the **Server Exceptions** tab.
4. (Optional)Configure search conditions to search for server exceptions. The conditions include **Asset**, **Event Name**, **Event Type**, **Risk Level**, and **Status**.

   > **Note** If you skip this step, all server exceptions appear in the event list.

5. In the server exception list, view and handle server exceptions.

   Find a server exception and click **View** in the **Actions** column. Then, you can view the information about the server exception and check whether the server exception is a false positive.

   - If the server exception proves to be a false positive, click **Mark as False Positive**. The system no longer reports alerts for the server exception.
   - If the server exception does not affect the security of your servers, click **Ignore** to ignore the alert.
   - If the server exception affects the security of your servers, manually handle it and click **Confirm**.
   - If the server exception is marked as a false positive but affects the security of your servers, click **Cancel Marking as False Positive**. The system reports an alert for the server exception if the server exception is detected again.

27.1.7.5. Server fingerprints

27.1.7.5.1. Configure data refresh frequencies

You can configure the frequencies at which the data of running processes, system accounts, listening ports, and software versions is collected and refreshed.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Server Fingerprints**.
3. In the upper-right corner of the Server Fingerprints page, click **Configure**.
4. In the **Configure** dialog box, configure the data refresh frequencies for the listening ports, running processes, system accounts, and software versions.
5. Click **OK**.

27.1.7.5.2. View listening ports

Apsara Stack Security regularly collects information about listening ports on a server.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Server Fingerprints**.
3. Click the **Listening Port** tab.
4. (Optional)Specify **Port Number** and **Process Name**. Then, click **Search** to search for the specified port or process.

   > **Note** If you skip this step, all listening ports appear in the port list.

5. In the port list, view **Port Number**, **Network Protocol**, and **Servers**.
6. Click a port number to view the information about the assets and processes that are associated with the port.

27.1.7.5.3. View running processes

Apsara Stack Security regularly collects the process information of a server.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Server Fingerprints**.
3. Click the **Running Process** tab.
4. (Optional)Specify **Process Name** and **User** and click **Search** to search for the specified process or user.

   > **Note** If you skip this step, all processes appear in the process list.

5. In the process list, view **Process Name** and **Servers**.

6. Click the name of a running process to view the information about the assets, paths, and running users that are associated with the process.

27.1.7.5.4. View account information

Apsara Stack Security regularly collects the account information of a server.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Server Fingerprints**.
3. Click the **Account Information** tab.
4. (Optional)Specify **Username** and click **Search** to search for the specific account.

   > **Note** If you skip this step, all accounts appear in the account list.

5. In the account list, view **Account** and **Servers**.
6. Click the name of an account to view the information about the assets and user groups that are associated with the account. You can also check whether the account has root permissions

27.1.7.5.5. View software versions

This topic describes how to view the information about the software versions of physical servers. The information facilitates the management of software assets.

Context

This topic covers the following scenarios:

- Check for software assets that are installed without authorization.
- Check for outdated versions of software assets.
- Find affected assets if vulnerabilities are detected.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Server Fingerprints**.
3. Click the **All Versions** tab.
4. (Optional)Specify **Software Name**, **Version Name**, and **Software Installation Path**. Then, click **Search** to search for specific software.

   > **Note** If you skip this step, all software appears in the software list.

5. In the software list, view the information in the **Software Name** and **Hosts** columns.
6. Click the name of the software to view the host, version, and installation directory of the software.

27.1.7.6. Log retrieval

27.1.7.6.1. Supported log sources and fields

This topic describes the log sources and fields that are supported by the log retrieval feature.

The log retrieval feature allows you to query the following types of log sources. You can click a log source link to view the fields that can be retrieved.

Log source	Description
Logon history	Log entries about successful system logons.
Logs of brute-force attacks	Log entries about failed system logons during brute-force attacks.
Process snapshot logs	Log entries about processes on a server at a specific point in time .
Logs of listening port snapshots	Log entries about listening ports on a server at a specific point in time.
Account snapshot logs	Log entries about account-based logons on a server at a specific point in time.
Process startup logs	Log entries about process startups on a server.
Network connection logs	Log entries about active connections from a server to the Internet.

Logon history

You can query the logon history by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
warn_ip	string	The source IP address for the logon.
warn_port	string	The logon port.
warn_user	string	The username for the logon.
warn_type	string	The logon type.
warn_count	string	The number of logon attempts.

Logs of brute-force attacks

You can query logs about brute-force attacks by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
warn_ip	string	The source IP address of the attack.

Field	Data type	Description
warn_port	string	The target port.
warn_user	string	The target username.
warn_type	string	The type.
warn_count	string	The number of brute-force attack attempts.

Process startup logs

You can query process startup logs by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
pid	string	The ID of the process.
groupname	string	The user group.
ppid	string	The ID of the parent process.
uid	string	The ID of the user.
username	string	The username.
filename	string	The file name.
pfilename	string	The name of the parent process file.
cmdline	string	The command line.
filepath	string	The path of the process file.
pfilepath	string	The path of the parent process file.

Logs of listening port snapshots

You can query logs about listening port snapshots by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
src_port	string	The listening port.
src_ip	string	The listening IP address.
proc_path	string	The path of the process file.
pid	string	The ID of the process.

Field	Data type	Description
proc_name	string	The name of the process.
proto	string	The protocol.

Account snapshot logs

You can query account snapshot logs by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
perm	string	Indicates whether the user has root permissions.
home_dir	string	The home directory.
warn_time	string	The time at which a password expiration notification is sent.
groups	string	The group to which the user belongs.
login_ip	string	The IP address of the last logon.
last_chg	string	The time at which the password was last changed.
shell	string	The Linux shell command.
domain	string	The Windows domain.
tty	string	The logon terminal.
account_expire	string	The time at which the account expires.
passwd_expire	string	The time at which the password expires.
last_logon	string	The last logon time.
user	string	The username.
status	string	The account status. Valid values: • 0: disabled • 1: normal

Process snapshot logs

You can query process snapshot logs by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.

Field	Data type	Description
IP	string	The IP address of the server.
path	string	The path of the process file.
start_time	string	The time at which the process was started.
uid	string	The ID of the user.
cmdline	string	The command line.
pname	string	The name of the parent process.
name	string	The name of the process.
pid	string	The ID of the process.
user	string	The username.
md5	string	The MD5 hash of the process file. If the size of the process file exceeds 1 MB, the system does not calculate the MD5 hash value of the process file.

Network connection logs

You can query network connection logs by using the fields in the following table.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
src_ip	string	The source IP address.
src_port	string	The source port.
proc_path	string	The path of the process file.
dst_port	string	The destination port.
proc_name	string	The name of the process.
dst_ip	string	The destination IP address.
status	string	The status.

27.1.7.6.2. Logical operators

The log retrieval feature supports multiple search conditions. You can add multiple logical operators to one search condition for one log source, or combine multiple search conditions for several log sources by using different logical operators. This topic describes the logical operators that are supported in log retrieval. Examples are provided to help you understand these operators.

The following table describes the logical operators that are supported in log retrieval.

Logical operators

Logical operator	Description
and	Binary operator. This operator is in the format of `query 1 and query 2`, which indicates the intersection of the query results of `query 1` and `query 2`. **Note** If no logical operators are used for multiple keywords, the default operator is AND.
or	Binary operator. This operator is in the format of `query 1 or query 2`, which indicates the union of the query results of `query 1` and `query 2`.
not	Binary operator. This operator is in the format of `query 1 not query 2`, which indicates the results that match `query 1` but do not match `query 2`. This format is equivalent to `query 1 - query 2`. **Note** If you use only `not query 1`, the log data that does not contain the query results of `query 1` is returned.

27.1.7.6.3. Query logs

This topic describes how to query and view the logs of physical servers.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   Note For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Log Retrieval**.
3. Specify search conditions.

   Note For more information about log sources, log fields, and logical operators, see Supported log sources and fields and Inference rules and logical operators.

4. Click **Search** and view the search result.
   - **Reset**: You can click **Reset** to clear the search condition configuration.
   - **Save Search**: You can click **Save Search** to save the search condition configuration for future use.
   - **Saved Searches**: You can click **Saved Searches** to select and apply a saved search condition configuration.

27.1.7.7. Configure security settings for physical servers

This topic describes how to configure security settings for physical servers. You can enable or disable periodic trojan scans. You can also configure the working mode of the Server Guard agent for physical servers.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Settings**.
3. Enable periodic trojan scans for physical servers.
   i. Click **Manage** in the Trojan Scan section.
   ii. Select the physical servers on which you want to perform periodic trojan scans from the All Servers section. Then, click the rightwards arrow.
   iii. Click **OK**.
4. On the **Protection First Mode** page, click **Manage** next to Protection Mode.

   Configure protection modes for servers.

   - **Business First Mode**: In this mode, the peak CPU utilization is less than 10%, and the peak memory usage is less than 50 MB.
   - **Protection First Mode**: In this mode, the peak CPU utilization is less than 20%, and the peak memory usage is less than 80 MB.

27.1.8. Application security

27.1.8.1. Quick start

This topic helps you get started with Web Application Firewall (WAF).

WAF uses intelligent semantic analysis algorithms to identify web attacks. WAF also integrates a learning model to enhance its analysis capabilities and meet your daily security protection requirements without relying on traditional rule libraries.

The following content describes the procedure for using WAF:

1. Customize WAF protection rules.

   WAF provides a default protection policy. You can also customize policies that suit your business requirements.

   - For more information about how to configure protection policies, see Configure protection policies.
   - For more information about how to configure custom rules, see Create a custom rule.
   - For more information about how to configure HTTP flood protection rules, see Configure an HTTP flood protection rule.

2. Add protected websites.

   WAF can protect Internet websites and virtual private cloud (VPC) websites.

   - For more information about how to add an Internet website to WAF for protection, see Add an Internet website for protection.
   - For more information about how to add a VPC website to WAF for protection, see Add a VPC website for protection.

3. Configure Domain Name System (DNS) resolution.

   For more information about how to change the DNS-resolved source IP address of a website to a virtual IP address of WAF, see Modify DNS resolution settings.

4. View WAF protection results.

- For more information about how to view the protection overview, see View protection overview.
- For more information about how to view the service access information, see View Web service access information.
- For more information about how to view the detection logs for web attacks, see View attack detection logs.
- For more information about how to view the detection logs for HTTP flood attacks, see View HTTP flood protection logs.

27.1.8.2. Detection overview

27.1.8.2.1. View protection overview

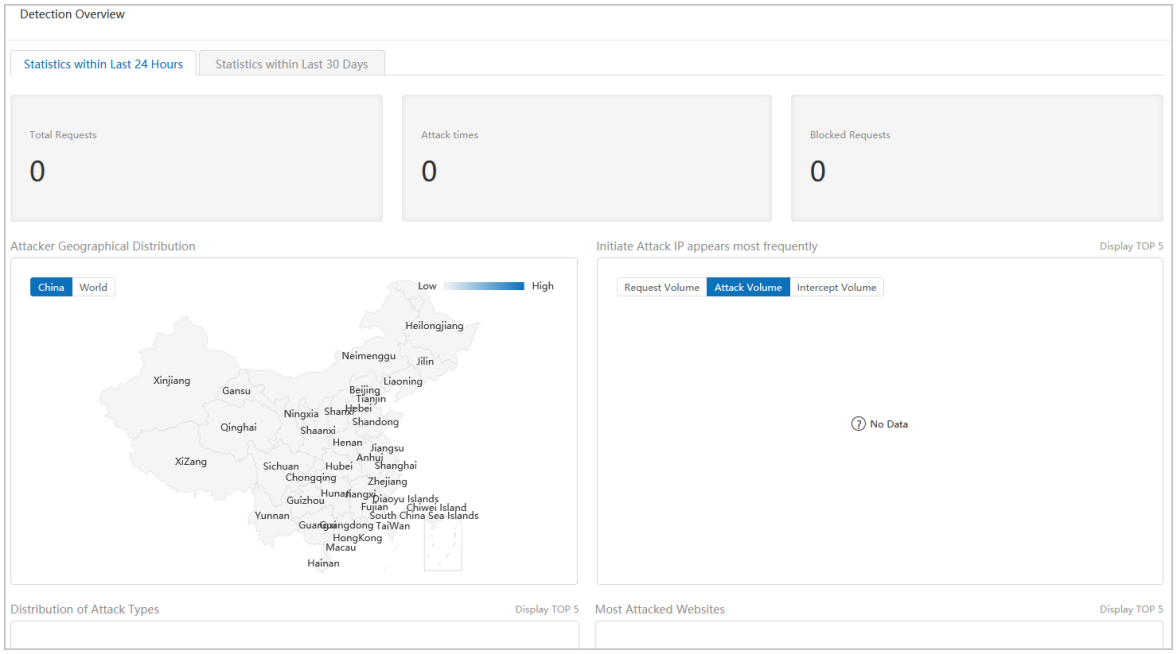
This topic describes how to view the Web Application Firewall (WAF) protection overview.

Context

The Detection Overview page displays information such as the statistics of previous attacks, the geographical distribution of attackers, the number of total requests, and the number of blocked requests. You can also view details about the attacks. This way, you can customize rules to protect your web services.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree, choose **Detection Overview > Detection Overview**.
4. On the **Detection Overview** page, you can view **Statistics within Last 24 Hours** and **Statistics within Last 30 Days**.



- Total Requests

  Displays the total number of requests.

- Attack times

  Displays the total number of attacks.

- Blocked Requests

  Displays the number of blocked requests.

- Geographical distribution of attackers on a map

  Displays the distribution of attackers on a map. You can select a map of China or a map of the world.

  Displays both the numbers of total requests and blocked requests.

- Distribution of the top five IP addresses that initiate attacks

  Displays the top five IP addresses that have launched the most attacks in a bar chart. The x-axis indicates the numbers of requests. The y-axis indicates the IP addresses.

- Distribution of the top five attack types

  Displays the distribution of the top five attack types and the number of attacks of each type in a pie chart.

- Top five attacked websites

  Displays the top five attacked websites and the number of attacks on each website in a bar chart.

27.1.8.2.2. View access information about web services

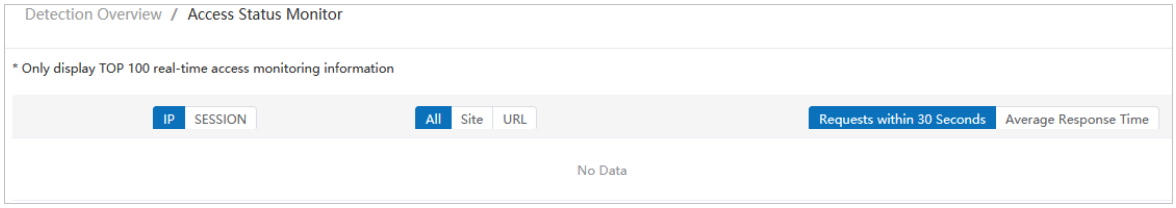
This topic describes how to view access information about web services.

Context

Web Application Firewall (WAF) monitors the access of web services. This allows security administrators to analyze the service access information and detect vulnerabilities.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. On the Detection Overview page, choose **Detection Overview > Access Status Monitor**.
4. Filter the access records to view the details.



27.1.8.3. Protection logs

27.1.8.3.1. View attack detection logs

This topic describes how to view attack detection logs.

Context

These logs allow you to analyze attacks on your web services. You can update the attack detection policies, custom rules, and fix the web service vulnerabilities based on the analysis results.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.

3. In the left-side navigation tree, choose **Detection Logs > Attack Detection Logs**.
4. Click **Filter**, specify filter conditions, and then click **OK**.

   > **Note** If you specify multiple conditions, all the conditions must be met.

5. View the attack detection logs.

27.1.8.3.2. View HTTP flood protection logs

This topic describes how to view HTTP flood protection logs.

Context

These logs allow you to analyze HTTP flood attacks on your web services. Based on the analysis, you can update the HTTP flood protection rules and HTTP flood whitelist and fix the web service vulnerabilities.

Procedure

1.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree, choose **Detection Logs > HTTP Flood Detection Logs**.
4. Click **Filter**, specify filter conditions, and then click **OK**.

   > **Note** If you specify multiple conditions, all of the conditions must be met.

5. View the HTTP flood detection result.

   The blocked HTTP flood attacks, related rules, and attack time are displayed.

27.1.8.3.3. View system operation logs

This topic describes how to view system operation logs.

Procedure

1.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree, choose **Detection Logs > System operation log**.
4. View the system operation logs.

   The usernames, content, IP addresses, and creation time are displayed.

27.1.8.3.4. View access logs

This topic describes how to view access logs.

Procedure

1.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. On the Detection Overview page, choose **Detection Logs > Access Log**.
4. Click **Filter**, specify filter conditions, and then click **OK**.

> **Note** If you specify multiple conditions, they use the AND logic. The system returns the required access logs only when all the conditions are met.

5. View the access logs.

   The requested IP addresses, destination IP addresses, source IP addresses, methods, and response codes are displayed.

27.1.8.4. Protection configuration

27.1.8.4.1. Configure protection policies

This topic describes how to configure Web Application Firewall (WAF) protection policies.

Context

WAF provides a default protection policy. You can also customize protection policies to suit your business requirements.

Procedure

1.
2. In the left-side navigation pane, choose **Application Security > WAF > Protection Configuration > Website Protection Policies**.
3. Click **Add protection policy**. In the panel that appears, specify **Policy name** and click **Confirm**.
4. In the **Operation** column of the new protection policy, click the icon to view details.

Parameter	Description
Decode	Select algorithms that you want to use to decode the requests.
Attack Detection Modules	Specify the types of attacks that you want to detect and the risk levels of attacks that you want to block.
Block Options	Specify the HTTP status code and image that you want WAF to return when it blocks an attack.
HTTP Response Processing	Specify **Enable HTTP response processing** and **Response Detection Max Body Size**.
HTTP Request Body Detection	Specify **Response Detection Max Body Size**.
Detection Timeout	Specify **Enable Detection Timeout** and **Timeout Threshold**.

For example, perform the following steps to configure modules in the **Attack Detection Modules** section:

i. Move the pointer over a specific module in the **Attack Detection Modules** section. For this example, move the pointer over **SQL Injection Detection Module** and click the **modify** icon.

ii. In the **SQL Injection Detection Module** dialog box, configure the following parameters.

Parameter	Description
Enabled	Indicates whether to enable the detection module.
Blocking Threshold	Valid values: **NotForbid**, **Only ForbidHigh Risk**, **ForbidMedium or High Risk**, and **Forbid All**.
Record Threshold	Valid values: **Notrecord**, **Onlyrecord High Risk**, **recordMedium or High Risk**, and **record All**.
Detect Non-Injected SQL	Indicates whether to enable detection for NoSQL injection vulnerabilities.

iii. Click **OK**.

5. Manage the protection policy.

   To delete a protection policy, click the protection policy first. Then, in the upper-right corner, choose **More > Delete Selected Protection Policies**. In the dialog box that appears, click **OK**.

   > **Note** You cannot delete the default protection policy.

27.1.8.4.2. Create a custom rule

This topic describes how to create a custom rule for Web Application Firewall (WAF).

Context

You can create custom rules to meet the different requirements for intrusion detection. You can create, edit, or delete custom rules in the WAF console as an administrator. You can use custom rules to filter out requests that meet specific conditions.

Multiple custom rules use the **OR** logic. If two custom rules use the same conditions but trigger different actions such as blocking traffic or allowing traffic, the system runs the first rule.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF > Protection Configuration > Customized Rules**.
3. In the upper-right corner, click **Add Rule**. In the **Add Customized Rule** panel, configure the parameters.

   Parameters for the creation of a custom rule

Parameter	Description
Type	The operating mode of the rule. Valid values: **Block**, **Allow**, **Monitor**, and **Detection module control**. ○ **Block**: If an HTTP request meets the conditions of the rule, the HTTP request is blocked. ○ **Allow**: If an HTTP request meets the conditions of the rule, the HTTP request is allowed. ○ **Monitor**: If an HTTP request meets the conditions of the rule, the HTTP request is recorded and allowed. ○ **Detection module control**

Parameter	Description
Remarks	The remarks about the rule, such as the purpose of the rule.
Risk Level	The risk level. Valid values: **No threat**, **Low Risk**, **Medium Risk**, and **High Risk**.
Matching Pattern	The conditions that trigger the rule. Click **Add Pattern** to specify more than one condition. Multiple conditions use the **AND** logic. The custom rule takes effect only if all conditions are met.
Apply to Websites	The websites that you want the rule to protect.
Log Recording Option	Whether to record a protection event in the intrusion detection logs when the rule is triggered. The default value is Enable Log Recording. After Log Recording Option is set to Enable Log Recording, all interception events are recorded in the intrusion detection logs.
Attack Type	The type of attack that you want the rule to block.
Expiration Time	The time at which the rule expires.

4. Click **Confirm**.
5. Manage the custom rule.
   - Edit the rule.

     To edit the rule, click the icon in the **Actions** column.
   - Enable the rule.

     To enable the rule, select the rule and click **Enable Selected Rules**.
   - Disable the rule.

     To disable the rule, select the rule and click **Disable Selected Rules**.
   - Delete the rule.

     To delete the rule, select the rule and click **Delete Selected Rules**.

27.1.8.4.3. Configure an HTTP flood mitigation rule

This topic describes how to configure an HTTP flood mitigation rule.

Context

An HTTP flood attack is a type of distributed denial of service (DDoS) attack that targets web applications. Attackers use proxy servers or zombies to overwhelm targeted web servers by sending a large number of HTTP requests.

Create an HTTP flood mitigation rule

1.
2. In the left-side navigation pane, choose **Application Security > WAF > Protection Configuration > HTTP Flood Detection**.
3. Click **Add Rule**. The **Add HTTP Flood Detection Rules** panel appears.
4. Configure parameters and click **Confirm**.

Parameter	Description
Rule Mode	The action on requests after the HTTP flood mitigation rule is triggered. Valid values: **Blocking Mode** and **Observe**. ○ Blocking Mode: blocks the requests that trigger the HTTP flood mitigation rule. ○ Observe: records the requests that trigger the HTTP flood mitigation rule, but does not limit the requests.
Rule Types	The type of the HTTP flood mitigation rule. Valid values: **Restrict Users by Policy** and **Restrict Known Users**. The difference between the two types is determined by whether requests of users are initiated from a specific IP address or in a specific session. ○ **Restrict Users by Policy**: limits requests that meet all the configuration items of the HTTP flood mitigation rule. Configuration items include **Restriction Trigger Threshold**, **Restricted URL Address**, **Restriction Mode**, **Restriction Time**, and **Statistical Range of Visits** in the Advanced section. ○ **Restrict Known Users**: limits requests that are initiated from specific IP addresses or in specific sessions based on the HTTP flood mitigation rule. To achieve this purpose, you must configure the IP address or session list and the restriction mode. After you configure the list, the HTTP flood mitigation rule limits requests based on the list.
Rule Name	The name of the HTTP flood mitigation rule.
Target Type	The type of sources for requests that are blocked. Valid values: **IP** and **Session**. **Note** You can set **Target Type** to **SESSION** only for a website to which the HTTP mitigation rule is applied and whose **User Identification** is set to **WAF User System**. For more information, see Add an Internet website for protection.
Restriction Trigger Threshold	If **Rule Types** is set to **Restrict Users by Policy**, you must configure the triggering conditions for the HTTP flood mitigation rule.
Restricted URL Address	If **Rule Types** is set to **Restrict Users by Policy**, you must specify the URL addresses to which requests are blocked based on the HTTP flood mitigation rule. ○ **URL Prefix** ○ **URL** ○ **Record all IP addresses**
Restricted IP List or **Restricted Session List**	If **Rule Types** is set to **Restrict Known Users**, enter the IP addresses or sessions from which you want to block requests based on the setting of **Target Type**. Specify only one IP address or session in each line.

Parameter	Description
Restricted URL Address	If **Rule Types** is set to **Restrict Known Users**, you must specify the URL addresses to which requests are blocked based on the HTTP flood mitigation rule. ○ **URL Prefix** ○ **URL** ○ **Restrict user access to all addresses**
Restriction Mode	The mode in which the HTTP flood mitigation rule limits requests. Valid values: ○ **Forbidden**: The rule blocks specific sources from accessing the specified URL address. ○ **Frequency control**: The rule limits the frequency at which specific sources access the specified URL address.
Restriction Time	The time at which the HTTP flood mitigation rule takes effect.
Statistical Range of Visits	If **Rule Type** is set to **Restrict Users by Policy**, you can specify the range of the limited requests that you want to analyze in the Advanced section. ○ Statistics Full Access Data: If you select this option, the HTTP flood mitigation rule applies to the requests that are redirected by WAF. If these requests meet the rule, they are limited. This decreases system performance. ○ Statistics TOP Access Data: If you select this option, the frequency of the requests that access the top 100 data records is limited. This option helps minimize the decrease in system performance. You can select this option when the number of accessed data records is larger than 100. Note that the top 100 data records are measured based on real-time monitoring.

Manage HTTP flood mitigation rules

1.
2.
3. In the rule list, manage existing HTTP flood mitigation rules.
   - Search for a rule.

     Click **Filter** and specify filter conditions to find a rule.
   - Enable a rule.

     Select a rule that is in the Disabled state and choose **More > Enable Selected Rules**.
   - Disable a rule.

     Select a rule that is in the Enabled state and choose **More > Disable Selected Rules**.
   - Delete a rule.

     Select a rule and choose **More > Delete Selected Rules**.

27.1.8.4.4. Configure an HTTP flood whitelist

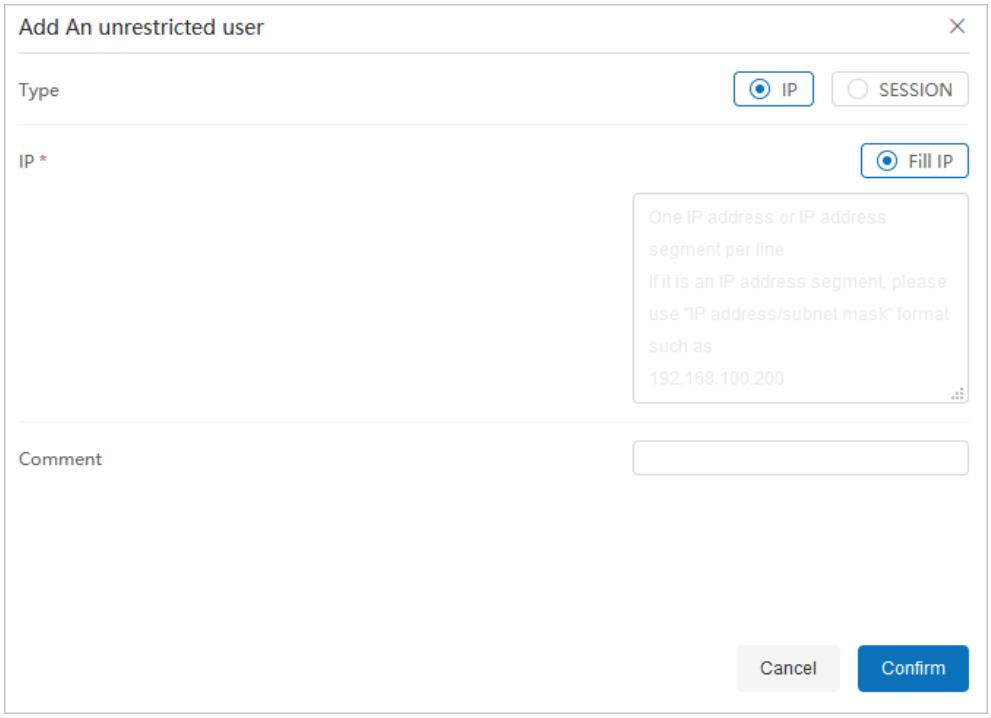
This topic describes how to configure an HTTP flood whitelist.

Context

If a request source is trusted, you can add this request source to an HTTP flood whitelist to allow the requests from this source.

Procedure

1.
2. In the left-side navigation pane, choose **Application Security > WAF > Protection Configuration > HTTP Flood Detection**. On the page that appears, click the **HTTP Flood Detection Whitelist** tab.
3. On the HTTP Flood Detection Whitelist tab, click **Add Whitelist Item** to add a request source to the whitelist. Then, click **Confirm**.



Parameter	Description
Type	Select the type of the request source. Valid values: **IP** or **Session**.
IP or **SESSION**	Specify the IP addresses or sessions based on the selected **Type**. Specify one IP address or session in each line.
Comment	Enter comments for the whitelist.

4. Manage the request sources in the whitelist.
   - Search for a request source in the whitelist.

     Click **Filter**. In the dialog box that appears, click **Add Filter Item** to find a request source.
   - Remove a request source from the whitelist.

     Select a request source and choose **More > Delete Selected Items**.

27.1.8.4.5. Manage SSL certificates

This topic describes how to upload or delete SSL certificates.

Context

After you upload an SSL certificate on the **SSL Certificate Management** page, you can select this certificate when you add an HTTPS website for protection.

> **Note** When you add an HTTPS website for protection on the **Protected Websites** page, you must select the SSL certificate that corresponds to the domain of the HTTPS website.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. On the Detection Overview page, choose **Protection Configuration > SSL Certificate Management**.
4. Upload a new certificate.
   i. Click **Upload SSL Certificate**.
   ii. In the **Add File** panel, specify **Name**.
   We recommend that you enter the domain name for easier management.
   > **Note** If your certificate and private key are in the same file, select **Include private key in certificate file**.
   iii. In the **File** section, upload the Certificate Authority (CA) certificate file and private key file.
   iv. Specify **Certificate Password**.
   v. Click **Confirm**.
5. (Optional)Delete the uploaded SSL certificate.
   You can delete expired SSL certificates.
   i. In the SSL certificate list, select the certificate that you want to delete.
   ii. Choose **More > Delete selected SSL Certificates**.
   iii. In the dialog box that appears, click **Confirm**.

27.1.8.4.6. Add Internet websites for protection

This topic describes how to add Internet websites to Web Application Firewall (WAF).

Context

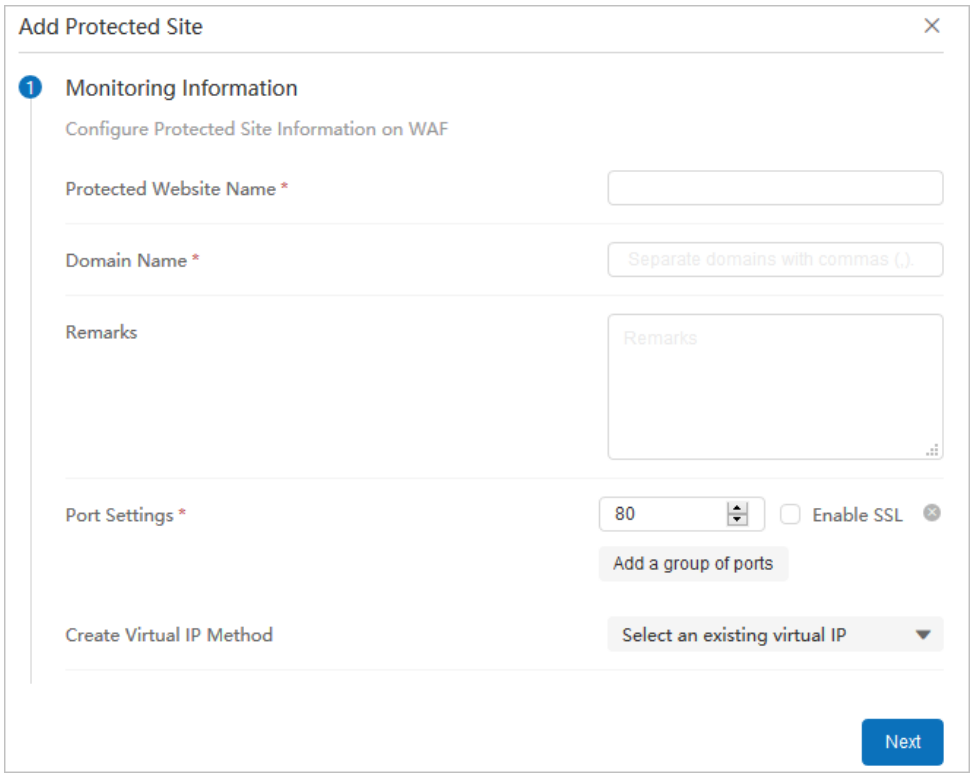
WAF can protect the following types of websites:

- Internet websites.
- Virtual Private Cloud (VPC) websites. For more information about how to add a VPC website to WAF, see Add a VPC website for protection.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree, choose **Protection Configuration > Protection Site Management**. On the page that appears, click the **Internet Websites** tab.
4. In the upper-right corner, click **Add a site**. The Add Protected Site panel appears.
5. In the Monitoring Information step, configure parameters and click **Next**.

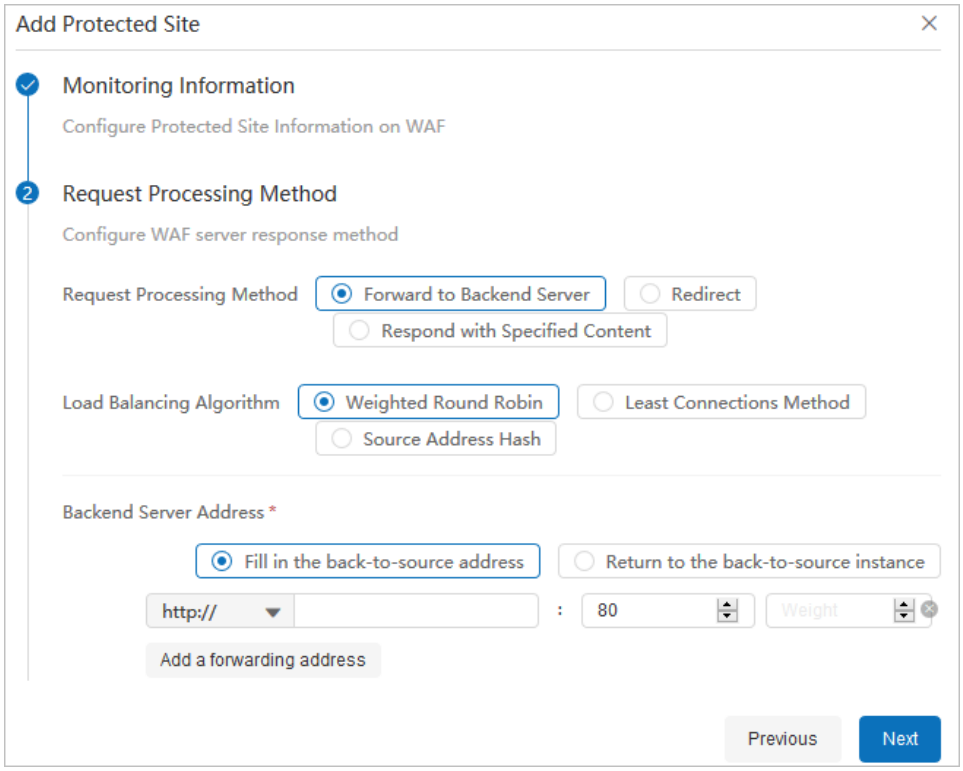
Specify the Internet website that you want WAF to protect. WAF can protect both HTTP and HTTPS websites.



Parameter	Description
Protected Website Name	The name of the website that you want WAF to protect.
Domain Name	The domain name of the website. ○ You can use an asterisk (*) as a wildcard. ○ If you specify multiple domain names, separate them with commas (,).
Port Settings	The port that WAF listens on. ○ If the website supports HTTPS requests, select **Enable SSL** and upload an HTTPS certificate. ○ If the website can be accessed over multiple ports, click **Add a group of ports** to add the required ports.

Parameter	Description
Cert Settings	The HTTPS certificate of the website. Valid values: *Upload a New Certificate* and *Choose an Existing Certificate*. ◦ *Upload a New Certificate*: If the HTTPS certificate used by the website has not been uploaded to WAF, select this option. By default, the HTTPS certificate and private key are separately uploaded. If you select **Include private key in certificate file**, upload only a file that contains both the HTTPS certificate and private key. ◦ *Choose an Existing Certificate*: If the HTTPS certificate used by the website has been uploaded to WAF, select this option. Then, select the required HTTPS certificate from the drop-down list. **Note** Specify this parameter only if you select **Enable SSL** next to the **Listening Port** field.
Name	The name of the HTTPS certificate. **Note** Specify this parameter only if you select **Enable SSL** next to **Port Settings** and set Cert Setting to Upload a New Certificate.
File	The HTTPS certificate and private key. By default, the HTTPS certificate and private key are separately uploaded. If you select **Include private key in certificate file** next to **Name**, upload only a file that contains both the HTTPS certificate and private key. **Note** Specify this parameter only if you select **Enable SSL** next to **Port Settings** and set Cert Setting to Upload a New Certificate.
Virtual IP	The IP address type and virtual IP address. **Note** You can select an IPv6 address as the virtual IP address of WAF. By default, WAF provides 10 virtual IP addresses. However, you can add more virtual IP addresses based on your business requirements. **Note** A virtual IP address is available only for the department to which the creator of the virtual IP address belongs.

6. In the Request Processing Method step, configure parameters and click **Next**.



Response mode	Parameter	Description
Forward to Backend Server	**Load Balancing Algorithm**	The algorithm for load balancing. Valid values: **Weighted Round Robin**, **Source Address Hash**, and **Least Connections Method**.
	Backend Server Address	The IP address of the origin server to which WAF forwards inbound traffic. Valid values: **Fill in the back-to-source address** and **Return to the back-to-source instance**. ○ **Fill in the back-to-source address**: Enter the address of the origin server. If you enter multiple addresses, load balancing is performed based on the specified **load balancing algorithm**. ○ **Return to the back-to-source instance**: Enter the address of a specific ECS or SLB instance. If you enter multiple addresses, load balancing is performed based on the specified **load balancing algorithm**.
	X-Forwarded-For	The passthrough mode of the actual source IP address. The X-Forwarded-For (XFF) HTTP header is used to identify the actual source IP address of an HTTP request. The X-Forwarded-For (XFF) HTTP header is used for request forwarding services, such as HTTP proxy and load balancing.

Response mode	Parameter	Description
Redirect	**Response Status Code**	The HTTP status code that WAF returns when it forwards inbound traffic to a specific URL. Valid values: **301**, **302**, and **307**. ○ **301**: The requested page has been permanently moved to another URL. ○ **302**: The requested page has been temporarily moved to another URL. The requester must continue to use the original URL for future requests. ○ **307**: The requested page has been temporarily moved to another URL. The requester must continue to use the original URL for future requests.
	Redirect address	The required URL of redirection.
Respond with Specified Content	**Response Status Code**	The HTTP status code that WAF returns when it forwards a response with specified content. Valid values: **200**, **404**, and **503**.
	Response	The content of the response. For example, you can upload an image for the **Response** parameter. When a user visits the website, WAF returns the uploaded image.

7. In the Protection Policy step, configure parameters and click Next. Then, go to the **Finish** step.

> **Note** You can configure a protection policy only if **Request Processing Method** is set to **Forward to Backend Server**.

Parameter	Description
Protection Policy	Select a WAF protection policy. For more information, see Configure protection policies.
User Identification	Specify whether to enable the user identification feature. **Note** If you enabled HTTP flood mitigation for the protected website and set **Target Type** to **Session** when you configured request limits, you must set **User Identification** to **WAF User System**.

27.1.8.4.7. Add VPC websites for protection

This topic describes how to add Virtual Private Cloud (VPC) websites to Web Application Firewall (WAF) for protection.

Context

WAF can protect the following types of websites:

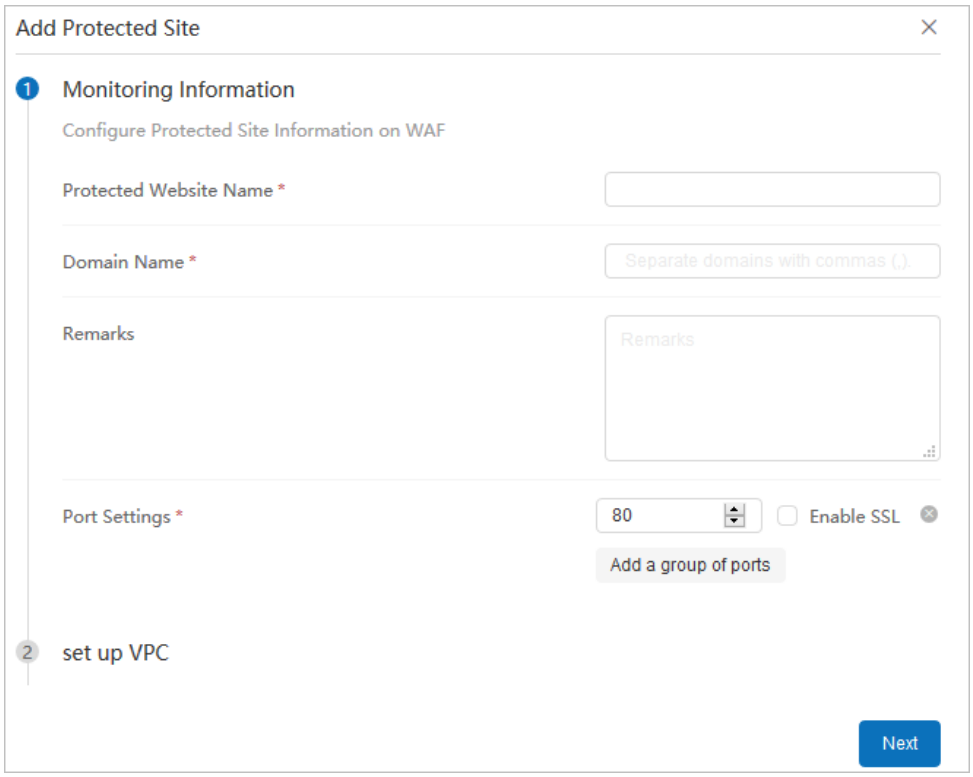
- Internet websites. For more information about how to add an Internet website for protection, see Add an Internet website for protection.

- VPC websites.

Procedure

1.
2. In the left-side navigation pane, choose **Application Security > WAF > Protection Configuration > Protection Site Management**. On the page that appears, click the **VPC Websites** tab.
3. In the upper-right corner, click **Add a site**. The **Add Protected Site** panel appears.
4. In the Monitoring Information step, configure parameters and click **Next**.

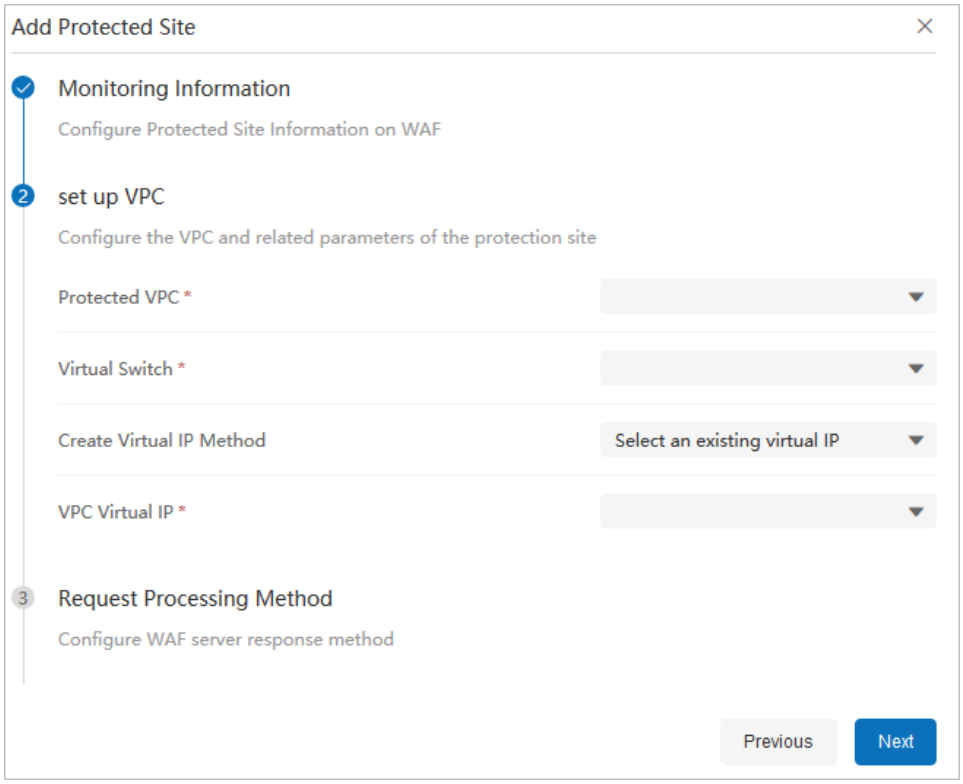
   Specify the VPC website that you want WAF to protect. WAF can protect both HTTP and HTTPS websites.



Parameter	Description
Protected Website Name	The name of the website that you want WAF to protect.
Domain Name	The domain name of the website. ○ You can use an asterisk (*) as a wildcard. ○ If you specify multiple domain names, separate them with commas (,).
Port Settings	The port that WAF listens on. ○ If the website supports HTTPS requests, select **Enable SSL** and upload an HTTPS certificate. ○ If the website can be accessed over multiple ports, click **Add a group of ports** to add the specific ports.

Parameter	Description
Cert Settings	The HTTPS certificate of the website. Valid values: **Upload a New Certificate** and **Choose an Existing Certificate**. **Note** Specify this parameter only if you select **Enable SSL** next to **Port Settings**. ○ **Upload a New Certificate**: If the HTTPS certificate used by the website has not been uploaded to WAF, select this option. By default, the HTTPS certificate and private key are separately uploaded. If you select **Include private key in certificate file**, upload only a file that contains both the HTTPS certificate and private key. ○ **Choose an Existing Certificate**: If the HTTPS certificate used by the website is uploaded to WAF, select this option. Then, select the specific HTTPS certificate from the drop-down list.
Name	The name of the HTTPS certificate. **Note** Specify this parameter only if you select **Enable SSL** next to **Port Settings** and set Cert Setting to Upload a New Certificate.
File	The HTTPS certificate and private key to upload. By default, the HTTPS certificate and private key are separately uploaded. If you select **Include private key in certificate file** next to **Name**, upload only a file that contains both the HTTPS certificate and private key. **Note** Specify this parameter only if you select **Enable SSL** next to **Port Settings** and set Cert Setting to Upload a New Certificate.

5. In the set up VPC step, configure parameters and click **Next**.



Parameter	Description
Protected VPC	The VPC to which the website belongs.
Virtual Switch	The vSwitch associated with the specified VPC.
Create Virtual IP Method	The method to create a virtual IP address. Valid values: **Select an existing virtual IP** and **Create virtual IP**.
VPC Virtual IP	◦ If you set **Create Virtual IP Method** to **Select an existing virtual IP**, select an existing virtual IP address from the **VPC Virtual IP** drop-down list. ◦ If you set **Create Virtual IP Method** to **Create virtual IP**, click **Click to Create Vip** next to **VPC Virtual IP** to generate a virtual IP address.

6. In the Request Processing Method step, configure parameters and click **Next**.

Response mode	Parameter	Description
	Load Balancing Algorithm	The algorithm for load balancing. Valid values: **Weighted Round Robin**, **Source Address Hash**, and **Least Connections Method**.

Response mode	Parameter	Description
Forward to Backend Server	**Backend Server Address**	The IP address of the origin server to which WAF forwards inbound traffic. Valid values: **Fill in the back-to-source address** and **Return to the back-to-source instance**. ○ **Fill in the back-to-source address**: Enter the address of the origin server. If you enter multiple addresses, load balancing is performed based on the specified **load balancing algorithm**. ○ **Return to the back-to-source instance**: Enter the address of a specific Elastic Compute Service (ECS) or Server Load Balancer (SLB) instance. If you enter multiple addresses, load balancing is performed based on the specified **load balancing algorithm**.
	X-Forwarded-For	The passthrough mode of the actual source IP address. The X-Forwarded-For (XFF) header is used to identify the actual source IP address of an HTTP client. The header is used for request forwarding services, such as HTTP proxy and load balancing.
Redirect	**Response Status Code**	The HTTP status code that WAF returns when it forwards inbound traffic to a specified address. Valid values: **301**, **302**, and **307**. ○ **301**: The requested page is permanently moved to another URL. ○ **302**: The requested page is temporarily moved to another URL. The requester must continue to use the original URL for future requests. ○ **307**: The requested page is temporarily moved to another URL. The requester must continue to use the original URL for future requests.
	Redirect address	The required URL for redirection.
Respond with Specified Content	**Response Status Code**	The HTTP status code that WAF returns when it returns specified content. Valid values: **200**, **404**, and **503**.
	Response	The content to return. For example, you can upload an image for the **Response** parameter. If a user visits the website, WAF returns the uploaded image.

7. In the Protection Policy step, configure parameters and click Next. Then, go to the **Finish** step.

Parameter	Description
Protection Policy	Select a WAF protection policy. For more information, see Configure protection policies.
User Identification	Specify whether to enable the user identification feature.

27.1.8.4.8. Verify the configurations of a website on your on-premises server

This topic describes how to verify the configurations of a website on your on-premises server.

Context

Before you use Web Application Firewall (WAF) to scrub traffic destined for a website, we recommend that you verify the configurations of the website on your on-premises server. After you add the virtual IP address and the domain of a website to the hosts file on your on-premises server, the request to access the domain from a local browser passes through WAF first.

Procedure

1.
2. Add the virtual IP address and domain name to the *hosts* file on your on-premises server.

   If your computer runs Windows 7, the hosts file is stored in the following path: *C:\Windows\System32\drivers\etc\hosts*.

   i. Open the hosts file by using a text editor, such as Notepad.

   ii. Add the following content to the end of the file: `<The virtual IP address that is assigned by WAF><Protected domain name>` .

   
   > **Note** The IP address preceding the domain name is the virtual IP address that is assigned by WAF.

3. Ping the protected domain name from your on-premises server.

   The returned IP address must be the virtual IP address that is assigned by WAF in the hosts file. If the returned IP address is still the IP address of the origin server, refresh the local Domain Name System (DNS) cache.

4. Enter the domain name in the address bar of your browser and press Enter.

   If the access configurations on WAF are correct, you can visit the website.

5. Verify the protection capability of WAF.

   Simulate a web attack request and check whether WAF blocks the request.

   For example, add `/?alert(xss)` after the URL. If you try to visit `www.example.com/?alert(xss)` , WAF is expected to block the request.

27.1.8.4.9. Modify DNS resolution settings

This topic describes how to modify the Domain Name System (DNS) resolution settings to connect your website to Web Application Firewall (WAF).

Context

Before you modify the DNS resolution settings, verify the configurations of the website on your computer and make sure that the configurations are correct.

The domain name of a protected website may not be resolved by a DNS provider. For example, a website may use a Server Load Balancer (SLB) instance to connect to the Internet. To protect the website by using WAF, perform the following steps. Specify the virtual IP address that WAF assigns to your website as the back-to-origin IP address of the SLB instance.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. On the Detection Overview page, choose **Protection Configuration > Protection Site Management**.
4. Find the required website and click the icon in the **Operation** column.
5. On the **Basic Information** tab, obtain the virtual IP address of the protected website.
6. Log on to the console of the DNS provider and find the DNS resolution settings for the domain name of the website. Then, change the IP address in the A record to the virtual IP address of the protected website.

> **Note** We recommend that you set the TTL to 600 seconds in DNS resolution settings. The greater the TTL is, the longer it takes to synchronize and update DNS records.

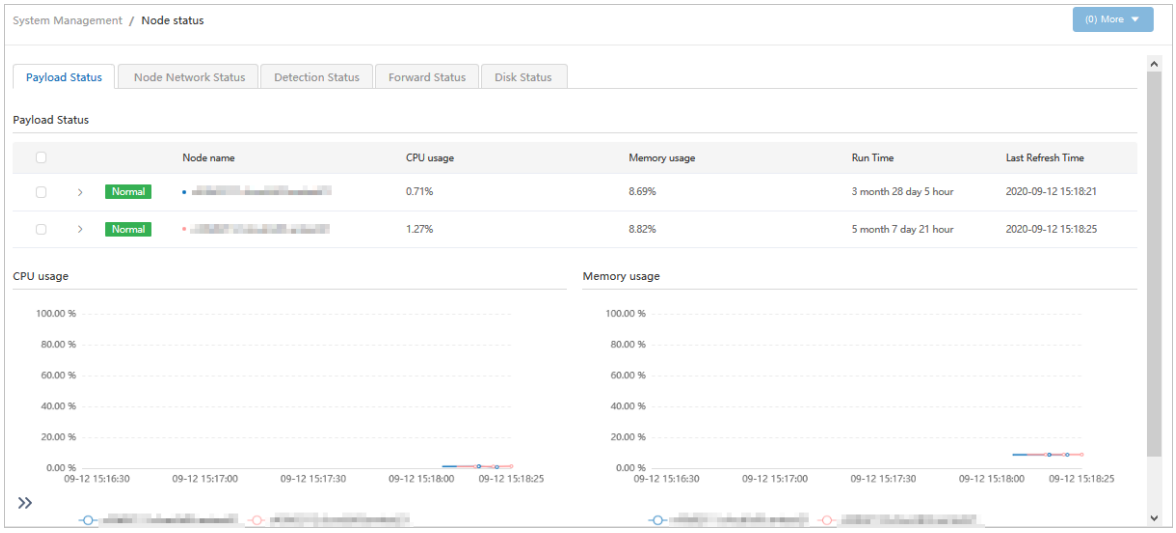
27.1.8.5. System management

27.1.8.5.1. View the load status of nodes

This topic describes how to view the load status of Web Application Firewall (WAF) nodes. The status information includes CPU utilization and memory usage. You can use the query results to identify faults or check whether scale-out is required.

Procedure

1.
2. In the left-side navigation pane, choose **Application Security > WAF**. On the Detection Overview page, choose **System Info > Node status**.
3. On the **Payload Status** tab, view the load status of WAF nodes.



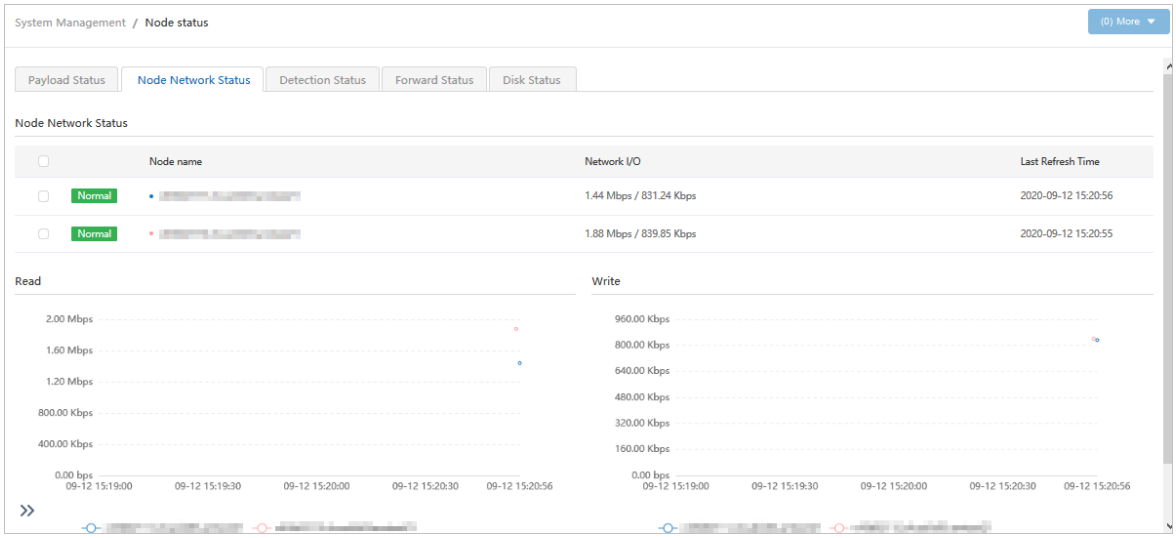
In the Payload Status section, you can view the CPU utilization and memory usage of each WAF node. In the CPU usage and Memory usage sections, you can view changes in the CPU utilization and memory usage over a specific period of time.

27.1.8.5.2. View the network status of nodes

This topic describes how to view the network status of WAF nodes, such as the network I/O, traffic detection status, and traffic forwarding status.

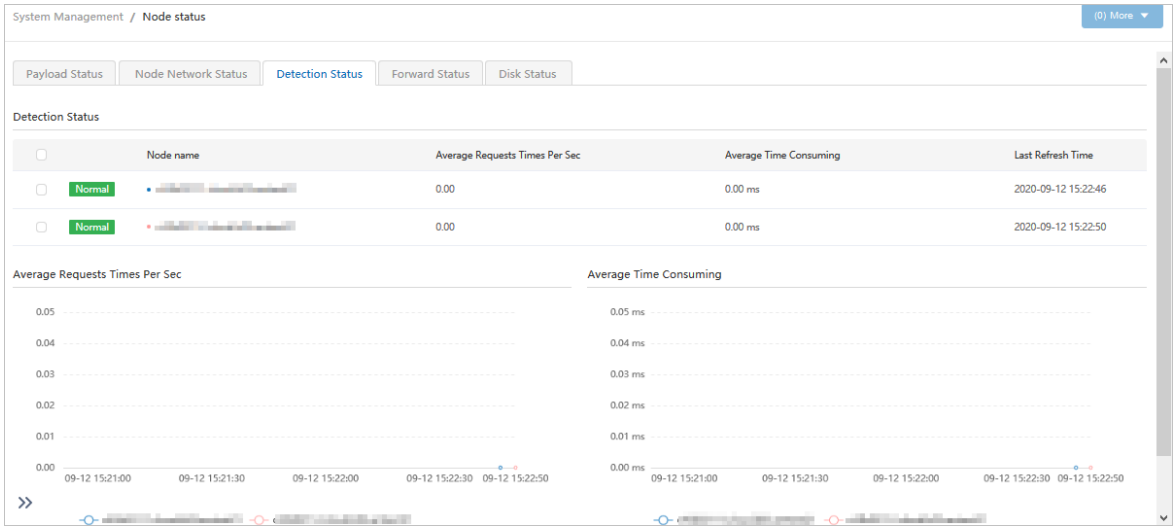
Node network status

1.
2. In the left-side navigation pane, choose **Application Security > WAF > System Management > Node status**.
3. Click the **Node Network Status** tab.
4. View the network I/O of WAF nodes.



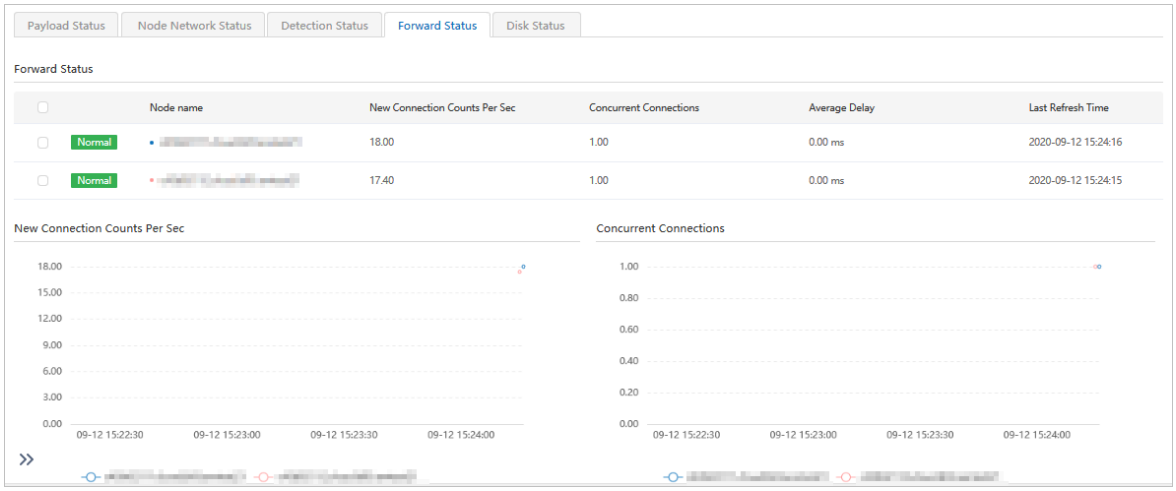
Traffic detection status

1.
2. In the left-side navigation pane, choose **Application Security > WAF > System Management > Node status**.
3. Click the **Detection Status** tab.
4. View the traffic detection status of WAF nodes.



Traffic forwarding status

1.
2. In the left-side navigation pane, choose **Application Security > WAF > System Management > Node status**.
3. Click the **Forward Status** tab.
4. View the traffic forwarding status of WAF nodes.

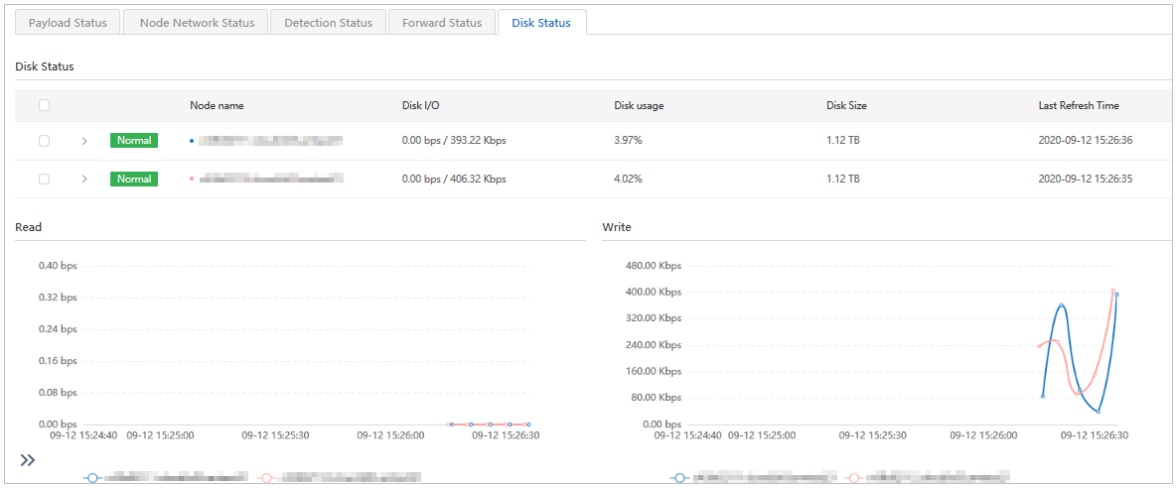


27.1.8.5.3. View the disk status of nodes

This topic describes how to view the disk status of Web Application Firewall (WAF) nodes. You can identify faults based on the status and check whether scaling is required.

Procedure

1.
2. In the left-side navigation pane, choose **Application Security > WAF > System Management > Node status**.
3. Click the **Disk Status** tab to view the disk status of WAF nodes.



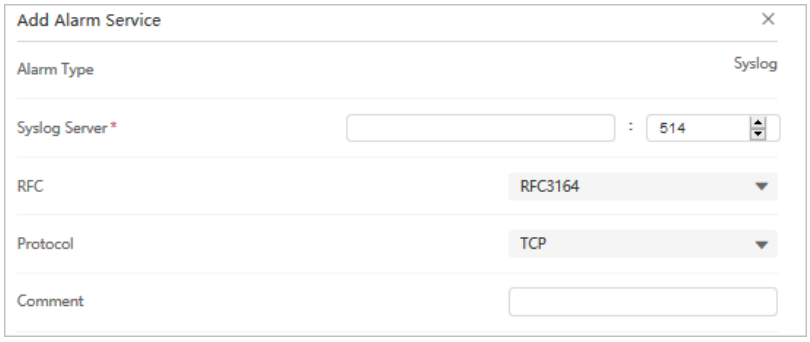
In the Disk Status section, you can view the disk I/O and disk usage of nodes. In the **Read** and **Write** sections, you can view the disk read and write changes over a period.

27.1.8.5.4. Configure alerts

This topic describes how to add a syslog server to Web Application Firewall (WAF). After the syslog server is added, WAF alert logs are pushed to the syslog server over the syslog protocol.

Procedure

1.
2. In the left-side navigation pane, choose **Application Security > WAF**. On the Detection Overview page, choose **System Management** > **Syslog Configuration**.
3. On the **Alarm Service Configuration** tab, click **Add alarm service**.
4. In the **Add Alarm Service** panel, configure parameters.



Parameter	Description
Syslog Server	The IP address and port number of the syslog server.
RFC	The Request for Comments (RFC) document that defines the Syslog protocol. Valid values: **RFC3164** and **RFC5424**.
Protocol	The transmission protocol. Valid values: **TCP** and **UDP**.
Comment	The description of the syslog server. This information facilitates subsequent identification and management.
Security	The module for which syslog logs are sent.

5. Click **Confirm**. The newly added syslog server appears in the syslog list.
6. Find the newly added syslog server and click the icon in the **Operation** column to test whether alerts are sent.
   - If a message appears, indicating that the alert test is successful, the syslog server is added.
   - If an error message appears, WAF cannot connect to the syslog server.

27.1.8.5.5. Configure alert thresholds

This topic describes how to configure alert thresholds.

Procedure

1.
2. In the left-side navigation pane, choose **Application Security > WAF**. On the Detection Overview page, choose **System Settings** > **Syslog Configuration**.
3. Click the **Alarm ThresholdConfiguration** tab and click the icon next to the thresholds that you want to modify.

4. In the Edit Queries per second panel, specify the thresholds.

Threshold	Description
Concurrent Connections	If a large number of concurrent connections exist, no alerts are sent.
Number of new connections	If a large number of new connections exist, no alerts are sent.
CPU usage is too high	If the CPU utilization exceeds this threshold in a period of time, alerts are sent.
Memory usage is too high	If the memory usage exceeds this threshold in a period of time, alerts are sent.
Disk usage is too high	If the disk usage exceeds this threshold, alerts are sent.

5. Click **Ok**.

27.1.9. Security Operations Center (SOC)

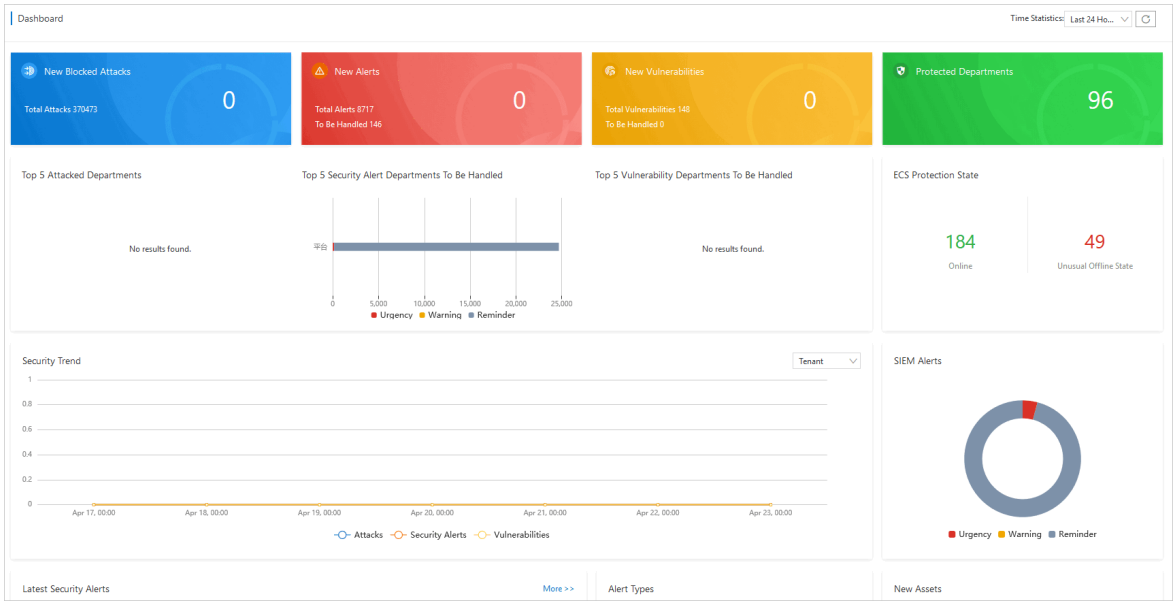
27.1.9.1. View the dashboard

This topic describes how to view the overall security information about the Apsara Stack network environment.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Overview**.
3. In the upper-right corner of the **Dashboard** page, select a time range from the **Time Statistics** drop-down list.

   Valid values: *Last 24 Hours*, *Last 7 Days*, and *Last 30 Days*.
4. View the overall security information.



The Dashboard page displays the following information:

- **New Blocked Attacks**, **New Alerts**, **New Vulnerabilities**, and **Protected Departments**
- **Top 5 Attacked Departments**, **Top 5 Security Alert Departments To Be Handled**, and **Top 5 Vulnerability Departments To Be Handled**

- **Security Trend** based on the tenant and the platform
- **Latest Security Alerts** and **Alert Types**
- **Latest Attacks** and **Attack Types**
- **ECS Protection State**, **SIEM Alerts**, **New Assets**, and **Protected Assets**

27.1.9.2. Security Monitoring

27.1.9.2.1. View the security monitoring data of tenants

This topic describes how to view the security monitoring data of tenants on the Attack Protections, Security Alerts, and Vulnerabilities tabs.

Attack Protections

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Tenant Security Monitoring**. On the page that appears, click the **Attack Protections** tab.
3. Specify search conditions.

   > **Note** If you want to view all attack events, skip this step.

   
Search condition	Description
Department	The department to which the assets affected by the attack belong.
Data source	The data source.
State	The attack status.
Attack type	The attack type.
Start time and end time	The time range to query.
Attack name or asset keyword	The keyword of the attack name or the affected asset.

4. View the details in the attack list.
5. Click the icons in the upper-left corner to refresh or export the list.

   The following list describes the operations:

   - Click the icon to refresh the attack list.
   - Click the icon to export the attack list.

6. In the Actions column of an attack event, you can block requests from a specific IP address, create a tag for the event, and view logs and details of the event.

   The following list describes the operations:

   - Block requests from a specific IP address: Click **Block IP Addresses**. In the **Block IP Addresses** dialog box, configure parameters to block requests from a specific IP address. For more information, see Block IP Addresses.

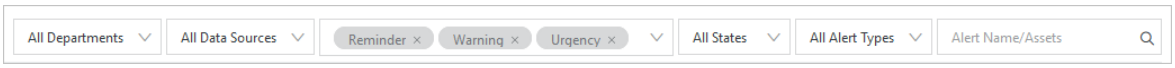
Click **View Blocked IPs** in the upper-right corner to view the blocked risk items.

- Create a tag: Click **Tag**. In the **Customize Tag** dialog box, create a tag for the attack event and click **OK**.
- View logs: Click **View Log**. On the **Cloud Tenant Logs** tab of the **Log Audit** page, view the logs of the tenant.
- View details: Click **Details** to view the details of the attack event.

Security Alerts

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Tenant Security Monitoring**. On the page that appears, click the **Security Alerts** tab.
3. (Optional)Specify search conditions.

   > **Note** If you want to view all security alerts, skip this step.

Search condition	Description
Department	The department to which the assets associated with the security alerts belong.
Source	The data source.
Level	The alert level. You can select one or more alert levels. Valid values: ○ Urgency ○ Warning ○ Reminder
Alert state	The alert status.
Type	The alert type. This can be set to **All Alert Types** or a specific alert type.
Start time and end time	The time range to query.
Alert name or asset keyword	The keyword of the alert name or the affected asset.

4. View details in the security alert list.
5. Click the icons in the upper-left corner to refresh or export the list.

   The following list describes the operations:

   - Click the icon to refresh the security alert list.
   - Click the icon to export the security alert list.

Vulnerabilities

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Tenant Security Monitoring**. On the page that appears, click the **Vulnerabilities** tab.

3. Click the **Vulnerabilities** or **Server Configurations** tab.
   - **Vulnerabilities**: provides vulnerability information.
   - **Server Configurations**: lists risks on server configuration.
4. Specify search conditions.

   > **Note** If you want to view all vulnerabilities or server configuration risks, skip this step.

Search condition	Description
Department	The department to which the assets affected by the vulnerability or server configuration risk belong.
Level	The vulnerability level or server configuration risk level.
Type	The vulnerability type or server configuration risk type.
State	The status of the vulnerability or the server configuration risk.
Start time and end time	The time range to query.
Vulnerability name, asset, or CVE ID keyword	The keyword of the name of the vulnerability or server configuration risk, CVE ID, or affected assets.

5. Click the icons in the upper-left corner to refresh or export a list of vulnerabilities or server configuration risks.

   The following list describes the operations:

   - Click the icon to refresh the list of vulnerabilities or server configuration risks.
   - Click the icon to export the list of vulnerabilities or server configuration risks.

27.1.9.2.2. View security monitoring data of platforms

This topic describes how to view the security monitoring data of platforms on the Attack Protections, Security Alerts, and Vulnerabilities tabs.

Attack Protections

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Platform Security Monitoring**. On the page that appears, click the **Attack Protections** tab.
3. Specify search conditions to search for attack protection events.

   > **Note** If you want to view all events, skip this step.

Search condition	Description
Data source	The data source.

Search condition	Description
Status	The attack status.
Attack Type	The attack type.
Start time and end time	The time range to query.
Attack name or asset keyword	The attack name or the keywords of the affected asset.

4. View the details in the attack list.
5. Click the buttons in the upper-left corner to refresh or export the list.

   The following list describes how to perform the operations:

   - Click the icon to refresh the attack event list.
   - Click the icon to export the attack event list.
6. In the Actions column of an attack event, you can block requests from a specific IP address, create a tag for the event, and view logs and details of the event.

   The following list describes how to perform the preceding operations:

   - Block requests from a specific IP address: Click **Block IP Addresses**. In the **Block IP Addresses** dialog box, configure parameters to block requests from a specific IP address. For more information, see Block IP Addresses.

     Click **View Blocked IPs** in the upper-right corner to view the blocked risk items.
   - Create a tag: Click **Tag**. In the **Customize Tag** dialog box, create a tag for the attack event and click **OK**.
   - View logs: Click **View Log**. On the **Cloud Platform Logs** tab of the **Global Log Audit** page, view the logs of the platform.
   - View details: Click **Details** to view the details of the attack event.

Security Alerts

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Platform Security Monitoring**. On the page that appears, click the **Security Alerts** tab.
3. (Optional)Specify search conditions.

   > **Note** If you want to view all security alerts, skip this step.

Search condition	Description
Data source	The data source.
Level	The alert level. You can select one or more alert levels. Valid values: ○ Urgency ○ Warning ○ Reminder
Alert state	The alert status.

Search condition	Description
Alert type	The alert type, which can be set to **All Alert Types** or a specific alert type.
Start time and end time	The time range to query.
Alert name or asset keyword	The alert name or the keywords of affected assets.

4. View details in the security alert list.
5. Click the buttons in the upper-left corner to refresh or export the list.

The following list describes how to perform the operations:

- Click the icon to refresh the security alert list.
- Click the icon to export the security alert list.

Vulnerabilities

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Platform Security Monitoring**. On the page that appears, click the **Vulnerabilities** tab and view baseline risks in the **Platform Baseline** section.
3. Specify search conditions.

> **Note** If you want to view all baseline risks of the platform, skip this step.

Search condition	Description
Level	The risk level.
Type	The baseline risk type.
State	The processing status.
Start time and end time	The time range to query.
Risk name or asset name	The risk name or the keywords of the affected asset.

4. Click the buttons in the upper-left corner to refresh or export the list of platform baseline risks.

   The following list describes the operations:

   - Click the icon to refresh the list of platform baseline risks.
   - Click the icon to export the list of platform baseline risks.

27.1.9.2.3. View the global traffic

This topic describes how to view the global traffic, including the average traffic, peak traffic, overall traffic trends, traffic of tenants, and traffic of platforms.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Global Traffic Analysis**.
3. On the **Global Traffic Analysis** page, view the global traffic.

   You can view the following information on this page:

   - View the average traffic and peak traffic
     a. In the upper-right corner of the **Global Traffic Analysis** page, select a time range and traffic direction.

        Valid values of time ranges: **Last 6 Hours**, **Last 24 Hours**, and **Last 7 Days**.

        Valid values of traffic directions: **Inbound** and **Outbound**.

     b. In the upper-left corner of the Global Traffic Analysis page, view the average and peak traffic of the specified traffic direction within the specified time range.
   - View traffic trends
     a. In the upper-right corner of the **Global Traffic Analysis** page, select a traffic type.
     b. View the overall traffic trends of each traffic type within the specified time range.
   - View the traffic of tenants on the **Tenant Traffic** tab
   - View the traffic of platforms on the **Platform Traffic** tab

27.1.9.3. Asset Management

27.1.9.3.1. View tenant assets

This topic describes how to view the assets of users. The assets include Elastic Compute Service (ECS) instances, ApsaraDB RDS instances, Object Storage Service (OSS) buckets, Server Load Balancer (SLB) instances, and elastic IP addresses (EIPs).

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Asset Management > Tenant Assets**.
3. Select the required service. Example: **Elastic Compute Service (ECS)**.
4. Specify search conditions to view a specific asset.

   > **Note** If you want to view all assets, skip this step.

Search condition	Description
Department	The department to which the asset belongs.
VPC	The virtual private cloud (VPC) to which the asset belongs.
Status	The running status of the asset.
New	Specifies whether the asset to query is newly added.
Server name or IP address	The keywords of the asset name.

5. View asset information in the asset list.

27.1.9.3.2. View platform assets

This topic describes how to view the assets of the platform.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Asset Management > Platform Assets**.
3. Specify search conditions to view a specific asset.

   > **Note** If you want to view all assets, skip this step.

4. View asset information in the asset list.

27.1.9.4. Log Analysis

27.1.9.4.1. View the Log Overview page

This topic describes how to view the logs that are displayed in the widgets on the Log Overview page.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Overview**.
3. On the **Log Overview** page, view the widgets of the logs.

   You can perform the following operations to **modify** or **delete** the widgets on the **Log Overview** page:

   - To modify a widget, click **Modify** in the upper-right corner of the widget.
     a. In the **Modify** dialog box, reconfigure the **Chart Type**, **Category**, and **Value** parameters. When you configure the **Category** and **Value** parameters, take note of the following points:
        - **Category**: If you set **Chart Type** to **Bar Chart**, **Line Chart**, **Pie Chart**, or **Sheet**, you must specify this parameter.
        - **Value**: If you set **Chart Type** to **Pie Chart** or **Individual Value Plot**, you must specify this parameter.

     b. Click **Refresh** to preview the widget in the right side of the Modify dialog box.
     c. Above the widget, enter a new name to rename the widget.
     d. Click **OK**. The widget is updated on the **Log Overview** page.
   - To delete a widget, click **Delete** in the upper-right corner of the widget.

   The widgets on the **Log Overview** page are created on the **Log Audit** page. To create a widget, click **Please go to the log audit page to add a chart** in the **Add custom visualization chart** section in the lower part of the **Log Overview** page. On the **Log Audit** page, create a custom widget. For more information, see View global logs.

27.1.9.4.2. View global logs

This topic describes how to view global logs. Global logs are classified into logs of tenants, logs of platforms, and logs of data centers based the department to which the logs belong.

View a log widget

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Audit**.
3. Click the tab on which you want to view the logs of a department. For example, if you want to view the logs of tenants, click the **Cloud Tenant Logs** tab.
4. Specify search conditions, click the icon, and then view the logs that meet the search conditions in the sections of log distribution chart and log list.

Search condition	Description
Department	If you want to view the logs of a tenant, you can specify this search condition. Select the department to which the tenant belongs.
Log Source	Select the type of the system of which you want to collect the logs, the name of the system of which you want to collect the logs, and the log type from the drop-down list.
Duration	Select the time range within which you want to view the logs. Valid values: **Last 15 Minutes**, **Last 30 Minutes**, **Last 1 Day**, **Last 7 Days**, **Last 30 Days**, and **Custom**.
Start Time	Specify the start and end time within which you want to view the logs.
Log Content	Enter the log content in the search box. To save the search conditions as frequently used search conditions, click **Save Search Condition**. If you want to use these frequently used search conditions, click **Historical Records** to view the logs that meet the search conditions.

If you want to search for logs by using JSON domain-specific language (DSL) statements, click **Advanced Search**. In the **Advanced Search** dialog box, enter JSON DSL statements and click **Submit**.

Create a log widget

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Audit**.
3. Click the tab on which you want to view the logs of a department. For example, if you want to view the logs of tenants, click the **Cloud Tenant Logs** tab.
4. In the lower part of the Log Audit page, click the **Visualization** tab.
5. On the **Visualization** tab, configure parameters in the **Chart** section.

Parameter	Description
Chart Type	The type of widget to be displayed on the **Overview** page. Valid values: **Bar Chart**, **Line Chart**, **Pie Chart**, **Individual Value Plot**, and **Sheet**.
Category	This parameter is required when you select **Bar Chart**, **Line Chart**, **Pie Chart**, or **Sheet** for **Chart Type**. The type of items that you want to display in the horizontal axis or the column header of the widget.
Value Category	The type of items that you want to display in the vertical axis or the row header of the widget.

Parameter	Description
Value Type	The value type that you want to display in the widget. Valid values: **count**, **max**, **min**, **avg**, **sum**, **unique_count**, and **median**. If you want to display multiple value types in the widget, click **Add Value Field**. Then, you can configure the **Value Category** and **Value Type** parameters.

6. In the upper-left corner of the Visualization tab, enter a name for the widget.
7. Click **Refresh**.

   After the widget is created, you can view the widget on the **Overview** page.

   To configure the content to be displayed in the log list, you can perform the following steps: In the lower part of the Log Audit page, click the **Log** tab. Then, click the icon. To export the log list, click the icon.

27.1.9.4.3. Log configurations

27.1.9.4.3.1. Manage log sources

This topic describes how to view and manage the log sources that are connected to Security Operations Center (SOC).

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Configurations**.
3. Click the **Log Sources** tab. On the **Log Sources** tab, view the log overview information and log list.

   This tab provides the following information:

   - In the upper section of the **Log Sources** tab, you can view the total volume of log data and the total number of connected log sources.
   - In the upper-right corner above the log source list, you can specify the following search conditions to search for specific log sources.

Search condition	Description
Access System Types	The type of the log source that is connected to SOC. Valid values: **Host**, **Storage**, **Application**, **Networking**, **Data**, **Security**, and **Other**.
Log Types	The type of log that is collected by SOC. Valid values: **Operations Log**, **Operational Log**, **Alert Log**, and **Others**.
Access Mode	The mode that is used to collect logs. Valid values: **Custom** and **Built-in**.
Statuses	The status of the log source that is connected to SOC. Valid values: **On** and **Off**. In the log source list, find a log source and in the **Status** column click the icon to set the log source to on or off. In the Tips message, click **OK**.

4. Find a log source and click **Modify** in the Actions column.
5. In the **Edit** dialog box, configure the Storage Days and View Permission parameters and click **OK**.

27.1.9.4.3.2. Create a log collection task

This topic describes how to create a log collection task.

Prerequisites

If you use Logtail to collect logs, ensure that the following conditions are met:

- Logtail is installed.
- A server group that you want to configure Logtail is created.

For more information, see Manage log collectors.

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Configurations**.
3. On the **Log Configuration** page, click the **Log Access Task** tab.
4. On the **Log Access Task** tab, click **Add**.
5. In the **Configure Log Source** step of the **Create Task** wizard, configure parameters and click **Next**.

Parameter	Description
Task Name	The name of the log collection task.
Access System Name	The name of the log source from which you want to collect the logs. Enter the name of the log source, such as Windows operating system.
Access System Type	The type of log source from which you want to collect the logs. Valid values:**Host**, **Storage**, **Application**, **Networking**, **Data**, **Security**, and **Other**.
Log Source Name	The name of the log source.
Log Type	The type of the logs that you want to collect. Valid values: **Operations Log**, **Operational Log**, **Alert Log**, and **Others**.
Source	The department to which the logs belong. Valid values: **Cloud Tenant**, **Cloud Platform**, and **On-Premises Data Center**.

6. In the left-side navigation tree of the **Configure Access Mode** step, select a data source type, configure parameters, and then click **Next**.

   Valid values of data source types: Syslog, SLS, and Logtail.

   - If you select Syslog, you must configure the following parameters.

Parameter	Description
IP address	The IP address or Classless Inter-Domain Routing (CIDR) block used to report syslog logs.
Protocol	The network protocol used when the logs of the log source are collected. Valid values **UDP** and **TCP**.
Access System Type	The type of log source from which you want to collect the logs. Valid values: **Host**, **Application**, **Networking**, and **Other**.
Keyword	The keyword of the log source.

   - If you select SLS, you must configure the following parameters.

Parameter	Description
Log Project	The name of the Log Service project.
Log Store	The name of a Logstore in Log Service.
Endpoint	The endpoint used to connect to the Log Service project.
accessKey	The AccessKey ID of your account to access the Log Service project.
secretKey	The AccessKey secret of your account to access the Log Service project.

- If you select Logtail, you must configure the following parameters.

Parameter	Description
Name	The name of Logtail.
Log Type	The type of the logs that you want to collect. Valid values: **JSON**, **Apsara**, **Separator**, and **Regular Expression**.
Log Pattern	The format of log file names. Example: *access*.log*.
Log Path	The path of the logs that you want to collect. Absolute paths and relative paths are supported. You can use wildcards in relative paths.
Log Sample	A sample log entry from the logs that you want to collect.
Regular Expression to Match First Log Entry	After you enter the **sample log entry**, click **Generate Automatically**. A regular expression is generated to match the first line of the log entry.
Regular Expression	Click **Regular Expression**. In the **Generate Regular Expression** dialog box, select the fields that you want to extract and click **Generate Regular Expression**. After the regular expression is generated, click **OK**.
Date Format	The date format that is automatically generated based on the extracted time fields.
Apply to Server Group	The server group for which you want to configure Logtail.

7. In the **Parse and Normalize Data** step, configure parameters and click **Next**.

Parameter	Description
Data Acquisition Method	Select the acquisition method used to query the sample log entry. Valid values: **Automatic Acquisition** and **Manual Input**.
Sample Data	If you set **Data Acquisition Method** to **Manual Input**, you must enter the sample log entry.
Parser	Select a parser based on the sample log entry. Valid values: **JSON** and **jsonArray**.

Parameter	Description
Extract Value	The content that can be extracted from the logs. Click **Add Field**. In the **Add Field** dialog box, configure the **Original Extract Field**, **Original Extract Value**, **Enrich Data**, and **Target Type** parameters, and click **OK**. Valid values of **Enrich Data**: **Retain Original Field**, **Field Masking**, **Delete Field**, **Rename Field**, **Automatically Fill System Time**, **Assign Value to Constant**, and **Assign Value to Variable**.

8. In the **Data Output** step, configure the **Log Source Name**, **Storage Duration**, and **View Permissions** parameters.
9. Click **Save**.

   After the log collection task is created, the task appears in the list for log collection tasks. You can publish, modify, and delete the task in the Actions column of the task.

   - **Publish**: After the log collection task is created, logs are not automatically collected. You must click **Publish**. After you publish the task, the  icon appears in the **Access Status** column of the task.

     You can click the switch in the **Access Status** column to change the status of the log collection task.
   - **Edit**: You can click **Edit** to change the configurations in the **Parse and Normalize Data** and **Data Output** steps. You cannot change the data source type and parser.
   - **Delete**: If you no longer need the log collection task, click **Delete** in the Actions column of the task.

27.1.9.4.3.3. Manage log collectors

Before you can use Logtail to collect logs, you must install Logtail, add log collectors, and create server groups. This topic describes how to install Logtail, add log collectors, and create server groups.

Install Logtail

If Logtail is installed, the system automatically uninstalls the existing version of Logtail, deletes the */usr/local/ilogtail* directory, and then reinstalls Logtail. After the new version of Logtail is installed, Logtail automatically runs when the system starts.

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Configurations**.
3. On the **Log Configurations** page, click the **Collectors** tab.
4. Install Logtail.

   On the **Collectors** tab, install Logtail based on the operating system of the server and the installation method that is supported by Logtail.

   - If the server runs Linux and Logtail supports manual installation, perform the following steps:
     a. In the **Linux Operating Systems** section, click **Download Installation Package** and specify whether to download a 32-bit or 64-bit installation file to your local computer.
     b. Log on to the server as an administrator. Then, run the installation command to install Logtail.
   - If the server runs Windows and Logtail supports manual installation, perform the following steps:
     a. In the **Windows Operating Systems** section, click **Download Installation Package** to download the installation file to your local computer.

b. Upload the installation file to the server. For example, you can use an FTP client to upload the installation file to the server.

c. Run the installation file on the server as an administrator.

After Logtail is installed, Logtail automatically runs when the system starts.

Add a log collector

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Configurations**.
3. In the **Collectors** section, click **Add Collector**.
4. In the **Add Collector** dialog box, configure the following parameters and click **OK**.

Parameter	Description
Collector IP Address	The IP address of the log source whose logs you want to collect.
Server Name	The name of the server where Logtail is installed.
Operating System	The operating system of the server where Logtail is installed.

After the log collector is added, you can view the information of the log collector in the **Collectors** section. The information includes **Collector IP Address** and **Server Name**.

If you want to view the details of Logtail, find the log collector and click **View Logtail Configurations** in the Actions column. In the **Configure Logtail** panel, you can view the details of Logtail.

Create a server group

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Configurations**.
3. In the **Server Groups** section, click **Create Server Group**.
4. In the **Create Server Group** dialog box, configure the following parameters and click **OK**.

Parameter	Description
Server Group Name	The name of the server group.
IP Addresses	The IP address of the server that you want to add to the server group. To add a server to the server group, perform the following steps: i. In the **Ungrouped Servers** section, select the server that you want to add to the group. ii. Click the > icon to add the server to the **Servers to Be Grouped** section.

After you create the server group, you can view the information of the server group in the **Server Groups** section. If you want to view the details of a server group or delete a server group, perform the following steps:

- Find the server group. Then, click **Details** in the Actions column to view the details of the server group.
- Find the server group. Then, click **Delete** in the Actions column to delete the server group.

27.1.9.4.3.4. Manage storage policies

This topic describes how to view and configure storage policies for logs.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Configurations**.
3. On the **Log Configurations** page, click **Policy Management**.
4. On the **Storage Policy** tab of the **Policy Management** page, view the storage policies for logs.
5. Click **Edit**.
6. On the **Storage Policy** tab, configure parameters in the Log Storage (Advanced) and Security Monitoring Data Storage (Advanced) sections and click **Modify**.

Section	Parameter	Description
Log Storage (Advanced)	Maximum Log Size	The upper limit of the storage space that can be occupied by logs.
	Maximum Storage Period	The maximum number of days during which logs can be stored.
Security Monitoring Data Storage (Advanced)	ApsaraDB RDS Storage Period	The maximum number of days during which security monitoring data can be stored.

27.1.9.4.4. Security Audit

27.1.9.4.4.1. Overview

A security audit refers to the systemic and independent inspection and verification of activities and behavior in the computer network environment. Delegated by property owners and authorized by management authorities, professional auditors give their assessments according to relevant laws and regulations. When the administrator needs to backtrack system operations, the administrator can perform a security audit.

Security audits are long-term security management activities throughout the lifecycle of cloud services. The security audit feature of Apsara Stack Security can collect system security data, analyze weaknesses in system operations, report audit events, and classify audit events into important, moderate, and low risk levels. The security administrator views and analyzes audit events to continuously improve the system and ensure the security and reliability of cloud services.

27.1.9.4.4.2. View security audit overview

This topic describes how to view the summarized information about security audit.

Context

The **Overview** tab provides reports on the raw log trend, audit event trend, audit risk distribution, and security event distribution. The reports are displayed in run charts or pie charts to help security administrators analyze the trend of risks in your cloud services.

On the **Overview** tab, security administrators can check the number of log entries and the storage usage in a specific time range.

Procedure

1.

2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Overview** tab.
3. On the **Overview** tab, view the audit summary for the last seven days.

   - Trends of Raw Log

     This chart displays the trend of logs generated by physical servers, network devices, ApsaraDB RDS instances, Elastic Compute Service (ECS) instances, and API calls in the last seven days. Security administrators can analyze the trend to check whether the number of log entries is at a normal level.

   - Audit Events

     This chart displays the trend of audit events that are generated by physical servers, network devices, ApsaraDB RDS instances, ECS instances, and API calls in the last seven days. Security administrators can analyze the trend to check whether the number of audit events is at a normal level.

   - Audit Risk Distribution

     This chart displays the percentage distribution of audit events at different risk levels in the last seven days. Risk levels are important, moderate, and low. Security administrators can analyze the trend to check whether the audit events are at acceptable risk levels.

   - Security Issue Distribution

     This chart displays the percentage distribution of different event types in the last seven days. Security administrators can analyze this chart to check for the most frequent audit events and identify high-risk events to improve security protection.

   - Log Size

     This chart displays the volume of online logs and offline logs. If these logs consume many storage resources, we recommend that you back up required audit logs and delete unnecessary logs.

   - Audit Log Size

     This chart displays the size of logs for each audit type.

4. View the audit summary in a specific time range.
   i. Specify **End Time** as the end of the time range to query.
   ii. In **Audit Type**, select the audit types to query.
   iii. Click **View** to view the audit summary in the last seven days before the specified end time.

27.1.9.4.4.3. Query audit events

This topic describes how to query audit events.

Context

On the **Audit Query** tab, you can view the details of audit events, including the log creation time, audit type, audit object, action type, risk level, and log content.

The system matches the logs that are collected by a security audit module with audit rules. If the log content matches the regular expression in an audit rule, an audit event is reported. For more information about audit rules, see Add an audit policy.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Audit Query** tab.
3. On the **Audit Query** tab, configure query conditions to view audit events within the specified time range.

   - Basic query
     a. Configure **Audit Type**, **Audit Target**, **Action Type**, **Risk Level**, and **Notify**.
     b. Specify a time range to query.
     c. In the **Full-Text Search** search box, enter a keyword.
     d. Click **Search**.
   - Advanced query

     In addition to the basic query conditions, you can configure advanced query conditions.
     a. Configure basic query conditions.
     b. Click **Advanced Search**.
     c. Below **Filter Condition**, configure **User**, **Target**, **Action**, **Result**, and **Cause**.
     d. Click **Save**.
4. Click **Export** to export the audit events.

   Download the exported file for analysis. For more information, see Manage export tasks.

27.1.9.4.4.4. View raw logs

This topic describes how to view raw audit logs.

Context

On the **Raw Log** tab, you can view the raw logs generated by a running audit object. Raw logs contain

information that is required for debugging. Security administrators can use these raw logs to troubleshoot system failures.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Raw Log** tab.
3. On the **Raw Log** tab, configure query conditions to view the log summary chart and raw logs within a specific time range.
   i. Specify **Audit Type** and **Audit Target**.
   ii. Enter a keyword.
   iii. Specify a time range to query.
   iv. Click **Search**.
4. Click **Export** to export the data.

   Download the exported file for analysis. For more information, see Manage export tasks.

27.1.9.4.4.5. Manage log sources

This topic describes how to view and manage log sources.

Context

You can view the number of log entries by log type or log source. You can also specify whether to display logs.

- The Log Types sub-tab provides the number of all log entries for a specific audit object of a specific device instance.
- The Log Sources sub-tab provides the number of log entries for all audit objects of a specific device instance.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Log Sources** tab.
3. Click the **Log Types** tab and view the number of log entries for each audit object.

   You can view the number of log entries that are recorded on the current day and the number of log entries that are recorded during the last 30 days for each audit object.

   If you do not want to display the log entries for an audit object, perform the following steps:

   i. Find the audit object and click **Hide** in the **Actions** column.
   ii. In the Note message, click **Confirm**.

   > **Note** The process that is used to display the log entries for an audit object is similar to the process that is used to hide the log entries.

4. Click the **Log Sources** sub-tab and view the number of log entries for each device instance.

   You can view the number of log entries that are recorded on the current day and the number of log entries that are recorded during the last 30 days for each device instance.

   If you do not want to display the log entries for an audit object from a specific device instance, perform the following steps:

   i. Find the device instance and click **Hide** in the **Actions** column.
   ii. In the Note message, click **Confirm**.

> **Note** The process that is used to display the log entries for an audit object is similar to the process that is used to hide the log entries.

27.1.9.4.4.6. Policy settings

Manage audit rules

This topic describes how to create, modify, or delete an audit rule.

Context

If a log entry matches an audit rule, an audit event is reported. You can specify regular expressions in an audit rule to match log entries. A regular expression defines a matching pattern for character strings and can be used to check whether a string contains a specific substring. The following table provides examples about the pattern.

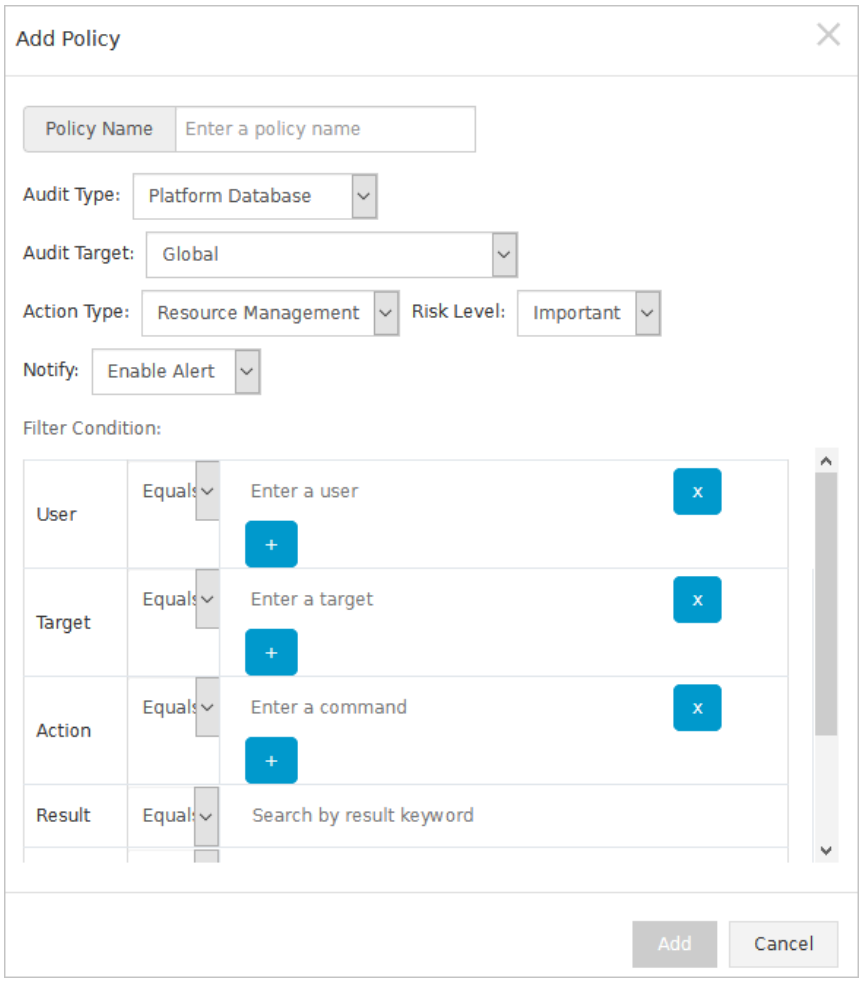
Regular expression	Description
`^\d{5,12}$`	Matches the consecutive numbers from the fifth number to the twelfth number.
`load_file\(`	Matches the "load_file(" string.

The security audit module defines the default audit rule based on the string that is generated in the log. This applies when an audit event is reported. The security administrator can also customize audit rules based on the string that is generated in the log. This applies when the system encounters an attack.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Policies** tab.
3. On the **Policies** tab, click the **Audit Rules** sub-tab.
4. Create an audit rule.
   i. Click **New** in the upper-right corner.

ii. In the **Add Policy** dialog box, configure parameters.



iii. Click **Add**.

The system sends an alert email to the specified alert recipient after you create an audit rule. This applies if one string in an audit log of the specified audit type, audit object, or risk level matches the regular expression of the audit rule.

5. Manage audit rules.

   You can create, query, disable, enable, and delete audit rules.

   - Query audit rules

     Specify **Audit Type** and **Audit Target**. Enter a keyword in the search box and click **Search**.

   - Disable an audit rule

     Find the audit rule that you want to disable and click **Disable** in the **Actions** column.

   - Enable an audit rule

     Find the audit rule that has been disabled and click **Enable** in the **Actions** column.

   - Delete an audit rule

     Find the audit rule that you want to delete and click **Delete** in the **Actions** column.

     > **Note** You can delete only custom rules.

Configure alert recipients

This topic describes how to configure the recipients of alerts on audit events.

Context

You can add an alert recipient by entering an email address that can be used to receive alerts on audit events.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Policies** tab.
3. On the **Policies** tab, click the **Alert Settings** sub-tab.
4. Create an alert recipient.
   i. Click **New**.
   ii. In the **Add Alert Recipient** dialog box, configure parameters.

   iii. Click **Confirm**.
5. Manage alert recipients.
   - Search for alert recipients

     Specify **Audit Type**, **Audit Target**, and **Risk Level**, enter the keyword of the email address, and then click **Search**.
   - Delete alert recipients

     Find the email address that you want to delete and click **Delete** in the Actions column.

Manage archives of events and logs

This topic describes how to query and download the archives of audit events and raw logs.

Context

You can download the archives of events and logs to analyze audit events. This ensures the security of the Apsara Stack environment.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security**

Audit. On the page that appears, click the **Policies** tab.

3. On the **Policies** tab, click the **Archiving** sub-tab.
4. Query the archives of events and logs.
   i. Specify **Audit Type** and **Archiving Type**.
   ii. Specify a time range to query.
   iii. Click **Search**.
5. Find the file where the archive information is stored and click **Download** in the **Actions** column to save the archive file to your on-premises machine.

Manage export tasks

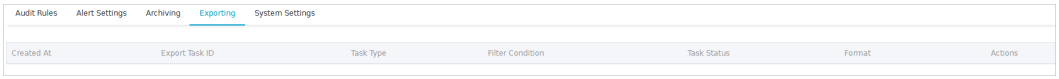
This topic describes how to download or delete exported audit events and logs.

Context

You can export audit events or logs on the **Audit Query** or **Raw Log** tab of the Security Audit page. After you export audit events or logs, you can manage the export tasks on the Exporting sub-tab.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Policies** tab.
3. On the **Policies** tab, click the **Exporting** sub-tab.
4. View the created export tasks.



5. Click **Download** to download audit events or logs to your on-premises server.
6. Click **Delete** to delete the export task.

Modify system settings

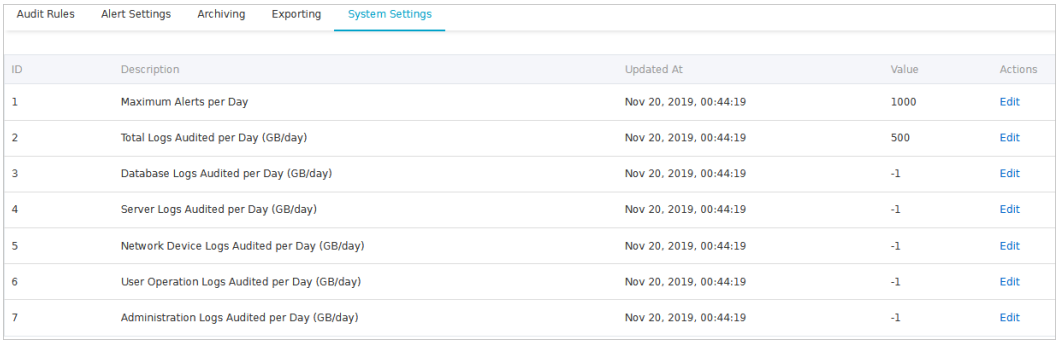
This topic describes how to configure system parameters for security audit.

Context

You can configure system parameters to specify the maximum number of system alerts per day and the maximum number of audits per day for raw logs.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Policies** tab.
3. On the **Policies** tab, click the **System Settings** sub-tab.
4. Find the configuration item that you want to modify and click **Edit** in the **Actions** column.



5. Enter a required value in the Value column and click **Confirm** in the Actions column.

27.1.9.5. Rules

27.1.9.5.1. Create an IPS rule for traffic monitoring

This topic describes how to create an intrusion prevention system (IPS) rule for traffic monitoring in Cloud Firewall. Cloud Firewall has built-in IPS rules. This topic describes how to customize IPS rules based on your business requirements and network environment.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Rules**.
3. On the Rules page, click the **Cloud Firewall IPS Rules** tab.
4. Click **Create Rule**.
5. In the **Create Rule** panel, configure parameters.

Parameter	Description
Rule Name	The name of the IPS rule. We recommend that you enter an informative name for easy management.
Rules Engine	The rules engine. Valid values: **Basic Policies** and **Virtual Patches**.
Attack Type	The type of attack to be detected by the rule.
Severity	The severity. Valid values: **Low**, **Medium**, and **High**.
CVE	The Common Vulnerabilities and Exposures (CVE) ID of the vulnerability listed in the rule. **Note** CVE provides a list of the public security vulnerabilities. CVE IDs are allocated by a CVE Numbering Authority (CNA).
Application	The name of the attacked application.
Rule Mode	The rule mode. Valid values: **Package** and **Traffic**.
Direction	The direction of traffic to be monitored by the IPS rule. Valid values: **Inbound and Outbound**, **Inbound**, and **Outbound**.

Parameter	Description
Rule Content	The rule content that is specified by using the Snort syntax. **Note** To avoid negative impacts on your business, make sure that you enter valid content for the rule.
Rule Description	The rule description. We recommend that you enter information such as the purpose and impact of the rule.
Description	The remarks for the rule. We recommend that you enter information such as the purpose and impact of the rule.

6. Click **OK**.

27.1.9.5.2. Manage IPS rules of Cloud Firewall

This topic describes how to view, enable, and disable the intrusion prevention system (IPS) rules of Cloud Firewall.

Context

On the **Cloud Firewall IPS Rules** tab of the Rules page in Apsara Stack Security Center, you can view the built-in and custom IPS rules, and enable or disable the rules based on your business requirements.

Procedure

1.
2. Choose **Global Platform Security > Alibaba Cloud Security**.
3. On the Rules page, click the **Cloud Firewall IPS Rules** tab.
4. Manage IPS rules of Cloud Firewall.

   In the list of IPS rules, you can view rule details, enable rules, and disable rules.

   - View rule details

     Find the rule whose details you want to view and click **Details** in the **Actions** column to view the rule details.

   - Enable a rule

     Find the rule that you want to enable and turn on the switch in the **Enable or not** column to change the status of the rule from **Disable** to **Enable**.

   - Disable a rule

     If a rule is not suitable for your business, you can disable the rule.

     Find the rule that you want to disable and turn off the switch in the **Enable or not** column to change the status of the rule from **Enable** to **Disable**.

27.1.9.5.3. Create IDS rules for traffic monitoring

This topic describes how to create intrusion detection system (IDS) rules for traffic monitoring.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Rules**.
3. On the Rules page, click the **Traffic Monitoring IDS Rules** tab.

4. Click **Create Rule**.
5. In the **Create Rule** panel, configure the following parameters.

Parameter	Description
Rule Name	The name of the IPS rule. We recommend that you enter a name that can help you identify and manage the IPS rule in an efficient manner.
Rules Engine	The rules engine that you want to use. Valid values: **Basic Policies** and **Virtual Patches**.
Attack Type	The type of the attack that you want to detect by using the IPS rule
Severity	The severity of the attack. Valid values: **Low**, **Medium**, and **High**.
CVE	The Common Vulnerabilities and Exposures (CVE) ID of the vulnerability that you want to add to the rule. **Note** CVE provides a list of public security vulnerabilities. CVE IDs are allocated by a CVE Numbering Authority (CNA).
Application	The name of the attacked application.
Rule Mode	The mode of the IPS rule. Valid values: **Packet** and **Traffic**.
Direction	The direction of traffic that you want to monitor by using the IPS rule. Valid values: **Inbound and Outbound**, **Inbound**, and **Outbound**.
Rule Content	The content of the IPS rule. You must use the Snort syntax to specify the content. **Note** To prevent a negative impact on your business, make sure that the content you enter for the IPS rule is valid.
Rule Description	The description of the IPS rule. We recommend that you enter information that can help you identify the IPS rule, such as the purpose or impact of the rule.
Description	The additional description of the IPS rule. We recommend that you enter information that can help you identify the IPS rule, such as the purpose or impact of the rule.

6. Click **OK**.

27.1.9.5.4. Manage IDS rules for traffic monitoring

This topic describes how to view, enable, and disable intrusion detection system (IDS) rules for traffic monitoring.

Context

On the **Traffic Monitoring IDS Rules** tab, you can view the built-in and custom IDS rules. It can also be used to enable or disable the rules based on your business requirements.

Procedure

1.
2. Choose **Global Platform Security > Alibaba Cloud Security**.

3. On the Rules page, click the **Traffic Monitoring IDS Rules** tab.
4. Manage IDS rules for traffic monitoring.

   In the IDS rule list, you can view rule details, enable rules, and disable rules.

   - View rule details

     Find the rule whose details you want to view and click **Details** in the **Actions** column to view the rule details.

   - Enable a rule

     Find the rule that you want to enable and turn on the switch in the **Enable or not** column to change the status of the rule from **Disable** to **Enable**.

   - Disable a rule

     If a rule is not suitable for your business, you can disable the rule.

     Find the rule that you want to disable and turn off the switch in the **Enable or not** column to change the status of the rule from **Enable** to **Disable**.

27.1.9.5.5. Customize DDoS traffic scrubbing policies and traffic redirection thresholds

This topic describes how to customize DDoS traffic scrubbing policies and traffic redirection thresholds. Default traffic redirection thresholds are provided. If you want to customize the thresholds, perform the following steps.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Rules**.
3. i. Choose **AliGuard Rules > Scrubbing Policy**.
   ii. Find a specific rule and click **Modify Threshold** in the **Actions** column
   iii. In the **Modify Threshold** dialog box, enter a threshold value.
   iv. Click **OK**.
4. Customize the traffic redirection threshold.
   i. Choose **AliGuard Rules > Reroute Threshold**.
   ii. Find a specific rule and click **Modify Threshold** in the **Actions** column.
   iii. In the **Modify Threshold** dialog box, enter a threshold value.
   iv. Click **OK**.

27.1.9.5.6. View Server Guard rules

This topic describes how to view the operations of Server Guard rules. You can view the list of vulnerabilities, baselines, and host exceptions.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Rules**. On the page that appears, click the **Server Guard Rules** tab.
3. In the overview section, you can view the total number of **vulnerability libraries**, number of **baselines**, and number of **host exceptions** as well as the available **engines**.
4. View the vulnerability list.

i. Click the **Vulnerabilities** tab.

ii. In the overview section, you can view the total number of **Linux vulnerabilities**, total number of **Windows vulnerabilities**, total number of **Web-CMS vulnerabilities**, and total number of **urgent vulnerabilities**.

iii. Specify search conditions to view the vulnerabilities that meet the search conditions.

> **Note** If you want to view all vulnerabilities, skip this step.

In the vulnerability list, you can view the **vulnerability name**, **CVE ID**, **vulnerability type**, **system**, **update time**, and **status**.

5. View the baseline list.

i. Click the **Baselines** tab.

ii. In the overview section, you can view the numbers of baseline types and check items.

iii. Specify search conditions to view the baselines that meet the search conditions

> **Note** If you want to view all baselines, skip this step.

In the baseline list, you can view the **baseline type**, **check item category**, **check item name**, **risk level**, **update time**, and **status**.

6. View the host exception list.

i. Click the **Server Exceptions** tab.

ii. In the overview section, you can view the number of **rule alert subcategories**, number of webshells, and number of malicious viruses.

iii. Specify search conditions to view the host exceptions that meet the search conditions.

> **Note** If you want to view all exceptions, skip this step.

In the host exception list, you can view the **subcategory name**, **rule category**, **risk level**, **update time**, **source**, and **status**.

27.1.9.6. Threat intelligence

27.1.9.6.1. Enable the service configuration feature

The threat intelligence module integrates threat monitoring and big data analysis. This can be used to obtain the latest information about developments in the threat intelligence field. After you enable the service configuration feature, the system starts to monitor and collect threat intelligence. This topic describes how to enable the service configuration feature.

Procedure

1.

2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Threat Intelligence > Service Configuration** .

3. On the **Service Configuration** page, view the data types and descriptions on the Situation Awareness and Web application firewall tabs.

4. Click the tab where you want to enable threat monitoring and turn on **Activation status**.

   After you turn on **Activation status**, the system starts to monitor and collect threat intelligence for the data types listed on the tab.

What's next

After you enable the service configuration feature, choose **Security Operations Center (SOC) > Threat Intelligence**. On the **Overview** page, you can view the overall situation and statistics of threats during the last 30 days. For more information, see View the Overview page.

27.1.9.6.2. View the Overview page

The Overview page displays the overall situation and statistics of threats to your assets over the last 30 days.

Prerequisites

The **service configuration** feature is enabled. For more information, see Enable the service configuration feature.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Threat Intelligence > Overview**.
3. On the **Overview** page, view the statistics and threats that are detected on Apsara Stack services by the threat intelligence module.

   On the **Overview** page, you can perform the following operations:

   - View **Total malicious metric intelligence**

     In the **Total malicious metric intelligence** section of the **Overview** page, view the information about the detected threats on Apsara Stack services. The information includes the number of malicious IP addresses, malicious domain names, and malicious URLs.
   - View **Threat trends in the last 30 days**
   - Search for an IP address to check whether the IP address is malicious.

     Enter the IP address that you want to check in the search box in the upper-right corner of the IP Report page and click the icon. To view the details of the IP address, choose **Security Operations Center (SOC) > Threat Intelligence > IP Address Search**. On the page that appears, click the **IP Report** tab. For more information, see Search for an IP address.
   - View **Top 10 active IP malicious addresses**

     In the **Top 10 active IP malicious addresses** section of the **Overview** page, view the information about the top 10 malicious IP addresses. The information includes **IP address**, **First malicious observation**, **Last malicious observation**, and **Malicious label**.

27.1.9.6.3. Search for and view the information about a suspicious or malicious IP address

The threat intelligence module allows you to search for threat intelligence. This module helps you handle suspicious or malicious IP addresses at the earliest opportunity.

Prerequisites

The **service configuration** feature is enabled. For more information, see Enable the service configuration feature.

Procedure

1.

2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Threat Intelligence > IP Address Search**.
3. In the search box on the **Search** page, enter the suspicious or malicious IP address that you want to query and click the icon.
4. On the **IP Report** page, view **Threat Level**, **Basic Information**, **Threat Overview**, **IP Details**, and **Attack Risk Level Analysis** of the IP address.

   You can view the following information on the IP Report page:

   - **Threat Level**: View the threat level of the suspicious or malicious IP address.

     The threat intelligence module classifies IP addresses into three threat levels. The levels are normal, suspicious, and high-risk. If the IP address is identified as high-risk, we recommend that you handle the IP address at the earliest opportunity.

   - **Basic Information**: View the basic information about the suspicious or malicious IP address.

     The basic information includes the server in a data center, Abstract Syntax Notation One (ASN.1), country and city to which the IP address belongs, and the number of domain names for the IP address.

   - View the statistics of the suspicious or malicious IP address.

     You can view **Threat Overview**, **IP Details**, and **Threat Details** of the IP address.

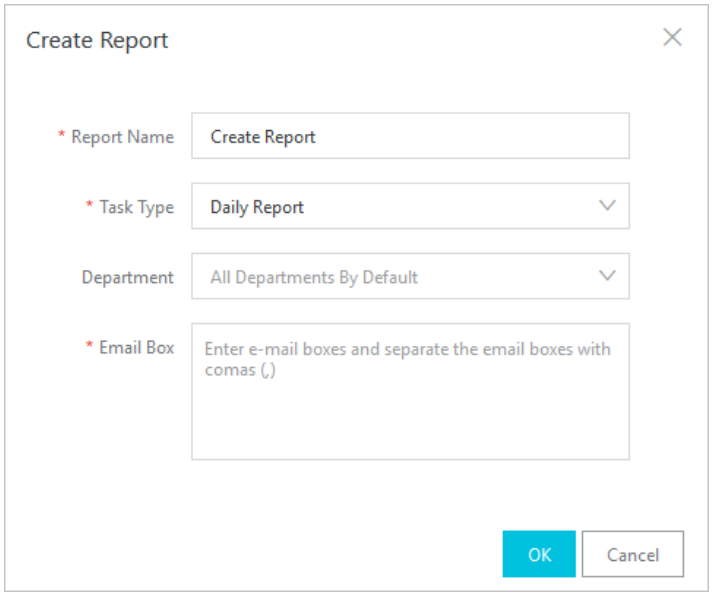
     - The **Threat Overview** tab displays **Top 5 Attack Preference**, **Attack Number**, and **Attack Level Analysis** of the IP address.
     - The **IP Details** tab displays **WHOIS** and **IP reverse check information** of the IP address.
     - The **Threat Details** tab displays the **threat tag** list of the IP address. The list contains specific information. The information includes the intelligence source, time when the IP address is detected for the first time, time when the IP address is active for the last time, and threat tag.

27.1.9.7. Create a report task

This topic describes how to create a report task. After you create a report task, the system sends reports on a regular basis.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Report Management**.
3. On the Report Management page, click **Create Report**.
4. In the **Create Report** dialog box, configure parameters.



Parameter	Description
Report Name	The name of the report task. We recommend that you enter information such as the report purpose for easier identification and management.
Task Type	The type of the task. Valid values: **Daily Report**, **Weekly Report**, and **Monthly Report**.
Department	The department related to the report.
Email Box	The email address of the report recipient. If you enter more than one email address, separate the email addresses with commas (,).

5. Click **Confirm**.

Result

In the report task list, you can view, edit, and delete the newly created report tasks.

27.1.9.8. System Configurations

27.1.9.8.1. View and manage metrics

Apsara Stack Security Center allows you to monitor security services. This helps find performance bottlenecks at the earliest opportunity. Then, you can scale out, scale up, or downgrade services to prevent system failures. This topic describes how to view the information about each security service in Apsara Stack Security Center and how to manage metrics.

View information about overall system monitoring

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Security Monitoring**.
3. On the **Overall System Monitoring** tab, view the overall information about each security service in Apsara Stack Security Center and the list of monitored security services.

   In the upper-left corner of the **Overall System Monitoring** page, you can view the overall information about security services.

- **Services**: the number of security services monitored by Apsara Stack Security Center.
- **Monitoring Items**: the number of metrics.
- **Abnormal Items**: the number of metrics whose status is abnormal.

In the list of monitored security services, you can view the following information.

Parameter	Description
Services	The security service monitored by Apsara Stack Security Center.
Metrics	The monitoring indicator for the monitored security service.
Description	The description of the monitoring indicator.
Monitoring Items	The number of metrics that belong to a monitoring indicator.
Abnormal Items	The number of metrics whose status is abnormal, and the numbers of metrics at each urgency level. The urgency levels are indicated by different colors. The red color indicates a critical exception, the orange color indicates an important exception, and the blue color indicates a moderate exception.
State	The running status of the monitoring indicator.

4. Click **Details** in the **Actions** column of a monitoring indicator. In the **Monitoring details** panel, view the details of the monitoring indicator.

   In the upper-left corner of the **Monitoring details** panel, you can view the overall information about the metrics.

   - **Total Monitoring Items**: the number of metrics that belong to the monitoring indicator.
   - **Normal Items**: the number of metrics in the normal state.
   - **Abnormal Items**: the number of metrics in the abnormal state.

   In the metric list, you can view the following information.

Parameter	Description
Monitoring Metrics	The name of the metric.
Adjust Alert Threshold	The threshold for the metric. If the value of the metric reaches the threshold and lasts for a specific period of time, the status of the metric becomes abnormal.
Duration	The time period. If the value of the metric reaches the threshold and lasts for the specified period of time, the status of the metric becomes abnormal.
Monitoring Level	The urgency level displayed when the status of the metric becomes abnormal.
Status	The status of the metric.
Alert Notifications	The switch in the **Alert Notifications** column. If the status of the metric becomes abnormal, you can turn on or off the switch.

Manage metrics

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Security Monitoring**.

3. On the **Overall System Monitoring** tab, click **Details** in the **Actions** column.
4. In the **Monitoring details** panel, click **Adjust Threshold**, **Handle**, or **Adjust Duration** in the **Actions** column to manage a metric.

   You can perform the following operations on the metric:

   - **Adjust Threshold**: In the **Adjust Threshold** dialog box, modify the threshold and click **OK**.

     After you modify the threshold, an alert is generated when the value of the metric reaches the new threshold.
   - **Handle**: You can configure the status of the metric based on your business requirements.
     - If you do not want to handle the alert generated from the metric, select **Ignore** from the drop-down list. The status of the metric is **Ignored**.
     - After you handle the alert generated from the metric, select **Handled** from the drop-down list. The status of the metric is **handled**.
   - **Adjust Duration**: In the **Adjust Duration** dialog box, modify the time and click **OK**.

     When the value of the metric reaches the threshold and lasts for the specified period of time, the status of the metric becomes abnormal.

27.1.9.8.2. Alert settings

27.1.9.8.2.1. Configure alert contacts

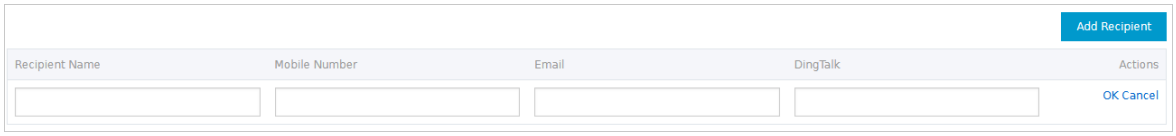
This topic describes how to configure and manage alert contacts.

Context

Apsara Stack Security sends alert notifications to alert contacts by text message, email, or DingTalk. When the detected information matches an alert rule, Apsara Stack Security sends an alert notification to the alert contacts.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Alert Settings**. On the page that appears, click the **Alert Recipient** tab.
3. Click **Add Recipient**.
4. Enter the contact information and click **OK**.



5. Manage alert contacts.

   In the contact list, find a contact and click **Edit** in the Actions column to edit the contact information.

27.1.9.8.2.2. Configure alert notifications

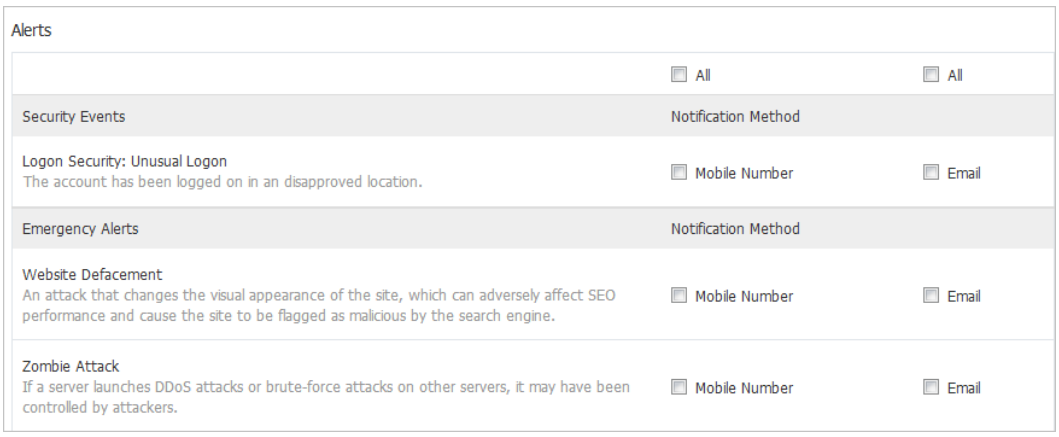
This topic describes how to configure the alert notification method for security events on tenants or platforms.

Context

In the **Alerts** section, security administrators can configure the alert notification method for security events. When a security event occurs, the system notifies the alert contacts by email, text message, or DingTalk. For more information about how to configure alert contacts, see Set alert recipients.

Alerts on tenants

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Alert Settings**. On the page that appears, click the **Tenant Alerts** tab.
3. In the **Alerts** section, select notification methods for each security event.



4. Click **Confirm**.

Alerts on the platform

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Alert Settings**. On the page that appears, click the **Platform Alerts** tab.
3. In the **Alerts** section, select notification methods for each security event.
4. Click **Confirm**.

27.1.9.8.3. Updates

27.1.9.8.3.1. Overview of the system updates feature

The system updates feature allows you to manually or automatically update the Apsara Stack Security and rule libraries for up-to-date protection.

The supported package import method depends on the Apsara Stack network environment.

- If Apsara Stack is connected to the Internet, you can choose **Automatically Download Update Packages**.
- If Apsara Stack is not connected to the Internet, you can choose **Manually Import Update Packages**.

The following table lists the update statuses of a rule library.

Update statuses of a rule library

Status	Description
To Be Updated	Indicates that a new version of the rule library is available for update.
Updating	Indicates that the rule library is being downloaded from Alibaba Cloud for update.
Updated	Indicates that the rule library has been updated.

Status	Description
Update Failed	Indicates that the rule library failed to be updated.

27.1.9.8.3.2. Enable automatic update check and update rule libraries

This topic describes how to enable automatic download of update packages and update rule libraries.

Context

If the Apsara Stack environment can connect to the Internet, you can enable automatic download of update packages to update the rule libraries.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Updates**.
3. Turn on **Auto Update Configuration** to enable automatic download of update packages.

   After this switch is turned on, the system automatically downloads update packages on a regular basis.
4. Update a rule library.

   You can update one or more rule libraries at a time.
   - Update multiple rule libraries at a time

     Click **Batch Update** in the upper-right corner to update all rule libraries.
   - Update a single rule library
     a. Click the tab of the rule type that you want to update. For example, click **Server Security**.
     b. In the **Actions** column, click **Update**.

27.1.9.8.3.3. Manually import an update package and update your service

This topic describes how to manually import an update package and update your service.

Prerequisites

The security administrator has obtained the offline update package.

Context

If the Apsara Stack environment cannot connect to the Internet, you can update a rule library after you import an offline update package.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Updates**.
3. Manually import an update package.
   i. Click **Import Update Package** next to **Manual Update** in the upper-left corner.

ii. In the **Import Update Package** dialog box, click **Browse** to select an offline update package that is downloaded to your on-premises server.

iii. Click **Confirm**.

4. Update a rule library.

   You can update one or more rule libraries at a time.

   - Update multiple rule libraries at a time

     Click **Batch Update** in the upper-right corner to update all rule libraries.

   - Update a single rule library

     a. Click the tab of the rule type that you want to update. For example, click **Server Security**.

     b. Click **Update** in the **Actions** column.

27.1.9.8.3.4. Roll back a rule library

This topic describes how to roll a rule library back to a previous version.

Context

If an error occurs with an updated rule library, you can roll the library back to a previous version to avoid service interruption.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Updates**.
3. Click the tab of the rule library that you want to roll back. Example: **Server Security**
4. In the Actions column for the rule library, choose **More > Roll Back**.
5. In the **Version Rollback** dialog box, click **Confirm**.

27.1.9.8.3.5. View the update history of a rule library

This topic describes how to view the update history of a rule library.

Context

You can view the update history of a rule library. If an error occurs with the latest version, you can locate the issue and roll back the rule library to an earlier version.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Updates**.
3. Click the tab of the specific rule library. Example: **Server Security**.
4. In the **Actions** column of a rule library, click **History**.

   On the **Previous Updates** page, you can view the update history of the rule library. Click **Details** to view the details of an update package.

27.1.9.8.4. Global configuration

27.1.9.8.4.1. Set CIDR blocks for traffic monitoring

Add a CIDR block for traffic monitoring

This topic describes how to add a Classless Inter-Domain Routing (CIDR) block for traffic monitoring. Network Traffic Monitoring System of Apsara Stack Security monitors the traffic of a specific CIDR block.

Context

CIDR blocks are configured for Network Traffic Monitoring System. Security administrators can change the CIDR blocks for monitoring based on business requirements. The settings of CIDR blocks apply only to a data center that is deployed in the region to which the specific CIDR block belongs.

> **Note**
>
> Changes to CIDR block settings immediately take effect without the intervention of security administrators.
>
> If you add the same CIDR block on the traffic collection CIDR block setting page and region setting page, make sure that you select the same region on both pages.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Traffic Collection IP Range** tab.
3. Click **Add**.
4. In the **Add CIDR Block for Monitoring** dialog box, configure parameters.

   - **CIDR Block**: Enter a CIDR block for traffic monitoring.

     > **Note** Take note that the CIDR block that you entered must be valid and unique.

   - **Region**: Select the region of the data center.
5. Click **Confirm**.

Manage CIDR blocks for traffic monitoring

This topic describes how to modify or delete Classless Inter-Domain Routing (CIDR) blocks for traffic monitoring.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Traffic Collection IP Range** tab.
3. Select a region, enter the CIDR block that you want to query, and then click **Search**.

   View the information about the CIDR block for traffic monitoring and the region in the search result.

4. In the **Actions** column, manage a CIDR block for traffic monitoring.
   - Modify the CIDR block for traffic monitoring

     Click **Modify** to modify the region of the CIDR block for traffic monitoring.
   - Delete the CIDR block for traffic monitoring

     Click **Delete** to delete the CIDR block for traffic monitoring.

27.1.9.8.4.2. Region settings

Add a CIDR block for a region

This topic describes how to add Classless Inter-Domain Routing (CIDR) blocks for regions that are detected and reported by using Server Guard.

Context

Region settings are used for region detection of the Server Guard agent. Server Guard servers automatically detect and match the regions of servers based on the IP address information that is reported by the Server Guard agent.

> **Note** You can change the region of a CIDR block. After the region is modified, you must also modify the region for all assets in the CIDR block on the Asset Overview page.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Region** tab.
3. Click **Add**.
4. In the **Add CIDR Block** dialog box, configure parameters.

   - **CIDR Block**: Enter a CIDR block for the region.

     > **Note** Enter a valid CIDR block. You cannot enter a CIDR block that has been configured for the region.
   - **Region**: Select a region.
5. Click **Confirm**.

Manage CIDR blocks for a region

This topic describes how to modify or delete Classless Inter-Domain Routing (CIDR) blocks for a region.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Region** tab.
3. Select a region, enter the CIDR block that you want to modify or delete, and then click **Search**.

   You can view the information about the CIDR block for the region in the search result.
4. In the **Actions** column, click Modify or Delete to manage the CIDR block for the region.
   - Modify the CIDR block for the region

     Click **Modify** to modify the CIDR block for the region.
   - Delete the CIDR block for the region

     Click **Delete** to delete the CIDR block for the region.

27.1.9.8.4.3. Configure whitelists

This topic describes how to configure the whitelist for the feature that blocks brute-force attacks in Server Guard and the following whitelists in Threat Detection Service (TDS). The whitelists contain IP addresses allowed by server brute-force attack blocking, IP addresses allowed by application attack blocking, and IP addresses allowed by web attack blocking.

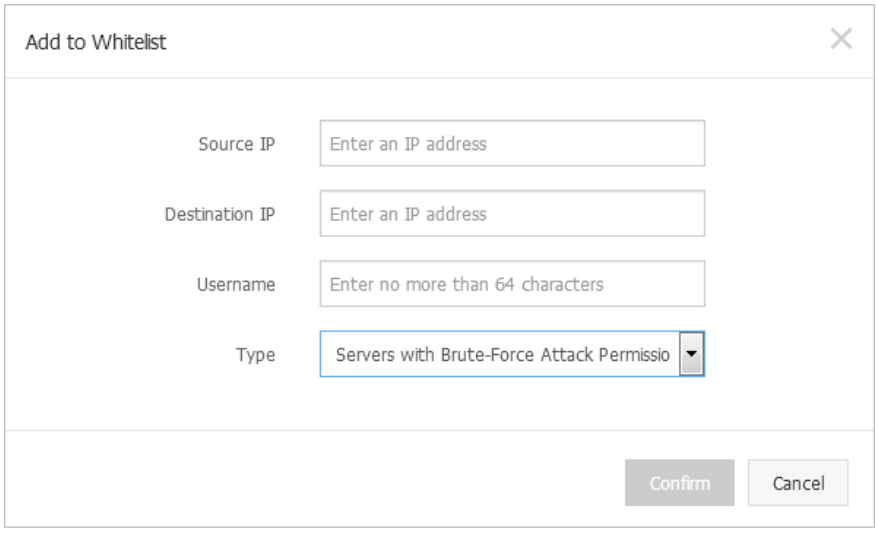
Context

If a normal request is regarded as an attack by the attack blocking feature of TDS or the unusual logon detection feature of Server Guard, you can add the source IP address of the request to a whitelist to avoid further false positives.

> **Note** Make sure that the IP addresses in the whitelist are trusted.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Whitelist** tab.
3. Click **Add**.
4. In the **Add to Whitelist** dialog box, configure the parameters.



Parameter	Description
Source IP	Enter a source IP address or Classless Inter-Domain Routing (CIDR) block.
Username	Enter the name of the user who creates the whitelist.
Type	○ **Brute-Force Attack Blocking Whitelist**: Server Guard does not generate alerts for brute-force attacks or unusual logons from the IP addresses that are contained in this whitelist. ○ **BWAF Whitelist**: The attack blocking feature does not generate alerts for the web attacks from the IP addresses that are contained in this whitelist. ○ **Servers with Brute-Force Attack Permissions**: The attack blocking feature does not generate alerts for the brute-force attacks from the IP addresses that are contained in this whitelist. ○ **IPs with Application Attack Permissions**: The traffic from the IP addresses in this whitelist is not detected as suspicious application attack traffic.

5. Click **OK**.
   If you want to delete an existing whitelist, click **Delete** in the Actions column. In the **Delete Whitelist** message, click **Confirm**.

27.1.9.8.4.4. Configure attack blocking policies

This topic describes how to enable web attack blocking and brute-force attack blocking.

Context

The attack blocking features protect your servers against web attacks and brute-force attacks.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings > Region**.
3. Turn on or off the switches in the Actions column to enable or disable **Web Attack Blocking** or **Brute-Force Attack Blocking**.

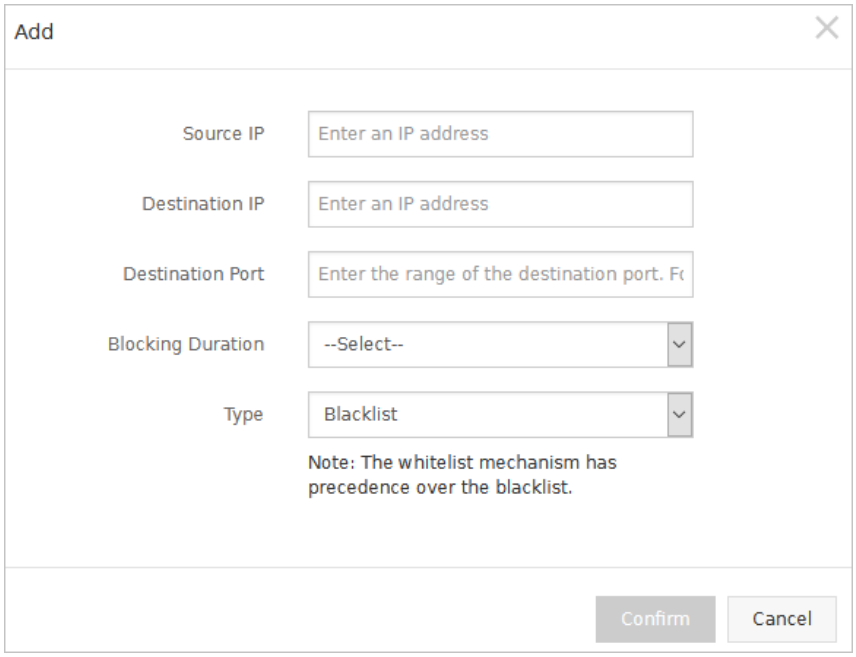
> **Note**
>
> In the Actions column, a red switch indicates a disabled feature and a green switch indicates an enabled feature.
>
> After you disable the blocking feature for an attack type, Apsara Stack Security Center generates only alerts for this type of attacks.

27.1.9.8.4.5. Block IP addresses

This topic describes how to manually block requests from a specific IP address based on traffic analysis results that are provided by Apsara Stack Security.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Block IP Addresses** tab.
3. Click **Add**.
4. In the **Add** dialog box, configure the parameters.



Parameter	Description
Protocol Type	Specify the protocol type. Valid values: **IPv4** and **IPv6**.
Source IP	Enter the source IP address that you want to block.
Destination IP	Enter the destination IP address that you want to block.
Destination Port	Enter the destination port that corresponds to the specified destination IP address.
Blocking Duration	Select a time range during which you want to block requests. Valid values: **1 Day**, **7 Days**, and **30 Days**.
Type	Select the blocking mode. Valid values: **Whitelist** and **Blacklist**.
Description	Enter the reason for blocking.

5. Click **Confirm**.

27.1.9.8.4.6. Configure custom IP addresses and locations

Add custom IP addresses and locations

This topic describes how to add custom IP addresses and locations. You can customize internal IP addresses based on your network plan. After you configure the internal IP addresses, IP addresses from the public address library do not match the addresses outside China.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Custom IP Location** tab.
3. Click **Add**.

   If you want to add multiple IP addresses and locations at a time, click **Batch Upload (.txt)**. This can be used to import multiple IP addresses and locations as a template.
4. In the **Add** dialog box, configure parameters.
5. Click **OK**.

Manage custom IP addresses and locations

This topic describes how to modify and delete custom IP addresses and locations.

Procedure

1.
2.
3. In the **Actions** column, manage custom IP addresses and locations.
   - To modify a custom IP address and a location:

     Click **Modify** to modify the custom IP address and location.
   - To delete a custom IP address and a location:

     Click **Delete** to delete the custom IP address and location.

27.1.9.8.5. System Monitoring

27.1.9.8.5.1. Configure CIDR blocks for traffic redirection in Cloud Firewall

Before you use Cloud Firewall, configure Classless Inter-Domain Routing (CIDR) blocks for traffic redirection.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > System Monitoring**.
3. On the **ICFW** tab in the **Service Monitoring** section of the **System Monitoring** page, click **Add** to the right of **Traffic Forwarding Configuration - Service CIDR Block**.
4. In the **Add** dialog box, configure **CIDR Block for Traffic Diversion** and **Type**.
5. Click **OK**.
   After you configure the CIDR blocks, you can view related information in **Traffic Forwarding Configuration - Service CIDR Block**, **Service Check Status**, and **Interface Status**.

27.1.9.8.6. Inspect services

This topic describes how to inspect services such as Cloud Firewall and Network Traffic Monitoring System in Apsara Stack Security Center. You can monitor the status and features of the services.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > System Monitoring**.
3. In the **System Inspection** section of the **Network Security** tab, inspect the services in the inspection list.

   To inspect a single service or multiple services at a time, perform the following operations:

   - Inspect multiple services at a time: In the **System Inspection** section, click **One-click Inspection** to inspect all services in the inspection list.
   - Inspect a single service: In the **System Inspection** section, click **Instant Inspection** in the **Actions** column of the service that you want to inspect.

   After you inspect the services, the status of the services changes to **Complete** in the **Inspection Status** column.
4. View the inspection results.

   You can view the following information about a service:

   - In the inspection list, view the service name, recent inspection time, number of inspection items, number of items whose status is normal, number of items whose status is abnormal, and inspection status.
   - Click **Details** in the **Actions** column of a service. In the **Inspection Details** dialog box, view the number of items whose status is normal, number of items whose status is abnormal, and the details of the items.
   - Click **Download** in the **Actions** column of a service. Download the inspection results to your computer as prompted for backup and reference.

27.1.9.8.7. Remote operations

27.1.9.8.7.1. Enable Remote O&M

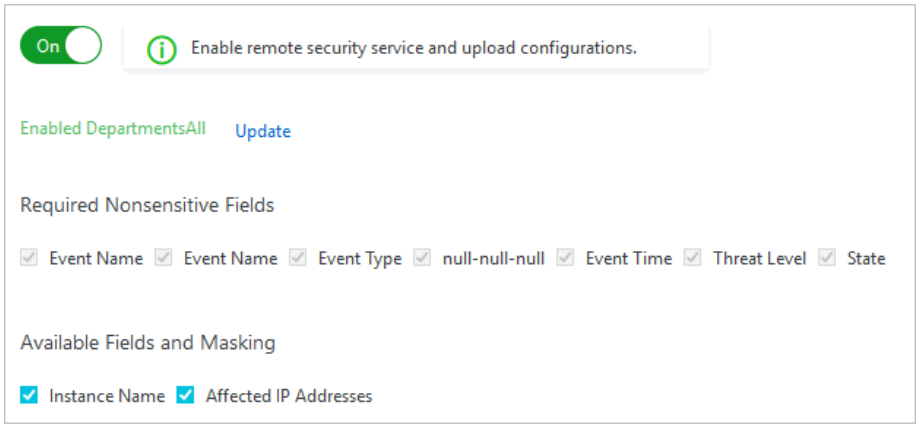
This topic describes how to enable remote operations.

Context

The **remote operations** function provides remote security operations and rules operations.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Remote O&M**.
3. On the **Remote O&M** page, turn on the switch to enable remote operations.



> **Note** The function is enabled if the switch turns green.

4. Select the departments for which you want to enable remote operations.
   i. Click **Update** on the right of **Enabled Departments**.
   ii. In the **Update Enabled Departments** dialog box, click the **Department** drop-down list to select the departments for which you want to enable remote operations.

   iii. Click **OK**.

> **Note** After you perform these operations, the security logs of **Enabled Departments** are encrypted and uploaded to Apsara Stack Security Center.

5. Select fields to encrypt and upload for remote operations.
   - If you select **Required Nonsensitive Fields**, the system encrypts and uploads the data.
   - If you select **Available Fields and Masking**, the system masks the data before encrypting and uploading it.

27.1.9.8.8. Account management

27.1.9.8.8.1. View and modify your Apsara Stack tenant account

This topic describes how to view and modify the information about your Apsara Stack tenant account that is bound to Apsara Stack Security.

Context

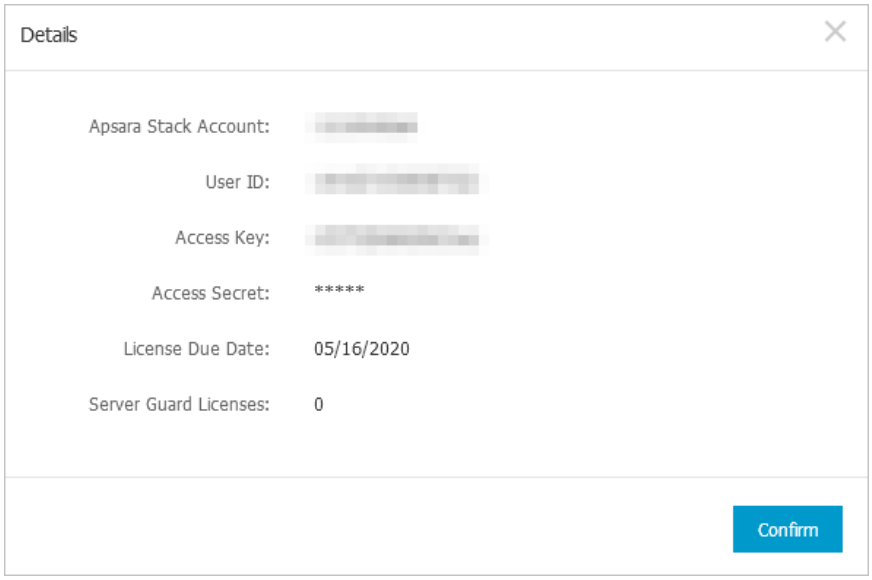
Note All assets in Apsara Stack Security are bound to your Apsara Stack tenant account. You can modify the account information. Proceed with caution.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Accounts**. On the page that appears, click the **Apsara Stack Account** tab.
3. Modify the information about your Apsara Stack tenant account.
   i. In the Actions column, click **Modify**.
   ii. In the **Change Account** dialog box, modify the account information.

   iii. Click **Confirm**.
4. View the details of your Apsara Stack tenant account.
   i. In the Actions column, click **Details**.
   ii. View the account details.

   The details include the license expiration date and the number of Server Guard licenses. The details are obtained based on the user ID and the AccessKey pair.



27.1.9.8.8.2. Add an Alibaba Cloud account

This topic describes how to add an Alibaba Cloud account in Apsara Stack Security Center. This allows you to use features in a hybrid cloud.

Context

After you add an Alibaba Cloud account in Apsara Stack, you can manage the Anti-DDoS Pro, Anti-DDoS Premium, and Web Application Firewall (WAF) instances that belong to the Alibaba Cloud account in Apsara Stack. This allows you to use features in a hybrid cloud.

Procedure

1.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Accounts**. On the page that appears, click the **Public Cloud Account** tab.
3. Click **Add**.
4. In the **Add Account** dialog box, enter the information about an Alibaba Cloud account and select Alibaba Cloud services to use.
   - Enter the **AccessKey ID** and **AccessKey secret** of the Alibaba Cloud account.
   - Select Alibaba Cloud services to use. Valid values:**Anti-DDoS Pro**, **Web Application Firewall**, and both.
5. Click **Confirm**.

Result

After an account is added, the account is displayed on the **Public Cloud Account** tab. To modify or delete an account, you can click **Modify** or **Delete** in the Actions column.

27.1.10. Optional security products

27.1.10.1. Anti-DDoS settings

27.1.10.1.1. Overview

In Distributed Denial of Service (DDoS) attacks, attackers exploit the client-server model to combine multiple computers into a platform that can launch attacks on one or more targets. This greatly increases the threat of attacks.

Common DDoS attack types include:

- **Network-layer attacks**: A typical example is UDP reflection attacks, such as NTP flood. These attacks use heavy traffic to congest the network of the victim, disabling proper responses to user requests.
- **Transport-layer attacks**: Typical examples include SYN flood and connection flood. These attacks consume a large number of connection resources of a server to cause denial of service.
- **Session-layer attacks**: A typical example is SSL flood. These attacks consume the SSL session resources of a server to cause denial of service.
- **Application-layer attacks**: Typical attack types include DNS flood, HTTP flood, and game zombie attacks. These attacks consume a large amount of application processing resources of a server to cause denial of service.

Apsara Stack Security can redirect, scrub, and re-inject attack traffic to protect your server against DDoS attacks and ensure normal business operations.

> **Note** Apsara Stack Security cannot scrub the traffic between internal networks.

27.1.10.1.2. View and configure DDoS mitigation policies

This topic describes how to view and configure distributed denial of service (DDoS) mitigation policies. Anti-DDoS provides default DDoS mitigation policies and DDoS traffic scrubbing policies.

Context

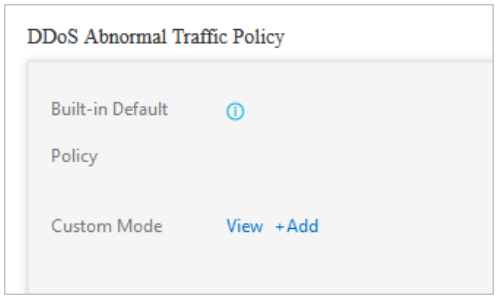
After an alert threshold of DDoS traffic for an IP address is set, an alert is triggered when traffic to the IP address reaches the threshold. The alert threshold for an IP address must be set based on the traffic volume. An abnormally large traffic volume indicates a possible DDoS attack. We recommend that you set an alert threshold to a value slightly higher than the peak traffic volume.

Apsara Stack Security supports a global alert threshold and alert thresholds for a specific Classless Inter-Domain Routing (CIDR) block or IP address.

- Global alert threshold: You cannot set a global alert threshold. It is automatically set when Apsara Stack Security is initialized.
- Alert threshold for a specific CIDR block: You can set an alert threshold for a specific CIDR block based on its traffic volume. CIDR block-specific alert thresholds allow you to control the traffic to each CIDR block.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Policy Configuration > DDoS Defense Policy**.
3. View and customize DDoS mitigation policies.



Operation	Description
View the default policy	Move the pointer over the icon indicated by the exclamation point in the preceding figure to view the default DDoS mitigation policy.
Customize a policy	Click View to view CIDR block-specific policies, and click +Add to customize a DDoS mitigation policy for a CIDR block.

To customize a policy for a CIDR block, perform the following steps:

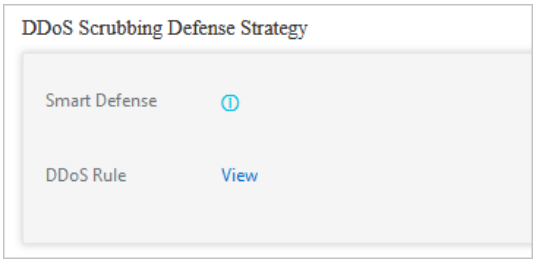
i. Click **+Add** next to **Custom Mode**.

ii. In the **Set Thresholds for Alerts** dialog box, configure the parameters.

Parameter	Description
CIDR Block	The CIDR block for which the alert thresholds are used.
Bandwidth Threshold	The alert threshold for bandwidth usage in a data center. When the sum of inbound and outbound traffic reaches this threshold, DDoS detection is triggered. Set this parameter to a value slightly higher than the peak traffic volume. We recommend that you set the value to 100 or higher. Unit: Mbit/s.
Packets Threshold	The alert threshold for the packet rate in a data center. When the sum of inbound and outbound packet rates reaches this threshold, DDoS detection is triggered. Set this parameter to a value slightly higher than the peak packet rate. We recommend that you set the value to 20000 or higher. Unit: packets per second (PPS).

iii. Click **OK**.

4. In the **DDoS Scrubbing Defense Strategy** section, click **View** to view DDoS traffic scrubbing policies.



27.1.10.1.3. View DDoS events

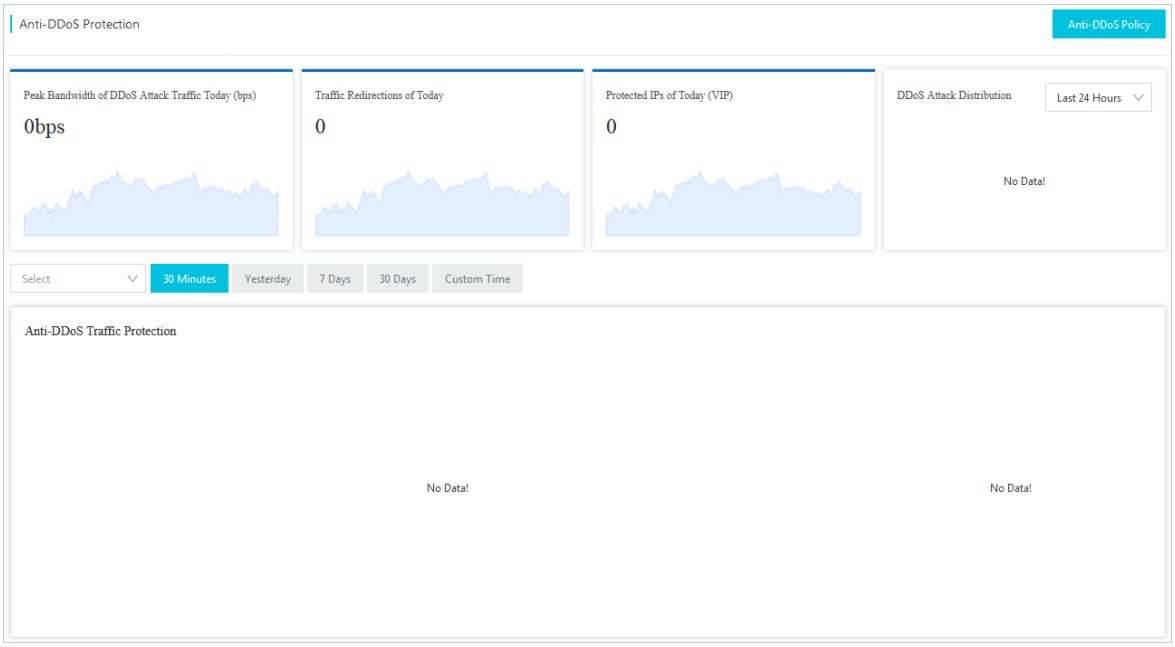
This topic describes how to view distributed denial of service (DDoS) events.

Context

During or after traffic scrubbing, Apsara Stack Security reports security events to Apsara Stack Security Center.

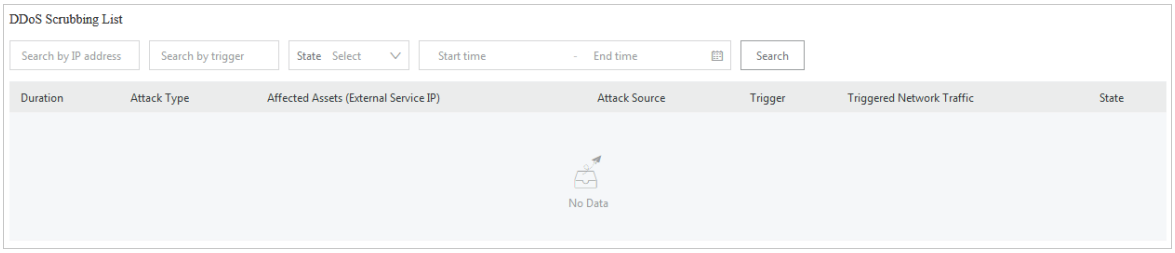
Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > DDoS Defense Policy**.
3. View anti-DDoS statistics.



4. (Optional)In the **DDoS Scrubbing List** section, specify search conditions and click **Search**.

> **Note** Skip this step if you need to view all traffic scrubbing events.



Search condition	Description
Search by IP address	The IP address that was under a DDoS attack.
Search by trigger	The metric that exceeds the configured alert threshold in the DDoS attack traffic.
State	○ Scrubbing: indicates that traffic scrubbing is in progress. ○ Scrubbing Complete: indicates that traffic scrubbing is complete.
Start time and End time	The start time and end time of DDoS traffic scrubbing.

5. In the DDoS Scrubbing List section, view details about DDoS traffic scrubbing events.

27.1.10.2. Cloud Firewall

27.1.10.2.1. Policy configuration

27.1.10.2.1.1. Synchronize assets for the Internet firewall

If new IP addresses are not in the IP address list of the Internet firewall, you can manually synchronize the IP address assets for the Internet firewall. This topic describes how to manually synchronize assets for the Internet firewall.

1.
2. In the left-side navigation pane, choose **Network Security > Policy Configuration > Firewall Switch Policy**.
3. Click the **Internet Firewall** tab. In the upper-right corner of the page, click **Update Assets**.
4. In the **Update Assets** message, click **OK**.
   After the assets are synchronized, the system updates the IP address list.

27.1.10.2.1.2. Create a VPC firewall

A virtual private cloud (VPC) firewall is a distributed firewall that can detect and control traffic between VPCs. Cloud Firewall can be used to analyze and control traffic between two VPCs only after a VPC firewall is created and enabled. This topic describes how to create a VPC firewall.

Context

A VPC firewall can be created only between two VPCs that are connected. VPCs can be connected by using Express Connect or Cloud Enterprise Network (CEN).

Procedure

1.
2. In the left-side navigation pane, click **Firewall Switch Policy**.
3. On the **Firewall Switches** page, click the **VPC-VPC** tab. Find the required instance and click **Create** in the Actions column.

Parameter	Description
Instance Name	Enter a name for the VPC firewall. We recommend that you enter a unique and informative name that indicates specific business to help identify the VPC firewall. The name can contain letters, digits, underscores (_), and hyphens (-). However, the name cannot contain only digits.
Route Table	When you create a VPC, the system automatically creates a default route table. You can add system routes to the route table to manage VPC traffic. VPC allows you to create multiple route tables. When you create a VPC firewall in the Cloud Firewall console, Cloud Firewall automatically reads your VPC route tables. Express Connect supports multiple route tables. If you create a VPC firewall for Express Connect, you can view multiple VPC route tables and can select specific route tables for protection.
Destination CIDR Block	After you select a route table from the Route Table drop-down list, the default destination Classless Inter-Domain Routing (CIDR) block of the route table appears in the Destination CIDR Block field. If you want to protect traffic destined for other CIDR blocks, you can manually modify the destination CIDR block. You can enter multiple CIDR blocks and separate them with commas (,).
Peer Route Table	Confirm the region and name of the peer VPC, and select the route table for protection.
Peer Destination CIDR Blocks	Confirm the destination CIDR block of the peer VPC.

Parameter	Description
Firewall Mode	○ Test: In this mode, the VPC firewall tests the health status of CIDR blocks or IP addresses to ensure normal links. ○ Active: In this mode, the VPC firewall redirects and protects traffic. ○ Bypass: In this mode, the VPC firewall does not redirect traffic. If a self-test or a health test fails, the VPC firewall automatically changes to the Bypass mode. When you create a VPC firewall, you can set Firewall Mode only to Test. After the firewall is created, you can change its mode to Active or Bypass. You cannot directly change the mode from Bypass to Active. You must change the mode from **Bypass** to **Test** first, and then to **Active**. In the **Health Test** section, enter 32-bit test IP addresses that belong to the local and peer VPCs.
IPS Mode	Select the working mode of the intrusion prevention system (IPS). Valid values: ○ Monitoring Mode: If Cloud Firewall detects malicious traffic, it monitors the traffic and sends alerts. ○ Traffic Control Mode: Cloud Firewall intercepts malicious traffic and blocks intrusion attempts.
IPS Capabilities	Select the intrusion prevention policies that you want to enable. Valid values: ○ Basic Policies: This feature provides basic intrusion prevention capabilities, such as protection against brute-force attacks and attacks that exploit command execution vulnerabilities. This feature also allows you to manage and control the connections from infected hosts to a command and control (C&C) server. ○ Virtual Patches: This feature defends against the most common and high-risk application vulnerabilities in real time.
Enable VPC Firewall	If you turn on Enable VPC Firewall, the VPC firewall is automatically enabled after it is created. If you do not require the VPC firewall to be automatically enabled, turn the switch off.

4. Click **Submit**.

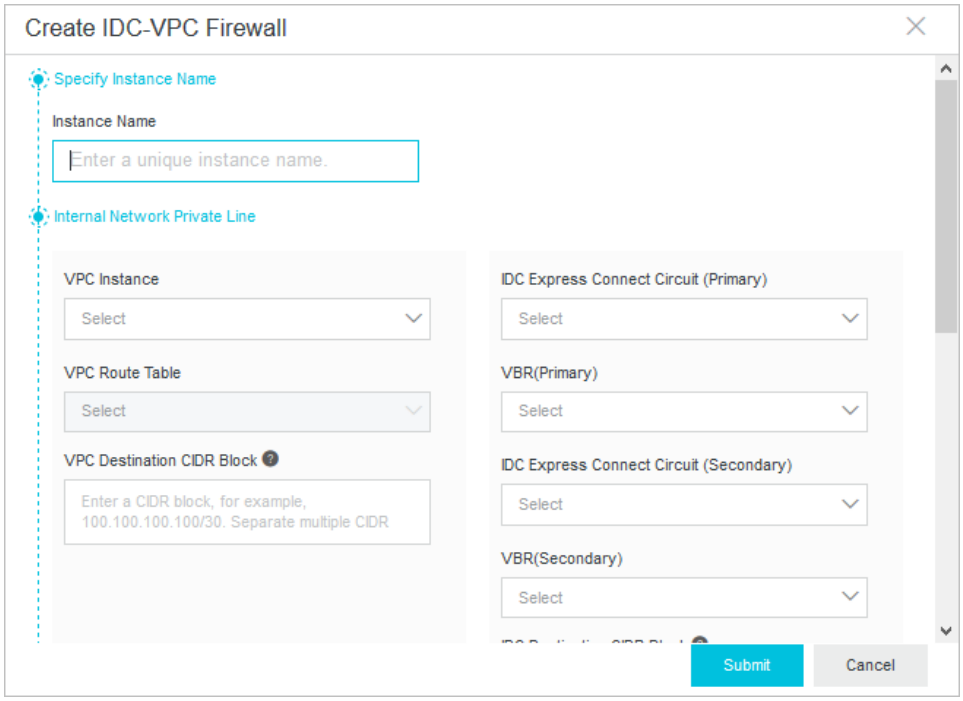
   If Firewall Status of the VPC firewall changes to **Enabled**, the VPC firewall takes effect.

27.1.10.2.1.3. Create an IDC-VPC firewall

An IDC-VPC firewall can detect the traffic between an on-premises data center and a virtual private cloud (VPC). Cloud Firewall allows you to control traffic through IDC-VPC firewalls. This topic describes how to create an IDC-VPC firewall.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, click **Firewall Switch Policy**.
3. On the **Firewalls** page, click the **IDC-VPC** tab. In the upper-right corner, click **Create**.



Parameter	Description
Instance Name	Enter a name for the VPC firewall. We recommend that you enter a unique name that indicates the specific business to make it easy to identify the VPC firewall. The name can contain letters, digits, underscores (_), and hyphens (-). However, the name cannot contain only digits.
VPC Instance	Select the ID of a VPC. The ID is the unique identifier of the VPC. Cloud Firewall automatically synchronizes the VPCs that are connected to the on-premises data center.
VPC Route Table	When you create a VPC, the system automatically creates a default route table. You can add system routes to the route table to manage VPC traffic. VPC allows you to create multiple route tables. When you create a VPC firewall in the Cloud Firewall console, Cloud Firewall automatically reads your VPC route tables. Express Connect supports multiple route tables. When you create a VPC firewall for an Express Connect, you can view multiple VPC route tables and can select the route tables that you want to protect.
VPC Destination CIDR Block	After you select a route table from the VPC Route Table drop-down list, the default destination Classless Inter-Domain Routing (CIDR) block of the route table is displayed in the Destination CIDR Block section. If you need to protect traffic to other CIDR blocks, you can manually modify destination CIDR blocks. You can add multiple CIDR blocks that are separated with commas (,).
IDC Express Connect Circuit (Primary)	Select a leased line ID that you create when you connect the on-premises data center to Apsara Stack. When the customer edge (CE) in the on-premises data center connects to the primary and secondary VSwitches, you must specify a primary leased line. The IDC-VPC firewall automatically synchronizes the primary leased line that you specify. You must specify this parameter when you create the IDC-VPC firewall.

Parameter	Description
VBR (Primary)	Select a virtual border router (VBR) that is bound to the primary leased line in the on-premises data center. The VBR facilitates communication between the VPC and the on-premises data center. The IDC-VPC firewall automatically synchronizes the VBR that you specify. You must specify this parameter when you create the IDC-VPC firewall.
IDC Express Connect Circuit (Secondary)	Select a leased line ID that you create when you connect the on-premises data center to Apsara Stack. You must specify a secondary leased line when the customer edge (CE) in the on-premises data center connects to the primary and secondary VSwitches. The value of this parameter cannot be the same as that of the IDC Express Connect Circuit (Primary) parameter. The IDC-VPC firewall automatically synchronizes the secondary leased line that you specify. You must specify this parameter when you create the IDC-VPC firewall.
VBR(Secondary)	Select a VBR that is bound to the secondary leased line in the on-premises data center. The VBR facilitates communication between the VPC and the on-premises data center. The IDC-VPC firewall automatically synchronizes the VBR that you specify. You must specify this parameter when you create the IDC-VPC firewall.
VPC Destination CIDR Block	The destination CIDR block of the peer VPC.
Firewall Mode	◦ Test: This mode is used to test the health status of the CIDR block or the IP address to ensure that the link is normal. ◦ Active: This mode is used to redirect and protect traffic. ◦ Bypass: The firewall does not redirect the traffic in this mode. If the self-test or the health test fails, the firewall is automatically changed to the Bypass mode. When you create a VPC firewall, you can set Firewall Mode only to Test. After the firewall is created, you can change its mode to Active or Bypass. You cannot directly change the mode from Bypass to Active. You must change the mode from **Bypass** to **Test** first and then to **Active**. In the **Health Test** section, enter a 32-bit test IP address that is created in the local VPC.
IPS Mode	Select the working mode of the intrusion prevention system (IPS). Valid values: ◦ Monitoring Mode: If Cloud Firewall detects malicious traffic, it monitors traffic and sends alerts. ◦ Traffic Control Mode: Cloud Firewall intercepts malicious traffic and blocks intrusion attempts.
IPS Capabilities	Select the intrusion prevention policies that you want to enable. Valid values: ◦ Basic Policies: This feature provides basic intrusion prevention capabilities such as protection against brute-force attacks and attacks that exploit command execution vulnerabilities. It also allows you to manage and control the connections from infected hosts to a command and control (C&C) server. ◦ Virtual Patches: This feature defends against the most common high-risk application vulnerabilities in real time.
Enable VPC Firewall	After you turn on Enable VPC Firewall, an IDC-VPC firewall is enabled automatically after it is created. If you do not require the IDC-VPC firewall to be automatically enabled after it is created, turn off this switch.

4. Click **Submit**.

   When the IDC-VPC firewall takes effect, Firewall Status of the IDC-VPC firewall changes to **Enabled**.

27.1.10.2.2. Access control

27.1.10.2.2.1. Manage address books

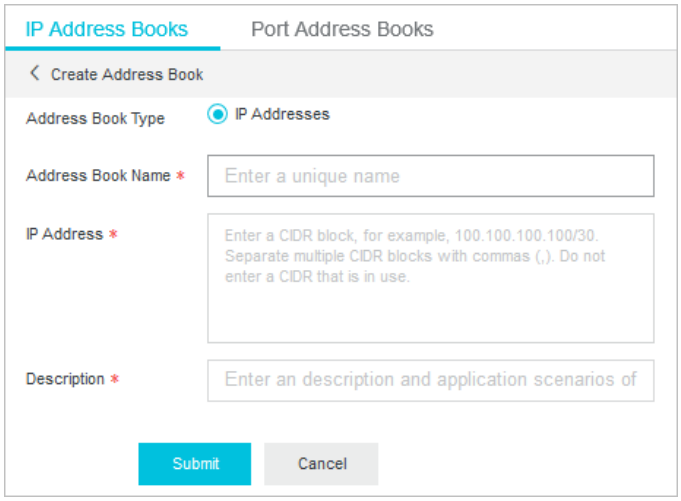
This topic describes how to create and manage IP address books and port address books. You can use address books to store one or more Classless Inter-Domain Routing (CIDR) blocks or ports.

Context

You can store frequently used IP addresses and ports in address books to facilitate configurations of the Internet firewall.

Create an IP address book

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. On the Access Control page, click the **Internet Firewall** tab.
4. In the upper-right corner, click **Address Books**. In the dialog box that appears, click the **IP Address Books** tab.
5. Click **+Create Address Book** to specify parameters.



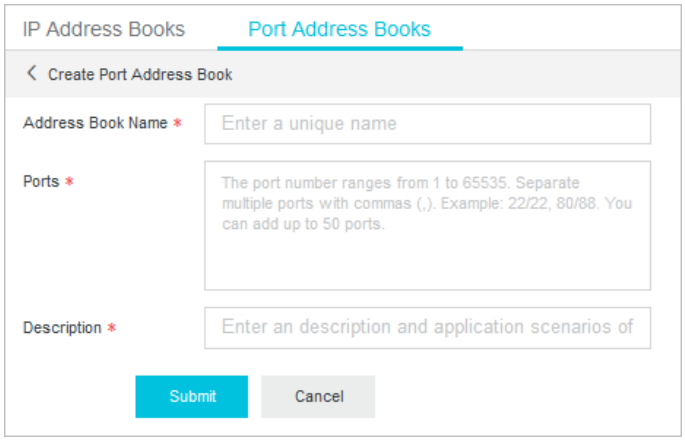
Parameter	Description
Address Book Type	Select the type of the address book. Set the value to **IP Addresses**.
Address Book Name	Specify the name of the address book. The name must be unique. The name can contain letters, digits, underscores (_), and hyphens (-). However, the name cannot contain only digits.
IP Address	Enter a CIDR block. Separate multiple CIDR blocks with commas (,).
Description	Enter the content and scenarios of the address book. The description must be 2 to 512 characters in length.

6. Click **Submit**.

After the address book is created, you can view the address book on the **IP Address Books** tab. You can click **Modify** or **Delete** to manage address books.

Create a port address book

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. On the Access Control page, click the **Internet Firewall** tab.
4. In the upper-right corner, click **Address Books**. In the dialog box that appears, click the **Port Address Books** tab.
5. Click **+Create Address Book** to specify parameters.



Parameter	Description
Address Book Name	Specify the name of the address book. The name must be unique. The name can contain letters, digits, underscores (_), and hyphens (-). However, the name cannot contain only digits.
Ports	Enter a port number or port range. Separate multiple port numbers or ranges with commas (,).
Description	Enter the content and scenarios of the address book. The description must be 2 to 512 characters in length.

6. Click **Submit**.
After the address book is created, you can view the address book on the **Port Address Books** tab. You can click **Modify** or **Delete** to manage address books.

27.1.10.2.2.2. Configure access control policies on the Internet firewall

The access control feature allows you to configure access control policies on the Internet firewall. You can configure inbound and outbound policies on the Internet Firewall tab to forbid unauthorized access between the Internet and your servers.

Context

The Internet firewall supports **Outbound Policies** and **Inbound Policies**.

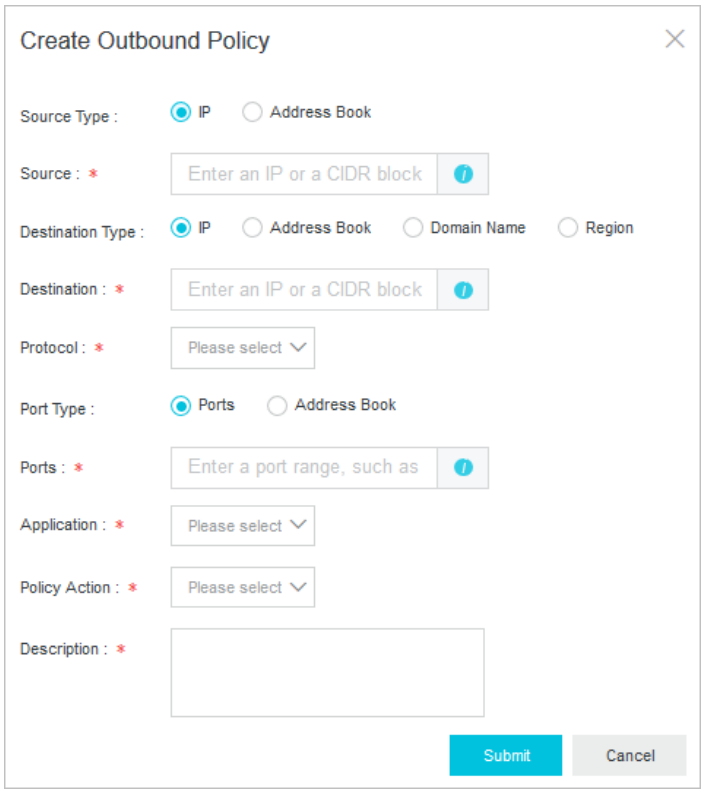
In this topic, IP address books, port address books, and domain address books are used. For more information about how to create these address books, see Manage address books.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. Click the **Internet Firewall** tab.
4. Click the **Outbound Policies** tab. You can also click the **Inbound Policies** tab if required.

   - **Outbound Policies** tab: You can configure control policies for traffic from your internal network to the Internet.
   - **Inbound Policies** tab: You can configure control policies for traffic from the Internet to your internal network.
5. Click **Create**.

   In the **Create Outbound Policy** dialog box, configure the parameters.



Parameter	Description

Parameter	Description
Source Type	The type of the traffic source. Valid values: **IP** and **Address Book**. ○ **IP**: If you select this option, enter only one CIDR block in the Source field. ○ **Address Book**: If you select this option, select a pre-configured IP address book for the Source field. An IP address book contains multiple CIDR blocks. This allows you to control traffic from multiple IP addresses.
Source	The source addresses that are allowed to access the Internet. ○ If you set **Source Type** to **IP**, enter a CIDR block. Example: 1.*.*.1/32. ○ If you set **Source Type** to **Address Book**, click **Select Address Book**. In the **Select Address Book as Source** dialog box, select an IP address book.
Destination Type	The type of the traffic destination. Valid values: **IP**, **Address Book**, **Domain Name**, and **Region**.
Destination	The destination addresses that can be accessed. You must set **Destination** to addresses on the Internet. ○ If you set **Destination Type** to **IP**, enter a CIDR block. Example: 1.*.*.1/32. ○ If you set **Destination Type** to **Address Book**, click **Select Address Book**. In the **Select Address Book as Destination** dialog box, select an IP address book. ○ If you set **Destination Type** to **Domain Name**, enter a domain name. Example: www.example.com. ○ If you set **Destination Type** to **Region**, select one or more destination regions from the drop-down list.
Protocol	The protocol of outbound traffic. Valid values: **TCP**, **UDP**, **ICMP**, and **ANY**. If you do not know which protocol is used, select ANY.
Port Type	The type of ports that are used for the selected protocol. Valid values: **Ports** and **Address Book**. ○ **Ports**: If you select this option, enter a port range in the Ports field. ○ **Address Book**: If you select this option, select a pre-configured port address book for the Ports field. A port address book contains multiple ports. This allows you to control traffic on multiple ports.
Ports	The ports on which you want to control traffic. Enter a port range or select a port address book based on how you set the Port Type parameter. ○ If you set **Port Type** to **Ports**, enter a port range. ○ If you set **Port Type** to **Address Book**, click **Select Address Book**. In the **Select Ports** dialog box, select a port address book.
Application	The application for the traffic.
Policy Action	The action on the traffic. ○ **Allow**: If outbound traffic meets the preceding conditions that you specify for the policy, the traffic is allowed. ○ **Monitor**: If outbound traffic meets the preceding conditions that you specify for the policy, the traffic is recorded and allowed. ○ **Deny**: If outbound traffic meets the preceding conditions that you specify for the policy, the traffic is blocked.

Parameter	Description
Description	The description of the policy. Enter an informative description to help identify the policy. The description can contain digits, letters, and underscores (_).

6. Click **Submit**.

Result

After the policy is created, it appears in the policy list. In the **Actions** column that corresponds to the policy, you can click **Modify**, **Delete**, **Insert**, or **Move** to manage the policy.

27.1.10.2.2.3. Create a policy group

This topic describes how to create a policy group for an internal firewall. You can configure access control policies to forbid unauthorized access between Elastic Compute Service (ECS) instances.

Context

An internal firewall is implemented by leveraging the security group module of ECS. The access control policies that you configure on the **Internal Firewall** tab are automatically synchronized to the security group module of ECS.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. Click the **Internal Firewall** tab.
4. In the upper-right corner, click **Create Policy Group**.
5. In the **Create Policy Group** dialog box, configure parameters based on your business requirements.

Parameter	Description	Configuration method
Name	The name of the policy group. The name must be 2 to 128 characters in length.	Enter an informative name to help identify the policy group.
VPC	The virtual private cloud (VPC) to which the policy group is applied.	Select a VPC from the **VPC** drop-down list. **Note** You can select only one VPC.
Instance ID	The ID of the ECS instance in the selected VPC.	Select an ECS instance ID from the **Instance ID** drop-down list. **Note** You can select multiple instance IDs.
Description	The description of the policy group. The description must be 2 to 256 characters in length.	Enter an informative description to help identify the policy group.

Parameter	Description	Configuration method
Template	The template of the policy group.	Select a template from the **Template** drop-down list. Valid values: ○ **default-accept-login**: allows all inbound traffic on ports 22 and 3389. ○ **default-drop-all**: blocks all traffic in the policy group. ○ **default-accept-all**: allows all traffic in the policy group.

6. Click **Submit**.

27.1.10.2.2.4. Configure access control policies on an internal firewall

This topic describes how to view the policy groups of an internal firewall, configure access control policies in the policy groups, and synchronize the policies to the security group module of Elastic Compute Service (ECS).

Context

On the **Internal Firewall** tab, you can view custom policy groups and security groups that are synchronized from ECS.

For more information about how to create a custom policy group, see Create a policy group.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. Click the **Internal Firewall** tab.
4. (Optional)Specify filter conditions and click **Search** to search for the required policy group.

   > **Note** If you want to view all policy groups, skip this step.

   The required policy group appears in the policy group list.
5. Find the required policy group and configure an access control policy in this group.
   i. In the **Actions** column, click **Configure Policy**.
   ii. On the **Policies** page, click **Create Policy**.

   > **Note** If you want to modify or delete an access control policy, you can perform the following steps: Click the **Inbound** or **Outbound** tab, find the policy, and then click **Modify** or **Delete** in the Actions column.

   iii. In the **Create Policy** dialog box, configure the parameters.

Parameter	Description
Network Type	The type of the network to which the policy is applied. Default value: **Internal**, which indicates that the policy is applied to an internal network.

Parameter	Description
Direction	The direction of traffic that is controlled by the policy. Valid values: ■ **Inbound**: Traffic is from other ECS instances to the specified ECS instance. ■ **Outbound**: Traffic is from the specified ECS instance to other ECS instances.
Policy Type	The action on traffic that is controlled by the policy. Valid values: ■ **Allow**: Traffic is allowed in the internal network. ■ **Deny**: Traffic is blocked in the internal network.
Protocol Type	The protocol of traffic that is controlled by the policy. Select a protocol from the **Protocol Type** drop-down list. Valid values: ■ **TCP** ■ **UDP** ■ **ICMP** ■ **ANY**: If you do not know which protocol is used, select **ANY**.
Port Range	The port range of traffic that is controlled by the policy. The traffic is destined for ports in this range. Enter a port range. Example: 22/22.
Priority	The priority of the policy. **Note** The priority number must be an integer from 1 to 100. Different policies can have the same priority. If an Allow policy and a Deny policy have the same priority, the **Deny** policy takes effect. If two **Allow** policies have the same priority, both policies take effect.
Source Type	The type of the traffic source. Valid values: ■ **CIDR Block**: The traffic source is a CIDR block. ■ **Policy Group**: The traffic source is an ECS instance in the policy group. **Note** If you create a policy in the security group module of ECS, you **cannot** set **Source Type** to **Policy Group**.
Source	The source of traffic that is controlled by the policy. Enter a CIDR block or select a policy group based on how you set the **Source Type** parameter. ■ If you set Source Type to **CIDR Block**, enter only one CIDR block. ■ If you set Source Type to **Policy Group**, select a policy group from the **Source** drop-down list. In this case, the traffic source is an ECS instance in the policy group. **Note** You can select only one policy group from the **Source** drop-down list.
Destination	The destination of traffic that is controlled by the policy. Valid values: ■ **All ECS Instances**: The policy is applied to traffic destined for your ECS instances. ■ **CIDR Block**: The policy is applied to traffic destined for the specified CIDR block.

Parameter	Description
Description	The description of the policy. Enter an informative description to help identify the policy. The description must be 2 to 256 characters in length.

iv. Click **Submit**.

6. Find the required policy group and click **Publish** in the **Actions** column to apply the policy and synchronize it to the security group module of ECS.

27.1.10.2.2.5. Configure access control policies on a VPC firewall

A virtual private cloud (VPC) firewall detects and controls the traffic between two VPCs. This topic describes how to configure access control policies on a VPC firewall.

Prerequisites

VPC firewalls are not automatically created. Before you configure access control policies for VPCs, you must create and enable a VPC firewall. For more information, see Create a VPC firewall.

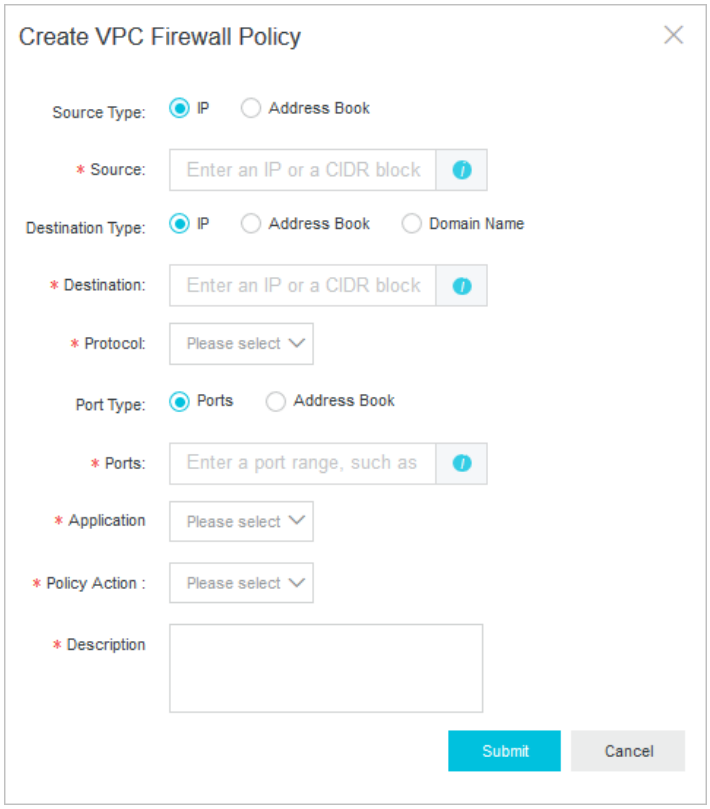
Context

Access control policies of a VPC firewall take effect only after you enable the VPC firewall.

By default, a VPC firewall allows all traffic. If you want to control traffic between VPCs, you can configure access control policies to block traffic from untrusted sources. You can also allow traffic from trusted sources and block traffic from all other sources.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. Click the **VPC Firewall** tab.
4. Click **Create**.
5. In the **Create VPC Firewall Policy** dialog box, configure an access control policy.



Parameter	Description
Source Type	The type of the traffic source. Valid values: IP and Address Book. ○ **IP**: If you select this option, you must enter a CIDR block in the Source field. ○ **Address Book**: If you select this option, you must select a pre-configured address book for the Source field. You can add multiple CIDR blocks to an address book to simplify policy configuration.
Source	The source of the traffic. **Note** You can enter only one CIDR block. Example: 1.*.*.1/32. If you set Source Type to Address Book, select a pre-configured address book.
Destination Type	The type of the traffic destination. Valid values: ○ **IP**: If you select this option, you must enter an IP address in the Destination field. ○ **Address Book**: If you select this option, you must select an address book for the Destination field. ○ **Domain Name**: If you select this option, you must enter a domain name in the Destination field. Wildcard domain names are supported. Example: **.aliyun.com*. **Note** By default, if an HTTP header does not contain the Host field or an HTTPS request does not contain the Server Name Indication (SNI), Cloud Firewall allows the traffic.

Parameter	Description
Destination	The destination of the traffic. You can enter only one CIDR block. If you set Destination Type to Domain Name, enter a domain name. Wildcard domain names are supported. Example: **.aliyun.com*.
Protocol	The protocol of the traffic. Valid values: ○ **ANY**: all protocols ○ **TCP** ○ **UDP** ○ **ICMP**
Ports	The port range of the traffic. The value 0/0 indicates all ports. **Note** If you set Protocol to ICMP, the port configuration does not take effect. If you set Protocol to ANY, the port configuration does not take effect in controlling ICMP traffic.
Application	The application for the traffic. Valid values: ANY, HTTP, HTTPS, Memcache, MongoDB, MQTT, MySQL, RDP, Redis, SMTP, SMTPS, SSH, and VNC If you set Protocol to TCP, multiple applications are supported. If you set Protocol to another value, only ANY is supported. **Note** Cloud Firewall identifies applications based on packet characteristics, instead of port numbers. If Cloud Firewall fails to identify the application for a packet, it allows the packet.
Policy Action	The action on the traffic. Valid values: ○ **Allow**: If traffic meets the preceding conditions that you specify for the policy, the traffic is allowed. ○ **Deny**: If traffic meets the preceding conditions that you specify for the policy, the traffic is blocked. ○ **Monitor**: If traffic meets the preceding conditions that you specify for the policy, the traffic is recorded and allowed. After you observe the traffic for a period of time, you can change the policy action to Allow or Deny.
Description	The description of the policy. Enter an informative description to help identify the policy.

6. Click **Submit**.

27.1.10.2.2.6. Configure access control policies on an IDC-VPC firewall

Cloud Firewall detects and controls access traffic between Internet data centers (IDCs) and virtual private clouds (VPCs). This topic describes how to create and manage access control policies on an IDC-VPC firewall.

Prerequisites

IDC-VPC firewalls are not automatically created. Before you configure access control policies between an IDC and a VPC, you must create and enable an IDC-VPC firewall.

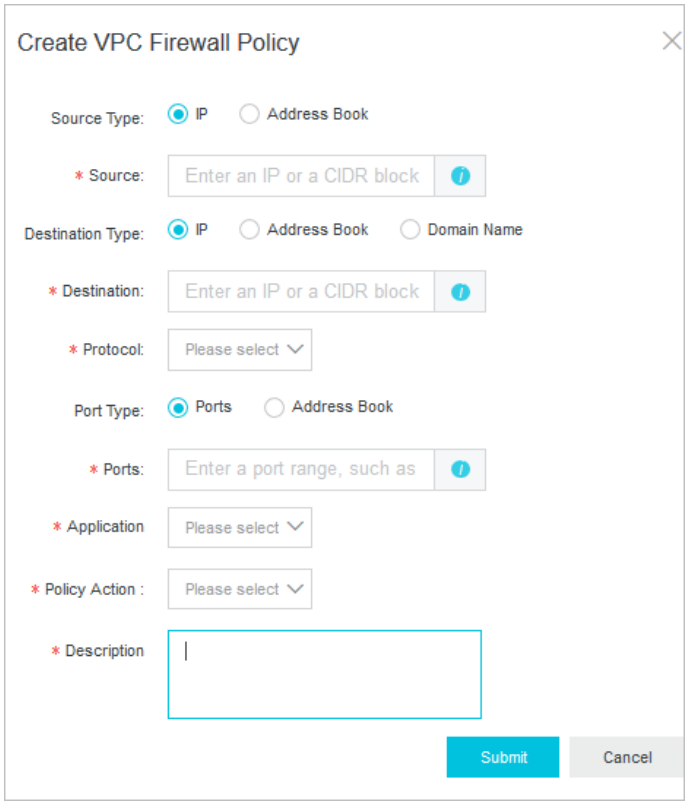
Access control policies of an IDC-VPC firewall take effect only after you enable the IDC-VPC firewall.

Context

By default, an IDC-VPC firewall allows all traffic. If you want to control traffic between an IDC and a VPC, you can configure access control policies to block traffic from untrusted sources. You can also allow traffic from trusted sources and block traffic from all other sources.

Procedure

1.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. On the page that appears, click the **IDC-VPC Firewall** tab.
4. Click **Create**.
5. In the **Create IDC-VPC Firewall Policy** dialog box, configure an access control policy.



Parameter	Description
Source Type	The type of the traffic source. Valid values: ○ **IP**: If you select this option, you must enter an IP address or a Classless Inter-Domain Routing (CIDR) block in the Source field. ○ **Address Book**: If you select this option, you must select a pre-configured address book for the Source field. You can add multiple CIDR blocks to an address book to simplify policy configuration.

Parameter	Description
Source	The source of the traffic. **Note** You can enter only one CIDR block. Example: 1.*.*.1/32. If you set Source Type to Address Book, select a pre-configured address book.
Destination Type	The type of the traffic destination. Valid values: ○ **IP**: If you select this option, you must enter an IP address or a CIDR block in the Destination field. ○ **Address Book**: If you select this option, you must select an address book for the Destination field. ○ **Domain Name**: If you select this option, you must enter a domain name in the Destination field. Wildcard domain names are supported. Example: **.aliyun.com*. **Note** By default, if an HTTP header does not contain the Host field or an HTTPS request does not contain the Server Name Indication (SNI), Cloud Firewall allows the traffic.
Destination	The destination of the traffic. You can enter only one CIDR block. If you set Destination Type to Domain Name, enter a domain name. Wildcard domain names are supported. Example: **.aliyun.com*.
Protocol	The protocol of the traffic. Valid values: ○ **ANY**: all protocols ○ **TCP** ○ **UDP** ○ **ICMP**
Ports	The port range of the traffic. The value 0/0 indicates all ports. **Note** If you set Protocol to ICMP, the port configuration does not take effect. If you set Protocol to ANY, the port configuration does not take effect in controlling ICMP traffic.
Application	The application for the traffic. Valid values: ANY, HTTP, HTTPS, Memcache, MongoDB, MQTT, MySQL, RDP, Redis, SMTP, SMTPS, SSH, SSL, and VNC If you set Protocol to TCP, multiple applications are supported. If you set Protocol to another value, only ANY is supported. **Note** Cloud Firewall identifies applications based on packet characteristics, instead of port numbers. If Cloud Firewall fails to identify the application for a packet, it allows the packet.

Parameter	Description
Policy Action	The action on the traffic. Valid values: ○ **Allow**: If traffic meets the preceding conditions that you specify for the policy, the traffic is allowed. ○ **Deny**: If traffic meets the preceding conditions that you specify for the policy, the traffic is blocked. ○ **Monitor**: If traffic meets the preceding conditions that you specify for the policy, the traffic is recorded and allowed. After you observe the traffic for a period of time, you can change the policy action to Allow or Deny.
Description	The description of the policy. Enter an informative description to help identify the policy.

6. Click **Submit**.

27.1.10.2.3. Intrusion prevention

27.1.10.2.3.1. Configure intrusion prevention policies

Cloud Firewall uses a built-in threat detection engine to defend against intrusions and common cyber attacks. It provides virtual patches against vulnerabilities to intelligently block intrusion attempts.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Policy Configuration > Intrusion Prevention Policies**.
3. Select a running mode for the threat engine.

Valid values: **Monitoring Mode** and **Traffic Control Mode**.

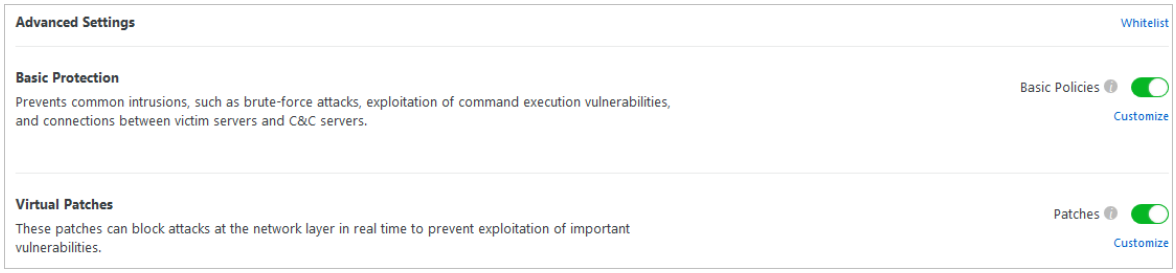
- **Monitoring Mode**: In monitoring mode, the system generates alerts on intrusions instead of blocking the malicious traffic.
- **Traffic Control Mode**: In traffic control mode, the system automatically blocks malicious traffic.

To configure **Traffic Control Mode**, perform the following steps:

i. Select **Traffic Control Mode**.

ii. In the dialog box that appears, click **OK**.

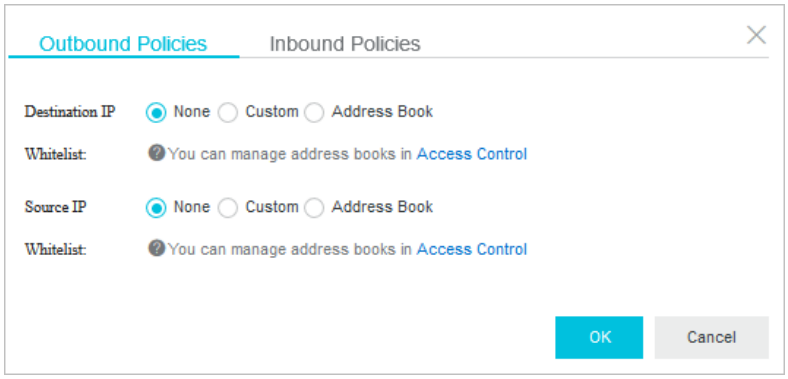
4. Configure the advanced features.



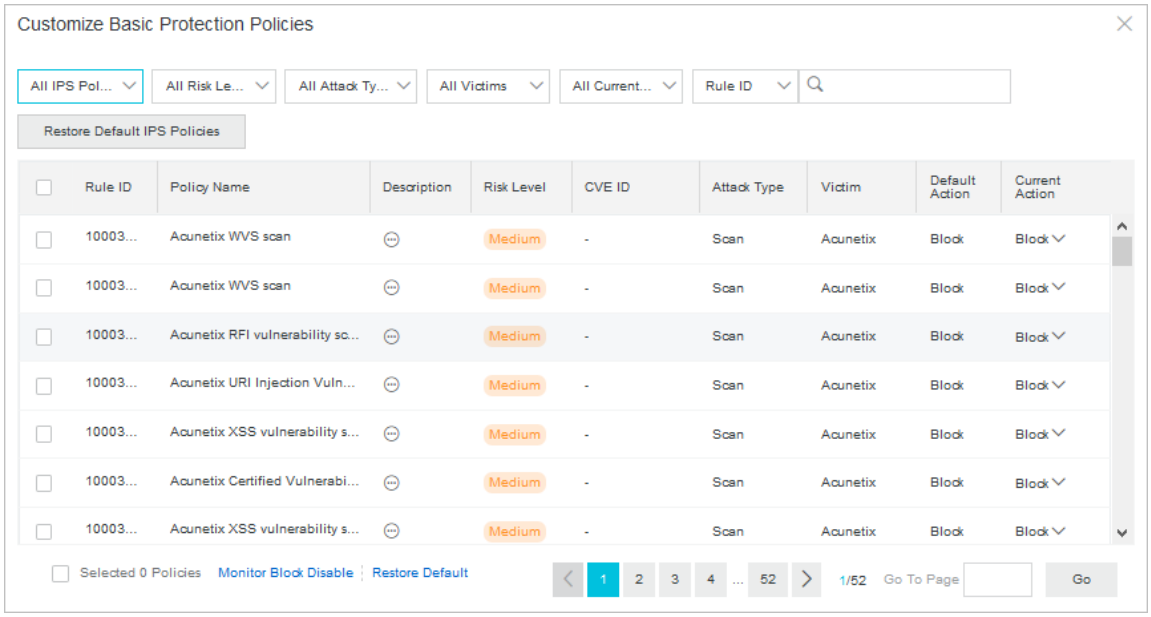
- Cloud Firewall allows traffic from IP addresses in the whitelist.

In the **Advanced Settings** section, click **Whitelist** to add trusted IP addresses to a whitelist.

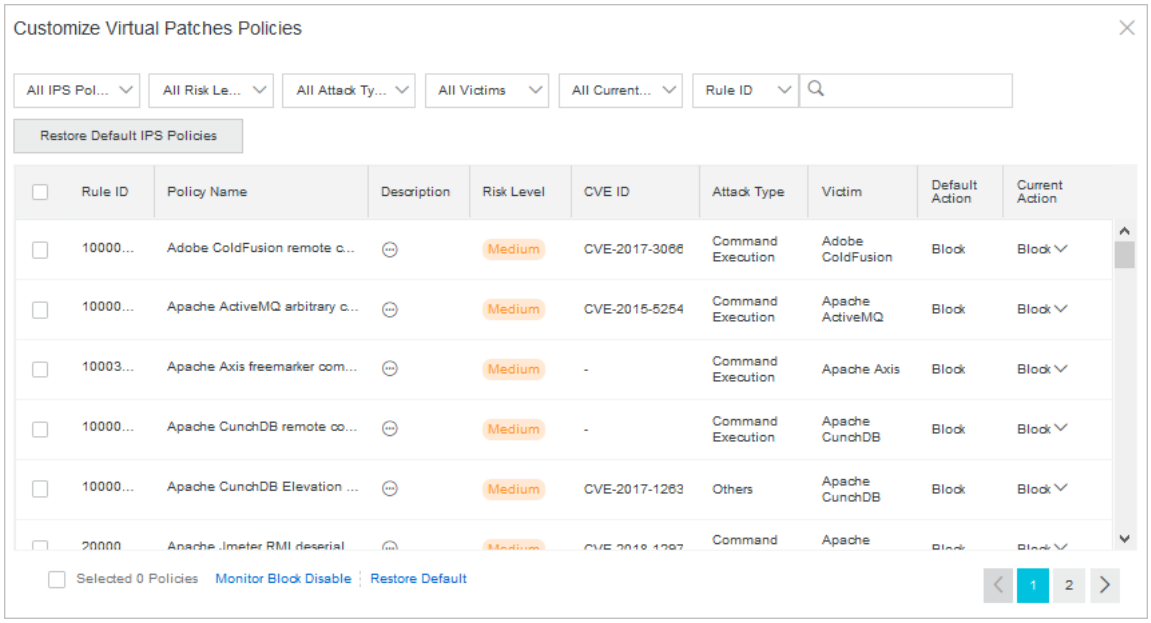
You can add the trusted source IP addresses, destination IP addresses, or address books of both inbound and outbound traffic to the whitelist.



- The basic protection feature defends your network against common intrusions, such as brute-force attacks and command execution vulnerabilities. The basic protection feature also manages connections from infected hosts to a command-and-control (C&C) server.
  a. Click **Basic Policies** to enable the basic protection feature.
  b. In the Basic Protection section, click **Customize**. In the **Customize Basic Protection Policies** dialog box, you can customize one or more basic protection policies.



- Virtual patches are installation-free. You can use them to defend against high-risk vulnerabilities.
  a. Click **Patches** to enable the virtual patch feature.
  b. In the **Virtual Patches** section, click **Customize**. In the **Customize Virtual Patches Policies** dialog box, configure one or more basic virtual patch policies.



27.1.10.2.3.2. View the traffic blocked by IPS

This topic describes how to view the details about Internet and VPC attacks that are blocked by the intrusion prevention system (IPS) feature of Cloud Firewall.

Procedure

1.
2. In the left-side navigation pane, choose **Network Security > Intrusion Prevention**.
3. Click the **Internet Traffic Blocking** and **VPC Traffic Blocking** tabs to view the details of the IPS-blocked traffic.
   - **Internet Traffic Blocking**

     On the **Internet Traffic Blocking** tab, you can view the blocking events of inbound and outbound traffic from the last one hour, one day, or seven days.

     The Internet Traffic Blocking tab contains the following sections:

     - **Defended Attacks**: displays the number and trend of attacks whose inbound or outbound traffic is blocked by IPS.
     - **Attack Types**: displays the distribution of attacks whose inbound or outbound traffic is blocked by IPS.
     - **Frequently Attacked Apps**: displays the applications whose inbound or outbound traffic is blocked by IPS.
     - **Frequently Attacked Destinations**: displays the traffic distribution of attack targets whose inbound or outbound traffic is blocked by IPS.
     - **Frequently Attacked Sources**: displays the traffic distribution of attack sources whose inbound or outbound traffic is blocked by IPS.
     - **Detailed Data**: displays the details of each traffic blocking event. The details include the risk level, number of times the event occurred, source IP address, and destination IP address.

       In the **Detailed Data** section, you can perform the following operations:

       - Specify a risk level, module, traffic direction, or time range to search for events.
       - Find a traffic blocking event and click **View Details** in the **Action** column to view the details. The details include the event description.

- **VPC Traffic Blocking**

  The **VPC Traffic Blocking** tab displays the suspicious traffic blocked by IPS between VPCs. You can view the details of a traffic blocking event over a specific time range. The details include the event name, risk level, and attack type.

  On the **VPC Traffic Blocking** tab, you can perform the following operations:

  - Specify a risk level, defense mode, attack type, or time range to search for events. After you specify the filter conditions, you must click **Search**.
  - Find a traffic blocking event and click **View Details** in the **Action** column to view the details. The details include the event description and defense mode.

27.1.10.2.4. View security groups

This topic describes how to view the details about and relationships between security groups and Elastic Compute Service (ECS) instances in a virtual private cloud (VPC).

1.
2. In the left-side navigation pane, choose **Network Security > Security Groups**.
3. On the **Visual Security Groups** page, view information about security groups and ECS instances in VPCs.

   Select a VPC and view the numbers of security groups, vSwitches, and ECS instances in the VPC.
4. Click the VPC of the security groups that you want to view. Then, you can view details about the security groups and ECS instances in the VPC.

   You can specify a time range to view the details. The time range can be one hour, one day, seven days, or one month.

   - View details about all security groups and ECS instances in the VPC.
     - On the right side of the **Visual Security Group** page, you can view the total numbers of security groups and ECS instances in the VPC, the number of first visits, and the list of security groups in the **Security Group** view.

       > **Note** **First Visits** indicates the total number of first visits between the ECS instances that have dependency relationships in a security group.

       By default, the **Visual Security Groups** page displays the icons of all security groups. In Security Group List, you can find a security group and click the icon in the **Actions** column to hide the icon of the security group on the Visual Security Groups page.
     - In the upper-right corner of the **Visual Security Groups** page, click **Data Details**. On the **Service Nodes** tab, you can view all the security groups in the VPC in the **Security Group** view.
   - View details about a single security group and the ECS instances in the security group.
     - On the **Visual Security Group** page, click the icon in the **Actions** column in Security Group List. On the **Service Nodes** tab, you can view details about the ECS instances in the security group in the **ECS** view.

- On the **Visual Security Groups** page, click the icon of a security group. On the right side of the page, you can view the total number of ECS instances in the security group, the number of dependency security groups, the number of dependent security groups, the number of first visits, and the lists of the two types of security groups in the **Security Group** view. Dependency security groups indicate the security groups on which the current security group depends, and dependent security groups indicate the security groups that depend on the current security group. The popover of the security group displays **data details**, including the following items:
  - ECS instance details: You can click the icon to view details about the ECS instances in the security group.
  - Dependency security groups: You can click the icon to view details about the dependency security groups.
  - Dependent security groups: You can click the icon to view details about the dependent security groups.
  - First visits: You can click the icon to view details about the security groups or ECS instances that have dependency relationships.
- View details about a single ECS instance.
  - On the **Visual Security Groups** page, double-click the icon of the security group that contains the ECS instance. Then, all ECS instances in the security group appear. On the right side of the page, you can view the total number of ECS instances in the security group, the numbers of dependency and dependent security groups, the number of first visits, and the ECS instance list in the **ECS** view.

    By default, the Visual Security Groups page displays the icons of all ECS instances in a security group. In ECS Instance List, you can find an ECS instance and click the icon in the **Actions** column to hide the icon of the ECS instance on the Visual Security Groups page.
  - On the **Visual Security Groups** page, click the icon of an ECS instance. On the right side of the page, you can view the total numbers of dependency and dependent ECS instances, the number of first visits, and the lists of the two types of security groups in the **ECS** view. The popover of the ECS instance displays **data details**, including the following items:
    - Dependency ECS instances: You can click the icon to view details about the dependency ECS instances.
    - Dependent ECS instances: You can click the icon to view details about the dependent ECS instances.
    - First visits: You can click the icon to view details about the ECS instances that have dependency relationships.

27.1.10.2.5. Log audit

27.1.10.2.5.1. View event logs

All traffic passing through Cloud Firewall is recorded on the Log Audit page. The logs are classified into traffic logs and event logs. You can use the logs to audit your network traffic in real time and take actions accordingly. This topic describes how to view event logs.

Procedure

1. Log on to Apsara Stack Security Center.

2. In the left-side navigation pane, choose **Network Security > Log Audit > Event Log**.
3. On the **Event Logs** tab, click **Internet Firewall**, **VPC-VPC Firewall** or **IDC-VPC Firewall**.
4. Specify the search conditions and click **Search**.

> **Note** If you want to view all event logs, skip this step.

Search condition	Description
Source IP	Specify the source IP address of the event.
Destination IP	Specify the destination IP address of the event.
Type	Select the event type
Action	Select the event action. Valid values: *All*, *Monitor*, and *Discard*.
Time	Set the time range.

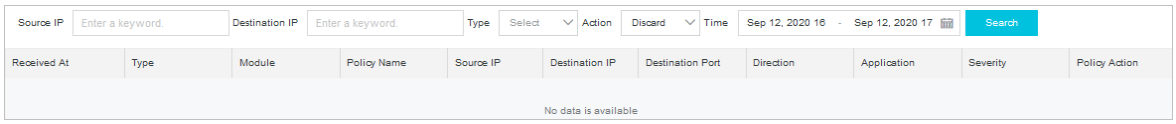
5. The event logs record the information of event. This includes the event detection time, threat type, traffic direction (inbound or outbound), source IP address, destination IP address, application type, severity, and policy action.

27.1.10.2.5.2. View traffic logs

All traffic passing through Cloud Firewall is recorded on the Log Audit page. The logs are classified into traffic logs and event logs. You can use the logs to audit your network traffic in real time and take actions accordingly. This topic describes how to view traffic logs.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Log Audit > Traffic Log**.
3. On the **Event Logs** tab of the page that appears, click **Internet Firewall**, **VPC-VPC Firewall**, or **IDC-VPC Firewall**.
4. Specify the search condition and click **Search**.



> **Note** If you want to view all traffic logs, skip this step.

Search condition	Description
Source IP	Specify the source IP address of the traffic.
Destination IP	Specify the destination IP address of the traffic.
Application	Select the application type.
Time	Set the time range.

To enable the advanced features, perform the following steps:

- **Show Advanced Search**

Click **Show Advanced Search** to configure more search conditions.

- **List Configuration**

  Click **List Configuration** to select items for the traffic list.

5. The traffic logs record the information of access traffic. This includes the start time and end time of the access traffic, traffic direction (inbound or outbound), source IP address, destination IP address, application type, supported protocol, bytes, and packets.

27.1.10.3. Sensitive Data Discovery and Protection

27.1.10.3.1. Grant access permissions

Before you use Sensitive Data Discovery and Protection (SDDP), you must grant access permissions to SDDP. This topic describes how to authorize SDDP to access the data of your department.

Prerequisites

The name and AccessKey pair of your department are obtained before you grant access permissions on the department. For more information, see the "Obtain the AccessKey pair of an organization" topic in *Apsara Uni-manager Management Console User Guide*. To find the topic, choose **Enterprise > Organizations > Obtain the AccessKey pair of an organization**.

Context

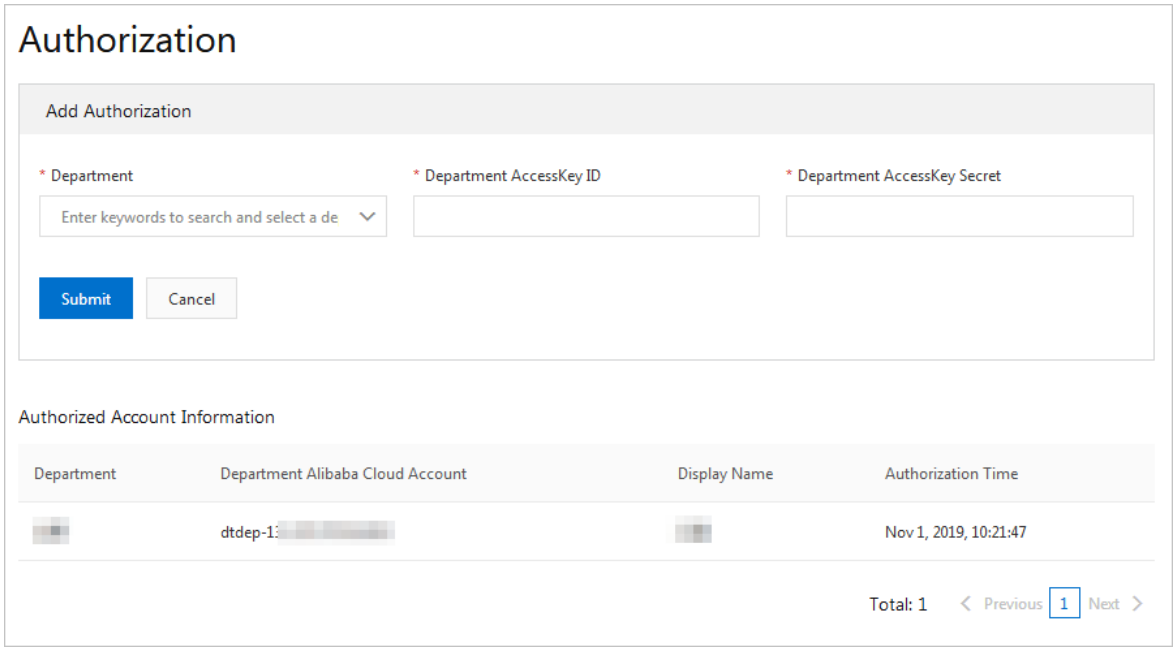
Before you use SDDP, you must complete the following operations:

- Authorize SDDP to access the data of your department.
- Authorize SDDP to access the data of Apsara Stack services of your department. The services include MaxCompute, Object Storage Service (OSS), and Tablestore.

Procedure

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Authorization**.

> **Note** If SDDP is not authorized to access the data of your department, the **Use authorization settings** page appears. You must configure the parameters on this page.



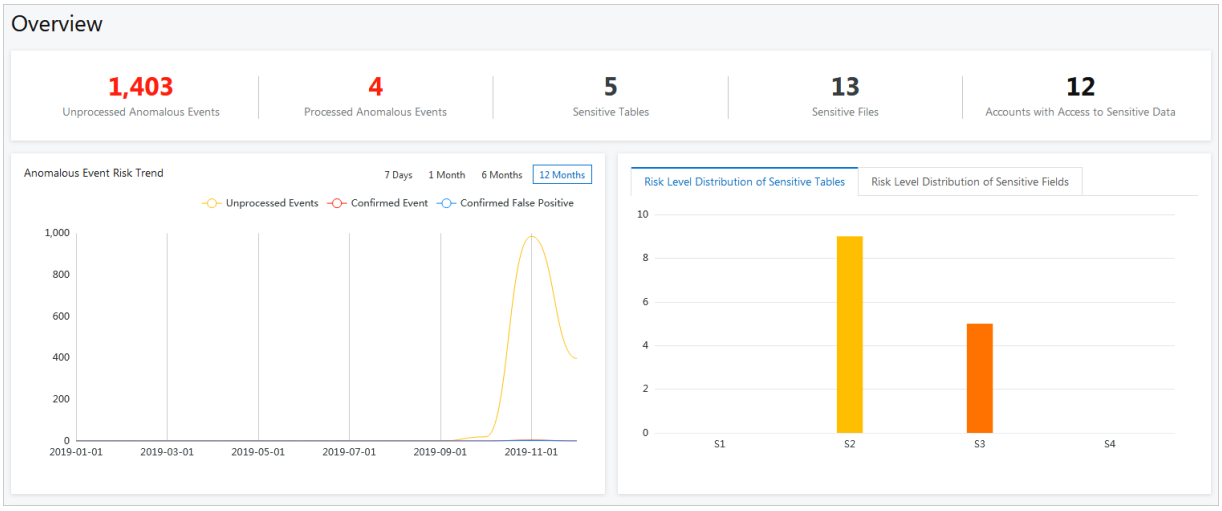
3. In the **Add Authorization** section, authorize SDDP to access the data of your department.
   i. In the **Department** drop-down list, enter a keyword and select the department.
   ii. Enter **Department AccessKey ID** and **Department AccessKey Secret**.
   iii. Click **Submit**.
4. In the **Authorized Account Information** section, view the departments that SDDP is authorized to access.

27.1.10.3.2. Overview

This topic describes the Overview page of Sensitive Data Discovery and Protection (SDDP). The Overview page displays the overall security status of data protected by SDDP. This allows security administrators to take an overview of sensitive data and take countermeasures in time.

SDDP can detect sensitive data in your data assets based on specific detection rules and track the use of sensitive data. SDDP also provides a data overview for you to obtain the security status of your data assets in real time.

If you want to view the overall security status of the sensitive data, log on to Apsara Stack Security Center. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Overview**.



- **Overview**: displays the overall information about sensitive data, including the number of **unhandled anomalous events**, the number of **handled anomalous events**, the number of **sensitive tables**, the

number of **sensitive objects**, and the **accounts that are used to access sensitive data**.

- **Abnormal Event Risk Trend**: displays the trends of different events in a line chart. You can select **7 Days**, **1 Month**, **6 Months**, or **12 Months** to view the trends of different events, such as **Unprocessed Events**, **Confirmed Event**, and **Confirmed False Positive**.
- **Sensitive table risk level distribution**: displays the distribution of sensitive tables at each sensitivity level, including L3 (highly sensitive), L2 (moderately sensitive), L1 (low sensitive), and N/A (non-sensitive).
- **Sensitive field risk level distribution**: displays the distribution of sensitive fields at each sensitivity level, including L3 (highly sensitive), L2 (moderately sensitive), L1 (low sensitive), and N/A (non-sensitive).
- **Data flow situation**:
  - Displays the dynamic statistics on core data flows in DataHub and Data Integration.
  - Provides a data flowchart. This flowchart dynamically shows data flows and abnormal output. You can click an anomalous event in the flowchart to go to the **Abnormal data flow** page.

    Monitors the data links among different entities, such as data storage services, data transmission services, the data flow processing service, external databases, and external files. The data storage services include MaxCompute, AnalyticDB for MySQL, Object Storage Service (OSS), and Tablestore. The data transmission services include DataHub and Data Integration. The data flow processing service includes Blink.

27.1.10.3.3. Data asset authorization

27.1.10.3.3.1. Authorize SDDP to access data assets

Sensitive Data Discovery and Protection (SDDP) must be authorized to access your data assets before it can detect sensitive data in the data assets. Supported data assets include Object Storage Service (OSS) buckets, ApsaraDB RDS instances, PolarDB-X databases, Tablestore instances, self-managed databases hosted on Elastic Compute Service (ECS) instances, MaxCompute projects, AnalyticDB for MySQL clusters, ApsaraDB for OceanBase clusters, and AnalyticDB for PostgreSQL instances. This topic describes how to authorize SDDP to access your data assets.

Context

SDDP can access and scan specific data assets to detect and mask sensitive data only after you grant the required permissions to SDDP.

> **Notice** 已开启授权的OSS Bucket（OSS文件桶）会消耗您的OSS存储容量，已开启授权的数据库或项目会消耗您的数据库和项目数。只有在OSS存储容量、数据库和项目数量充足时，您才可以成功进行相应授权操作。您可以在**云上托管**页面查看剩余的OSS存储容量、数据库和项目数。

For more information about how to authorize SDDP to access supported data assets, see the following sections:

- Authorize SDDP to access OSS buckets
- Authorize SDDP to access ApsaraDB RDS instances
- Authorize SDDP to access PolarDB-X databases
- Authorize SDDP to access Tablestore instances
- Authorize SDDP to access self-managed databases hosted on ECS instances
- Authorize SDDP to access MaxCompute projects
- Authorize SDDP to access AnalyticDB for MySQL clusters
- Authorize SDDP to access AnalyticDB for PostgreSQL instances
- Authorize SDDP to access ApsaraDB for OceanBase clusters

Authorize SDDP to access OSS buckets

1. Log on to Apsara Stack Security Center.

2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data protection authorization > Data Asset authorization**.
3. On the **OSS** tab, grant the required permissions on instances or buckets.
   - If you want to grant permissions on a single instance or bucket, turn on or off the switches in the **Identify permissions**, **Desensitization permissions**, **OCR Authority**, and **Audit permissions** columns of the instance or bucket. Then, configure the **Sensitive data sampling** and **Audit log archiving** parameters.

Parameter	Description
Identify permissions	The permissions to detect sensitive data in selected data assets.
Desensitization permissions	The permissions to mask sensitive data in selected data assets.
OCR Authority	The permissions to detect sensitive data in text on images.
Audit permissions	The permissions to audit data in selected data assets.
Sensitive data sampling	The number of sensitive data samples to reserve after SDDP detects sensitive data. If you turn on the switch in **Identify permissions**, you must also specify this parameter. If SDDP detects sensitive data in a data asset, it collects samples of the detected data. You can use the sensitive data samples for further analysis. Valid values: **0**, **5**, and **10**.
Audit log archiving	The duration to retain the audit logs of selected data assets. If you turn on the switch in **Audit permissions**, you must also specify this parameter. Valid values: **30 days**, **90 days**, and **180 days**. **Note** You do not need to activate Log Service to archive the audit logs generated by SDDP.

   - If you want to grant permissions on multiple instances or buckets at the same time, perform the following steps:
     a. Select the required instances or buckets and click **Batch operation**.
     b. In the **Batch processing for selected assets** dialog box, turn on or off the switches of detection, audit, masking, and OCR permissions, and configure the parameters that remain.
     c. Click **Confirm**.

   After SDDP is authorized, SDDP scans the OSS buckets to detect sensitive data. If SDDP scans an OSS bucket for the first time, SDDP automatically performs a full scan.

   In the list of OSS buckets on which SDDP has access permissions, you can modify or revoke permissions on the OSS buckets. If you revoke permissions on an OSS bucket, SDDP no longer scans the OSS bucket.

   Note SDDP scans only the accessible OSS buckets and analyzes the risks of sensitive data detected in these OSS buckets.

Authorize SDDP to access ApsaraDB RDS instances

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data protection authorization > Data Asset authorization**.

3. On the **Cloud hosting** page, click the **RDS** tab.
4. On the **RDS** tab, click **Unauthorized**.
5. Find the instance that you want SDDP to access and enter the required database username and its password in the **Username** and **Password** columns.

   You can also click **Batch password import** in the upper-right corner and upload an authorization file to import the logon information of multiple databases at the same time. For more information, see Import the logon information for multiple data assets at the same time.

   > **Notice** If the username or password is not correct, the authorization fails. Make sure that the information you enter is correct.

6. Select the databases that you want SDDP to access and click **Batch operation**.

   You can also click **Authorization** in the Actions column of an instance to grant all its permissions.

7. In the Batch processing for selected assets dialog box, turn on or off the switches of detection, audit, and masking permissions, and configure the parameters that remain.

Parameter	Description
Identify permissions	The permissions to detect sensitive data in selected data assets.
Audit permissions	The permissions to audit data in selected data assets. SDDP allows you to collect audit logs that cover the data generation, update, and use of your data assets. The log information includes the audit rule that is triggered for a data asset, the type of the data asset, the type of the operation that triggers the audit rule, and the operator account. SDDP安全审计功能的使用，请参见Create an audit rule。
Desensitization permissions	The permissions to mask sensitive data in selected data assets.
Sensitive data sampling	The number of sensitive data samples to reserve after SDDP detects sensitive data. If you turn on the switch in **Identify permissions**, you must also specify this parameter. If SDDP detects sensitive data in a data asset, it collects samples of the detected data. You can use the sensitive data samples for further analysis. Valid values: **0**, **5**, and **10**.
Audit log archiving	The duration to retain the audit logs of selected data assets. If you turn on the switch in **Audit permissions**, you must also specify this parameter. Valid values: **30 days**, **90 days**, and **180 days**.

8. Click **Confirm**.

   > **Note** If the authorization fails, check whether the username and password are correct.

   After SDDP is authorized, SDDP scans the databases to detect sensitive data.

   In the list of databases on which SDDP has access permissions, you can modify or revoke permissions on the databases. You can modify only the username and password of a valid database account. If you revoke permissions on a database, SDDP no longer scans the database.

Authorize SDDP to access PolarDB-X databases

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data protection authorization > Data Asset authorization**.
3. On the **Cloud hosting** page, click the **DRDS** tab.
4. On the **DRDS** tab, click **Unauthorized**.
5. Find the instance that you want SDDP to access and enter the required database username and its password in the **Username** and **Password** columns.

   You can also click **Batch password import** in the upper-right corner and upload an authorization file to import the logon information of multiple databases at the same time. For more information, see Import the logon information for multiple data assets at the same time.

   > **Notice** If the username or password is not correct, the authorization fails. Make sure that the information you enter is correct.

6. Select the databases that you want SDDP to access and click **Batch operation**.

   You can also click **Authorization** in the Actions column of an instance to grant all its permissions.

7. In the Batch processing for selected assets dialog box, turn on or off the switches of detection, audit, and masking permissions, and configure the parameters that remain.

Parameter	Description
Identify permissions	The permissions to detect sensitive data in selected data assets.
Audit permissions	The permissions to audit data in selected data assets. SDDP allows you to collect audit logs that cover the data generation, update, and use of your data assets. The log information includes the audit rule that is triggered for a data asset, the type of the data asset, the type of the operation that triggers the audit rule, and the operator account. SDDP安全审计功能的使用，请参见Create an audit rule。
Desensitization permissions	The permissions to mask sensitive data in selected data assets.
Sensitive data sampling	The number of sensitive data samples to reserve after SDDP detects sensitive data. If you turn on the switch in **Identify permissions**, you must also specify this parameter. If SDDP detects sensitive data in a data asset, it collects samples of the detected data. You can use the sensitive data samples for further analysis. Valid values: **0**, **5**, and **10**.
Audit log archiving	The duration to retain the audit logs of selected data assets. If you turn on the switch in **Audit permissions**, you must also specify this parameter. Valid values: **30 days**, **90 days**, and **180 days**.

8. Click **Confirm**.

   > **Note** If the authorization fails, check whether the username and password are correct.

   After SDDP is authorized, SDDP scans the databases to detect sensitive data.

In the list of databases on which SDDP has access permissions, you can modify or revoke permissions on the databases. You can modify only the username and password of a valid database account. If you revoke permissions on a database, SDDP no longer scans the database.

Authorize SDDP to access Tablestore instances

You can authorize SDDP to access one or more Tablestore instances.

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data protection authorization > Data Asset authorization**.
3. On the **Cloud hosting** page, click the **OTS** tab.
4. On the **OST** tab, grant the required permissions on instances or buckets.
   - If you want to grant permissions on a single instance or bucket, turn on or off the switches in the **Identify permissions**, **Desensitization permissions**, and **Audit permissions** columns of the instance or bucket. Then, configure the **Sensitive data sampling** and **Audit log archiving** parameters.

Parameter	Description
Identify permissions	The permissions to detect sensitive data in selected data assets.
Desensitization permissions	The permissions to mask sensitive data in selected data assets.
Audit permissions	The permissions to audit data in selected data assets.
Sensitive data sampling	The number of sensitive data samples to reserve after SDDP detects sensitive data.If you turn on the switch in **Identify permissions**, you must also specify this parameter. If SDDP detects sensitive data in a data asset, it collects samples of the detected data. You can use the sensitive data samples for further analysis. Valid values: **0**, **5**, and **10**.
Audit log archiving	The duration to retain the audit logs of selected data assets. If you turn on the switch in **Audit permissions**, you must also specify this parameter. Valid values: **30 days**, **90 days**, and **180 days**.

   - If you want to grant permissions on multiple instances or buckets at the same time, perform the following steps:
     a. Select the required instances or buckets and click **Batch operation**.
     b. In the **Batch processing for selected assets** dialog box, turn on or off the switches of detection, audit, and masking permissions, and configure the parameters that remain.
     c. Click **Confirm**.

   After SDDP is authorized, SDDP scans the instances to detect sensitive data.

Authorize SDDP to access self-managed databases hosted on ECS instances

A self-managed database hosted on an ECS instance must meet the following requirements before it can be scanned by SDDP:

- The ECS instance resides in a virtual private cloud (VPC).
- The database is a MySQL or SQL Server database.

1. Log on to Apsara Stack Security Center.

2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data protection authorization > Data Asset authorization**.
3. On the **Cloud hosting** page, click the **ECS self-built database** tab.
4. On the **ECS self-built database** tab, click **Add data assets**.
5. In the **Asset authorization** dialog box, configure the parameters and click **Next**.

   The following table describes the parameters.

Parameter	Description
Region	The region of the self-managed database that you want to authorize SDDP to access.
ECS instance ID	The ID of the ECS instance on which the self-managed database is hosted.
Database type	The type of the self-managed database that you want to authorize SDDP to access. Valid values: MySQL and SQL Server.
Library name	The name of the self-managed database that you want to authorize SDDP to access. **Note** If you want to authorize SDDP to access other self-managed databases hosted on the same ECS instance, click **Add Database**.
Port	The port number used to connect to the self-managed database.
User name	The username of the account that you use to connect to the self-managed database.
Password	The password of the account that you use to connect to the self-managed database.

6. In the Batch processing for selected assets dialog box, turn on or off the switches of detection, audit, and masking permissions, and configure the parameters that remain.

Parameter	Description
Identify permissions	The permissions to detect sensitive data in selected data assets.
Audit permissions	The permissions to audit data in selected data assets. SDDP allows you to collect audit logs that cover the data generation, update, and use of your data assets. The log information includes the audit rule that is triggered for a data asset, the type of the data asset, the type of the operation that triggers the audit rule, and the operator account. SDDP安全审计功能的使用，请参见Create an audit rule。
Desensitization permissions	The permissions to mask sensitive data in selected data assets.

Parameter	Description
Sensitive data sampling	The number of sensitive data samples to reserve after SDDP detects sensitive data. If you turn on the switch in **Identify permissions**, you must also specify this parameter. If SDDP detects sensitive data in a data asset, it collects samples of the detected data. You can use the sensitive data samples for further analysis. Valid values: **0**, **5**, and **10**.
Audit log archiving	The duration to retain the audit logs of selected data assets. If you turn on the switch in **Audit permissions**, you must also specify this parameter. Valid values: **30 days**, **90 days**, and **180 days**.

7. Click **Confirm**.
   After SDDP is authorized, SDDP scans the databases to detect sensitive data.

Authorize SDDP to access MaxCompute projects

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data protection authorization > Data Asset authorization**.
3. On the **Cloud hosting** page, click the **MaxCompute** tab.
4. On the **MaxCompute** tab, grant the required permissions on instances or buckets.
   - If you want to grant permissions on a single instance or bucket, turn on or off the switches in the **Identify permissions**, **Desensitization permissions**, and **Audit permissions** columns of the instance or bucket. Then, configure the **Sensitive data sampling** and **Audit log archiving** parameters.

Parameter	Description
Identify permissions	The permissions to detect sensitive data in selected data assets.
Desensitization permissions	The permissions to mask sensitive data in selected data assets.
Audit permissions	The permissions to audit data in selected data assets.
Sensitive data sampling	The number of sensitive data samples to reserve after SDDP detects sensitive data. If you turn on the switch in **Identify permissions**, you must also specify this parameter. If SDDP detects sensitive data in a data asset, it collects samples of the detected data. You can use the sensitive data samples for further analysis. Valid values: **0**, **5**, and **10**.
Audit log archiving	The duration to retain the audit logs of selected data assets. If you turn on the switch in **Audit permissions**, you must also specify this parameter. Valid values: **30 days**, **90 days**, and **180 days**.

   - If you want to grant permissions on multiple instances or buckets at the same time, perform the following steps:
     a. Select the required instances or buckets and click **Batch operation**.
     b. In the **Batch processing for selected assets** dialog box, turn on or off the switches of detection, audit, and masking permissions, and configure the parameters that remain.

5. Run the following commands on the MaxCompute client to add the SDDP account **yundun_sddp** to the MaxCompute project. SDDP uses this account to access the MaxCompute project.

```
add user aliyun$yundun_sddp;
grant admin to aliyun$yundun_sddp;
```

You can perform one of the following operations based on the returned result:

- If no error messages are returned, go to .
- If an error message is returned, go to .

6. (Optional)Run the following command on the MaxCompute client to add the service IP addresses of SDDP to the IP address whitelist of the MaxCompute project:

If the IP address whitelist feature is enabled for the MaxCompute project, you must add the service IP addresses of SDDP to the IP address whitelist of the MaxCompute project. You can run the `setproject;` command to check whether the IP address whitelist feature is enabled. If the value of the `odps.security.vpc.whitelist=` parameter is empty, the IP address whitelist feature is not enabled. In this case, you can skip this step.

```
setproject odps.security.ip.whitelist=11.193.236.0/24,11.193.64.0/24,11.193.58.0/24 odps.security.vpc.whitelist=<VPC ID>;
// In this command, 11.193.236.0/24, 11.193.64.0/24, and 11.193.58.0/24 are the Classless Inter-Domain Routing (CIDR) blocks used by SDDP on the classic network. You must add them to the IP address whitelist.
// Replace the VPC ID with the ID of the region where the MaxCompute project resides. The following table describes the relationships between the VPC IDs and region IDs.
```

Region	Region ID	VPC ID
China (Zhangjiakou)	cn-zhangjiakou	cn-zhangjiakou_399229
China (Beijing)	cn-beijing	cn-beijing_691047
China (Shenzhen)	cn-shenzhen	cn-shenzhen_515895
China (Shanghai)	cn-shanghai	cn-shanghai_28803
China (Hangzhou)	cn-hangzhou	cn-hangzhou_551733

> **Note** After you configure the IP address whitelist, wait for 5 minutes before you go to the next step.

7. Click **Confirm**.

> **Note** If the authorization fails, check whether the permission parameters are correctly configured and whether the SDDP account is added to the project.

After SDDP is authorized, SDDP scans the projects to detect sensitive data.

In the list of projects on which SDDP has access permissions, you can revoke permissions on the projects. If you revoke permissions on a project, SDDP no longer scans the project.

Authorize SDDP to access AnalyticDB for MySQL clusters

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data protection authorization > Data Asset authorization**.

3. On the **Cloud hosting** page, click the **ADS** tab.
4. On the **ADS** tab, click **Add data assets**.
5. In the **Add data assets** dialog box, configure the parameters and click **Confirm**.

   The following table describes the parameters.

Parameter	Description
Region	The region of the AnalyticDB for MySQL database that you want to authorize SDDP to access.
Instance Name	The name of the cluster to which the AnalyticDB for MySQL database belongs.
Database Name	The name of the AnalyticDB for MySQL database.
User name	The username and password of the account that you use to connect to the AnalyticDB for MySQL database.
Password	
Automatic scanning	The switch of triggering scans on the AnalyticDB for MySQL database each time identification rule settings are modified.

6. On the **ADS** tab, grant the required permissions on multiple instances or buckets at the same time.
   - If you want to grant permissions on a single instance or bucket, turn on or off the switches in the **Identify permissions**, **Desensitization permissions**, and **Audit permissions** columns of the instance or bucket. Then, configure the **Sensitive data sampling** and **Audit log archiving** parameters.

Parameter	Description
Identify permissions	The permissions to detect sensitive data in selected data assets.
Desensitization permissions	The permissions to mask sensitive data in selected data assets.
Audit permissions	The permissions to audit data in selected data assets.
Sensitive data sampling	The number of sensitive data samples to reserve after SDDP detects sensitive data.If you turn on the switch in **Identify permissions**, you must also specify this parameter. If SDDP detects sensitive data in a data asset, it collects samples of the detected data. You can use the sensitive data samples for further analysis. Valid values: **0**, **5**, and **10**.
Audit log archiving	The duration to retain the audit logs of selected data assets. If you turn on the switch in **Audit permissions**, you must also specify this parameter. Valid values: **30 days**, **90 days**, and **180 days**.

   - If you want to grant permissions on multiple instances or buckets at the same time, perform the following steps:
     a. Select the required instances or buckets and click **Batch operation**.
     b. In the **Batch processing for selected assets** dialog box, turn on or off the switches of detection, audit, and masking permissions, and configure the parameters that remain.
     c. Click **Confirm**.

After SDDP is authorized, SDDP scans the databases to detect sensitive data.

Authorize SDDP to access AnalyticDB for PostgreSQL instances

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data protection authorization > Data Asset authorization**.
3. On the **Cloud hosting** page, click the **GPDB** tab.
4. On the **GPDB** tab, click **Add data assets**.
5. In the **Add data assets** dialog box, configure the parameters and click **Confirm**.

   The following table describes the parameters.

Parameter	Description
Region	The region of the AnalyticDB for PostgreSQL database that you want to authorize SDDP to access.
Instance Name	The name of the instance that hosts the AnalyticDB for PostgreSQL database.
Database Name	The name of the AnalyticDB for PostgreSQL database.
User name	The username and password of the account that you use to connect to the AnalyticDB for PostgreSQL database.
Password	
Automatic scanning	The switch of triggering scans on the AnalyticDB for PostgreSQL database each time identification rule settings are modified.

6. On the **GPDB** tab, grant the required permissions on multiple instances or buckets at the same time.
   - If you want to grant permissions on a single instance or bucket, turn on or off the switches in the **Identify permissions**, **Desensitization permissions**, and **Audit permissions** columns of the instance or bucket. Then, configure the **Sensitive data sampling** and **Audit log archiving** parameters.

Parameter	Description
Identify permissions	The permissions to detect sensitive data in selected data assets.
Desensitization permissions	The permissions to mask sensitive data in selected data assets.
Audit permissions	The permissions to audit data in selected data assets.
Sensitive data sampling	The number of sensitive data samples to reserve after SDDP detects sensitive data.If you turn on the switch in **Identify permissions**, you must also specify this parameter. If SDDP detects sensitive data in a data asset, it collects samples of the detected data. You can use the sensitive data samples for further analysis. Valid values: **0**, **5**, and **10**.
Audit log archiving	The duration to retain the audit logs of selected data assets. If you turn on the switch in **Audit permissions**, you must also specify this parameter. Valid values: **30 days**, **90 days**, and **180 days**.

- If you want to grant permissions on multiple instances or buckets at the same time, perform the following steps:
  a. Select the required instances or buckets and click **Batch operation**.
  b. In the **Batch processing for selected assets** dialog box, turn on or off the switches of detection, audit, and masking permissions, and configure the parameters that remain.
  c. Click **Confirm**.

After SDDP is authorized, SDDP scans the databases to detect sensitive data.

Authorize SDDP to access ApsaraDB for OceanBase clusters

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data protection authorization > Data Asset authorization**.
3. On the **Cloud hosting** page, click the **OceanBase** tab.
4. On the **OceanBase** tab, click **Add data assets**.
5. In the **Add data assets** dialog box, configure the parameters and click **Next**.

   The following table describes the parameters.

Parameter	Description
Region	The region of the ApsaraDB for OceanBase database that you want to authorize SDDP to access.
Database type	The type of the ApsaraDB for OceanBase database. Valid values: MySQL and Oracle.
Cluster Name	The name of the cluster to which the ApsaraDB for OceanBase database belongs.
Tenant Name	The name of the tenant to which the ApsaraDB for OceanBase database belongs.
Database Name	The name of the ApsaraDB for OceanBase database. **Note** If you want to authorize SDDP to access other ApsaraDB for OceanBase databases hosted on the same ECS instance, click **Add Database**.
Link Address	The endpoint that you use to connect to the ApsaraDB for OceanBase database.
User name	The username and password of the account that you use to connect to the ApsaraDB for OceanBase database.
Password	

6. In the Batch processing for selected assets dialog box, turn on or off the switches of detection, audit, and masking permissions, and configure the parameters that remain.

Parameter	Description
Identify permissions	The permissions to detect sensitive data in selected data assets.

Parameter	Description
Audit permissions	The permissions to audit data in selected data assets. SDDP allows you to collect audit logs that cover the data generation, update, and use of your data assets. The log information includes the audit rule that is triggered for a data asset, the type of the data asset, the type of the operation that triggers the audit rule, and the operator account. SDDP安全审计功能的使用，请参见Create an audit rule。
Desensitization permissions	The permissions to mask sensitive data in selected data assets.
Sensitive data sampling	The number of sensitive data samples to reserve after SDDP detects sensitive data. If you turn on the switch in **Identify permissions**, you must also specify this parameter. If SDDP detects sensitive data in a data asset, it collects samples of the detected data. You can use the sensitive data samples for further analysis. Valid values: **0**, **5**, and **10**.
Audit log archiving	The duration to retain the audit logs of selected data assets. If you turn on the switch in **Audit permissions**, you must also specify this parameter. Valid values: **30 days**, **90 days**, and **180 days**.

7. Click **Confirm**.
   After SDDP is authorized, SDDP scans the databases to detect sensitive data.

Import the logon information for multiple data assets at the same time

SDDP allows you to upload an Excel file to import the logon information for multiple data assets, including RDS databases, PolarDB-X databases, and self-managed databases hosted on ECS instances, at the same time to improve authorization efficiency. The following procedure describes how to import the logon information for multiple data assets at the same time:

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data protection authorization > Data Asset authorization**.
3. On the **Cloud hosting** page, click **Batch password import** in the upper-right corner.
4. In the **Batch password import** dialog box, click **SDDP Authorization File Template.xlsx**.
5. Open the downloaded file, enter the usernames and passwords used to access each data asset in the **username** and **password** columns, and then save the file.

   If you modify the existing usernames and passwords in the downloaded file and upload the file to SDDP, the logon information saved in SDDP is updated.
6. In the **Batch password import** dialog box, click **File Upload** to upload the template file that you have edited.
7. Click **OK**.
   After you upload the Excel file, the usernames and passwords that you enter in the file are synchronized to the **Username** and **Password** columns for the relevant databases on the **RDS**, **DRDS**, and **ECS self-built database** tabs. Then, you can authorize SDDP to access these data assets without the need to manually enter the logon information on the **Cloud hosting** page.

27.1.10.3.3.2. Manage usernames and passwords of databases

Sensitive Data Discovery and Protection (SDDP) can detect sensitive data that is stored in a data source only after it is authorized. To authorize SDDP, you must add the username and password that are used to connect to a database of the data source. This topic describes how to view and add the username and password that are used to connect to a database.

Context

SDDP allows you to manage the usernames and passwords that are used to connect to databases of ApsaraDB RDS, PolarDB-X, and ApsaraDB for OceanBase instances.

View the username and password of a database

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data protection authorization > Authorized account management**.
3. Click the required data source. In this example, click the **RDS** tab.
4. (Optional)Specify filter conditions to search for the specific ApsaraDB RDS instance.

   > **Note** If you want to view all ApsaraDB RDS instances, skip this step.

Filter condition	Description
Region	The region where the ApsaraDB RDS instance resides.
Instance/Bucket	The name of the ApsaraDB RDS instance.
Database type	The type of the database engine that is run by the ApsaraDB RDS instance. Different data sources support different database engines: ○ ApsaraDB RDS and PolarDB-X support the MySQL and SQL Server database engines. ○ ApsaraDB for OceanBase supports the MySQL and Oracle database engines.

5. In the instance list, view the usernames and databases that are used to connect to the databases of the ApsaraDB RDS instance.

Add the username and password of a database

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data protection authorization > Authorized account management**.
3. Click the required data source. In this example, click the **RDS** tab.
4. Find the required ApsaraDB RDS instance and enter a database username and password for the **Username** and **Password** parameters.

   > **Notice** If the username or password is invalid, SDDP fails to be authorized. Make sure that the information you enter is valid.

5. Click **Add**.
   After the username and password of the database are added, **Status** of the ApsaraDB RDS instance changes to **Added successfully**.

What's next

If you want to modify the username or password of a database, find the required instance and click **Edit** in the **Actions** column.

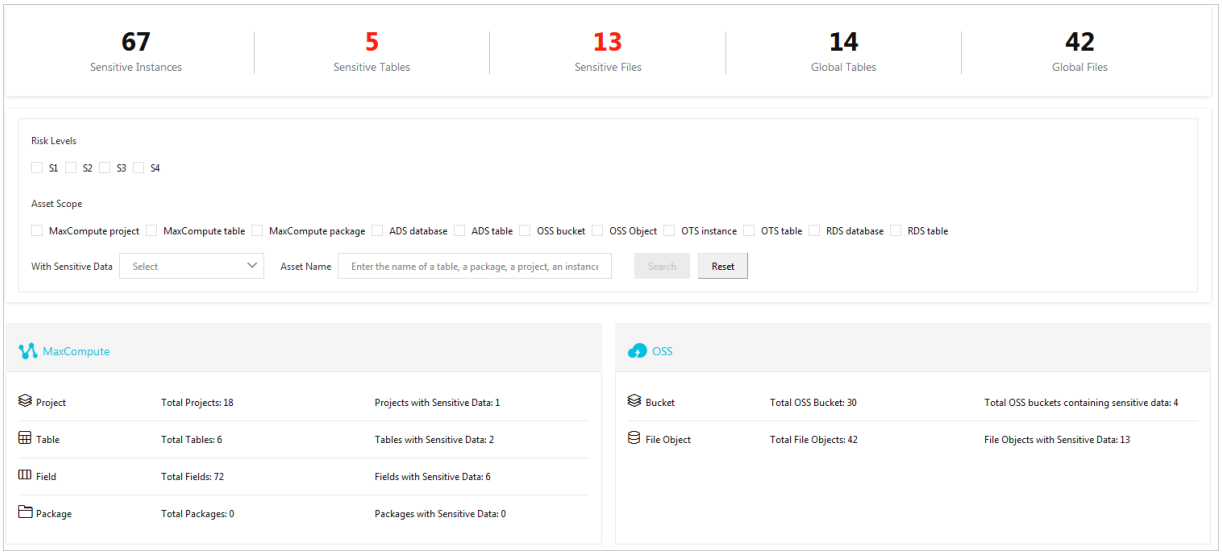
Click **Save**.

27.1.10.3.4. Sensitive data discovery

27.1.10.3.4.1. Sensitive data overview

This topic describes the Sensitive Data Overview page that displays the overall security status of your data assets.

Choose **Data Security > Sensitive Data Protection > Sensitive data Identification > Sensitive Data Overview**. On the Sensitive Data Overview page, you can view the overall security status of your data assets.



- You can view the overall information about sensitive data. The information includes the total numbers of **sensitive instances**, **sensitive tables**, **sensitive files**, **global tables**, and **global files**.
- You can search for sensitive data based on conditions such as the risk level, asset type, sensitive data type, and asset name.
- You can view the statistics on the access information and sensitive data in cloud assets, such as **MaxCompute**, **Object Storage Service (OSS)**, **AnalyticDB for MySQL**, and **Tablestore** in real time.

27.1.10.3.4.2. View statistics on sensitive data

Sensitive Data Discovery and Protection (SDDP) can detect sensitive data in data sources, such as Object Storage Service (OSS), ApsaraDB RDS, and MaxCompute. This topic describes how to view statistics on sensitive data that is detected by using SDDP.

View statistics on sensitive data detected in OSS

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Sensitive Data Identification > Sensitive data assets**.
3. On the **OSS** tab, find the required OSS bucket and click **File Details** in the Actions column.
4. In the **OSS object query** panel, you can view the proportions of sensitive objects at each sensitivity level, top five sensitive data detection rules that are hit, and the list of objects in which the sensitive data is detected.
   - **Proportions of sensitive objects**

     In the **Proportions of sensitive objects** section, you can view the numbers of objects at the sensitivity levels of L3 (highly sensitive), L2 (moderately sensitive), L1 (low sensitive), and N/A (non-sensitive). You can also view a pie chart that shows the proportions of objects at each level.

- **Top five rules that are hit**

  In the **Top five rules that are hit** section, you can view the top five sensitive data detection rules that are hit and the number of times that each rule is hit.

- **List of objects in which the sensitive data is detected**

  In the object list, you can view the information about the objects in which the sensitive data is detected. The information includes the object name, size, type, and number of sensitive fields that are detected in the object. You can click **Hit details** in the Actions column for an object to view the details about the sensitive data detection rules that the object hits.

View statistics on sensitive data detected in ApsaraDB RDS

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Sensitive Data Identification** > **Sensitive data assets**.
3. On the **Sensitive data assets** page, click the **RDS** tab.
4. On the **RDS** tab, find the ApsaraDB RDS instance whose details you want to view and click **Table details** in the Actions column.
5. In the **Table Query** panel, view the proportions of sensitive tables, top five sensitive data detection rules that are hit, and the list of tables in which the sensitive data is detected.
   - **Proportions of tables**

     In the **Proportions of tables** section, you can view the numbers of objects at the sensitivity levels of L3 (highly sensitive), L2 (moderately sensitive), L1 (low sensitive), and N/A (non-sensitive). You can also view a pie chart that shows the proportions of objects at each level.

   - **Top five rules that are hit**

     In the **Top five rules that are hit** section, you can view the top five sensitive data detection rules that are hit and the number of times that each rule is hit.

   - **List of tables in which the sensitive data is detected**

     In the table list, you can view the information about the tables in which the sensitive data is detected, such as the table name, total number of rows and fields, number of sensitive fields, and rules that are hit. You can click **Column details** in the Actions column to view the field details, such as the fields that hit sensitive data detection rules and the risk levels of the sensitive fields.

View statistics on sensitive data detected in MaxCompute

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Sensitive Data Identification** > **Sensitive data assets**.
3. On the **Sensitive data assets** page, click the **MaxCompute** tab.
4. On the **MaxCompute** tab, find the required MaxCompute project and click **Table Details** in the Actions column.
5. In the **Table Query** panel, view the proportions of sensitive tables, top five sensitive data detection rules that are hit, and the list of tables in which the sensitive data is detected.
   - **Proportions of tables**

     In the **Proportions of tables** section, you can view the numbers of objects at the sensitivity levels of L3 (highly sensitive), L2 (moderately sensitive), L1 (low sensitive), and N/A (non-sensitive). You can also view a pie chart that shows the proportions of objects at each level.

   - **Top five rules that are hit**

     In the **Top five rules that are hit** section, you can view the top five sensitive data detection rules that are hit and the number of times that each rule is hit.

- **List of tables in which the sensitive data is detected**

  In the table list, you can view the information about the tables in which the sensitive data is detected, such as the table name, total number of rows and fields, number of sensitive fields, and rules that are hit. You can click **Column details** in the Actions column to view the field details, such as the fields that hit sensitive data detection rules and the risk levels of the sensitive fields.

View statistics on sensitive data detected in self-managed databases hosted on ECS instances

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Sensitive Data Identification** > **Sensitive data assets**.
3. On the **Sensitive data assets** page, click the **ECS self-built database** tab.
4. On the **ECS self-built database** tab, find the required database and click **Table Details** in the Actions column.
5. In the **Table Query** panel, view the proportions of sensitive tables, top five sensitive data detection rules that are hit, and the list of tables in which the sensitive data is detected.
   - **Proportions of tables**

     In the **Proportions of tables** section, you can view the numbers of objects at the sensitivity levels of L3 (highly sensitive), L2 (moderately sensitive), L1 (low sensitive), and N/A (non-sensitive). You can also view a pie chart that shows the proportions of objects at each level.
   - **Top five rules that are hit**

     In the **Top five rules that are hit** section, you can view the top five sensitive data detection rules that are hit and the number of times that each rule is hit.
   - **List of tables in which the sensitive data is detected**

     In the table list, you can view the information about the tables in which the sensitive data is detected, such as the table name, total number of rows and fields, number of sensitive fields, and rules that are hit. You can click **Column details** in the Actions column to view the field details, such as the fields that hit sensitive data detection rules and the risk levels of the sensitive fields.

View statistics on sensitive data detected in PolarDB-X

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Sensitive Data Identification** > **Sensitive data assets**.
3. On the **Sensitive data assets** page, click the **DRDS** tab.
4. On the **DRDS** tab, find the required database and click **Table Details** in the Actions column.
5. In the **Table Query** panel, view the proportions of sensitive tables, top five sensitive data detection rules that are hit, and the list of tables in which the sensitive data is detected.
   - **Proportions of tables**

     In the **Proportions of tables** section, you can view the numbers of objects at the sensitivity levels of L3 (highly sensitive), L2 (moderately sensitive), L1 (low sensitive), and N/A (non-sensitive). You can also view a pie chart that shows the proportions of objects at each level.
   - **Top five rules that are hit**

     In the **Top five rules that are hit** section, you can view the top five sensitive data detection rules that are hit and the number of times that each rule is hit.
   - **List of tables in which the sensitive data is detected**

In the table list, you can view the information about the tables in which the sensitive data is detected, such as the table name, total number of rows and fields, number of sensitive fields, and rules that are hit. You can click **Column details** in the Actions column to view the field details, such as the fields that hit sensitive data detection rules and the risk levels of the sensitive fields.

View statistics on sensitive data detected in Tablestore

You can view statistics on sensitive data detected in Tablestore.

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Sensitive Data Identification** > **Sensitive data assets**.
3. On the **Sensitive data assets** page, click the **OTS** tab.
4. On the **OTS** tab, find the required Tablestore instance and click **Table Details** in the Actions column.
5. In the **Table Query** panel, view the proportions of sensitive tables, top five sensitive data detection rules that are hit, and the list of tables in which the sensitive data is detected.
   - **Proportions of tables**

     In the **Proportions of tables** section, you can view the numbers of objects at the sensitivity levels of L3 (highly sensitive), L2 (moderately sensitive), L1 (low sensitive), and N/A (non-sensitive). You can also view a pie chart that shows the proportions of objects at each level.
   - **Top five rules that are hit**

     In the **Top five rules that are hit** section, you can view the top five sensitive data detection rules that are hit and the number of times that each rule is hit.
   - **List of tables in which the sensitive data is detected**

     In the table list, you can view the information about the tables in which the sensitive data is detected, such as the table name, total number of rows and fields, number of sensitive fields, and rules that are hit. You can click **Column details** in the Actions column to view the field details, such as the fields that hit sensitive data detection rules and the risk levels of the sensitive fields.

View statistics on sensitive data detected in AnalyticDB for PostgreSQL

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Sensitive Data Identification** > **Sensitive data assets**.
3. On the **Sensitive data assets** page, click the **GPDB** tab.
4. On the **GPDB** tab, find the required AnalyticDB for PostgreSQL instance and click **Table Details** in the Actions column.
5. In the **Table Query** panel, view the proportions of sensitive tables, top five sensitive data detection rules that are hit, and the list of tables in which the sensitive data is detected.
   - **Proportions of tables**

     In the **Proportions of tables** section, you can view the numbers of objects at the sensitivity levels of L3 (highly sensitive), L2 (moderately sensitive), L1 (low sensitive), and N/A (non-sensitive). You can also view a pie chart that shows the proportions of objects at each level.
   - **Top five rules that are hit**

     In the **Top five rules that are hit** section, you can view the top five sensitive data detection rules that are hit and the number of times that each rule is hit.
   - **List of tables in which the sensitive data is detected**

In the table list, you can view the information about the tables in which the sensitive data is detected, such as the table name, total number of rows and fields, number of sensitive fields, and rules that are hit. You can click **Column details** in the Actions column to view the field details, such as the fields that hit sensitive data detection rules and the risk levels of the sensitive fields.

View statistics on sensitive data detected in AnalyticDB for MySQL

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Sensitive Data Identification** > **Sensitive data assets**.
3. On the **Sensitive data assets** page, click the **ADS** tab.
4. On the **ADS** tab, find the required AnalyticDB for MySQL cluster and click **Table Details** in the Actions column.
5. In the **Table Query** panel, view the proportions of sensitive tables, top five sensitive data detection rules that are hit, and the list of tables in which the sensitive data is detected.
   - **Proportions of tables**

     In the **Proportions of tables** section, you can view the numbers of objects at the sensitivity levels of L3 (highly sensitive), L2 (moderately sensitive), L1 (low sensitive), and N/A (non-sensitive). You can also view a pie chart that shows the proportions of objects at each level.
   - **Top five rules that are hit**

     In the **Top five rules that are hit** section, you can view the top five sensitive data detection rules that are hit and the number of times that each rule is hit.
   - **List of tables in which the sensitive data is detected**

     In the table list, you can view the information about the tables in which the sensitive data is detected, such as the table name, total number of rows and fields, number of sensitive fields, and rules that are hit. You can click **Column details** in the Actions column to view the field details, such as the fields that hit sensitive data detection rules and the risk levels of the sensitive fields.

View statistics on sensitive data detected in DataWorks

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Sensitive Data Identification** > **Sensitive data assets**.
3. On the **Sensitive data assets** page, click the **DataWorks** tab.
4. On the **DataWorks** tab, find the required DataWorks workspace and click **Table Details** in the Actions column.
5. In the **Table Query** panel, view the proportions of sensitive tables, top five sensitive data detection rules that are hit, and the list of tables in which the sensitive data is detected.
   - **Proportions of tables**

     In the **Proportions of tables** section, you can view the numbers of objects at the sensitivity levels of L3 (highly sensitive), L2 (moderately sensitive), L1 (low sensitive), and N/A (non-sensitive). You can also view a pie chart that shows the proportions of objects at each level.
   - **Top five rules that are hit**

     In the **Top five rules that are hit** section, you can view the top five sensitive data detection rules that are hit and the number of times that each rule is hit.
   - **List of tables in which the sensitive data is detected**

In the table list, you can view the information about the tables in which the sensitive data is detected, such as the table name, total number of rows and fields, number of sensitive fields, and rules that are hit. You can click **Column details** in the Actions column to view the field details, such as the fields that hit sensitive data detection rules and the risk levels of the sensitive fields.

27.1.10.3.4.3. Query sensitive data

The Sensitive data search page displays all the sensitive data that is detected in your data assets. You can specify one or more types of sensitive data to query and view the distribution of the sensitive data across your data assets. This topic describes how to query sensitive data.

Procedure

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Sensitive Data Identification** > **Sensitive data search**.
3. On the **Sensitive data search** page, specify filter conditions based on your business requirements.

   Sensitive Data Discovery and Protection (SDDP) provides the following filter conditions:

   - **Hit data**: the type of sensitive data. You can select multiple types at a time, such as email addresses and mobile phone numbers.
   - **Enter file name to search/Enter table name to search**: the name of the object or table in which the sensitive data is detected. Fuzzy match is supported.
   - **Region**: the region where the data asset resides.
   - **Bucket/Instance/Project**: the name of the bucket, instance, or project in which the sensitive data is detected.

   > **Note** If you specify multiple filter conditions, SDDP displays the sensitive data that meets all the specified filter conditions.

4. Click **Search**.

   In the result list, you can view the information about the objects or tables where the sensitive data is detected. The information can be grouped or sorted by using the following methods:

   - **Group sensitive data by risk level**

     On the **OSS-file** tab, set the **Sensitivity level** parameter to S1, S2, or S3. This can be used to view sensitive data at the specified sensitivity level.

   - **Sort sensitive data based on the total number of rows or sensitive fields in ascending or descending order**

     On a specific tab such as the **RDS-table** tab, click the icon to the right of **Total number of rows** or **Sensitive column**. This can be used to sort sensitive data based on the total number of rows or sensitive fields. Then, these results can be further sorted in ascending or descending order. The data is sorted in descending order after you click the icon for the first time. Then, the next time you click the icon, these results are sorted in ascending order.

5. Find the specific sensitive data, and click **Details** in the **Operation** column or click **Column details** in the **Operation** column.

   In the **Hit query** panel for a bucket or the **Column details** panel for a table, you can view the information about all the sensitive data that is detected in the current object or table. The information includes the following content:

   - **Column name**: the name of the sensitive field detected in the table.

> **Note** This parameter is displayed only in the **Column details** panel for a table in an ApsaraDB RDS instance, MaxCompute project, self-managed database that is hosted on an Elastic Compute Service (ECS) instance, PolarDB-X database, Tablestore instance, AnalyticDB for MySQL cluster, or AnalyticDB for PostgreSQL instance. The **Hit query** panel for an OSS bucket does not display this parameter.

- **Hit Rules**: the type and name of the sensitive data detection rule that is hit.
- **Sensitivity level**: the risk level of the detected sensitive data.
- **Number of hits**: the number of times that the sensitive data detection rule is hit in the object.

  > **Note** The **Hit query** panel for an OSS bucket does not display this parameter.

- **Data Sampling**: the samples that are collected from the data asset. If you want to configure the **Sensitive data sampling** parameter, choose **Data Security > Sensitive Data Protection > Data protection authorization > Data Asset authorization**. On the **Cloud hosting** page, you can set this parameter to 0, 5, or 10. Make sure that the value you set is the same as the value of **Sensitive data sampling** that you set when you authorize SDDP to protect your data assets.

27.1.10.3.4.4. Manage scan tasks

Sensitive Data Discovery and Protection (SDDP) is authorized to automatically scan data assets for sensitive data. On the Identify Task Monitoring page, you can view the details of scan tasks that are generated by SDDP. These tasks are used to scan data assets and rerun the scan tasks.

Context

SDDP can monitor scan tasks that are generated for sensitive data in Object Storage Service (OSS), ApsaraDB RDS, MaxCompute, self-managed databases that are hosted on Elastic Compute Service (ECS) instances, PolarDB-X, Tablestore, AnalyticDB for MySQL, and AnalyticDB for PostgreSQL.

After you authorize SDDP to access specific data assets, SDDP can be used to automatically create and run scan tasks for these data assets to detect sensitive data. By default, the **automatic scan** feature is enabled for scan tasks that you create. This feature allows SDDP to run a full scan on authorized data assets and scan the data that is newly written to or modified in these data assets at an interval of 4 hours. In addition, after you create or modify a sensitive data detection rule, SDDP automatically reruns scan tasks for which the automatic scan feature is enabled.

View the details of scan tasks

On the **Identify task monitoring** page, you can view the details of each scan task, such as the related data asset, task status, and time when the task is complete. To view the details of scan tasks, perform the following steps:

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Sensitive Data Identification > Identify task monitoring**.
3. On the Identify task monitoring page, click the tab of the data asset for which you want to view scan tasks.
4. (Optional)Select the region, enter the name of the data asset, specify the start and end of the time range to query, and then click **Search**.
5. In the task list, view the details of each scan task, such as the related data asset, task status, and time when the task is complete.

Rescan your data assets

You can rerun scan tasks in the following scenarios:

- If the **automatic scan** feature is not enabled for a scan task, the scan task is not run after the task is created. In this case, you must rerun the scan task.
- If you enable the **automatic scan** feature for a scan task, SDDP can be used to automatically rerun the scan task and scan the data that is newly written to or modified in the specific data asset at an interval of 4 hours. You can also rerun the scan task to immediately scan the specific data asset after you modify the data in the data asset.

To rescan a data asset for sensitive data, perform the following steps:

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Sensitive Data Identification > Identify task monitoring**.
3. On the Identify task monitoring page, click the tab of the data asset for which you want to rescan data.
4. Find the specific data asset and click **Rescan** in the **Operation** column.
5. In the **Confirm rescan** dialog box, click **OK**.

   In most cases, the rescan process requires about 10 minutes to complete. Wait until the data asset is scanned.

   After the rescan is started, the scan task enters the **Scanning** or **Waiting** state. The percentage that appears in the **Scan Status** column indicates the progress of the scan task.

What's next

After the scan is complete, the scan task enters the **Complete** state. To view the latest scan results, choose **Data Security > Sensitive Data Protection > Sensitive Data Identification > Sensitive data assets** and click the tab of the data asset for which you want to view the scan results.

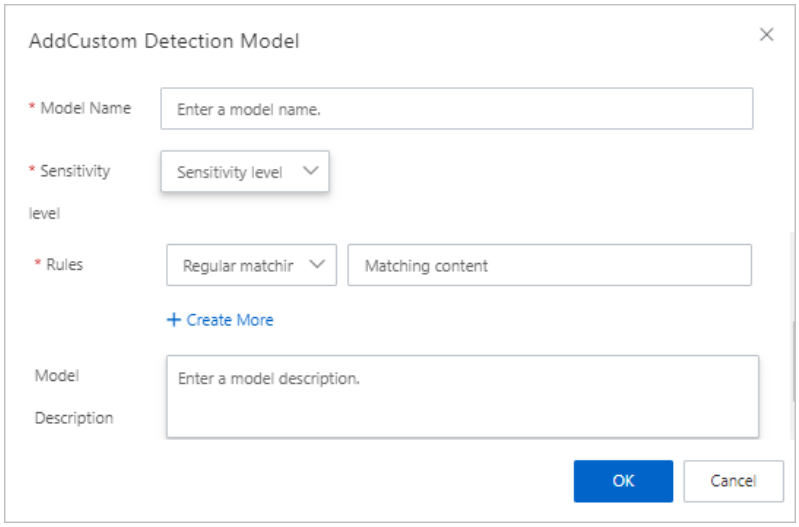
27.1.10.3.4.5. Manage detection rules

Sensitive Data Discovery and Protection (SDDP) allows you to customize the detection rules for classifying sensitive data. You can view and configure detection rules to detect sensitive data. This topic describes how to create and manage custom detection rules, view built-in detection rules, and modify sensitivity levels.

Create a custom detection rule

SDDP detects sensitive data in files or tables based on specified rules and generates alerts. You can customize detection rules to detect sensitive data based on your business requirements. To customize a detection rule, perform the following steps:

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Sensitive Data Identification > Identification Rules**.
3. On the **Identification Rules** page, click **Add Rule**.
4. In the **Add Rule** panel, configure parameters.



The following table describes the parameters to create a custom detection rule.

Parameter	Description
Rule name	The name of the detection rule.
Rule source	The source of the detection rule. The default value is **Customize** and cannot be changed.
Rule type	The type of the detection rule. Valid values: ○ **Algorithm**: Select an algorithm to detect sensitive data. ○ **Regular expression**: Select a regular expression to detect sensitive data. **Note** ○ If you have not created custom detection rules, SDDP detects sensitive data based on algorithm-based built-in detection rules. ○ The built-in detection rules that SDDP provides apply to various types of common sensitive data, including mobile phone numbers and ID card numbers. We recommend that you view built-in detection rules to check whether the sensitive data that you want to detect can be detected by built-in detection rules before you create the custom detection rule. For more information, see View built-in detection rules.
Sensitivity level	The sensitivity level for the detection rule. Valid values: ○ **N/A**: non-sensitive ○ **L1**: low sensitive ○ **L2**: moderately sensitive ○ **L3**: highly sensitive

Parameter	Description
Rule classification	The class of the sensitive data that the detection rule can detect. Valid values: ○ Personal and sensitive information ○ Sensitive device information ○ Sensitive key information ○ Sensitive picture information ○ Sensitive corporate information ○ Sensitive location information ○ Universal sensitive information
Rules	The content of the detection rule. The content is used to match sensitive fields or text. This parameter is based on the **Rule type** parameter. ○ If the **Rule type** parameter is set to **Keywords**, you must set the **Method** parameter and enter the keyword that is used to detect sensitive data in the **Keywords** field. If you want to create a custom detection rule to detect the mobile phone number *1331234*****. You can set the **Method** parameter to **Contains** and enter *1331234***** in the **Keywords** field. **Note** The keyword must be a precise value, such as a specific mobile phone number, email address, or ID card number. ○ If the **Rule Type** parameter is set to **Regular Expression**, you must enter the regular expression that is used to detect sensitive data in the **Regular Expression** field. If you want to create a custom detection rule to detect mobile phone numbers, you can enter *^((13[0-9])|(14[5,7])|(15[0-3,5-9])|(17[0,3,5-8])|(18[0-9])|166|198|199|(147))\\d{8}$* in the **Regular Expression** field. **Note** After a detection rule is created, the detection rule appears in the rule list. However, the rule list does not display the details of the rule. You can click **Details** in the Operation column to view the details of the detection rule.

5. Click **Enable** or **Save**.
   - **Enable**: If you click **Enable**, the detection rule is created and enabled. SDDP starts to detect sensitive data based on the detection rule.
   - **Save**: If you click **Save**, the detection rule is created but not enabled. To enable the detection rule, you must turn on the switch in the Status column for the detection rule in the rule list.

Note
- SDDP detects sensitive data based on all sensitive data detection rules that are enabled.
- A detection rule takes effect after it is created and enabled. If you want to temporarily exclude specific data from sensitive data, you can disable the specific detection rule. After you disable a detection rule, SDDP no longer detects sensitive data based on the detection rule. We recommend that you enable all detection rules to reduce risks.
- You can modify and delete custom detection rules. You can view built-in detection rules but cannot modify or delete them.

View built-in detection rules

The built-in detection rules that SDDP provides apply to various types of common sensitive data, such as mobile phone numbers and ID card numbers. You can view all information about a built-in detection rule, such as the rule type, rule name, and sensitivity level. You cannot view the rule definition. To view built-in detection rules, perform the following steps:

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Sensitive Data Identification > Identification Rules**.
3. On the **Identification Rules** page, set the **Rule Source** parameter to **Built-in**.
4. View built-in detection rules in the list that appears.

   You can view the information about each built-in detection rule, such as **Rule name**, **Rule classification**, **Rule source**, and **Rule type**.
5. To view the details about a specific built-in detection rule, find the built-in detection rule and click **Details** in the Operation column.
6. In the **Rule details** dialog box, view the details of the built-in detection rule.

   You can view **Rule name**, **Rule source**, **Rule type**, **Sensitivity level**, and **Rule classification** of a built-in detection rule. You cannot view the **algorithm** or **regular expression** of a built-in detection rule.

Modify a sensitivity level

SDDP allows you to modify the name and description of a sensitivity level. To modify a sensitivity level, perform the following steps:

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Sensitive Data Identification > Identification Rules**.
3. On the Identification Rules page, click the **Level settings** tab.
4. Find the sensitivity level that you want to modify and click **Edit** in the Actions column.
5. In the **Sensitivity level** dialog box, modify the information in the Sensitivity level and Description fields.

   By default, SDDP marks sensitive data with the following sensitivity levels: **N/A**, **S1**, **S2**, and **S3**. **N/A** indicates an unknown risk level. The sensitivity level of S1, S2, and S3 increases in sequence. You can customize the names and descriptions of the four sensitivity levels to classify the sensitive data detected in your data assets based on your business requirements. SDDP provides the following default descriptions for the S1, S2, and S3 levels:

   - **S1**: low risk.

- **S2**: medium risk.
- **S3**: high risk.

6. Click **Confirm**.
   The modification immediately takes effect after you submit it. Refresh the **Identification Rules** page. You can view the new sensitivity level on the **Level settings** tab.

27.1.10.3.5. Check data permissions

27.1.10.3.5.1. View permission statistics

This topic describes how to view permission statistics.

Context

On the Permission Management page, you can view the overall permission distribution of Apsara Stack. You can also identify vulnerable accounts and users, and troubleshoot and handle security issues at your earliest opportunity.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Data Security > Security Data Protection > Data Permissions > Permission Management**.
3. View the overall permission statistics.

   - **Accounts with Access to Sensitive Data**: the number of accounts that can access sensitive data.
   - **Departments**: the number of departments in Apsara Stack.
   - **Users**: the number of users in Apsara Stack.
   - **Accounts**: the number of accounts in Apsara Stack.
4. View the department-level permission statistics.
   You can view the statistics on the users, accounts, and anomalous events that are related to permissions for each department.

27.1.10.3.5.2. View the permissions of an account

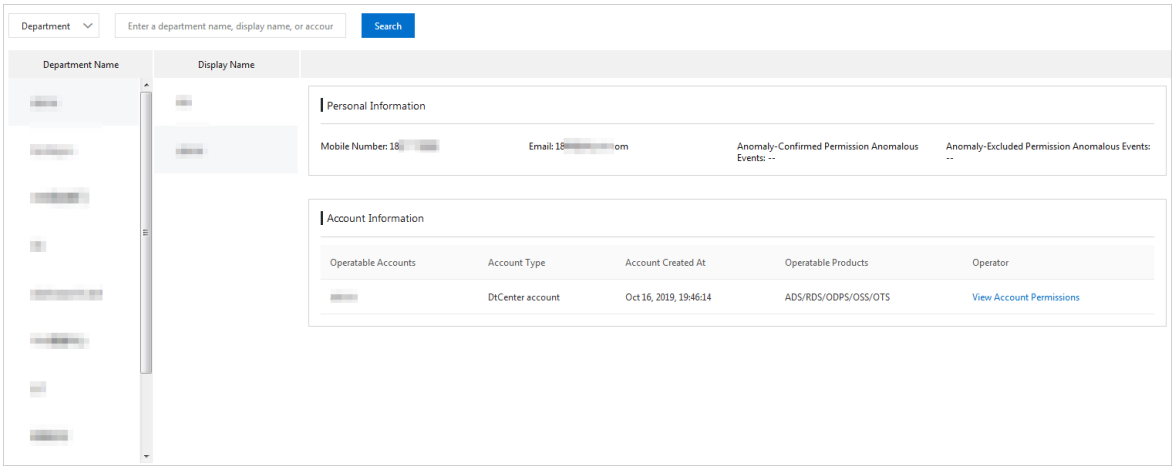
This topic describes how to view the permissions of an account.

Context

You can search for an account to view its information so that you can quickly find the owner of sensitive data.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Data Security > Security Data Protection > Data Permissions > Permission Search**.



3. Search for a specific account.

   To search for an account, perform the following steps:

   i. Select **Department** or **Employee** from the drop-down list.

   ii. Enter a keyword, such as a department name or account.

   iii. Click **Search** to view the search results in the **Display Name** column.

   > **Note** You can also click a department in the Department Name column. All accounts of the department are listed in the Display Name column.

4. In the **Display Name** column, click the specific account.
5. View information in the **Personal Information** and **Account Information** sections on the right.
   - **Personal Information**

     You can view the contact information about the account owner, and the number of confirmed anomalous events that are related to permission access. You can also view the number of excluded anomalous events that are related to permission access.
   - **Account Information**

     You can view the accounts that the owner can use, the types and the time when the accounts are created, and Apsara Stack services that the accounts can access.

     You can click **View Account Permissions** in the Actions column of an account to view the resources, resource types, resource paths, and operation permissions.

27.1.10.3.6. Monitor data flows

27.1.10.3.6.1. View data flows in DataHub

This topic describes how to view data flows in DataHub.

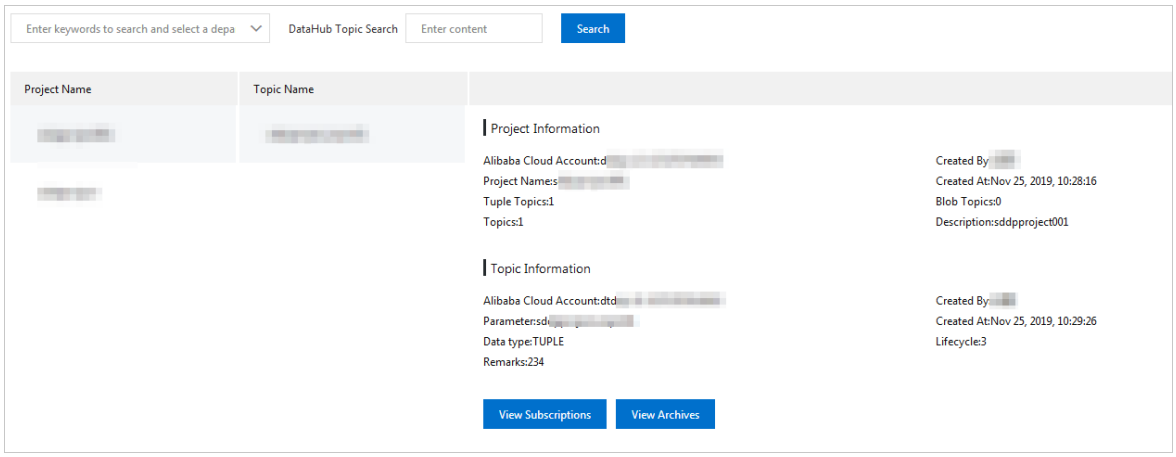
Context

DataHub is a platform that is designed to process streaming data. You can publish and subscribe to streaming data in DataHub, and distribute the data to other platforms. DataHub allows you to analyze streaming data and build applications based on the streaming data.

On the **DataHub** page, you can view the details about data flows in DataHub. The details include the relationships between DataHub projects and topics, and the relationships among topics, subscribed applications, and archive sources.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Data Security > Security Data Protection > Data Flow Monitoring > DataHub**.
3. In the search box, enter a keyword and select a department from the drop-down list. Enter a topic keyword in the **DataHub Topic Search** field and click **Search**.



> **Note**
>
> You can also click the required project in the **Project Name** column and click the required topic in the **Topic Name** column.

In the **Project Information** and **Topic Information** sections, you can view the information about the project and the topic.

- **Project Information**

  Displays information such as the project name, Apsara Stack account, creator, creation time, and number of topics.

- **Topic Information**

  Displays information such as the topic name, Apsara Stack account, creator, creation time, and topic type.

4. Click **View Subscriptions** to view the subscription list.

   The subscription list contains information such as the subscription name, Apsara Stack account of the creator, display name, name of the subscribed application, and application contact.

   i. Enter a keyword and select a department from the drop-down list.
   ii. Enter a keyword in the **DataHub Topic Search** field.
   iii. Click **Search** to search for the required DataHub topic.

5. Click **View Archives** to view the archive list.

   The archive list contains information such as the name of the connected instance, Apsara Stack account of the creator, display name, source service, resource path, and risk level.

   i. Enter a keyword and select a department from the drop-down list.

   ii. Enter a keyword in the **DataHub Topic Search** field.

   iii. Click **Search** to find the required DataHub topic.

27.1.10.3.6.2. View data flows in Data Integration

This topic describes how to view data flows in Data Integration.

Context

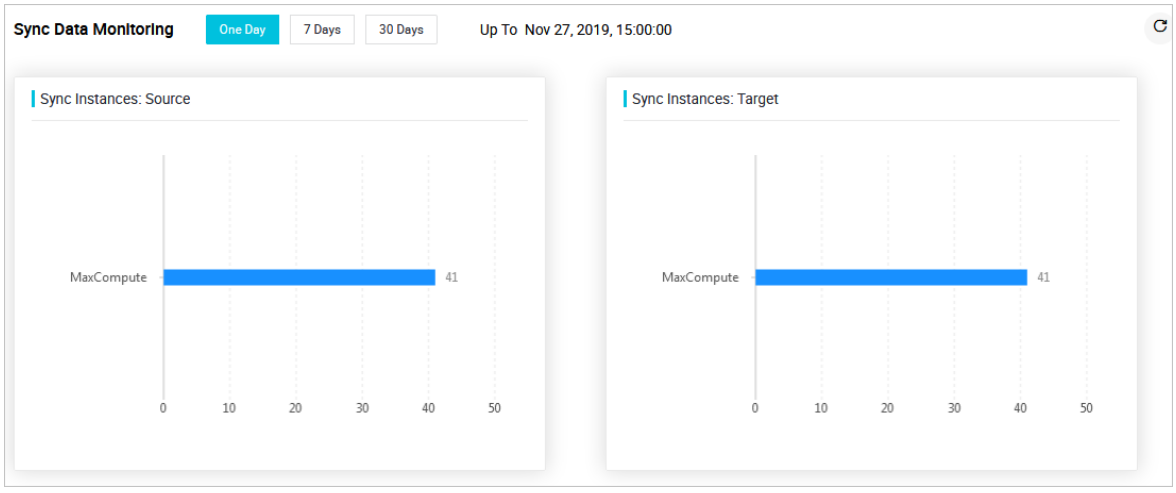
DataWorks is a comprehensive, professional cloud research and development (R&D) platform for big data. DataWorks is used as an operating system that delivers intelligent, efficient, secure, and reliable big data services. DataWorks meets your requirements for data and quality management. It can also be used to provide data services for external systems.

DataWorks includes the Data Integration feature that provides a stable, efficient, and scalable data synchronization platform on Apsara Stack. Data Integration implements fast and stable data transmission and synchronization between various data sources in complex networks.

Procedure

1.
2. In the left-side navigation pane, choose **Data Security > Security Data Protection > Data Flow Monitoring > CDP Flow Monitoring**.
3. On the **Data Integration** page, click **Sync Data Monitoring**.
4. View the statistical graph for the number of synchronized instances.

   > **Note**
   > - The number of synchronized instances is measured from two aspects: **Sync Instances: Source** and **Sync Instances: Target**.
   > - You can view statistics within different periods (**One Day**, **7 Days**, and **30 Days**).

5. In the **Sync Instances** section, view information such as the ID, time, node name, data type, and the amount of synchronized data.

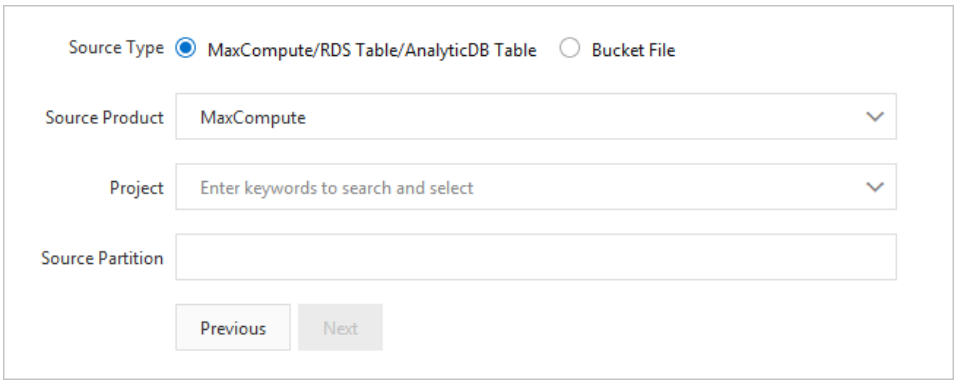
27.1.10.3.7. Sensitive data masking

27.1.10.3.7.1. Create a static masking task

This topic describes how to create a static masking task and run the task to mask sensitive data.

Procedure

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Sensitive Data Desensitization > Static Desensitization**.
3. In the upper-right corner of the **Desensitization task configuration** tab, click **Add Desensitization Task**.
4. On the **Add Desensitization Task** page, configure parameters.
   i. In the **Basic Task Information** step, specify **Task Name** and **Task notes**. Then, click **Next**.
   ii. In the **Desensitization Source Configuration** step, specify the source of data that you want to mask and click **Next**.



You can use Sensitive Data Discovery and Protection (SDDP) to create masking tasks for the following data sources: tables in ApsaraDB RDS, MaxCompute, AnalyticDB for MySQL, and ApsaraDB for OceanBase. You can also create masking tasks for objects in Object Storage Service (OSS). You cannot create masking tasks for tables in PolarDB. The following table describes the parameters used to create a masking task for each data source.

Data source	Parameter	Description
MaxCompute	**Types of data storage**	Select **RDS Table / MaxCompute Table /PolarDB Table /ADS Table /OceanBase Table**.
	Source Product	Select **MaxCompute**.
	Source Database/Project	Select the source database or project whose data you want to mask from the drop-down list.
	Source table name	Select the source table whose data you want to mask from the drop-down list.

Data source	Parameter	Description
	Source Partition	Enter the name of the source partition whose data you want to mask. You can configure partitions when you create a MaxCompute table. Partitions define different logical divisions of a table. When you query data, you can specify partitions to improve query efficiency **Note** **Source Partition** is optional. If you leave this parameter unspecified, SDDP masks sensitive data in all partitions of the source table.
ApsaraDB RDS	**Types of data storage**	Select **RDS Table / MaxCompute Table /PolarDB Table /ADS Table /OceanBase Table**.
	Source Product	Select **RDS**.
	Source Database/Project	Select the source database or project whose data you want to mask from the drop-down list.
	Source table name	Select the source table whose data you want to mask from the drop-down list.
	Sample SQL	Optional. Enter an SQL statement and specify the data that you want to mask.
ApsaraDB for OceanBase	**Types of data storage**	Select **RDS Table / MaxCompute Table /PolarDB Table /ADS Table /OceanBase Table**.
	Source Product	Select **OceanBase**.
	Source Database/Project	Select the source database or project whose data you want to mask from the drop-down list.
	Source table name	Select the source table whose data you want to mask from the drop-down list.
	Sample SQL	Optional. Enter an SQL statement and specify the data that you want to mask.
ADS	**Types of data storage**	Select **RDS Table / MaxCompute Table /PolarDB Table /ADS Table /OceanBase Table**.
	Source Product	Select **ADS**.
	Source Database/Project	Select the source project whose data you want to mask from the drop-down list.
	Source table name	Select the source table whose data you want to mask from the drop-down list.
	Types of data storage	Select **OSS files**.

Data source	Parameter	Description
OSS	**File source**	Upload a file from your computer or select a bucket. Valid values: ■ **Uploaded Local File**: If you select this option, click **Select a local file** and select a source file from your computer. ■ **OSS Bucket**: If you select this option, select the OSS bucket to which the source object belongs.
	Source file description	Enter an informative description for the bucket to help identify the task. **Note** This parameter is required only when you set **File source** to **Uploaded Local File**.
	OSS Bucket where the source file is located	Select the OSS bucket to which the source object belongs. **Note** This parameter is required only when you set **File source** to **OSS Bucket**.
	Source file names	Optional. Enter the name of the source object. **Note** This parameter is required only when you set **File source** to **OSS Bucket**. If you want to use wildcards to specify objects, turn on **Open the pass**. After you turn on Open the pass, you can use asterisks (*) as wildcards to specify multiple OSS objects at a time. However, you can use asterisks only in object names. For example, enter test*.xls. After you specify an object name by using an asterisk, SDDP masks the data of the matched objects. Make sure that these objects use the same column structure.
	Separator selection	Optional. Select a column delimiter based on the format of the object that you specify. This parameter is required for objects in the CSV or TXT format. Valid values: ■ **Semicolon ";" (MacOS/Linux default)** ■ **Comma "," (Windows default)**
	Table contains header rows	Optional. Specify whether the data to be masked contains header rows.

iii. In the **Desensitization algorithm** step, specify the algorithm to mask data and click **Next**.

In this step, you must specify the algorithm type, select an algorithm, and turn on the masking switch for the source field of data that you want to mask.

iv. (Optional)In the **Data Watermark** step, turn on **Open data watermark**. Specify the following parameters: Please select the field to embed the watermark, Please select a watermark algorithm, and Please enter watermark information. Then, click **Next**.

The Please select a watermark algorithm parameter has the following values:

- **Space Algorithm**: If you want to add watermarks for fields of a string type, select this value.
- **Modify the least significant bit algorithm**: If you want to add watermarks for fields of a numeric type, select this value.

v. In the **Destination Location Configuration** step, specify the destination table to store the data after masking, test and make sure that you have write permissions on the destination table, and then click **Next**. The parameters for the destination table include **Types of data storage** and **Target**.

vi. In the **Confirm Process Logic** step, configure the processing logic of the task.

Parameter	Description
How the task is triggered	Select a method to run the masking task. Valid values: ■ **Manual Only**: You must manually run the masking task on the Static Desensitization page. ■ **Scheduled Only**: The masking task is automatically run at a specific point in time on an hourly, daily, or monthly basis. ■ **Manual + Scheduled**: You can manually run the masking task or enable automatic running of the masking task at a specific point in time on an hourly, daily, or monthly basis.
Turn on incremental desensitization	Optional. Enable incremental masking based on your business requirements. If you turn on this switch, SDDP masks only the data that is added after the last masking task is completed. You must specify a field whose value is increased over time as the incremental identifier. For example, you can specify the creation time field or the auto-increment ID field as the incremental identifier. **Note** SDDP supports incremental masking only for data in ApsaraDB RDS.
Shard field	Optional. Select a field based on which SDDP divides the source data into multiple shards and concurrently masks the data in these shards. In this case, data masking is more efficient. You can specify one or more shard fields based on your business requirements. **Note** ■ SDDP supports incremental masking only for data in ApsaraDB RDS. We recommend that you use a primary key or a field on which a unique index is created as the shard field. ■ If you leave this parameter unspecified, a primary key is used as the shard field. SDDP divides the source data based on the primary key and masks the data. If the source data does not have a primary key, you must specify a shard field. Otherwise, the masking task fails. ■ If you specify excessive shard fields, query performance and data accuracy may deteriorate. Proceed with caution.

Parameter	Description
Table name conflict resolution	Select a method to handle a table name conflict. Valid values: ■ **Delete the target table and create a new table with the same name.** ■ **Attach data to the target table**: This method is recommended.
Row Conflict Resolution	Select a method to handle a row conflict. Valid values: ■ **Keep conflicting rows in the target table and discard the new data**: This method is recommended. ■ **Delete conflicting rows in the target table and insert the new data.**

vii. Click **Submit**.

After you create the masking task, you can view the task in the list of masking tasks on the **Desensitization task configuration** tab.

5. In the list of masking tasks, turn on the switch and run the masking task.
6. On the **Task Execution Status** tab, view **Execution Progress** and **Status** of the masking task.

27.1.10.3.7.2. View dynamic data masking tasks

Sensitive Data Discovery and Protection (SDDP) provides the dynamic data masking feature. You can call the ExecDatamask operation to dynamically mask sensitive data.

Context

When you call this operation, you must specify the ID of the data masking template to use. Static data masking and dynamic data masking can use the same template. To obtain the template ID, you must log on to Apsara Stack Security Center and choose **Data Security > Sensitive Data Protection > Sensitive Data Desensitization > Desensitization Template**. You can also create custom data masking templates. For more information, see Create a data masking template.

Limits

Before you can call the ExecDatamask operation to dynamically mask sensitive data, make sure that the size of the sensitive data is less than 2 MB. The size is specified by the `Data` parameter.

View the call history of the ExecDatamask operation

Log on to Apsara Stack Security Center. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Sensitive Data Desensitization > Dynamic desensitization**. On the page that appears, you can view the call history of the ExecDatamask operation. Each record includes the name of the operation, the UID of the Alibaba Cloud account or Resource Access Management (RAM) user that was used to call the operation, the IP address of the user who initiated the call, the times at which the operation was first and last called, and the total number of calls.

Note Only one record is generated for calls initiated by the same Alibaba Cloud account or RAM user from the same IP address. The number of calls is accumulated in this case.

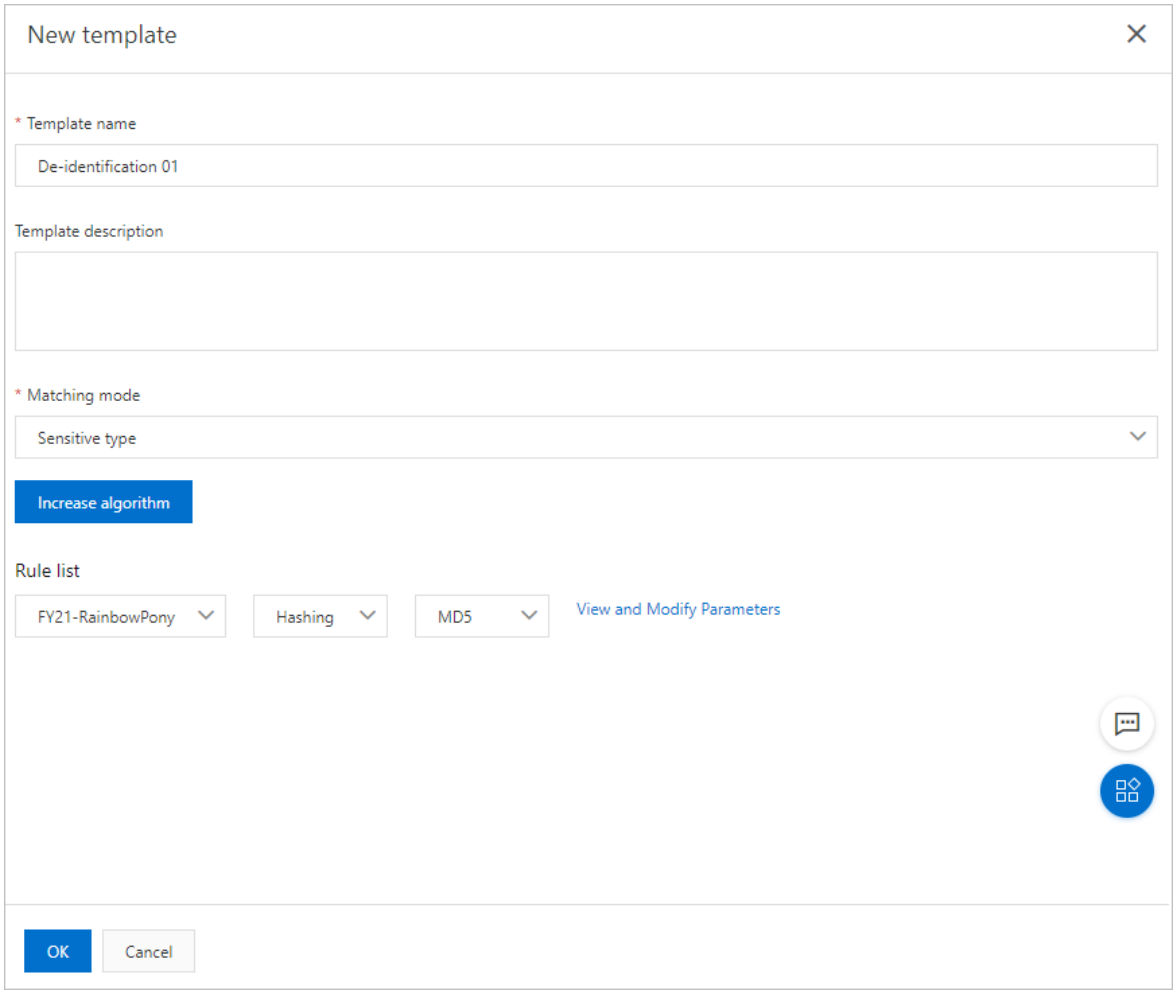
27.1.10.3.7.3. Create a data masking template

Sensitive Data Discovery and Protection (SDDP) allows you to create data masking templates. You can create a data masking template and add data masking algorithms that are frequently used in the same scenario to the template. This avoids repeated configuration of data masking algorithms and improves the efficiency in sensitive data processing. This topic describes how to create and manage data masking templates.

Create a data masking template

You can create an unlimited number of data masking templates.

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Sensitive Data Desensitization > Desensitization Template**.
3. On the **Desensitization Template** page, click **New template**.
4. In the **New template** panel, configure parameters. The following table describes the parameters to create a data masking template.



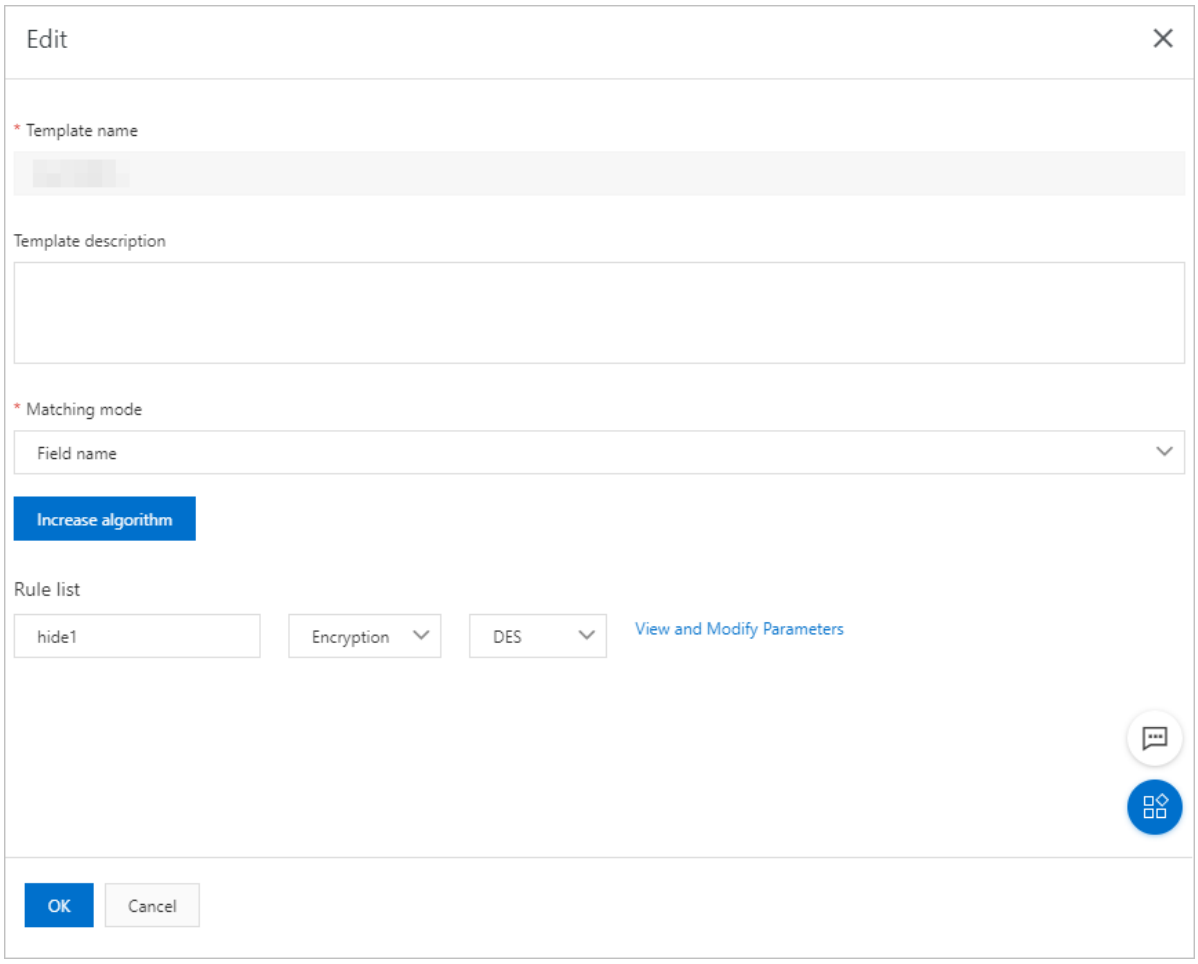
Parameter	Description
Template name	The name of the data masking template.
Template description	The description of the data masking template. You can enter information such as the scenario to which the template is applied.
Matching mode	The mode in which the data masking template handles its matched sensitive data. Valid values: ○ **Sensitive type**: If you select this option, you must select the types of sensitive data that you want to mask, such as vehicle identification numbers and unified social credit codes, and the data masking algorithm for each type of sensitive data. ○ **Field name**: If you select this option, you must specify the fields that you want to mask and the data masking algorithm for each field.

Parameter	Description
Rule list	The rules that are used to mask sensitive data. To configure a rule, select a sensitive data type or enter a field that you want to mask and specify a data masking algorithm. SDDP supports the following data masking algorithms. ○ Hashing ○ Redaction ○ Substitution ○ Rounding ○ Encryption ○ Shuffling ○ Data decryption For more information, see Configure data masking algorithms. You can configure multiple rules in a template. To configure more rules, click **Increase Algorithm**.

Manage data masking templates

- **Edit a data masking template**

  To edit a data masking template, find the template on the **Desensitization Template** page and click **Edit** in the Actions column. In the **Edit** panel, modify the description or rules of the data masking template.



- **Delete a data masking template**

  To delete a data masking template that you no longer use, find the template on the **Desensitization Template** page and click **Delete** in the Actions column.

  > **Note** If you deleted a data masking template, it cannot be restored. Proceed with caution.

27.1.10.3.7.4. Configure data masking algorithms

This topic describes how to configure data masking algorithms.

Context

The following table describes the data masking algorithms that are supported by Sensitive Data Discovery and Protection (SDDP).

Category	Description	Algorithm	Input	Suitable sensitive data and scenario
Hashing	Raw data cannot be retrieved after it is masked. This type of algorithms is suitable for password masking and the scenarios in which you must check whether data is sensitive by comparison. You can use common hashing algorithms and specify a salt value.	MD5	Salt value	• Sensitive data: keys • Scenario: data storage
		SHA-1	Salt value	
		SHA-256	Salt value	
		HMAC	Salt value	

Redaction by using asterisks (*) or number signs (#)	Raw data cannot be retrieved after it is masked.
	This type of algorithms is suitable for the scenario in which you need to show sensitive data on a graphical user interface (GUI) or share sensitive data.
	This type of algorithms masks specific content in sensitive data by using asterisks (*) or number signs (#).
		Keeps the first N characters and the last M characters	Values of N and M	• Sensitive data: sensitive personal information
				• Scenarios:
				  ◦ Data usage
				  ◦ Data sharing

		Keeps characters from the Xth position to the Yth position	Values of X and Y	
		Masks the first N characters and the last M characters	Values of N and M	
		Masks characters from the Xth position to the Yth position	Values of X and Y	
		Masks characters that precede a special character when the special character appears for the first time	At sign (@), ampersand (&), or period (.)	

Category	Description	Algorithm	Input	Suitable sensitive data and scenario
		Masks characters that follow a special character when the special character appears for the first time	At sign (@), ampersand (&), or period (.)	
Substitution (customization supported)	Raw data can be retrieved after it is masked by using some of the algorithms. This type of algorithms can be used to mask fields in fixed formats. For example, you can use the algorithms to mask ID card numbers.	Substitutes specific content in ID card numbers with mapped values	Mapping table for randomly substituting IDs of administrative regions	• Sensitive data: ◦ Sensitive personal information ◦ Sensitive information of enterprises ◦ Sensitive information of devices • Scenarios: ◦ Data storage ◦ Data sharing
		Randomly substitutes specific content in ID card numbers	Mapping table for randomly substituting IDs of administrative regions	
		Randomly substitutes specific content in IDs of military officer cards	Mapping table for randomly substituting type codes	
		Randomly substitutes specified content in passport numbers	Mapping table for randomly substituting purpose fields	
		Randomly substitutes specific content in permit numbers of Mainland Travel Permits for Hong Kong and Macao Residents	Mapping table for randomly substituting purpose fields	
		Randomly substitutes specific content in bank card numbers	Mapping table for randomly substituting bank identification numbers (BINs)	
		Randomly substitutes specific content in landline telephone numbers	Mapping table for randomly substituting IDs of administrative regions	
		Randomly substitutes specific content in mobile phone numbers	Mapping table for randomly substituting mobile network codes	
		Randomly substitutes specific content in unified social credit codes	Mapping table for randomly substituting IDs of registration authorities, mapping table for randomly substituting type codes, and mapping table for randomly substituting IDs of administrative regions	

Category	Description	Algorithm	Input	Suitable sensitive data and scenario
	This type of algorithms substitutes the entire value or a part of the value of a field with a mapped value by using a mapping table. In this case, raw data can be retrieved after it is masked. This type of algorithms also substitutes the entire value or a part of the value of a field randomly based on a random interval. In this case, raw data cannot be retrieved after it is masked. SDDP provides multiple built-in mapping tables and allows you to customize substitution algorithms.	Substitutes specific content in general tables with mapped values.	Mapping table for substituting uppercase letters, mapping table for substituting lowercase letters, mapping table for substituting digits, and mapping table for substituting special characters	
		Randomly substitutes specific content in general tables	Mapping table for randomly substituting uppercase letters, mapping table for randomly substituting lowercase letters, mapping table for randomly substituting digits, and mapping table for randomly substituting special characters	

Rounding	Raw data can be retrieved after it is masked by using some of the algorithms.
	This type of algorithms can be used to analyze and collect statistics on sensitive datasets.
	SDDP provides two types of rounding algorithms. One algorithm rounds numbers and dates, and raw data cannot be retrieved after it is masked. The other algorithm bit-shifts text, and raw data can be retrieved after it is masked.
		Rounds down a number to the Nth digit before the decimal point	N	• Sensitive data: general sensitive information
				• Scenarios:
				  ◦ Data storage
				  ◦ Data usage

		Rounds dates	Date rounding level	
		Shifts characters	Number of places by which specific bits are moved and shift direction (left or right)	

Category	Description	Algorithm	Input	Suitable sensitive data and scenario

Encryption	Raw data can be retrieved after it is masked.
	This type of algorithms can be used to encrypt sensitive fields that need to be retrieved after encryption.
	Common symmetrical encryption algorithms are supported.
		Data Encryption Standard (DES) algorithm	Encryption key	• Sensitive data:
				  ◦ Sensitive personal information
				  ◦ Sensitive information of enterprises
				• Scenario: data storage

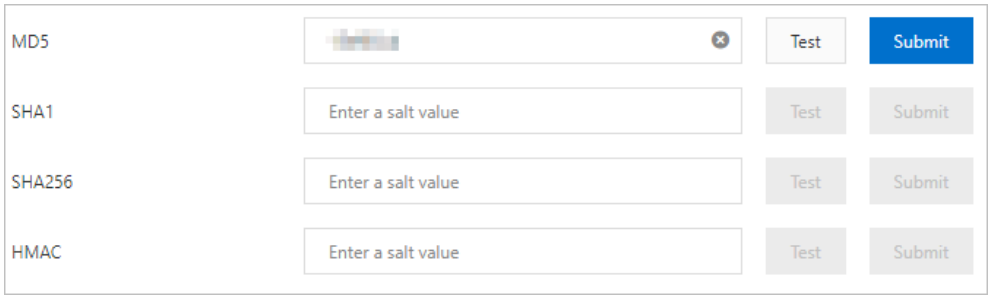
		Triple Data Encryption Standard (3DES) algorithm	Encryption key	
		Advanced Encryption Standard (AES) algorithm	Encryption key	

Shuffling	Raw data cannot be retrieved after it is masked.
	This type of algorithms can be used to mask structured data columns.
	This type of algorithms extracts values of a field in a specified range from the source table and rearranges the values in a specific column. Alternatively, this type of algorithms randomly selects values from a specific column within the value range and rearranges the selected values. This way, the values are mixed up and masked.
		Randomly shuffles data	Rearranged values or randomly selected values	• Sensitive data:
				  ◦ Sensitive information of devices
				  ◦ Location-sensitive information
				• Scenario: data storage

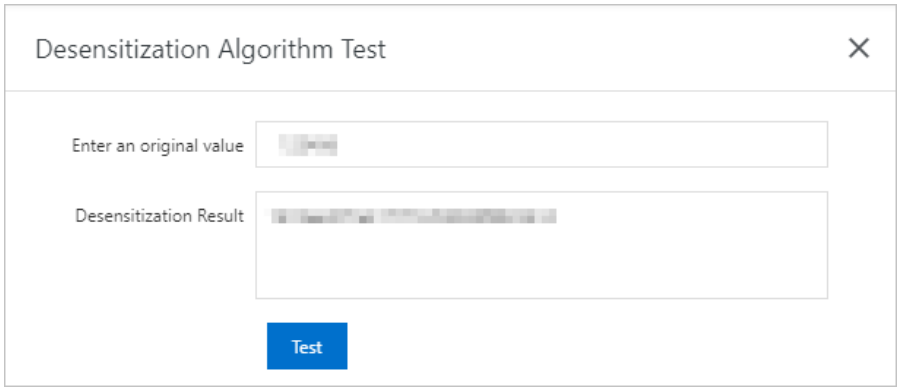
Hashing

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection.Sensitive Data DeidentificationDeidentification algorithms**.
3. Click the **Hashing** tab.
4. Specify a salt value for each algorithm.

> **Note** In cryptography, you can insert a specific string to a fixed position of a password to generate a hash value that is different from that of the original password. This process is called salting.
>
> A salt value is the specific string that you insert.



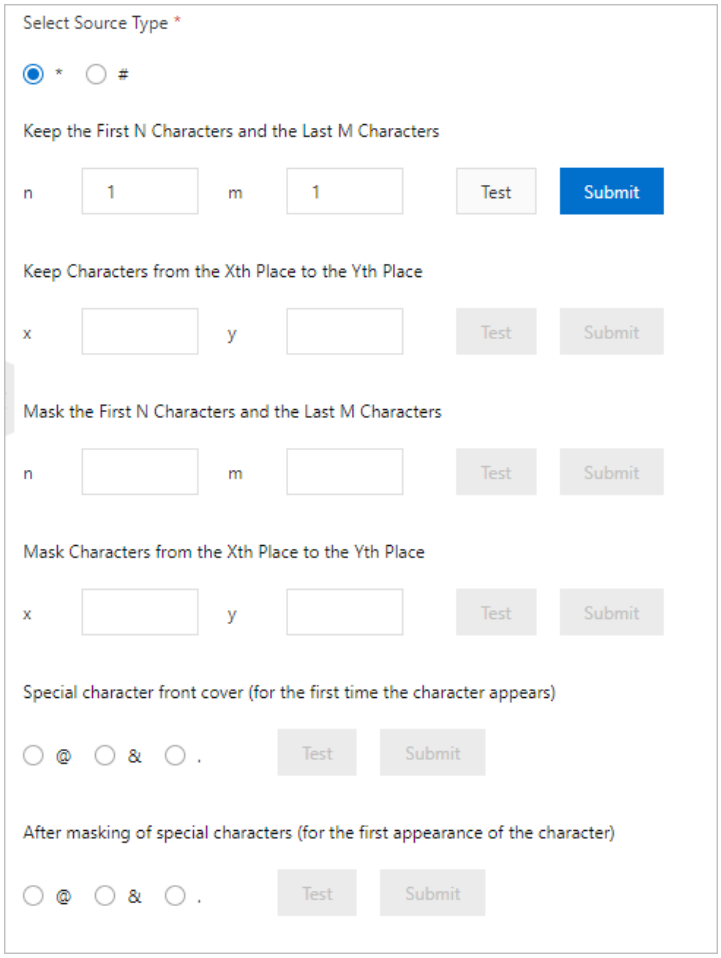
5. In the **Desensitization Algorithm Test** dialog box, enter the original value and click **Test** to check whether the algorithm works.



6. After the configuration is complete, click **Submit**.

Redaction

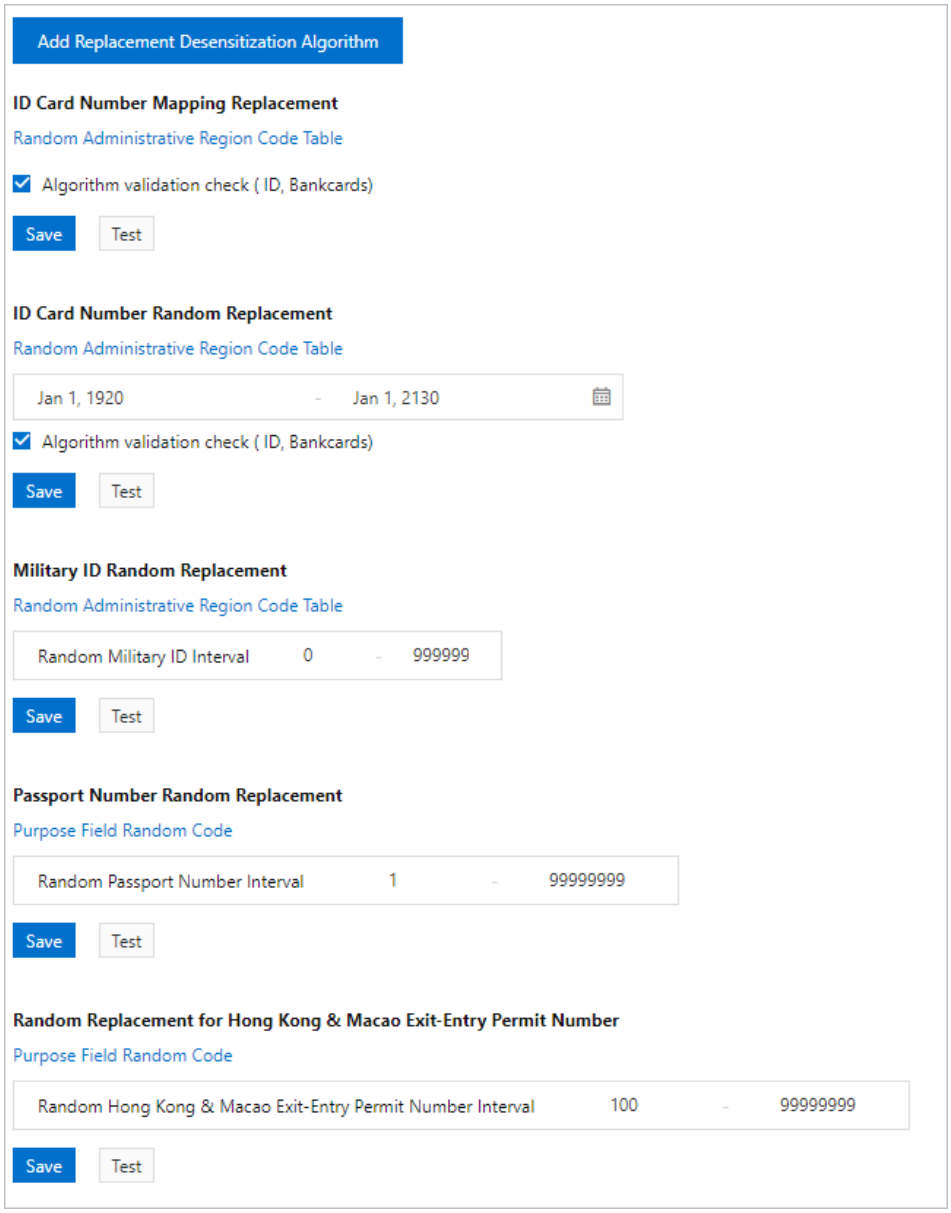
1.
2. Choose **Data Security > Sensitive Data Discovery and Protection**.
3. Click the **Masking** tab.
4. Configure the parameters.



5. In the **Desensitization Algorithm Test** dialog box, enter the original value and click **Test** to check whether the algorithm works.
6. After the configuration is complete, click **Submit**.

Substitution

1.
2. Choose **Data Security > Sensitive Data Discovery and Protection**.
3. Click the **Replacement** tab.
4. Configure the parameters.



Note By default, SDDP provides multiple common substitution algorithms, such as ID Card Number Mapping Replacement and Telephone Number Random Replacement.

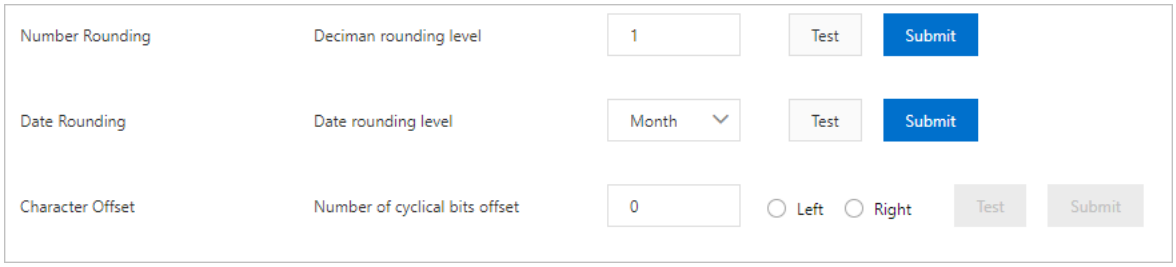
- If you want to customize a mapping table, click the required mapping table, replace the original content with your own mapping table, and then click **Save**.
- If you need to customize an algorithm, click **Add Replacement Desensitization Algorithm** and specify the interval and mapping table.

5. In the **Desensitization Algorithm Test** dialog box, enter the original value and click **Test** to check whether the algorithm works.
6. After the configuration is complete, click **Save**.

Rounding

1.
2. Choose **Data Security > Sensitive Data Discovery and Protection**.
3. Click the **Transformation** tab.

4. Configure the parameters.



5. In the **Desensitization Algorithm Test** dialog box, enter the original value and click **Test** to check whether the algorithm works.
6. After the configuration is complete, click **Submit**.

Encryption

1.
2. Choose **Data Security > Sensitive Data Discovery and Protection**.
3. Click the **Encryption** tab.
4. Specify a key for an algorithm.

5. In the **Desensitization Algorithm Test** dialog box, enter the original value and click **Test** to check whether the algorithm works.
6. After the configuration is complete, click **Submit**.

Shuffling

1.
2. Choose **Data Security > Sensitive Data Discovery and Protection**.
3. Click the **Shuffling** tab.
4. Select a shuffling method.

5. Click **Submit**.

27.1.10.3.7.5. Extract watermarks

You can add watermarks when you create a data masking task. If data is leaked after it is distributed, you can use watermarks to trace operations. This minimizes the impacts of data leaks. SDDP extracts and identifies watermarks from the leaked data to trace the data flow process and identify the organization or user that is responsible for the data leaks. This topic describes how to extract watermarks.

Procedure

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Sensitive Data Desensitization** > **Extract watermark**.
3. On the **Extract watermark** page, configure the **Source Product**, **Source database/project name**, and **Source table name** parameters, and click **Extract watermark**.

Parameter	Description
Source Product	The name of the source data asset to which the table containing watermarks belongs.
Source database/project name	The name of the database or project to which the table containing watermarks belongs.
Source table name	The name of the table that contains watermarks.

   The extracted watermarks appear in the field below this parameter. If you want to copy the information, click **Copy Result**.

27.1.10.3.8. Data security lab

27.1.10.3.8.1. View data assets

The Data Asset map page displays statistics on your data assets and charts of sensitive data for the last seven days. This topic describes how to view data assets on the Data Asset map page.

Prerequisites

Sensitive Data Discovery and Protection (SDDP) is authorized to protect your data assets. For more information, see Authorize SDDP to access data assets.

View the statistics and charts of data assets

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data security lab > Data Asset map**.
3. On the Data Asset map page, click the tab of the data assets that you want to view. You can click **OSS**, **RDS**, **MaxCompute**, **ECS self-built database**, **DRDS**, **OTS**, **ADS**, or **GPDB**.
4. View the statistics and charts of your data assets.

   You can view the following statistics and charts:

   > **Note** In this example, the statistics and charts on the **OSS** tab are described. For more information about other data assets, log on to Apsara Stack Security Center.

   - **Number of buckets**: displays the total number of OSS buckets that are protected by SDDP. It also displays the total number of OSS buckets that contain sensitive data.
   - **Number of files**: displays the total number of OSS objects that are protected by SDDP. It also displays the total number of OSS objects that contain sensitive data.
   - **Hit Rule TOP10**: displays the top 10 sensitive data detection rules that are hit.
   - **Proportion of sensitive files**: displays the proportions of public, less sensitive, private, and confidential objects in OSS by using a pie chart.

- **Data volume change**: displays the change curve of the total number of OSS objects that are protected by SDDP. It also displays the total number of OSS objects that contain sensitive data.

View the detailed information about the data assets

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data security lab > Data Asset map**.
3. On the Data Asset map page, click the tab of the data assets that you want to view. You can click **OSS**, **RDS**, **MaxCompute**, **ECS self-built database**, **DRDS**, **OTS**, **ADS**, or **GPDB**.
4. View the detailed information about the data assets.

   You can perform the following operations to view the detailed information about the data assets:

   > **Note** In this example, the detailed information about the data assets on the **OSS** tab is described. For more information about other data assets, log on to Apsara Stack Security Center.

   - View buckets. You can view the information about buckets at highly sensitive, moderately sensitive, low sensitive, and non-sensitive levels. The information includes regions where buckets reside, bucket names, the total number of objects, data security scores, the number of sensitive objects, and the last scan time of each bucket.
   - View details of an object. Find a specific bucket and click **Details** in the Actions column. On the OSS page, you can view the proportion of sensitive objects in the bucket, the top five sensitive data detection rules that are hit, and file details list. In the file details list, find a specific object and click **Hit details** in the Actions column. Then, you can view the information about the sensitive data detection rules that are hit.
   - View an asset portrait of a bucket. Find a specific object and click **Asset portrait** in the Actions column. On the Asset portrait page, you can view the security score of the bucket, number of objects, number of accounts, number of IP addresses, change curve of the security scores, anomalous events, and alert details.

27.1.10.3.8.2. View account information

The user account analysis feature provides the statistics and security scores of the last seven days for all accounts in your assets. This gives you an overview of your accounts and the security status. This topic describes how to use the user account analysis feature.

Procedure

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data security lab > User account analysis**.
3. On the **User account analysis** page, perform the following steps:
   - View account statistics: In the upper part of the page, you can view the statistics in the **Total Users**, **Dormant users**, **Active users**, and **High-risk users** sections. You can also view the **Account number change** line chart.
   - View account details: In the account list, you can filter accounts by account type and view the information of the accounts. The account types are Main account, RAM account number, and RDS account. The information includes Instance, Account security point, Account creation time, First occurrence time, Authorized assets, and Number of alarms. In the Actions column of an account, you can click **Account portrait** to view the profile details of the account. The profile details include the security score, user information, trend in the security score, trend in the number of anomalous events, and alert details.

> **Notice** If the security score of an account is low, it indicates that the account may have performed unauthorized operations, such as accessing or downloading sensitive data. We recommend that you view the reasons that cause a low security score on the **Account portrait** page of the account, and handle the alerts and anomalous events.

27.1.10.3.8.3. Handle anomalous events

Sensitive Data Discovery and Protection (SDDP) detects anomalous events that are related to sensitive data and generates alerts. The SDDP console displays statistics about different types of anomalous events. You can process detected anomalous events in a centralized manner.

Background information

SDDP classifies anomalous events into the following types:

- **Permission Usage Anomalous Event**: Permissions are used in an inappropriate manner. For example, a user logs on from a disapproved IP address or by using the AccessKey pair of another user.
- **Data Flow Anomalous Event**: Anomalous events are detected in data flows. For example, a user unnecessarily downloads sensitive data files or downloads sensitive data files during an unusual period of time.
- **Data Operation Anomalous Event**: Unusual operations are performed on sensitive data. For example, a user modifies sensitive fields.
- **Custom Anomalous Event**: Anomalous events are detected and alerts are triggered based on custom rules. For more information, see Create a custom rule.

Step 1: View anomalous events

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data security lab > Data Asset map**.
3. On the **Anomalous Event Processing** page, view statistics about anomalous events and the anomalous event list.

   You can click the **Permission Usage Anomalous Event**, **Data Flow Anomalous Event**, **Data Operation Anomalous Event**, or **Custom Anomalous Event** tab to view the information about related events.

   - In the upper part of the **Anomalous Event Processing** page, you can view statistics about anomalous events. The statistics include the types of anomalous events, number of unhandled anomalous events, number of handled anomalous events, and number of anomalous events that are marked as false positives.

     
   - In the lower part of the **Anomalous Event Processing** page, you can view the list of anomalous events that are detected. You can filter anomalous events by **Event Type**, **Status**, and time range. An anomalous event can be in one of the following states: To be processed, Processed, and False positive. A time range specifies the period of time during which alerts are generated for anomalous events.

     > **Note** You can specify a time range based on your business requirements.

Step 2: Handle anomalous events

In the list of anomalous events on the **Anomalous Event Processing** page, you can view the details about anomalous events and handle the anomalous events.

- To view the details about an anomalous event, click **View Details** in the Actions column of the anomalous event. On the Anomalous event details page, you can view the basic information about the anomalous event, the service where the anomalous event occurs, event description, and suggestions on how to handle the event.
- To handle an anomalous event, click **Process** in the Actions column of the anomalous event. On the **Exception event handling** page, handle the event.

  In most cases, SDDP reports an anomalous event if an unauthorized user accesses or downloads sensitive data, an authorized user accesses or downloads sensitive data in an unusual period of time, or a user accesses sensitive data from an unusual terminal. After SDDP detects anomalous events, it displays them on the Exception event handling page.

  You can handle anomalous events on the **Exception event handling** page. Configure the following parameters:

  - **Anomalous Event Verification**
    - **Confirmed and Processed**: If you verify that a detected event is an anomalous event, select this option. In this case, find the event based on the information provided on the **Anomalous event details** page. Follow the instructions in the **Event Processing Suggestion** section of the page and manually handle the event in the data source of the event. If you select this option but do not handle the event, SDDP continues to generate alerts for the event.
    - **False Positive**: If you verify that a detected event is a false positive and can be ignored, select this option. After you select this option, SDDP no longer generates alerts for this event. This event no longer appears on the Anomalous Events page.
  - **Processing method**: Turn on **Set Bucket Acl to private**. The  icon indicates that the bucket access control list (ACL) is set to private. In this case, you must use AccessKey pairs to access the bucket. You can click **Ban history** to access the **Ban history** page, view the buckets whose ACL is set to private, and change the ACL of a bucket.
  - **Add Processing Record**: Enter a description for the anomalous event to facilitate subsequent analysis.
  - **Sample-based enhancement for anomalous events**: If you select **False Positive** in the **Anomalous Event Verification** section and select this option, SDDP adds the anomalous event to a library of false positive samples. The library helps SDDP accurately detect anomalous events.

27.1.10.3.8.4. Create a custom rule

Sensitive Data Discovery and Protection (SDDP) allows you to create custom rules to detect anomalous events and generates alerts for the events. SDDP captures log data of the anomalous events that match the custom rules. This topic describes how to create a custom rule to detect anomalous events.

Context

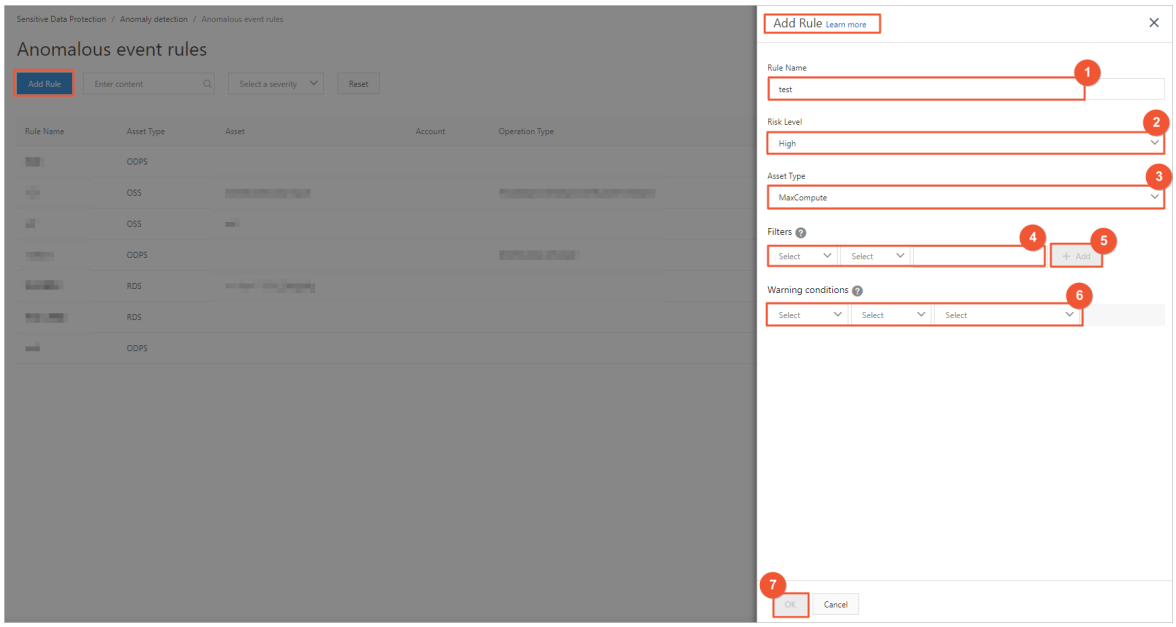
SDDP can detect anomalous events and generate alerts based on both built-in and custom rules.

> **Note** Custom rules are supported only for the following data sources: Object Storage Service (OSS), MaxCompute, and ApsaraDB RDS. Only built-in rules are supported for other data sources.

Procedure

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection > Data security lab > Custom rules**.
3. Click **Add Rule**.

4. In the **Add Rule** panel, configure the parameters to create a custom rule.



The following table describes the parameters.

Parameter	Description
Rule Name	The name of the custom rule to detect anomalous events. We recommend that you enter an informative name to identify the rule.
Risk Level	The risk level of the anomalous events to be detected. Valid values: ○ **High** ○ **Medium** ○ **Low**
Asset Type	The type of the asset for which SDDP checks for anomalous events based on the rule. Valid values: ○ **OSS** ○ **MaxCompute** ○ **RDS**
Filters	The filter that specifies the anomalous events to be detected. The filters of a rule have logical AND relations. Click **Add** to add a filter. You can add multiple filters.

Parameter	Description
Warning Conditions	The time interval to detect anomalous events and the alert triggering conditions. SDDP detects anomalous events based on the Filters parameter that you specify. If the specified alert triggering conditions are met in the specified time interval, SDDP generates alerts for the events. **Note** The **Any UA** option in Warning Conditions specifies that the User-Agent information of all types of browsers is detected. User-Agent information includes the hardware platform, system software, application software, and user preferences. You can obtain the following information based on User-Agent information: the name, version number, and rendering engine of the browser, and the operating system on which the browser runs. If you select **Any UA** in Warning Conditions, SDDP detects for anomalous events based on User-Agent information.

5. Click **OK**.

   After you create the custom rule, you can view the enabling status, matching results, and details of the rule on the **Custom rules** page. You can also edit the rule.

   Note A custom rule automatically enters the **Enabled** state after it is created. You can also manually disable the rule on the **Custom rules** page. After you disable a rule, SDDP no longer detects for anomalous events based on the rule.

What's next

After you create and enable a custom rule, SDDP provides the detection result based on this rule on the **Exception event handling** page in about 1 hour. You can view the result on this page. For more information, see Handle anomalous events.

27.1.10.3.8.5. Configure alerts

Sensitive Data Discovery and Protection (SDDP) detects anomalous event in your data assets and generates alerts based on built-in and custom anomalous event detection rules. On the Built-in detection model page, you can configure the general settings for alerts and enable alerts for different types of anomalous event based on your business requirements. This topic describes how to configure alerts.

Configure the general settings for alerts

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Data security lab > Built-in rules**.
3. On the **Built-in detection model** page, find the required item in the **General Configuration for Anomaly Alerts** section and click **Modify** next to the item.
4. Modify the threshold to trigger an alert.

   SDDP allows you to set thresholds for the following types of anomalous events:

   - **Data access inactivity**: After you enable alerts for this anomalous event in the **Enable Anomaly Alerts** section, SDDP generates an alert when the idle period of a permission exceeds the specified threshold. You can view the detailed alert information on the **Anomalous Events** page.
   - **Log output anomaly detected**: After you enable alerts for this anomalous event in the **Enable Anomaly Alerts** section, SDDP generates an alert when the amount of logs that are generated in a day is lower than the specified threshold. You can view the detailed alert information on the **Anomalous Events**

page.

- **Unauthorized resource access attempts**: After you enable alerts for this anomalous event in the **Enable Anomaly Alerts** section, SDDP generates an alert when the number of access attempts exceeds the specified threshold. You can view the detailed alert information on the **Anomalous Events** page. For more information, see Handle anomalous events.

5. Click **Submit**.

Enable alerts for anomalous event

1.
2. In the left-side navigation pane, choose **Data Security > Sensitive Data Protection**. In the left-side navigation tree, choose **Data security lab > Built-in rules**.
3. On the **Built-in detection model** page, select the required anomalous event for which you want to enable alerts in the **Enable Anomaly Alerts** section.

   After alerts are generated for the selected anomalous event, you can view the detailed alert information on the **Anomalous Events** page. For more information, see Handle anomalous events.

28.Log Service

28.1. User Guide

28.1.1. What is Log Service?

Log Service (SLS) is a one-stop logging service developed by Alibaba Cloud that is widely used by Alibaba Group in big data scenarios. You can use Log Service to collect, query, and consume log data.

Without the need to invest in in-house data collection and processing systems. This enables you to focus on your business, improving business efficiency and helping your business to expand.

Log Service provides the following features:

- Log collection: Log Service allows you to collect events, binary logs, and text logs in real time by using multiple methods, such as Logtail and JavaScript.
- Query and analysis: Log Service allows you to query and analyze the collected log data and view analysis results on charts and dashboards.
- Status alert: Log Service can automatically run query statements at regular intervals after you create an alert task. If the query results meet the conditions of the alert task, Log Service sends an alert to the specified recipients in real time.
- Real-time consumption: Log Service provides real-time consumption interfaces through which log consumers can consume log data.

28.1.2. Quick start

28.1.2.1. Procedure

This topic provides the basic procedure to use Log Service. You can use this procedure to create projects, create Logstores, and collect log data.

1. Optional. Obtain an AccessKey pair.

   Before you can use Log Service through APIs or SDKs, you must have an AccessKey pair.

2. Create a project.

   Create a project in a specified region and add a description.

3. Create a Logstore.

   Create a Logstore for the project and specify the number of shards.

4. Collect text logs.

   Select a method to collect log data based on your business requirements. Text log collection is used as an example.

5. Enable the index feature and configure indexes for a Logstore, and query and analyze logs.

   Log Service supports real-time log query and analysis. After you enable the indexing feature, you can query and analyze logs and configure Overview and dashboards.

6. Configure alerts.

   Log Service allows you to configure alerts based on log query results. Then, Log Service sends alerts by using multiple methods, such as a custom webhook.

7. Consume logs in real time.

   Log Service allows you to consume logs by using multiple methods, such as a Spark Streaming client, Storm spout, and Flink connector.

28.1.2.2. Log on to the Log Service console

This topic describes how to log on to the Log Service console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 10 to 32 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Log On**.
4. In the top navigation bar, choose **Products > Log Service**.
5. On the page that appears, select the organization and region, and then click **SLS**. The home page of the Log Service console is displayed.

28.1.2.3. Obtain an AccessKey pair

An AccessKey pair consists of an AccessKey ID and an AccessKey secret. The AccessKey pair is used to implement symmetric encryption to verify the identity of the requester. The AccessKey ID is used to identify a user. The AccessKey secret is used to encrypt the signature string. This topic describes how to obtain an AccessKey pair.

Prerequisites

Only the operation administrators or level-1 organization administrators can obtain the AccessKey pair of an organization.

Context

To call Apsara Uni-manager and cloud service APIs, we recommend that you use the AccessKey pair of a personal account. If you use the AccessKey pair of a personal account, you must configure header parameters as described in the following table for access control.

Parameter	Description
x-acs-regionid	The region ID, such as cn-hangzhou-*.
x-acs-organizationid	The ID of the organization in the Apsara Uni-manager Management Console.

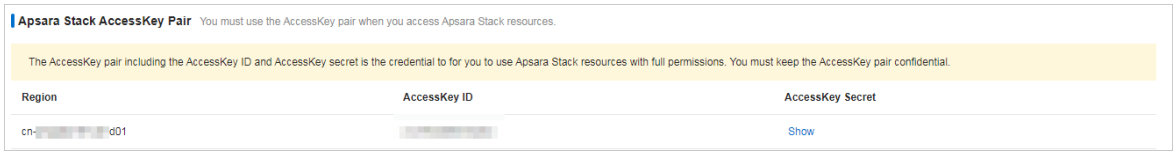
Parameter	Description
x-acs-resourcegroupid	The ID of the resource set in the Apsara Uni-manager Management Console.
x-acs-instanceid	The ID of the instance on which you want to perform operations.

Warning The AccessKey pairs of personal accounts are under control of the Apsara Uni-manager permission system. AccessKey pairs of organization accounts have higher permissions. For security purposes, organization operations must be approved by administrators.

Obtain the AccessKey pair of a personal account

To obtain the AccessKey pair of a personal account, perform the following operations:

1. Log on to the Apsara Uni-manager Management Console.
2. In the upper-right corner of the homepage, move the pointer over the profile picture and click **Personal Information**.
3. In the **Apsara Stack AccessKey Pair** section, view your AccessKey pair.



Note The AccessKey pair consists of an AccessKey ID and an AccessKey secret. AccessKey pairs allow you to access Apsara Stack resources with full permissions for your account. You must keep your AccessKey pair confidential.

Obtain the AccessKey pair of an organization

To obtain the AccessKey pair of an organization, perform the following operations:

1. Log on to the Apsara Uni-manager Management Console as an administrator.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Organizations**.
4. In the organization navigation tree, click an organization name.
5. In the Current Organization section, click **Management Accesskey**.
6. In the Management AccessKey, view the AccessKey pair of the organization.

Note An AccessKey pair is automatically allocated to each level-1 organization. Subordinate organizations use the same AccessKey pair of their level-1 organization.

28.1.2.4. Manage projects

This topic describes how to create, modify, and delete projects in the Log Service console.

Context

A project in Log Service is a resource management unit. The resources in each project are isolated from resources in other projects. We recommend that you store the log data of different applications in dedicated projects. You can manage Logstores, Logtail configurations, log sources, log data, and machine groups in a project. Each

project provides an endpoint for you to access the resources.

A project provides the following features:

- Allows you to store log data from different sources in different Logstores of a project. You can use Log Service to collect log data from multiple sources such as business projects, products, and environments. You can then store the log data of each source in a separate Logstore. This simplifies the downstream processes such as the consuming, exporting, and indexing of log data. In addition, you can manage access permissions at the project level.
- Provides an endpoint for you to access the resources in the project. Log Service allocates an exclusive endpoint to each project. You can use the endpoint to read, write, and manage the log data in the project.

Create a project

> **Note**
> - You can create a project only by using the Log Service console.
> - You can create up to 50 projects under each Apsara Stack tenant account.

1. Log on to the Log Service console.
2. In the **Projects** section, click **Create Project**.
3. Set the parameters based on your requirements. The following table describes the parameters.

Parameter	Description
Project Name	The name of the project. The project name must be unique across all regions. Use the following naming conventions: ○ The name can contain lowercase letters, digits, and hyphens (-). ○ The name must start and end with a lowercase letter or digit. ○ The name must be 3 to 63 characters in length. **Note** After a project is created, its name cannot be modified.
Description	The description of the project. After the project is created, the description is displayed in the **Projects** section. If you need to modify the description after the project is created, find the project in the **Projects** section, and click **Edit** in the **Actions** column. The description must be 0 to 64 characters in length and cannot contain the following characters: `< > ' \ " \\` .
Region	The region to which the project belongs. We recommend that you select a region that is closer to the log source. After a project is created, its region cannot be modified. This means that projects cannot be migrated across regions.

4. Click **OK**.

Modify the description of a project

To modify the description of a project, perform the following steps:

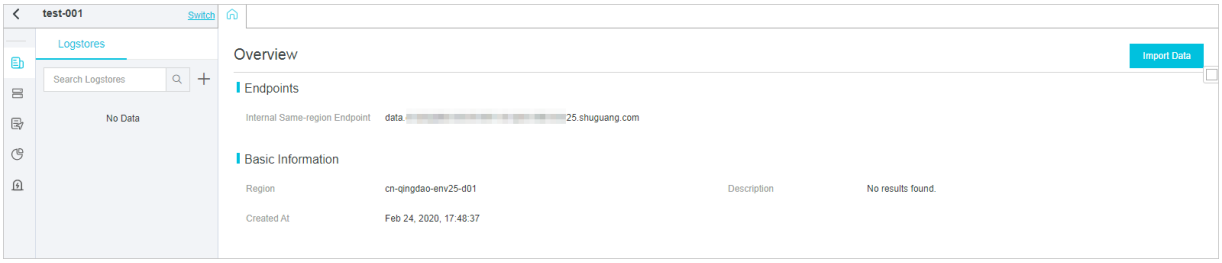
1. In the **Projects** section, find the project.
2. In the **Actions** column, click **Edit**.
3. In the **Modify Project** dialog box, modify the description of the project.

> **Note** You cannot modify the project name or region.

4. Click **OK**.

View the information of a project

To view the information of a project, click the project name in the **Projects** section. On the **Overview** page, you can view the project information such as the endpoint and region.



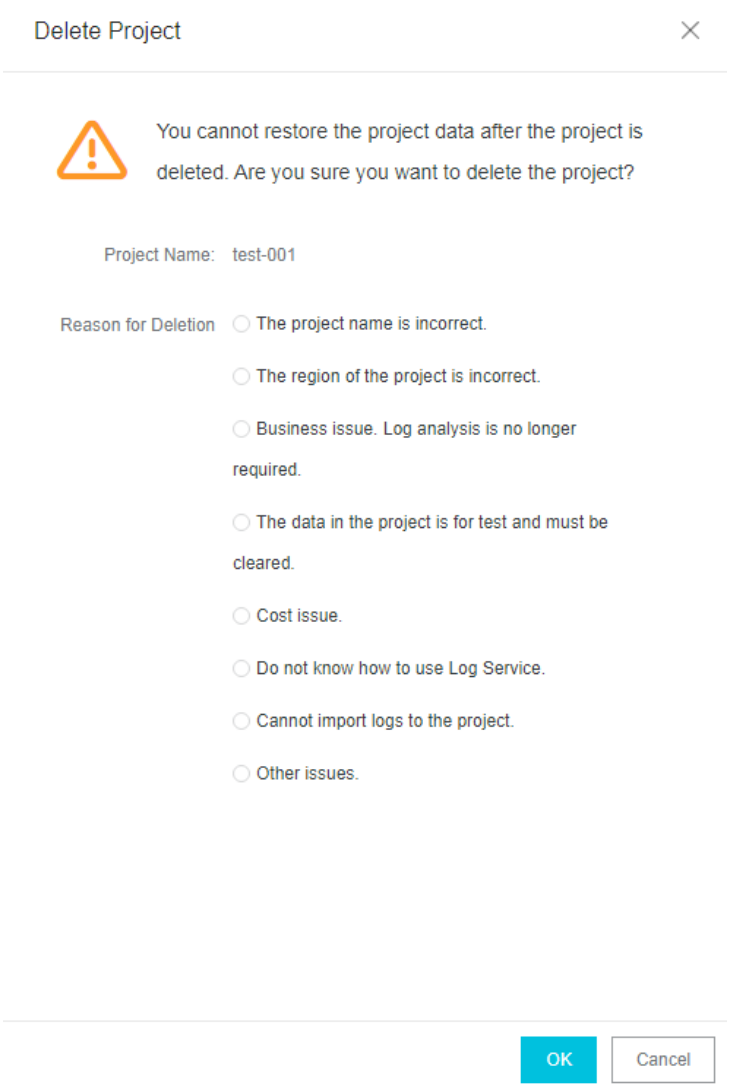
Delete a project

To delete a project, perform the following steps:

> **Warning** After you delete a project, all logs and configurations in the project are deleted and cannot be restored.

1. In the **Projects** section, find the project.
2. In the **Actions** column, click **Delete**.
3. In the dialog box that appears, select a reason for deletion.

   If you select **Other issues**, enter the reason in the text box.



4. Click **OK**.

28.1.2.5. Manage Logstores

This topic describes how to create, modify, and delete a Logstore in the Log Service console. A Logstore is a collection of resources inside a project. The log data in a Logstore is collected from the same source.

Context

You can create multiple Logstores in a project. We recommend that you create a Logstore for each type of application log.

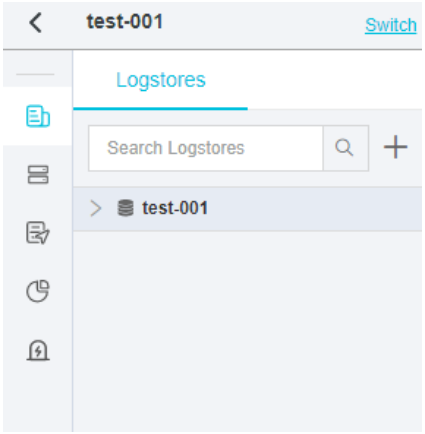
Logstores provide the following features:

- Real-time log collection
- Log storage and real-time log consumption
- Log indexing and real-time log query

Create a Logstore

> **Note** You can create a maximum of 100 Logstores in each project.

1. Log on to the Log Service console.
2. In the **Projects** section, click the name of a project.
3. On the page that appears, click next to the search box.



4. In the **Create Logstore** pane, set the parameters and click **OK**.

Parameter	Description
Logstore Name	The name of the Logstore. The Logstore name must be unique in the project to which the Logstore belongs. ○ The name can contain lowercase letters, digits, hyphens (-), and underscores (_). ○ The name must start and end with a lowercase letter or digit. ○ The name must be 3 to 63 characters in length. **Note** After a Logstore is created, its name cannot be modified.
WebTracking	Specifies whether to enable the WebTracking feature for the Logstore. You can use WebTracking to collect the log data of HTML websites, HTML5 websites, iOS apps, or Android apps and forward the data to Log Service. This feature is not enabled by default.
Permanent Storage	Specifies whether to permanently store the log data in the Logstore. If you disable this feature, you must specify a retention period for log data.
Data Retention Period	The duration for which log data is stored in the Logstore after the log data is collected. Unit: days. Valid values: 1 to 3000. When this period expires, the log data is deleted.
Shards	The number of shards in the Logstore. You can divide a Logstore into 1 to 10 shards.
Automatic Sharding	Specifies whether to enable the automatic sharding feature. This feature is not enabled by default. If you enable this feature, Log Service automatically splits shards in the Logstore when the data transfer exceeds the capacity of the existing shards.
Maximum Shards	The maximum number of shards. This parameter is required if you enable the automatic sharding feature. Maximum value: 64.

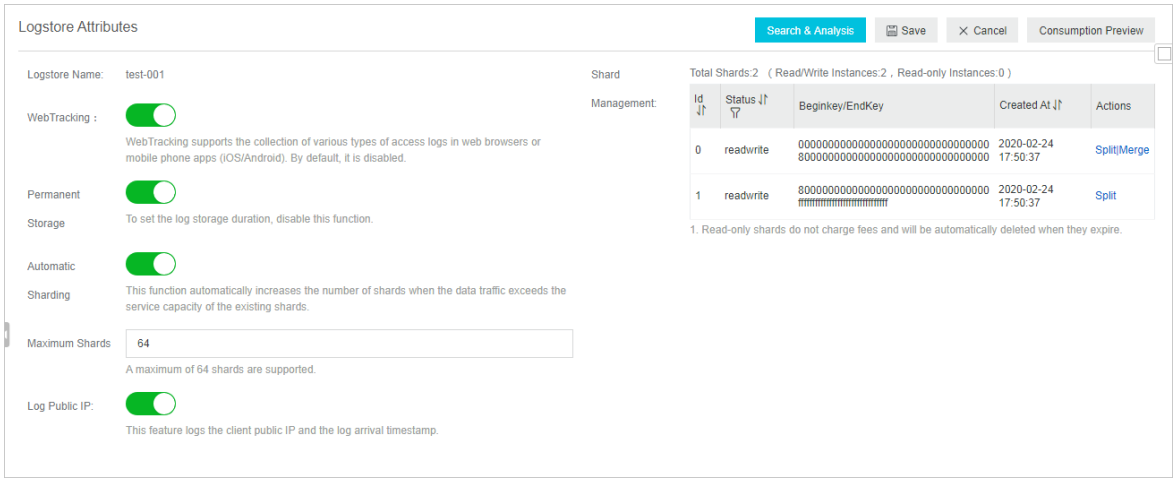
Parameter	Description
Log Public IP	Specifies whether to add the following information to the Tag field of each collected log entry: ○ `__client_ip__`: the public IP address of the log source. ○ `__receive_time__`: the time when Log Service receives the log entry. The value is a UNIX timestamp.

Modify the configurations of a Logstore

To modify the configurations of a Logstore, perform the following steps:

1. In the **Projects** section, click the name of the project to which the Logstore belongs.
2. On the page that appears, click the icon next to the Logstore, and select **Modify** from the shortcut menu.
3. In the upper-right corner of the **Logstore Attributes** page, click **Modify**.

   You can modify the **Data Retention Period**, **WebTracking**, **Automatic Sharding**, **Maximum Shards**, and **Log Public IP** parameters. You can also split or merge the existing shards.



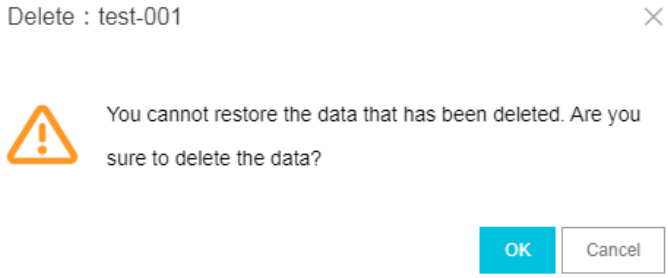
4. Click **Save**.

Delete a Logstore

To delete a Logstore, perform the following steps:

> **Note**
> - After you delete a Logstore, the log data in the Logstore is deleted and cannot be restored.
> - Before you can delete a Logstore, you must delete the Logtail configurations that are associated with the Logstore.

1. In the **Projects** section, click the name of the project to which the Logstore belongs.
2. On the page that appears, click the icon next to the Logstore, and select **Delete** from the shortcut menu.
3. In the message that appears, click **OK**.



28.1.2.6. Manage shards

This topic describes how to split, merge, and delete shards in the Log Service console. Logs are stored on shards in a Logstore. Each Logstore can have multiple shards. When you create a Logstore, you must specify the number of shards in the Logstore. After a Logstore is created, you can split or merge the shards.

Hash key

Log Service uses 128-bit MD5 hashes as the hash key of a Logstore. The entire MD5 hash range is [00000000000000000000000000000000,ffffffffffffffffffffffffffffffff). The hash key range of a Logstore falls within the entire MD5 hash range. When you create a Logstore, you must specify the number (N) of shards in the Logstore. The hash key range of the Logstore is evenly divided into N parts. Each part is assigned to a shard.

The hash key range of a shard is a left-closed and right-open interval that is specified by the following parameters:

- BeginKey: the start of the hash key range. The value of this parameter is included in the range.
- EndKey: the end of the hash key range. The value of this parameter is excluded from the range.

If you split a shard, the hash key range of the shard is evenly split. If you merge two shards, the hash key ranges of the shards are also merged. A hash key range determines the scope of a shard. When you push log data to a Logstore, you can specify a hash key for the log data. Log Service then writes the log data to the shard whose hash key range includes the specified hash key. This is called the hash key mode. If you do not specify a hash key for log data, the load balancing mode is used and Log Service writes the log data to a random available shard. However, when you pull log data from a Logstore, you must specify the shard where the log data is stored.

For example, a Logstore is divided into four shards and the hash key range of the Logstore is [00,FF). Example shards lists the hash key range of each shard.

Example shards

Shard	Hash key range
Shard0	[00,40)
Shard1	[40,80)
Shard2	[80,C0)
Shard3	[C0,FF)

If you set the hash key of log data to 5F, Log Service writes the log data to shard 1 because the hash key range of shard 1 includes 5F. If you set the hash key to 8C, the log data is written to shard 2 because the hash key range of shard 2 includes 8C.

Read/write capacity

Each shard provides an identical read/write capacity. Therefore, the read/write capacity of a Logstore depends on the number of shards in the Logstore. We recommend that you adjust the capacity of a Logstore based on the data traffic. For a Logstore, if the data traffic exceeds the read/write capacity, you can split shards to increase the Logstore capacity. If the data traffic is much less than the read/write capacity, you can merge shards to reduce the Logstore capacity and save costs.

For example, a Logstore consists of two read/write shards and the shards provide a maximum write capacity of 10 MB/s. If log data is written to the Logstore at a rate of 14 MB/s, we recommend that you split one of the shards into two shards. However, if log data is written at a rate of 3 MB/s, you can merge the two shards because the capacity of one shard already meets the read/write requirements.

> Note
> - If an API operation that writes data to a Logstore constantly returns 403 or 500 errors, you can check the data traffic metrics that are provided by Log Service and determine whether to split shards.
> - If the data traffic of a Logstore exceeds the read/write capacity of the Logstore, Log Service provides the best possible service but does not guarantee the service quality.

Shard status

A shard can be in one of the following states:

- Read/write
- Read-only

After a shard is created, the default status of the shard is read/write. If you split or merge shards, the status of the original shards changes to read-only and the new shards are in the read/write state. You can write data to and read data from a read/write shard. However, you can only read data from a read-only shard and cannot write data to the shard.

If you need to split a shard in a Logstore, you must specify the ID of the shard and an MD5 hash. The shard must be in the read/write state. The MD5 hash must be greater than the value of the BeginKey parameter of the shard and less than the value of the EndKey parameter of the shard. After the shard is split, the Logstore has two more shards. The status of the original shard changes from read/write to read-only. You can consume the log data in the original shard but cannot write log data to the shard. The new shards are in the read/write state and are listed below the original shard. The hash key ranges of the new shards cover that of the original shard.

If you need to merge shards in a Logstore, you must specify a read/write shard. The shard cannot be the last read/write shard in the shard list. Log Service finds the shard whose hash key range follows the hash key range of the specified shard, and merges the two shards into a new shard. The status of the original shards changes from read/write to read-only. You can consume the log data in the original shards but cannot write log data to the shards. The new shard is in the read/write state. The hash key range of the new shard covers those of the original shards.

You can perform the following operations on shards in the Log Service console:

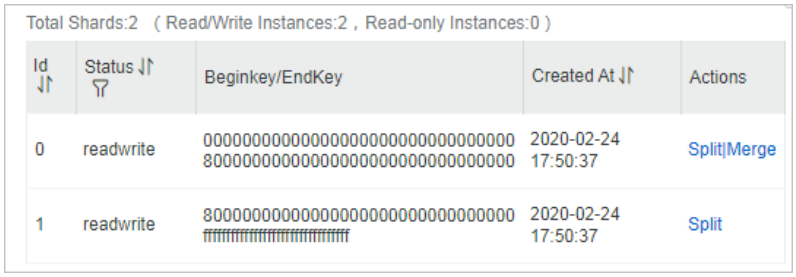
- Split a shard.
- Merge shards.

Split a shard

Each shard provides a write capacity of 5 MB/s and a read capacity of 10 MB/s. For a Logstore, if the data traffic exceeds the total read/write capacity of existing shards, we recommend that you split shards to increase the capacity.

1. Log on to the Log Service console.
2. In the Projects section, click the name of the project in which you want to create a Logstore.
3. In the left-side navigation pane, choose **Log Storage > Logstores**. On the Logstores tab, find the Logstore that you want to modify, click the  icon, and then select **Modify**.

4. In the upper-right corner of the **Logstore Attributes** page, click **Modify**.
5. In the **Shard Management** section, find the shard that you want to split, and click **Split** in the **Actions** column.



6. In the drop-down list, click the number of new shards.
7. In the **Actions** column, click **OK**.
8. In the upper-right corner of the **Logstore Attributes** page, click **Save**.

Enable the automatic sharding feature

Log Service provides the automatic sharding feature.

If you enable the automatic sharding feature for a Logstore, shards are automatically split if the following conditions are met:

- The data traffic of the Logstore exceeds the total capacity of the shards in the Logstore for more than five minutes.
- The number of read/write shards does not exceed the maximum number of shards that is allowed in the Logstore after an automatic shard split.

> **Note** After a shard is split into multiple shards, the new shards will not be automatically split within 15 minutes.

When you create or modify a Logstore, you can enable the automatic sharding feature. If this feature is enabled, you must specify the maximum number of shards that is allowed in the Logstore after an automatic shard split. For more information, see Manage Logstores.

- Automatic Sharding

  Specifies whether to enable the automatic sharding feature. If you turn on this switch, the shards are automatically split when the preceding conditions are met.

- Maximum Shards

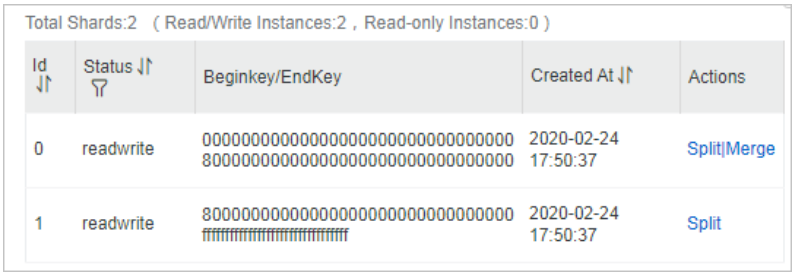
  The maximum number of shards that is allowed in the Logstore after an automatic shard split. The maximum value is 64.

Merge shards

You can merge shards in a Logstore to reduce the capacity of the Logstore.

1. In the upper-right corner of the **Logstore Attributes** page, click **Modify**.
2. In the **Shard Management** section, find the shard that you want to merge with another shard, and click

Merge in the **Actions** column.



3. In the upper-right corner of the **Logstore Attributes** page, click **Save**.

Delete a shard

- Automatic deletion

  When you create a Logstore, you can set a retention period for log data. When the retention period expires, the shards in the Logstore and the log data in the shards are automatically deleted.

- Manual deletion

  If you turn on the **Permanent Storage** switch when you create a Logstore, the shards in the Logstore and the log data in the shards are not automatically deleted. If you need to delete the shards and the log data in the shards, you can delete the Logstore. For more information, see Delete a Logstore.

28.1.3. Data collection

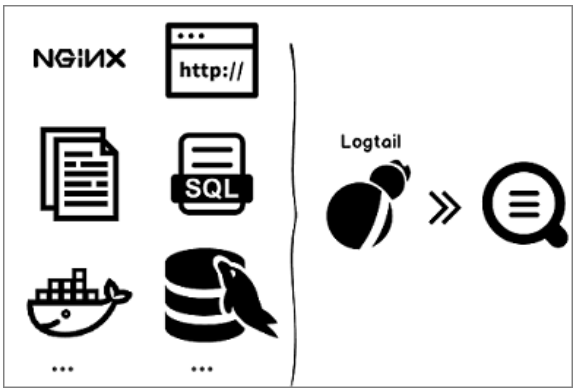
28.1.3.1. Collection by Logtail

28.1.3.1.1. Overview

28.1.3.1.1.1. Logtail overview

Logtail is a log collection agent provided by Log Service. You can use Logtail in Log Service console to collect logs in real time from multiple sources. These sources include Alibaba Cloud Elastic Compute Service (ECS) instances, servers deployed in on-premises data centers, and servers provided by other cloud service providers.

Logtail-based log collection



Benefits

- Provides non-intrusive log collection based on log files. You do not need to modify the application code. Log collection does not affect the operation logic of your applications.
- Supports the collection of multiple logs, such as text logs, binlogs, HTTP logs, and container stdout logs.
- Collects data from standard containers and various container clusters, such as swarm clusters and Kubernetes

clusters.

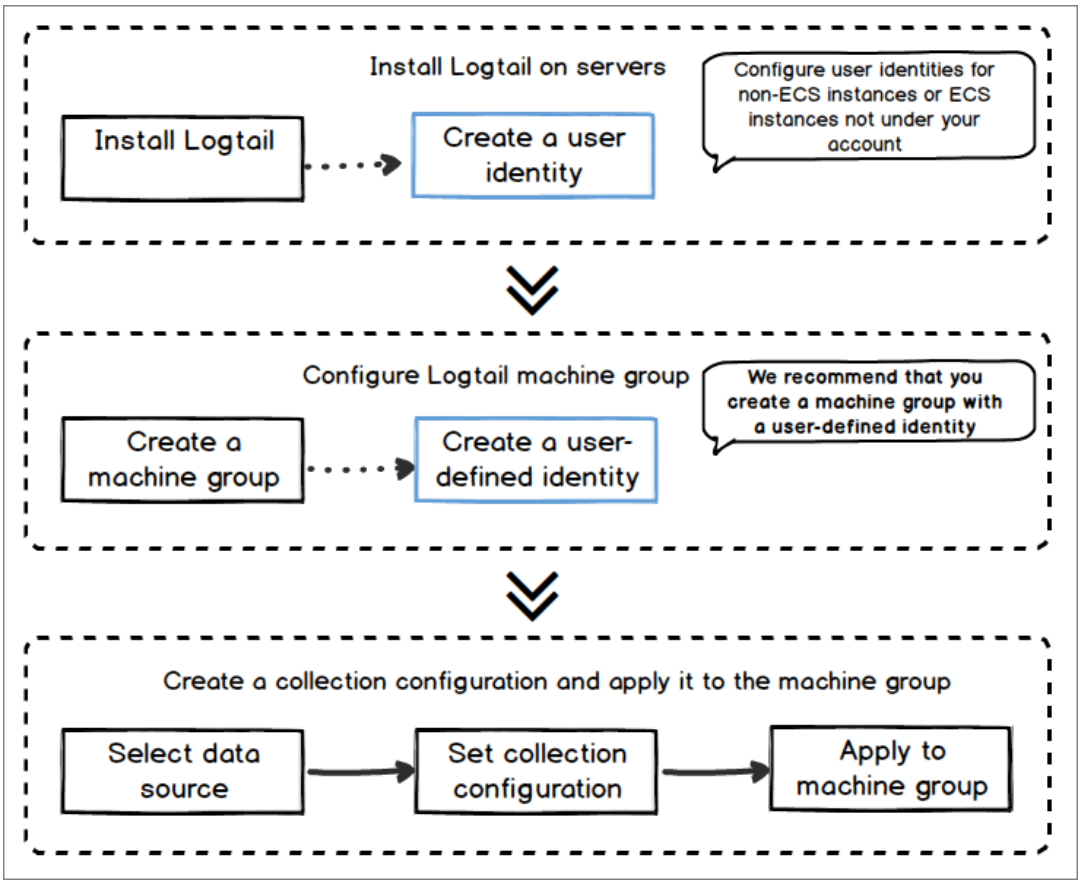
- Handles various exceptions that occur in the log collection process. If a network or server exception occurs, Logtail retries log collection and locally caches logs to ensure data security.
- Provides centralized management based on Log Service. After you install Logtail on the servers from which you want to collect logs, you can configure these servers and the collection method in the Log Service console. You do not need to log on to the servers.
- Provides a comprehensive self-protection mechanism. To minimize the impact of Logtail on the performance of the related servers, Logtail limits the usage of CPU, memory, and network resources.

Processing capabilities and limits

For more information, see Limits.

Configuration process

Configuration process



To collect logs from servers by using Logtail, follow these steps:

1. Install Logtail. For more information about how to install Logtail on a server from which you want to collect logs, see Install Logtail in Linux and Install Logtail in Windows.
2. Log Service use server groups to manage all servers from which you want to collect logs by using Logtail. Log Service allows you to define server groups by using IP addresses or custom identifiers. You can create a server group as prompted when you apply Logtail configurations to server groups.
3. Create a Logtail configuration and apply it to the server group. For more information about how to create a Logtail configuration, see Configure text log collection.

After the preceding process is complete, logs on the server are automatically collected and sent to the selected Logstore. However, historical logs are not collected. You can use the Log Service console, SDKs, or APIs to query these logs. Log Service allows you to view the status of log collection and check whether errors occur.

For more information, see Collect logs by using Logtail.

Containers

- For information about Alibaba Cloud Container Service for Kubernetes or user-created Kubernetes clusters, see Collect Kubernetes logs.
- For information about other user-created Docker clusters, see Collect standard Docker logs.

Terms

- Server group: A server group contains one or more servers from which logs of a specific type are collected. You can apply Logtail configurations to a server group. This enables Log Service to collect logs from all servers in the server group. You can use the Log Service console to manage a sever group. For example, you can create, delete, add, or remove a server. Each server group can contain different versions of Windows servers or Linux servers.
- Logtail: Logtail is the agent that collects logs from the servers on which Logtail runs. For more information, see Install Logtail in Linux and Install Logtail in Windows. After you install Logtail on a server, you must create a Logtail configuration and apply it to the server group to which the server belongs.
  - In Linux, Logtail is installed in the `/usr/local/ilogtail` directory. Logtail initiates two separate processes whose names start with ilogtail. One is a collection process and the other is a daemon process. The program running log is `/usr/local/ilogtail/ilogtail.LOG`.
  - In Windows, Logtail is installed in the `C:\Program Files\Alibaba\Logtail` (for 32-bit systems) or `C:\Program Files (x86)\Alibaba\Logtail` (for 64-bit systems) directory. You can choose Administrative Tools > Services to view the two Windows services generated from Logtail. One is LogtailWorker (log collection process) and the other is LogtailDaemon. The program running log is `logtail_*.log` in the installation directory.
- Logtail configuration: A Logtail configuration is a set of policies that are used by Logtail to collect logs. You can specify Logtail parameters such as the data source and collection mode. This allows you to customize log collection policies for all servers in a server group. A Logtail configuration determines how to collect a type of logs from a server, parse the logs, and send them to a specified Logstore. You can create a Logtail configuration for a Logstore in the Log Service console. This enables the Logstore to receive logs that are collected by using this Logtail configuration.

Features

Logtail provides the following features:

Feature	Description
Real-time log collection	Logtail dynamically monitors log files and reads and parses incremental logs in real time. In most cases, logs are sent to Log Service within 3 seconds after they are generated. **Note** Logtail does not collect historical data. If Logtail reads a log later than 12 hours after the log was generated, Logtail drops the log.
Automatic log rotation	Some applications rotate log files based on the file size or date. In the rotation process, the original log files are renamed and empty log files are created. For example, files such as *app.LOG.1* and *app.LOG.2* are generated for the *app.LOG* file after log rotation. You can specify the file (for example, *app.LOG*) to which collected logs are written. Logtail monitors the log rotation process to ensure that no logs are lost.
Multiple data sources	Logtail can collect text logs, syslogs, HTTP logs, and MySQL binlogs.

Feature	Description
Automatic exception handling	If data transmission fails due to exceptions such as Log Service errors, network errors, or quota exhaustion, Logtail retries log collection based on the specific scenario. If the retry fails, Logtail writes the data to the local cache and resends the data after the exception no longer exists.
Flexible collection policy configuration	You can create a Logtail configuration to specify how logs are collected from an ECS instance. You can select log directories and files by using exact match or wildcard match based on actual scenarios. You can also customize the extraction method of collected logs and the names of extracted fields. Log Service allows you to extract logs by using regular expressions. The log data models of Log Service require that each log has a precise timestamp. Logtail provides custom log time formats. This allows you to extract the required timestamps from log data of different formats.
Automatic synchronization of Logtail configurations	After you create or update a Logtail configuration in the Log Service console, Logtail receives and validates the configuration within 3 minutes. No data loss occurs during the configuration update process.
Automatic upgrade	After you install Logtail on a server, Log Service manages the automatic upgrade of Logtail without manual intervention. No data loss occurs during the Logtail upgrade process.
Status monitoring	Logtail monitors its consumption of CPU and memory in real time. This prevents Logtail from excessively consuming your resources. If the resource consumption exceeds the limit, Logtail restarts to avoid affecting other services on the server. Logtail limits network traffic to avoid excessive bandwidth consumption.
Data transmission with a signature	Logtail obtains your Alibaba Cloud AccessKey pair and uses it to sign all log data packets before they are sent. This prevents data tampering during transmission. **Note** Logtail obtains your Alibaba Cloud AccessKey pair over HTTPS to ensure the security of your AccessKey pair.

Data collection reliability

During data collection, Logtail stores the collected checkpoints to the local directory on a regular basis. If an exception (for example, an unexpected server shutdown or a process crash) occurs, Logtail restarts and then collects data from the last recorded checkpoint to prevent data loss. Logtail runs based on the resource limits specified in the configuration file. If the usage of a resource exceeds the limit for more than 5 minutes, Logtail restarts. After the restart, duplicate data may be generated.

Logtail uses multiple internal mechanisms to improve log collection reliability. However, logs may be lost in the following conditions:

- Logtail is not running but logs are rotated multiple times.
- The log rotation rate is high, for example, one rotation per second.
- The log collection rate is lower than the log generation rate for a long period of time.

28.1.3.1.1.2. Log collection process of Logtail

This topic describes the process that Logtail uses to collect server logs. The process consists of the following steps: monitor files, read files, process logs, filter logs, aggregate logs, and send logs.

> **Note** After the Logtail configuration is applied to a machine group, unmodified logs on the servers in the machine group are considered as historical logs. Logtail does not collect historical logs in normal running mode. If you want to collect historical logs, see Import historical logs.

Monitor files

After you install Logtail on a server and create a Logtail configuration based on a data source, the Logtail configuration is delivered from Log Service to Logtail in real time. Then, Logtail starts to monitor files based on the Logtail configuration.

1. Logtail scans log directories and files that comply with the specified file naming rules based on the specified log path and maximum monitoring directory depth.

   Logtail registers event monitoring and periodical polling for the directory from which Logtail collect logs. In Linux, Inotify is used. In Windows, ReadDirectoryChangesW is used. This method ensures the timeliness and stability of log collection.

2. If the compliant log files in the specified directory are not modified after the configuration is applied, Logtail does not collect these files. If modification events are generated for log files, Logtail triggers the collection process and reads these files.

Read files

After Logtail detects that a log file has been updated, Logtail reads the log file.

- If Logtail reads the log file for the first time, it checks the file size.
  - If the file size is less than 1 MB, Logtail reads the file from the beginning.
  - If the file size is greater than 1 MB, Logtail reads the file from the last 1 MB of data.
- If Logtail has read the file before, Logtail reads the file from the last checkpoint.
- Logtail can read up to 512 KB of data at a time. Therefore, you must limit the log size to 512 KB.

> **Notice** If you have changed the system time on your server, you must manually restart Logtail. Otherwise, the log time is incorrect and logs are dropped.

Process logs

When Logtail reads a log, it divides the log into multiple lines, parses the log, and sets the time field of the log.

- Divide each log into multiple lines

  If you specifies **Regex to Match First Line Only** in the Logtail configuration, the log data read by Logtail at one time is divided into multiple lines based on the specified beginning of the line. If the beginning of the line is not specified, each data block is processed as a log.

- Parse each log

  Logtail parses each log based on the Logtail configuration, such as regular expressions, delimiters, and JSON.

  > **Notice** A complicated regular expression may lead to high CPU usage. Therefore, we recommend that you use an efficient regular expression.

- Handle parsing failures

  Logtail determines how to handle parsing failures based on whether the Drop Failed to Parse Logs switch is turned on in the Logtail configuration.

  - If the **Drop Failed to Parse Logs** is turned on, Logtail drops the logs that fail to be parsed and reports an error.

  - If the **feature** switch is turned off, Logtail uploads the logs that fail to be parsed. In these logs, the key is set to **raw_log** and the value is set to the log content.

- Set the time field of a log
  - If the time field of the log is not specified, the log time is the current parsing time.
  - If the time field of the log is specified, the following operations are performed:
    - The log time is extracted from the parsed log fields if the difference between the log time and the current time is less than 12 hours.
    - The log is dropped and an error is reported if the difference between the log time and the current time is greater than 12 hours.

Filter logs

After Logtail process logs, it filters the logs based on the filter configuration.

- If the **Filter Configuration** is not specified, Logtail does not filter logs and proceed with the next step.
- If the **Filter Configuration** is specified, Logtail traverses and verifies all the fields of each log.
  - Logtail collects a log if the log matches the filter configuration.
  - Logtail does not collect a log if the log does not match the filter configuration.

Aggregate logs

Logtail sends the logs that match the filter configuration to Log Service. To reduce the number of network requests, Logtail caches the processed and filtered logs for a period of time. Then, Logtail aggregates and packages these logs before sending them to Log Service.

If one of the following conditions is met during caching, logs are immediately packaged and sent to Log Service.

- The log aggregation period exceeds three seconds.
- The number of aggregated logs exceeds 4,096.
- The total size of aggregated logs exceeds 512 KB.

Send logs

Logtail sends the aggregated logs to Log Service. You can set the `max_bytes_per_sec` and `send_request_concurrency` parameters in Set Logtail startup parameters to adjust the log data sending rate and the maximum concurrent requests. In this case, Logtail ensures that the sending rate and the concurrent requests do not exceed the limits.

If the log data fails to be sent, Logtail retries or stops the operation based on the error message.

Error	Description	Handling method
401	Logtail is not authorized to collect data.	Logtail drops the log packets.
404	The specified project or Logstore does not exist in the Logtail configuration.	Logtail drops the log packets.
403	The shard quota is exhausted.	Logtail waits for three seconds and retries.
500	A Log Service exception has occurred.	Logtail waits for three seconds and retries.
Network timeout	A network connection error has occurred.	Logtail waits for three seconds and retries.

28.1.3.1.1.3. Logtail configuration files and record files

This topic describes the basic configuration files and record files of Logtail. When Logtail is active, it uses a series of configuration files and generates record files.

The basic configuration files are as follows:

- Startup configuration file (ilogtail_config.json)
- Account ID configuration file
- User-defined identifier file (user_defined_id)
- Logtail configuration file (user_log_config.json)

The basic record files are as follows:

- AppInfo record file (app_info.json)
- Logtail operational log file (ilogtail.LOG)
- Logtail plug-in log file (logtail_plugin.LOG)
- Container path mapping file (docker_path_config.json)

Startup configuration file (ilogtail_config.json)

This file is used to query or set Logtail runtime parameters. The file is in the JSON format.

After you install Logtail, you can use the startup configuration file to perform the following operations:

- Change the values of the Logtail runtime parameters.

  You can change the CPU usage threshold, usage threshold of terminate and stay resident (TSR) programs, and other settings.

- Check whether the installation commands are correct.

  The settings of `config_server_address` and `data_server_list` in this file depend on the parameters and installation commands selected when you installed Logtail. If the region specified in config_server_address is unreachable or is different from the region where Log Service resides, the selected parameters or commands are incorrect. In this case, Logtail cannot collect logs and must be reinstalled.

> **Warning**
> - The file must be a valid JSON file. Otherwise, Logtail cannot be started.
> - If you modify the file, you must restart Logtail to validate your modifications.

The following table describes the default parameters in the startup configuration file. You can also add other parameters. For more information, see Set Logtail startup parameters.

Default parameters

Parameter	Description
config_server_address	The address that Logtail uses to receive the configuration file from Log Service. This address depends on the parameters and installation commands that you selected when you installed Logtail. Ensure that the address is reachable and is in the same region as Log Service.
data_server_list	The data server address. This address depends on the parameters and installation commands that you selected when you installed Logtail. Ensure that the address is reachable and is in the same region as Log Service.
cluster	The name of the region where a server resides.
endpoint	The endpoint of Log Service. For more information, see View the information of a project.
cpu_usage_limit	The CPU usage threshold, which is calculated by core.

Parameter	Description
mem_usage_limit	The TSR usage threshold.
max_bytes_per_sec	The traffic limit on the raw data that is sent by Logtail. If the value of this parameter is greater than 20 Mbit/s, traffic limiting does not take effect.
process_thread_count	The number of threads that Logtail uses to write data to log files.
send_request_concurrency	The number of concurrent requests for sending data packets asynchronously. Logtail sends data packets asynchronously by default. If the write transactions per second (TPS) is high, you can set a greater value for this parameter.

- File path
  - Linux: The file is stored in */usr/local/ilogtail/ilogtail_config.json*.
  - Container Service: The file is stored in a Logtail container. The file path is specified in the environment variable `ALIYUN_LOGTAIL_CONFIG` of the Logtail container. You can run the command `docker inspect ${logtail_container_name} | grep ALIYUN_LOGTAIL_CONFIG` to query the file path. For example, the file path is */etc/ilogtail/conf/cn-hangzhou/ilogtail_config.json*.
  - Windows:
    - 64-bit: The file is stored in *C:\Program Files (x86)\Alibaba\Logtail\ilogtail_config.json*.
    - 32-bit: The file is stored in *C:\Program Files\Alibaba\Logtail\ilogtail_config.json*.
- Sample file

```
$cat /usr/local/ilogtail/ilogtail_config.json
{
    "config_server_address" : "http://logtail.cn-hangzhou-intranet.log.aliyuncs.com",
    "data_server_list" :
    [
        {
            "cluster" : "ap-southeast-2",
            "endpoint" : "cn-hangzhou-intranet.log.aliyuncs.com"
        }
    ],
    "cpu_usage_limit" : 0.4,
    "mem_usage_limit" : 100,
    "max_bytes_per_sec" : 2097152,
    "process_thread_count" : 1,
    "send_request_concurrency" : 4,
    "streamlog_open" : false
}
```

Account ID configuration file

This file contains the ID of your Apsara Stack tenant account. The file indicates that the account can collect logs from the server where Logtail is installed. If you want to collect logs from ECS instances that do not belong to your account or from on-premises data centers, you must create an account ID configuration file.

> **Note**
> - The file is used only when you collect logs from ECS instances that do not belong to your account and or from on-premises data centers.
> - The file can contain only the ID of your Apsara Stack tenant account. It cannot contain the IDs of RAM users under your Apsara Stack tenant account.
> - The file name cannot contain a suffix.
> - Each Logtail can have multiple account ID configuration files. Each Logtail container can have only one account ID configuration file.

- File path
  - Linux: The file is stored in `/etc/ilogtail/users/`.
  - Container Service: The file is stored in a Logtail container. The file path is specified in the environment variable `ALIYUN_LOGTAIL_USER_ID` of the Logtail container. You can run the command `docker inspect ${logtail_container_name} | grep ALIYUN_LOGTAIL_USER_ID` to query the file path.
  - Windows: The file is stored in `C:\LogtailData\users\`.
- Sample file

```
$ls /etc/ilogtail/users/
*************** ****************
```

User-defined identifier file (user_defined_id)

This file is used to configure machine groups with user-defined identifiers. For more information, see Create a machine group based on a custom ID.

> **Note**
> - This file is used only when you configure a machine group with user-defined identifiers.
> - If you configure multiple user-defined identifiers for a machine group, separate them with line breaks.

- File path
  - Linux: The file is stored in */etc/ilogtail/user_defined_id*.
  - Container Service: The file is stored in a Logtail container. The file path is specified in the environment variable `ALIYUN_LOGTAIL_USER_DEFINED_ID` of the Logtail container. You can run the command *docker inspect ${logtail_container_name} | grep ALIYUN_LOGTAIL_USER_DEFINED_ID* to query the file path.
  - Windows: The file is stored in *C:\LogtailData\user_defined_id*.
- Sample file

```
$cat /etc/ilogtail/user_defined_id
aliyun-ecs-rs1e16355
```

Logtail configuration file (user_log_config.json)

This file contains the Logtail configuration that Logtail receives from Log Service. The file is in the JSON format and is updated along with configuration updates. You can use this file to check whether the Logtail configuration is delivered to the server where Logtail is installed. If the Logtail configuration file exists and all contents in the file are up to date, the Logtail configuration is delivered.

> **Notice**
>
> - We recommend that you do not modify the Logtail configuration file unless you need to specify sensitive information, such as the AccessKey pair and database password.
> - You must upload this file when you submit a ticket.

- File path
  - Linux: The file is stored in */usr/local/ilogtail/user_log_config.json*.
  - Container Service: The file is stored in */usr/local/ilogtail/user_log_config.json*.
  - Windows
    - 64-bit: The file is stored in *C:\Program Files (x86)\Alibaba\Logtail\user_log_config.json*.
    - 32-bit: The file is stored in *C:\Program Files\Alibaba\Logtail\user_log_config.json*.
- Sample file

```
$cat /usr/local/ilogtail/user_log_config.json
{
   "metrics" : {
      "##1.0##k8s-log-c12ba2028*****939f0b$app-java" : {
         "aliuid" : "16542189*****50",
         "category" : "app-java",
         "create_time" : 1534739165,
         "defaultEndpoint" : "cn-hangzhou-intranet.log.aliyuncs.com",
         "delay_alarm_bytes" : 0,
         "enable" : true,
         "enable_tag" : true,
         "filter_keys" : [],
         "filter_regs" : [],
         "group_topic" : "",
         "local_storage" : true,
         "log_type" : "plugin",
         "log_tz" : "",
         "max_send_rate" : -1,
         "merge_type" : "topic",
         "plugin" : {
            "inputs" : [
               {
                  "detail" : {
                     "IncludeEnv" : {
                        "aliyun_logs_app-java" : "stdout"
                     },
                     "IncludeLable" : {
                        "io.kubernetes.container.name" : "java-log-demo-2",
                        "io.kubernetes.pod.namespace" : "default"
                     },
                     "Stderr" : true,
                     "Stdout" : true
                  },

         "version" : 1
      }
   }
}
```

AppInfo record file (app_info.json)

This file contains the startup time of Logtail. It also contains the IP address and hostname that Logtail obtains. You must check the IP address obtained by Logtail when you configure an IP address-based machine group.

In most cases, Logtail obtains server IP addresses based on the following rules:

- If the IP address of a server is associated with its hostname in the */etc/hosts* server file, Logtail obtains the IP address.
- If the IP address of a server is not associated with its hostname, Logtail obtains the IP address of the first

network interface card (NIC) on the server.

> **Note**
> - The AppInfo record file contains only the basic Logtail information, which cannot be manually modified.
> - If you modify the hostname or other network settings of the server, you must restart Logtail to obtain a new IP address.

Parameters

Parameter	Description
UUID	The serial number of the server.
hostname	The hostname.
instance_id	The unique identifier of Logtail. This identifier is randomly generated.
ip	The IP address that is obtained by Logtail. If this parameter is not specified, Logtail has not obtained the IP address of a server. In this case, Logtail cannot function properly. You must set an IP address for your server and restart Logtail. **Note** If the machine group is an IP address-based machine group, ensure that the IP address specified for the machine group is the same as the value of this parameter. If the two IP address are different, modify the IP address that you specified for the machine group in the Log Service console. Check the IP addresses again after 1 minute.
logtail_version	The version of Logtail.
os	The version of the operating system.
update_time	The last startup time of Logtail.

- File path
  - Linux: The file is stored in */usr/local/ilogtail/app_info.json*.
  - Container Service: The file is stored in */usr/local/ilogtail/app_info.json*.
  - Windows
    - 64-bit: The file is stored in *C:\Program Files (x86)\Alibaba\Logtail\app_info.json*.
    - 32-bit: The file is stored in *C:\Program Files\Alibaba\Logtail\app_info.json*.
- Sample file

```
$cat /usr/local/ilogtail/app_info.json
{
   "UUID" : "",
   "hostname" : "logtail-ds-slpn8",
   "instance_id" : "E5F93BC6-B024-11E8-8831-0A58AC14039E_1**. ***. ***.***_1536053315",
   "ip" : "1**. ***. ***.***",
   "logtail_version" : "0.16.13",
   "os" : "Linux; 3.10.0-693.2.2.el7.x86_64; #1 SMP Tue Sep 12 22:26:13 UTC 2017; x86_64",
   "update_time" : "2018-09-04 09:28:36"
}
```

Logtail operational log file (ilogtail.LOG)

This file contains operational information about Logtail. Log severity levels are ranked as follows in ascending order: `INFO`, `WARN`, `ERROR`. Logs of the `INFO` level can be ignored.

- File path
  - For Linux: The file is stored in */usr/local/ilogtail/ilogtail.LOG*.
  - Container Service: The file is stored in */usr/local/ilogtail/ilogtail.LOG*.
  - Windows
    - 64-bit: The file is stored in *C:\Program Files (x86)\Alibaba\Logtail\logtail_*.log*.
    - 32-bit: The file is stored in *C:\Program Files\Alibaba\Logtail\logtail_*.log*.
- Sample file

```
$tail /usr/local/ilogtail/ilogtail.LOG
[2018-09-13 01:13:59.024679]    [INFO]    [3155]    [build/release64/sls/ilogtail/elogtail.cpp:123
]    change working dir:/usr/local/ilogtail/
[2018-09-13 01:13:59.025443]    [INFO]    [3155]    [build/release64/sls/ilogtail/AppConfig.cpp:17
5]    load logtail config file, path:/etc/ilogtail/conf/ap-southeast-2/ilogtail_config.json
[2018-09-13 01:13:59.025460]    [INFO]    [3155]    [build/release64/sls/ilogtail/AppConfig.cpp:17
6]    load logtail config file, detail:{
   "config_server_address" : "http://logtail.ap-southeast-2-intranet.log.aliyuncs.com",
   "data_server_list" : [
      {
         "cluster" : "ap-southeast-2",
         "endpoint" : "ap-southeast-2-intranet.log.aliyuncs.com"
      }
]
```

Logtail plug-in log file (logtail_plugin.LOG)

This file contains operational information about plug-ins, such as stdout, binlog, and HTTP plug-ins. Log severity levels are ranked as follows in ascending order: `INFO`, `WARN`, `ERROR`. Logs of the `INFO` level can be ignored.

- File path
  - Linux: The file is stored in */usr/local/ilogtail/logtail_plugin.LOG*
  - Container Service: The file is stored in */usr/local/ilogtail/logtail_plugin.LOG*.
  - Windows: The file is not supported.
- Sample file

```
$tail /usr/local/ilogtail/logtail_plugin.LOG
2018-09-13 02:55:30 [INF] [docker_center.go:525] [func1] docker fetch all:start

```

Container path mapping file (docker_path_config.json)

This file is automatically created only when container files are collected. It records path mappings between container files and actual files. The file is in the JSON format.

> **Note** This file is only an information record file. Modifications to this file do not take effect. If you delete this file, another one is automatically created without service interruptions.

- File path

  The file is stored in */usr/local/ilogtail/docker_path_config.json*.

- Sample file

```
$cat /usr/local/ilogtail/docker_path_config.json
{
   "detail" : [
      {
         "config_name" : "##1.0##k8s-log-c12ba2028cfb444238cd9ac1286939f0b$nginx",
         "container_id" : "df19c06e854a0725ea7fca7e0378b0450f7bd3122f94fe3e754d8483fd330d10",
         "params" : "{\n   \"ID\" : \"df19c06e854a0725ea7fca7e0378b0450f7bd3122f94fe3e754d8483fd330d10\",\n   \"Path\" : \"/logtail_host/var/lib/docker/overlay2/947db346695a1f65e63e582ecfd10ae1f57019a1b99260b6c83d00fcd1892874/diff/var/log\",\n   \"Tags\" : [\n      \"nginx-type\",\n      \"access-log\",\n      \"_image_name_\",\n      \"registry.cn-hangzhou.aliyuncs.com/log-service/docker-log-test:latest\",\n      \"_container_name_\",\n      \"nginx-log-demo\",\n      \"_pod_name_\",\n      \"nginx-log-demo-h2lzc\",\n      \"_namespace_\",\n      \"default\",\n      \"_pod_uid_\",\n      \"87e56ac3-b65b-11e8-b172-00163f008685\",\n      \"_container_ip_\",\n      \"172.20.4.224\",\n      \"purpose\",\n      \"test\"\n   ]\n}\n"
      }
   ],
   "version" : "0.1.0"
}
```

28.1.3.1.2. Installation

28.1.3.1.2.1. Install Logtail in Linux

This topic describes how to install Logtail on a Linux server.

Supported systems

Logtail supports the following x86-64 (64-bit) Linux operating systems:

- Aliyun Linux
- Ubuntu
- Debian
- CentOS
- openSUSE
- Red Hat

Procedure

> **Note** If you have installed Logtail, the installer will uninstall the existing version of Logtail, delete the `/usr/local/ilogtail` directory, and then reinstall Logtail. By default, Logtail runs after the installation and at startup.

1. Run the following command to download the Logtail installer:

   ```
   wget http://${service:sls-backend-server:sls_data.endpoint}/logtail.sh -O logtail.sh; chmod 755 logtail.sh
   ```

   > **Note** You must replace `${service:sls-backend-server:sls_data.endpoint}` in the command with the actual endpoint. For more information about endpoints, see View the information of a project.

2. Run the installation command.

   Start Linux PowerShell and run the following command as an administrator to install Logtail:

   ```
   ./logtail.sh install
   ```

3. Configure an account ID for a server.

View the version of Logtail

To view the version of Logtail, open the file in the `/usr/local/ilogtail/app_info.json` directory. The `logtail_version` field shows the version of Logtail.

```
$cat /usr/local/ilogtail/app_info.json
{
   "UUID" : "0DF18E97-0F2D-486F-B77F-*********",
   "hostname" : "david*******",
   "instance_id" : "F4FAFADA-F1D7-11E7-846C-00163E30349E_*********_1515129548",
   "ip" : "**********",
   "logtail_version" : "0.16.0",
   "os" : "Linux; 2.6.32-220.23.2.ali1113.el5.x86_64; #1 SMP Thu Jul 4 20:09:15 CST 2013; x86_64",
   "update_time" : "2018-01-05 13:19:08"
}
```

Upgrade Logtail

You can use the Logtail installer (logtail.sh) to upgrade Logtail. The installer selects an upgrade method based on the configurations of the existing Logtail.

> **Note** During the upgrade, Logtail is temporarily stopped. Only related files are overwritten. The configuration file, checkpoint file, and logs are retained.

Run the following commands to upgrade Logtail:

```
# Download the Logtail installer.
wget http://${service:sls-backend-server:sls_data.endpoint}/logtail.sh -O logtail.sh; chmod 755 logtail.sh
# Upgrade Logtail.
sudo ./logtail.sh upgrade
```

Response:

```
# The upgrade is successful.
Stop logtail successfully.
ilogtail is running
Upgrade logtail success
{
   "UUID" : "***",
   "hostname" : "***",
   "instance_id" : "***",
   "ip" : "***",
   "logtail_version" : "0.16.11",
   "os" : "Linux; 3.10.0-693.2.2.el7.x86_64; #1 SMP Tue Sep 12 22:26:13 UTC 2017; x86_64",
   "update_time" : "2018-08-29 15:01:36"
}
# The upgrade fails because the current version is the latest version.
[Error]:    Already up to date.
```

Start and stop Logtail

- Start Logtail

  Run the following command as an administrator:

  ```
  /etc/init.d/ilogtaild start
  ```

- Stop Logtail

  Run the following command as an administrator:

  ```
  /etc/init.d/ilogtaild stop
  ```

Uninstall Logtail

Run Linux PowerShell as an administrator to uninstall Logtail:

```
wget http://${service:sls-backend-server:sls_data.endpoint}/logtail.sh -O logtail.sh
chmod 755 logtail.sh
./logtail.sh uninstall
```

28.1.3.1.2.2. Install Logtail in Windows

This topic describes how to install Logtail on a Windows server.

Supported systems

Logtail supports the following Windows operating systems:

- Windows 7 (Client) 32-bit
- Windows 7 (Client) 64-bit
- Windows Server 2008 32-bit
- Windows Server 2008 64-bit
- Windows Server 2012 64-bit
- Windows Server 2016 64-bit

Procedure

1. Download the installation package.

   Run the following command to download the installation package:

   ```
   wget http://${service:sls-backend-server:sls_data.endpoint}/windows/logtail_installer.zip
   ```

   > **Note** You must replace `${service:sls-backend-server:sls_data.endpoint}` in the command with the actual endpoint. For more information about endpoints, see View the information of a project.

2. Decompress the `logtail_installer.zip` package to the current directory.
3. Run the installation command.

   Run Windows PowerShell or Command Prompt as an administrator. Enter the `logtail_installer` directory, and then run the installation command based on the network type.

   ```
   .\logtail_installer.exe install me-east-1
   ```

   > **Note** You must replace `${region}` in the command with the actual endpoint. For more information about endpoints, see View the information of a project.

4. Configure an account ID for a server.

Installation directory

After you run the installation command, Logtail is installed in the specified directory. The directory cannot be changed. In the directory, you can View the version of Logtail in the *app_info.json* file or Uninstall Logtail.

The installation directory is as follows:

- 32-bit Windows: *C:\Program Files\Alibaba\Logtail*
- 64-bit Windows: *C:\Program Files (x86)\Alibaba\Logtail*

> **Note** You can run 32-bit or 64-bit applications in a 64-bit Windows operating system. However, the operating system stores 32-bit applications in separate x86 folders to ensure compatibility.
>
> Logtail for Windows is a 32-bit application. Therefore, it is installed in the *Program Files (x86)* folder in 64-bit Windows. If Logtail for 64-bit Windows becomes available in the future, it will be installed in the *Program Files* folder.

View the version of Logtail

To view the version of Logtail, go to the default installation directory, and then use the notepad or another text editor to open the *app_info.json* file. The `logtail_version` field shows the version of Logtail.

In the following example, the version of Logtail is 1.0.0.0:

```
{
    "logtail_version" : "1.0.0.0"
}
```

Upgrade Logtail

- Automatic upgrade

  Logtail later than 1.0.0.0 is automatically upgraded in Windows.

- Manual upgrade

  Logtail earlier than 1.0.0.0 must be manually upgraded. The manual upgrade procedure is the same as the installation procedure.

  > **Note** During a manual upgrade, the files in the original installation directory are deleted. We recommend that you back up the files before you perform a manual upgrade.

Start and stop Logtail

Open the **Control Panel**, choose System and Security > **Administrative Tools**, and then double-click **Services**.

Find the service based on your Logtail version.

- Logtail 0.x.x.x: LogtailWorker.
- Logtail 1.0.0.0 and later: LogtailDaemon.

Perform the following operations as required:

- Start Logtail

  Right-click the service and select **Start** from the shortcut menu.

- Stop Logtail

  Right-click the service and select **Stop** from the shortcut menu.

- Restart Logtail

  Right-click the service and select **Restart** from the shortcut menu.

Uninstall Logtail

Run Windows PowerShell or Command Prompt as an administrator. Enter the `logtail_installer` directory, and then run the following command:

```
.\logtail_installer.exe uninstall
```

After Logtail is uninstalled, the installation directory is deleted. However, some residual configuration data is still maintained in the *C:\LogtailData* directory. You can manually delete the data. The residual configuration data includes the following information:

- *checkpoint*: checkpoints of all plug-ins, for example, the Windows event log plug-in.
- *logtail_check_point*: checkpoints of Logtail.
- *users*: IDs of Apsara Stack tenant accounts.

28.1.3.1.2.3. Set Logtail startup parameters

This topic describes how to set Logtail startup parameters.

Context

You may need to set Logtail startup parameters in the following scenarios:

- You need to collect a large number of log files that consume much memory. You want to maintain the metadata (such as the file signature, collection location, and file name) of each file in the memory.
- The CPU usage is high due to heavy log data traffic.
- The traffic sent to Log Service is heavy due to a large amount of log data.
- You want to collect syslogs or TCP data streams.

Startup configurations

- File path

```
/usr/local/ilogtail/ilogtail_config.json
```

- File format

  JSON

- Sample file (only partial configurations are provided)

```
{
    ...
    "cpu_usage_limit" : 0.4,
    "mem_usage_limit" : 100,
    "max_bytes_per_sec" : 2097152,
    "process_thread_count" : 1,
    "send_request_concurrency" : 4,
    "streamlog_open" : false,
    "streamlog_pool_size_in_mb" : 50,
    "streamlog_rcv_size_each_call" : 1024,
    "streamlog_formats":[],
    "streamlog_tcp_port" : 11111,
    "buffer_file_num" : 25,
    "buffer_file_size" : 20971520,
    "buffer_file_path" : "",
    ...
}
```

Startup parameters

Parameter	Description	Example
cpu_usage_limit	The CPU usage threshold for a single core. Data type: double.	For example, the value 0.4 indicates that the CPU usage of Logtail is limited to 40% processing capacity of a single core. In most cases, the processing capacity of a single core is about 24 MB/s in the simple mode and 12 MB/s in the full regex mode.
mem_usage_limit	The usage threshold of the resident memory. Data type: integer. Unit: MB.	For example, the value 100 indicates that the memory usage of Logtail is limited to 100 MB. If the threshold is exceeded, Logtail restarts. If you want to collect more than 1,000 log files, you can increase the threshold value.
max_bytes_per_sec	The traffic limit on the raw data that is sent by Logtail. Data type: integer. Unit: bytes/s.	For example, the value 2097152 indicates that the data transfer rate of Logtail is limited to 2 MB/s.

Parameter	Description	Example
process_thread_count	The number of threads that Logtail uses to process data.	Default value: 1. Each thread provides a write speed of 24 MB/s in the simple mode and 12 MB/s in the full regex mode. We recommend that you do not modify the default value.
send_request_concurrency	Logtail sends data packets asynchronously by default. If the write transactions per second (TPS) is high, you can set this parameter to a greater value.	Twenty asynchronous concurrencies are provided by default. Each concurrency can provide 0.5 MB/s to 1 MB/s network throughput. The number of concurrencies varies with the network delay.
streamlog_open	Specifies whether to receive syslogs. Data type: Boolean.	The value false indicates that syslogs are not received. The value true indicates that syslogs are received.
streamlog_pool_size_in_mb	The size of memory pool that the syslog server uses to cache syslogs. Unit: MB.	Logtail requests memory when it starts. Set the memory pool size based on the server memory size and your business requirements.
streamlog_rcv_size_each_call	The size of the buffer that Logtail uses when the linux socket rcv API is called. Unit: bytes. Valid values: 1024 to 8192.	You can set a greater value if the syslog traffic is high.
streamlog_formats	The method that is used to parse received syslogs.	N/A
streamlog_tcp_addr	The associated address that Logtail uses to receive syslogs. Default value: 0.0.0.0.	N/A
streamlog_tcp_port	The TCP port that Logtail uses to receive syslogs.	Default value: 11111.
buffer_file_num	The maximum number of cached files. If a network exception occurs or the writing quota is exceeded, Logtail writes parsed logs to local files in the installation directory. After the network recovers or a new writing quota is available, Logtail retries to send the logs to Log Service.	Default value: 25.
buffer_file_size	The maximum number of bytes that can be contained in each cache file. The maximum disk space available for cache files is the value of buffer_file_num multiplied by the value of buffer_file_size.	Default value: 20971520 bytes (20 MB).

Parameter	Description	Example
buffer_file_path	The directory in which cached files are stored. If you modify this parameter, you must move the files (for example, *logtail_buffer_file_**) in the old cache directory to the new directory. Then, Logtail can read, send, and delete the cache files.	The default value is null, which indicates that the cached files are stored in the Logtail installation directory */usr/local/ilogtail*.
bind_interface	The name of the NIC associated with the local machine, for example, eth1. This parameter is valid only for Logtail that runs in Linux.	By default, the available NICs are automatically associated with the local machine. If you specify this parameter, Logtail will use the specified NIC to upload logs.
check_point_filename	The full path in which the checkpoint file is stored. This parameter is used to customize the path to store the checkpoint file of Logtail.	Default value: */tmp/logtail_check_point*. We recommend that Docker users modify this path and mount the directory where the checkpoint file resides to the host. Otherwise, duplicate collection occurs due to checkpoint data loss when the container is released. For example, you can set check_point_filename to `/data/logtail/check_point.dat` in Docker and add `-v /data/docker1/logtail:/data/logtail` to the Docker startup command. Then, the */data/docker1/logtail* directory of the host is mounted to the */data/logtail* directory of Docker.

Note

- The preceding table lists only the common startup parameters. If the *ilogtail_config.json* file contains parameters that are not listed in the table, the default settings are used for these parameters.
- We recommend that you do not add unnecessary parameters to the *ilogtail_config.json* file.

Modify configurations

1. Configure the *ilogtail_config.json* file as needed.

   Ensure that the modified configurations are in the valid JSON format.

2. Restart Logtail to apply the modified configurations.

```
/etc/init.d/ilogtaild stop
/etc/init.d/ilogtaild start
/etc/init.d/ilogtaild status
```

28.1.3.1.3. Logtail machine group

28.1.3.1.3.1. Overview

Log Service uses machine groups to manage the servers from which you want to collect logs by using Logtail.

A machine group is a virtual group that contains multiple servers. If you want to use a Logtail configuration file to collect logs from multiple servers, you can add the servers to a machine group. Then, you can apply the Logtail configuration file to the machine group.

To define a machine group, you can use one of the following methods:

- IP address: Add the IP addresses of all servers to a machine group. Each server can be identified by using its unique IP address.
- Custom ID: Use a custom ID to identify the machine group and use the same ID for servers in the machine group.

> **Note** Windows and Linux servers cannot be added to the same machine group.

IP address-based machine groups

You can add multiple servers to a machine group by adding their IP addresses to the machine group. Then, you can create a Logtail configuration file for all the servers at the same time.

- If you use ECS instances and have not associated them with hostnames or changed their network types, you can add their private IP addresses to the machine group.
- In other cases, you must add the server IP addresses obtained by Logtail to a machine group. The IP address of each server is recorded in the IP address field of the *app_info.json* file on the server.

> **Note** The *app_info.json* file records the internal information of Logtail. This file includes the server IP addresses obtained by Logtail. If you modify the IP address field of the file, the IP addresses obtained by Logtail remain unchanged.

Logtail obtains a server IP address by using the following methods:

- If the IP address of a server is associated with the hostname in the */etc/hosts* file of the server, Logtail obtains this IP address.
- If the IP address of a server is not associated with the hostname, Logtail obtains the IP address of the first network interface controller (NIC) on the server.

For more information, see Create an IP address-based server group.

Custom ID-based machine groups

You can use custom IDs to dynamically define machine groups.

An application system consists of multiple modules. You can scale out each module by adding multiple servers to the module. If you want to collect logs by module, you can create a machine group for each module. Therefore, you must specify a custom ID for each server in each module. For example, a website consists of an HTTP request processing module, a caching module, a logic processing module, and a storage module. The custom IDs of these modules can be http_module, cache_module, logic_module, and store_module.

For more information, see Create a machine group based on a custom ID.

28.1.3.1.3.2. Create a machine group based on a server IP address

This topic describes how to create a machine group based on a server IP address. You can create a machine group based on a server IP address that is obtained by using a Logtail configuration file. You can then use the same Logtail configuration file to collect logs from the machine group.

Prerequisites

- A project is created. A Logstore is created in the project.
- One or more servers are available. The IP addresses of the servers are obtained.
- Logtail is installed on the servers. For more information, see Install Logtail in Linux or Install Logtail in Windows.
- The ID of your Apsara Stack tenant account is configured on the server. For more information, see Configure an account ID for a server.

Procedure

1. Log on to the Log Service console.
2. In the **Projects** section, click the name of a project.
3. In the left-side navigation pane, click the **Machine Groups** icon.
4. In the pane that appears, click the icon next to **Machine Group** and select **Create Machine Group** from the shortcut menu.

   You can also create a machine group in the Logtail configuration wizard.
5. Create a machine group.
   i. Enter a machine group name in the **name** field.

   The machine group name must be 3 to 128 characters in length and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit.

   > **Notice** After the machine group is created, its name cannot be modified.

   ii. Select **IP Addresses** from the **Identifier** drop-down list.
   iii. Enter a topic name in the **Topic** field.

   For more information about topics, see Generate a topic.
   iv. Enter the IP addresses of the servers in the **IP Addresses** text box.

   > **Notice**
   > - Separate each IP address with a line break.
   > - Do not add Windows servers and Linux servers to the same machine group.
6. Click **OK**.

Result

You can view the created machine group in the **Machine Groups** pane.

28.1.3.1.3.3. Create a machine group based on a custom ID

This topic describes how to create a machine group based on a custom ID.

Context

You can use a custom ID to identify a machine group in the following scenarios:

- Servers reside in multiple custom network environments such as virtual private clouds (VPCs). IP addresses of different servers may be the same. In this scenario, Log Service cannot distinguish between servers based on IP addresses.
- You want to implement automatic server discovery. To do this, you only need to set a custom ID of a new server to the custom ID of an existing machine group. Log Service automatically identifies the server and adds it to the machine group.

Procedure

1. Set a custom ID on a server.
   - **Linux Logtail**

     Set a custom ID in the `/etc/ilogtail/user_defined_id` file.

     For example, if you need to set a custom ID of a server to `userdefined`, run the following command to open the file:

     ```
     # vim /etc/ilogtail/user_defined_id
     ```

     In the file, enter `userdefined`.
   - **Windows Logtail**

     Set a custom ID in the `C:\LogtailData\user_defined_id` file.

     For example, if you need to set a custom ID of a server, run the following command:

     ```
     C:\LogtailData>more user_defined_id
     userdefined_windows
     ```

   > **Notice**
   > - A machine group cannot include both Linux and Windows servers. Therefore, do not set a custom ID of a Linux server and a custom ID of a Windows server to the same value.
   > - You can set multiple custom IDs for a single server. Separate each custom ID with a line break.
   > - If the */etc/ilogtail/* or *C:\LogtailData* directory or the */etc/ilogtail/user_defined_id* or *C:\LogtailData\user_defined_id* file does not exist, create the directory or the file.

2. Create a machine group.
   i. Log on to the Log Service console.
   ii. In the **Projects** section, click a project.
   iii. In the left-side navigation pane, click the **Machine Groups** icon.
   iv. Click the icon next to **Machine Groups**, and select **Create Machine Group** from the shortcut menu.

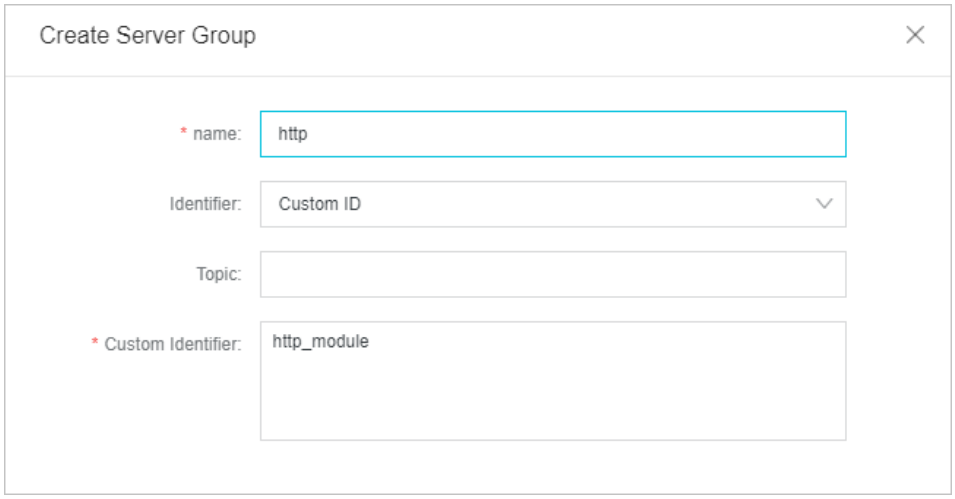
v. Set the parameters of the machine group.

- **name**: Enter a machine group name.

  The machine group name must be 3 to 128 characters in length and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit.

  > **Note** After the machine group is created, its name cannot be modified.

- **Identifier**: Select **Custom ID**.
- **Topic**: Enter a topic name for the machine group. For more information, see Generate a topic.
- **Custom Identifier**: Enter the custom ID that you set in Step 1.

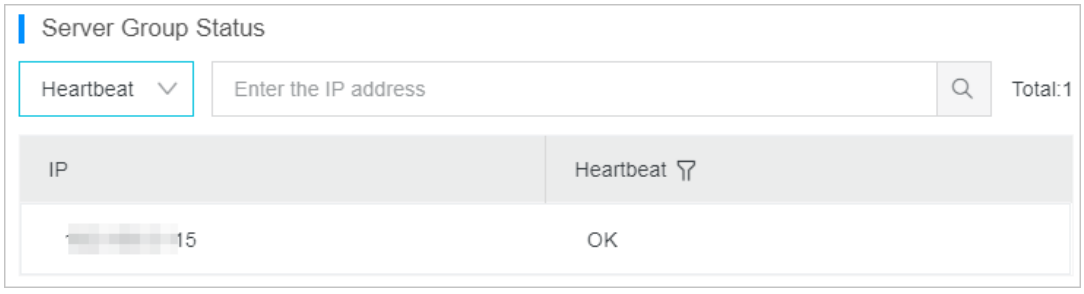


vi. Click **OK**.

> **Note** If you need to add a server to the machine group, set a custom ID of the server to the custom ID of the machine group. The server is then listed in the **Machine Group Status** section.

3. View the status of the machine group.

   In the **Machine Groups** pane, click the name of the machine group. On the **Machine Group Settings** page, view the status of the machine group. You can view the IP address list of the servers in the machine group and their heartbeat status.



> **Note**
>
> - The **Machine Group Status** section lists the IP addresses of the servers whose custom ID is the same as the custom ID that you set for the machine group.
>
> For example, the custom ID of a machine group is userdefined and the IP addresses in the **Machine Group Status** section are 10.10.10.10, 10.10.10.11, and 10.10.10.12. This means that the custom ID userdefined is set for the three servers. If you need to add the server whose IP address is 10.10.10.13 to the machine group, set the custom ID userdefined for the server. Then, the IP address of the server is displayed in the **Machine Group Status** section. Log Service collects logs from the server based on the Logtail configuration file of the machine group.
> - The heartbeat status indicates whether the connection between a server and Log Service is normal. For information about how to troubleshoot heartbeat errors, see What can I do if no heartbeat packet is received from a Logtail client?

Delete the custom IDs of a server

If you need to change the ID of a server from a custom ID to the server IP address, delete the user_defined_id file. The change takes effect within 1 minute.

- In Linux, run the following command to delete the file:

```
rm -f /etc/ilogtail/user_defined_id
```

- In Windows, run the following command to delete the file:

```
del C:\LogtailData\user_defined_id
```

Time required for a change to take effect

After you create, edit, or delete a user_defined_id file, the change takes effect within 1 minute.

If you need the change to take immediate effect, restart Logtail.

- In Linux, run the following commands to restart Logtail:

```
/etc/init.d/ilogtaild stop
/etc/init.d/ilogtaild start
```

- In Windows, perform the following steps to restart Logtail:

  Open the Control Panel. In the window that appears, choose **Control Panel > Administrative Tools > Services**. Right-click **LogtailWorker**, and select **Restart** from the shortcut menu.

Example

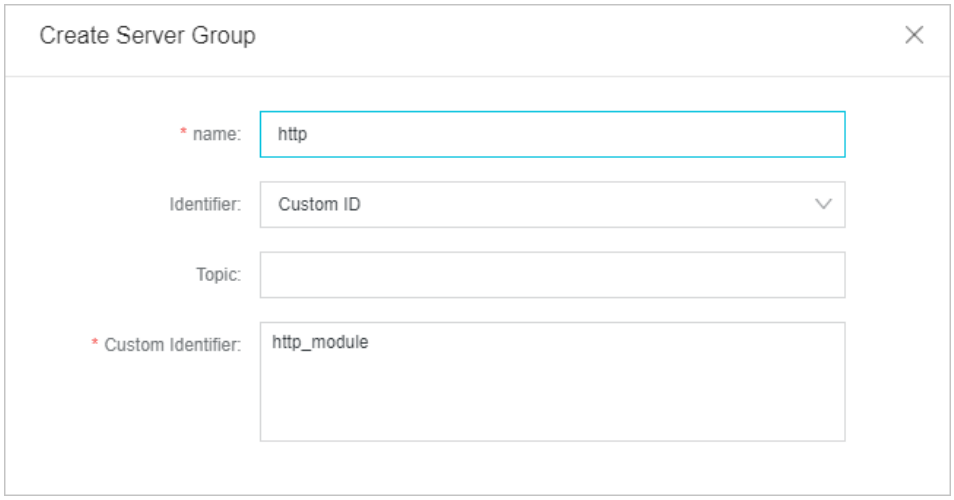
An application consists of multiple modules. Each module runs on multiple servers. For example, a website consists of an HTTP request processor, a cache, a logic processor, and a storage. You may scale out each module by adding multiple servers. You need to collect logs from both the existing and new servers.

1. Set a custom ID for each server.

   Install Logtail on the servers and set a custom ID for each server. In this example, you can use four custom IDs: http_module, cache_module, logic_module, and store_module. Each custom ID corresponds to a module.

2. Create a machine group for each module.

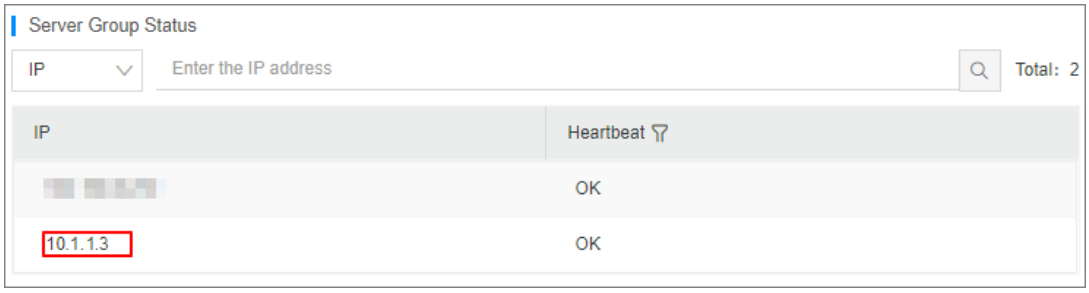
   When you create a machine group for a module, enter the custom ID of the module in the **Custom Identifier** field.



3. View the status of the machine group.

   On the **Machine Group Settings** page of the machine group, you can view the status of the machine group in the **Machine Group Status** section. You can view the list of servers in the machine group and their heartbeat status.

4. If you need to add a server whose IP address is 10.1.1.3 to the machine group whose custom ID is http_module, set the custom ID http_module for the server. Then, you can view the server in the **Machine Group Status** section.



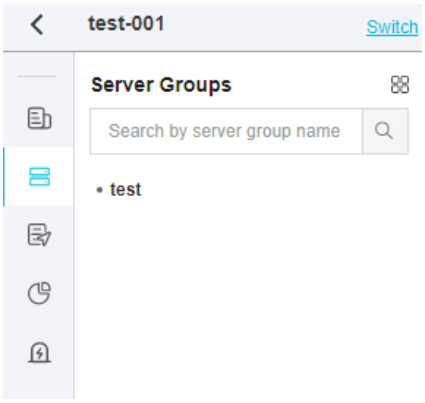
28.1.3.1.3.4. View server groups

This topic describes how to view the server groups of a project on the **Server Groups** page in the Log Service console.

Procedure

1. Log on to the Log Service console.
2. Find the target project in the project list and click the project name.
3. In the left-side navigation pane of the page that appears, click the **Server Groups** icon to display the list of server groups.

   You can view all server groups of the project.



28.1.3.1.3.5. Modify a server group

This topic describes how to modify a server group in the Log Service console. After you create a server group, you can modify the parameters of the server group.

Procedure

1. Log on to the Log Service console.
2. Find the target project in the project list and click the project name.
3. In the left-side navigation pane of the page that appears, click the **Server Groups** icon to display the list of server groups.
4. Click the name of the server group to be modified. On the **Server Group Settings** page, click **Modify**.

   > **Note** The name of the server group cannot be modified.

5. Modify the parameters of the server group, and then click **Save**.

28.1.3.1.3.6. View the status of a server group

This topic describes how to view the status of a server group in the Log Service console. You can view the heartbeat information of Logtail to check whether Logtail is installed on the servers in a server group.

Procedure

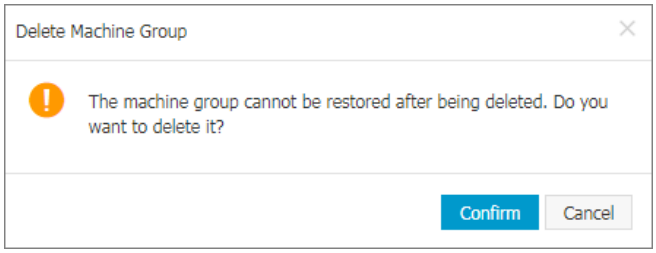
1. Log on to the Log Service console.
2. Find the target project in the project list and click the project name.
3. In the left-side navigation pane of the page that appears, click the **Server Groups** icon to display the list of server groups.
4. Click the name of the server group. On the **Server Group Settings** page, check the server group status.
   - If the heartbeat is OK, Logtail is installed on the servers in the server group and Logtail is connected to Log Service.
   - If the heartbeat status is FAIL, Logtail fails to connect to Log Service. If the FAIL state persists, perform troubleshooting based on the instructions provided in What can I do if no heartbeat packet is received from a Logtail client?

28.1.3.1.3.7. Delete a server group

This topic describes how to delete a server group in the Log Service console. You can delete a server group if you no longer need to collect logs from the server group.

Procedure

1. Log on to the Log Service console.
2. Find the target project in the project list and click the project name.
3. In the left-side navigation pane of the page that appears, click the **Server Groups** icon to display the list of server groups.
4. Find the server group that you want to delete, click the icon next to the server group, and then select **Delete**.
5. In the dialog box that appears, click **OK**.



28.1.3.1.3.8. Manage server group configurations

This topic describes how to manage server group configurations in the Log Service console. Log Service uses server groups to manage the servers from which you collect logs by using Logtail. In the Log Service console, you can create, view, modify, and delete server groups. You can also view the status of server groups, manage server group configurations, and apply server group identifiers.

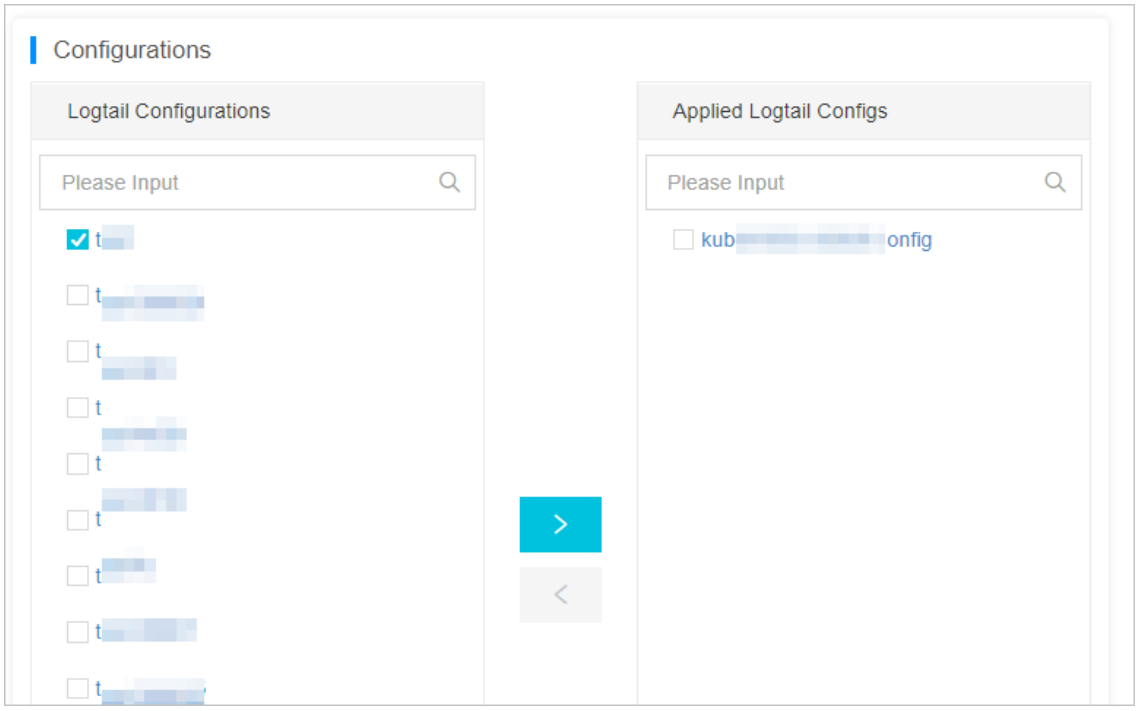
Context

Log Service allows you to manage the Logtail configurations that you create for Logtail installed on the servers in a server group. You can apply Logtail configurations to a server group. The Logtail configurations determine what logs are collected on each server, how the logs are parsed, and which Logstore the logs are written to.

Procedure

1. Log on to the Log Service console.
2. Find the target project in the project list and click the project name.
3. In the left-side navigation pane of the page that appears, click the **Server Groups** icon to display the list of server groups.
4. Click the name of the server group whose configurations you want to modify. On the **Server Group Settings** page, click **Modify**.
5. In the **Configurations** section, modify the Logtail configuration that you want to apply to the server group and click **Save**.

   After a Logtail configuration is added, it is delivered to Logtail on each server in the server group. After a Logtail configuration is removed, it is removed from Logtail.



28.1.3.1.3.9. Manage a Logtail configuration

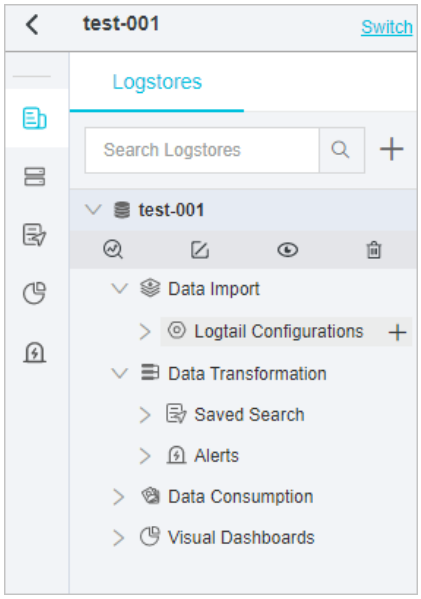
This topic describes how to manage a Logtail configuration in the Log Service console. Before you can collect logs from a server, you must install Logtail on the server. After you install Logtail, you must create a Logtail configuration in the Log Service console and apply the Logtail configuration to the server. You can create and modify Logtail configurations in Logstores.

Create a Logtail configuration

For information about how to create a Logtail configuration in the Log Service console, see Configure text log collection.

View Logtail configurations

1. Log on to the Log Service console.
2. Find the target project in the project list and click the project name.
3. In the left-side navigation pane, click the closing angle bracket (>) next to the target Logstore and choose **Data Import > Logtail Configurations**. Each item under **Logtail Configurations** indicates a Logtail configuration.



Modify a Logtail configuration

Under **Logtail Configurations**, click the name of the Logtail configuration. On the **Logtail Config** page, click **Modify**.

You can also change the log collection mode of the Logtail configuration, and then apply the Logtail configuration to the server group again. The process of modifying a Logtail configuration is the same as the process of creating a Logtail configuration.

Delete a Logtail configuration

Click the icon next to the Logtail configuration, and then select **Delete**.

After the Logtail configuration is deleted, it is disassociated from the server group. Logtail no longer collects logs specified by the Logtail configuration.

28.1.3.1.3.10. Configure an account ID on a server

This topic describes how to configure the ID of an Apsara Stack tenant account on a server.

Prerequisites

Logtail is installed on the server. For more information, see Install Logtail in Linux or Install Logtail in Windows.

Context

You must configure the ID if the server is an on-premises server or an ECS instance that belong to another Apsara Stack tenant account. You must also configure the ID if the server is a cloud server that is provided by a third-party vendor. Then, the Apsara Stack tenant account can use Logtail to collect logs from the server. If you do not configure the account ID on the server, Log Service cannot receive the heartbeat of the server and Logtail cannot collect logs from the server.

Procedure

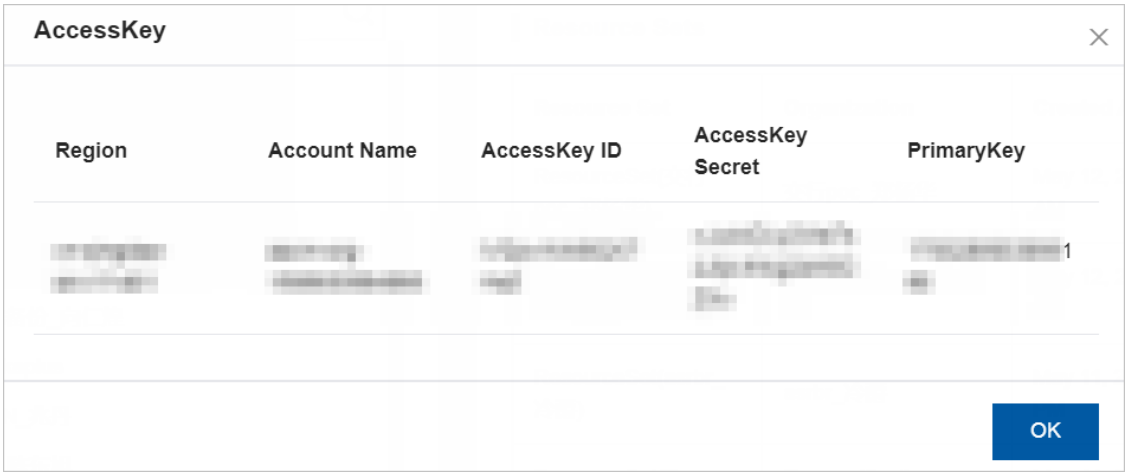
1. View the ID of your Apsara Stack tenant account.
   i. Log on to the Apsara Uni-manager Management Console.

      For more information, see Log on to the Log Service console.
   ii. In the top navigation bar, click **Enterprise**.

iii. In the left-side navigation pane, click **Organizations**.

iv. Select the destination account and click **Obtain an accesskey**

v. In the **AccessKey** dialog box, view the account ID.



2. Log on to the server and configure the account ID on the server.
   - Linux server:

     In the */etc/ilogtail/users* directory, create a file. Set the name of the file to the account ID. If the directory does not exist, create the directory first. You can configure multiple account IDs for a server. Examples:

     ```
     touch /etc/ilogtail/users/1**************
     touch /etc/ilogtail/users/1**************
     ```

     If you no longer need to collect logs from the server to a Log Service project, run the following command to delete the account ID:

     ```
     rm /etc/ilogtail/users/1**************
     ```

   - Windows server:

     In the *C:\LogtailData\users* directory, create a file. Set the name of the file to the account ID. To delete the account ID, delete the file.

     For example, you can delete the file of an account ID from the *C:\LogtailData\users\1**************** directory.

     > **Note**
     > - After you configure the ID of an Apsara Stack tenant account on a server, the account is authorized to use Logtail to collect logs from the server. If an account is no longer used to collect logs from the server, delete the account ID file from the server at the earliest opportunity.
     > - After you configure or delete an account ID, the change takes effect within 1 minute.

28.1.3.1.4. Text logs

28.1.3.1.4.1. Configure text log collection

This topic describes how to configure Logtail in the Log Service console to collect text logs from specified servers.

Prerequisites

Logtail is installed. Logtail can be installed on a Windows or Linux operating system. For more information, see Install Logtail in Linux and Install Logtail in Windows.

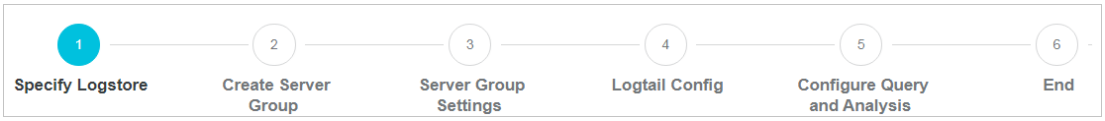
Limits

- Each log file can be collected by using only one Logtail configuration. If you want to collect a log file by using more than one Logtail configuration, we recommend that you use symbolic links. For example, to collect a log file by using two Logtail configurations in the `/home/log/nginx/log` directory, you can use the original log path for one Logtail configuration. Then, run the `ln -s /home/log/nginx/log /home/log/nginx/link_log` command to create a symbolic link for this directory and use the symbolic link as the log path for the other Logtail configuration.
- Logtail supports only Windows or Linux operating systems. For more information, see Logtail overview.

Logtail configuration procedure

You can specify Logtail configurations in the Log Service console. Logtail supports various collection modes, such as simple mode, NGINX configuration mode, Apache configuration mode, IIS configuration mode, delimiter mode, JSON mode, and full regex mode.

Configuration procedure



Collection modes

Logtail supports various collection modes, such as simple mode, NGINX configuration mode, Apache configuration mode, IIS configuration mode, delimiter mode, JSON mode, and full regex mode.

- Simple mode

  Logtail can be used to collect logs in the simple mode. For more information, see Collect logs by line.
- Full regex mode

  Logtail can be used to collect logs in the full regex mode. For more information, see Use regular expressions to collect logs.
- Delimiter mode

  Logtail can be used to collect logs in the delimiter mode. For more information, see Collect DSV formatted logs.
- JSON mode

  Logtail can be used to collect logs in the JSON mode. For more information, see Collect JSON logs.
- NGINX configuration mode

  Logtail can be used to collect logs in the NGINX configuration mode. For more information, see Collect NGINX logs.
- IIS configuration mode

  Logtail can be used to collect logs in the IIS configuration mode. For more information, see Collect IIS logs.
- Apache configuration mode

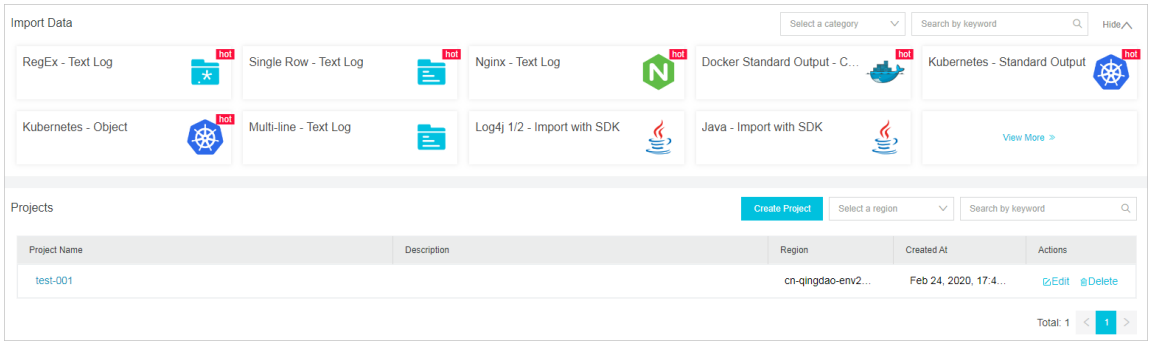
  Logtail can be used to collect logs in the Apache configuration mode. For more information, see Collect logs in Apache mode.

Procedure

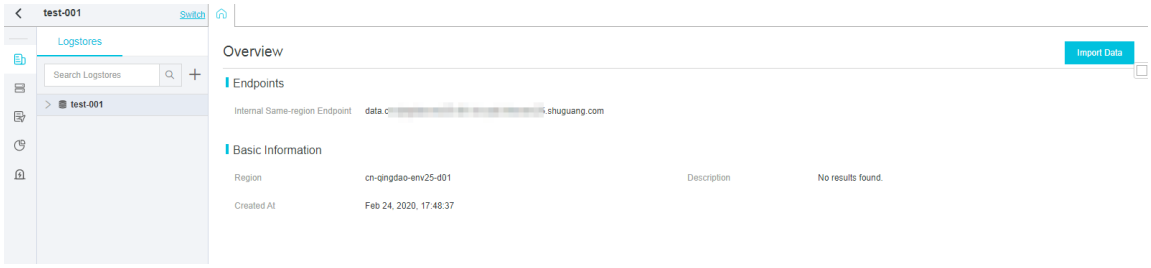
1. Log on to the Log Service console.
2. Select a data source.

   You can use one of the following three methods to select a data source:

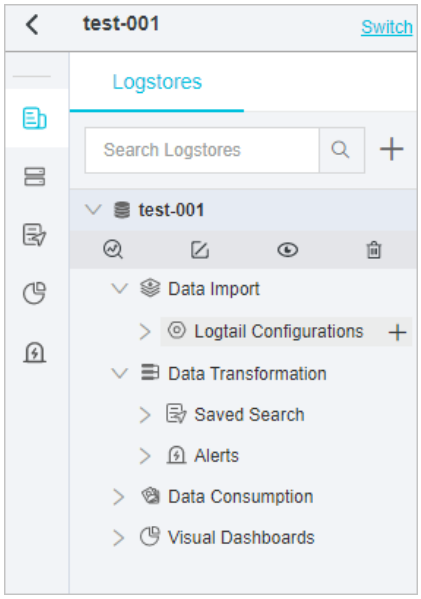
- On the homepage of the Log Service console, select a data source in the **Import Data** section.



- In the **Projects** section, click a project name. On the **Overview** page, click **Import Data**.



- On the Logstores tab in the left-side navigation pane, find a Logstore and click the closing angle bracket (>) in front of the Logstore name. Then, click the plus sign (+) next to **Data Import**.



Select a data source based on your business requirements. Log Service supports the following log sources of text logs: **RegEx-Text Log**, **Single Row-Text Log**, **Multi-Row-Text Log**, **Delimiter Mode-Text Log**, **JSON-Text Log**, **Nginx-Text Log**, **IIS-Text Log**, and **Apache-Text Log**.

3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.

4. Create a server group.

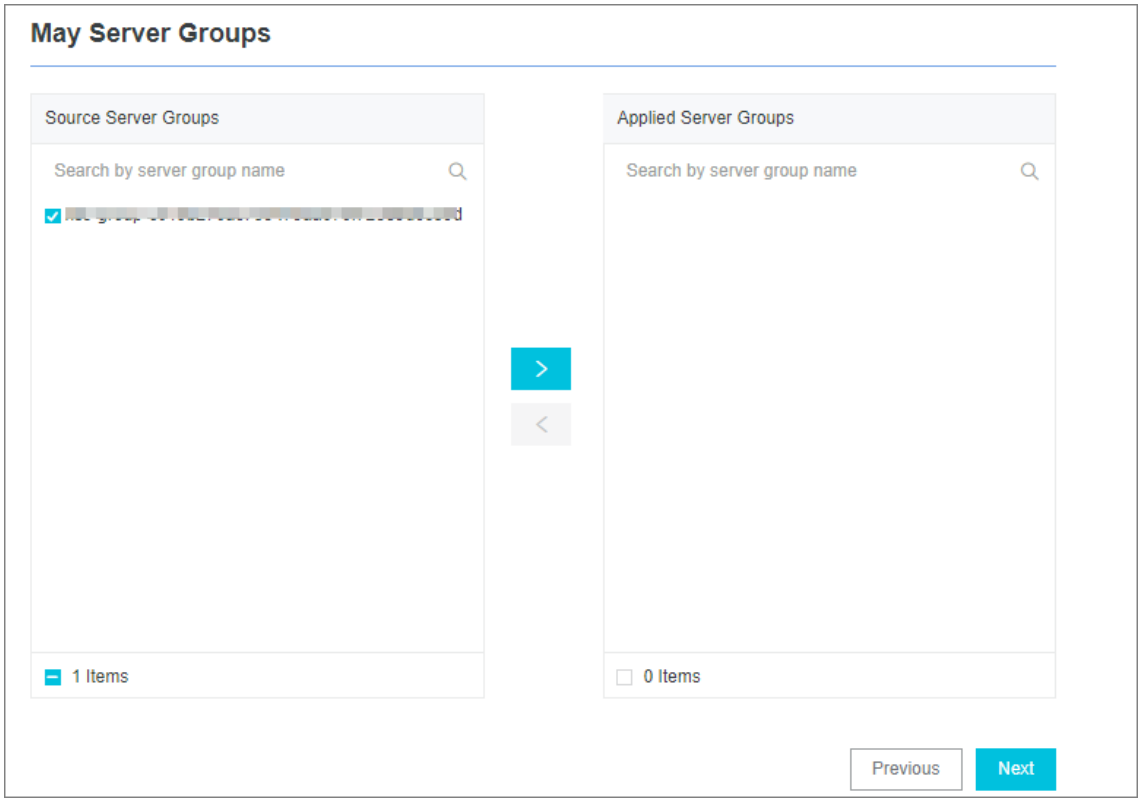
   Before you create a server group, ensure that Logtail is installed.

Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.

5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Specify Logtail parameters.

   Logtail parameters vary based on collection modes. For more information, see the relevant parameters for specific collection modes.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Specify **Advanced Options** based on your business requirements. We recommend that you do not modify the default settings unless otherwise required.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs.
Upload Raw Log	Specifies whether to upload raw logs. If you turn on this switch, raw logs are written to the __raw__ field and uploaded with the parsed logs.
Topic Generation Mode	◦ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic is set to an empty string and you can query logs without the need to enter a topic. ◦ **Server Group Topic Attributes**: This mode is used to differentiate log data that is generated by different frontend servers. ◦ **File Path RegEx**: If you select this mode, you must enter a value in the **Custom RegEx** field to extract part of the path as the topic. This mode is used to differentiate log data that is generated by users or instances.

Parameter	Description
Custom RegEx	Specifies a custom regular expression. If you select **File Path RegEx** for **Topic Generation Mode**, you must enter a custom regular expression.
Log File Encoding	○ utf8: indicates UTF-8 encoding. ○ gbk: indicates GBK encoding.
Timezone	Specifies the time zone where logs are collected. ○ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ○ Custom: Select a time zone.
Timeout	If a log file is not updated within a specific period of time, Logtail considers the file to be timed out. ○ Never: All log files are continuously monitored and never time out. ○ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ○ Collect logs that meet a condition: Set the condition to `Key:level Regex:WARNING|ERROR`. It indicates that only logs with the severity level of WARNING or ERROR are collected. ○ Filter logs that do not meet a condition: ■ Set the condition to `Key:level Regex:^(?!.*(INFO|DEBUG)).*`. It indicates that logs with the severity level of INFO or DEBUG are not collected. ■ Set the condition to `Key:url Regex:.*^(?!.*(healthcheck)).*`. It indicates that logs whose URL contains the keyword healthcheck are not collected. For example, logs in which the key is url and the value is `/inner/healthcheck/jiankong.html` are not collected.

8. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

After you complete the settings, you can start to collect logs.

28.1.3.1.4.2. Collect logs by line

This topic describes how to collect logs by line and configure indexes. You can specify the required settings in the Log Service console.

Context

To collect logs by line, you must select the simple mode. The simple mode can be divided into two types:

- Singleline mode

  In this mode, each line of log data is considered as a log. Two logs in a log file are separated by a line break.

Logtail does not extract log fields in this mode. The default regular expression is `(.*)`. Logtail records the system time of the current server as the timestamp of a log. You can modify or manage advanced Logtail settings after you have completed the configuration procedure. For more information, see Manage a Logtail configuration.

- Multi-line mode

  In the multi-line mode, a regular expression is used to match the first line of a log. The settings in the multi-line mode are similar to the settings in the full regex mode. For more information, see Use regular expressions to collect logs.

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **Single Row-Text Log**.
3. Select a destination project and Logstore, and then click **Next**.

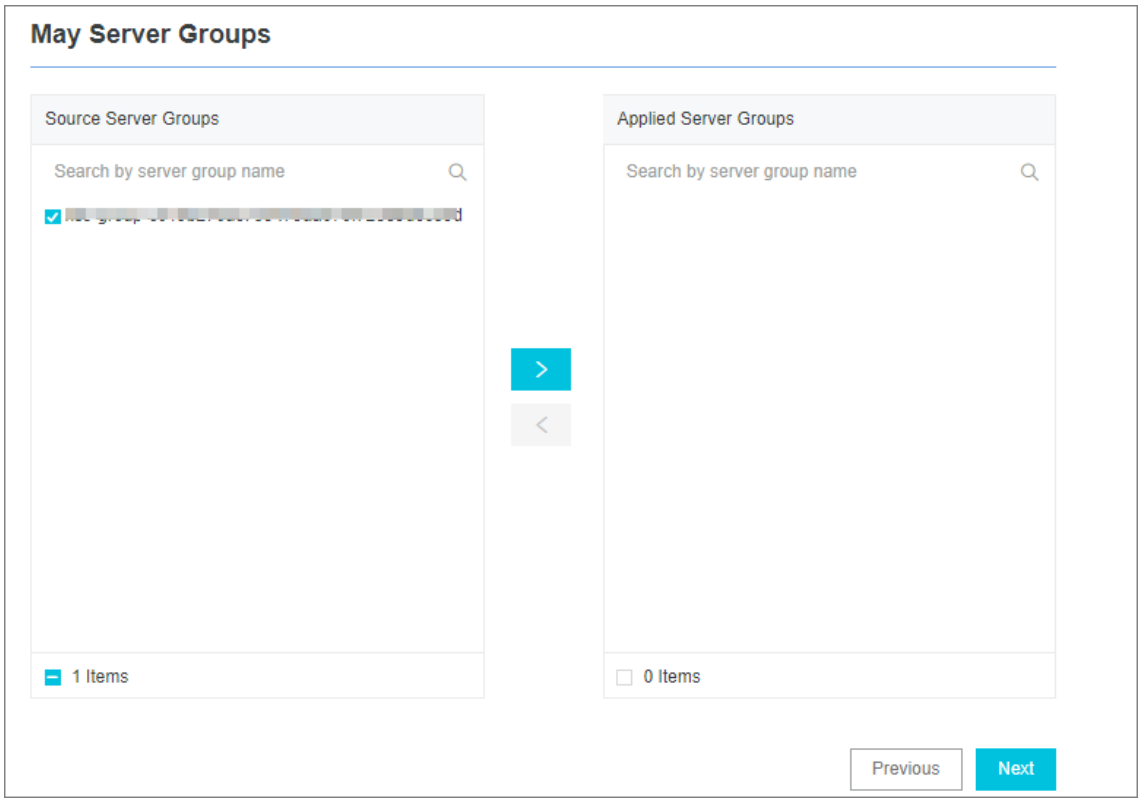
   You can also click **Create Now** to create a project and a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.
5. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



> **Notice** If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

6. Create a Logtail configuration.

   The following table lists the Logtail parameters.

Parameter	Description
Config Name	The configuration name must be 3 to 128 characters in length, and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.
Log Path	The directory and name of the log file. ○ The specified log file name can be a complete file name or a file name that contains wildcards. ○ Recursive directory matching is used in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ■ Example 1: `/apsara/nuwa/ … /*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ■ Example 2: `/var/logs/app_* … /*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ■ Each log file can be collected by using only one Logtail configuration. ■ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If the log file to be collected is in a Docker container, you can configure the internal path and container tag. Logtail monitors the creation and destruction of the container, filters logs of the container based on the tag, and collects the filtered logs.
Mode	If you have specified **Single Row-Text Log** for the data source, the default mode is **Simple Mode**. You can change the mode.
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory that is specified in the log path is monitored.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Set the parameters in the Advanced Options section based on your business requirements. We recommend

that you do not modify the settings. The following table describes the parameters in the Advanced Options section.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs. **Note** If you turn on **Enable Plug-in Processing**, specific parameters such as Upload Raw Log, Timezone, Drop Failed to Parse Logs, Filter Configuration, and Incomplete Entry Upload (Delimiter mode) become unavailable.
Upload Raw Log	If you turn on **Upload Raw Log**, each raw log is uploaded to Log Service as a value of the __raw__ field together with the parsed log.
Topic Generation Mode	The topic generation mode. ○ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic field is set to an empty string. You do not need to enter a topic to query logs. ○ **Machine Group Topic Attributes**: This mode is used to differentiate logs that are generated by different servers. ○ **File Path RegEx**: In this mode, you must specify a regular expression in the **Custom RegEx** field. The part of a log path that matches the regular expression is used as the topic. This mode is used to differentiate logs that are generated by different users or instances.
Custom RegEx	If you set the Topic Generation Mode parameter to **File Path RegEx**, you must enter a custom regular expression.
Log File Encoding	The encoding format of log files. Valid values: ○ utf8: UTF-8 encoding format ○ gbk: GBK encoding format
Timezone	The time zone where logs are collected. Valid values: ○ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ○ Custom: If you select this value, you must select a time zone.
Timeout	The timeout period of log files. If a log file is not updated within the specified period, Logtail reckons the file to be timed out. Valid values: ○ Never: All log files are continuously monitored and never time out. ○ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file. If you select **30 Minute Timeout**, you must specify the **Maximum Timeout Directory Depth** parameter. Valid values: 1 to 3.

Parameter	Description
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ○ Collect logs that meet specified conditions: If you set **Key** to **level** and **Regex** to **WARNING|ERROR**, only WARNING-level and ERROR-level logs are collected. ○ Filter out logs that do not meet specified conditions. ■ If you set **Key** to **level** and **Regex** to **^(?!.*(INFO|DEBUG)).***, INFO-level or DEBUG-level logs are not collected. ■ If you set **Key** to **url** and **Regex** to **.*^(?!.*(healthcheck)).***, logs whose URLs contain healthcheck are not collected. For example, the log is not collected if the value of the Key field is url and the value of the Value field is /inner/healthcheck/jiankong.html.

8. Configure indexes in the Configure Query and Analysis step. Click **Next**.

   By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

   > **Note**
   > ○ To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
   > ○ If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

After you complete the settings, you can start to collect logs by line.

28.1.3.1.4.3. Use regular expressions to collect logs

This topic describes how to collect logs by using regular expressions and configure indexes. You can specify the required settings in the Log Service console.

Context

If you need to collect multi-line logs and extract fields from logs, we recommend that you use regular expressions. Log Service can generate a regular expression based on a sample log that you enter in the **Import Data** wizard. However, you must modify the expression to match fields in the sample log as expected. For more information, see How do I test a regular expression?.

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **RegEx-Text Log**.
3. Select a destination project and Logstore, and then click **Next**.

   You can also click **Create Now** to create a project and a Logstore.

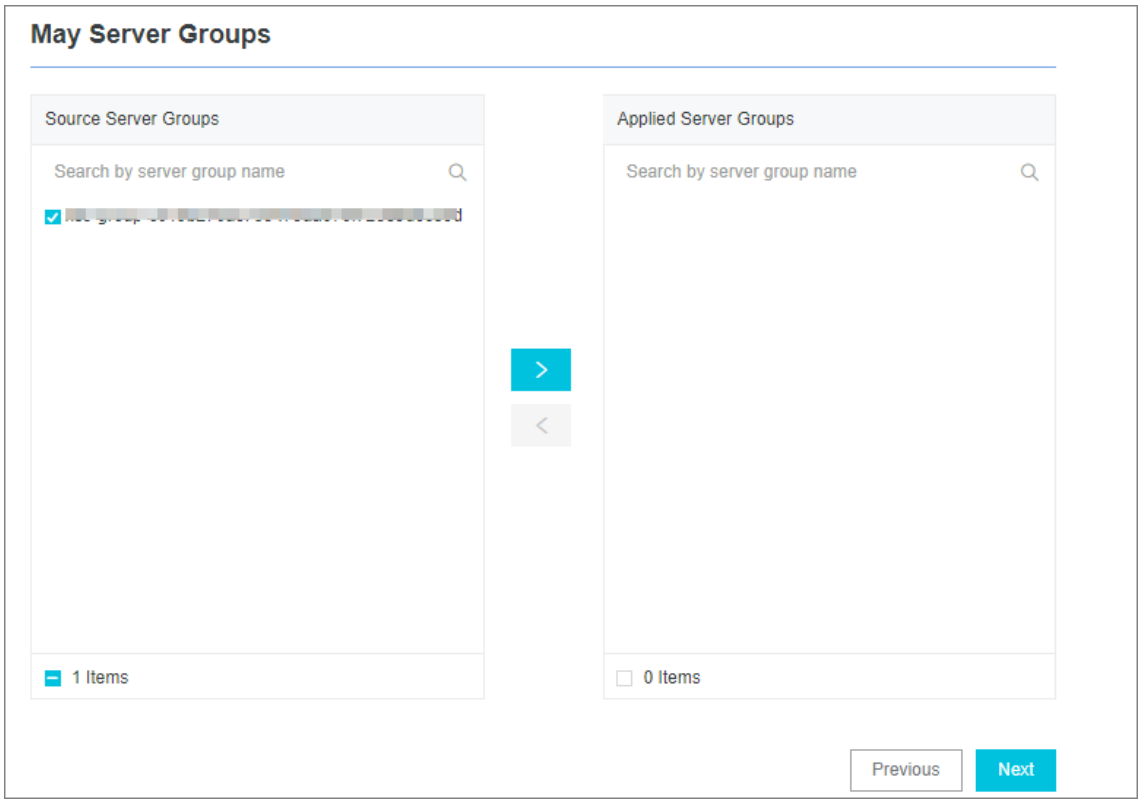
   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.

5. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



> **Notice** If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

6. Create a Logtail configuration.

The following table lists the Logtail parameters.

Parameter	Description
Config Name	The configuration name must be 3 to 128 characters in length, and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.

Parameter	Description
Log Path	The directory and name of the log file. ○ The specified log file name can be a complete file name or a file name that contains wildcards. ○ Recursive directory matching is used in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ■ Example 1: `/apsara/nuwa/ … /*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ■ Example 2: `/var/logs/app_* … /*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ■ Each log file can be collected by using only one Logtail configuration. ■ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If the log file to be collected is in a Docker container, you can configure the internal path and container tag. Logtail monitors the creation and destruction of the container, filters logs of the container based on the tag, and collects the filtered logs.
Mode	If you have specified **RegEx-Text Log** for the data source, the default mode is **Full Regex Mode**. You can change the mode.
Singleline	The singleline mode is enabled by default. In this mode, logs are separated by line. To collect multi-line logs, such as Java program logs, you must disable the **Singleline** mode and configure **Regex to Match First Line**.
Log Sample	Enter a sample log that is retrieved from the data source. Then, Log Service generates a regular expression.
Regex to Match First Line	You can click **Auto Generate** or **Manual**. After you enter a sample log entry and click **Auto Generate**, the system generates a regular expression. If no regular expression is generated, you can switch to the manual mode and enter a regular expression for verification.
Extract Field	To analyze and process specific fields in logs, you can turn on the **Extract Field** switch. Then, the specified fields are converted to key-value pairs and sent to Log Service. You must specify a regular expression to parse the log content.

Parameter	Description
RegEx	If you turn on the Extract Field switch, you must specify this setting. ○ Automatically generate a regular expression You can select the fields to be extracted from the sample log and then click Generate Regular Expression. The system generates a regular expression. ○ Enter a regular expression You can also enter a regular expression. Click **Manually** to switch to the manual mode. After you enter a regular expression, click **Validate** to check whether the regular expression can parse the log content. For more information, see How do I test a regular expression?.
Extracted Content	If you turn on the **Extract Field** switch, you must specify this setting. After a regular expression is automatically generated or manually specified, you must specify the key name for each extracted field.
Use System Time	If you turn on the **Extract Field** switch, you must specify this setting. If you turn off the **Use System Time** switch, you must specify a field as the time field and name this field `time`. After you specify the `time` field, click **Auto Generate** in the **Time Conversion Format** field to automatically parse the time. For more information, see Configure the time format.
Drop Failed to Parse Logs	Specifies whether to upload logs to Log Service if the logs fail to be parsed. ○ If you turn on this switch, logs that fail to be parsed are not uploaded to Log Service. ○ If you turn off this switch, raw logs are uploaded to Log Service when logs fail to be parsed.
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory specified in the log path is monitored.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Set the parameters in the Advanced Options section based on your business requirements. We recommend that you do not modify the settings. The following table describes the parameters in the Advanced Options section.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs. **Note** If you turn on **Enable Plug-in Processing**, specific parameters such as Upload Raw Log, Timezone, Drop Failed to Parse Logs, Filter Configuration, and Incomplete Entry Upload (Delimiter mode) become unavailable.

Parameter	Description
Upload Raw Log	If you turn on **Upload Raw Log**, each raw log is uploaded to Log Service as a value of the __raw__ field together with the parsed log.
Topic Generation Mode	The topic generation mode. ○ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic field is set to an empty string. You do not need to enter a topic to query logs. ○ **Machine Group Topic Attributes**: This mode is used to differentiate logs that are generated by different servers. ○ **File Path RegEx**: In this mode, you must specify a regular expression in the **Custom RegEx** field. The part of a log path that matches the regular expression is used as the topic. This mode is used to differentiate logs that are generated by different users or instances.
Custom RegEx	If you set the Topic Generation Mode parameter to **File Path RegEx**, you must enter a custom regular expression.
Log File Encoding	The encoding format of log files. Valid values: ○ utf8: UTF-8 encoding format ○ gbk: GBK encoding format
Timezone	The time zone where logs are collected. Valid values: ○ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ○ Custom: If you select this value, you must select a time zone.
Timeout	The timeout period of log files. If a log file is not updated within the specified period, Logtail reckons the file to be timed out. Valid values: ○ Never: All log files are continuously monitored and never time out. ○ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file. If you select **30 Minute Timeout**, you must specify the **Maximum Timeout Directory Depth** parameter. Valid values: 1 to 3.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ○ Collect logs that meet specified conditions: If you set **Key** to **level** and **Regex** to **WARNING|ERROR**, only WARNING-level and ERROR-level logs are collected. ○ Filter out logs that do not meet specified conditions. ■ If you set **Key** to **level** and **Regex** to **^(?!.*(INFO|DEBUG)).***, INFO-level or DEBUG-level logs are not collected. ■ If you set **Key** to **url** and **Regex** to **.*^(?!.*(healthcheck)).***, logs whose URLs contain healthcheck are not collected. For example, the log is not collected if the value of the Key field is url and the value of the Value field is /inner/healthcheck/jiankong.html.

8. Configure indexes in the Configure Query and Analysis step. Click **Next**.

   By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

   > **Note**
   > - To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
   > - If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

After you complete the settings, you can start to use regular expressions to collect logs.

28.1.3.1.4.4. Collect DSV formatted logs

This topic describes how to collect delimiter-separated values (DSV) formatted logs and configure indexes. You can specify the required settings in the Log Service console.

Context

DSV formatted logs use line feeds as boundaries. Each line is a log entry. The fields of each log entry are separated with a fixed delimiter. The characters that can be used as delimiters include the tab (\t), space, vertical bar (|), comma (,), and semicolon (;). A field that contains a delimiter must be enclosed in double quotation marks (""), which are used as quotes.

Log formats

Common DSV formatted logs include comma-separated values (CSV) and tab-separated values (TSV) formatted logs.

A delimiter can contain a **single character** or **multiple characters**.

Single-character delimiter

You can specify a single-character delimiter and a quote in the console.

- **Delimiter**: The fields of each log entry are separated with a single-character delimiter, such as the tab (`\t`), vertical bar (`|`), space, comma (`,`), and semicolon (`;`). You can also specify a non-printable character as the delimiter.

  > **Note** A double quotation mark (`"`) cannot be used as a delimiter.

  If a double quotation mark (") is included in a log entry but not used as a quote, it must be escaped and processed as double quotation marks (`""`). When Log Service parse logs, it restores double quotation marks (`""`) into a double quotation mark (`"`). You can use a double quotation mark (`"`) on each boundary of a field as a quote. You can also use a double quotation mark (escaped as `""`) in the content of a field. If the use of a double quotation mark (") does not comply with the defined format, you can use the simple mode or full regex mode to parse fields.

  For example, assume that you use commas (,) as delimiters and include double quotation marks (“”) and commas (,)in a field. Enclose the field with quotes and escape the double quotation marks into `""` . For example, a processed log is `1999,Chevy,"Venture ""Extended Edition, Very Large""",,5000.00` . The log can be parsed into five fields: `1999` , `Chevy` , `Venture "Extended Edition, Very Large"` , empty field, and `5000.00` .

- **Quote**: If a log field contains delimiters, you must specify a quote to enclose the field. Otherwise, the field cannot be parsed as expected. Log Service parses the content enclosed in quotes as one field. Only delimiters

can exist between fields.

You can use one of the following characters as the quote: tab (`\t`), vertical bar (`|`), space, comma (`,`), semicolon (`;`), and non-printable characters.

For example, a log is `1997,Ford,E350,"ac, abs, moon",3000.00` . In this example, the comma (`,`) is used as the delimiter and the double quotation mark (") is used as the quote. The log entry can be parsed into five fields: `1997` , `Ford` , `E350` , `ac, abs, moon` , and `3000.00` . Among the five fields, `ac, abs, moon` enclosed in quotes is regarded as one field.

Note Log Service allows you to use a non-printable character as a delimiter or quote. Non-printable characters are characters whose decimal ASCII codes are within the range of 1 to 31 and 127. If you use a non-printable character as a delimiter or quote, you must find the hexadecimal ASCII code of this character and enter the character in the following format: `0x`*the hexadecimal ASCII code of the non-printable character* . For example, to use the non-printable character whose decimal ASCII code is 1 and hexadecimal ASCII code is 01, you must enter `0x01` .

Multi-character delimiter

Each **multi-character delimiter** can contain two or three characters, such as `||` , `&&&` , and `^_^` . If you specify a multi-character delimiter, Log Service parses logs only based on the delimiter. You do not need to use quotes to enclose log fields.

Note You must ensure that log fields do not contain the delimiter. Otherwise, Log Service cannot parse these fields as expected.

For example, if the delimiter is set to `&&` , the log `1997&&Ford&&E350&&ac&abs&moon&&3000.00` is parsed into five fields: `1997` , `Ford` , `E350` , `ac&abs&moon` , and `3000.00` .

Sample logs

- **Single-character delimiter**

```
05/May/2016:13:30:28,10.10. *. *,"POST /PutData? Category=YunOsAccountOpLog&AccessKeyId=**********
******&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=********************

**************** HTTP/1.1&&401&&23472&&aliyun-sdk-java
```

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **Delimiter-Text Log**.
3. Select a destination project and Logstore, and then click **Next**.

   You can also click **Create Now** to create a project and a Logstore.

If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.

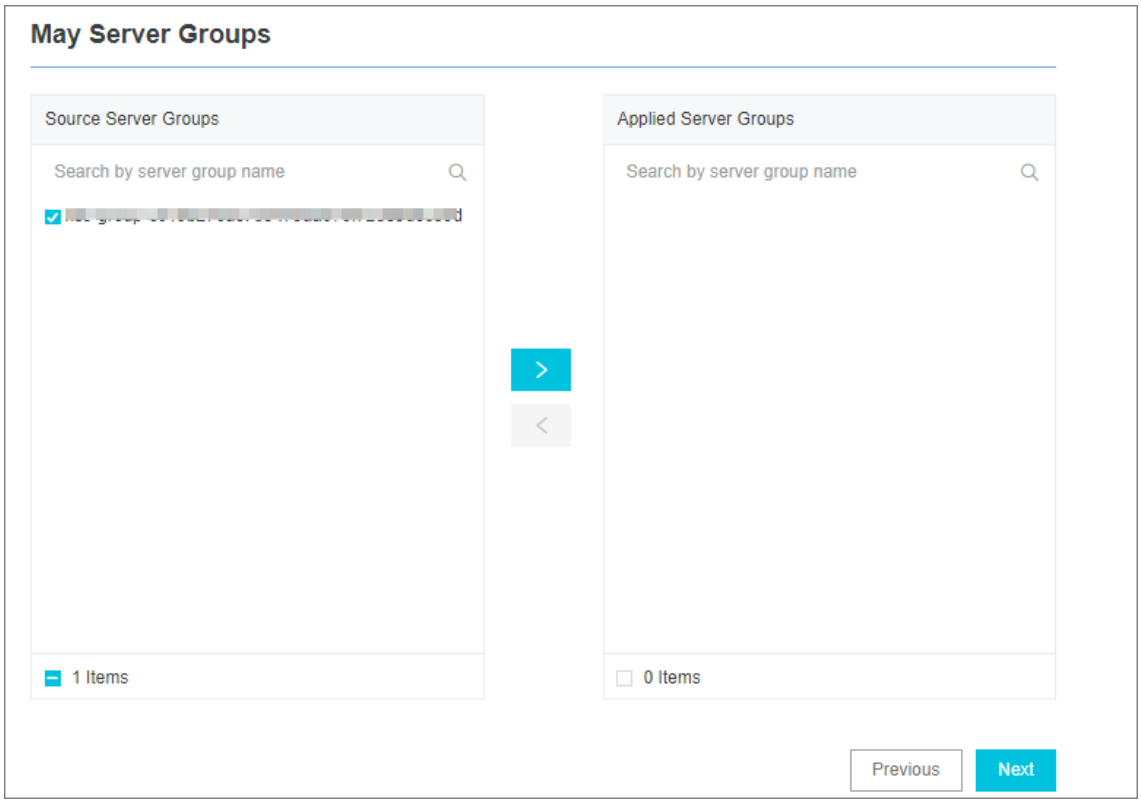
4. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.

5. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



> **Notice** If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

6. Create a Logtail configuration file.

   The following table lists the Logtail parameters.

Parameter	Description
Config Name	The name must be 3 to 128 characters in length, and can contain only lowercase letters, digits, hyphens (-), and underscores (_). The name must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.

Parameter	Description
Log Path	The directory and name of the log file. ○ The specified log file name can be a complete file name or a file name that contains wildcards. ○ Recursive directory matching is used in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ■ Example 1: `/apsara/nuwa/ … /*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ■ Example 2: `/var/logs/app_* … /*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ■ Each log file can be collected by using only one Logtail configuration file. ■ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If you collect logs from Docker containers, you can configure the paths and tags of the containers. Logtail monitors the containers when they are created and destroyed, filters the logs of the containers by tag, and collects the filtered logs.
Mode	If you have specified **Delimiter-Text Log** for the data source, the default mode is **Delimiter Mode**. You can change the mode.
Log Sample	Enter a sample log entry that is retrieved from a log source in an actual scenario. Then, Log Service extracts a regular expression from the log entry.
Delimiter	Select a delimiter. Select a delimiter based on the log format. Otherwise, logs may fail to be parsed. **Note** If you use a non-printable character as a delimiter, you must find the hexadecimal ASCII code of this character and enter the character in the following format: `0x`*the hexadecimal ASCII code of the non-printable character*. For example, to use the non-printable character whose decimal ASCII code is 1 and hexadecimal ASCII code is 01, you must enter `0x01`.

Parameter	Description
Quote	Select a quote. Select a quote based on the log format. Otherwise, logs may fail to be parsed. **Note** If you use a non-printable character as a quote, you must find the hexadecimal ASCII code of this character and enter the character in the following format: `0x`*the hexadecimal ASCII code of the non-printable character*. For example, to use the non-printable character whose decimal ASCII code is 1 and hexadecimal ASCII code is 01, you must enter `0x01`.
Extracted Content	After you enter a sample log and select a delimiter, Log Service extracts log fields based on the delimiter and defines the fields as values. You must specify a key for each value.
Incomplete Entry Upload	This feature specifies whether to upload a log entry whose number of parsed fields is less than the number of the specified keys. If you turn on this switch, the log entry is uploaded. Otherwise, the log entry is dropped. For example, if you set the delimiter to the vertical bar (`|`), the log entry `11|22|33|44|55` can be parsed into the following fields: `11`, `22`, `33`, `44`, and `55`. You can set the keys to `A`, `B`, `C`, `D`, and `E`. If you turn on the **Incomplete Entry Upload** switch, the `55` field is uploaded as the value of the `D` key when Log Service collects the log entry `11|22|33|55`. If you turn off the **Incomplete Entry Upload** switch, Log Service drops the log entry because the fields and keys do not match.
Use System Time	If you turn on the Extract Field switch, you must specify this setting. If you turn off the Use System Time switch, you must specify a field as the time field and name this field `time`. After you specify the `time` field, click **Auto Generate** in the **Time Conversion Format** field to automatically parse the time. For more information, see Configure the time format.
Drop Failed to Parse Logs	Specifies whether to upload logs to Log Service if the logs fail to be parsed. ○ If you turn on this switch, logs that fail to be parsed are not uploaded to Log Service. ○ If you turn off this switch, raw logs are uploaded to Log Service when logs fail to be parsed.
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory that is specified in the log path is monitored.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Set the parameters in the Advanced Options section based on your business requirements. We recommend that you do not modify the settings. The following table describes the parameters in the Advanced Options section.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs. **Note** If you turn on **Enable Plug-in Processing**, specific parameters such as Upload Raw Log, Timezone, Drop Failed to Parse Logs, Filter Configuration, and Incomplete Entry Upload (Delimiter mode) become unavailable.
Upload Raw Log	If you turn on **Upload Raw Log**, each raw log is uploaded to Log Service as a value of the __raw__ field together with the parsed log.
Topic Generation Mode	The topic generation mode. ○ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic field is set to an empty string. You do not need to enter a topic to query logs. ○ **Machine Group Topic Attributes**: This mode is used to differentiate logs that are generated by different servers. ○ **File Path RegEx**: In this mode, you must specify a regular expression in the **Custom RegEx** field. The part of a log path that matches the regular expression is used as the topic. This mode is used to differentiate logs that are generated by different users or instances.
Custom RegEx	If you set the Topic Generation Mode parameter to **File Path RegEx**, you must enter a custom regular expression.
Log File Encoding	The encoding format of log files. Valid values: ○ utf8: UTF-8 encoding format ○ gbk: GBK encoding format
Timezone	The time zone where logs are collected. Valid values: ○ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ○ Custom: If you select this value, you must select a time zone.
Timeout	The timeout period of log files. If a log file is not updated within the specified period, Logtail reckons the file to be timed out. Valid values: ○ Never: All log files are continuously monitored and never time out. ○ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file. If you select **30 Minute Timeout**, you must specify the **Maximum Timeout Directory Depth** parameter. Valid values: 1 to 3.

Parameter	Description
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ○ Collect logs that meet specified conditions: If you set **Key** to **level** and **Regex** to **WARNING|ERROR**, only WARNING-level and ERROR-level logs are collected. ○ Filter out logs that do not meet specified conditions. ■ If you set **Key** to **level** and **Regex** to **^(?!.*(INFO|DEBUG)).***, INFO-level or DEBUG-level logs are not collected. ■ If you set **Key** to **url** and **Regex** to **.*^(?!.*(healthcheck)).***, logs whose URLs contain healthcheck are not collected. For example, the log is not collected if the value of the Key field is url and the value of the Value field is /inner/healthcheck/jiankong.html.

8. Configure indexes in the Configure Query and Analysis step. Click **Next**.

   By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

   > **Note**
   > ○ To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
   > ○ If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

After you complete the settings, you can start to collect DSV formatted logs.

28.1.3.1.4.5. Collect JSON logs

This topic describes how to use Logtail to collect JSON logs and configure indexes. You can specify the required settings in the Log Service console.

Context

Logtail can parse JSON objects from logs. It extracts the keys and values from the first layer of an object as the names and values of log fields. The valid data types of field values include object, array, and primitive data types such as string or number.

JSON logs can be written in the following two types of structures:

- Object: a collection of key-value pairs.
- Array: an ordered list of values.

Lines of JSON logs are separated with `\n`. Each line is extracted as a single log.

Logtail can parse only JSON logs of the object type. If you want to parse JSON logs of other types, such as JSON arrays, you must use regular expressions to extract the fields or specify the simple mode to collect logs by line.

Sample log

A sample JSON log is as follows:

{"url": "POST /PutData? Category=YunOsAccountOpLog&AccessKeyId=U0Ujpek********&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=pD12XYLmGxKQ%2Bmkd6x7hAgQ7b1c%3D HTTP/1.1", "ip": "10.200.98.220", "user-agent": "aliyun-sdk-java", "request": {"status": "200", "latency": "18204"}, "time": "05/May/2016:13:30:28"}
{"url": "POST /PutData? Category=YunOsAccountOpLog&AccessKeyId=U0Ujpek********&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=pD12XYLmGxKQ%2Bmkd6x7hAgQ7b1c%3D HTTP/1.1", "ip": "10.200.98.210", "user-agent": "aliyun-sdk-java", "request": {"status": "200", "latency": "10204"}, "time": "05/May/2016:13:30:29"}

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **JSON-Text Log**.
3. Select a destination project and Logstore, and then click **Next**.

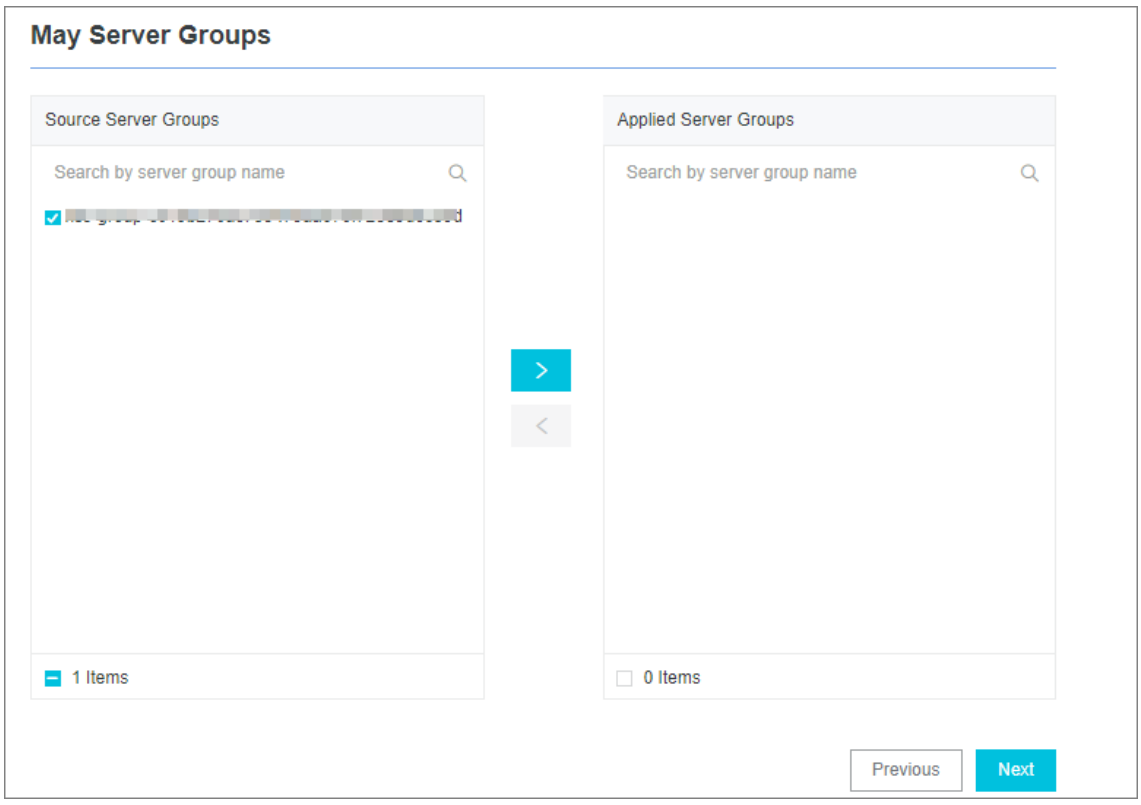
   You can also click **Create Now** to create a project and a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.
5. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



> **Notice** If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

6. Create a Logtail configuration.

   The following table lists the Logtail parameters.

Parameter	Description
Config Name	The configuration name must be 3 to 128 characters in length, and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.
Log Path	The directory and name of the log file. ○ The specified log file name can be a complete file name or a file name that contains wildcards. ○ Recursive directory matching is used in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ■ Example 1: `/apsara/nuwa/ … /*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ■ Example 2: `/var/logs/app_* … /*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ■ Each log file can be collected by using only one Logtail configuration. ■ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If the log file to be collected is in a Docker container, you can configure the internal path and container tag. Logtail monitors the creation and destruction of the container, filters logs of the container based on the tag, and collects the filtered logs.
Mode	If you have specified **JSON-Text Log** for the data source, the default mode is **JSON Mode**. You can change the mode.
Use System Time	If you turn on the Extract Field switch, you must specify this parameter. If you turn off the Use System Time switch, you must specify a field as the time field and name this field `time` . After you specify the `time` field, click **Auto Generate** in the **Time Conversion Format** field to automatically parse the time. For more information, see Configure the time format.

Parameter	Description
Drop Failed to Parse Logs	Specifies whether to upload logs to Log Service if the logs fail to be parsed. ○ If you turn on this switch, logs that fail to be parsed are not uploaded to Log Service. ○ If you turn off this switch, raw logs are uploaded to Log Service when logs fail to be parsed.
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory specified in the log path is monitored.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Set the parameters in the Advanced Options section based on your business requirements. We recommend that you do not modify the settings. The following table describes the parameters in the Advanced Options section.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs. **Note** If you turn on **Enable Plug-in Processing**, specific parameters such as Upload Raw Log, Timezone, Drop Failed to Parse Logs, Filter Configuration, and Incomplete Entry Upload (Delimiter mode) become unavailable.
Upload Raw Log	If you turn on **Upload Raw Log**, each raw log is uploaded to Log Service as a value of the __raw__ field together with the parsed log.
Topic Generation Mode	The topic generation mode. ○ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic field is set to an empty string. You do not need to enter a topic to query logs. ○ **Machine Group Topic Attributes**: This mode is used to differentiate logs that are generated by different servers. ○ **File Path RegEx**: In this mode, you must specify a regular expression in the **Custom RegEx** field. The part of a log path that matches the regular expression is used as the topic. This mode is used to differentiate logs that are generated by different users or instances.
Custom RegEx	If you set the Topic Generation Mode parameter to **File Path RegEx**, you must enter a custom regular expression.
Log File Encoding	The encoding format of log files. Valid values: ○ utf8: UTF-8 encoding format ○ gbk: GBK encoding format

Parameter	Description
Timezone	The time zone where logs are collected. Valid values: ○ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ○ Custom: If you select this value, you must select a time zone.
Timeout	The timeout period of log files. If a log file is not updated within the specified period, Logtail reckons the file to be timed out. Valid values: ○ Never: All log files are continuously monitored and never time out. ○ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file. If you select **30 Minute Timeout**, you must specify the **Maximum Timeout Directory Depth** parameter. Valid values: 1 to 3.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ○ Collect logs that meet specified conditions: If you set **Key** to **level** and **Regex** to **WARNING|ERROR**, only WARNING-level and ERROR-level logs are collected. ○ Filter out logs that do not meet specified conditions. ■ If you set **Key** to **level** and **Regex** to **^(?!.*(INFO|DEBUG)).***, INFO-level or DEBUG-level logs are not collected. ■ If you set **Key** to **url** and **Regex** to **.*^(?!.*(healthcheck)).***, logs whose URLs contain healthcheck are not collected. For example, the log is not collected if the value of the Key field is url and the value of the Value field is /inner/healthcheck/jiankong.html.

8. Configure indexes in the Configure Query and Analysis step. Click **Next**.

   By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

   > **Note**
   > ○ To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
   > ○ If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

After you complete the settings, you can start to collect JSON logs.

28.1.3.1.4.6. Collect NGINX logs

This topic describes how to collect NGINX logs and configure indexes. You can connect Log Service to NGINX and specify the required settings in the Log Service console.

Context

The NGINX log format and path are specified in the */etc/nginx/nginx.conf* configuration file.

NGINX log format

In the configuration file, the format of NGINX logs is defined as follows:

```
log_format main  '$remote_addr - $remote_user [$time_local] "$request" '
                 '$request_time $request_length '
                 '$status $body_bytes_sent "$http_referer" '
                 '"$http_user_agent"';
```

The path of the log file is declared as follows. The "main" portion that follows the path indicates that logs are written in the preceding format.

```
access_log /var/logs/nginx/access.log main
```

Sample log

A sample NGINX log is as follows:

```
192.168.1.2 - - [10/Jul/2015:15:51:09 +0800] "GET /ubuntu.iso HTTP/1.0" 0.000 129 404 168 "-" "Wget/1
.11.4 Red Hat modified"
```

NGINX log fields

Field	Description
remote_addr	The IP address of the client.
remote_user	The username of the client.
request	The URL and HTTP protocol of the request.
status	The status of the request.
body_bytes_sent	The number of bytes in the response that is returned to the client, excluding the size of the response header.
connection	The serial number of a connection.
connection_requests	The number of requests that are received from a connection.
msec	The time when the log is written. The time is measured in seconds, accurate to milliseconds.
pipe	Indicates whether the request is pipelined. If the request is pipelined, the field value is `p`. Otherwise, the field value is `.`.
http_referer	The URL of the web page linked to the resource that is being requested.
“http_user_agent”	The browser information of the client. The information must be enclosed by double quotation marks ("").
request_length	The length of the request. The length includes the request line, request header, and request body.

Field	Description
request_time	The time period for which the request is processed. The time period is measured in seconds, accurate to milliseconds. The time period starts when the first byte is read from the client and ends when the log is written after the last byte is sent to the client.
[$time_local]	The local time in the Common Log Format. The time must be enclosed by brackets [].

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **Nginx-Text Log**.
3. Select a destination project and Logstore, and then click **Next**.

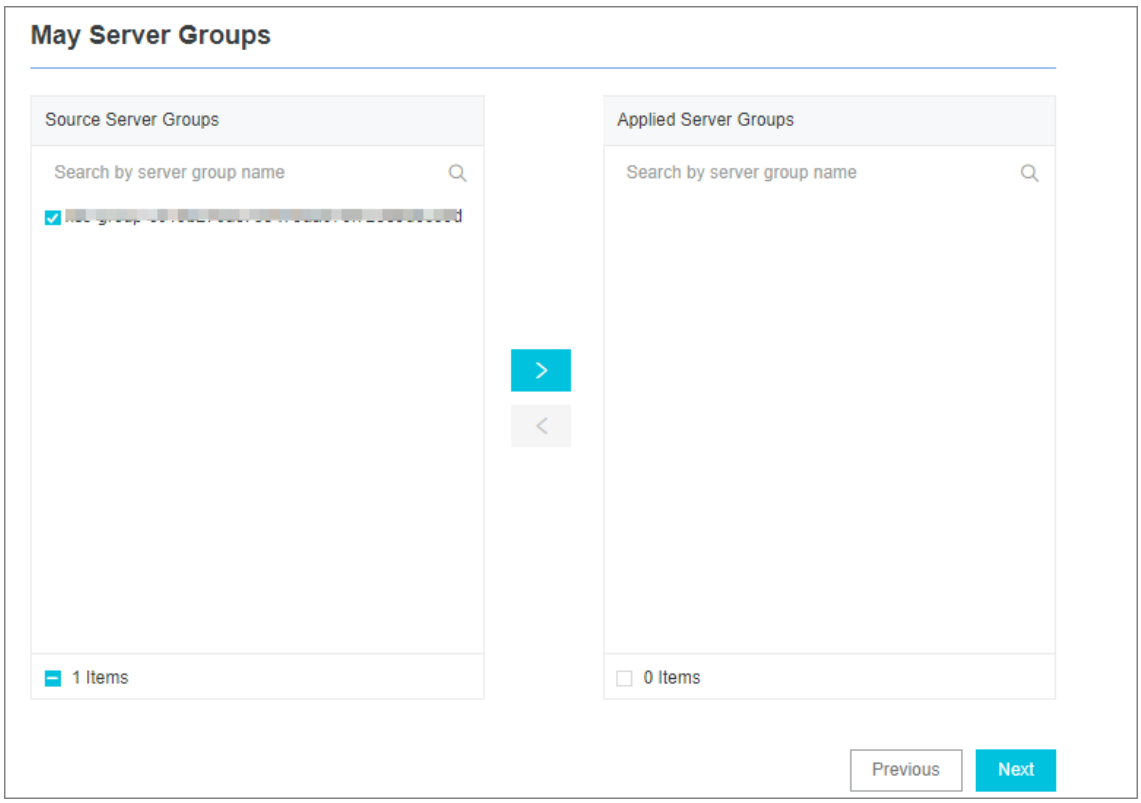
   You can also click **Create Now** to create a project and a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.
5. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



> **Notice** If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

6. Create a Logtail configuration.

   The following table lists the Logtail parameters.

Parameter	Description
Config Name	The configuration name must be 3 to 128 characters in length, and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.
Log Path	The directory and name of the log file. ○ The specified log file name can be a complete file name or a file name that contains wildcards. ○ Recursive directory matching is adopted in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ■ Example 1: `/apsara/nuwa/ … /*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ■ Example 2: `/var/logs/app_* … /*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ■ Each log file can be collected by using only one Logtail configuration. ■ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If the log file to be collected is in a Docker container, you can configure the internal path and container tag. Logtail monitors the creation and destruction of the container, filters logs of the container based on the tag, and collects the filtered logs.
Mode	If you have specified **Nginx-Text Log** for the data source, the default mode is **NGINX Configuration Mode**. You can change the mode.
NGINX Log Configuration	Enter the log configuration section that is specified in a standard NGINX configuration file. The section starts with `log_format`.
NGINX Key	Log Service reads the keys of NGINX logs.

Parameter	Description
Drop Failed to Parse Logs	Specifies whether to upload logs to Log Service if the logs fail to be parsed. ○ If you turn on this switch, logs that fail to be parsed are not uploaded to Log Service. ○ If you turn off this switch, raw logs are uploaded to Log Service when logs fail to be parsed.
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory specified in the log path is monitored.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Set the parameters in the Advanced Options section based on your business requirements. We recommend that you do not modify the settings. The following table describes the parameters in the Advanced Options section.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs. **Note** If you turn on **Enable Plug-in Processing**, specific parameters such as Upload Raw Log, Timezone, Drop Failed to Parse Logs, Filter Configuration, and Incomplete Entry Upload (Delimiter mode) become unavailable.
Upload Raw Log	If you turn on **Upload Raw Log**, each raw log is uploaded to Log Service as a value of the __raw__ field together with the parsed log.
Topic Generation Mode	The topic generation mode. ○ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic field is set to an empty string. You do not need to enter a topic to query logs. ○ **Machine Group Topic Attributes**: This mode is used to differentiate logs that are generated by different servers. ○ **File Path RegEx**: In this mode, you must specify a regular expression in the **Custom RegEx** field. The part of a log path that matches the regular expression is used as the topic. This mode is used to differentiate logs that are generated by different users or instances.
Custom RegEx	If you set the Topic Generation Mode parameter to **File Path RegEx**, you must enter a custom regular expression.
Log File Encoding	The encoding format of log files. Valid values: ○ utf8: UTF-8 encoding format ○ gbk: GBK encoding format

Parameter	Description
Timezone	The time zone where logs are collected. Valid values: ○ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ○ Custom: If you select this value, you must select a time zone.
Timeout	The timeout period of log files. If a log file is not updated within the specified period, Logtail reckons the file to be timed out. Valid values: ○ Never: All log files are continuously monitored and never time out. ○ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file. If you select **30 Minute Timeout**, you must specify the **Maximum Timeout Directory Depth** parameter. Valid values: 1 to 3.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ○ Collect logs that meet specified conditions: If you set **Key** to **level** and **Regex** to **WARNING|ERROR**, only WARNING-level and ERROR-level logs are collected. ○ Filter out logs that do not meet specified conditions. ■ If you set **Key** to **level** and **Regex** to **^(?!.*(INFO|DEBUG)).***, INFO-level or DEBUG-level logs are not collected. ■ If you set **Key** to **url** and **Regex** to **.*^(?!.*(healthcheck)).***, logs whose URLs contain healthcheck are not collected. For example, the log is not collected if the value of the Key field is url and the value of the Value field is /inner/healthcheck/jiankong.html.

8. Configure indexes in the Configure Query and Analysis step. Click **Next**.

   By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

   > **Note**
   > ○ To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
   > ○ If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

After you complete the settings, you can start to collect NGINX logs.

28.1.3.1.4.7. Collect IIS logs

This topic describes how to collect Internet Information Services (IIS) logs and configure indexes. You can specify the required settings in the Log Service console.

Context

To meet log analysis requirements, we recommend that you use the W3C Extended Log File Format. To use this format, click **Select Fields** in the IIS Manager, and then select sc-bytes and cs-bytes in the Standard Fields list.

Log format

The W3C Extended Log File Format is as follows:

```
logExtFileFlags="Date, Time, ClientIP, UserName, SiteName, ComputerName, ServerIP, Method, UriStem, UriQuery, HttpStatus, Win32Status, BytesSent, BytesRecv, TimeTaken, ServerPort, UserAgent, Cookie, Referer, ProtocolVersion, Host, HttpSubStatus"
```

- Field prefixes

Prefix	Description
s-	The server action.
c-	The client action.
cs-	The client-to-server action.
sc-	The server-to-client action.

- Fields

Field	Description
date	The date on which the client sends the request.
time	The time when the client sends the request.
s-sitename	The Internet service name and instance number of the site visited by the client.
s-computername	The name of the server on which the log is generated.
s-ip	The IP address of the server on which the log is generated.
cs-method	The HTTP request method that is used by the client, for example, GET or POST.
cs-uri-stem	The URI resource requested by the client.
cs-uri-query	The query string that follows the question mark (?) in the HTTP request.
s-port	The port number of the server to which the client is connected.
cs-username	The username used by the client to access the server. Authenticated users are referenced as `domain\username`. Anonymous users are indicated by a hyphen (-).
c-ip	The IP address of the client that sends the request.
cs-version	The protocol version that is used by the client, for example, HTTP 1.0 or HTTP 1.1.
user-agent	The browser that is used by the client.
Cookie	The content of the sent or received cookie. A hyphen (-) is used if no cookie is sent or received.

Field	Description
referer	The site that the client last visited. This site provides a link to the current site.
cs-host	The header name of the host.
sc-status	The HTTP or FTP status code that is returned by the server.
sc-substatus	The HTTP substatus code that is returned by the server.
sc-win32-status	The Windows status code that is returned by the server.
sc-bytes	The number of bytes that are sent by the server.
cs-bytes	The number of bytes that are received by the server.
time-taken	The processing time of the request. Unit: milliseconds.

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **IIS-Text Log**.
3. Select a destination project and Logstore, and then click **Next**.

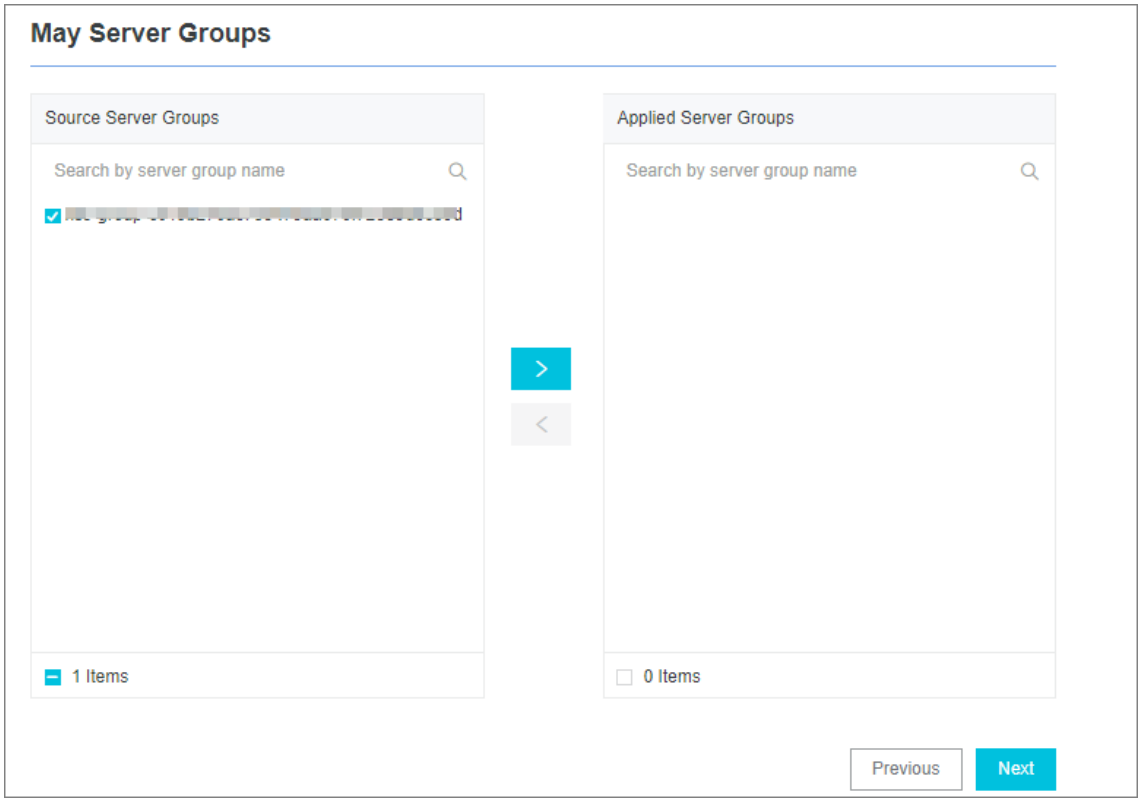
   You can also click **Create Now** to create a project and a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.
5. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



Notice If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

6. Create a Logtail configuration.

   The following table lists the Logtail parameters.

Parameter	Description
Config Name	The configuration name must be 3 to 128 characters in length, and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.

Parameter	Description
Log Path	The directory and name of the log file. ○ The specified log file name can be a complete file name or a file name that contains wildcards. ○ Recursive directory matching is used in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ■ Example 1: `/apsara/nuwa/ … /*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ■ Example 2: `/var/logs/app_* … /*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ■ Each log file can be collected by using only one Logtail configuration. ■ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If the log file to be collected is in a Docker container, you can configure the internal path and container tag. Logtail monitors the creation and destruction of the container, filters logs of the container based on the tag, and collects the filtered logs. For more information, see Collect container text logs.
Mode	If you have specified **IIS-Text Log** for the data source, the default mode is **IIS Configuration Mode**. You can change the mode.
Log Format	Select the log format of your IIS server logs. Valid values: ○ IIS: Microsoft IIS log file format ○ NCSA: NCSA Common log file format ○ W3C: W3C Extended Log File Format
IIS Configuration	Enter the log configuration section that is specified in an IIS configuration file. ○ If you select IIS or NCSA, the fields of the IIS log format are preconfigured. ○ If you select W3C, enter the content that is specified for the logFile logExtFileFlags in the configuration file. For more information, see Specify the IIS Configuration field.
IIS Key Name	Log Service reads the keys of IIS logs.

Parameter	Description
Drop Failed to Parse Logs	Specifies whether to upload logs to Log Service if the logs fail to be parsed. ○ If you turn on this switch, logs that fail to be parsed are not uploaded to Log Service. ○ If you turn off this switch, raw logs are uploaded to Log Service when logs fail to be parsed.
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory that is specified in the log path is monitored.

7. Specify the IIS Configuration field.
   i. Open the IIS configuration file.
      - Default path of the IIS5 configuration file: *C:\WINNT\system32\inetsrv\MetaBase.bin*
      - Default path of the IIS6 configuration file: *C:\WINDOWS\system32\inetsrv\MetaBase.xml*
      - Default path of the IIS7 configuration file: *C:\Windows\System32\inetsrv\config\applicationHost.config*
   ii. Find the `logFile logExtFileFlags` field and copy the text in the quotation marks that follow the field name.
   iii. Paste the text into the quotation marks ("") in the **IIS Configuration** field.
8. (Optional)Specify **Advanced Options** and click **Next**.

   Set the parameters in the Advanced Options section based on your business requirements. We recommend that you do not modify the settings. The following table describes the parameters in the Advanced Options section.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs. **Note** If you turn on **Enable Plug-in Processing**, specific parameters such as Upload Raw Log, Timezone, Drop Failed to Parse Logs, Filter Configuration, and Incomplete Entry Upload (Delimiter mode) become unavailable.
Upload Raw Log	If you turn on **Upload Raw Log**, each raw log is uploaded to Log Service as a value of the __raw__ field together with the parsed log.
Topic Generation Mode	The topic generation mode. ○ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic field is set to an empty string. You do not need to enter a topic to query logs. ○ **Machine Group Topic Attributes**: This mode is used to differentiate logs that are generated by different servers. ○ **File Path RegEx**: In this mode, you must specify a regular expression in the **Custom RegEx** field. The part of a log path that matches the regular expression is used as the topic. This mode is used to differentiate logs that are generated by different users or instances.

Parameter	Description
Custom RegEx	If you set the Topic Generation Mode parameter to **File Path RegEx**, you must enter a custom regular expression.
Log File Encoding	The encoding format of log files. Valid values: ○ utf8: UTF-8 encoding format ○ gbk: GBK encoding format
Timezone	The time zone where logs are collected. Valid values: ○ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ○ Custom: If you select this value, you must select a time zone.
Timeout	The timeout period of log files. If a log file is not updated within the specified period, Logtail reckons the file to be timed out. Valid values: ○ Never: All log files are continuously monitored and never time out. ○ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file. If you select **30 Minute Timeout**, you must specify the **Maximum Timeout Directory Depth** parameter. Valid values: 1 to 3.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ○ Collect logs that meet specified conditions: If you set **Key** to **level** and **Regex** to **WARNING|ERROR**, only WARNING-level and ERROR-level logs are collected. ○ Filter out logs that do not meet specified conditions. ■ If you set **Key** to **level** and **Regex** to **^(?!.*(INFO|DEBUG)).***, INFO-level or DEBUG-level logs are not collected. ■ If you set **Key** to **url** and **Regex** to **.*^(?!.*(healthcheck)).***, logs whose URLs contain healthcheck are not collected. For example, the log is not collected if the value of the Key field is url and the value of the Value field is /inner/healthcheck/jiankong.html.

9. Configure indexes in the Configure Query and Analysis step. Click **Next**.

   By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

   > **Note**
   > ○ To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
   > ○ If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

After you complete the settings, you can start to collect IIS logs.

28.1.3.1.4.8. Collect Apache logs

This topic describes how to collect Apache logs and configure indexes. You can specify the required settings in the Log Service console.

Log formats

The Apache configuration file defines two log formats: combined log format and common log format. You can also customize a log format.

- Syntax of the combined log format:

```
LogFormat "%h %l %u %t \"%r\" %>s %b \"%{Referer}i\" \"%{User-Agent}i\"" combined
```

- Syntax of the common log format:

```
LogFormat "%h %l %u %t \"%r\" %>s %b"
```

- Syntax of a custom log format:

```
LogFormat "%h %l %u %t \"%r\" %>s %b \"%{Referer}i\" \"%{User-Agent}i\" %D %f %k %p %q %R %T %I %O
" customized
```

You must specify the log format, log file directory, and log file name in the Apache configuration file. For example, the following declaration in the configuration file indicates that the combined log format is used. The log file directory is */var/log/apache2/access_log* and the log file name is access_log.

```
CustomLog "/var/log/apache2/access_log" combined
```

Apache log fields

Format string	Key name	Description
%a	client_addr	The IP address of the client in the request.
%A	local_addr	The local private IP address.
%b	response_size_bytes	The size of the response. Unit: bytes. If no bytes are sent, the value is “-”.
%B	response_bytes	The size of the response. Unit: bytes. If no bytes are sent, the value is 0.
%D	request_time_msec	The time period for which the request is processed. Unit: milliseconds.
%h	remote_addr	The name of the remote host.
%H	request_protocol_supple	The request protocol.
%l	remote_ident	The identity information that is provided by a remote computer.
%m	request_method_supple	The request method.
%p	remote_port	The port number of the server.
%P	child_process	The ID of the child process.
%q	request_query	The query string. If it does not exist, the value is an empty string.

Format string	Key name	Description
“%r”	request	The request, which includes the method name, address, and HTTP protocol.
%s	status	The HTTP status code for the response.
%>s	status	The HTTP status code for the final response.
%f	filename	The name of the requested file.
%k	keep_alive	The number of keep-alive requests.
%R	response_handler	The type of the handler that generates the response on the server.
%t	time_local	The local time when the server receives the request.
%T	request_time_sec	The time period for which the request is processed. Unit: seconds.
%u	remote_user	The username that you used to log on to the client.
%U	request_uri_supple	The requested URL, excluding query strings.
%v	server_name	The name of the server.
%V	server_name_canonical	The server name based on the UseCanonicalName setting.
%I	bytes_received	The number of bytes that are received by the server. To use this field, you must enable the mod_logio module.
%O	bytes_sent	The number of bytes that are sent by the server. To use this field, you must enable the mod_logio module.
“%{User-Agent}i”	http_user_agent	The information about the client.
“%{Rererer}i”	http_referer	The URL of the web page linked to the resource that is being requested.

Sample log

```
192.168.1.2 - - [02/Feb/2016:17:44:13 +0800] "GET /favicon.ico HTTP/1.1" 404 209 "http://localhost/x1.html" "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_11_3) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/48.0.2564.97 Safari/537.36"
```

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **Apache-Text Log**.
3. Select a destination project and Logstore, and then click **Next**.

You can also click **Create Now** to create a project and a Logstore.

If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.

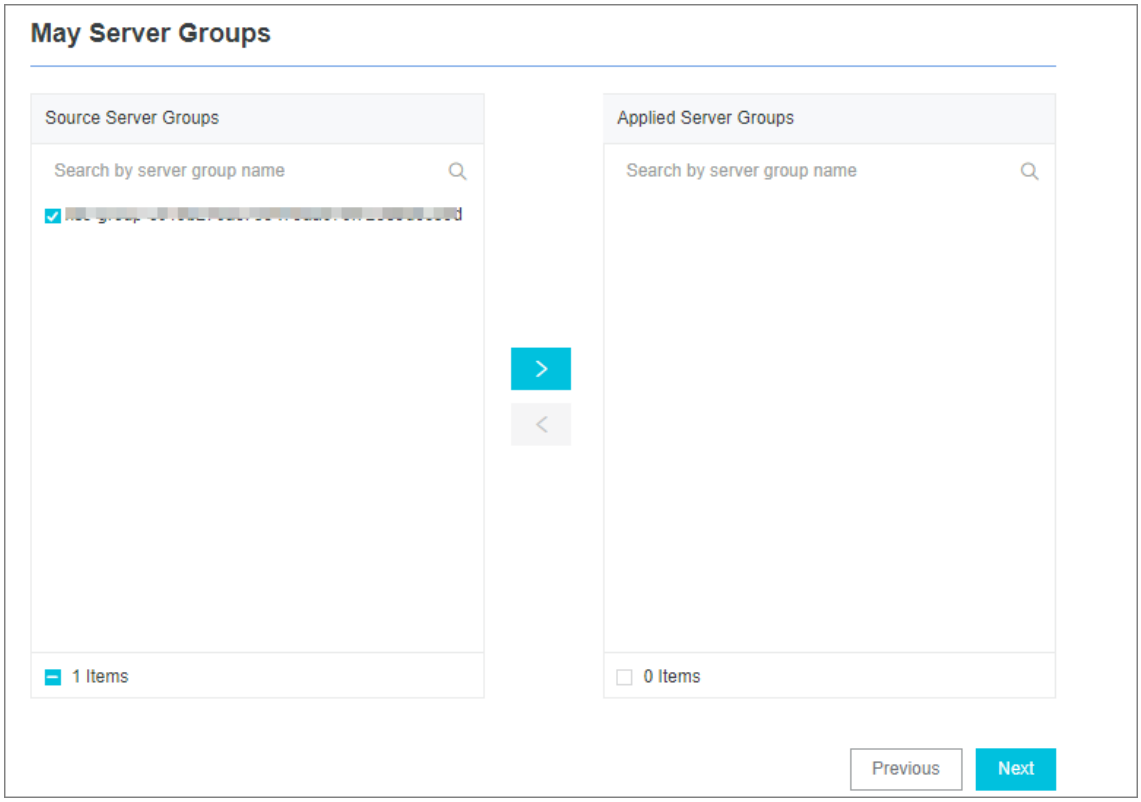
4. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.

5. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



Notice If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

6. Create a Logtail configuration.

   The following table lists the Logtail parameters.

Parameter	Description
Config Name	The configuration name must be 3 to 128 characters in length, and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.

Parameter	Description
Log Path	The directory and name of the log file. ○ The specified log file name can be a complete file name or a file name that contains wildcards. ○ Recursive directory matching is used in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ■ Example 1: `/apsara/nuwa/ … /*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ■ Example 2: `/var/logs/app_* … /*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ■ Each log file can be collected by using only one Logtail configuration. ■ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If the log file to be collected is in a Docker container, you can configure the internal path and container tag. Logtail monitors the creation and destruction of the container, filters logs of the container based on the tag, and collects the filtered logs. For more information, see Collect container text logs.
Mode	If you have specified **Apache-Text Log** for the data source, the default mode is **Apache Configuration Mode**. You can change the mode.
Log Format	Select a log format based on the format declared in your Apache log configuration file. To facilitate the query and analysis of log data, we recommend that you use a custom Apache log format.
APACHE Logformat Configuration	Enter the log configuration section that is specified in the Apache configuration file. The section starts with LogFormat. **Note** If the specified **Log Format** is **Common** or **Combined**, the system enters a commonly used syntax of the log format. Check whether the log format is the same as that defined in the Apache configuration file.
APACHE Key Name	Log Service reads the keys of Apache logs. Confirm the key names on the Logtail configuration page.

Parameter	Description
Drop Failed to Parse Logs	Specifies whether to upload logs to Log Service if the logs fail to be parsed. ○ If you turn on this switch, logs that fail to be parsed are not uploaded to Log Service. ○ If you turn off this switch, raw logs are uploaded to Log Service when logs fail to be parsed.
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory specified in the log path is monitored.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Set the parameters in the Advanced Options section based on your business requirements. We recommend that you do not modify the settings. The following table describes the parameters in the Advanced Options section.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs. **Note** If you turn on **Enable Plug-in Processing**, specific parameters such as Upload Raw Log, Timezone, Drop Failed to Parse Logs, Filter Configuration, and Incomplete Entry Upload (Delimiter mode) become unavailable.
Upload Raw Log	If you turn on **Upload Raw Log**, each raw log is uploaded to Log Service as a value of the __raw__ field together with the parsed log.
Topic Generation Mode	The topic generation mode. ○ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic field is set to an empty string. You do not need to enter a topic to query logs. ○ **Machine Group Topic Attributes**: This mode is used to differentiate logs that are generated by different servers. ○ **File Path RegEx**: In this mode, you must specify a regular expression in the **Custom RegEx** field. The part of a log path that matches the regular expression is used as the topic. This mode is used to differentiate logs that are generated by different users or instances.
Custom RegEx	If you set the Topic Generation Mode parameter to **File Path RegEx**, you must enter a custom regular expression.
Log File Encoding	The encoding format of log files. Valid values: ○ utf8: UTF-8 encoding format ○ gbk: GBK encoding format

Parameter	Description
Timezone	The time zone where logs are collected. Valid values: ○ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ○ Custom: If you select this value, you must select a time zone.
Timeout	The timeout period of log files. If a log file is not updated within the specified period, Logtail reckons the file to be timed out. Valid values: ○ Never: All log files are continuously monitored and never time out. ○ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file. If you select **30 Minute Timeout**, you must specify the **Maximum Timeout Directory Depth** parameter. Valid values: 1 to 3.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ○ Collect logs that meet specified conditions: If you set **Key** to **level** and **Regex** to **WARNING|ERROR**, only WARNING-level and ERROR-level logs are collected. ○ Filter out logs that do not meet specified conditions. ■ If you set **Key** to **level** and **Regex** to **^(?!.*(INFO|DEBUG)).***, INFO-level or DEBUG-level logs are not collected. ■ If you set **Key** to **url** and **Regex** to **.*^(?!.*(healthcheck)).***, logs whose URLs contain healthcheck are not collected. For example, the log is not collected if the value of the Key field is url and the value of the Value field is /inner/healthcheck/jiankong.html.

8. Configure indexes in the Configure Query and Analysis step. Click **Next**.

   By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

   > **Note**
   > ○ To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
   > ○ If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

After you complete the settings, you can start to collect Apache logs.

28.1.3.1.4.9. Configure parsing scripts

This topic describes how to configure log contents for log collection.

Specify a method to separate log lines

A complete access log such as an NGINX access log occupies a line. Separate multiple log entries with line breaks. For example, the following shows two access logs:

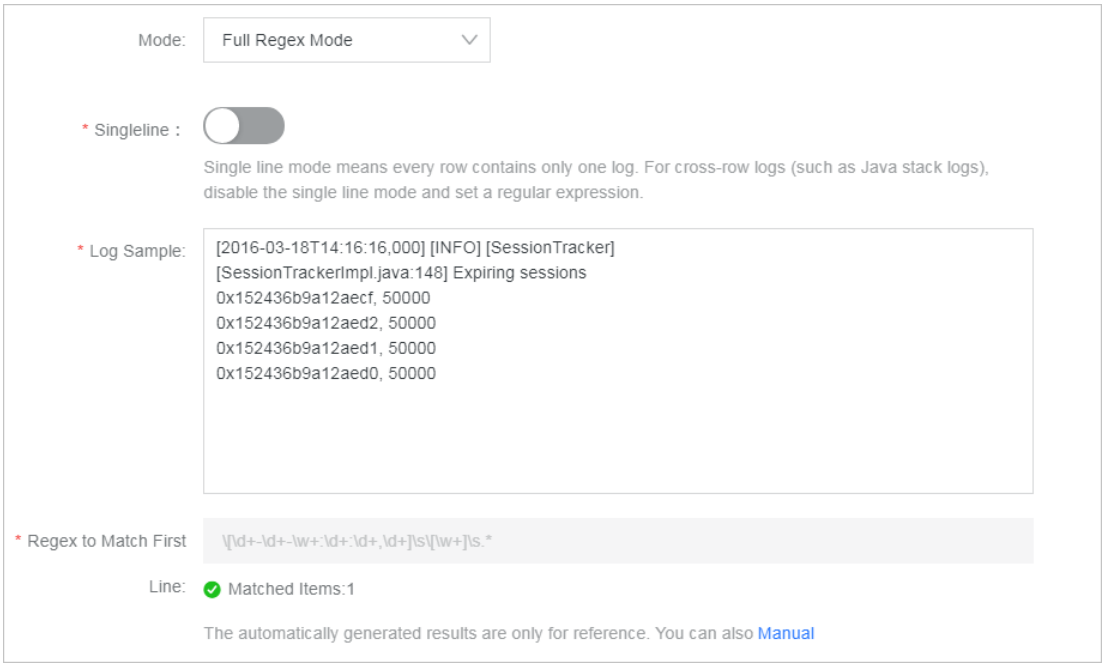
```
10.1.1.1 - - [13/Mar/2016:10:00:10 +0800] "GET / HTTP/1.1" 0.011 180 404 570 "-" "Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1; 360se)"
10.1.1.1 - - [13/Mar/2016:10:00:11 +0800] "GET / HTTP/1.1" 0.011 180 404 570 "-" "Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1; 360se)"
```

For Java applications, a log entry usually spans several lines. Therefore, log entries are separated based on the identifier at the beginning of each log entry. The following example shows a Java application log.

```
[2016-03-18T14:16:16,000] [INFO] [SessionTracker] [SessionTrackerImpl.java:148] Expiring sessions
0x152436b9a12aecf, 50000
0x152436b9a12aed2, 50000
0x152436b9a12aed1, 50000
0x152436b9a12aed0, 50000
```

The preceding Java application log entries each start with a time field. The regular expression that matches these time fields is `[\d+-\d+-\w+:\d+:\d+,\d+]\s. .*`. You can enter information in the Log Service console as shown in the following figure.

Full regular expression mode



Extract log fields

To conform to the data models of Log Service, a log contains one or more key-value pairs. If you want to extract specific fields for analysis, you must set a regular expression. If you do not want to process the contents of a log, you can treat the log as a key-value pair.

You can determine whether to extract fields from the preceding NGINX access log.

- Extract fields

  The regular expression is `(\S+)\s-\s-\s\[(\S+)\s[^]]+]\s"(\w+). *`. The extracted fields are `10.1.1.1`, `13/Mar/2016:10:00`, and `GET`.

- Extract all

  The regular expression is `(. *)`. The extracted field is `10.1.1.1 - - [13/Mar/2016:10:00:10 +0800] "GET / HTTP/1.1" 0.011 180 404 570 "-" "Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1; 360se)"`.

Specify a log time

To conform to the data models of Log Service, a log must have a time field in the Unix timestamp format. You can use the system time when Logtail collects a log or the time in the log contents as the log time.

For the preceding NGINX access log:

- If you extract the time field from the log contents as the log time, the time is `13/Mar/2016:10:00:10` and the time expression is `%d/%b/%Y:%H:%M:%S`.
- If you use the system time when the log was collected as the log time, the log time is converted into a timestamp.

28.1.3.1.4.10. Configure the time format

Each log in Log Service must have a timestamp that records the log generation time. When you collect logs from log files, Logtail must extract the timestamp string of each log and parse it into a timestamp. Therefore, you need to specify a timestamp format to facilitate parsing.

In Linux, Logtail supports all time formats provided by the strftime() function. If a timestamp string can match one of the time formats that are provided by the strftime() function, Logtail can parse and use the timestamp string.

> **Note**
> - The log timestamp is accurate to seconds. Therefore, you need to specify seconds in a time format, without the need for other information such as milliseconds or microseconds.
> - In addition, you need to configure the time field rather than other information.

Common log time formats supported by Logtail

The timestamp strings of logs have diverse formats. To make configuration easier, the following table lists the common log time formats supported by Logtail:

Format	Description	Example
%a	The abbreviation of a day in a week.	Fri
%A	The day in a week.	Friday
%b	The abbreviation of a month.	Jan
%B	The month name.	January
%d	The numerical day in a month. Valid values: 01 to 31.	07 and 31
%h	The abbreviation of a month. The format is equivalent to `%b`.	Jan
%H	The hour in the 24-hour format.	22
%I	The hour in the 12-hour format.	11
%m	The numerical month.	08
%M	The numerical minute. Valid values: 00 to 59.	59
%n	A line break.	Line break

Format	Description	Example
%p	The local time in the a.m. or p.m. format.	AM and PM
%r	The time in the 12-hour format. The format is equivalent to `%I:%M:%S %p`.	11:59:59 AM
%R	The time includes hours and minutes. The format %R is equivalent to `%H:%M`.	23:59
%S	The numerical second. Valid values: 00 to 59.	59
%t	A tab.	Tab
%y	The two-digit numerical year. Valid values: 00 to 99.	04 and 98
%Y	The four-digit numerical year.	2004 and 1998
%C	The numerical century. Valid values: 00 to 99.	16
%e	The numerical day in a month. Valid values: 1 to 31. A single digit is preceded by a space.	7 and 31
%j	The numerical day in a year. Valid values: 001 to 366.	365
%u	The numerical day in a week. Valid values: 1 to 7, in which 1 represents Monday.	2
%U	The numerical week in a year. Sunday is the first day of a week. Valid values: 00 to 53.	23
%V	The numerical week in a year. Monday is the first day of a week. If a week has four or more days that start from January 1, the week is treated as the first week. Otherwise, the next week is treated as the first week. Valid values: 01 to 53.	24
%w	The numerical day in a week. Valid values: 0 to 6, in which 0 represents Sunday.	5
%W	The numerical week in a year. Monday is the first day of a week. Valid values: 00 to 53.	23

Format	Description	Example
%c	The standard date and time.	To specify more information such as the long date and short date, you can use the preceding formats to provide exact expression.
%x	The standard date.	To specify more information such as the long date and short date, you can use the preceding formats to provide exact time expressions.
%X	The standard time.	To specify more information such as the long date and short date, you can use the preceding formats to provide exact expression.
%s	The Unix timestamp.	1476187251

Example

The following table lists the common log time formats, examples, and corresponding time expressions.

Log time format	Example	Time expression
Custom	2017-12-11 15:05:07	%Y-%m-%d %H:%M:%S
Custom	[2017-12-11 15:05:07.012]	[%Y-%m-%d %H:%M:%S]
RFC822	02 Jan 06 15:04 MST	%d %b %y %H:%M
RFC822Z	02 Jan 06 15:04 -0700	%d %b %y %H:%M
RFC850	Monday, 02-Jan-06 15:04:05 MST	%A, %d-%b-%y %H:%M:%S
RFC1123	Mon, 02 Jan 2006 15:04:05 MST	%A, %d-%b-%y %H:%M:%S
RFC3339	2006-01-02T15:04:05Z07:00	%Y-%m-%dT%H:%M:%S
RFC3339Nano	2006-01-02T15:04:05.999999999Z07:00	%Y-%m-%dT%H:%M:%S

28.1.3.1.4.11. Import historical logs

Logtail collects incremental logs by default. If you want to import historical logs, use the historical log importing feature of Logtail.

Prerequisites

To collect logs from Linux servers, use Logtail 0.16.15 or later. To collect logs from Windows servers, use Logtail 1.0.0.1 or later. To ensure successful log collection, update Logtail to the latest version.

Context

Logtail collects log files based on events. The system captures events by detecting or polling files for changes at intervals. Additionally, Logtail can load events from local files to trigger log collection. Logtail implements historical log collection based on these local events.

You can import historical log files from the Logtail installation directory. The location of the directory varies based on the operating system.

- Linux: */usr/local/ilogtail*
- Windows:
  - 32-bit: *C:\Program Files\Alibaba\Logtail*
  - 64-bit: *C:\Program Files (x86)\Alibaba\Logtail*

> **Note**
> - The maximum interval between the time a local event is generated and the time the local event is imported is one minute.
> - Loading local configurations is a special action. Therefore, Logtail sends the `LOAD_LOCAL_EVENT_ALARM` alert to your server to notify you of this action.
> - If you want to import a large number of log files, we recommend that you modify the Logtail startup configuration to increase the upper limit of CPU to 2.0 GHz or more and the upper limit of the memory size to 512 MB or more. For more information, see Set Logtail startup parameters.

Procedure

1. Configure log collection.

   If a collection configuration is only used to import historical log files, you can specify a collection directory that does not exist. For more information, see Configure text log collection.

2. Obtain a unique identifier for a collection configuration.

   Obtain the unique identifier in the *user_log_config.json* file stored in the installation directory of Logtail. In Linux, use the **grep** command in the directory to query the unique identifier. In Windows, use tools such as Notepad to query the unique identifier.

   To query a unique identifier in a Linux operating system, run the following command:

   ```
   grep "##" /usr/local/ilogtail/user_log_config.json | awk '{print $1}'
                       "##1.0##log-config-test$multi"
                       "##1.0##log-config-test$ecs-test"
                       "##1.0##log-config-test$metric_system_test"
                       "##1.0##log-config-test$redis-status"
   ```

3. Add local events.

   Local events are stored in the *local_event.json* file that resides in the installation directory of Logtail. The file is in the JSON format. The syntax is:

   ```
   [
     {
       "config" : "${your_config_unique_id}",
       "dir" : "${your_log_dir}",
       "name" : "${your_log_file_name}"
      },
     {
      ...
      }
      ...
   ]
   ```

   - Parameters

Parameter	Description	Example
config	The unique identifier that is obtained in Step 2.	##1.0##log-config-test$ecs-test

Parameter	Description	Example
dir	The directory where logs are stored. **Note** The directory cannot end with a slash (/).	/data/logs
name	The name of a log file. Wildcards are supported.	For example, access.log.2018-08-08 and access.log*

Note To prevent Logtail from loading invalid JSON files, save local event configurations to a temporary file, edit the configurations in the temporary file, and copy the contents to the *local_event.json* file.

- Configuration examples

  In a Windows system, you can use tools such as Notepad to add local events to the *local_event.json* file. In a Linux system, add local events as follows:

```
$ cat /usr/local/ilogtail/local_event.json
[
  {
    "config": "##1.0##log-config-test$ecs-test",
    "dir": "/data/log/",
    "name": "access.log.
  },
  {
    "config": "##1.0##log-config-test$ecs-test",
    "dir": "/tmp",
    "name": "access.log.2017-08-09"
  }
]
```

What's next

- Check whether Logtail has loaded configurations

  After you save the local_event.json file, Logtail loads the configuration file to the memory within one minute and clears the contents of the local_event.json file.

  To check whether Logtail has read local events, use the following methods:

  - If the contents of the local_event.json file are cleared, it indicates that Logtail has read the local events.
  - Check whether the *ilogtail.LOG* file in the Logtail installation directory contains the process local event keywords. If the contents of the local_event.json are cleared and these keywords cannot be found, the local configuration file may be screened due to invalid contents.

- Check whether the configuration is loaded but no data is collected

  Possible causes are as follows:

  - The configuration is invalid.
  - The local config file does not exist.
  - The log file does not exist in the path specified in the collection configuration.

- The log file has been collected by Logtail.

28.1.3.1.4.12. Generate a topic

This topic describes how to generate a topic in the Log Service console. After you generate a topic, you can use the topic to group logs. You can specify topics for logs when these logs are written. You can use a topic as a filter when you query logs.

Topic generation modes

You can set a topic when you use Logtail to collect logs or when you use API operations or SDKs to upload logs. The following topic generation modes are available in the Log Service console: **Null - Do not generate topic**, **Server Group Topic Attributes**, and **File Path RegEx**.

- **Null - Do not generate topic**

  When you configure Logtail in the Log Service console to collect text logs, the default topic generation mode is **Null - Do not generate topic**. In this mode, no topic is generated and query logs without specifying a topic.

- **Server Group Topic Attributes**

  You can use this mode to identify logs that are generated from multiple servers. Logs from multiple servers can be stored in the same file or directory. To identify these logs based on topics during log collection, you can create server groups and add the servers into different groups. When you create server groups, you must specify a unique **topic attribute** for each server group and set **Topic Generation Mode** to **Server Group Topic Attributes**. After you complete the configuration, apply the Logtail settings to the server groups.

  If the **Server Group Topic Attributes** mode is selected, Logtail uploads the topic attribute of each server group as topics to Log Service. When you query logs, you must specify the topic of the target server group as a filter.

- **File Path RegEx**
  - You can use this mode to differentiate between logs that are generated by multiple users or instances. If Log Service stores logs in different directories for different users or instances, duplicate sub-directory names or log file names may exist in these directories. As a result, Log Service cannot identify the source of logs. You can select **File Path RegEx** in the **Topic Generation Mode** field. Enter a regular expression that matches an absolute file path, and set an instance name as a topic.
  - If you select **File Path RegEx**, Logtail uses an instance name as the topic of the logs that Logtail uploads to Log Service. The topic generated varies based on your directory structure and configuration. You must specify an instance name as a topic when you query logs. For example, the following directory structure includes directories that each store logs generated by different users or instances:

    ```
    /logs
      | - /userA/serviceA
        | - service.log
      | - /userB/serviceA
        | - service.log
      | - /userC/serviceA
        | - service.log
    ```

- If you want to extract multiple separate fields from a file path, use a multi-layer extraction method of `?P<key>`. The value of the key can contain lowercase letters and digits. For example:

  ```
  /home/admin/serviceA/userB/access.log
  \/home\/admin\/(? P<service>[^\/]+)/(? P<user>[^/]+)/. *
  ```

  The following custom tags are created for logs:

  ```
  "__tag__ : service : serviceA"
  "__tag__ : user : userB"
  ```

  > **Note** Logtail 0.16.19 and later are supported.

- If you specify the */logs* file path and the *service.log* file name in a regular expression, Logtail collects logs from the preceding directories that contain the service.log file and uploads the logs to Log Service. However, Log Service cannot identify the log source based on log contents. You can select **File Path RegEx** in the **Topic Generation Mode** field, and enter the `\/(.*)\/serviceA\/.*` regular expression to extract instance names. After the configuration is complete, the following topics are generated for logs in different directories: userA, userB, and userC. You can specify a topic as a filter to query logs.

> **Note** You must escape the forward slashes (`/`) in the file path that the regular expression contains.

- **Static topic generation**

  You can select **File Path RegEx** in the **Topic Generation Mode** field, and enter **customized:// + custom topic** in the `Custom RegEx` field.

  > **Note** Logtail 0.16.21 and later are supported.

Set a log topic

1. Configure Logtail in the Log Service console. For more information, see Configure text log collection.

   To set the topic generation mode to **Server Group Topic Attributes**, go to the **Topic** section on the server group creation or modification page.
2. In the Logtail Configuration for Data Import step, click **Advanced Options** and select a **topic generation mode**.

28.1.3.1.5. Custom plug-ins

Context

Log Service allows you to collect text logs and system logs through Logtail. Logtail supports connections with multiple data sources, such as HTTP or MySQL query results and MySQL binary logs.

You can collect HTTP request data and upload the processing results to Log Service in real time to check service availability check and continuous availability monitoring. You can configure MySQL query results as the data source, and then synchronize incremental data based on custom IDs or time. You can also configure an SQL data source to synchronize MySQL binary logs, subscribe to database changes, and query or analyze logs in real time.

> **Note** This feature is only supported on Linux and must be used together with Logtail. 0.16.0 or later versions. For more information, see Install Logtail in Linux.

Configuration process

1. Configure a method that is used to collect logs from the data source.

   Different Logtail configurations for different data sources. Select a Logtail configuration according to your data source.

2. Configure a processing method.

   Logtail provides multiple processing methods for binary logs, MySQL query results, NGINX monitoring data, and HTTP input sources. You can configure multiple processing methods for a single input source. Each input source supports all processing methods. Logtail runs the configured processing methods in sequence.

   For more information, see Configure data processing methods.

3. Apply the configurations to the machine group.

   After you configure the collection and processing methods, apply them to the specified machine group. Then, Logtail automatically applies the configurations and starts data collection.

28.1.3.1.5.1. Collect MySQL binary logs

Logtail is used as a MySQL slave. It is used to collect binary logs from a MySQL master. Logtail collects binary logs by using a similar method to Alibaba Canal. This improves the efficiency of log collection.

Features

- Allows you to collect incremental data of databases in the form of binary logs to improve performance. Supports MySQL databases such as ApsaraDB RDS for MySQL.
- Supports multiple database filters, such as regular expressions.
- Allows you to set binary log file positions.
- Allows you to record synchronization statuses by using the checkpoint mechanism.

Limits

- MySQL binary logs are available only for Logtail 0.16.0 or later versions that you install on Linux. For more information about how to update Logtail and view Logtail versions, see Install Logtail in Linux.
- Binary logs in the ROW format must be enabled for MySQL databases. By default, binary logs in the ROW format are enabled for RDS instances.

```
# Check whether binary logs are enabled.
mysql> show variables like "log_bin";
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| log_bin       | ON    |
+---------------+-------+
1 row in set (0.02 sec)
# View the format of binary logs.
mysql> show variables like "binlog_format";
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| binlog_format | ROW   |
+---------------+-------+
1 row in set (0.03 sec)
```

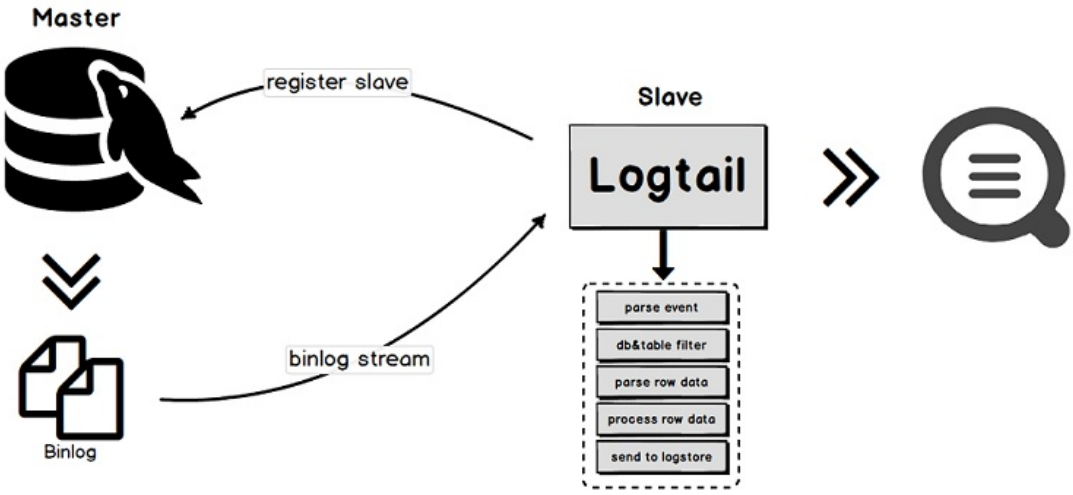
- Each server ID must be unique. Make sure that the ID of each slave to be synchronized is unique.
- Limits for RDS databases:
  - Logtail cannot be installed on an RDS instance. You must install Logtail on an ECS instance that can communicate with the destination RDS instance.

- Secondary RDS databases cannot be used to collect binary logs. You must configure a primary RDS database to collect binary logs.

Implementation

Logtail enables communication between master and slave MySQL servers. The process of how master and slave MySQL servers communicate is provided in the following information:

1. Logtail is used as a MySQL slave. It can also be used to send dump requests to the MySQL master.
2. After the dump requests are received, the MySQL master delivers its binary logs to Logtail in real time.
3. Logtail parses and filters binary logs, and then uploads the results to Log Service.



Scenarios

The MySQL binary logging feature applies to scenarios in which you need to synchronize large amounts of data and meet high performance requirements.

- Query the incremental data of databases in real time.
- Audit operations that are performed on databases.
- Use Log Service to query data, visualize query results, transform data for stream processing, export data to MaxCompute for offline computing, and export log to Object Storage Service (OSS) for long-term storage.

Data reliability

We recommend that you enable the global transaction identifier (GTID) feature of the MySQL server and upgrade Logtail to version 0.16.15 or later. This prevents repeated data collection during a primary/secondary server switchover and ensures data reliability.

- Incomplete data collection: If the network between Logtail and the MySQL server is disconnected for a long period of time, some data may not be collected.

  A MySQL binary log plug-in is used as a MySQL slave to collect binary logs from the master server. Logtail establishes a connection with the master server to obtain data from the server. If the network between Logtail and the master node is disconnected, the master node still generates new binary logs and deletes expired binary logs. After the connection is reestablished and Logtail is reconnected to the master server, Logtail uses the last checkpoint to request binary log data from the master server. However, if the network is disconnected for a long period of time, the data generated after the checkpoint may be deleted. In this case, the recovery mechanism specifies the new point at which Logtail resumes collecting binary logs. The new point is the most recent binary log file position. If the network is disconnected for a long period of time, some data generated between the checkpoint and the new data collection point may not be collected.

- Repeated data collection: If the ordinal numbers of binary logs on the master and slave servers are different and a master/slave switchover occurs, repeated data collection may occur.

If the MySQL master-slave synchronization is configured, the master server synchronizes the generated binary log data to the slave server. Then, the slave server stores the received binary log data to the local binary log file. If the ordinal numbers of binary logs on the master and slave servers are different, a master/slave switchover occurs. In this case, the mechanism that uses a binary log file name and an offset as the checkpoint causes repeated data collection.

For example, assume that a data entry ranges from `(binlog.100, 4)` to `(binlog.105, 4)` on the master server, and ranges from `(binlog.1000, 4)` to `(binlog.1005, 4)` on the slave. Logtail has obtained the data from the master server and updated the checkpoint to `(binlog.105, 4)`. In this case, if a master/slave switchover occurs without exception, Logtail continues to obtain binary logs from the new master server based on the local checkpoint `(binlog.105, 4)`. The new master server returns the data entries that range from `(binlog.1000, 4)` to `(binlog.1005, 4)` to Logtail. This is because the ordinal numbers of these data entries on the new master server are greater than the ordinal numbers of data entries requested by Logtail. As a result, log data is repeatedly collected.

Parameter

The type of input sources is `service_canal`.

Parameter	Type	Required	Description
Host	string	No	The IP address of the host where the database resides. Default value: 127.0.0.1.
Port	int	No	The port number that you can use to connect with the database. Default value: 3306.

User	string	No	The database username. Default value: root.
			The configured user must have the read permissions on the source database and the MySQL REPLICATION permission. Example:
			`CREATE USER canal IDENTIFIED BY 'canal';`
			`GRANT SELECT, REPLICATION SLAVE, REPLICATION CLIENT ON *. * TO 'canal'@'%';`
			`-- GRANT ALL PRIVILEGES ON *. * TO 'canal'@'%' ;`
			`FLUSH PRIVILEGES;`

Parameter	Type	Required	Description
Password	string	No	The database password. By default, this parameter is unspecified. If you require a high level of data security, we recommend that you set both the username and the password to xxx. After your configurations are synchronized to the on-premises server, find the Password parameter in the */usr/local/ilogtail/user_log_config.json* file and modify the value. **Note** • After you modify the password, use the **sudo /etc/init.d/ilogtaild stop; sudo /etc/init.d/ilogtaild start** command to restart Logtail. • If you modify the value of the Password parameter on the web and synchronize your configurations to the on-premises server, the configurations on the on-premises server are overwritten. You can change the configurations on the on-premises server later.
ServerID	int	No	The ID of a MySQL slave whose role is assumed by Logtail. Default value: 125. **Note** In a MySQL database, each ID must be unique. Otherwise, synchronization fails.
IncludeTables	String array	Yes	The names of matched tables. Each value contains a database name and a table name, for example, `test_db.test_table`. You must specify a regular expression for the parameter. Logtail does not collect incremental data from tables whose names do not match the regular expression. To collect incremental data from all tables of a database, set the value of the IncludeTables parameter to `.*\\..*`. **Note** If an exact match is required, make sure that the regular expression is prefixed by `^`. In this case, you must also make sure that the regular expression is suffixed by `$`. Example: `^test_db\\.test_table$`.

Parameter	Type	Required	Description
ExcludeTables	String array	No	The names of excluded tables expressed as a regular expression. The name of a table must include the name of the database to which the table belongs, for example, `test_db.test_table`. If a table meets one of the conditions specified in the parameter, the table is not collected. If you do not specify this parameter, incremental data from all tables is collected. **Note** If an exact match is required, make sure that the regular expression is prefixed by `^`. In this case, you must also make sure that the regular expression is suffixed by `$`. Example: `^test_db\\.test_table$`.

StartBinName	string	No	The name of the first binary log file that is collected by Logtail. If you do not specify this parameter, Logtail starts to collect binary log files that are generated from the current time.
			To collect data from a specific location, view the name of the current binary log file and the file offset. Then, set `StartBinName` and `StartBinLogPos` to actual values. Example:
			`# Set StartBinName to mysql-bin.000063 and StartBinLogPos to 0.`
			`mysql> show binary logs;`
			`+------------------+-----------+`
			`| Log_name | File_size |`
			`+------------------+-----------+`
			`| mysql-bin.000063 | 241 |`
			`| mysql-bin.000064 | 241 |`
			`| mysql-bin.000065 | 241 |`
			`| mysql-bin.000066 | 10778 |`
			`+------------------+-----------+`
			`4 rows in set (0.02 sec)`
			Note
			If you set the `StartBinName` parameter, a large amount of traffic is generated during the first collection.

StartBinLogPos	int	No	The offset of the first binary log file that is collected. Default value: 0.
EnableGTID	bool	No	Specifies whether to add GTID. Default value: true. If the value is false, no GTID is added to uploaded data.
EnableInsert	bool	No	Specifies whether to collect log events triggered by INSERT operations. Default value: true. If the value is false, INSERT events are not collected.
EnableUpdate	bool	No	Specifies whether to collect UPDATE events. Default value: true. If the value is false, UPDATE events are not collected.

Parameter	Type	Required	Description
EnableDelete	bool	No	Specifies whether to collect DELETE events. Default value: true. If the value is false, DELETE events are not collected.
EnableDDL	bool	No	Specifies whether to collect data definition language (DDL) events. Default value: false. If the value is false, DDL events are not collected. **Note** This parameter does not support the `IncludeTables` or `ExcludeTables` filtering methods.
Charset	string	No	The encoding method. Default value: `utf-8`.
TextToString	bool	No	Specifies whether to convert data of the text type into a string. Default value: false.
PackValues	bool	No	Specifies whether to encapsulate event data into the JSON format. Default value: false. If the value is false, event data is not encapsulated. If this feature is enabled, Logtail encapsulates event data into the data and old_data fields in the JSON format. The old_data field is available only for ROW_UPDATE events. For example, assume that a table has three fields named c1, c2, and c3. If this feature is disabled, the ROW_INSERT event data contains three fields c1, c2, and c3. If this feature is enabled, c1, c2, and c3 are encapsulated into one data field and the value is `{"c1":"...", "c2": "...", "c3": "..."}`. **Note** This parameter is available only for Logtail V0.16.19 and later.
EnableEventMeta	bool	No	Specifies whether to collect event metadata. Default value: false. If the value is false, event metadata is not collected. The metadata of binary log events includes `event_time`, `event_log_position`, `event_size`, and `event_server_id`. **Note** This parameter is available only for Logtail V0.16.21 and later.

Procedure

Synchronize data from tables whose names do not end with `_inner` in the `user_info` RDS database.

1. Log on to the Log Service console.
2. Select a data source.

   Click **Import Data**. On the **Import Data** page, select **MYSQL BinLog**.
3. Select a destination project and Logstore, and then click **Next**.

   You can also click **Create Now** to create a project and a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.

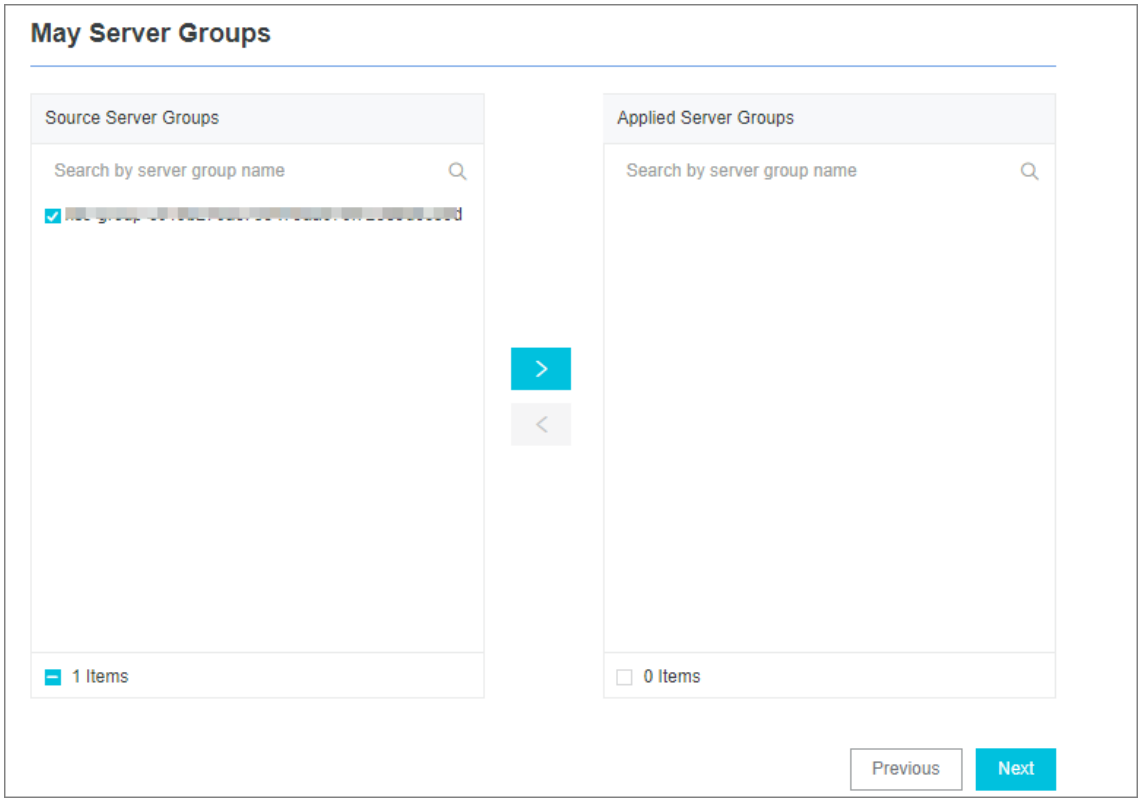
4. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.

5. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



> **Notice** If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

6. Configure the data source.

   Set the Config Name and Plug-in Config fields.

   In the **Plug-in Config** field, modify the parameter settings in the default configuration template based on your business requirements.

```
{
 "inputs": [
     {
         "type": "service_canal",
         "detail": {
             "Host": "************.mysql.rds.aliyuncs.com",
             "Port": 3306,
             "User" : "root",
             "ServerID" : 56321,
             "Password": "*******",
             "IncludeTables": [
                 "user_info\\.. *"
             ],
             "ExcludeTables": [
                 ". *\\. \\S+_inner"
             ],
             "TextToString" : true,
             "EnableDDL" : true
         }
     }
 ]
}
```

- *inputs*: specifies the collection configurations. This parameter is required. You must configure statements to collect data based on your data source.
- *processors*: specifies the processing method. This parameter is optional. For more information about how to set a processing method, see Configure data processing methods.

7. Configure indexes in the Configure Query and Analysis step. Click **Next**.

   By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

   > **Note**
   > - To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
   > - If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

8. (Optional)Modify the configurations on the server.

   If you do not enter the actual URL, username, or password in **Plug-in Config**, you must replace them with actual values after the configurations are synchronized to the server.

   > **Note** If you have entered the actual information, skip this step.

   i. Log on to the server where Logtail is installed, find the `service_canal` keyword in the `/usr/local/ilogtail/user_log_config.json` file, and then set related fields. These fields include `Host`, `User`, and `Password`.

   ii. Run the following command to restart Logtail:

   ```
   sudo /etc/init.d/ilogtaild stop; sudo /etc/init.d/ilogtaild start
   ```

The configurations that are used to collect binary logs are completed. If changes are made to your database, Logtail immediately collects the updated data and uploads the data to Log Service.

> **Note** Logtail collects incremental binary logs. If no data is collected, check whether changes are made to the table in your database after the configurations are updated.

Metadata fields

When you collect binary logs, some metadata is also uploaded. The following table lists the fields of uploaded metadata.

Parameter	Description	Example
`_host_`	The name of the host where the database resides.	`*********.mysql.rds.aliyuncs.com`
`_db_`	The name of the RDS database.	`my-database`
`_table_`	The name of the table.	`my-table`
`_event_`	The type of the event. Valid values:	`row_update`, `row_insert`, and `row_delete`
`_id_`	The ID of the current collection. The value starts from 0 and increments by 1 each time a binary log event is collected.	`1`
`_gtid_`	The GTID.	`7d2ea78d-b631-11e7-8afb-00163e0eef52:536`
`_filename_`	The name of the binary log file.	`binlog.001`
`_offset_`	The offset of the binary log file. The value is updated after each COMMIT operation.	`12876`

Example

After you completed the preceding steps to set a processing method, perform `INSERT`, `UPDATE`, and `DELETE` operations on the `SpecialAlarm` table in the `user_info` database. The following information shows the schema, database operations, and sample logs that are collected by Logtail.

- Schema

```
CREATE TABLE `SpecialAlarm` (
`id` int(11) unsigned NOT NULL AUTO_INCREMENT,
`time` datetime NOT NULL,
`alarmtype` varchar(64) NOT NULL,
`ip` varchar(16) NOT NULL,
`count` int(11) unsigned NOT NULL,
PRIMARY KEY (`id`),
KEY `time` (`time`) USING BTREE,
KEY `alarmtype` (`alarmtype`) USING BTREE
) ENGINE=MyISAM AUTO_INCREMENT=1;
```

- Database operations

  Perform the INSERT, DELETE, and UPDATE operations on the database.

```
insert into specialalarm (`time`, `alarmType`, `ip`, `count`) values(now(), "NO_ALARM", "10.10. **
.***", 55);
delete from specialalarm where id = 4829235  ;
update specialalarm set ip = "10.11. ***.**" where id = "4829234";
```

Create an index for `zc.specialalarm`.

```
ALTER TABLE `zc`.`specialalarm`
ADD INDEX `time_index` (`time` ASC);
```

- Sample logs

  On the data preview or Search & Analysis page, you can view a sample log that corresponds to each operation.

  - INSERT statement

```

ErrorCode:  0
ExecutionTime:  0
Query:  ALTER TABLE `zc`.`specialalarm`
ADD INDEX `time_index` (`time` ASC)
StatusVars:
```

Usage notes

We recommend that you increase resource limits on Logtail to process traffic surges and prevent data security risks. If the limits are exceeded, Logtail may be forcibly restarted.

You can modify the resource limits in the */usr/local/ilogtail/ilogtail_config.json* file. Then, you can run the **sudo /etc/init.d/ilogtaild stop;sudo /etc/init.d/ilogtaild start** command to restart Logtail.

The following example shows how to set the CPU limit to two and memory limit to 2,048 MB:

```
{
    ...
    "cpu_usage_limit":2,
    "mem_usage_limit":2048,
    ...
}
```

28.1.3.1.5.2. Collect MySQL query results

This topic describes how to configure Logtail in the Log Service console to collect MySQL query results.

Context

If you want to collect data from a MySQL database, you can install Logtail on a server and connect the server with the database. Then, you can create a Logtail configuration file by executing a custom SQL statement in the Log Service console and deliver the configuration file to Logtail. Logtail can use the custom SQL statement to collect data from the database at regular intervals.

> **Note** This feature applies only to Logtail 0.16.0 and later versions that run on Linux. For more information, see Install Logtail in Linux.

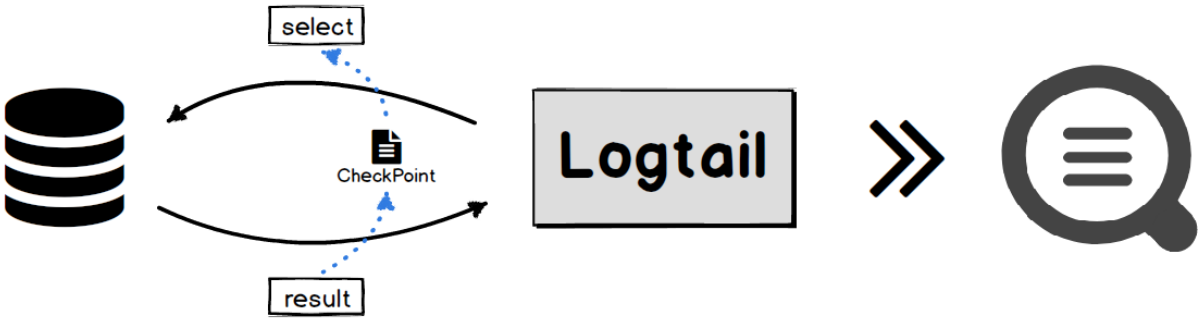
Benefits

Supports MySQL databases such as ApsaraDB RDS for MySQL. When you collect data, you can perform the following operations:

- Paginate query results.
- Set time zones.
- Set timeout periods.
- Store checkpoints.
- Transmit data over the SSL protocol.
- Set the maximum size of data that can be collected at a time.

Implementation

Logtail executes the specified SELECT statement at a regular interval based on the Logtail configurations, and then uploads the query results to Log Service.



When Logtail obtains a query result, Logtail saves the value of the CheckPoint field in the on-premises server. The next time Logtail executes the SELECT statement, Logtail adds the saved value of the CheckPoint field to the SELECT statement. This way, Logtail collects the incremental data of MySQL databases.

Scenarios

- Collect incremental data based on specific marks such as an auto-increment ID or a point in time.
- Customize data synchronization based on specified filtering conditions.

Parameters

The following table describes Logtail parameters. The type of the data source is `service_mysql`.

Parameter	Type	Required	Description
Address	string	No	The address of the MySQL database. Default value: 127.0.0.1:3306.

Parameter	Type	Required	Description
User	string	No	The username of the MySQL database. Default value: root.
Password	string	No	The password of the MySQL database. By default, this parameter is unspecified.
DialTimeOutMs	int	No	The timeout period for the database connection. Unit: milliseconds. Default value: 5000.
ReadTimeOutMs	int	No	The timeout period for data reading. Unit: milliseconds. Default value: 5000.
StateMent	string	Yes	The SQL statement.
Limit	bool	No	Specifies whether to paginate query results by using the LIMIT clause. Default value: false.
PageSize	int	No	The number of log entries to return on each page. You must specify this parameter if you set the Limit parameter to true.
MaxSyncSize	int	No	The maximum number of log entries that are synchronized at a time. Default value: 0. This value indicates that no limit is set for the size of data that can be synchronized at a time.
CheckPoint	bool	No	Specifies whether to use checkpoints during data collection. Default value: false.
CheckPointColumn	string	No	The name of the checkpoint column. You must specify this parameter if you set the CheckPoint parameter to true.
CheckPointColumnType	string	No	The type of the checkpoint column. Valid values: `int` and `time`.

Parameter	Type	Required	Description
CheckPointStart	string	No	The initial value of the checkpoint.
CheckPointSavePerPage	bool	No	If this parameter is set to true, a checkpoint is saved each time query results are paginated. If this parameter is set to false, a checkpoint is saved after each synchronization.
IntervalMs	int	Yes	The synchronization interval. Unit: milliseconds.

Limits

- We recommend that you paginate query results by specifying the `Limit` parameter. If you set the `Limit` parameter to true, the LIMIT clause is automatically appended to the SQL statement specified by the `StateMent` parameter when you run a query.
- If you set the `CheckPoint` parameter to true, the data that is selected based on the `StateMent` parameter must contain the checkpoint column. In addition, the WHERE clause must contain the checkpoint field. The value of the checkpoint field is a question mark (`?`).

  For example, assume that the checkpoint is "id" and the value of the `StateMent` parameter is `SELECT * from ... where id > ?` .
- If you set the `CheckPoint` parameter to true, you must specify the `CheckPointColumn` , `CheckPointColumnType` , and `CheckPointStart` parameters.
- The value of `CheckPointColumnType` can only be set to `int` or `time` . If the value is set to `int` , the int64 data type is used for internal storage. If the value is set to `time` , MySQL DATE, DATETIME, and TIME are supported.

Procedure

The following procedure describes how to synchronize incremental data from a MySQL database to Log Service. In this procedure, the logtail.VersionOs field is synchronized every 10 seconds. The value of the count parameter in this field is greater than 0. The value of the initial checkpoint is 2017-09-25 11:00:00. Log entries are paginated and each page contains 100 log entries. The checkpoint of each page is saved.

1. Log on to the Log Service console.
2. Select a data source.

   Click **Import Data**. On the **Import Data** page, select **MYSQL Query Result-Plug-in**.
3. Select a destination project and Logstore, and then click **Next**.

   You can also click **Create Now** to create a project and a Logstore.

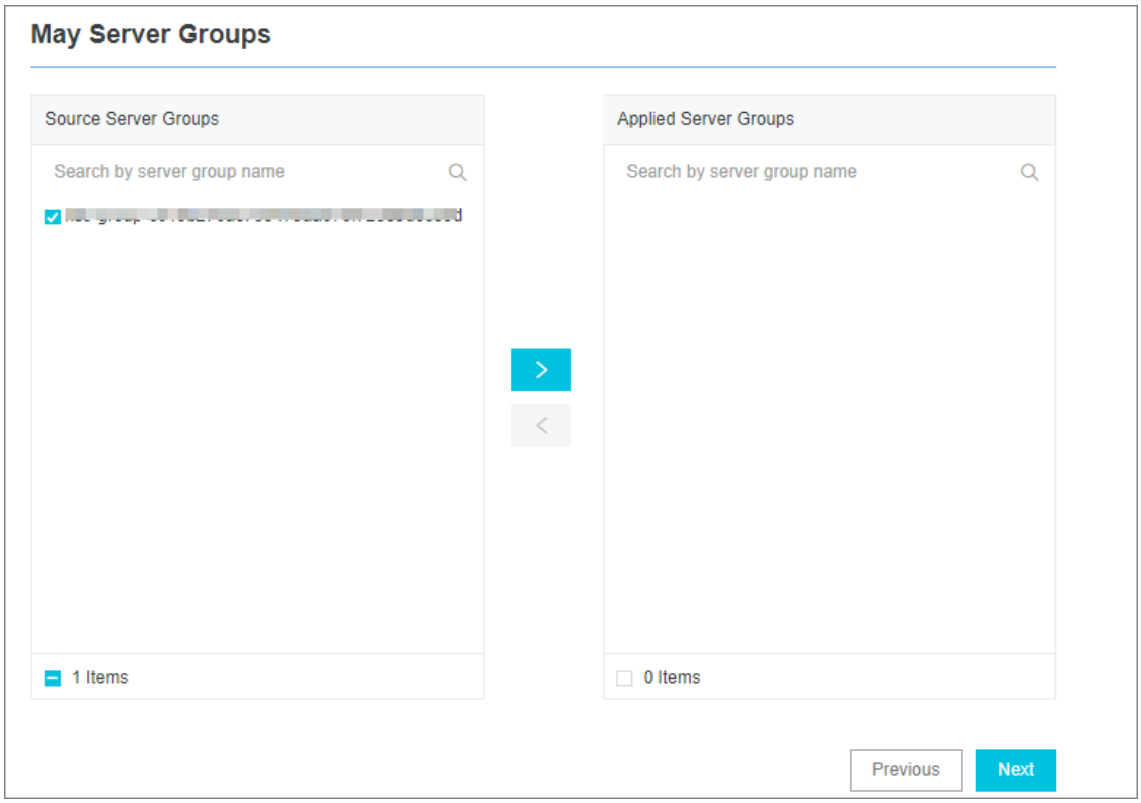
   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.

5. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



> **Notice** If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

6. Configure the data source.
   - In the **Plug-in Config** field, modify the parameter settings in the default configuration template based on your business requirements.
   - `inputs`: specifies the collection configurations. This parameter is required. `processors`: specifies the processing method. This parameter is optional. You must configure statements to collect data based on your data source. You can specify one or more processing methods. For more information, see Configure data processing methods.

> **Note** If you require a high level of data security, we recommend that you set both the username and the password to xxx. After your configurations are synchronized to the on-premises server, find the Password parameter in the /usr/local/ilogtail/user_log_config.json file and modify the value.

The following example shows the configurations:

```
{
 "inputs": [
     {
         "type": "service_mysql",
         "detail": {
             "Address": "********:3306",
             "User": "logtail",
             "Password": "*******",
             "DataBase": "logtail",
             "Limit": true,
             "PageSize": 100,
             "StateMent": "SELECT * from logtail.VersionOs where time > ?",
             "CheckPoint": true,
             "CheckPointColumn": "time",
             "CheckPointStart": "2017-09-25 11:00:00",
             "CheckPointSavePerPage": true,
             "CheckPointColumnType": "time",
             "IntervalMs": 10000
         }
     }
 ]
}
```

7. Configure indexes in the Configure Query and Analysis step. Click **Next**.

   By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

   > **Note**
   > - To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
   > - If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

8. (Optional)Modify the configurations on the server.

   If you do not enter the actual URL, username, or password in the **Specify Data Source** page, you must replace them with actual values after the configurations are synchronized to the server.

   > **Note** If you have entered the actual information, skip this step.

   i. Log on to the server where Logtail is installed, find the `service_mysql` keyword in the `/usr/local/ilogtail/user_log_config.json` file, and then set related fields. These fields include: `Address`, `User`, and `Password`.

   ii. Run the following command to restart Logtail:

   ```
   sudo /etc/init.d/ilogtaild stop; sudo /etc/init.d/ilogtaild start
   ```

Example

After you configure the processing method, you can view the processed data in the Log Service console. The following information shows the schema and sample logs that are collected by Logtail.

- Schema

```
CREATE TABLE `VersionOs` (
  `id` int(11) unsigned NOT NULL AUTO_INCREMENT COMMENT 'id',
  `time` datetime NOT NULL,
  `version` varchar(10) NOT NULL DEFAULT '',
  `os` varchar(10) NOT NULL,
  `count` int(11) unsigned NOT NULL,
  PRIMARY KEY (`id`),
  KEY `timeindex` (`time`)
)
```

- Sample output

```
"count":  "4"
"id:  "721097"
"os:  "Windows"
"time:  "2017-08-25 13:00:00"
"version":  "1.3.0"
```

28.1.3.1.5.3. Collect syslogs

This topic describes how to use the syslog plug-in of Logtail to collect syslogs from a server.

Prerequisites

Logtail 0.16.13 or a later version is installed on the server.

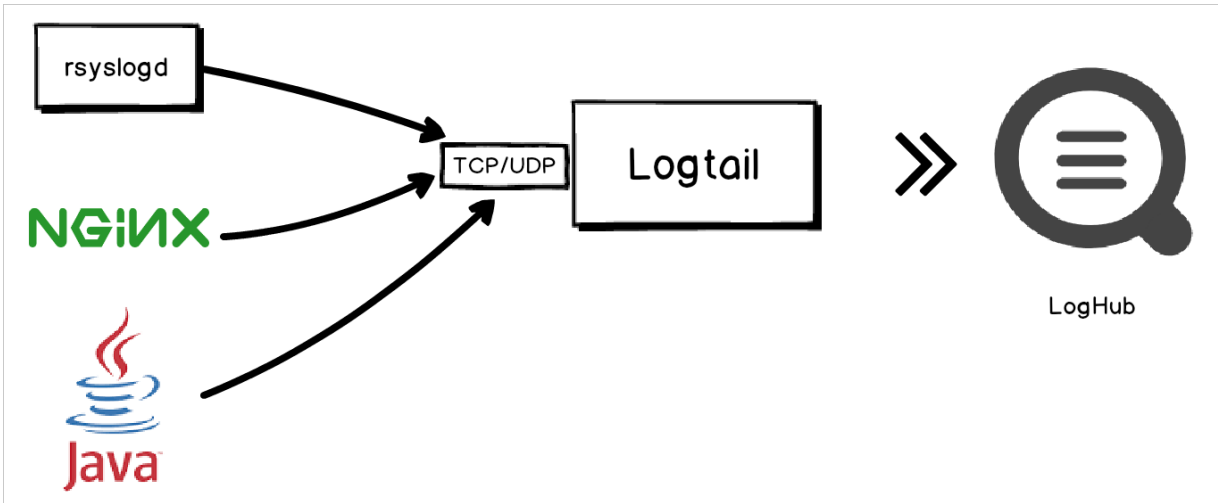
Overview

On a Linux server, local syslogs can be forwarded to the IP address and port of a specified server by using syslog agents such as rsyslog. After you create a Logtail configuration for the specified server, the syslog plug-in of Logtail receives the syslogs over TCP or UDP. In addition, the syslog plug-in parses the received syslogs and extract log fields such as facility, tag (program), severity, and content based on the specified syslog protocol. The syslog protocol can be RFC 3164 or RFC 5424.

> **Note**
> - Logtail installed on a Windows server does not support the syslog plug-in.
> - You can configure multiple syslog plug-ins for Logtail. For example, you can use both TCP and UDP to listen on 127.0.0.1:9999.

Implementation

After the syslog plug-ins start to listen on a specified IP address and port, Logtail can act as a syslog server to collect syslogs from various data sources. These syslogs include system logs collected by rsyslog, access or error logs forwarded by NGINX, and logs forwarded by syslog clients in languages such as Java.



Logtail parameters

The following table describes Logtail parameters. The type of the input is `service_syslog`.

Parameter	Type	Required	Description
Address	String	No	The protocol, address, and port on which the syslog plug-in listens. The syslog plug-in obtains logs based on the value of this parameter. Format: `[tcp/udp]://[ip]:[port]`. Default value: `tcp://127.0.0.1:9999`. **Note** • The specified protocol, address, and port must be the same as those specified for the forwarding rule in the rsyslog configuration file. • If the server on which Logtail is installed has multiple IP addresses, you can set the IP address to 0.0.0.0. It means that the syslog plug-in listens on all IP addresses of the server.
ParseProtocol	String	No	The protocol that is used to parse logs. This parameter is not specified by default, indicating that logs are not parsed. Valid values: • rfc3164: The RFC 3164 protocol is used to parse logs. • rfc5424: The RFC 5424 protocol is used to parse logs. • auto: The syslog plug-in selects a protocol based on the log content.

Parameter	Type	Required	Description
IgnoreParseFailure	Boolean	No	Specifies whether to ignore a parsing failure. Default value: true. Valid values: • true: Logs that fail to be parsed are included in the returned content field. • false: Logs that fail to be parsed are dropped.

Default fields

Field	Type	Description
hostname	String	The hostname. If a hostname is not provided in the log, the hostname of the current host is obtained.
program	String	The tag field in the protocol.
priority	String	The priority field in the protocol.
facility	String	The facility field in the protocol.
severity	String	The severity field in the protocol.
unixtimestamp	String	The timestamp of the log.
content	String	The log content. If the log fails to be parsed, this field contains the complete content of the log.
_ip_	String	The IP address of the current host.

Configure the plug-in of Logtail to collect syslogs

1. Add a forwarding rule for rsyslog.

   Modify the */etc/rsyslog.conf* rsyslog configuration file on the server from which syslogs are collected. Add a forwarding rule at the end of the configuration file. Then, rsyslog forwards syslogs to the specified IP address and port.

   - If you want to collect syslogs of the server by using Logtail on this server, set the forwarding address to 127.0.0.1 and the port to an idle port.
   - If you want to collect syslogs of the server by using Logtail on a second server (Server B), set the forwarding address to the public IP address of the second server and port to an idle port.

   For example, the following forwarding rule indicates that logs are forwarded to 127.0.0.1:9000 over TCP.

   ```
   *. * @@127.0.0.1:9000
   ```

2. Run the following command to restart rsyslog and validate the log forwarding rule:

   ```
   sudo service rsyslog restart
   ```

3. Log on to the Log Service console.
4. Select the data source **Custom Data Plug-in**.

   You can use one of the following three methods to select a data source:

   - On the homepage of the Log Service console, select a data source in the **Import Data** section.
   - In the **Projects** section, click a project name. On the **Overview** page, click **Import Data**, and then select a data source.

- On the Logstores tab in the left-side navigation pane, find a Logstore and click the closing angle bracket (>) in front of the Logstore name. Click the plus sign (+) next to **Data Import**, and then select a data source.

5. Select a destination project and Logstore, and then click **Next**.

   You can also click **Create Now** to create a project and a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.

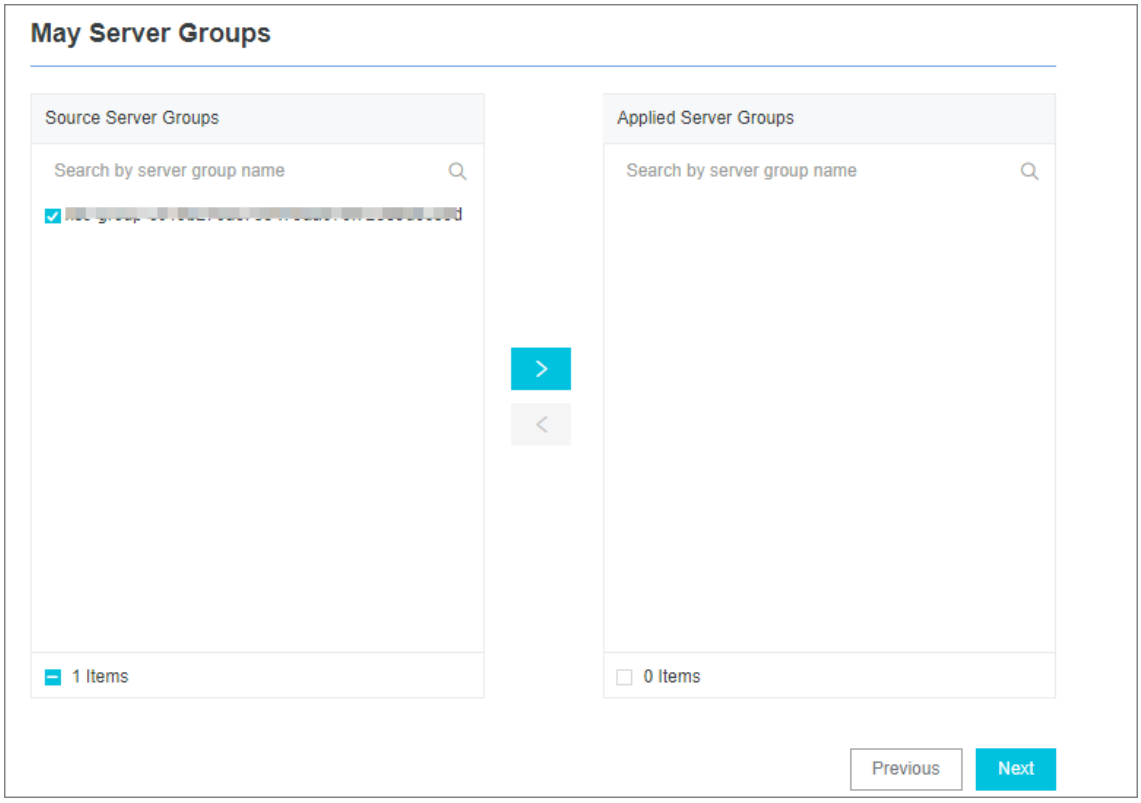
6. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.

7. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



> **Notice** If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

8. Configure the data source.

   Set **Config Name** and **Plug-in Config**.

   The `inputs` section is required. It specifies the collection configuration. The `processors` section is optional. It specifies the processing configuration. You must specify a collection statement for the collection configuration based on the data source. You can specify one or more processing methods for the processing configuration. For more information, see Configure data processing methods.

   The following sample code shows how to use UDP and TCP to listen on 127.0.0.1:9000:

```
{
     "inputs": [
         {
             "type": "service_syslog",
             "detail": {
                 "Address": "tcp://127.0.0.1:9000",
                 "ParseProtocol": "rfc3164"
             }
         },
         {
             "type": "service_syslog",
             "detail": {
                 "Address": "udp://127.0.0.1:9001",
                 "ParseProtocol": "rfc3164"
             }
         }
     ]
 }
```

9. Configure indexes in the Configure Query and Analysis step. Click **Next**.

   By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

   > **Note**
   > - To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
   > - If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

Configure the plug-in of Logtail to collect NGINX logs

NGINX access logs can be forwarded to specified addresses and ports over the syslog protocol. To deliver NGINX access logs as syslogs from a server to Log Service, you can create a Logtail configuration and apply it to the server group to which the server belongs.

1. Add a forwarding rule to the *nginx.conf* configuration file on the NGINX server.

   For example, add the following content to the configuration file.

   ```
   http {
       ...
       # Add this line.
       access_log syslog:server=127.0.0.1:9000,facility=local7,tag=nginx,severity=info combined;
       ...
   }
   ```

2. Run the following command to restart the NGINX service and validate the configuration.

   ```
   sudo service nginx restart
   ```

3. Create a Logtail configuration and apply it to the server group to which the server belongs.

   For more information, see Configure the plug-in of Logtail to collect syslogs.

4. Check whether the Logtail configuration takes effect.

   Run the `curl http://127.0.0.1/test.html` command in shell to generate an access log. If the Logtail configuration takes effect, you can view the log information on the query page of the Log Service console.

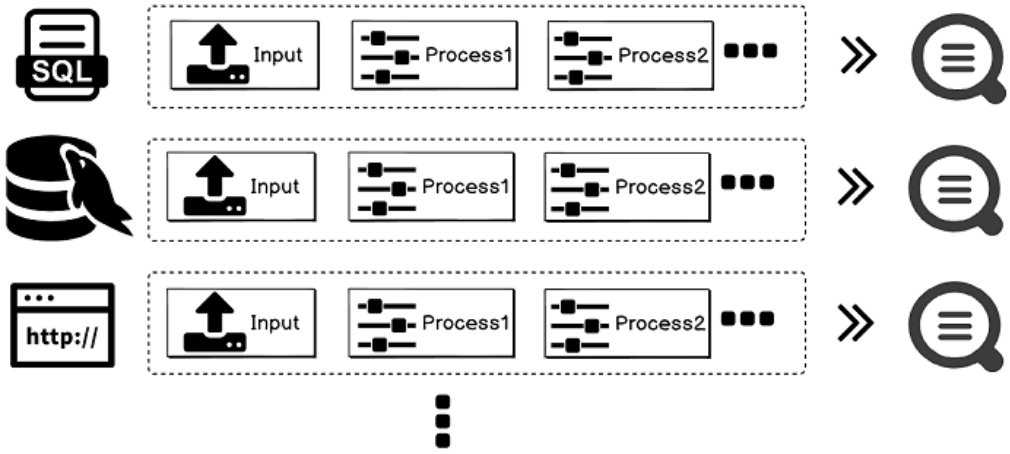
28.1.3.1.5.4. Configure data processing methods

Logtail allows you to configure plug-ins for data processing. Each plug-in defines a processing method. You can configure one or more processing methods for a data source. Then, Logtail executes the processing methods in sequence. This topic describes the available data processing methods and describes how to configure the methods.

Implementation

The following figure shows how collected data is processed.

Implementation



Plug-in elements

When you configure the data processing methods, you must set the key parameter to `processors` and the value parameter to an array of JSON objects. Each object contains the details of a processing method.

Each object contains the `type` and `detail` fields. The `type` field specifies the type of a processing method. The `detail` field contains configuration details.

```
"processors" : [
        {
            "type" : "processor_anchor",
            "detail" : {
                ...
            }
        },
        {
            "type" : "processor_regex",
            "detail" : {
                ...
            }
        }
    ]
```

Processing methods

The following processing methods are supported:

- Extract log fields by using a regular expression
- Extract log fields by using start and stop keywords
- Extract log fields by using a single-character delimiter

- Extract log fields by using a multi-character delimiter
- Convert an IP address into a geographical location
- Filter log fields by using a regular expression
- Add log fields
- Remove log fileds
- Extract log time (Go)
- Expand log fields (JSON)
- Combine log fields (JSON)
- Rename fields
- Extract log time (Strptime)

You can also create a custom method that includes several of the preceding methods. For more information, see Custom methods.

Extract log fields by using a regular expression

This method extracts the fields that match a specified regular expression.

The type of the plug-in is `processor_regex`.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field to extract by using the regular expression.
Regex	string	Yes	The regular expression. Enclose the value of fields to extract with parentheses `()`.
Keys	String array	Yes	The array of fields to extract, for example, ["key1", "key2" ...].
NoKeyError	bool	No	Specifies whether to report an error if no field matches the regular expression. Default value: false.
NoMatchError	bool	No	Specifies whether to report an error if the specified regular expression does not match logs. Default value: false.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: false. This value specifies that the SourceKey parameter is not returned.
FullMatch	bool	Yes	Specifies whether to extract fields that exactly match the `Regex` parameter. Default value: true. This value specifies that fields that partially match the Regex parameter are extracted.

The following example shows how to extract fields from an access log.

- Input data

```
"content" : "10.200. **. ** - - [10/Aug/2017:14:57:51 +0800] \"POST /PutData?
Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3
A30%20GMT&Topic=raw&Signature=<yourSignature> HTTP/1.1\" 0.024 18204 200 37 \"-\" \"aliyun-sdk-jav
a"
```

- Configurations

```
{
    "type" : "processor_regex",
    "detail" : {"SourceKey" : "content",
         "Regex" : "([\\d\\.] +) \\S+ \\S+ \\[(\\S+) \\S+\\] \"(\\w+) ([^\\\"]*)\" ([\\d\\.]+) (\\
d+) (\\d+) (\\d+|-) \"([^\\\"]*)\" \"([^\\\"]*)\" (\\d+)",
         "Keys"   : ["ip", "time", "method", "url", "request_time", "request_length", "status", "l
ength", "ref_url", "browser"],
         "NoKeyError" : true,
         "NoMatchError" : true,
         "KeepSource" : false
    }
}
```

- Output data

```
"ip" : "10.200. **.**"
"time" : "10/Aug/2017:14:57:51"
"method" : "POST"
"url" : "/PutData? Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun
%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=<yourSignature>"
"request_time" : "0.024"
"request_length" : "18204"
"status" : "200"
"length" : "27"
"ref_url" : "-"
"browser" : "aliyun-sdk-java"
```

Extract log fields by using start and stop keywords

This method uses the `start` and `stop` keywords to extract fields. You can extract fields from the JSON string between the start and stop keywords. You can also expand the JSON string into other forms.

The type of the plug-in is `processor_anchor`.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field to extract.
Anchors	Array	Yes	The array of anchors. For more information, see the following table.
NoAnchorError	bool	No	Specifies whether to report an error if no specified keyword is found. Default value: false.
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: false.

Parameter	Type	Required	Description
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: false. This value specifies that the SourceKey parameter is not returned.

Anchor fields

Parameter	Type	Required	Description
Start	string	Yes	The start keyword. If you do not specify the parameter, Logtail matches the first character of a string.
Stop	string	Yes	The stop keyword. If you do not specify the parameter, Logtail matches the last character of a string.
FieldName	string	Yes	The name of the field to extract.
FieldType	string	Yes	The type of the field to extract. Valid values: `string` and `json`.
ExpondJson	bool	No	Specifies whether to expand JSON strings. Default value: false. This parameter is available only if you specify `json` for the `FieldType` parameter.
ExpondConnecter	string	No	The connector that combines separate field names into a string. Default value: `_`.
MaxExpondDepth	int	No	The maximum depth of JSON expansion. Default value: `0`. This indicates no limit.

The following example shows how to use this method to process input data of multiple types.

- Input data

```
"content" : "time:2017.09.12 20:55:36\tjson:{\"key1\" : \"xx\", \"key2\": false, \"key3\":123.456,
\"key4\" : { \"inner1\" : 1, \"inner2\" : false}}"
```

- Configurations

```
{
   "type" : "processor_anchor",
   "detail" : {"SourceKey" : "content",
      "Anchors" : [
          {
              "Start" : "time",
              "Stop" : "\t",
              "FieldName" : "time",
              "FieldType" : "string",
              "ExpondJson" : false
          },
          {
              "Start" : "json:",
              "Stop" : "",
              "FieldName" : "val",
              "FieldType" : "json",
              "ExpondJson" : true
          }
      ]
  }
}
```

- Output data

```
"time" : "2017.09.12 20:55:36"
"val_key1" : "xx"
"val_key2" : "false"
"val_key3" : "123.456"
"value_key4_inner1" : "1"
"value_key4_inner2" : "false"
```

Extract log fields by using a single-character delimiter

This method uses `single-character delimiters` to split logs into several fields. You can enclose delimited fields by using characters that you specify in the Quote parameter.

The type of the plug-in is `processor_split_char`.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field to extract.
SplitSep	string	Yes	The single-character delimiter. You must specify a single character as a delimiter. You can specify a non-printable character such as `\u0001` as a delimiter.
SplitKeys	String array	Yes	The names of the fields that are split, for example, ["key1", "key2"...].
QuoteFlag	bool	No	Specifies whether to use the `Quote` parameter. Default value: false.
Quote	string	No	You must specify a single character. The parameter is available only if you specify true for the `QuoteFlag` parameter. You can specify non-printable characters, such as `\u0001`.

Parameter	Type	Required	Description
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: false.
NoMatchError	bool	No	Specifies whether to report an error if the specified delimiter is not found. Default value: false.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: false. This value specifies that the SourceKey parameter is not returned.

The following example shows how to use this method to process logs.

- Input data

```
"content" : "10. **. **. **|10/Aug/2017:14:57:51 +0800|POST|PutData?
Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3
A30%20GMT&Topic=raw&Signature=<yourSignature>|0.024|18204|200|37|-|
aliyun-sdk-java"
```

- Configurations

```
{
   "type" : "processor_split_char",
   "detail" : {"SourceKey" : "content",
      "SplitSep" : "|",
      "SplitKeys" : ["ip", "time", "method", "url", "request_time", "request_length", "status", "l
ength", "ref_url", "browser"]
  }
}
```

- Output data

```
"ip" : "10. **. **.**"
"time" : "10/Aug/2017:14:57:51 +0800"
"method" : "POST"
"url" : "/PutData? Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun
%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=<yourSignature>"
"request_time" : "0.024"
"request_length" : "18204"
"status" : "200"
"length" : "27"
"ref_url" : "-"
"browser" : "aliyun-sdk-java"
```

Extract log fields by using a multi-character delimiter

Similar to the single-character delimiter method, this method uses multi-character delimiters to split logs into several fields. The Quote parameter is unavailable for this method.

The type of the plug-in is `processor_split_string`.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field to extract.

Parameter	Type	Required	Description
SplitSep	string	Yes	The multi-character delimiter. You can specify non-printable characters such as `\u0001\u0002`.
SplitKeys	String array	Yes	The names of the fields that are split, for example, ["key1", "key2"...].
PreserveOthers	bool	No	Specifies whether to retain excess fields when the number of split fields exceeds the number of fields defined in the `SplitKeys` parameter. Default value: false.
ExpandOthers	bool	No	Specifies whether to parse excess fields. Default value: false.
ExpandKeyPrefix	string	No	The prefix of the names of excess fields. For example, if you specify `expand_` for the parameter, excess fields are named `expand_1` and `expand_2`.
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: false.
NoMatchError	bool	No	Specifies whether to report an error if no multi-character delimiter is found. Default value: false.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: false. The value false specifies that the SourceKey parameter is not returned.

The following example shows how to use this method to process logs.

- Input data

```
"content" : "10. **. **. **|#|10/Aug/2017:14:57:51 +0800|#|POST|#|PutData?
Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3
A30%20GMT&Topic=raw&Signature=<yourSignature>|#|0.024|#|18204|#|200|#|37|#|-|#|
aliyun-sdk-java"
```

- Configurations

```
{
   "type" : "processor_split_string",
   "detail" : {"SourceKey" : "content",
      "SplitSep" : "|#|",
      "SplitKeys" : ["ip", "time", "method", "url", "request_time", "request_length", "status"],
      "PreserveOthers" : true,
      "ExpandOthers" : true,
      "ExpandKeyPrefix" : "expand_"
   }
}
```

- Output data

```
"ip" : "10. **. **.**"
"time" : "10/Aug/2017:14:57:51 +0800"
"method" : "POST"
"url" : "/PutData? Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun
%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=<yourSignature>"
"request_time" : "0.024"
"request_length" : "18204"
"status" : "200"
"expand_1" : "27"
"expand_2" : "-"
"expand_3" : "aliyun-sdk-java"
```

Convert an IP address into a geographical location

This method converts IP address into a geographical location, such as a country, province, city, or geographical coordinates.

Note By default, the Logtail installation package does not include GeoIP databases. You must download these databases to your local host and configure the required parameters. We recommend that you download a version of the GeoIP database that includes the `City` database.

The type of the plug-in is `processor_geoip`.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field whose IP address you want to convert into a geographical location.
DBPath	string	Yes	The absolute path of the GeoIP database. The database format is `MMDB`, for example, `/user/data/GeoLite2-City_20180102/GeoLite2-City.mmdb`.
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: false.
NoMatchError	bool	No	Specifies whether to report an error if the specified IP address is invalid or does not match the IP addresses stored in the library. Default value: false.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: true.
Language	string	No	The language of the GeoIP database. Default value: `zh-CN`. Make sure that your GeoIP database can be displayed in a language that is suitable for your business.

The following example shows how to use this method to convert an IP address into a geographical location.

- Input data

```
"source_ip" : "**. **. **. **"
```

Download a GeoIP database and install the database on the host where Logtail resides. We recommend that you download MaxMind GeoLite2 that includes the city database.

> **Note** Make sure that the database format is MMDB.

- Configurations

```
{
   "type": "processor_geoip",
    "detail": {
         "SourceKey": "ip",
         "NoKeyError": true,
         "NoMatchError": true,
         "KeepSource": true,
         "DBPath" : "/user/local/data/GeoLite2-City_20180102/GeoLite2-City.mmdb"
    }
}
```

- Output result

```
"source_ip_city_" : "**. **. **.**"
"source_ip_province_" : "Zhejiang"
"source_ip_city_" : "Hangzhou"
"source_ip_province_code_" : "ZJ"
"source_ip_country_code_" : "CN"
"source_ip_longitude_" : "120.********"
"source_ip_latitude_" : "30. ********"
```

Filter log fields by using a regular expression

This method uses regular expressions to filter logs. You can specify conditions in the `Include` and `Exclude` parameters.

The type of the plug-in is `processor_filter_regex`.

Parameters

Parameter	Type	Required	Description
Include	The JSON object that includes key-value pairs.	No	Each key includes a log field. Each value includes a regular expression. If the field value matches the regular expression, the log is collected.
Exclude	The JSON object that includes key-value pairs.	No	Each key includes a log field. Each value includes a regular expression. If the field value matches the regular expression, the log is dropped.

> **Note** A log is collected only if the field value matches the regular expression specified in the `Include` parameter and does not match the regular expression specified in the `Exclude` parameter. Otherwise, the log is dropped.

The following example shows how to use this method to process logs.

- Input data

- Log 1

```
"ip" : "10. **. **.**"
"method" : "POST"
...
"browser" : "aliyun-sdk-java"
```

- Log 2

```
"ip" : "10. **. **.**"
"method" : "POST"
...
"browser" : "chrome"
```

- Log 3

```
"ip" : "192.168. *.*"
"method" : "POST"
...
"browser" : "ali-sls-ilogtail"
```

- Configurations

```
{
   "type" : "processor_filter_regex",
    "detail" : {
         "Include" : {
            "ip" : "10\\..*",
            "method" : "POST"
         },
         "Exclude" : {
            "browser" : "aliyun. *"
         }
    }
}
```

- Output data

Log	Matched	Reason
Log 1	No	The match failed because the value of the browser field matches the regular expression specified in the Exclude parameter.
Log 2	Yes	-
Log 3	No	The match failed because the value of the ip field does not match the regular expression specified in the `Include` parameter. The regular expression matches `IP` addresses that start with `10`.

Add log fields

You can use this method to add multiple fields to a log.

The type of the plug-in is `processor_add_fields`.

> **Note** This method is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
Fields	map	No	The JSON object that includes key-value pairs. You can specify multiple key-value pairs in the parameter.
IgnoreIfExist	bool	No	Specifies whether to ignore key-value pairs that have the same keys. Default value: false.

The following example shows how to use this method to add fields to logs.

- Input data

```
"aaa1":"value1"
```

- Configurations

```
{
  "processors":[
    {
      "type":"processor_add_fields",
      "detail": {
        "Fields": {
          "aaa2": "value2",
          "aaa3": "value3"
        }
      }
    }
  ]
}
```

- Output data

```
"aaa1":"value1"
"aaa2":"value2"
"aaa3":"value3"
```

Remove log fileds

You can use this method to remove specific fields from logs.

The type of the plug-in is `processor_drop`.

> **Note** The method is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
DropKeys	array	No	The array that includes a set of strings. You can remove multiple fields from a log.

The following example shows how to remove the `aaa1` and `aaa2` fields from a log.

- Input data

```
"aaa1":"value1"
"aaa2":"value2"
"aaa3":"value3"
```

- Configurations

```
{
  "processors":[
    {
      "type":"processor_drop",
      "detail": {
        "DropKeys": ["aaa1","aaa2"]
      }
    }
  ]
}
```

- Output data

```
"aaa3":"value3"
```

Extract log time (Go)

You can use this method to extract time from a log field and convert the time format.

The type of the plug-in is `processor_gotime`.

> **Note** This plug-in is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the log field from which you want to extract time.
SourceFormat	string	Yes	The time that is parsed in Go.
SourceLocation	int	Yes	The source time zone. If the parameter is not specified, it indicates the time zone of the local host.
DestKey	string	Yes	The destination field.
DestFormat	string	Yes	The destination time format in Go.
DestLocation	int	No	The destination time zone. If the parameter is not specified, it indicates the time zone of the local host.
SetTime	bool	No	Specifies whether to overwrite the original time. Default value: true.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: true.
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: true.
AlarmIfFail	bool	No	Specifies whether to send alerts when extraction failed. Default value: true.

Use `2006-01-02 15:04:05` (UTC+8) of the `s_key` field as the source time. Convert the time into `2006/01/02 15:04:05` (UTC+9) and save the new time in the `d_key` field. The following example shows how to use this method to process logs.

- Input data

```
"s_key":"2019-07-05 19:28:01"
```

- Configurations

```
{
  "processors":[
    {
      "type":"processor_gotime",
      "detail": {
        "SourceKey": "s_key",
        "SourceFormat":"2006-01-02 15:04:05",
        "SourceLocation":8,
        "DestKey":"d_key",
        "DestFormat":"2006/01/02 15:04:05",
        "DestLocation":9,
        "SetTime": true,
        "KeepSource": true,
        "NoKeyError": true,
        "AlarmIfFail": true
      }
    }
  ]
}
```

- Output data

```
"s_key":"2019-07-05 19:28:01"
"d_key":"2019/07/05 20:28:01"
```

Expand log fields (JSON)

You can use this method to expand a log field.

The type of the plug-in is `processor_json`.

> **Note** This plug-in is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field you want to expand.
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: true.
ExpandDepth	int	No	The depth of JSON expansion. The value must be a non-negative integer. Default value: 0. This indicates the depth is not limited. The value n specifies that the number of levels to expand is n.

Parameter	Type	Required	Description
ExpandConnector	string	No	The delimiter that you use to connect expanded levels. Default value: `_`. You can leave this parameter unspecified.
Prefix	string	No	The prefix that you want to add to the name of each new field after expansion.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: true.
UseSourceKeyAsPrefix	bool	No	Specifies whether to retain the name of the source field as the prefix of each new field after expansion. Default value: false.

The following example shows how to use the field expansion (JSON) method to expand the `s_key` field.

- Input data

```
"s_key":"{\"k1\":{\"k2\":{\"k3\":{\"k4\":{\"k51\":\"51\",\"k52\":\"52\"},\"k41\":\"41\"}}})"
```

- Configurations

```
{
  "processors":[
    {
      "type":"processor_json",
      "detail": {
        "SourceKey": "s_key",
        "NoKeyError":true,
        "ExpandDepth":0,
        "ExpandConnector":"-",
        "Prefix":"j",
        "KeepSource": false,
        "UseSourceKeyAsPrefix": true
      }
    }
  ]
}
```

- Output data

```
"s_key":"{\"k1\":{\"k2\":{\"k3\":{\"k4\":{\"k51\":\"51\",\"k52\":\"52\"},\"k41\":\"41\"}}})"
"js_key-k1-k2-k3-k4-k51":"51"
"js_key-k1-k2-k3-k4-k52":"52"
"js_key-k1-k2-k3-k41":"41"
```

Combine log fields (JSON)

You can use this method to combine multiple log fields into one field.

The type of the plug-in is `processor_packjson`.

> **Note** This plug-in is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
SourceKeys	array	Yes	The array that includes the names of fields that you want to combine.
DestKey	string	No	The name of the destination field after combination.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: true.
AlarmIfIncomplete	bool	No	Specifies whether to send alerts if no source fields exist. Default value: true.

The following example shows how to use the method to combine the `a` and `b` fields into the `d_key` field.

- Input data

```
"a":"1"
"b":"2"
```

- Configurations

```
{
  "processors":[
    {
      "type":"processor_packjson",
      "detail": {
        "SourceKeys": ["a","b"],
        "DestKey":"d_key",
        "KeepSource":true,
        "AlarmIfEmpty":true
      }
    }
  ]
}
```

- Output data

```
"a":"1"
"b":"2"
"d_key":"{\"a\":\"1\",\"b\":\"2\"}"
```

Rename fields

You can use this method to rename multiple fields.

The type of the plug-in is `processor_rename`.

> **Note** This plug-in is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: true.

Parameter	Type	Required	Description
SourceKeys	array	Yes	The array that includes the names of fields that you want to rename.
DestKeys	array	Yes	The array that includes the new names of the fields.

The following example shows how to use this method to rename the `aaa1` and `aaa2` fields to `bbb1` and `bbb2` fields.

- Input data

```
"aaa1":"value1"
"aaa2":"value2"
"aaa3":"value3"
```

- Configurations

```
{
  "processors":[
    {
      "type":"processor_rename",
      "detail": {
        "SourceKeys": ["aaa1","aaa2"],
        "DestKeys": ["bbb1","bbb2"],
        "NoKeyError": true
      }
    }
  ]
}
```

- Output data

```
"bbb1":"value1"
"bbb2":"value2"
"aaa3":"value3"
```

Extract log time (Strptime)

You can use this method to extract time from a log field and parse the time by using the Linux strptime() function.

The type of the plug-in is `processor_strptime`.

> **Note** This plug-in is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field from which you want to extract time.
Format	string	Yes	The time format to parse the time.
AdjustUTCOffset	bool	No	Specifies whether to adjust the time zone. Default value: false.

Parameter	Type	Required	Description
UTCOffset	int	No	The offset that is used to adjust the time zone. Unit: seconds. For example, if you set the value to 14400, the time zone is changed to UTC+8.
AlarmIfFail	bool	No	Specifies whether to send alerts if a field fails to be extracted.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: true.

Parse the value of the `log_time` in the `%Y/%m/%d %H:%M:%S` time format and use the time zone of your local host. The following examples show how to use this method to process logs.

- Example 1: The time zone is UTC+8.
  - Input data

    ```
    "log_time":"2016/01/02 12:59:59"
    ```

  - Configurations

    ```
    {
      "processors":[
        {
          "type":"processor_strptime",
          "detail": {
            "SourceKey": "log_time",
            "Format": "%Y/%m/%d %H:%M:%S"
          }
        }
      ]
    }
    ```

  - Output data

    ```
    "log_time":"2016/01/02 12:59:59"
    Log.Time = 1451710799
    ```

- Example 2: The time zone is UTC+7.
  - Input data

    ```
    "log_time":"2016/01/02 12:59:59"
    ```

- Configurations

```
{
  "processors":[
    {
      "type":"processor_strptime",
      "detail": {
        "SourceKey": "log_time",
        "Format": "%Y/%m/%d %H:%M:%S",
        "AdjustUTCOffset": true,
        "UTCOffset": 25200
      }
    }
  ]
}
```

- Output data

```
"log_time":"2016/01/02 12:59:59"
Log.Time = 1451714399
```

Custom methods

You can use a combination of multiple processing methods to process logs. The following example shows how to use a single-character delimiter to split a log into several fields and then specify anchor points to extract content from the `detail` field.

- Input data

```
"content" :
"ACCESS|QAS|11. **. **.**|1508729889935|52460dbed4d540b88a973cf5452b1447|1238|appKey=ba,env=pub,requestTime=1508729889913,latency=22ms,
request={appKey:ba,optional:{\\domains\\:\\daily\\,\\version\\:\\v2\\},rawQuery:{\\query\\:\\The route to Location A\\,\\domain\\:\\Navigation\\,\\intent\\:\\navigate\\,\\slots\\:\\to_geo:level3=Location A\\,\\location\\:\\Location B\\},
requestId:52460dbed4d540b88a973cf5452b1447},
response={answers:[],status:SUCCESS}|"
```

- Configurations

```
"processors" : [
      {
          "type" : "processor_split_char",
          "detail" : {"SourceKey" : "content",
              "SplitSep" : "|",
              "SplitKeys" : ["method", "type", "ip", "time", "req_id", "size", "detail"]
          }
      },
      {
          "type" : "processor_anchor",
          "detail" : "SourceKey" : "detail",
              "Anchors" : [
                  {
                          "Start" : "appKey=",
                      "Stop" : ",env=",
                      "FieldName" : "appKey",
                      "FieldType" : "string"
                  },
                  {
                      "Start" : ",env",
                      "Stop" : ",requestTime=",
                      "FieldName" : "env",
                      "FieldType" : "string"
                  },
                  {
                      "Start" : ",requestTime=",
                      "Stop" : ",latency",
                      "FieldName" : "requestTime",
                      "FieldType" : "string"
                  },
                  {
                      "Start" : ",latency=",
                      "Stop" : ",request=",
                      "FieldName" : "latency",
                      "FieldType" : "string"
                  },
                  {

```

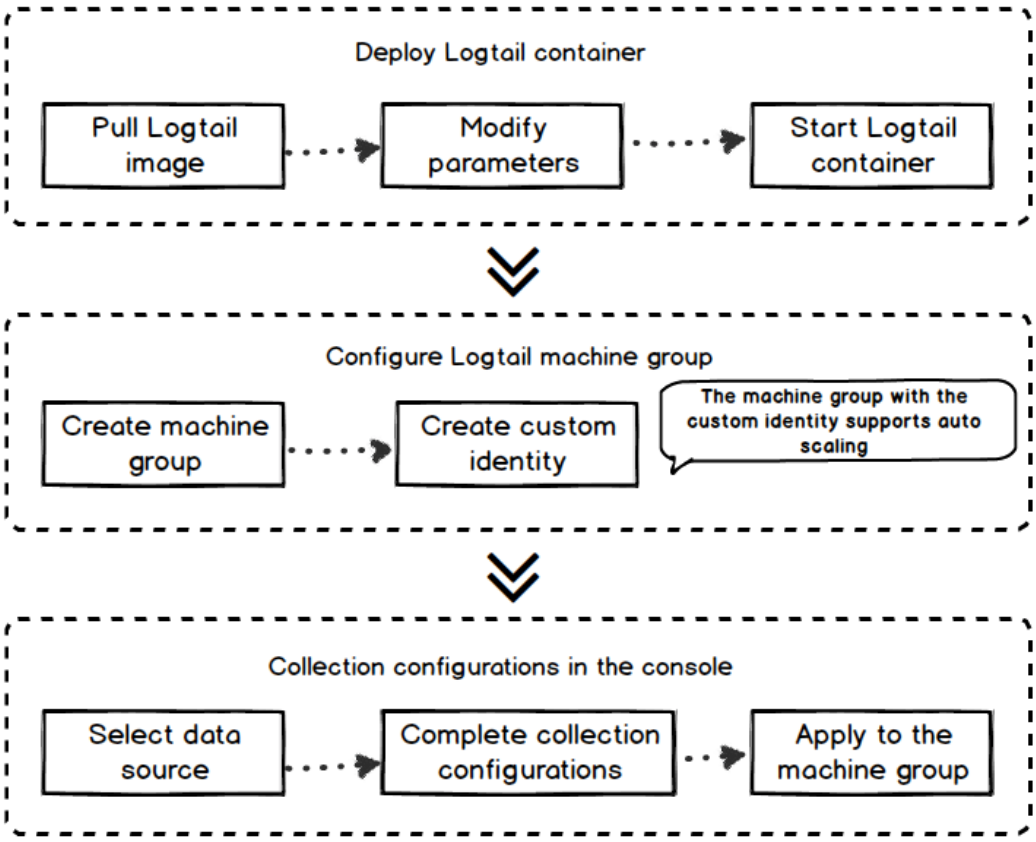
28.1.3.1.6. Collect container logs

28.1.3.1.6.1. Collect standard Docker logs

This topic describes how to use Logtail to collect standard Docker logs and upload these logs together with the container metadata to Log Service.

Procedure

Procedure



1. Deploy a Logtail container.

2. Configure a Logtail server group.

   Create a server group with a custom ID in the Log Service console. The container cluster can automatically scale up or down based on data traffic.

3. Create a Logtail configuration.

   Create a Logtail configuration in the Log Service console. The Logtail configuration process is completed in the Log Service console. No local configuration is needed.

Deploy a Logtail container

1. Run the following command to pull the Logtail image.

```
docker pull registry.cn-hangzhou.aliyuncs.com/log-service/logtail
```

2. Start a Logtail container.

   Set the `${your_region_name}`, `${your_aliyun_user_id}`, and `${your_machine_group_user_defined_id}` parameters in the startup template.

```
docker run -d -v /:/logtail_host:ro -v /var/run:/var/run --env
ALIYUN_LOGTAIL_CONFIG=/etc/ilogtail/conf/${your_region_name}/ilogtail_config.json
--env ALIYUN_LOGTAIL_USER_ID=${your_aliyun_user_id} --env
 ALIYUN_LOGTAIL_USER_DEFINED_ID=${your_machine_group_user_defined_id} registry.cn-hangzhou.aliyun
cs.com/log-service/logtail
```

   Notice Before you set the parameters, you must complete one of the following configurations. Otherwise, the `container text file busy` error may occur when you delete another container.

   - For CentOS 7.4 and later versions, set fs.may_detach_mounts to 1. For more information, see Bug 1468249, Bug 1441737, and Issue 34538.
   - Grant the `privileged` permission to Logtail by adding the `--privileged` flag to the startup parameters. For more information, see Docker run reference.

Parameter	Description
`${your_region_name}`	The region of the project. For more information, see View the information of a project.
`${your_aliyun_user_id}`	The user ID. Set this parameter to the ID of your Alibaba Cloud account, which is a string. For information about how to view the ID, see Step 1 in Configure an account ID for a server.
`${your_machine_group_user_defined_id}`	The custom ID of your server group. For information about how to set the custom ID, see Step 1 in Create a machine group based on a custom ID.

   After you set the parameters, run the following command to start the Logtail container.

```
docker run -d -v /:/logtail_host:ro -v /var/run:/var/run
--env ALIYUN_LOGTAIL_CONFIG=/etc/ilogtail/conf/cn_hangzhou/ilogtail_config.json --env
 ALIYUN_LOGTAIL_USER_ID=1654218******--env ALIYUN_LOGTAIL_USER_DEFINED_ID=log-docker-demo registr
y.cn-hangzhou.aliyuncs.com/log-service/logtail
```

> **Notice**
>
> You can customize the startup parameters of the Logtail container if the following conditions are met:
>
> - The following environment variables exist before you start the Logtail container: `ALIYUN_LOGTAIL_USER_DEFINED_ID`, `ALIYUN_LOGTAIL_USER_ID`, and `ALIYUN_LOGTAIL_CONFIG`.
> - The */var/run* directory is mounted on the */var/run* directory of the Logtail container.
> - To collect container standard output, container logs, or host files, you must mount the root directory on the `/logtail_host` directory of the Logtail container.
> - If an error showing *The parameter is invalid : uuid=none* occurs in the `/usr/local/ilogtail/ilogtail.LOG` Logtail log file, create a file named *product_uuid* on the host. Add a valid UUID such as `169E98C9-ABC0-4A92-B1D2-AA6239C0D261` to the file, and mount the file on the */sys/class/dmi/id/product_uuid* directory of the Logtail container.

Configure a Logtail server group

1. Log on to the Log Service console.
2. Click a project name.
3. In the left-side navigation pane, click the **Server Groups** icon to show the server group list.
4. Click the icon next to Server Groups, and then select **Create Server Group**.

   You can also create a server group when you import data to Log Service.
5. In the dialog box that appears, select **Custom ID** from the Identifier drop-down list. Enter the value of `ALIYUN_LOGTAIL_USER_DEFINED_ID` set in the previous step in the **Custom Identifier** field.

Click OK. One minute later, click the name of the server group in the **Server Groups** list. On the **Server Group Settings** page that appears, you can view the heartbeat status of the Logtail container. For more information, see View the status of a server group.

Create a Logtail configuration

Create a Logtail configuration in the console.

- For more information about Docker logs, see Collect container text logs.
- For more information about Docker standard output, see Collect stdout and stderr logs from containers.
- Host text logs.

  The root directory of a host is mounted on the `/logtail_host` directory of the Logtail container by default. You must add the /logtail_host prefix to the log path. For example, if you want to collect data from the `/home/logs/app_log/` directory of the host, you must set the log path as `/logtail_host/home/logs/app_log/`.

What to do next

- View the status of the Logtail container.

  You can run the `docker exec ${logtail_container_id} /etc/init.d/ilogtaild status` command to view the status of Logtail.
- View the version number, IP address, and startup time of Logtail.

  You can run the `docker exec ${logtail_container_id} cat /usr/local/ilogtail/app_info.json` command to view Logtail information.
- View the operations logs of Logtail.

  The operations logs of Logtail are stored in the `ilogtail.LOG` file in the `/usr/local/ilogtail/` directory. If the log file is rotated and compressed, it is stored as a file named `ilogtail.LOG.x.gz`.

For example:

```
[root@iZbp17enxc2us3624wexh2Z ilogtail]# docker exec a287de895e40 tail -n 5 /usr/local/ilogtail/ilogtail.LOG
[2018-02-06 08:13:35.721864]    [INFO]    [8]    [build/release64/sls/ilogtail/LogtailPlugin.cpp:104]    logtail plugin Resume:start
[2018-02-06 08:13:35.722135]    [INFO]    [8]    [build/release64/sls/ilogtail/LogtailPlugin.cpp:106]    logtail plugin Resume:success
[2018-02-06 08:13:35.722149]    [INFO]    [8]    [build/release64/sls/ilogtail/EventDispatcher.cpp:369]    start add existed check point events, size:0
[2018-02-06 08:13:35.722155]    [INFO]    [8]    [build/release64/sls/ilogtail/EventDispatcher.cpp:511]    add existed check point events, size:0    cache size:0    event size:0    success count:0
[2018-02-06 08:13:39.725417]    [INFO]    [8]    [build/release64/sls/ilogtail/ConfigManager.cpp:3776]    check container path update flag:0    size:1
```

Ignore the following standard output:

```
start umount useless mount points, /shm$|/merged$|/mqueue$
umount: /logtail_host/var/lib/docker/overlay2/3fd0043af174cb0273c3c7869500fbe2bdb95d13b1e110172ef57fe840c82155/merged: must be superuser to unmount
umount: /logtail_host/var/lib/docker/overlay2/d5b10aa19399992755de1f85d25009528daa749c1bf8c16edff44beab6e69718/merged: must be superuser to unmount
umount: /logtail_host/var/lib/docker/overlay2/5c3125daddacedec29df72ad0c52fac800cd56c6e880dc4e8a640b1e16c22dbe/merged: must be superuser to unmount
...
xargs: umount: exited with status 255; aborting
umount done
start logtail
ilogtail is running
logtail status:
ilogtail is running
```

- Restart Logtail.

  To restart Logtail, use the following sample code:

```
[root@iZbp17enxc2us3624wexh2Z ilogtail]# docker exec a287de895e40 /etc/init.d/ilogtaild stop
kill process Name: ilogtail pid: 7
kill process Name: ilogtail pid: 8
stop success
[root@iZbp17enxc2us3624wexh2Z ilogtail]# docker exec a287de895e40 /etc/init.d/ilogtaild start
ilogtail is running
```

28.1.3.1.6.2. Collect Kubernetes logs

This topic describes how to install and use Logtail to collect logs from Kubernetes clusters.

Configuration procedure

Perform the following steps to collect logs from Kubernetes clusters:

1. Install the alibaba-log-controller Helm package.
2. Use the Log Service console to manage log collection configurations.

Step 1: Install Logtail

- Install Logtail in an Alibaba Cloud Container Service for Kubernetes cluster.

  If Log Service components are not installed in your cluster, you must manually install the components.

  i. Connect to the Kubernetes cluster by using CloudShell.

ii. Run the following command in CloudShell to obtain the ID of your Apsara Stack tenant account.

```
echo $ALIBABA_CLOUD_ACCOUNT_ID
```

iii. After you set the `${your_k8s_cluster_id}`, `${your_ali_uid}`, and `${your_k8s_cluster_region_id}` parameters, run the following command:

```
wget https://acs-logging.oss-cn-hangzhou.aliyuncs.com/alicloud-k8s-log-installer.sh -O alicloud-k8s-log-installer.sh; chmod 744 ./alicloud-k8s-log-installer.sh; ./alicloud-k8s-log-installer.sh --cluster-id ${your_k8s_cluster_id} --ali-uid ${your_ali_uid} --region-id ${your_k8s_cluster_region_id}
```

- Install Logtail in a user-created Kubernetes cluster.

> **Notice**
> - The version of the Kubernetes cluster must be 1.8 or later.
> - Helm 2.6.4 or later must be installed.

i. In the Log Service console, create a project whose name starts with `k8s-log-custom-`.

ii. Replace the parameters in the following command based on your business requirements:

```
wget http://logtail-release-cn-hangzhou.oss-cn-hangzhou.aliyuncs.com/kubernetes/alicloud-log-k8s-custom-install.sh; chmod 744 ./alicloud-log-k8s-custom-install.sh; sh ./alicloud-log-k8s-custom-install.sh {your-project-suffix} {region-id} {aliuid} {access-key-id} {access-key-secret}
```

The following table lists the parameters in the preceding command.

Parameter	Description
{your-project-suffix}	The portion of the project name at the end of `k8s-log-custom-`. For example, if you create a project whose name is `k8s-log-custom-xxxx`, set this parameter to `xxxx`.
{regionId}	The ID of the region where the project resides. For more information, see View the information of a project.
{aliuid}	The user ID. Set this parameter to the ID of your Apsara Stack tenant account. **Note** The ID of an Apsara Stack tenant account is a string. For more information about how to obtain the ID, see Configure an account ID for a server.
{access-key-id}	The AccessKey ID of your Apsara Stack tenant account.
{access-key-secret}	The AccessKey secret of your Apsara Stack tenant account.

After Logtail is installed in the Kubernetes cluster, Log Service automatically creates a machine group named `k8s-group-${your_k8s_cluster_id}` for the project.

> **Note**
>
> - A Logstore named `config-operation-log` is automatically created in the project. Do not delete the Logstore.
> - When you install Logtail in a user-created Kubernetes cluster, Logtail is granted `privileged` permissions by default. This prevents the `container text file busy` error when you delete a pod. For more information, visit Bug 1468249, Bug 1441737, and Issue 34538.

The following example shows a successful installation:

```
[root@iZbp1dsxxxxxqfbiaZ ~]#  wget http://logtail-release-cn-hangzhou.oss-cn-hangzhou.aliyuncs.com
/kubernetes/alicloud-log-k8s-custom-install.sh; chmod 744 ./alicloud-log-k8s-custom-install.sh; sh
./alicloud-log-k8s-custom-install.sh xxxx cn-hangzhou 165xxxxxxxx050 LTAxxxxxxxxxxx AIxxxxxxxxxxxx
xxxxxxxxxxxxxxxxxe

aliyunlogconfigs.log.alibabacloud.com  0s
==> v1beta1/ClusterRole
alibaba-log-controller  0s
[INFO] your k8s is using project : k8s-log-custom-xxx, region : cn-hangzhou, aliuid : ************
***, accessKeyId : LTA**********
[SUCCESS] install helm package : alibaba-log-controller success.
```

To check the status of each Log Service component in the Kubernetes cluster, run the `helm status alibaba-log-controller` command. If all pods are in the Running state, Logtail is installed.

Log on to the Log Service console to find the project. If you have multiple projects, search for the project by using the `k8s-log` keyword.

Step 2: Configure log collection

Create Logtail configurations for log collection in the console as required.

- For information about how to collect Kubernetes text logs, see Collect container text logs.
- For information about how to collect Kubernetes stdout logs, see Collect stdout and stderr logs from containers.
- Host text logs.

  By default, the root directory of a host is mounted to the `/logtail_host` directory of the Logtail container. You must add the /logtail_host prefix to the log path. For example, if you want to collect data from the `/home/logs/app_log/` directory of the host, you must set the log path to `/logtail_host/home/logs/app_log/`.

Other common commands

- Store logs of multiple clusters in one project

  You can collect logs from multiple Kubernetes clusters. If you want to store these logs in the same project, you can specify the same cluster ID for the `${your_k8s_cluster_id}` parameter when you install Log Service components on multiple Kubernetes clusters.

  For example, if you have three Kubernetes clusters whose IDs are abc001, abc002, and abc003, specify `abc001` for the `${your_k8s_cluster_id}` parameter when you install Log Service components for each Kubernetes cluster.

  > **Notice** This feature is unavailable for Kubernetes clusters that reside in different regions.

- Logtail container logs

  Logtail log files named `ilogtail.LOG` and `logtail_plugin.LOG` are stored in the `/usr/local/ilogtail/` directory of a Logtail container. Ignore the following standard output:

  ```
  start umount useless mount points, /shm$|/merged$|/mqueue$
  umount: /logtail_host/var/lib/docker/overlay2/3fd0043af174cb0273c3c7869500fbe2bdb95d13b1e110172ef5
  7fe840c82155/merged: must be superuser to unmount
  umount: /logtail_host/var/lib/docker/overlay2/d5b10aa19399992755de1f85d25009528daa749c1bf8c16edff4
  4beab6e69718/merged: must be superuser to unmount
  umount: /logtail_host/var/lib/docker/overlay2/5c3125daddacedec29df72ad0c52fac800cd56c6e880dc4e8a64
  0b1e16c22dbe/merged: must be superuser to unmount
  ......
  xargs: umount: exited with status 255; aborting
  umount done
  start logtail
  ilogtail is running
  logtail status:
  ilogtail is running
  ```

- View the status of each Log Service component in a Kubernetes cluster

  ```
  helm status alibaba-log-controller
  ```

- Troubleshoot alibaba-log-controller startup failures

  Make sure that the following conditions are met:

  - Log Service components are installed on the master node of the Kubernetes cluster.
  - The Kubernetes cluster ID that you specified is valid when you install Log Service components.

  If Log Service components fail to be installled because the preceding conditions are not met, run the `helm del --purge alibaba-log-controller` command to delete the installation package and install Log Service components again.

- View the status of Logtail DaemonSet in a Kubernetes cluster

  Run the `kubectl get ds -n kube-system` command.

> **Note** The default namespace of Logtail is `kube-system`.

- View the version number, IP address, and startup time of Logtail.

  Example:

```
[root@iZbp1dsu6v77zfb40qfbiaZ ~]# kubectl get po -n kube-system | grep logtail
NAME            READY     STATUS    RESTARTS   AGE
logtail-ds-gb92k   1/1       Running   0          2h
logtail-ds-wm7lw   1/1       Running   0          4d
[root@iZbp1dsu6v77zfb40qfbiaZ ~]# kubectl exec logtail-ds-gb92k -n kube-system cat /usr/local/ilog
tail/app_info.json
{
   "UUID" : "",
   "hostname" : "logtail-ds-gb92k",
   "instance_id" : "0EBB2B0E-0A3B-11E8-B0CE-0A58AC140402_172.20.4.2_1517810940",
   "ip" : "172.20.4.2",
   "logtail_version" : "0.16.2",
   "os" : "Linux; 3.10.0-693.2.2.el7.x86_64; #1 SMP Tue Sep 12 22:26:13 UTC 2017; x86_64",
   "update_time" : "2018-02-05 06:09:01"
}
```

- View the operational logs of Logtail

  Logtail operational logs are stored in the `ilogtail.LOG` file in the `/usr/local/ilogtail/` directory. If the log file is rotated and compressed, it is stored as a file named `ilogtail.LOG.x.gz`.

  Example:

```
[root@iZbp1dsu6v77zfb40qfbiaZ ~]# kubectl exec logtail-ds-gb92k -n kube-system tail /usr/local/ilo
gtail/ilogtail.LOG
[2018-02-05 06:09:02.168693] [INFO] [9] [build/release64/sls/ilogtail/LogtailPlugin.cpp:104] logta
il plugin Resume:start
[2018-02-05 06:09:02.168807] [INFO] [9] [build/release64/sls/ilogtail/LogtailPlugin.cpp:106] logta
il plugin Resume:success

[2018-02-05 06:09:02.168827] [INFO] [9] [build/release64/sls/ilogtail/EventDispatcher.cpp:511] add
existed check point events, size:0 cache size:0 event size:0 success count:0
```

- Restart Logtail in a pod

  Example:

```
[root@iZbp1dsu6v77zfb40qfbiaZ ~]# kubectl exec logtail-ds-gb92k -n kube-system /etc/init.d/ilogtai
ld stop
kill process Name: ilogtail pid: 7
kill process Name: ilogtail pid: 9
stop success
[root@iZbp1dsu6v77zfb40qfbiaZ ~]# kubectl exec logtail-ds-gb92k -n kube-system /etc/init.d/ilogtai
ld start
ilogtail is running
```

28.1.3.1.6.3. Collect container text logs

Logtail collects text logs generated in containers and uploads these logs together with the container-related metadata information to Log Service.

Features

Compared with basic log file collection, Docker file collection has the following characteristics:

- Allows you to configure the log path of a container, without the need to consider the mapping between the path and the host.
- Allows you to use labels to specify the containers whose logs are to be collected.
- Allows you to use labels to exclude specific containers.
- Allows you to use environment variables to specify the containers whose logs are to be collected.
- Allows you to use environment variables to exclude specific containers.
- Supports multiline logs such as Java Stack logs.
- Supports automatic labeling for container data.
- Supports automatic labeling for Kubernetes containers.

Limits

- Collection stop policy: When a container is stopped and Logtail detects the `die` event on the container, Logtail stops collecting logs of the container (with a latency of no more than 3 seconds). In this case, if a collection latency occurs, some logs generated before the stop action may be lost.
- Docker storage driver: Only overlay and overlay2 are supported. For other storage drivers, you must mount the log directory to the local host.
- Logtail running mode: Logtail must run in a container and must be deployed based on Logtail deployment solutions.
- Label: refers to the label information in docker inspect. It is not synonymous with labels in Kubernetes.
- Environment: refers to the environment information configured during container startup.

Procedure

1. Deploy and configure the Logtail container.
2. Configure log collection in Log Service.

Logtail deployment and configuration

- Kubernetes

  For more information about Kubernetes log collection, see Logtail deployment solution for collecting Kubernetes logs.

- Management methods for other containers

  For more information about management methods for other containers, such as Swarm and Mesos, see Common deployment solution for collecting Docker logs.

Collection configuration

1. Log on to the Log Service console.
2. Click the **Import Data** button. On the **Import Data** page that appears, select **Docker File**.
3. Select a destination project and Logstore, and then click **Next**.

   You can also click **Create Now** to create a project and a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.

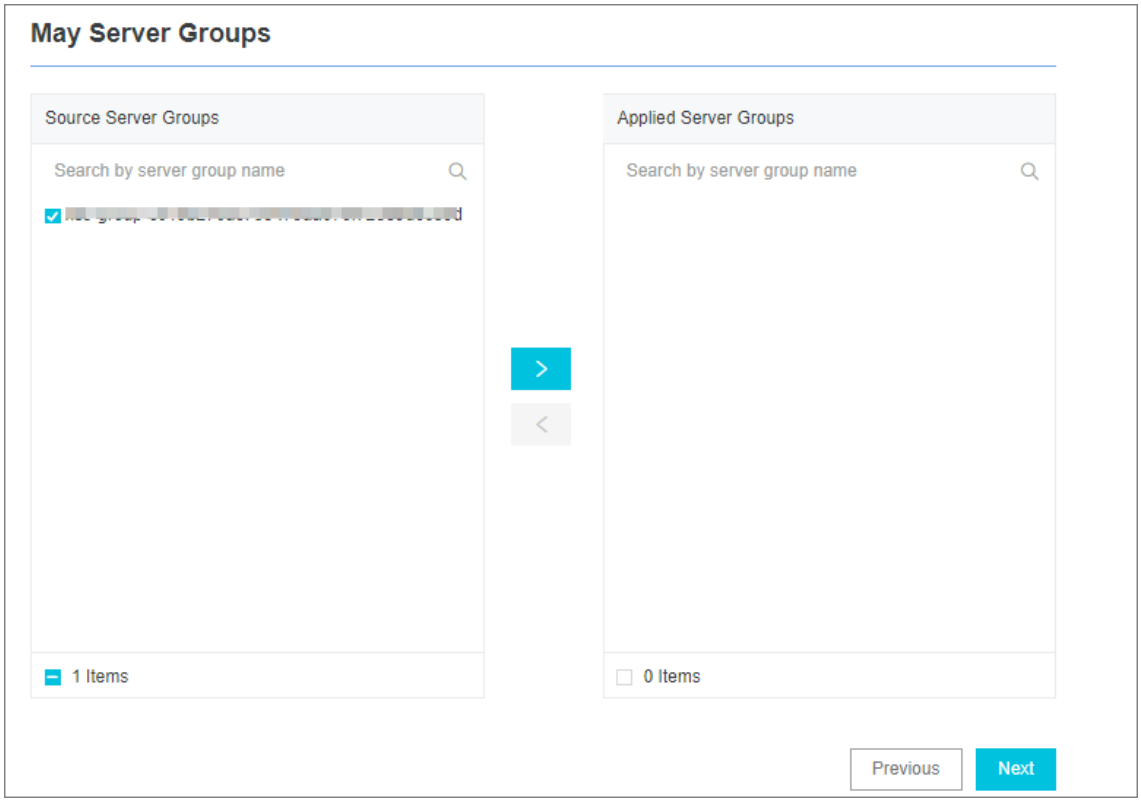
4. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.

5. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



> **Notice** If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

6. Configure Logtail.

   The following table lists data source-specific parameters. For more information about common parameters, see Configure text log collection.

Parameter	Description
Docker File	This parameter is used to check whether the collected target file is a Docker file.
Label Whitelist	LabelKey is required. If LabelValue is not empty, only containers whose labels contain LabelKey = LabelValue are collected. If LabelValue is empty, all the containers whose labels contain LabelKey are collected. **Note** ○ Key-value pairs are disjunctive with each other. If the label of a container contains one of the key-value pairs you specify, logs of the container are collected. ○ Labels refer to Docker labels.

Parameter	Description
Label Blacklist	LabelKey is required. If LabelValue is not empty, only containers whose labels contain LabelKey = LabelValue are excluded. If LabelValue is empty, all containers whose labels contain LabelKey are excluded. **Note** ○ Key-value pairs are disjunctive with each other. If the label of a container contains one of the key-value pairs you specify, the container is excluded. ○ Labels described in this topic refer to the label information in docker inspect.
Environment Variable Whitelist	EnvKey is required. If EnvValue is not empty, only containers whose environment variables contain EnvKey = EnvValue are collected. If EnvValue is empty, all containers whose environment variables contain EnvKey are collected. **Note** ○ Key-value pairs are disjunctive with each other. If the environment variable of a container contains one of the key-value pairs you specify, logs of the container are collected. ○ The environment variable refers to the environment information configured in container startup.
Environment Variable Blacklist	EnvKey is required. If EnvValue is not empty, only containers whose environment variables contain EnvKey = EnvValue are excluded. If EnvValue is empty, all containers whose environment variables contain EnvKey are excluded. **Note** ○ Key-value pairs are disjunctive with each other. If the environment variable of a container contains one of the key-value pairs you specify, the container is excluded. ○ The environment variable refers to the environment information configured in container startup.

Note

- Labels in whitelist and blacklist are different from those defined in Kubernetes. Labels in this topic refer to the label information in docker inspect.
- A namespace and a container name in Kubernetes can be mapped to Docker labels. LabelKey corresponding to a namespace is `io.kubernetes.pod.namespace`. LabelKey corresponding to a container name is `io.kubernetes.container.name`. For example, the namespace of the pod you created is backend-prod and the container name is worker-server. In this case, you can configure a whitelist label: `io.kubernetes.pod.namespace : backend-prod` or `io.kubernetes.container.name : worker-server`, so that only logs of the container are collected.
- In Kubernetes, we recommend that you only use the `io.kubernetes.pod.namespace` and `io.kubernetes.container.name` labels. In other cases, use an environment variable whitelist or blacklist.

7. Configure indexes in the Configure Query and Analysis step. Click **Next**.

By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

> **Note**
> - To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
> - If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

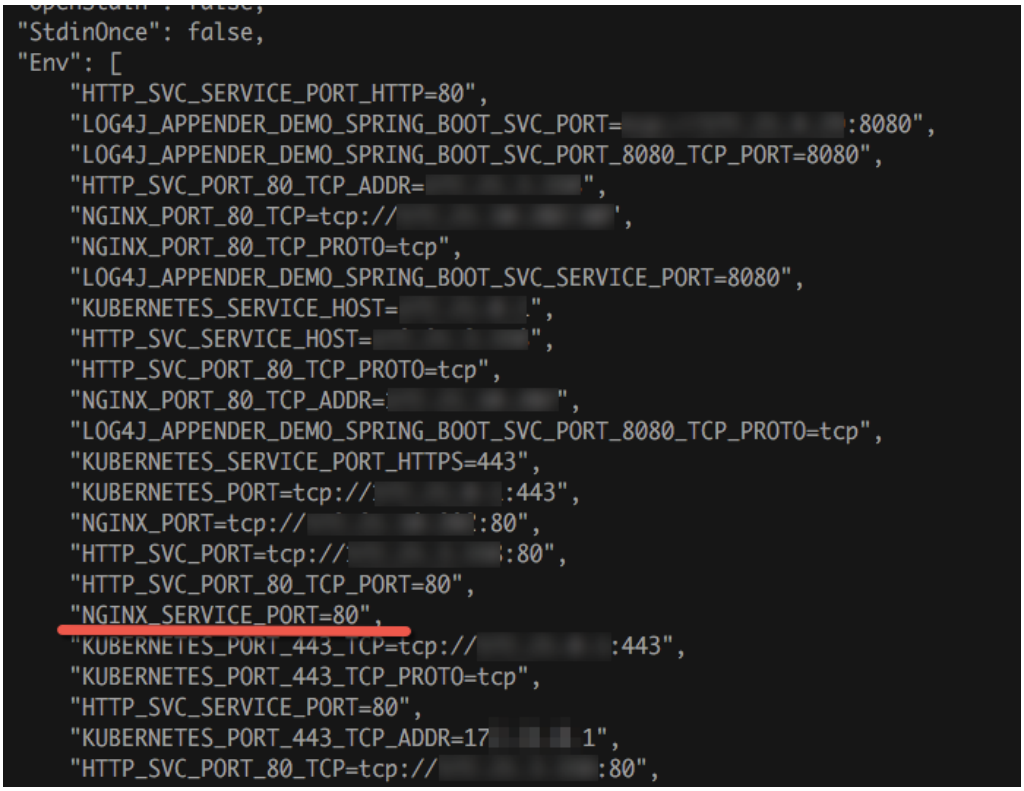
Configuration examples

- Environment configuration

  Collect the logs of the container whose environment variable is `NGINX_PORT_80_TCP_PORT=80` but not `POD_NAMESPACE=kube-system`. The log file path is `/var/log/nginx/access.log` and logs are parsed in simple mode.

  > **Note** The environment variable refers to the environment information configured in container startup.

  Environment configuration example



- Label configuration

  Collect the logs of a container that meets the following conditions: the container label is `io.kubernetes.container.name=nginx`, the log file path is `/var/log/nginx/access.log`, and logs are parsed in simple mode.

  > **Note** Labels refer to Docker labels.

  Label configuration example

Default fields

Each uploaded log of a common Docker container contains the following fields.

Field	Description:
_image_name_	The name of the image.
_container_name_	The name of the container.
_container_ip_	The IP address of the container.

If a Kubernetes cluster is used, each uploaded log contains the following fields.

Field	Description
_image_name_	The name of the image.
_container_name_	The name of the container.
_pod_name_	The name of the pod.
namespace	The namespace to which the pod belongs.
_pod_uid_	The unique identifier of the pod.
_container_ip_	The IP address of the pod.

28.1.3.1.6.4. Collect stdout and stderr logs from containers

This topic describes how to use Logtail to collect standard output (stdout) and standard error (stderr) logs from containers. After you collect stdout and stderr logs, you can upload the logs together with the container-related metadata to Log Service.

Features

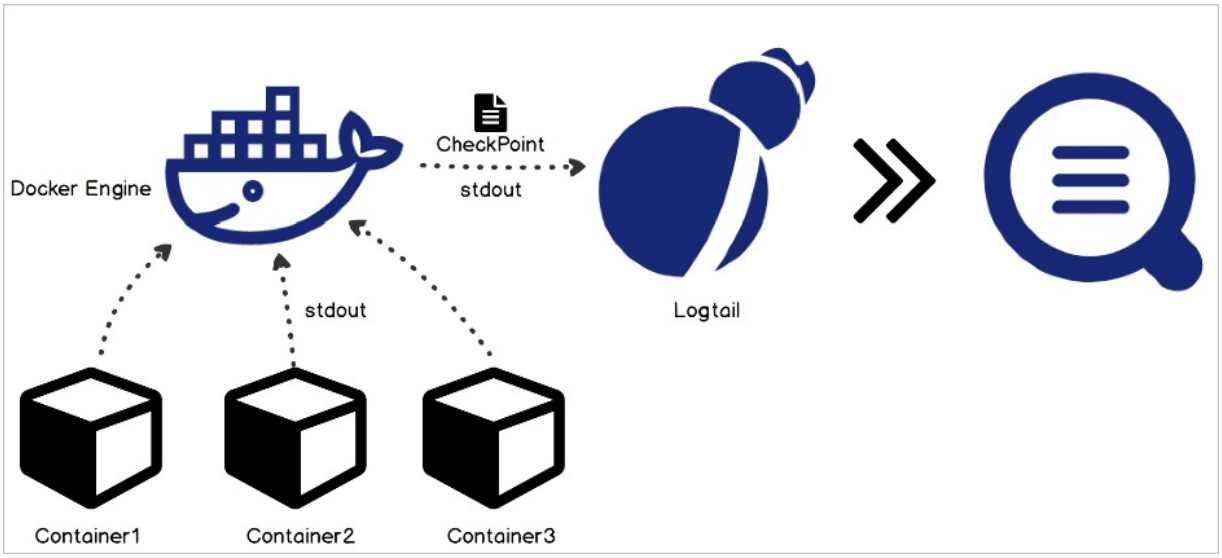
- Collects stdout and xxx logs.
- Labels the containers from which you want to collect stdout and stderr logs.
- Uses tags to exclude specific containers.
- Allows you to use environment variables to specify the containers whose logs are to be collected.
- Allows you to use environment variables to exclude specific containers.
- Supports multiline logs such as Java Stack logs.

- Supports automatic labeling for container data.
- Supports automatic labeling for Kubernetes containers.

Implementation

As shown in the following figure, Logtail communicates with the domain socket of the Docker engine to query containers that run on the Docker engine. Logtail also locates containers from which you want to collect logs based on the specified labels and environment variables. Logtail then uses the docker logs command to collect logs from the specified containers.

When Logtail collects the stdout logs of a container, Logtail records information about log file positions to the checkpoint file at regular intervals. If Logtail is restarted, Logtail collects logs from the last log file position.



Limits

- This feature is available only for Logtail 0.16.0 or later that runs on Linux. For more information about Logtail versions and version updates, see Install Logtail in Linux.
- The domain socket must exist and can access the Docker engine. Otherwise, Logtail cannot access the Docker engine by running the `/var/run/docker.sock` file.
- The last multiline log that you collect must be cached for at least 1,000 seconds. By default, the retention period for a multiline log is 3 seconds. You can specify the period by configuring the `BeginLineTimeoutMs` parameter. The value of the parameter must be a minimum of 1,000 ms. Otherwise, a false positive error may occur.
- Collection stop policy: When a container is stopped and Logtail detects the `die` event on the container, Logtail stops collecting stdout logs of the container. In this case, if a collection latency occurs, some stdout logs that are generated before the stop action may be lost.
- Docker log driver: Only log drivers of the JSON type are supported in the collection of stdout logs.
- Context: By default, a collection configuration is in the same context. If you need to configure different types of containers in different contexts, configure each type separately.
- Data processing: By default, collected logs start with the `content` field. You can apply standard processing methods to these logs. For more information about how to configure one or more processing methods, see Configure data processing methods.
- Label: refers to the label information in docker inspect. It is not related to labels in Kubernetes configurations.
- Environment: refers to environment information that you specified during container startup.

Procedure

1. Deploy and configure Logtail on one or more containers.

2. Create a Logtail configuration and deliver it to Logtail.

Logtail deployment and configuration

- Kubernetes

  For more information about how to collect Kubernetes logs, see Logtail deployment solution for collecting Kubernetes logs.

- Configure Logtail on other containers

  For more information about how to configure Logtail on other containers, such as Swarm and Mesos, see Common Logtail deployment solution for collecting Docker logs.

Configure a data source

1. Log on to the Log Service console.
2. Click **Import Data**. On the **Import Data** page that appears, select **Docker Standard Output**.
3. Select a destination project and Logstore, and then click **Next**.

   You can also click **Create Now** to create a project and a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.

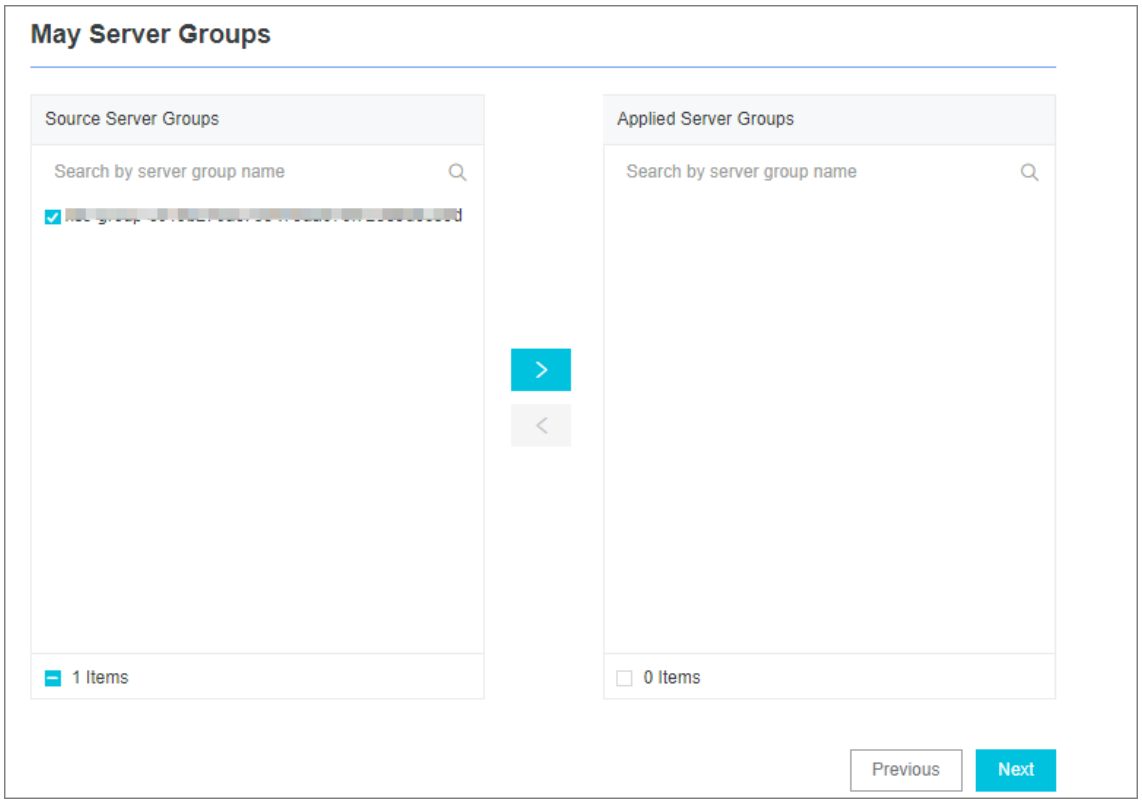
4. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.

5. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



> **Notice** If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

6. Configure a data source.

   In the **Plug-in Config** section, set the required parameters. The following example shows how to set these parameters. For more information, see Parameters.

```
{
 "inputs": [
     {
         "type": "service_docker_stdout",
         "detail": {
             "Stdout": true,
             "Stderr": true,
             "IncludeLabel": {
                 "io.kubernetes.container.name": "nginx"
             },
             "ExcludeLabel": {
                 "io.kubernetes.container.name": "nginx-ingress-controller"
             },
             "IncludeEnv": {
                 "NGINX_SERVICE_PORT": "80"
             },
             "ExcludeEnv": {
                 "POD_NAMESPACE": "kube-system"
             }
         }
     }
 ]
}
```

7. Configure indexes in the Configure Query and Analysis step. Click **Next**.

   By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

> **Note**
> - To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
> - If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

Parameters

The type of the input source is `service_docker_stdout`.

> **Note** Before Logtail uploads data to Log Service, Logtail can process collected data. For more information about processing methods, see Configure data processing methods.

Parameter	Type	Required	Description

Parameter	Type	Required	Description
IncludeLabel	JSON text. Key: JSON string. Value: JSON string.	Yes	By default, this parameter is not specified. If the parameter is not specified, Logtail collects logs from all containers. If you set the key field and leave the value field empty, Logtail collects logs from containers whose labels include this key. **Note** • Key-value pairs are disjunctive with each other. If the label of a container matches one of the key-value pairs, logs of the container are collected. • Labels refer to docker labels.
ExcludeLabel	JSON text. Key: JSON string. Value: JSON string.	No	This parameter is not specified by default. If the parameter is empty, no containers are excluded. If the key is not empty but the value is empty, the containers whose labels include this key are excluded. **Note** • Key-value pairs are disjunctive with each other. If the label of a container matches one of the key-value pairs, the container is excluded. • Labels described in this topic refer to Docker labels.
IncludeEnv	Map. Key: string. Value: string	No	This parameter is empty by default. If the parameter is empty, logs of all containers are collected. If the key is not empty but the value is empty, logs of the containers whose environment variables include this key are collected. **Note** • Key-value pairs are disjunctive with each other. If the environment variable of a container includes one of the key-value pairs, the container is excluded. • The environment variable refers to the environment information configured in container startup.

Parameter	Type	Required	Description
ExcludeEnv	Map. Key: string. Value: string	No	This parameter is empty by default. If you leave the parameter empty, no container is excluded. If you set the key and leave the value empty, the containers whose environment variables include this key are excluded. **Note** • Key-value pairs are disjunctive with each other. When the environment variable of a container includes one of the key-value pairs, the container is excluded. • The environment variable refers to the environment information configured in container startup.
Stdout	Boolean	No	If the value of the parameter is false, stdout data is not collected. Default value: true.
Stderr	Boolean	No	Default value: true. If the value of the parameter is false, stderr data is not collected.
BeginLineRegex	String	No	This parameter is not specified by default. If the parameter is not empty, the regular expression is used to match the first line of each log. If a line matches this regular expression, this line is assumed as the start of a new log. Otherwise, this line is assumed as part of the previous log.
BeginLineTimeoutMs	Integer	No	The timeout period for the regular expression to match a line. Default value: 3000. Unit: ms. If no new log appears within 3 seconds, the most recent log is uploaded.
BeginLineCheckLength	Integer	No	The length of data for the regular expression to match. Default value: 10×1024. Unit: bytes. You can set this parameter to check whether the beginning part of a line can match the regular expression. This improves matching efficiency.
MaxLogSize	Integer	No	The maximum length of a log. Default value: 512×1024. Unit: bytes. If the length exceeds this value, the log data is uploaded directly without finding the first line of logs.

Note

- Labels defined in IncludeLabel and ExcludeLabel are different from those defined in Kubernetes. Labels in this topic refer to Docker labels.
- A namespace and a container name in Kubernetes can be mapped to Docker labels. The LabelKey parameter corresponding to a namespace is `io.kubernetes.pod.namespace`. The LabelKey parameter corresponding to a container name is `io.kubernetes.container.name`. For example, the namespace of the pod you created is backend-prod and the container name is worker-server. In this case, you can configure a whitelist label: `io.kubernetes.pod.namespace : backend-prod` or `io.kubernetes.container.name : worker-server`, so that only logs of the container are collected.
- In Kubernetes, we recommend that you use the `io.kubernetes.pod.namespace` and `io.kubernetes.container.name` labels. In other cases, use IncludeEnv or ExcludeEnv.

Default fields

- Common Docker containers

  Each uploaded log contains the following fields.

Field	Description:
`_time_`	The data upload time. Example: `2018-02-02T02:18:41.979147844Z`.
`_source_`	The type of the input source. Valid values: stdout and stderr.
`_image_name_`	The name of the image.
`_container_name_`	The name of the container.
`_container_ip_`	The IP address of the container.

- Kubernetes containers

  Each uploaded log contains the following fields.

Field	Description
`_time_`	The data upload time. Example: `2018-02-02T02:18:41.979147844Z`.
`_source_`	The type of input sources. Valid values: stdout and stderr.
`_image_name_`	The name of the image.
`_container_name_`	The name of the container.
`_pod_name_`	The name of the pod.
`_namespace_`	The namespace where the pod is located.
`_pod_uid_`	The unique identifier of the pod.
`_container_id_`	The IP address of the pod.

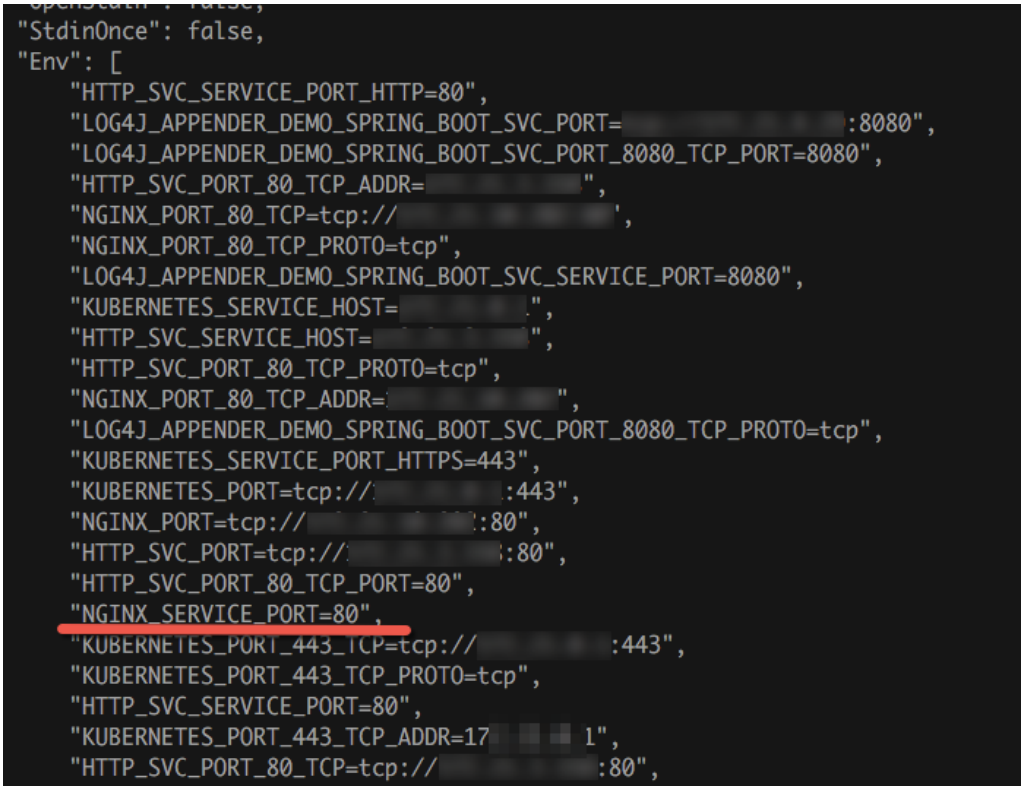
Common configuration examples

- Environment configuration

  Collect the logs of the container whose environment variable is `NGINX_PORT_80_TCP_PORT=80` but not `POD_NAMESPACE=kube-system`.

  > **Note** The environment variable refers to the environment information configured in container startup.

  Environment configuration example



Collection configuration

```
{
    "inputs": [
        {
            "type": "service_docker_stdout",
            "detail": {
                "Stdout": true,
                "Stderr": true,
                "IncludeEnv": {
                    "NGINX_PORT_80_TCP_PORT": "80"
                },
                "ExcludeEnv": {
                    "POD_NAMESPACE": "kube-system"
                }
            }
        }
    ]
}
```

- Label configuration

  Collect the stdout and stderr logs of the container whose label is `io.kubernetes.container.name=nginx` but not `type=pre`.

  > **Note** Labels refer to Docker labels.

  Label configuration example

```
{
    "inputs": [
        {
            "type": "service_docker_stdout",
            "detail": {
                "Stdout": true,
                "Stderr": true,
                "IncludeLabel": {
                    "io.kubernetes.container.name": "nginx"
                },
                "ExcludeLabel": {
                    "type": "pre"
                }
            }
        }
    ]
}
```

Example of configuring multiline log collection

Configuring multiline log collection is important for the collection of Java exception stack logs. The following section introduces a standard collection configuration for Java stdout logs.

- Sample log

```
2018-02-03 14:18:41.968  INFO [spring-cloud-monitor] [nio-8080-exec-4] c.g.s.web.controller.DemoCo
ntroller : service start
2018-02-03 14:18:41.969 ERROR [spring-cloud-monitor] [nio-8080-exec-4] c.g.s.web.controller.DemoCo
ntroller : java.lang.NullPointerException
at org.apache.catalina.core.ApplicationFilterChain.internalDoFilter(ApplicationFilterChain.java:19
3)
at org.apache.catalina.core.ApplicationFilterChain.doFilter(ApplicationFilterChain.java:166)
at org.apache.catalina.core.StandardWrapperValve.invoke(StandardWrapperValve.java:199)
at org.apache.catalina.core.StandardContextValve.invoke(StandardContextValve.java:96)
...
2018-02-03 14:18:41.968  INFO [spring-cloud-monitor] [nio-8080-exec-4] c.g.s.web.controller.DemoCo
ntroller : service start done
```

- Collection configuration

  Collect logs of the container whose label is `app=monitor`. The first line of each log to be collected is of the date type. To improve matching efficiency, only the first 10 bytes of each line are checked.

```
{
"inputs": [
  {
    "detail": {
      "BeginLineCheckLength": 10,
      "BeginLineRegex": "\\d+-\\d+-\\d+. *",
      "IncludeLabel": {
        "app": "monitor"
      }
    },
    "type": "service_docker_stdout"
  }
]
}
```

Process collected data

Logtail can process the collected Docker stdout logs by using a common data processing method. Use a regular expression to extract the time, module, thread, class, and info fields.

- Collection configuration

  Collect logs from a container whose label is `app=monitor`. The first line of each log to be collected is of the date type. To improve matching efficiency, only the first 10 bytes of each line are checked.

```
{
"inputs": [
  {
    "detail": {
      "BeginLineCheckLength": 10,
      "BeginLineRegex": "\\d+-\\d+-\\d+. *",
      "IncludeLabel": {
        "app": "monitor"
      }
    },
    "type": "service_docker_stdout"
  }
],
"processors": [
    {
        "type": "processor_regex",
        "detail": {
            "SourceKey": "content",
            "Regex": "(\\d+-\\d+-\\d+ \\d+:\\d+:\\d+\\.\\d+)\\s+(\\w+)\\s+\\[([^]]+)]\\s+\\[([^]]+
)]\\s+:\\s+([\\s\\S]*)",
            "Keys": [
                "time",
                "module",
                "thread",
                "class",
                "info"
            ],
            "NoKeyError": true,
            "NoMatchError": true,
            "KeepSource": false
        }
    }
]
}
```

- Sample output

  After the `2018-02-03 14:18:41.968 INFO [spring-cloud-monitor] [nio-8080-exec-4] c.g.s.web.controller.DemoController : service start done` log is processed, the following output is returned:

```
__tag__:__hostname__:logtail-dfgef
_container_name_:monitor
_image_name_:registry.cn-hangzhou.aliyuncs.xxxxxxxxxxxxxx
_namespace_:default
_pod_name_:monitor-6f54bd5d74-rtzc7
_pod_uid_:7f012b72-04c7-11e8-84aa-00163f00c369
_source_:stdout
_time_:2018-02-02T14:18:41.979147844Z
time:2018-02-02 02:18:41.968
level:INFO
module:spring-cloud-monitor
thread:nio-8080-exec-4
class:c.g.s.web.controller.DemoController
message:service start done
```

28.1.3.1.7. Limits

This topic describes the limits of Logtail. These limits apply when you collect files, manage resources, and resolve errors.

Limits on file collection

Item	Description
File encoding	Log files encoded in UTF-8 and GBK are supported. We recommend that you use UTF-8 encoding for better processing performance. If log files are encoded in other formats, errors such as garbled characters and data loss may occur.
Log file size	Unlimited.
Log file rotation	Supported. Both `.log*` and `.log` are supported for file names.
Log collection behavior when log parsing is restricted	When log parsing is restricted, Logtail keeps the log file descriptor (FD) open. If log file rotation occurs multiple times during the restriction, Logtail attempts to keep the log parsing sequence of each rotation. If the number of rotated logs to be parsed exceeds 20, Logtail does not process subsequent log files.
Symbolic link	Monitored directories can be soft links.
Size of a single log entry	The maximum size of a single log entry is 512 KB. If a multi-line log entry is divided by using a regular expression to match the first line, the maximum size of each log entry after division is still 512 KB. If the size of a log entry exceeds 512 KB, the log entry is forcibly separated into multiple parts for collection. For example, if the size of a log entry is 1,025 KB, it will be split into three parts: 512 KB, 512 KB, and 1 KB. These log parts are collected in sequence.
Regular expression	Perl-based regular expressions can be used.
Multiple Logtail configuration files for the same log file	Not supported. We recommend that you collect and store log files to one Logstore, and configure multiple subscriptions. If this feature is required, configure symbolic links for log files to bypass this limit.

Item	Description
File opening behavior	When Logtail collects a log file, Logtail opens the log file. If the log file is not modified for more than 5 minutes and log rotation does not occur, Logtail closes the log file.
First log collection behavior	Logtail collects only incremental log files. If a log file is modified for the first time and the log file size exceeds 1 MB, Logtail collects the logs from the last 1 MB. Otherwise, Logtail collects the logs from the beginning of the log file. If the log file is not modified after the Logtail configuration file is sent to the server where the log file resides, Logtail does not collect the log file.
Non-standard text logs	If a log entry contains \0 in multiple lines, the log entry is truncated at the first \0.

Limits on checkpoints

Item	Description
Checkpoint timeout period	If a log file is not modified for more than 30 days, the checkpoint of the log file is deleted.
Checkpoint storage policy	Checkpoints are saved every 15 minutes and are automatically saved when you exit Logtail.
Checkpoint storage path	By default, checkpoints are stored in the `/tmp/logtail_checkpoint` directory. For more information about how to modify the values of the related parameters, see Set Logtail startup parameters.

Limits on configurations

Item	Description
Configuration update	A custom configuration update requires about 30 seconds to take effect.
Dynamic loading of Logtail configuration files	Supported. The update of a Logtail configuration file does not affect other Logtail configuration files.
Number of Logtail configuration files	Unlimited. However, we recommend that you create a maximum of 100 Logtail configuration files on a server.
Multi-tenant isolation	Logtail configuration files for different tenants are isolated.

Limits on resources and performance metrics

Item	Description
Throughput for log processing	The default traffic of raw logs is limited to 2 MB/s. Data is uploaded after it is encoded and compressed. The compression ratio ranges from 5:1 to 10:1. Logs may be lost if the traffic exceeds the limit. For more information about how to modify the values of the related parameters, see Set Logtail startup parameters.

Item	Description
Maximum processing speed	Single-core processing speed: The maximum processing speed is 100 MB/s for logs in simple mode, 40 MB/s for logs in delimiter mode, and 30 MB/s for logs in JSON mode. By default, the maximum processing speed is 20 MB/s for logs in full regex mode based on the complexity of regular expressions. If multiple processing threads are enabled, the performance can be improved by 1.5 to 3 times.
Number of monitored directories	Logtail limits the depth of monitored directories to reduce the consumption of your resources. If the upper limit is reached, Logtail stops monitoring additional directories and log files. Logtail monitors a maximum of 3,000 directories, including subdirectories.
Number of monitored files	A Logtail configuration file on each server can be used to monitor a maximum of 10,000 files by default. A Logtail client on each server can monitor a maximum of 100,000 files by default. Excessive files are not monitored. If the upper limit is reached, you can perform the following operations: • Improve the depth of the monitored directory in each Logtail configuration file. • Modify the value of the mem_usage_limit parameter to increase the Logtail memory usage threshold. For more information, see Set Logtail startup parameters. You can set a memory usage threshold of 2 GB for Logtail. In this case, the maximum number of files that each Logtail configuration file can be used to monitor is increased to 100,000. The maximum number of files that each Logtail client can monitor is increased to 1,000,000.
Default resources	By default, Logtail consumes up to 40% of CPU usage and 256 MB of memory. If logs are generated at a high speed, you can modify relevant parameters. For more information, see Set Logtail startup parameters.
Processing policy of threshold-crossing resources	If the resources occupied by Logtail exceed the upper limit and this issue lasts for five or more minutes, Logtail is forcibly restarted. The restart may cause data loss or duplication.

Limits on error handling

Item	Description
Network error handling	If a network error occurs, Logtail retries and adjusts the retry interval.
Processing policy of threshold-crossing resources	If the data transmission speed exceeds the quota of the Logstore, Logtail restricts the log collection speed and retries the log collection.
Maximum retry period before timeout	If data fails to be transmitted and the failure lasts for more than six consecutive hours, Logtail discards the data.
Status self-check	Logtail restarts if an exception occurs, for example, an application unexpectedly exits or the resource usage exceeds the quota.

Other limits

Item	Description

Item	Description
Log collection latency	A latency of less than 1 second exists between the time when a log is written to a disk and the time when Logtail collects the log. However, if the log collection speed is restricted, the latency increases.
Log upload policy	Before Logtail uploads logs, it aggregates the logs in the same file. The log upload starts if the number of logs exceeds 2,000, the total size of logs exceeds 2 MB, or the log collection duration exceeds 3 seconds.

28.1.3.2. Other collection methods

28.1.3.2.1. WebTracking

This topic describes how to use WebTracking to collect logs from websites that are written in HTML or HTML5, iOS, and Android.

Context

Log Service uses WebTracking to collect logs from websites written in HTML or HTML5, iOS, and Android. You can customize dimensions and metrics.

In the preceding figure, WebTracking allows you to collect user information from various browsers, iOS apps, and Android apps (except for SDK for iOS or Android). For example:

- Browsers, operating systems, and resolutions used by users.
- Browsing history such as preferences on different websites.
- The length of time that users stay on an app and whether the users are active in the app.

Precautions

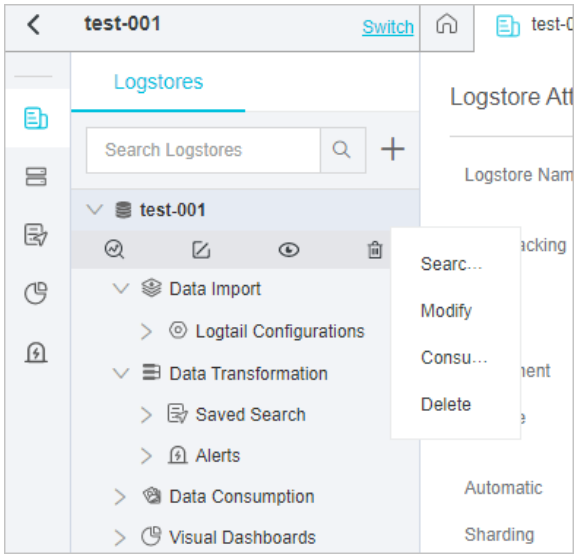
- Dirty data may occur due to the use of WebTracking. This occurs because WebTracking allows unauthorized write access from Internet anonymous users to a Logstore.
- GET and POST requests are supported. The size of a request body cannot exceed 16 KB.
- The same limits apply to POST requests and the PutLogs API operation. The maximum number of logs that you can use a POST request to collect at a time is 4,096. The total size of these logs cannot exceed 3 MB.

Step 1: Enable WebTracking

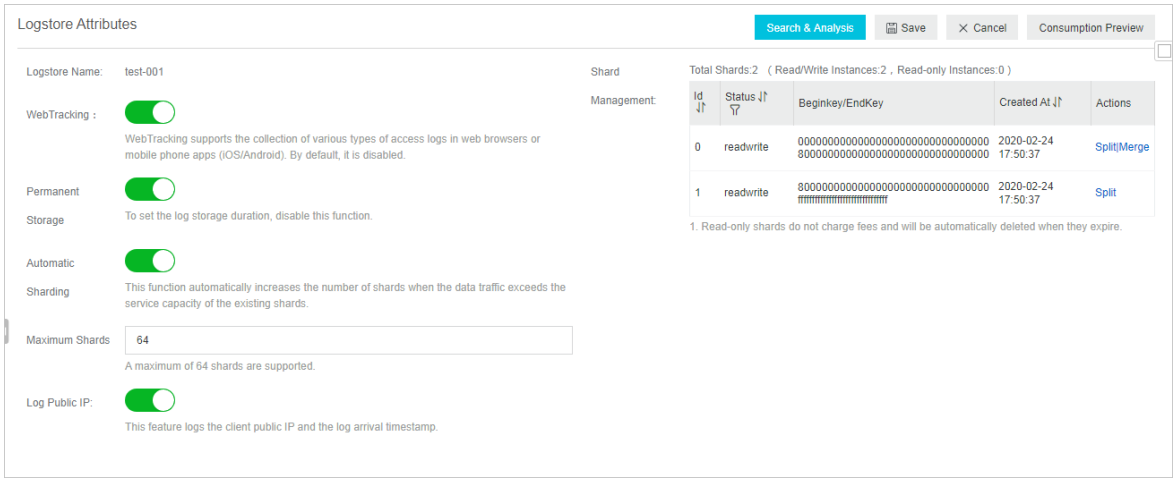
Log on to the Log Service console and enable WebTracking.

1. Log on to the Log Service console.

2. Select the target Logstore, go to the **Logstore Attributes** page.
   - Method 1: Click the Modify icon under the name of the Logstore.
   - Method 1: Click the icon next to the name of the Logstore, and select **Modify**.



3. On the **Logstore Attributes** page, click **Modify** in the upper-right corner.
4. Turn on the WebTracking switch.



Use SDK for Java to enable WebTracking

Example:

```
import com.aliyun.openservices.log.Client;
import com.aliyun.openservices.log.common.LogStore;
import com.aliyun.openservices.log.exception.LogException;
public class WebTracking {
  static private String accessId = "your accesskey id";
  static private String accessKey = "your accesskey";
  static private String project = "your project";
  static private String host = "log service data address";
  static private String logStore = "your logstore";
  static private Client client = new Client(host, accessId, accessKey);
  public static void main(String[] args) {
      try {
          //Enable WebTracking on an existing Logstore.
          LogStore logSt = client.GetLogStore(project, logStore).GetLogStore();
          client.UpdateLogStore(project, new LogStore(logStore, logSt.GetTtl(), logSt.GetShardCount()
, true));
          //Disable WebTracking.
          //client.UpdateLogStore(project, new LogStore(logStore, logSt.GetTtl(), logSt.GetShardCount
(), false));
          //Create a Logstore on which you want to enable WebTracking.
          //client.UpdateLogStore(project, new LogStore(logStore, 1, 1, true));
      }
      catch(LogException e){
          e.printStackTrace();
      }
  }
}
```

Step 2: Collect logs

After you enable WebTracking for a Logstore, you can use the following methods to upload data to the Logstore.

- Use the JavaScript SDK
  i. Copy the *loghub-tracking.js* file to the *web* directory and add the following script to the file.

     Click here to copy the script.

     ```
     <script type="text/javascript" src="loghub-tracking.js" async></script>
     ```

     > **Note** To ensure that a page loads, the script asynchronously sends HTTP requests. If data must be sent several times during the page loading, the newest request overwrites the previous HTTP request. A message showing WebTracking is about to exit appears in the browser. To eliminate the issue, send requests in a synchronous manner. To implement the method, perform the following step.
     >
     > Original statement:
     >
     > ```
     > this.httpRequest_.open("GET", url, true)
     > ```
     >
     > Replace the original statement with the following statement:
     >
     > ```
     > this.httpRequest_.open("GET", url, false)
     > ```

  ii. Create a tracker.

```
var logger = new window.Tracker('${host}','${project}','${logstore}');
logger.push('customer', 'zhangsan');
logger.push('product', 'iphone 6s');
logger.push('price', 5500);
logger.logger();
logger.push('customer', 'lisi');
logger.push('product', 'ipod');
logger.push('price', 3000);
logger.logger();
```

The following table lists the parameters:

Parameter	Description
`${host}`	The endpoint of the region where Log Service resides. For more information, see the *Obtain an endpoint topic in the Log Service Developer Guide* .
`${project}`	The name of the project that you create in Log Service.
`${logstore}`	The name of the Logstore in the `${project}` .

After you run the following code, the following logs appear in Log Service.

```
customer:zhangsan
product:iphone 6s
price:5500
```

```
customer:lisi
product:ipod
price:3000
```

- Use HTTP GET requests

```
curl --request GET 'http://${project}.${host}/logstores/${logstore}/track? APIVersion=0.6.0&key1=val1&key2=val2'
```

The following table lists the parameters.

Parameter	Description
${project}	The name of the project that you create in Log Service.
${host}	The endpoint of the region where Log Service resides.
${logstore}	The name of a Logstore that has WebTracking enabled in the `${project}` .
APIVersion=0.6.0	(Required) A reserved parameter.
__topic__=yourtopic	(Optional) A reserved parameter that specifies the topic of the log.
key1=val1, key2=val2	The key-value pairs that you want to upload to Log Service. You can specify multiple pairs. Make sure that the length of each request URL is less than 16 KB.

- Use HTML img tags

```
<img src='http://${project}.${host}/logstores/${logstore}/track.gif? APIVersion=0.6.0&key1=val1&key2=val2'/>
<img src='http://${project}.${host}/logstores/${logstore}/track_ua.gif? APIVersion=0.6.0&key1=val1&key2=val2'/>
```

The parameters that you need to specify are the same as the preceding parameters. In addition to custom parameters that are uploaded by track_ua.gif, Log Service also uses UserAgent and referer fields in the HTTP header as the fields of logs.

28.1.3.2.2. Use SDKs to collect logs

28.1.3.2.2.1. Producer Library

The Aliyun LOG Java Producer supports Java applications that run in big data processing scenarios with high concurrency. The library is easy to use and highly customizable.

For more information about the related GitHub project, visit Aliyun LOG Java Producer.

28.1.3.2.2.2. Log4j Appender

Log4j is an open-source logging framework of Apache. You can use Log4j to write logs to the Log Service console, files, graphical user interface (GUI) components, socket servers, NT kernel loggers, or Unix syslog daemons. You can specify the output format of each log. You can also specify the severity level of each log to implement a fine-grained control on log generation.

Log4j consists of three components: loggers, appenders, and layouts.

- Loggers allow you to specify the severity level of each log.

  Severity levels are sorted into ERROR, WARN, INFO, and DEBUG in descending order of severity.
- Appenders allow you to specify the destination of each log.

  A destination can be the Log Service console or a file.
- Layouts allow you to specify the output format of each log.

  The output format defines how logs are displayed.

To write logs to Log Service, use the Alibaba Cloud Log Log4j Appender. For information about where to download the library and how to use it, see Log4j Appender.

28.1.3.2.2.3. Logback Appender

Logback was created by the same developer of Log4j. Logback allows you to write logs to multiple destinations. These destinations include the Log Service console, files, graphical user interface (GUI) components, socket servers, NT kernel loggers, and Unix syslog daemons. You can define the output format of each log. If you define the severity level of each log, you can implement a fine-grained control on the log generation process.

You can set the destination of logs to Log Service by using the Aliyun Log Logback Appender. The following example shows the format of logs that are uploaded to Log Service.

```
level: ERROR
location: com.aliyun.openservices.log.logback.example.LogbackAppenderExample.main(LogbackAppenderExam
ple.java:18)
message: error log
throwable: java.lang.RuntimeException: xxx
thread: main
time: 2018-01-02T03:15+0000
log: 2018-01-02 11:15:29,682 ERROR [main] com.aliyun.openservices.log.logback.example.LogbackAppender
Example: error log
__source__: xxx
__topic__: yyy
```

For information about where to download the library and how to use it, see Logback Appender.

28.1.3.2.2.4. Golang Producer Library

The Aliyun LOG Go Producer Library supports Go applications that run in big data processing scenarios with high concurrency. The library is easy to use and highly customizable. You can use the library to create producers that allow you to resend failed logs. Before Go applications send log data to Log Service, you can use these producers to compress the log data. This improves write performance.

For more information about the related GitHub project, visit Aliyun Log Go Producer.

28.1.3.2.2.5. Python logging

Configurations

For more information about the configurations that are related to the Python logging module, see Logging configuration.

The Python logging module allows you to configure logging by using code or a configuration file. The following example shows how to configure logging by using the `logging.conf` configuration file.

```
[loggers]
keys=root,sls
[handlers]
keys=consoleHandler, slsHandler
[formatters]
keys=simpleFormatter, rawFormatter
[logger_root]
level=DEBUG
handlers=consoleHandler
[logger_sls]
level=INFO
handlers=consoleHandler, slsHandler
qualname=sls
propagate=0
[handler_consoleHandler]
class=StreamHandler
level=DEBUG
formatter=simpleFormatter
args=(sys.stdout,)
[handler_slsHandler]
class=aliyun.log.QueuedLogHandler
level=INFO
formatter=rawFormatter
args=(os.environ.get('ALIYUN_LOG_SAMPLE_ENDPOINT', ''), os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSID',
''), os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSKEY', ''), os.environ.get('ALIYUN_LOG_SAMPLE_TMP_PROJECT
', ''), "logstore")
[formatter_simpleFormatter]
format=%(asctime)s - %(name)s - %(levelname)s - %(message)s
[formatter_rawFormatter]
format=%(message)s
```

Two handlers named `root` and `sls` are created. The `sls` handler is an object of the `aliyun.log.QueuedLogHandler` class. The following shows the parameters that are specified for the sls handler. For more information, see Parameters.

```
args=(os.environ.get('ALIYUN_LOG_SAMPLE_ENDPOINT', ''), os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSID',
''), os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSKEY', ''), os.environ.get('ALIYUN_LOG_SAMPLE_TMP_PROJECT
', ''), "logstore")
```

> **Note** In this case, the `os.environ` function is used to retrieve configurations from environment variables. You can also specify values for these parameters based on your business requirements.

Upload logs

You can use the configuration file to upload logs to Log Service.

```
import logging
import logging.config
# Configurations
logging.config.fileConfig('logging.conf')
logger = logging.getLogger('sls')
# Use the logger
logger.info("test1")
try:
    1/0
except ZeroDivisionError as ex:
    logger.exception(ex)
```

Then, logs are automatically uploaded to Log Service. To use the LogSearch/Analytics feature, you must enable the index feature on the corresponding Logstore.

Configure an index for a Logstore

Enable the index feature on the Logstore that receives logs and configure an index for specific fields. We recommend that you use CLI (Command Line Interface) to configure the index as follows:

```
aliyunlog log update_index --project_name="project1" --logstore_name="logstore1" --index_detail="file
:///Users/user1/loghandler_index.json"
```

For more information, see the python_logging_handler_index.json configuration file.

Specify log fields to be collected

The following table lists supported log fields that you can collect. By default, all of the fields are collected.

Field	Description
message	The contents of a log.
record_name	The name of a handler. In the preceding example, the name is `sls`.
level	The output level of a logger, such as INFO and ERROR.
file_path	The full path of a configuration file.
func_name	The name of a function.
line_no	The number of a log line.
module	The name of a module where the function resides.
thread_id	The ID of the thread that runs the function.
thread_name	The name of the thread that runs the function.
process_id	The ID of the process that runs the function.
process_name	The name of the process that runs the function.

You can specify log fields to be collected based on the fields parameter of the `QueuedLogHandler` class. For more information, see aliyun.log.LogFields.

The following example shows how to modify the preceding configuration file and collect several fields, such as module and func_name.

```
[handler_slsHandler]
class=aliyun.log.QueuedLogHandler
level=INFO
formatter=rawFormatter
args=('cn-beijing.log.aliyuncs.com', 'ak_id', 'ak_key', 'project1', "logstore1", 'mytopic', ['level',
'func_name', 'module', 'line_no']  )
```

Note

- The message field is collected regardless of your configurations.
- To add a prefix and suffix to the names of these fields, use the `buildin_fields_prefix` and `buildin_fields_suffix` parameters. For example, `__level__`.

Configure logging by using a JSON text

You can use a JSON text to create more flexible logging configurations than code does.

```
#encoding: utf8
import logging, logging.config, os
# Configurations
conf = {'version': 1,
        'formatters': {'rawformatter': {'class': 'logging.Formatter',
                                        'format': '%(message)s'}
                       },
        'handlers': {'sls_handler': {'()':
                                     'aliyun.log.QueuedLogHandler',
                                     'level': 'INFO',
                                     'formatter': 'rawformatter',
                                     # custom args:
                                     'end_point': os.environ.get('ALIYUN_LOG_SAMPLE_ENDPOINT', ''),
                                     'access_key_id': os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSID', ''
),
                                     'access_key': os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSKEY', ''),
                                     'project': 'project1',
                                     'log_store': "logstore1"
                                     }
                     },
        'loggers': {'sls': {'handlers': ['sls_handler', ],
                                    'level': 'INFO',
                                    'propagate': False}
                    }
        }
logging.config.dictConfig(conf)
# Use the logger
logger = logging.getLogger('sls')
logger.info("Hello world")
```

Note To instantiate an object of the `aliyun.log.QueuedLogHandler` class, pass named parameters to the constructor. For more information, see Parameters.

28.1.3.2.3. Common log formats

28.1.3.2.3.1. Log4j logs

Log Service allows you to collect Log4j logs.

Collect Log4j logs by using LogHub Log4j Appender

For more information, see Log4j Appender.

Configure Logtail to collect Log4j logs

This topic describes how to configure regular expressions based on the default configuration of Log4j 1 logs. If Log4j 2 is used, you must modify the default configuration to record the complete date information. Log4j logs are sorted into Log4j 1 logs and Log4j 2 logs.

```
<Configuration status="WARN">
  <Appenders>
    <Console name="Console" target="SYSTEM_OUT">
      <PatternLayout pattern="%d{yyyy-MM-dd HH:mm:ss:SSS zzz} [%t] %-5level %logger{36} - %msg%n"/>
    </Console>
  </Appenders>
  <Loggers>
    <Logger name="com.foo.Bar" level="trace">
      <AppenderRef ref="Console"/>
    </Logger>
    <Root level="error">
      <AppenderRef ref="Console"/>
    </Root>
  </Loggers>
</Configuration>
```

For more information about how to configure Logtail to collect Log4j logs, see Python logs. Configure the required parameters based on your network environment and business requirements.

The automatically generated regular expression is based on the sample log and may not be suitable for other logs. Therefore, you must make minor changes to the regular expression after it is automatically generated

The following shows a sample log of the default Log4j format.

```
2013-12-25 19:57:06,954 [10.207.37.161] WARN impl.PermanentTairDaoImpl - Fail to Read Permanent Tair, key:e:470217319319741_1,result:com.example.tair.Result@172e3ebc[rc=code=-1, msg=connection error or timeout,value=,flag=0]
```

Regular expression that matches IP addresses that each indicate the start of a line:

```
\d+-\d+-\d+\s. *
```

Regular expression used to extract log information:

```
(\d+-\d+-\d+\s\d+:\d+:\d+,\d+)\s\[([^\]]*)\]\s(\S+)\s+(\S+)\s-\s(. *)
```

Time conversion format:

```
%Y-%m-%d %H:%M:%S
```

The following table lists the extraction results of the sample log.

Key	Value
time	2013-12-25 19:57:06,954

Key	Value
ip	10.207.37.161
level	WARN
class	impl.PermanentTairDaoImpl
message	Fail to Read Permanent Tair,key:e:470217319319741_1,result:com.example.tair.Result@172e3ebc[rc=code=-1, msg=connection error or timeout,value=,flag=0]

28.1.3.2.3.2. Python logs

The Python logging module provides a general logging system, which can be used by third-party modules or applications.

The Python logging module provides different log levels and logging methods, such as file-based, HTTP GET, HTTP POST, SMTP, and Socket logging. You can also create a custom logging method. The Python logging module works in the same way as the Log4j logging module except for some implementation details. The Python logging module includes the logger, handler, filter, and formatter objects.

Log format

A formatter specifies the output format of logs. To instantiate a formatter, pass two parameters to the constructor. One parameter includes a message format string and the other parameter includes a date format string. The parameters are optional.

Log format:

```
import logging
import logging.handlers
LOG_FILE = 'tst.log'
handler = logging.handlers.RotatingFileHandler(LOG_FILE, maxBytes = 1024*1024, backupCount = 5) # Ins
tantiate the handler
fmt = '%(asctime)s - %(filename)s:%(lineno)s - %(name)s - %(message)s'
formatter = logging.Formatter(fmt)   # Instantiate the formatter
handler.setFormatter(formatter)      # Add the formatter to the handler
logger = logging.getLogger('tst')    # Obtain a logger named tst
logger.addHandler(handler)           # Add the handler to the logger
logger.setLevel(logging.DEBUG)
logger.info('first info message')
logger.debug('first debug message')
```

Attributes

Formatter attributes are specified in the `%(key)s` format. The following table lists the attributes.

Format	Description
%(name)s	The name of a logger that generates logs.
%(levelno)s	The log output level in the numeric format. Valid values: DEBUG, INFO, WARNING, ERROR, and CRITICAL
%(levelname)s	The log output level in the text format. Valid values: 'DEBUG', 'INFO', 'WARNING', 'ERROR', and 'CRITICAL'.

Format	Description
%(pathname)s	The full path of a source file that contains the logging module.
%(filename)s	The name of the source file.
%(module)s	The name of a module where the statement that you use to generate logs resides.
%(funcName)s	The name of the function that is used to call the log output function.
%(lineno)d	The number of a code line that contains the statement used to call the log output function.
%(created)f	The time when the log was created. The value is a UNIX timestamp representing the number of seconds that have elapsed since January 1, 1970, 00:00:00 (UTC).
%(relativeCreated)d	The interval between the time when a log was created and the time when the logging module was loaded. Unit: milliseconds.
%(asctime)s	The time when the log was created. The value of 2003-07-08 16:49:45,896 is an example of the default format. The number after the comma (,) indicates the number of milliseconds.
%(msecs)d	The time when the log was created. The value is a UNIX timestamp representing the number of milliseconds that have elapsed since January 1, 1970, 00:00:00 (UTC).
%(thread)d	The thread ID.
%(threadName)s	The thread name.
%(process)d	The process ID.
%(message)s	The contents of a log.

Sample logs

Sample log:

```
2015-03-04 23:21:59,682 - log_test.py:16 - tst - first info message
2015-03-04 23:21:59,682 - log_test.py:17 - tst - first debug message
```

Common Python logs and the corresponding regular expressions:

- Sample log:

  ```
  2016-02-19 11:03:13,410 - test.py:19 - tst - first debug message
  ```

  Regular expression:

  ```
  (\d+-\d+-\d+\s\S+)\s+-\s+([^:]+):(\d+)\s+-\s+(\w+)\s+-\s+(. *)
  ```

- Log format

  ```
  %(asctime)s - %(filename)s:%(lineno)s - %(levelno)s %(levelname)s %(pathname)s %(module)s %(funcName)s %(created)f %(thread)d %(threadName)s %(process)d %(name)s - %(message)s
  ```

  Sample log:

```
2016-02-19 11:06:52,514 - test.py:19 - 10 DEBUG test.py test <module> 1455851212.514271 1398659966
87072 MainThread 20193 tst - first debug message
```

Regular expression:

```
(\d+-\d+-\d+\s\S+)\s-\s([^:]+):(\d+)\s+-\s+(\d+)\s+(\w+)\s+(\S+)\s+(\w+)\s+(\S+)\s+(\S+)\s+(\d+)\s
+(\w+)\s+(\d+)\s+(\w+)\s+-\s+(. *)
```

Configure Logtail to collect Python logs

1. Log on to the Log Service console.
2. Click **Import Data**. On the **Import Data** page that appears, select **RegEx-Text Log**.
3. Select a destination project and Logstore, and then click **Next**.

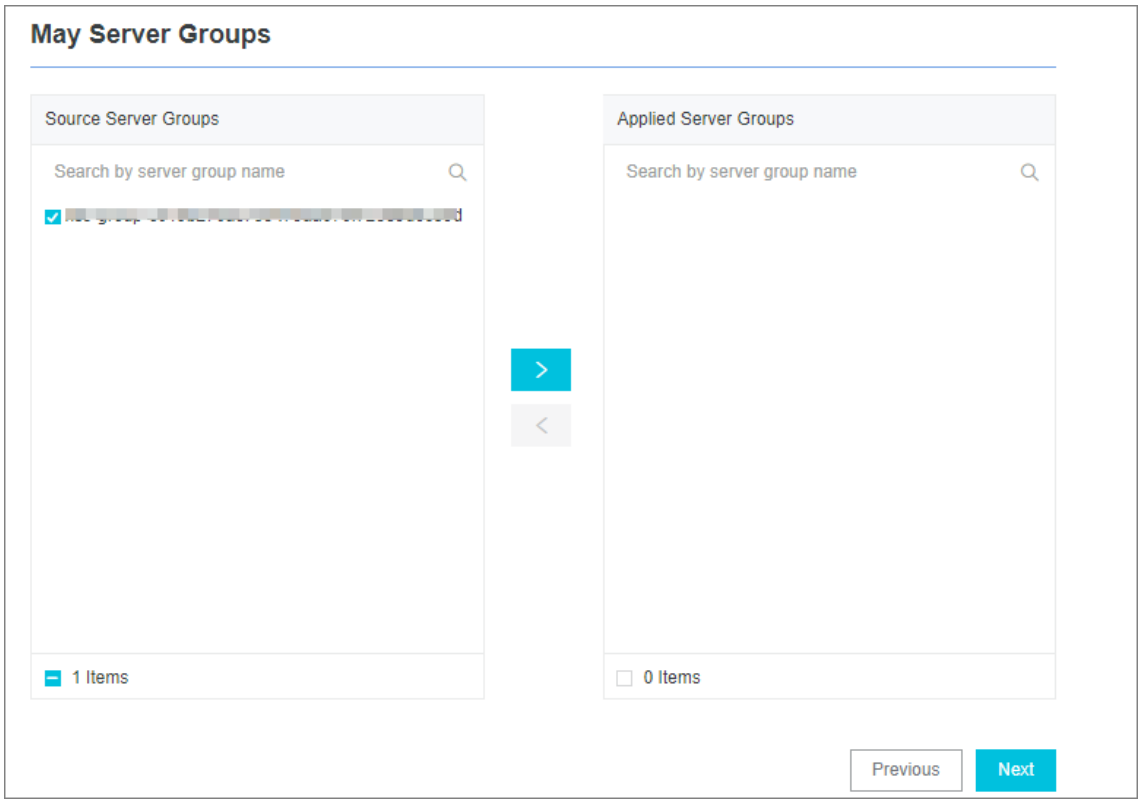
   You can also click **Create Now** to create a project and a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a machine group and click **Next**.

   Before you can create a machine group, you must install Logtail.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a machine group. If a machine group is created, click **Use Existing Machine Groups** to select the machine group.
5. Select a machine group, move the machine group from **Source Machine Groups** to **Applied Server Groups**, and then click **Next**.



Notice If you want to apply a machine group immediately after it is created, the heartbeat status of the machine group may be **FAIL**. This issue occurs because no servers in the machine group are connected to Log Service. In this case, you can click **Automatic Retry**.

6. Create a Logtail configuration.
   i. Enter a **configuration name** and **log path** and select **Full Regex Mode** in the Mode field.
   ii. Turn on **Singleline**.
   iii. Enter a snippet in the **Log Sample** field.
   iv. Turn on **Extract Field**.
   v. Set a regular expression in the **RegEx** field.
      a. Select fields to generate a regular expression

         If the regular expression that is automatically generated does not match your sample log, you can select fields in the sample log to generate a regular expression. Log Service can automatically parse the highlighted fields of the sample log to generate a regular expression. In the **Log Sample** field, select the required fields, and click **Generate Regular Expression**. The regular expression of the selected field is displayed in the **RegEx** field. To obtain a full regular expression for the sample log, generate regular expressions for each log field.

      b. Modify the regular expression

         Actual data formats may vary. In this case, click **Manual** under the RegEx field to adjust the regular expression that is automatically generated based on your business requirements. This ensures that the regular expression is suitable for all formats of the collected logs.

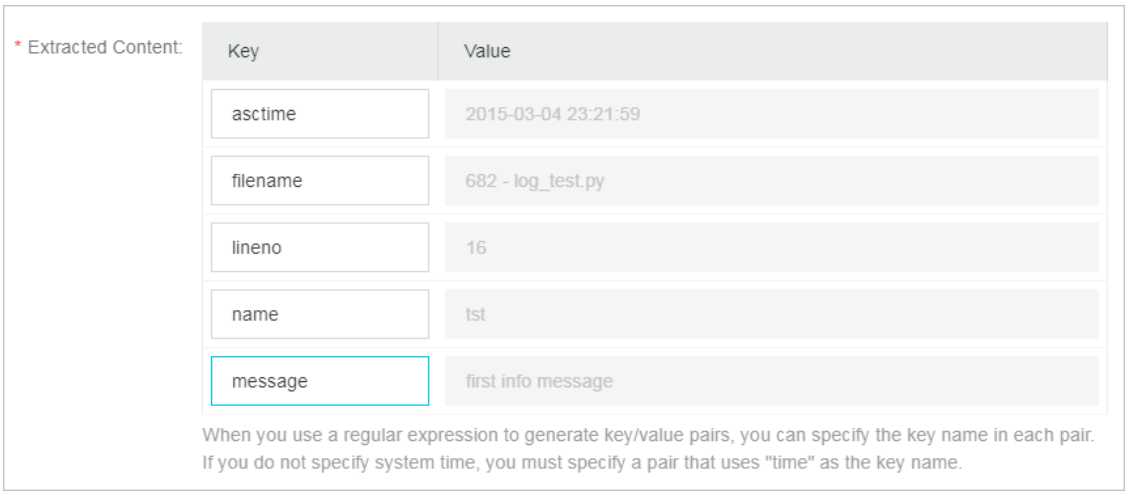
      c. Verify the regular expression

         After you modify the regular expression, click **Validate** next to the RegEx field. If the regular expression is valid, the extraction results are displayed. If the regular expression is invalid, modify the regular expression again.

vi. Confirm **the extraction results of log fields**.

View the extraction results of log fields and specify keys for the extracted fields.

Specify an informative name for each log field in the extraction results. For example, time as the name for a time field. If you do not use the system time, you must specify the name of a time field in the Value fields and time in the Key field.



7. (Optional)Specify **Advanced Options** and click **Next**.

Set the parameters in the Advanced Options section based on your business requirements. We recommend that you do not modify the settings. The following table describes the parameters in the Advanced Options section.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs. **Note** If you turn on **Enable Plug-in Processing**, specific parameters such as Upload Raw Log, Timezone, Drop Failed to Parse Logs, Filter Configuration, and Incomplete Entry Upload (Delimiter mode) become unavailable.
Upload Raw Log	If you turn on **Upload Raw Log**, each raw log is uploaded to Log Service as a value of the __raw__ field together with the parsed log.
Topic Generation Mode	The topic generation mode. ○ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic field is set to an empty string. You do not need to enter a topic to query logs. ○ **Machine Group Topic Attributes**: This mode is used to differentiate logs that are generated by different servers. ○ **File Path RegEx**: In this mode, you must specify a regular expression in the **Custom RegEx** field. The part of a log path that matches the regular expression is used as the topic. This mode is used to differentiate logs that are generated by different users or instances.
Custom RegEx	If you set the Topic Generation Mode parameter to **File Path RegEx**, you must enter a custom regular expression.

Parameter	Description
Log File Encoding	The encoding format of log files. Valid values: ○ utf8: UTF-8 encoding format ○ gbk: GBK encoding format
Timezone	The time zone where logs are collected. Valid values: ○ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ○ Custom: If you select this value, you must select a time zone.
Timeout	The timeout period of log files. If a log file is not updated within the specified period, Logtail reckons the file to be timed out. Valid values: ○ Never: All log files are continuously monitored and never time out. ○ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file. If you select **30 Minute Timeout**, you must specify the **Maximum Timeout Directory Depth** parameter. Valid values: 1 to 3.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ○ Collect logs that meet specified conditions: If you set **Key** to **level** and **Regex** to **WARNING|ERROR**, only WARNING-level and ERROR-level logs are collected. ○ Filter out logs that do not meet specified conditions. ■ If you set **Key** to **level** and **Regex** to **^(?!.*(INFO|DEBUG)).***, INFO-level or DEBUG-level logs are not collected. ■ If you set **Key** to **url** and **Regex** to **.*^(?!.*(healthcheck)).***, logs whose URLs contain healthcheck are not collected. For example, the log is not collected if the value of the Key field is url and the value of the Value field is /inner/healthcheck/jiankong.html.

8. Configure indexes in the Configure Query and Analysis step. Click **Next**.

   By default, Log Service enables Full Text Index to query and analyze logs. You can manually or automatically configure Field Search. For more information, see Enable the index feature and configure indexes for a Logstore.

   > **Note**
   > ○ To query and analyze logs, you must enable Full Text Index or Field Search. If you enable both Full Text Index and Field Search, the settings of Field Search prevail.
   > ○ If the data type of the index is long or double, the Case-Sensitive switch and the Delimiter field are unavailable.

After the configuration is complete, apply the settings to the server group to collect Python logs.

28.1.3.2.3.3. Node.js logs

Node.js logs are displayed in the Log Service console by default. This impedes data collection and troubleshooting. You can use the log4js function to write logs into files and customize the log format. This facilitates data collection and consolidation.

Example:

```
var log4js = require('log4js');
log4js.configure({
  appenders: [
    {
      type: 'file', //Output to a file
      filename: 'logs/access.log',
      maxLogSize: 1024,
      backups:3,
      category: 'normal'
    }
  ]
});
var logger = log4js.getLogger('normal');
logger.setLevel('INFO');
logger.info("this is a info msg");
logger.error("this is a err msg");
```

Log format

After logs are written to text files by using the log4js function, these logs are displayed in the following format:

```
[2016-02-24 17:42:38.946] [INFO] normal - this is a info msg
[2016-02-24 17:42:38.951] [ERROR] normal - this is a err msg
```

The log4js function defines six log severity levels. They are TRACE, DEBUG, INFO, WARN, ERROR, and FATAL in ascending order of severity.

Use Logtail to collect Node.js logs

For more information about how to configure Logtail to collect Python logs, see Python logs. Use configurations based on your network environment and business requirements.

The automatically generated regular expression is based on the sample log and may not apply to other logs. Therefore, you must make minor changes to the regular expression after it is generated. You can use the following sample Node.js logs to configure appropriate regular expressions for your logs.

Sample Node.js logs:

- Example 1
  - Sample log

    ```
    [2016-02-24 17:42:38.946] [INFO] normal - this is a info msg
    ```

  - Regular expression:

    ```
    \[([^]]+)]\s\[([^\]]+)]\s(\w+)\s-(. *)
    ```

  - Extracted fields:

    `time` , `level` , `loggerName` , and `message`

- Example 2
  - Sample log

    ```
    [2016-01-31 12:02:25.844] [INFO] access - 42.120.73.203 - - "GET /user/projects/ali_sls_log? ign
    oreError=true HTTP/1.1" 304 - "http://
    aliyun.com/" "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_10_3) AppleWebKit/537.36 (KHTML, like Ge
    cko) Chrome/48.0.2564.97 Safari/537.36"
    ```

- Regular expression:

```
\[([^]]+)]\s\[(\w+)]\s(\w+)\s-\s(\S+)\s-\s-\s"([^"]+)"\s(\d+)[^"]+("[^"]+)"\s"([^"]+). *
```

- Extracted fields:

`time` , `level` , `loggerName` , `ip` , `request` , `status` , `referer` , and `user_agent`

28.1.3.2.3.4. WordPress logs

This topic describes the format of WordPress logs and extraction results of a sample log.

Log format

Sample log:

```
172.64.0.2 - - [07/Jan/2016:21:06:39 +0800] "GET /wp-admin/js/password-strength-meter.min.js? ver=4.4 HTTP/1.0" 200 776 "http://wordpress.c4a1a0aecdb1943169555231dcc4adfb7.cn-hangzhou.alicontainer.com/wp-admin/install.php" "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_10_5) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/47.0.2526.106 Safari/537.36"
```

Configure Logtail to collect WordPress logs

Configurations required to collect WordPress logs:

- Regular expression that matches IP addresses that each indicate the start of a line

```
\d+\.\d+\.\d+\.\d+\s-\s. *
```

- Regular expression used to extract information from the log:

```
(\S+) - - \[([^\]]*)] "(\S+) ([^"]+)" (\S+) (\S+) "([^"]+)" "([^"]+)"
```

- Time conversion format:

```
%d/%b/%Y:%H:%M:%S
```

- Results after Logtail extracts information from the sample log

Key	Value
ip	10.10.10.1
time	07/Jan/2016:21:06:39 +0800
method	GET
url	/wp-admin/js/password-strength-meter.min.js? ver=4.4 HTTP/1.0
status	200
length	776
ref	http://wordpress.c4a1a0aecdb1943169555231dcc4adfb7.cn-hangzhou.alicontainer.com/wp-admin/install.php
user-agent	Mozilla/5.0 (Macintosh; Intel Mac OS X 10_10_5) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/47.0.2526.106 Safari/537.36

28.1.3.2.3.5. Unity3D logs

Log Service can use the WebTracking feature to collect Unity3D logs. The following example shows how to collect *Unity logs* of the debug type.

Context

Unity3D is a cross-platform game engine developed by Unity Technologies. The engine allows you to create 3D video games, VR buildings, real-time 3D animation, and other interactive content.

Procedure

1. Enable the WebTracking feature.

   For more information about how to enable this feature, see WebTracking.

2. Create a Unity3D LogHandler.

   In a Unity editor, create a C# file named *LogOutputHandler.cs*, add the following code, and modify the following variables.

   - project: specifies the name of the project.
   - logstore: specifies the name of the Logstore.
   - serviceAddr: specifies the endpoint of the project.

     For more information about serviceAddr, see View the information of a project.

```
using UnityEngine;
using System.Collections;
public class LogOutputHandler : MonoBehaviour
{
    //Register the HandleLog function on scene start to fire on debug.log events
    public void OnEnable()
    {
        Application.logMessageReceived += HandleLog;
    }
    //Remove callback when object goes out of scope
    public void OnDisable()
    {
        Application.logMessageReceived -= HandleLog;
    }
    string project = "your project name";
    string logstore = "your logstore name";
    string serviceAddr = "http address of your log service project";
    //Capture debug.log output, send logs to Loggly
    public void HandleLog(string logString, string stackTrace, LogType type)
    {
        string parameters = "";
        parameters += "Level=" + WWW.EscapeURL(type.ToString());
        parameters += "&";
        parameters += "Message=" + WWW.EscapeURL(logString);
        parameters += "&";
        parameters += "Stack_Trace=" + WWW.EscapeURL(stackTrace);
        parameters += "&";
        //Add any User, Game, or Device MetaData that would be useful to finding issues later
        parameters += "Device_Model=" + WWW.EscapeURL(SystemInfo.deviceModel);
        string url = "http://" + project + "." + serviceAddr + "/logstores/" + logstore + "/track
? APIVersion=0.6.0&" + parameters;
        StartCoroutine(SendData(url));
    }
    public IEnumerator SendData(string url)
    {
        WWW sendLog = new WWW(url);
        yield return sendLog;
    }
}
```

The preceding code allows you to send logs to Log Service in an asynchronous manner. In the code, you can specify more fields you want to collect.

3. Generate Unity logs.

   In the project, create a C# file named *LogglyTest.cs* and add the following code.

```
using UnityEngine;
using System.Collections.Generic;
public class LogglyTest : MonoBehaviour {
    void Start () {
        Debug.Log ("Hello world");
    }
}
```

4. View logs in the console.

   After you complete the preceding steps, run the Unity application. In the Log Service console, view logs that are sent to Log Service.

The preceding code shows how to use *Debug.Log*, *Debug.LogError*, and *Debug.LogException* methods to collect logs. Unity provides Component Object Model (COM)-based exception handling and log handling APIs. These APIs allow you to easily collect device details of clients.

28.1.4. Query and analysis

28.1.4.1. Overview

Log Service provides the LogSearch/Analytics feature that you can use to query and analyze a large number of logs. If you do not enable indexes, raw data is consumed in sequence based on shards. The procedure is similar to the sequential consumption of Kafka messages. If you enable indexes, you can query logs and perform statistical analysis on query results in addition to consuming logs in sequence.

Benefits

- Real-time: Logs can be analyzed immediately after they are written.
- Fast:
  - Query: Billions of data records can be processed and queried within one second. Each search statement has a maximum of five conditions specified.
  - Analysis: Hundreds of millions of data records can be aggregated and analyzed within one second. Each query has a maximum of five aggregate functions and a GROUP BY clause specified.
- Flexible: Query and analysis conditions can be changed as required and the results are returned in real time.
- All-in-one: Reports and dashboards are available in the console for quick analysis. In addition to these features, Log Service can work together with Grafana, DataV, Jaeger, and other services. It also supports RESTful APIs, Java Database Connectivity (JDBC) APIs, and other APIs.

Indexing

Indexes refer to a data structure that you can use to sort the values of one or more columns of logs. Indexes allow you to obtain the required information in a timely manner from logs that Log Service collects. Before you use the LogSearch/Analytics feature, you must collect logs and Enable the index feature and configure indexes for a Logstore on the collected logs.

In Log Service, indexes are sorted into **full-text indexes** and **field-specific indexes**.

- **Full-text index**: Indexing is enabled for the full contents of a log. The values of all fields in a log are queried by default. The log can be queried if one of the fields matches the search term.
- **Field-specific index**: You can configure a field-specific index for a key. Then, you can query logs based on specific keys to narrow the query scope.

To use **field-specific indexes**, you must specify the data type for a field. Available data types for fields in Log Service include Text, JSON, Long, and Double. For more information about Overview.

Query methods

- Console

  In the Log Service console, you can query logs by specifying time ranges and search statements. For more information about the procedure and search statements, see Query logs and Query syntax.

- API

  To query logs, you can call the GetLogs and GetHistograms API operations of the Log Service API.

> **Note** Before you query logs, make sure that you collect logs and Enable the index feature and configure indexes for a Logstore.

Search and analysis statements

To apply real-time LogSearch/Analytics to collected logs, you must specify query statements. Each query statement includes the search section and the analytics section. Separate the sections with a vertical bar (|).

```
$Search |$Analytics
```

Statement	Required	Description
Search	No	A search statement contains search conditions. These conditions include keywords, fuzzy keywords, values, ranges, and combined conditions. If you leave the statement empty or specify an asterisk (*) for the statement, it indicates that no condition is specified and all data is returned. For more information, see Query syntax.
Analytics	No	You can use an analytics statement to aggregate or analyze data based on query results. If you leave the statement empty, it indicates that no analytics is required and all query results are returned. For more information, see Real-time analysis.

Precautions

You may query a large number of logs. For example, if the number of logs to be queried is more than 1,000,000,000, Log Service may fail to return all results. Log Service returns a partial result set and notifies you that the returned data set includes partial results.

Query results are cached every 15 minutes. If a partial result set is matched in the cache, Log Service continues to scan logs that are not cached. Log Service combines query results of the current query with results of cached results.

Therefore, Log Service enables you to obtain results by calling the API operation multiple times with the same parameters.

28.1.4.2. Real-time analysis

Log Service supports SQL-like aggregate calculation. This feature integrates search statements with SQL aggregate functions to calculate query results.

Sample statement:

```
status>200 |select avg(latency),max(latency) ,count(1) as c GROUP BY  method  ORDER BY c DESC  LIMIT 20
```

Basic syntax:

```
[search query] | [sql query]
```

Separate a search statement and a calculation statement with a vertical bar (|). You can use the search statement to query logs and obtain the required results. Then, use the calculation statement for further aggregation. The search query syntax is specific to Log Service. For more information, see Query syntax.

Prerequisites

To use the statistical analysis feature, click **Index Attributes**. Turn on the **Enable Analytics** switch for the required field. For more information, see Enable the index feature and configure indexes for a Logstore.

- If you turn off the switch, Log Service calculates up to 10,000 rows of data in each shard along with high latency of calculation.
- If you turn on the switch, Log Service analyzes data in seconds.
- The update applies only to new data.
- No extra fee is incurred for the update.

Supported SQL syntax

Log Service supports the following SQL syntax. For more information about a specific topic, click the corresponding link.

- Aggregate functions that are available for SELECT statements include:
  - General aggregate functions
  - Security check functions
  - Map functions
  - Approximate functions
  - Mathematical statistics functions
  - Mathematical calculation functions
  - String functions
  - Date and time functions
  - URL functions
  - Regular expression functions
  - JSON functions
  - Type conversion functions
  - IP functions
  - Array functions
  - Binary string functions
  - Bitwise operations
  - Interval-valued comparison and periodicity-valued comparison functions
  - Comparison functions and operators
  - Lambda functions
  - Logical functions
  - Geospatial functions
  - Geography functions
  - Machine learning functions
- GROUP BY syntax
- Window functions
- HAVING syntax
- ORDER BY syntax
- LIMIT syntax
- Syntax for CASE statements and if() functions
- UNNEST function
- Field aliases
- Nested subqueries

Precautions

Before you use SQL statements, note the following items:

- You do not need to specify FROM and WHERE clauses for SQL statements. By default, Log Service queries logs from the current Logstore, and each WHERE clause is specified in the [search query] section.
- The supported clauses include SELECT, GROUP BY, ORDER BY [ASC,DESC], LIMIT, and HAVING.

> **Note** By default, only the first 10 results are returned. If you want to return more results, add a LIMIT clause to the statement. For example, `* | select count(1) as c, ip group by ip order by c desc limit 100`.

Built-in fields

Log Service has multiple built-in fields for statistical analysis. A built-in field is automatically added to a valid column that you create.

Field	Type	Description
`__time__`	Bigint	The time when a log was created.
`__source__`	Varchar	The source IP address of a log. When you query logs, the name of the field is source. If you specify the field for an SQL statement, you must add two underscores (_) at both the start and end of source.
`__topic__`	Varchar	The topic of a log.

Limits

- Maximum number of Logstores from which you can query logs at the same time is 15.
- Maximum length for a field value of the varchar type is 2,048. Extra data will be truncated.
- By default, up to 100 lines of a log file are returned and pagination is not supported. If you want to return more lines, use LIMIT syntax.

Example

Calculate the hourly PV and UV, and the user request of the highest latency.

```
*|select date_trunc('hour',from_unixtime(__time__)) as time,
     count(1) as pv,
     approx_distinct(userid)  as uv,
     max_by(url,latency) as top_latency_url,
     max(latency,10) as top_10_latency
     group by  1
     order by time
```

28.1.4.3. Enable the indexing feature and configure indexes for a Logstore

This topic describes how to enable the indexing feature and configure indexes for a Logstore.

Context

Before you can query logs that are stored in a Logstore, you must enable the indexing feature and configure indexes for the Logstore. We recommend that you configure indexes for your Logstores based on your business requirements.

> **Note** After you enable the indexing feature, the indexes occupy extra storage space and transferring the indexes occupies extra bandwidth.

When you collect a log entry, Log Service adds the relevant information (such as the source and time fields) to the log entry as key-value pairs. These fields are reserved in Log Service. If you enable the indexing feature for a Logstore and configure indexes for fields in the Logstore, the indexing and analytics features are automatically enabled for these fields.

Reserved fields in Log Service

Field	Description
`__topic__`	The topic of a log entry. If you specify a topic for a log entry, Log Service adds the topic field to the log entry. The key of the field is __topic__ and the value of the field is the log topic. For more information, see `Specify a log topic`.
`__source__`	The source of a log entry. The source device that generates the log entry.
`__time__`	The time when a log entry is written to the Logstore by using an SDK.

> **Note** If the values of the `__topic__` and `__source__` fields are null, the keywords that you use to query the two fields must exactly match the field values.

Procedure

1. Log on to the Log Service console.
2. In the Projects section, click the target project.
3. Find the target Logstore, and choose > **Search & Analysis**.
4. On the page that appears, click **Enable** in the upper-right corner.

   > **Note** If you have created indexes for the Logstore, choose **Index Attributes** > **Modify** to modify the indexes.

5. Configure the indexes.

   > **Note** If you enable a full-text index and a field-specific index at the same time, the field-specific index takes precedence over the full-text index.

   Index types

Index type	Description
Full text index	An index is created in the text format for all fields. You can search for key-value pairs that are included in these fields. For fields of the LONG type, you must specify the key name of a field when you query a value of the field. For fields of the other types, you do not need to specify a key name in queries.

Index type	Description
Field-specific index	After you configure a field-specific index, you must specify the name of a key when you query logs. If you configure the field-specific index on a field, the field-specific index takes effect when you query logs. The full-text index does not take effect. Available data types that you can specify for fields include: ○ Query text data ○ JSON indexes ○ Numeric (LONG and DOUBLE)

- Configure a full-text index.

  After you configure a full-text index for a Logstore, the values of all fields in the Logstore are queried by default.

Parameter	Description	Example value
Full Text Index	If you turn on the switch, Log Service traverses the values of all fields in a log entry. If the value of one of the fields matches the keyword, the log entry is returned.	-
Case Sensitive	Specifies whether queries are case-sensitive. ■ If you turn off the switch, queries are not case-sensitive. For example, if you search for internalError, you can use either INTERNALERROR or internalerror as the keyword. ■ If you turn on the switch, queries are case-sensitive. For example, if you search for internalError, you can use only internalError as the keyword.	-
Include Chinese	Specifies whether to differentiate the Chinese content and English content. ■ If you turn on the switch, Log Service separates the Chinese content based on the Chinese semantics and English content based on the specified delimiters. ■ If you turn off the switch, the content of a log entry is separated by the specified delimiters.	-
Delimiter	The delimiters that you use to separate the content of a log entry into multiple keywords. For example, the content of a log entry is `a,b;c;D-F`. You can specify commas (,), semicolons (;), and hyphens (-) as delimiters to delimit the log content. Then you can use the five letters a, b, c, D, and F as keywords to match the log entry.	`, '";=()[]{}? @&<>/:\n\t`

- Configure a field-specific index.

  You can specify fields to be indexed. Field-specific indexes allow you to query log data based on the values of specific fields. This narrows down the query scope.

Parameter	Description	Example value
Key Name	The name of a log field. **Note** ■ If you want to configure an index for fields of the tag type, such as fields that include public IP addresses or UNIX timestamps, you must set the value of the **Key Name** parameter in the `__tag__:key` format, for example, `__tag__:__receive_time__`. ■ Indexes of the numeric types are unavailable for tag fields. You must select text in the **Type** field for all tag fields.	`_address_`
Type	The type of a field. Valid values: ■ **text**: The data type of the field is TEXT. ■ **long**: The data type of the field is LONG. You must specify a numeric range to query log data. ■ **double**: The data type of the field is DOUBLE. You must specify a numeric range to query log data. ■ **json**: The data type of the field is JSON. **Note** The **Case Sensitive**, **Include Chinese**, and **Delimiter** parameters are unavailable for fields of numeric types (LONG and DOUBLE).	-
Alias	The alias of a column. Aliases are applied only to SQL statistics. Original names are applied when you store and query log data in Log Service. For more information, see Field aliases.	`address`
Case Sensitive	Specifies whether queries are case-sensitive. ■ If you turn off the switch, queries are not case-sensitive. For example, if you search for internalError, you can use either INTERNALERROR or internalerror as the keyword. ■ If you turn on the switch, queries are case-sensitive. For example, if you search for internalError, you can use only internalError as the keyword.	-

Parameter	Description	Example value
Delimiter	The delimiters that you use to separate the content of a log entry into multiple keywords. For example, the content of a log entry is `a,b;c;D-F`. You can specify commas (,), semicolons (;), and hyphens (-) as delimiters to delimit the log content. Then you can use the five letters a, b, c, D, and F as keywords to match the log entry.	`, '";=()[]{}? @&<>/:\n\t`
Include Chinese	Specifies whether to differentiate the Chinese content and English content. ■ If you turn on the switch, Log Service separates the Chinese content based on the Chinese semantics and English content based on the specified delimiters. ■ If you turn off the switch, the content of a log entry is separated by the specified delimiters.	-
Enable Analytics	Specifies whether to enable the analytics feature. The switch is turned on by default. After you turn on the switch, you can use search and analytic statements to obtain statistical results.	-

6. Click **OK**.

> **Note**
> - The index configurations take effect within one minute.
> - After an index is enabled or modified, the updates on the index apply only to new data that is written to Log Service.

28.1.4.4. Query logs

This topic describes how to query logs in a Logstore. After you enable and configure the index of the Logstore, you can query and analyze logs in a Logstore in real time.

Prerequisites

- Logs are collected and stored in a Logstore.
- Indexes are enabled and configured. For more information, see Enable the index feature and configure indexes for a Logstore.

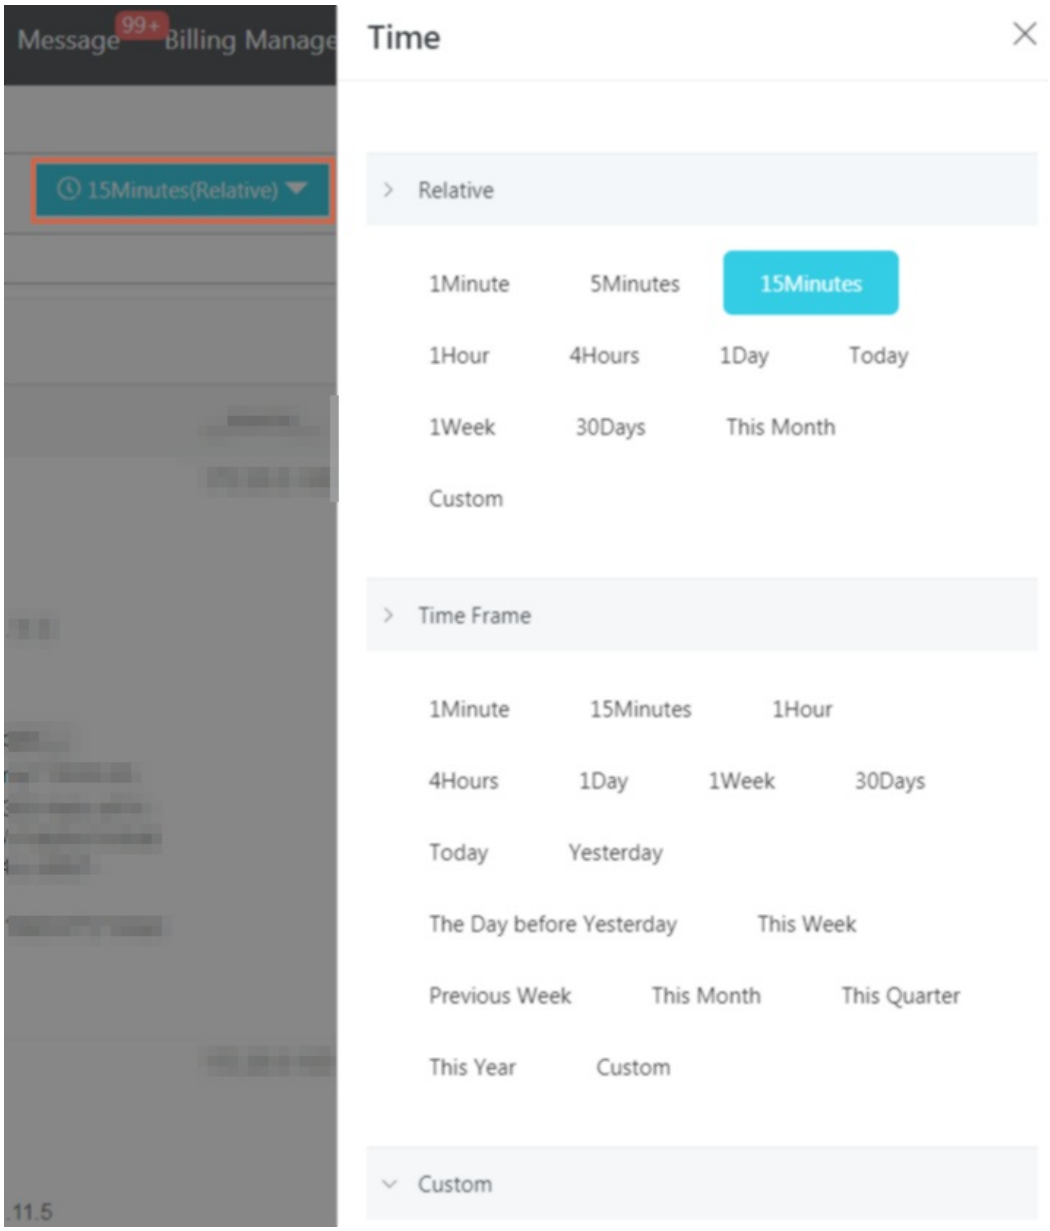
Procedure

1. Log on to the Log Service console.
2. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
3. Enter a query statement in the search box.

   A query statement consists of a search statement and an analytic statement. The syntax is `search statement|analytic statement`. For more information, see Search and analysis statements.
4. On the Search & Analysis page, select **15 Minutes** in the Relative section to set the time range for the query.

You can select a relative time, time frame, or a custom time range.

> **Note** The query results may contain logs that are generated 1 minute earlier or later than the specified time period.



5. Click **Query & Analyze** to view the query results.

   Log Service illustrates query results on log distribution histograms, Raw Logs tab, or statistical graphs.

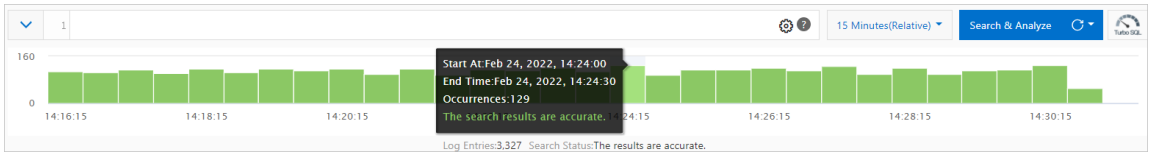
   > **Note** 100 results are returned by default. For information about how to retrieve more results, see LIMIT syntax.

   - Log distribution histogram

     The log distribution histogram shows the distribution of query results across different time ranges.

     - Move the pointer over a green block to view a time range and the number of logs obtained within the time range.

- Click a data block to view finer-grained log distribution. You can also view the query results on the **Raw Logs** tab.



- Raw Logs tab

  On the **Raw Logs** tab, view logs that match your search conditions.

  - Quick analysis: Use this feature to analyze the distribution of values for a specific field within a period of time. For more information, see Quick analysis.
  - Log download: Click the download icon in the upper-right corner of the tab, select a time range, and then click **OK**.
  - Column settings: Click **Column Settings** in the upper-right corner of the tab, select the required fields and click **Add** to add the fields. Then, the columns that correspond to the fields appear on the tab. The field names are also column names. The columns list the field values.

    > **Note** To view the log contents on the tab, select **Content**.

- Content column settings: If the content of a field exceeds 3,000 characters, extra characters will be hidden. In this case, the message "The character string is too long and has been truncated" will be displayed before the Key field. Click **Display Content Column**. In the dialog box that appears, set the **Key-Value Arrangement** and **Truncate Character String** parameters.

  > **Note** If the content limit is set to 10,000 characters, no delimiter will be specified for extra characters.

Parameter		Description
Key-Value Pair Arrangement		You can set this parameter to **New Line** or **Full Line**.
Truncate Character String	**Key**	If a field value contains more than 3,000 characters, the field value is truncated. However, this parameter remains unspecified if no field value exceeds 3,000 characters. The value of this parameter is the key of the truncated value.
	Status	This parameter determines whether to enable the value truncation feature. By default, the feature is enabled. ■ **Enable**: If the value in a key-value pair exceeds the specified **Truncate Step**, extra characters will be truncated. You can click the Show button at the end of the value to show the truncated characters. The increment per click is the specified truncate step. ■ **Disable**: If the value in the key-value pair exceeds the specified **Truncate Step**, extra characters will not be truncated.
	Truncate Step	This parameter specifies the maximum number of characters that a field value shows by default. The parameter also specifies the number of extra characters that you displayed each time you click the Show button. Valid values: 500 to 10000. Default value: 3000.

- Graph

  If you enable the Analytics feature on the Search & Analysis page and use search and analytic statements to query logs, you can view the analytical results on the **Graph** tab.

  - Graphs of multiple types are provided in Log Service, including tables, line charts, and bar charts. You can select a graph to show the required analytical results. For more information, see Graphs.
  - Log Service allows you to create dashboards for real-time data analysis. For more information, see Create and delete a dashboard. Click **Add to New Dashboard** to save a common chart as query statements to a dashboard.
  - Drill-down analysis allows you to move to deeper data layers, which reveals more detailed information. You can set the drill-down parameters and add the chart to the dashboard. Then, you can click the values in the chart to view the analysis results from more dimensions. For more information, see Drill-down analysis.

  You can also click **Save Search** or **Save as Alarm** on the Search & Analysis page to use the saved search and alarm features. For more information, see Save a query statement as a search and Configure an alert.

28.1.4.5. Export logs

You can export logs on the current page to a CSV file and save the file to your localhost.

Procedure

1. Log on to the Log Service console.
2. Click a project name.
3. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
4. Click the icon next to the **Raw Logs** tab.
5. In the **Download Log** dialog box, select **Download Log in Current Page**.
6. Click **OK** to export logs of the current page to a .CSV file and save the file to the localhost.

28.1.4.6. Index data type

28.1.4.6.1. Overview

Log Service allows you to use full-text indexes or field-specific indexes to query collected logs. If you set a full-text index for a log, the value is the entire log. If you set a field-specific index for a log, you can specify a data type for each key.

Date types

The following table lists the supported data types.

Query type	Data type (index)	Description	Example
Basic query	Text	The text type. You can use keywords and fuzzy matches to query logs.	`uri:"login*" method:"post"`
	Long	The numeric type. You can specify numeric ranges to query logs.	`status>200 and status in [200, 500]`
	Double	The floating-point type.	`price>28.95 and t in [20.0, 37]`
Combined query	JSON	Indicates that the index is a JSON field that supports nested queries. By default, the data type of the field is text. You can set indexes of the Text, Long, and Double types for the b elements at layer a in the a.b path format. The fields adopt the configured types.	`level0.key>29.95 level0.key2:"action"`
	Text	Indicates that the full contents of the log are queried as text.	`error and "login fail"`

Query examples

The following table lists the keys included in the sample log.

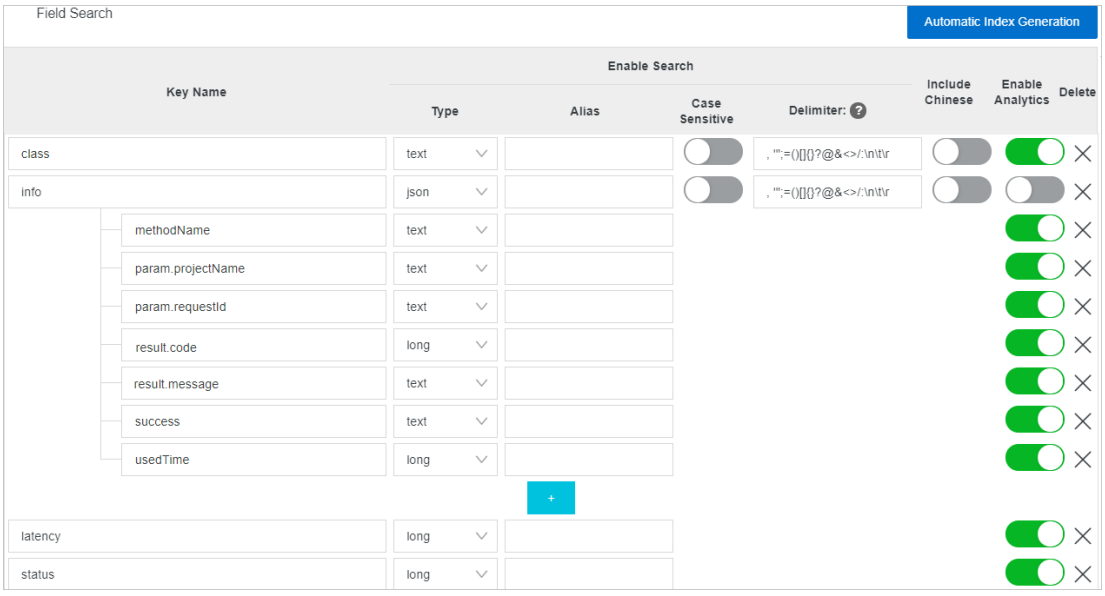
No.	Key	Type
0	time	N/A
1	class	text

No.	Key	Type
2	status	long
3	latency	double
4	message	json

```
0. time:2018-01-01 12:00:00
  1. class:central-log
  2. status:200
  3. latency:68.75
  4. message:
  {
      "methodName": "getProjectInfo",
      "success": true,
      "remoteAddress": "1.1.1.1:11111",
      "usedTime": 48,
      "param": {
              "projectName": "ali-log-test-project",
              "requestId": "d3f0c96a-51b0-4166-a850-f4175dde7323"
      },
      "result": {
          "message": "successful",
          "code": "200",
          "data": {
              "clusterRegion": "ap-southeast-1",
              "ProjectName": "ali-log-test-project",
              "CreateTime": "2017-06-08 20:22:41"
          },
          "success": true
      }
  }
```

You can set an index as follows.

Set an index



In the preceding figure,

- ① specifies that Log Service can query data of the string and Boolean types in JSON fields.
- ② specifies that Log Service can query data of the long type.
- ③ enables SQL analysis for specified fields.

Example

1. Query data of the string and Boolean types
   - You do not need to configure JSON fields.
   - JSON maps and arrays are automatically expanded and can contain nested fields. Separate multiple levels with periods (`.`). .

   ```
   class : cental*
   message.traceInfo.requestId : 92.137_1518139699935_5599
   message.param.projectName : ali-log-test-project
   message.success : true
   ```

2. Query data of the double and long types

   Each JSON field must be specified separately and cannot be contained in a JSON array.

   ```
   latency>40
   message.usedTime > 40
   ```

3. Combined query

   ```
   class : cental* and message.usedTime > 40 not message.param.projectName:ali-log-test-project
   ```

28.1.4.6.2. Query text data

This topic describes how to query text data.

Similar to search engines, Log Service queries text data based on terms. Therefore, you must set the Delimiter, Case Sensitive fields.

Configurations

- Case sensitivity

  You can specify whether log queries are case-sensitive. For example, you want to query logs by using a search term named `internalError` .

  - *false* specifies a case-insensitive query. Both `INTERNALERROR` and `internalerror` can be the keywords.
  - *true* specifies a case-sensitive query. Only the `internalError` can be the keyword.

- Delimiter

  You can use delimiters to split a search term into multiple keywords.

  For example, you want to query logs by using the following search term.

  ```
  /url/pic/abc.gif
  ```

  - If no delimiter is set, the entire `/url/pic/abc.gif` string is treated as a keyword. You must use the entire string as a keyword or a fuzzy string named `/url/pic/*` to query logs.
  - If the delimiter is set to `/` , the search term is split into three words: `url` , `pic` , and `abc.gif` . You can use one of these words or a fuzzy word to query logs. For example, `url` , `abc.gif` , or `pi*` . You can also use the `/url/pic/abc.gif` string as a search term to query logs. However, the search term is split into three keywords named `url, pic, and abc.gif` .
  - If the delimiter is set to `/.` , the search term is split into four keywords named `url` , `pic` , `abc` , and `gif` .

> **Note** You can extend query ranges by setting appropriate delimiters.

- Full-text index

  By default, full-text indexes treat each log except for the time field as text data. You do not need to specify any keys for a full-text index. For example, the following log includes the time field, status field, level field, and message field.

  ```
  [20180102 12:00:00] 200,error,some thing is error in this field
  ```

  - `time:2018-01-02 12:00:00`
  - `level:"error"`
  - `status:200`
  - `message:”some thing is error in this field”`

  > **Note**
  > - Prefixes are not required for full-text indexes. If you set the search term to error, the level and message fields that include error match the search term.
  > - You must set delimiters for full-text indexes. For example, if you set a space ( ) as a delimiter, the `status:200` string is a search term. If you set a colon (`:`) as a delimiter, the search term is split into two keywords named `status` and `200` .
  > - Numbers are treated as text data. For example, you can use 200 to query logs. Values in the time field are not treated as text data.
  > - You can query logs by using keys such as `status` .

28.1.4.6.3. Numeric type

When you configure indexes, you can set the data type of a key to number. To query logs, you can specify a numeric range for the key.

Configurations

Supported types: `long` (long integers) and `double` (decimals). After you set the data type of a key to number, you must specify a numeric range for the key to query logs.

Query examples

To specify a numeric range from 1000 to 2000 (excluding 1000) for a key of the long type, you can use the following methods:

- Query syntax for numbers. For example:

  ```
  longKey > 1000 and longKey <= 2000
  ```

- Query grammar for numeric ranges. For example:

  ```
  longKey in (1000 2000]
  ```

For more information about query syntax, see Query syntax.

28.1.4.6.4. JSON indexes

Log Service can query and analyze logs in the JSON format. You can set the data type of indexes to JSON.

JSON texts include data of multiple types, including string, Boolean, number, array, and map. JSON-formatted data is self-parsed and flexible. You can use JSON-formatted data in various scenarios. In most cases, variable log fields are recorded in the JSON format. For example, HTTP request and response parameters are recorded in a log in the JSON format.

Log Service allows you to set the data type of index fields to JSON so that you can query and analyze logs in the JSON format.

Configurations

- Log Service can parse JSON-formatted fields and generate indexes for all the fields of the text and Boolean types.

```
json_string.key_map.key_text : test_value
json_string.key_map.key_bool : true
```

- To query fields of the double or long type that is not in a JSON array, you can specify a JSON path.

```
Set the data type of the key_map.key_long field to long.
Search condition: json_string.key_map.key_long > 50
```

- To query fields of the text, double, or long type that is not in a JSON array, you can enable the Analytics feature and use SQL statements to analyze these fields.

```
json_string.key_map.key_long > 10 | select count(*) as c ,
    "json_string.key_map.key_text" group by
    "json_string.key_map.key_text"
```

> **Note**
>
> - JSON objects and JSON arrays are not supported.
> - Fields cannot be contained in JSON arrays.
> - Fields of the Boolean type can be converted into the text type.
> - To query and analyze logs, JSON-formatted fields must be enclosed with double quotation marks (" ").

- Log Service cannot parse invalid JSON-formatted data.

  Log Service does not stop parsing logs until it detects an invalid field.

  In the following example, data after the key_3 field is truncated and lost in the following text. Log Service can parse the json_string.key_map.key_2 field and the contents before this field.

```
"json_string":
{
     "key_1" :  "value_1",
     "key_map" :
      {
             "key_2" : "value_2",
             "key_3" : "valu
```

Query syntax

To query a specific key, you must add the JSON parent path to the query statement as the prefix of the key. The query syntax for the fields of the text and numeric types is the same for both JSON-formatted data and other data. For more information, see Query syntax.

Query example

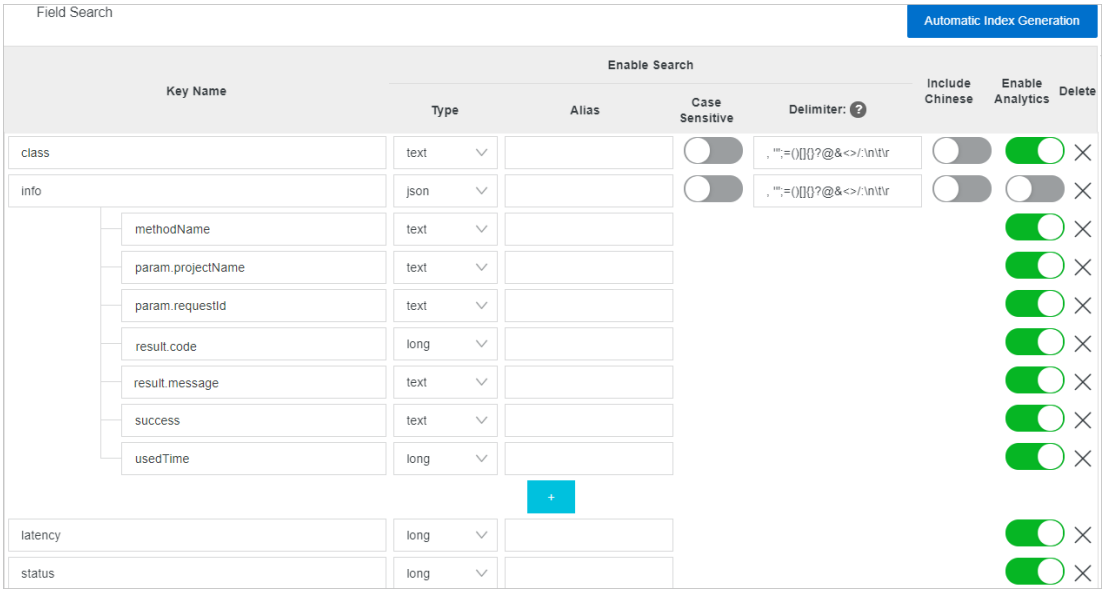
The following table lists the keys included in the sample log. The data type of the `message` key is JSON.

Number	Key	Type
0	time	N/A
1	class	text
2	status	long
3	latency	double
4	message	json

```
0. time:2018-01-01 12:00:00
  1. class:central-log
  2. status:200
  3. latency:68.75
  4. message:
  {
      "methodName": "getProjectInfo",
      "success": true,
      "remoteAddress": "1.1.1.1:11111",
      "usedTime": 48,
      "param": {
              "projectName": "ali-log-test-project",
              "requestId": "d3f0c96a-51b0-4166-a850-f4175dde7323"
      },
      "result": {
          "message": "successful",
          "code": "200",
          "data": {
              "clusterRegion": "ap-southeast-1",
              "ProjectName": "ali-log-test-project",
              "CreateTime": "2017-06-08 20:22:41"
          },
          "success": true
      }
  }
```

You can set indexes for the log as follows:

Set an index



In the preceding figure:

- ① specifies that Log Service can query data of the string and Boolean types in JSON fields.
- ② specifies that Log Service can query data of the long type.
- ③ enables SQL analysis for specified fields.

Examples

1. Query data of the string and Boolean types

   > **Note**
   > - You do not need to configure JSON fields.
   > - JSON maps and arrays are automatically expanded and can include hierarchical levels. Separate multiple levels with periods (`.`).

   ```
   message.traceInfo.requestId : 92.137_1518139699935_5599
   message.param.projectName : ali-log-test-project
   message.success : true
   message.result.data.ProjectStatus : Normal
   ```

2. Query fields of the double and long types

   > **Note** Each JSON field must be configured and cannot be contained in an array.

   ```
   message.usedTime > 40
   ```

3. Use SQL statements to analyze fields

   > **Note**
   > - Each JSON field must be configured and cannot be contained in an array.
   > - Each field to be queried must be enclosed with double quotation marks (" ") or be configured with an alias.

   ```
   * | select avg("message.usedTime") as avg_time ,
   "message.methodName"  group by "message.methodName"
   ```

28.1.4.7. Query syntax and functions

28.1.4.7.1. Search syntax

This topic describes the search syntax that is used in Log Service.

Search types

After you enable and configure the index feature of a Logstore, you can enter a search statement on the search and analysis page to query logs.

A query statement consists of two sub-statements in sequence: a search statement and an analytic statement. A search statement specifies one or more search conditions and returns the log entries that match the search conditions. You can execute a search statement to perform a full-text search or field-specific search.

- Full-text search

  During full-text search, a log entry is considered a key-value pair. The value in the key-value pair indicates the content of the log entry. A full-text search statement returns the log entries that include or exclude the specified keywords.

  Full-text search is divided into basic full-text search, phrase search, and wildcard-based search.

  - Basic full-text search: You can specify keywords and operators in search conditions of a search statement. You can then execute the search statement to query the log entries that match the search conditions.

    For example, the `a and b` statement returns the log entries that include the `a` and `b` keywords.

  - Phrase search: A phrase is a string that is enclosed in double quotation marks (""). Substrings in a phrase are separated by space characters. Each substring is a keyword.

    For example, the `"http error"` statement returns the log entries that contain the http and error keywords. This statement is equivalent to `http and error`.

  - Wildcard-based search: You can use an asterisk (`*`) or a question mark (`?`) as a wildcard character in a keyword. Each keyword that includes wildcards can contain 1 to 64 characters in length and cannot start with a wildcard character. If a search condition contains a keyword that includes a wildcard character, Log Service returns a maximum of 100 log entries and each log entry contains a word that matches the keyword pattern.

    For example, if you execute the `addr?` statement, Log Service returns a maximum of 100 log entries and each log entry contains a word that is prefixed with `addr`.

    When you use wildcard-based search, note the following information:

    - A keyword cannot start with an asterisk (`*`) or a question mark (`?`).
    - The more accurate the keyword is, the more accurate the search results will be.
    - Wildcard-based search is not supported for a keyword that contains more than 64 characters in length.
    - A search statement returns a maximum of 100 log entries that match the search conditions.

- Field-specific search

  After you configure the field index, you can search log entries based on the keys and values of the fields in the field index. For a field of the DOUBLE or LONG type, you can specify a value range for search. For example, the `Latency>5000 and Method:Get* and not Status:200` statement returns the log entries that meet the following conditions: The value of the `Latency` field is greater than 5000, the value of the `Method` field is prefixed with `Get`, and the value of the `Status` field is not 200.

  You can perform a basic query or combined query, depending on the data types of the fields in the field index. For more information, see Overview.

Additional considerations

- If you execute a search statement to perform both full-text search and field-specific search and you set different delimiters for the two search types, the delimiter that is set for field-specific search is used.
- You must set the data type of a field to DOUBLE or LONG before you specify a value range to search the field. If the data type of a field is not DOUBLE or LONG or the value range syntax is incorrect, the field-specific search condition is considered a full-text search condition. In this case, unexpected search results may be returned.
- If you change the data type of a field from TEXT to DOUBLE or LONG, only the equal-to operator (`=`) can be used to search for the log entries that are collected before the change.

Operators

The following table lists the operators that are supported by search statements.

Operator	Description
and	A binary operator. The syntax is `query1 and query2`. It indicates the intersection of the search results of `query1` and `query2`. The default operator between keywords is `and`.
or	A binary operator. The syntax is `query1 or query2`. It indicates the union of the search results of `query1` and `query2`.
not	A binary operator. The syntax is `query1 not query2`. It indicates that the log entries that match `query1` but do not match `query2` are returned. The syntax is equivalent to `query1-query2`. You can also use the `not query1` syntax. It indicates that the log entries that do not match `query1` are returned.
(,)	The operator that merges one or more sub-conditions into one search condition. The search based on a sub-condition that is enclosed in parentheses () is performed first.
:	The operator that is used to specify a pattern of key-value pairs. The syntax is `term1:term2`. If the key or value contains reserved characters such as spaces and colons (:), use double quotation marks (`""`) to enclose the entire key or value.
"	The operator that converts another operator into a common character. All terms enclosed in double quotation marks ("") are considered keywords rather than operators. In a field-specific search statement, you can enclose the entire key or value in double quotation marks.
\	The operator that escapes a double quotation mark. The escaped double quotation mark is considered a symbol instead of an operator. Example: `"\""`.
|	The pipeline operator that is used to chain a search statement and an analytic statement. The analytic statement that follows the pipeline operator is executed based on the result of the search statement that the pipeline operator follows. Example: `query1 | select count(1)`.
count	The count operator that is used to summarize the number of log entries.
*	The wildcard character that is used to replace zero or more characters. For example, the `que*` statement returns the log entries with a word that is prefixed with `que`. **Note** A wildcard-based search statement returns a maximum of 100 log entries that match the search condition.

Operator	Description
?	The wildcard character that replaces a single character. The `qu?ry` statement returns the log entries with a word that is prefixed with `qu`, is suffixed with `ry`, and contains a character in between.
`__topic__`	The operator that specifies zero or more topics from which to query log entries. Example: `__topic__:mytopicname`.
`__tag__`	The operator that specifies a tag value of a tag key to query. Example: `__tag__:tagkey:tagvalue`.
source	The operator that specifies the IP address of a log source whose log entries you want to query. Example: `source:127.0.0.1`.
>	The greater-than operator. You can use this operator to query the log entries whose value of a field is greater than a specified number. Example: `latency > 100`.
>=	The greater-than-or-equal-to operator. You can use this operator to query the log entries whose value of a field is greater than or equal to a specified number. Example: `latency >= 100`.
<	The less-than operator. You can use this operator to query the log entries whose value of a field is less than a specified number. Example: `latency < 100`.
<=	The less-than-or-equal-to operator. You can use this operator to query the log entries whose value of a field is less than or equal to a specified number. Example: `latency <= 100`.
=	The equal-to operator. You can use this operator to query the log entries whose value of a field is equal to a specified number. Example: `latency = 100`.
in	The operator that is used to query the log entries whose value of a field falls in a specified range. Brackets [] indicate closed intervals and parentheses () indicate open intervals. The beginning number and ending number of the range are enclosed in brackets or parentheses and separated by one or more space characters. The in operator must be in lowercase. Example: `latency in [100 200]` or `latency in (100 200]`.

Note

- All operators except the in operator are case-insensitive.
- You can use the following operators, which are sorted in descending order of precedence: `:`, `"`, `()`, `and`, `not`, and `or`.
- Log Service uses the following operators: `sort`, `asc`, `desc`, `group by`, `avg`, `sum`, `min`, `max`, and `limit`. If you need to use these operators as keywords, enclose them in double quotation marks ("").

Search statement examples

Expected search result	Search statement
Log entries that contain a and b	`a and b` or `a b`
Log entries that contain a or b	`a or b`

Expected search result	Search statement
Log entries that contain a but do not contain b	`a not b`
Log entries that do not contain a	`not a`
Log entries that contain a and b but do not contain c	`a and b not c`
Log entries that contain a or b and contain c	`(a or b ) and c`
Log entries that contain a or b but do not contain c	`(a or b ) not c`
Log entries that contain a and b and may contain c	`a and b or c`
Log entries whose FILE field contains apsara	`FILE:apsara`
Log entries whose FILE field contains apsara and shennong	`FILE:"apsara shennong"` , `FILE:apsara FILE:shennong` , or `FILE:apsara and FILE:shennong`
Log entries that contain the following keyword: and	`and`
Log entries whose FILE field contains apsara or shennong	`FILE:apsara or FILE:shennong`
Log entries whose file info field contains apsara	`"file info":apsara`
Log entries that contain double quotation mark (")	`\"`
Log entries with words that are prefixed with shen	`shen*`
Log entries whose FILE field is prefixed with shen	`FILE:shen*`
Log entries whose value of the FILE field is shen*	`FILE: "shen*"`
Log entries with words that are prefixed shen, are suffixed with ong, and contain a single character in between	`shen?ong`
Log entries with words that are prefixed with shen and words that are prefixed with aps	`shen* and aps*`
Log entries of topic1 and topic2	`__topic__:topic1 or __topic__ : topic2`
Log entries with a tag whose key is tagkey1 and value is tagvalue2	`__tag__ : tagkey1 : tagvalue2`
Log entries whose value of the latency field is greater than or equal to 100 and less than 200	`latency>= 100 and latency < 200` or `latency in [100 200)`
Log entries whose value of the latency field is greater than 100	`latency > 100`
Log entries that do not contain spider and whose http_referer field does not contain opx	`not spider not bot not http_referer:opx`
Log entries whose cdnIP field is not empty	`not cdnIP:""`
Log entries that do not contain the cdnIP field	`not cdnIP:*`

Expected search result	Search statement
Log entries that contain the cdnIP field	`cdnIP:*`
Log entries that contain a specified URL	`* | select * where url = 'www.xxxxx.com'`

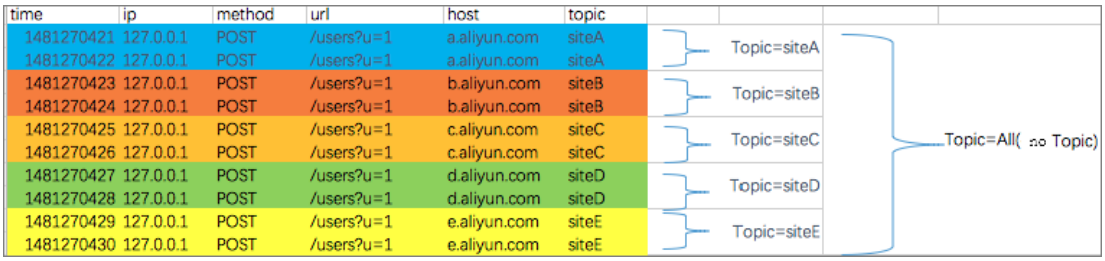
Topic-specific search

Each Logstore is divided into one or more topics. You can divide a Logstore into multiple topics if you need level-2 categories of log entries. When you query logs, you can specify topics to increase efficiency.

In a search statement, you can specify one or more topics to query. If no topic is specified, log entries are queried from all topics.

For example, you can classify log entries into multiple topics based on domain names.

Log topics



Syntax of topic-specific search:

- In a search statement, you can specify one or more topics to query. If no topic is specified, log entries are queried from all topics.
- The topic-specific search syntax is `__topic__:topicName`. You can also specify a topic in a URL.
- You can query log entries from multiple topics. For example, the `__topic__:topic1 or __topic__:topic2` statement returns the log entries in topic1 and topic2.

28.1.4.7.2. LiveTail

This topic describes how to use LiveTail to monitor and analyze log data. LiveTail is an interactive feature provided in the Log Service console to monitor and extract key log data in real time.

Prerequisites

- LiveTail is available only after logs are collected.
- LiveTail can only monitor and extract log data collected by Logtail.

Context

In online O&M scenarios, you often need to monitor collected log data in real time and extract key information from the latest log data to locate error causes. In traditional O&M, you must run the `tail -f` command on servers to monitor log files in real time. To easily obtain the required real-time log information, you can include the `grep` or `grep -v` command to filter log entries by keyword. To simplify online O&M, Log Service provides LiveTail in the console to monitor and analyze online log data in real time.

Benefits

- Monitors real-time log information and filters log data by keyword.
- Logs collected based on the log collection configurations are identified by index.
- Log fields are delimited. This allows you to query contextual logs that contain delimiters.
- Log files can be tracked based on a single log entry and monitored in real time without the need to connect to

online servers.

Use LiveTail to monitor logs in a Logstore in real time

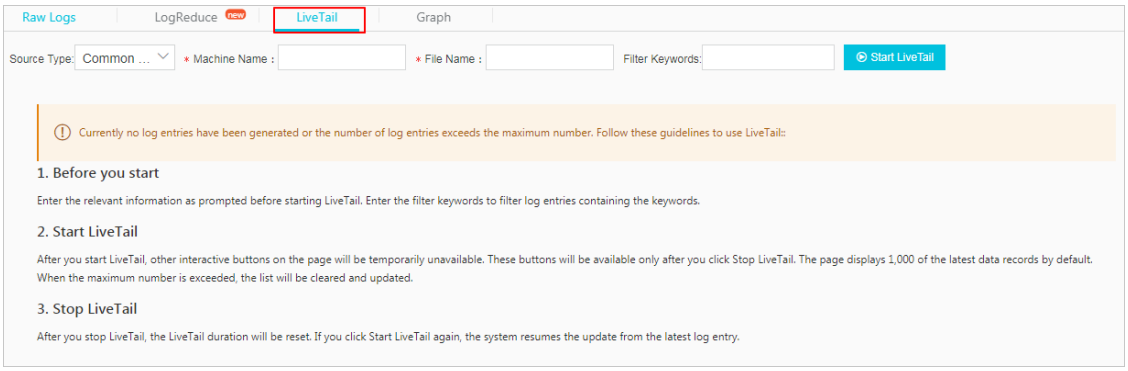
1. Log on to the Log Service console.
2. In the Projects section, click the target project.
3. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
4. (Optional)Start LiveTail.
   i. On the **Raw Logs** tab, click the icon next to the sequence number of the specified raw log entry, and then select **LiveTail**.

      The system starts LiveTail and starts timing. The **Source Type**, **Machine Name**, and **File Name** fields are automatically filled in based on the specified raw log entry.

      After LiveTail is started, log data collected by Logtail is displayed in order on the page in real time. The latest log data is displayed at the bottom of the page by default. You can view the latest log data without the need to drag the scroll bar. Up to 1,000 log entries can be displayed on the page. If more than 1,000 log entries are collected, the page is automatically refreshed to show the latest 1,000 log entries.

      
   ii. (Optional)You can also enter keywords in the search box to display log entries that contain the keywords in the monitoring list. By filtering log entries that contain the keyword, you can monitor specific log entries in real time.
5. Customize LiveTail.

i. On the Search & Analysis page, click the **LiveTail** tab.



ii. Configure LiveTail.

Parameter	Required	Description
Source Type	Yes	The source of log entries. Valid values: ■ Physical servers ■ Kubernetes containers ■ Docker
Machine Name	Yes	The name of the server from which log entries are collected.
File Name	Yes	The full path and name of the log file.
Filter Keywords	No	A keyword. After you set a keyword, only log entries that contain the keyword are displayed in the log monitoring list.

iii. Click **Start LiveTail**.

After LiveTail is started, log data collected by Logtail is displayed in order on the page in real time. The latest log data is displayed at the bottom of the page by default. You can view the latest log data without the need to drag the scroll bar. Up to 1,000 log entries can be displayed on the page. When more than 1,000 log entries are collected, the page is refreshed to show the latest 1,000 log entries.

6. To analyze logs during real-time log monitoring, click **Stop LiveTail**.

After you stop LiveTail, the LiveTail timing and the real-time log data update also stop.

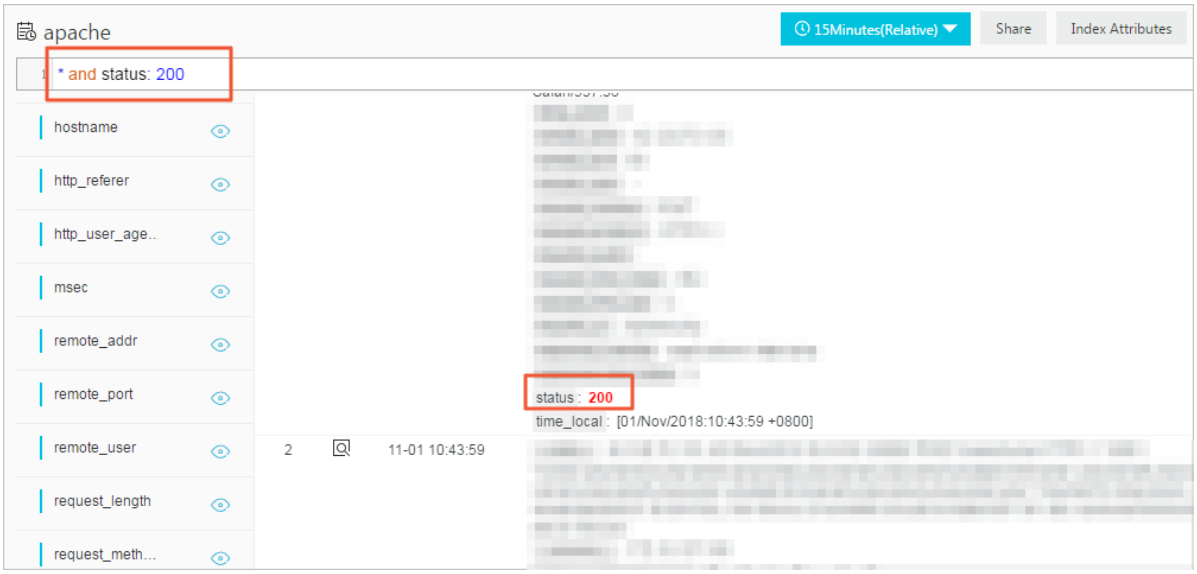
Log Service provides multiple methods to analyze exceptions that are found during log monitoring. For more information, see Use LiveTail to analyze logs.

Use LiveTail to analyze logs

After you stop LiveTail, real-time log updates in the log monitoring list also stop. You can analyze and fix errors that are found during log monitoring.

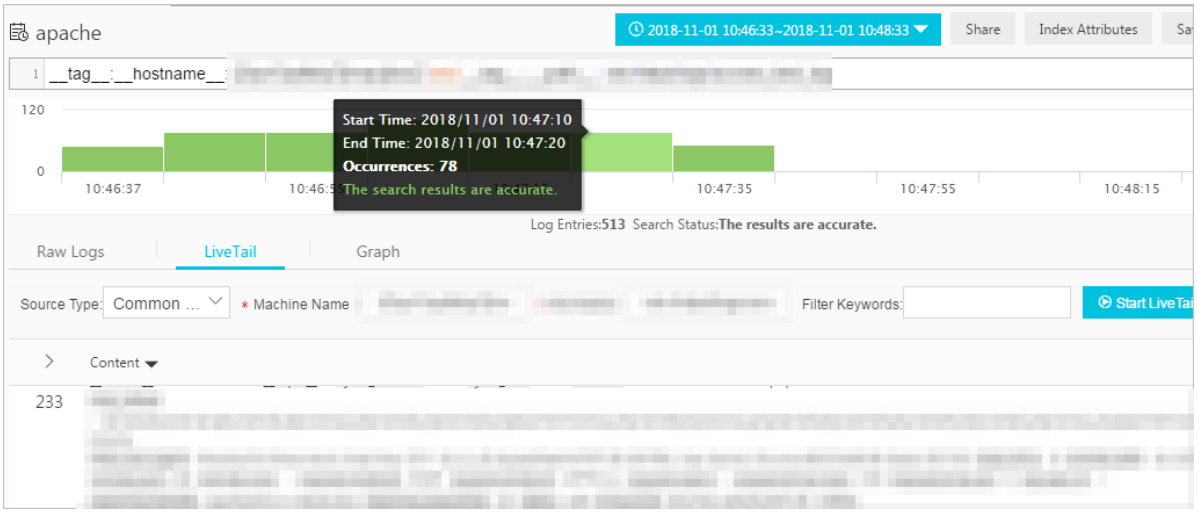
- View log entries that contain specified fields

  Log fields are delimited. You can click the value of the specified exception field on the **LiveTail** tab. Then, you are automatically forwarded to the **Raw logs** tab and the value of the exception field is used as a keyword to filter all log entries that contain the field and the keyword. You can also analyze log entries that contain the keyword based on contextual queries and statistical charts.



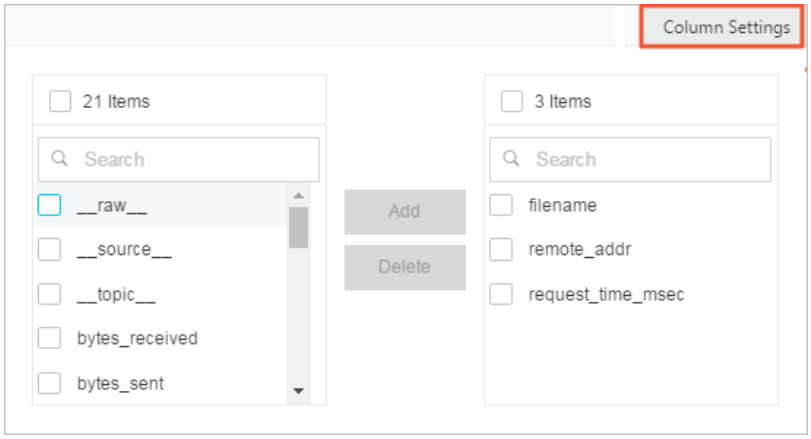
- Narrow down the time range of a log query based on the log distribution histogram

  After LiveTail is started, the log distribution histogram is updated at the same time. If you find a distribution exception (for example, a big increase in the number of log entries) in a time range, you can click the corresponding green rectangle to narrow down the time range of the log query. The timeline of the raw logs is associated with the timeline that you click on the LiveTail tab. You can view all relevant raw logs and log distribution details during this time range.



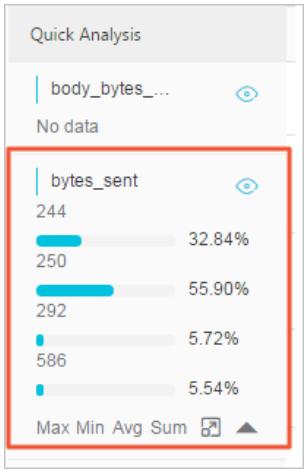
- Highlight key information based on column settings

  On the **LiveTail** tab, click **Column Settings** in the upper-right corner of the log monitoring list. Then, you can specify a field as a separate column to highlight relevant data.



- Analyze log data

  On the **LiveTail** tab, click the arrow in the upper-left corner of the log monitoring list to show the Quick Analysis pane. The time range for quick analysis starts from the time when LiveTail is started and ends at the time when LiveTail is stopped. The quick analysis provided on the LiveTail tab is the same as that provided on the Raw Logs tab. For more information, see Quick analysis.



28.1.4.7.3. LogReduce

This topic describes how to use LogReduce to group log data in Log Service. The LogReduce feature groups similar log entries by detecting same log patterns during text log collection.

Context

The LogReduce feature allows you to group text logs of multiple formats. You can locate errors, detect anomalies, roll back versions, and perform other O&M operations in DevOps scenarios. You can also detect network intrusions to ensure data security. In addition, you can save the log grouping result to a dashboard as an analysis chart, and then view the grouped data in real time.

Benefits

- Various formats of logs such as Log4j logs, JSON-formatted logs, and syslog logs can be grouped.
- Hundreds of millions of log entries can be grouped in seconds.
- Log entries can be grouped in any pattern.
- Raw log entries can be retrieved based on the signature of log entries grouped in a pattern.
- The number of log entries grouped in a log pattern in different time ranges can be compared.
- The precision of log grouping can be adjusted based on your needs.

Billing method

After the LogReduce feature is enabled, the size of indexes increases by 10% of the raw log size. For example, if the size of raw log data is 100 GB per day, the size of log indexes increases by 10 GB.

Raw log size	Index percentage	Size of indexes generated by LogReduce	Index size
100 GB	20% (20 GB)	100 × 10%	30 GB
100 GB	40% (40 GB)	100 × 10%	50 GB
100 GB	100% (100 GB)	100 × 10%	110 GB

Enable LogReduce of a Logstore

The LogReduce feature is disabled by default.

1. Log on to the Log Service console.
2. Click the target project in the Projects section.
3. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
4. Configure an index.
   - If you have enabled the index feature and configured indexes for the Logstore, choose **Index Attributes > Modify**.
   - If you have not enabled the index feature, click **Enable**.
5. Set the index attributes and turn on the **LogReduce** switch. Click **OK**.

   After LogReduce is enabled, Log Service groups log data that has been collected. Then, you can perform the following operations:
   - View log grouping results and raw logs
   - Adjust the precision of log grouping
   - Compare the number of log entries grouped in different time ranges

View log grouping results and raw logs

1. On the Search & Analysis page, enter a search and analytic statement in the search box, and then click **Search & Analytics**.

   You can use keywords to filter grouped log entries.

   > **Note** SQL statements are not supported. This means analysis results cannot be grouped.

2. Click the **LogReduce** tab to view the log grouping result.

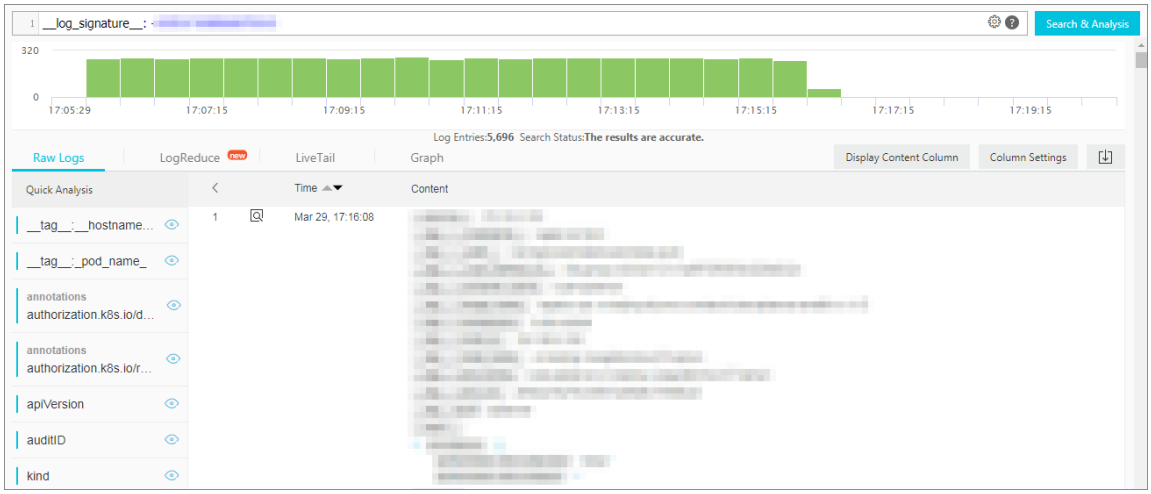
   The filtered log grouping result is displayed on the **LogReduce** tab.

Item	Description
Number	The sequence number of a log group.
Count	The number of log entries in a log group.
Pattern	The log pattern. Each log group has one or more sub-patterns.

   - Move the pointer over a value in the **Count** column to view the sub-patterns of the corresponding log group and the percentage of each sub-pattern in the log group. You can also click the plus sign (+) before

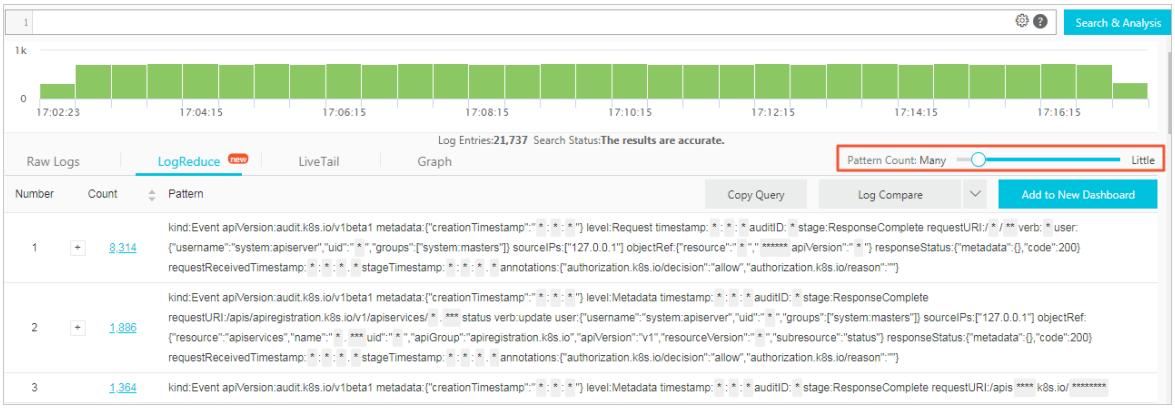
the count value to expand the sub-pattern list.

- Click a count value to view the raw log entries of the corresponding log group.



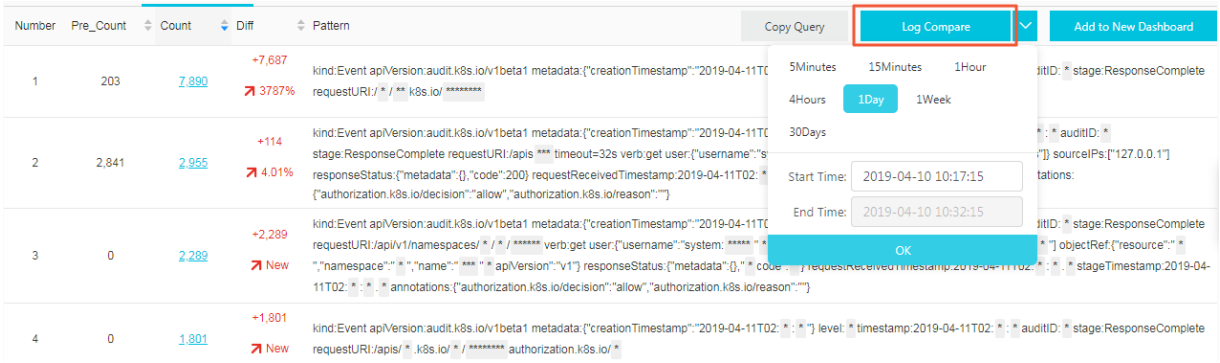
Adjust the precision of log grouping

1. On the Search & Analysis page, click the **LogReduce** tab.
2. In the upper-right corner of the tab, drag the **Pattern Count** slider to adjust the precision of log grouping.
   - If you drag the slider towards **Many**, you can obtain a more precise log grouping result with more detailed patterns.
   - If you drag the slider towards **Little**, you can obtain a less precise log grouping result with less detailed patterns.



Compare the number of log entries grouped in different time ranges

Click **Log Compare** on the **LogReduce** tab, select a time range, and then click **OK**.



Item	Description
Number	The sequence number of a log group.
Pre_Count	The number of log entries grouped by the current pattern in the previous time range.
Count	The number of log entries grouped by the current pattern in the current time range.
Diff	The difference between the Pre_Count value and Count value.
Pattern	The pattern of a log group.

SQL statement examples:

- Obtain a log grouping result.
  - SQL statement:

    ```
    * | select a.pattern, a.count,a.signature, a.origin_signatures from (select log_reduce(3) as a from log) limit 1000
    ```

    > **Note** When you view the log grouping result in the Log Service console, you can click **Copy Query** to obtain the relevant SQL statement.

  - Input parameter: log_reduce (precision)

    precision: an integer from 1 to 16 that can be set as the log grouping precision. A smaller value indicates a higher precision and more patterns. The default value is 3.

  - Returned fields:
    - pattern: the sub-patterns of log entries in a log group.
    - count: the number of log entries in a log group.
    - signature: the log pattern of a log group.
    - origin_signatures: the original signature of a log group. You can use this field to query raw log entries of the log group.
- Compare the number of log entries grouped in different time ranges.

- SQL statement:

```
* | select v.pattern, v.signature, v.count, v.count_compare, v.diff from (select compare_log_reduce(3, 86400) as v from log) order by v.diff desc limit 1000
```

> **Note** After you click **Log Compare** in the Log Service console, you can click **Copy Query** to obtain the SQL statement.

- Input parameters: compare_log_reduce(precision, compare_interval)
  - precision: an integer from 1 to 16 that can be set as the log grouping precision. A smaller value indicates a higher precision and more patterns. The default value is 3.
  - compare_interval: the number of seconds between when the previous log entries and the current log entries were generated. The value of this parameter must be a positive integer.
- Returned fields:
  - pattern: the sub-patterns of log entries in a log group.
  - signature: the log pattern of a log group.
  - count: the number of log entries in a log group.
  - count_compare: the number of log entries for a same-pattern log group within the specified time range.
  - Diff: the difference between the values of the count field and the count_compare field.

28.1.4.7.4. Contextual query

This topic describes the contextual query feature provided in the Log Service console. You can use this feature to query the full context of the log file where specified log entries are obtained.

Prerequisites

The index feature is enabled.

Context

The contextual query feature identifies the server and file where a specified log entry resides. It then queries several log entries before and after the log entry in the original log file. This helps you locate errors during troubleshooting.

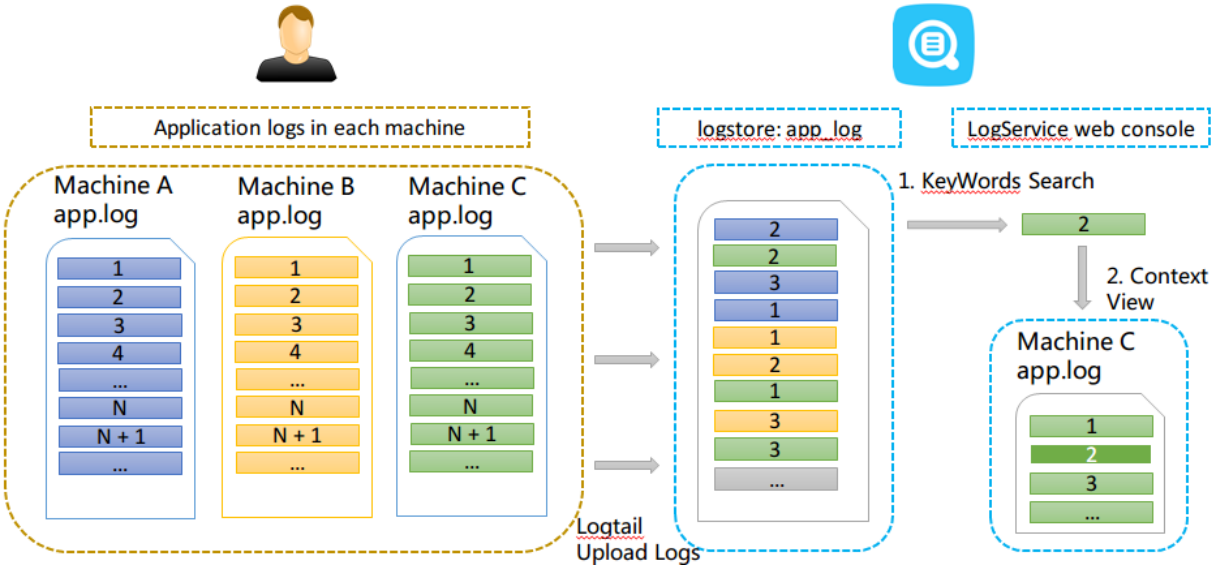
Scenarios

For example, a transaction on an O2O takeout website is logged in an application log file on a server as follows: **User logon** > **Browse products** > **Select an item** > **Add to a shopping cart** > **Place an order** > **Payment** > **Deduction** > **Generate an order**.

If the order fails, the O&M personnel must locate the cause at the earliest opportunity. In traditional contextual queries, the O&M personnel must be authorized before logging on to each server where the application is deployed. Then, the O&M personnel must use the order ID as a keyword to search application log files to locate the cause of the failure.

In Log Service, the O&M personnel can perform the following steps to locate the cause of the failure:

1. Install Logtail on servers. Then log on to the Log Service console to add the servers to machine groups and configure log collection. After the configurations are complete, Logtail starts to upload incremental logs.
2. On the search and analysis page of the Log Service console, specify the time range and find the error log entry based on the order ID.
3. Based on the error log entry, page up until you find log entries related to the error log entry. For example, you may want to find a log entry that records a credit card payment failure.



Note The contextual query feature does not support syslog.

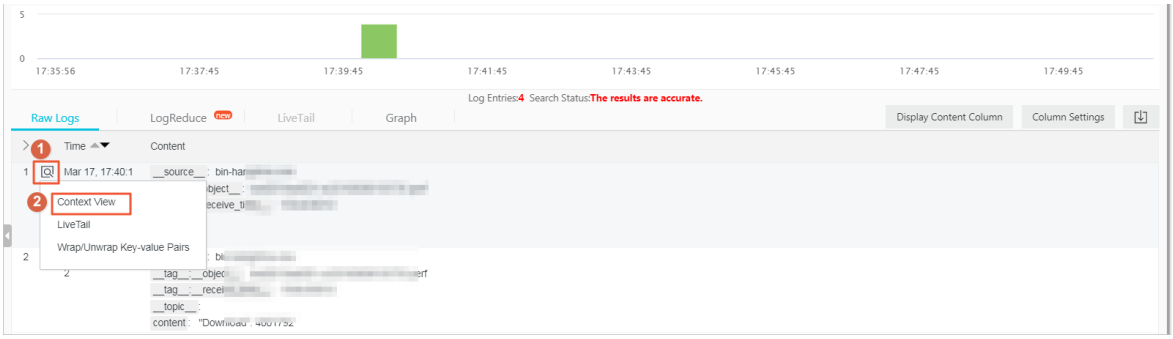
Benefits

- Intrusions into applications or changes to log file formats are avoided.
- You can view contextual log entries of a specified log entry in a log file on a server that has been registered in the Log Service console. This helps you avoid logging on to each server to search for logs that you want.
- You can specify the time range based on the time when an event occurs to locate suspicious log entries. Then you can perform a contextual query in the Log Service console. This improves troubleshooting efficiency.
- Data loss caused by log file rotation or insufficient storage space is avoided. You can view historical log data in the Log Service console at any time.

Procedure

1. Log on to the Log Service console.
2. Click the target project in the Projects section.
3. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
4. Enter a search and analytic statement, select a time range, and then click **Search & Analytics**.

   On the query results page, if the **Context View** icon is available in the drop-down list of the icon to the left of a log entry, the log entry supports contextual query.



5. Click the icon to the left of a log entry, and select **Context View** from the drop-down list. On the page that appears, view the contextual log entries of the selected log entry.
6. Scroll up and down to view more contextual log entries. To view earlier or later contextual log entries, click

Old or **New**.

28.1.4.7.5. Saved search

This topic describes how to save a search and analytic statement as a saved search for a Logstore. The saved search feature allows you to search and analyze log data in an efficient way.

Prerequisites

The index feature is enabled and configured.

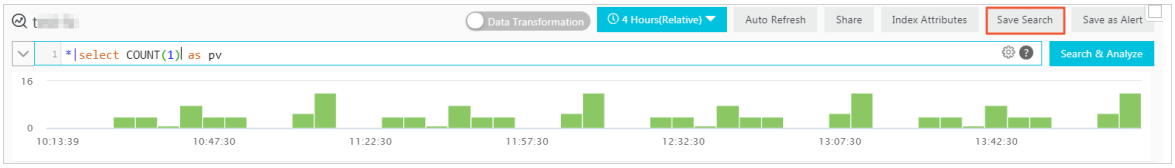
Context

If you need to frequently run a search and analytic statement, you can save the statement as a saved search. In later queries, you can click the name of the saved search on the left side of the search page to run the statement and view the result. You can also use the saved search in alert configurations. Log Service periodically runs the search and analytic statement and sends an alert if a query result meets the trigger condition.

If you want to select **Open Saved Search** in the Event Action field when you configure drill-down analysis, you must preset a saved search and set a **placeholder** in the query statement. For more information, see Drill-down analysis.

Procedure

1. Log on to the Log Service console.
2. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
3. Enter a search and analytic statement in the search box, set a time range, and then click **Search & Analyze**.
4. Click **Save Search** in the upper-right corner of the page.



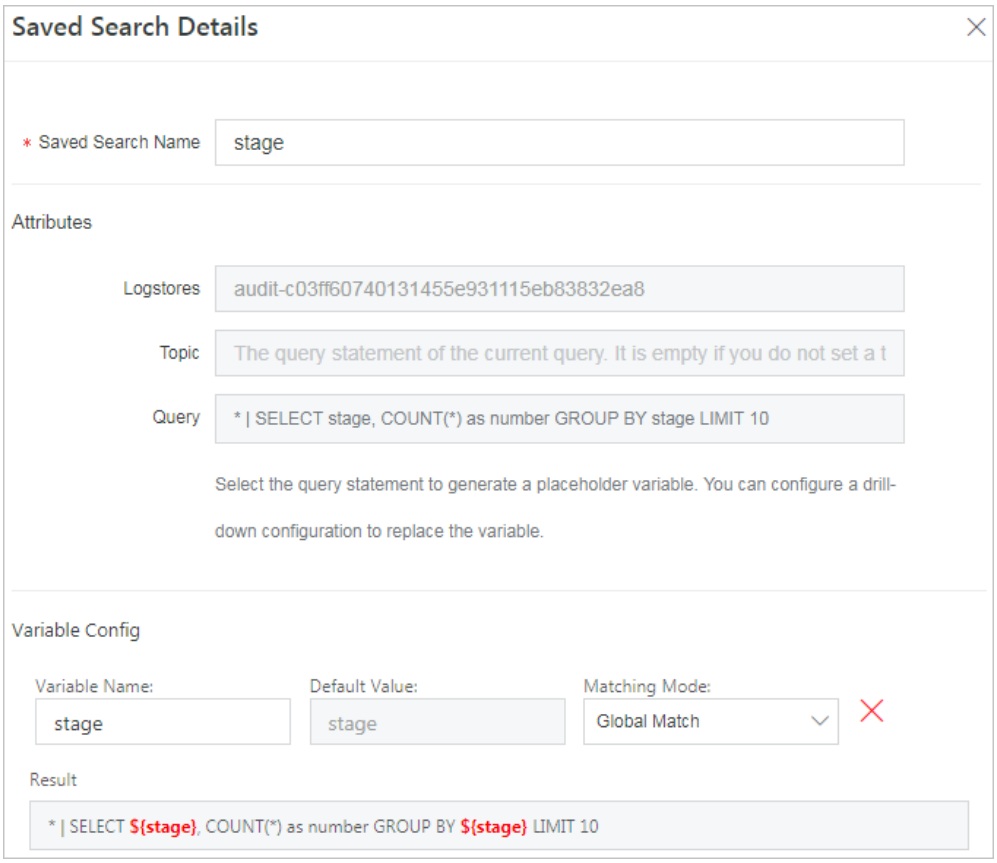
5. Configure the saved search.
   i. Enter a **Saved Search Name**.
      - The name can contain only lowercase letters, digits, hyphens (-), and underscores (_).
      - The name must start and end with a lowercase letter or digit.
      - The name must be 3 to 63 characters in length.
   ii. Check the values of the **Logstores**, **Topic**, and **Query** parameters.

      If the values of the **Logstores** and **Topic** parameters do not meet your requirements, follow these steps: Return to the Logstores page. On this page, find and click the name of the target Logstore. On the page that appears, enter the search and analytic statement in the Search & Analyze search box, and then click **Save Search** again.

iii. (Optional)Select a part of the query statement, and then click **Generate Variable**.

The generated variable is a placeholder variable. You can set the placeholder name in the **Variable Name** field. The selected characters are displayed in the **Default Value** field.

> **Note** If you use this saved search for drill-down analysis in another chart where the **variable** is the same as the **Variable Name**, the **Default Value** is replaced with the chart value that you click to trigger the drill-down event. The search and analytic statement with the replaced chart value is executed. For more information, see Drill-down analysis.

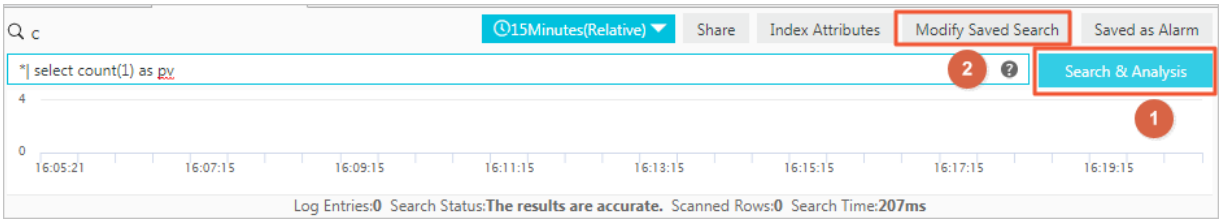


6. Click **OK**.

What's next

To modify a saved search, perform the following operations:

Enter a new search and analytic statement, click **Search & Analytics** to run the statement, and then click **Modify Saved Search**.



28.1.4.7.6. Quick analysis

This topic describes the quick analysis feature of Log Service. You can use this feature to query log data with one click. This feature allows you to analyze the distribution of a field in a specified time range and reduce the query cost of key data.

Features

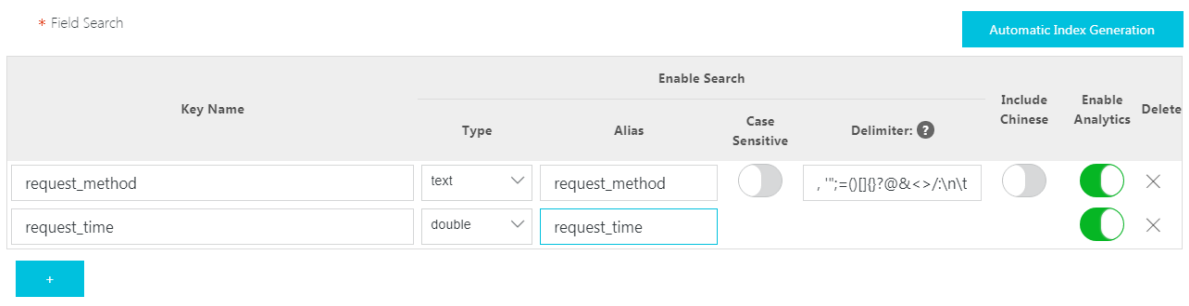
- Groups the first 100,000 values of a `text` field and provides statistics for the top 10 groups.
- Generates `approx_distinct` statements for `text` fields.
- Allows you to perform histogram-based statistics for the approximate distribution of `long` or `double` fields.
- Allows you to search for the maximum, minimum, and average of `long` or `double` fields and calculate the sum of the fields.
- Generates a query statement based on the quick analysis feature.

Prerequisites

Field indexes are configured.

- Indexes are configured for the fields that you need to search and analyze. For more information about how to enable the indexing feature, see Enable the index feature and configure indexes for a Logstore.
- The name of a field is specified as the `key`. The data type, alias, and delimiter of the field are configured.

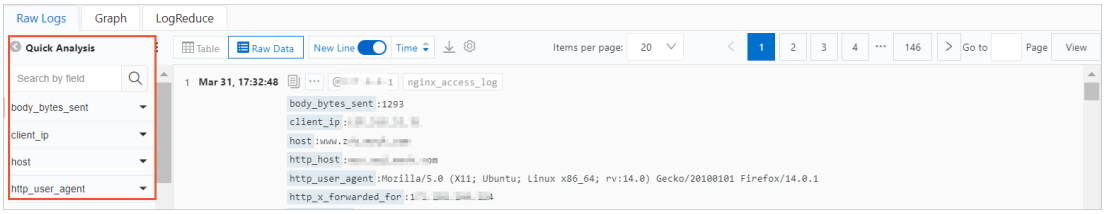
  For example, if a log entry contains the `request_method` and `request_time` fields, you can configure indexes for the two fields, as shown in the following figure.



Instructions

After you configure indexes for specified fields, you can go to the Search & Analysis page and click the **Raw Logs** tab to view the specified fields. The fields are listed in the **Quick Analysis** pane on the left of the raw log entries. You can click the icon above the serial number to hide the Quick Analysis pane. You can also click the **Eye** icon to perform quick analysis based on the **Current Time Zone** and **Current Search** conditions.

Quick analysis



Data of the text type

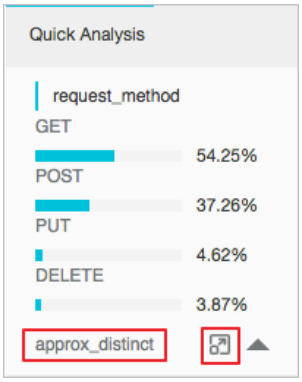
- Group and analyze log data

  Click the **Eye** icon next to a **text** field to group the first 100,000 field values and return the percentages of the top 10 groups.

  The following statement is used:

```
$Search | select ${keyName} , pv, pv *1.0/sum(pv) over() as percentage from( select count(1) as pv , "${keyName}" from (select "${keyName}" from log limit 100000) group by "${keyName}" order by pv desc) order by pv desc limit 10
```

The following figure shows the grouping and analytics result of the `request_method` field. `GET` requests account for the majority of requests.



- Calculate the number of unique values in a field

  Under the target fields in the **Quick Analysis** pane, click **Count Distinct Values** to calculate the number of unique values in the `${keyName}` field.

- Fill the Search & Analyze search box with the grouping and analytics statement

  Click the **Count Distinct Values** button on the right of the icon. The Search & Analyze search box is filled with the grouping and analytics statement. You can edit the statement.

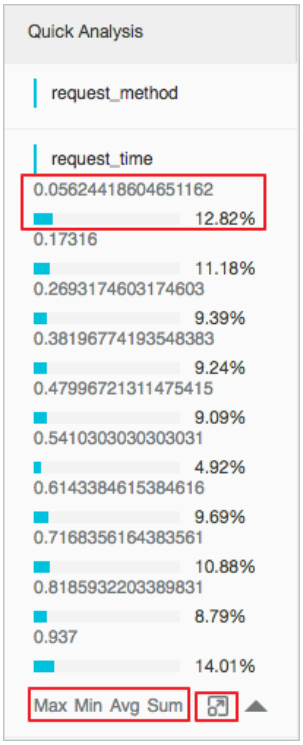
Data of the long and double types

- Display approximate distribution by using histograms

  The number of `long and double` field values is large. The preceding grouping and analytics method is not suitable for the long and double data types. You can use the following statement to divide field values into 10 groups and display the approximate distribution of the values in a histogram:

```
$Search | select numeric_histogram(10, ${keyName})
```

The following figure shows the approximate distribution of the values in the `request_time` field. The largest percentage of request time is distributed around 0.059 seconds.



- Perform quick analysis by using the `Max`, `Min`, `Avg`, and `Sum` functions

  You can click `Max` under a field to search for the maximum value, `Min` to search for the minimum value, `Avg` to calculate the average value, and `Sum` to calculate the sum of the values.

- Fill the Search & Analyze search box with the query statement of the histogram approximate distribution

  Click the icon next to `Sum`. The Search & Analyze search box is filled with the query statement of the histogram approximate distribution. You can edit the statement.

28.1.4.7.7. Other features

Log Service allows you to query log data by using various statements. It also provides many features for data search and analysis. This topic describes the raw log query, chart, saved search, dashboard, quick analysis, and alert features that Log Service supports.

Raw log query

After the index feature is enabled, enter one or more keywords in the search box and set the query time range. Then, click **Search & Analyze** to view the number of log entries displayed in a histogram, the raw logs, and the available charts.

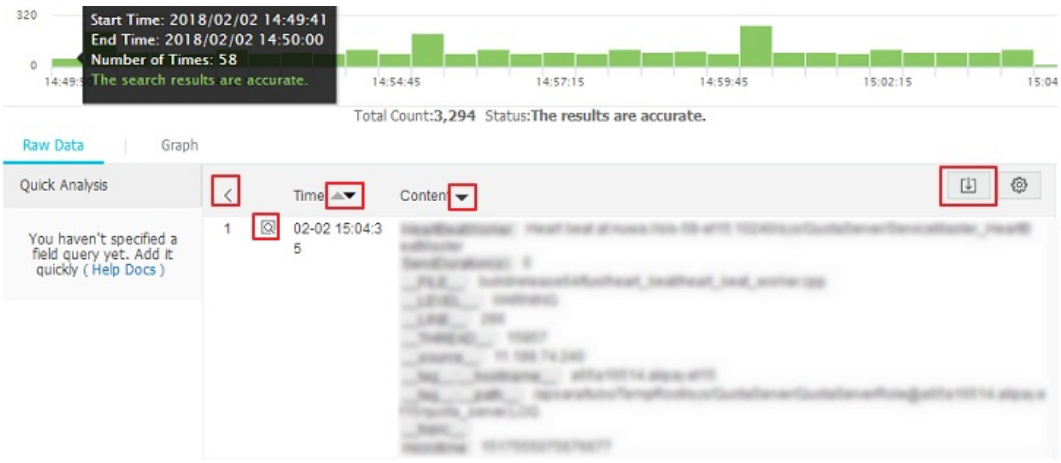
The histogram shows the time-based distribution of log entry occurrences. In the histogram, you can view the changes in the number of matched log entries over a period of time. You can click a rectangular to view the information about the occurrences within the specified time.

On the Raw Logs tab, you can view the matched log data in chronological order.

- You can click the triangle symbol next to **Time** to switch between the **chronological order** and **reverse chronological order**.
- You can click **Display Content Column** and then you can select **New Line** or **Full Line** to display the log entries. You can also set Truncate Character String.

- You can click the **keyword** of a field value in the log content to view all log entries that contain this keyword.
- You can click the icon in the upper-right corner of the Raw Logs tab to download the query results in the CSV format. You can also click **Column Settings** to select fields from the displayed raw log entries. This provides you with an easier way to view target field values of each raw log entry in new columns.
- You can click **Context View** to view the 15 log entries before and after the current log entry in a log file. For more information, see Contextual query.

> **Note** The contextual query feature applies only to the data that is uploaded by using Logtail.



Charts

After you have enabled the index feature and entered a search and analytic statement, you can select a chart on the **Graph** tab to visualize the query results.

- Multiple types of charts are provided, such as the table and line chart.

  You can select a chart type and configure the chart based on your business requirements.
- You can add charts to a **dashboard**. For more information, see Create and delete a dashboard.
- You can configure drill-down analysis for a chart. After you add a chart to a dashboard, you can click the chart data to trigger a drill down event and explore in-depth details about the data. For more information about how to configure drill-down analysis, see Drill-down analysis.

Dashboards

Log Service provides the dashboard feature that can visualize the results of search and analytic statements. For more information, see Create and delete a dashboard.

Alerts

Log Service allows you to configure alerts for your dashboard or the charts on your dashboard. You can configure rules to receive alerts from Log Service.

For more information, see Configure alerts.

28.1.4.8. SQL syntax and functions

28.1.4.8.1. General aggregate functions

This topic describes the syntax and examples of general aggregate functions.

The search and analytics feature of Log Service allows you to use general aggregate functions for log analysis. The following table describes the supported general aggregate functions.

Function	Description	Example
`arbitrary(x)`	Returns a random value from among the values in the x field.	`latency > 100 | select arbitrary(method)`
`avg(x)`	Returns the arithmetic mean of all values in the x field.	`latency > 100 | select avg(latency)`
`checksum(x)`	Returns a Base64-encoded checksum of the values of the x field.	`latency > 100 | select checksum(method)`
`count(*)`	Calculates the number of values of a field.	-
`count(x)`	Counts the number of non-null values of the x field.	`latency > 100 | select count(method)`
`count(digit)`	Counts the number of values of a field. The `count(digit)` function is equivalent to the `count(1)` and `count(*)` functions.	-
`count_if(x)`	Returns the number of the occurrences of the TRUE value.	`latency > 100 | select count_if(url like '%abc')`
`geometric_mean(x)`	Returns the geometric mean of the values in the x field.	`latency > 100 | select geometric_mean(latency)`
`max_by(x,y)`	Returns the value of the x field that corresponds to the maximum value of the y field.	`* | select min_by(method,latency,3)`: queries the method that corresponds to the maximum latency.
`max_by(x,y,n)`	Returns n values of the x field that corresponds to the n largest value of the y field.	`* | select min_by(method,latency,3)`: queries the three methods that corresponds to the three maximum latencies.
`min_by(x,y)`	Returns the value of the x field that corresponds to the smallest value of the y field.	`* | select min_by(x,y)`: queries the method that corresponds to the minimum latency.
`min_by(x,y,n)`	Returns n values of the x field that corresponds to the n smallest values of the y field.	`* | select min_by(method,latency,3)`: queries the three methods that corresponds to the three minimum latencies.
`max(x)`	Returns the maximum value among all values in the x field.	`latency > 100| select max(inflow)`
`min(x)`	Returns the minimum value among all values in the x field.	`latency > 100| select min(inflow)`
`sum(x)`	Returns the sum among all values in the x field.	`latency > 10 | select sum(inflow)`

Function	Description	Example
`bitwise_and_agg(x)`	Returns the bitwise AND of all values in the x field in two's complement representation.	-
`bitwise_or_agg(x)`	Returns the bitwise OR of all values in the x field in two's complement representation.	-

28.1.4.8.2. Security check functions

Security check functions in Log Services are designed based on the globally shared WhiteHat Security asset library. This topic describes security check functions that you can use to check whether an IP address, domain name, or URL in logs is secure.

Scenarios

- O&M personnel of enterprises and institutions in Internet, gaming, information, and other industries that require robust O&M services can use security check functions to identify suspicious requests or attacks. They can also use the functions to implement in-depth analysis and defend against potential attacks.
- O&M personnel of enterprises and institutions in banking, securities, e-commerce, and other industries that require strong protection for internal assets can use security check functions to identify requests to suspicious websites and downloads initiated by trojans. Then the O&M personnel can take immediate actions to prevent potential losses.

Features

- Reliability: built upon the globally shared WhiteHat Security asset library that is updated in a timely manner.
- Efficiency: capable of screening millions of IP addresses, domain names, and URLs within seconds.
- Ease of use: supports the analysis of network logs by using the security_check_ip, security_check_domain, and security_check_url functions.
- Flexibility: supports interactive queries, report creation, and alert configurations and subsequent actions.

Functions

Function	Description	Example
security_check_ip	Checks whether an IP address is secure. • The value 1 indicates that the specified IP address is suspicious. • The value 0 indicates that the specified IP address is secure.	`select security_check_ip(real_client_ip)`
security_check_domain	Checks whether a domain name is secure. • The value 1 indicates that the specified domain name is suspicious. • The value 0 indicates that the specified domain name is secure.	`select security_check_domain(site)`

Function	Description	Example
security_check_url	Checks whether a URL is secure. • The value 1 indicates that the specified URL is suspicious. • The value 0 indicates that the specified URL is secure.	`select security_check_domain(concat(host, url))`

Examples

- Check external suspicious requests and generate reports

  For example, an e-commerce enterprise collects logs from its NGINX servers and wants to scan suspicious client IP addresses. To do this, the enterprise can pass the ClientIP field in logs that are collected from the NGINX servers to the `security_check_ip` function and filter out IP addresses associated with the returned value 1. Then the enterprise can query the countries where the IP addresses are located and ISPs to which the IP addresses belong.

  SQL statement for this scenario:

  ```
  * | select ClientIP, ip_to_country(ClientIP) as country, ip_to_provider(ClientIP) as provider, count(1) as PV where security_check_ip(ClientIP) = 1 group by ClientIP order by PV desc
  ```

  Display the ISPs and countries in a map.

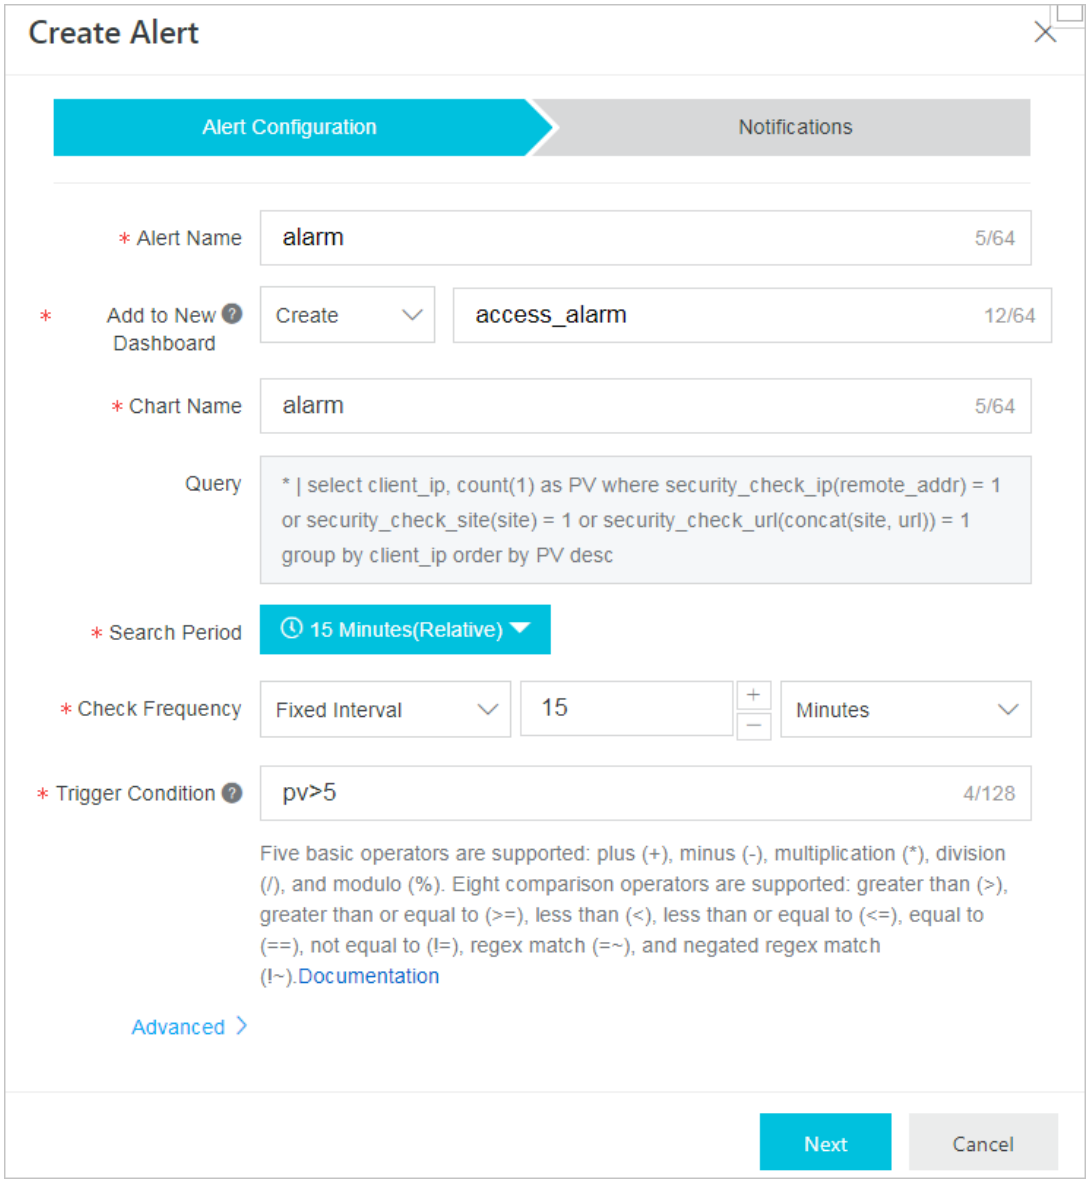
client_ip	country	provider	PV
180 3	CN		3
103	CN		3
180 7	CN		1

- Check internal suspicious requests and send alerts

  For example, a securities operator collects logs of its internal devices that access the Internet through gateways. To check requests to suspicious websites, the operator can run the following statement:

  ```
  * | select client_ip, count(1) as PV where security_check_ip(remote_addr) = 1 or security_check_site(site) = 1 or security_check_url(concat(site, url)) = 1 group by client_ip order by PV desc
  ```

  The operator can save this statement as a saved search and configure an alert. An alert is triggered when a client frequently accesses suspicious websites. The statement in the alert can be configured to run every five minutes to check if a client has frequently (more than five times) accessed suspicious websites in the past one hour. The following figure shows the configurations of an alert.



28.1.4.8.3. Map functions

This topic describes the syntax and examples of map functions.

The following table describes the supported map functions.

Function	Description	Example
Subscript operator []	Retrieves the value corresponding to a specified key from a map.	-

Function	Description	Example
histogram(x)	Groups the values of the parameter x and calculates the number of occurrences of each value. The syntax is equivalent to `select count group by x`. **Note** The returned data is in the JSON format.	The statement `latency > 10 | select histogram(status)` is equivalent to the statement `latency > 10 | select count(1) group by status`.
histogram_u(x)	Groups the values of the parameter x and calculates the number of occurrences of each value. **Note** The returned data is in the format of multiple rows and columns.	The statement `latency > 10 | select histogram_u(status)` is equivalent to the statement `latency > 10 | select count(1) group by status`.
map_agg(Key,Value)	Returns a random value of the key in the format of a map that consists of key-value pairs.	`latency > 100 | select map_agg(method,latency)`
multimap_agg(Key,Value)	Returns all values of the key in the format of a map that consists of key-value pairs.	`latency > 100 | select multimap_agg(method,latency)`
cardinality(x) → bigint	Returns the cardinality of the map x.	-
element_at(map `<K, V>`, key) → V	Returns the value for the specified key.	-
map() → map `<unknown, unknown>`	Returns an empty map.	-
map(array `<K>`, array `<V>`) → map `<K,V>`	Returns a map where each key-value pair consists of two elements from two separate arrays.	`SELECT map(ARRAY[1,3], ARRAY[2,4]); - {1 -> 2, 3 -> 4}`
map_from_entries(array `<row<K, V>>`) → map `<K,V>`	Converts a multi-dimensional array to a map.	`SELECT map_from_entries(ARRAY[(1, 'x'), (2, 'y')]); - {1 -> 'x', 2 -> 'y'}`
map_concat(map1 `<K, V>`, map2 `<K, V>`, ..., mapN `<K, V>`) → map `<K,V>`	Returns a map that is the union of all specified maps. If a key is found in multiple specified maps, the value of the key in the returned map is the value of the key that occurs in the last specified map.	-
map_filter(map `<K, V>`, function) → map `<K,V>`	For more information, see the map_filter function in Lambda functions.	-

Function	Description	Example
map_keys(x <K, V>) → array <K>	Returns an array of keys in the specified map.	-
map_values(x <K, V>) → array <V>	Returns an array of values in the specified map.	-

28.1.4.8.4. Approximate functions

This topic describes the syntax and examples of approximate functions that Log Service supports for log analysis.

The following table describes the supported approximate functions.

Function	Description	Example
`approx_distinct(x)`	Returns the approximate number of distinct values of the x field.	-
`approx_percentile(x,percentage)`	Returns the value located at the specified approximate percentage among the sorted values of the x field.	`approx_percentile(x,0.5)`: returns the median among the sorted values of the x field.
`approx_percentile(x,percentages)`	Returns values located at multiple specified approximate percentages among the sorted values of the x field. This function works in a similar manner to the `approx_percentile(x,percentage)` function.	`approx_percentile(x,array[0.1,0.2])`
`numeric_histogram(buckets,Value)`	Distributes all values of the *Value* field into multiple buckets. The *buckets* parameter specifies the number of buckets. The key of every bucket and the number of values in a bucket are returned. This function is equivalent to `select count group by`. **Note** The response is in the JSON format.	`method:POST | select numeric_histogram(10,latency)`: distributes the latencies of POST requests into 10 buckets and calculates the number of latencies in each bucket.

Function	Description	Example
`numeric_histogram_u(buckets, Value)`	Distribute all values of the *Value* field into multiple buckets. The *buckets* parameter specifies the number of buckets. The key of every bucket and the number of values in a bucket are returned. This function is equivalent to `select count group by` . **Note** The returned data is in the format of multiple rows and columns.	`method:POST | select numeric_histogram(10,latency)` : distributes the latency data of POST requests into 10 buckets and calculates the number of latency data in each bucket.

Note The number of values in every bucket is evenly distributed. It is returned along with the average value of all values in a bucket.

28.1.4.8.5. Mathematical statistics functions

This topic describes the syntax and examples of mathematical statistics functions.

The search and analytics feature of Log Service allows you to use mathematical statistics functions for log analysis. The following table describes the supported mathematical statistics functions.

Function	Description	Example
`corr(y, x)`	Returns the correlation coefficient of input values. The result ranges from 0 to 1.	`latency>100| select corr(latency,request_size)`
`covar_pop(y, x)`	Returns the population covariance of input values.	`latency>100| select covar_pop(request_size,latency)`
`covar_samp(y, x)`	Returns the sample covariance of input values.	`latency>100| select covar_samp(request_size,latency)`
`regr_intercept(y, x)`	Returns the linear regression intercept of input values. y is the dependent value. x is the independent value.	`latency>100| select regr_intercept(request_size,latency)`
`regr_slope(y,x)`	Returns the linear regression slope of input values. y is the dependent value. x is the independent value.	`latency>100| select regr_slope(request_size,latency)`
`stddev(x)` or `stddev_samp(x)`	Returns the sample standard deviation of the values in the x field.	`latency>100| select stddev(latency)`
`stddev_pop(x)`	Returns the population standard deviation of the values in the x field.	`latency>100| select stddev_pop(latency)`

Function	Description	Example
`variance(x)` or `var_samp(x)`	Returns the sample variance of the values in the x field.	`latency>100| select variance(latency)`
`var_pop(x)`	Returns the population variance of the values in the x field.	`latency>100| select variance(latency)`

28.1.4.8.6. Mathematical calculation functions

This topic describes the syntax and examples of mathematical calculation functions.

By including mathematical calculation functions in SQL statements, you can perform mathematical calculation on log query results.

Mathematical operators

Mathematical operators include the plus sign (+), minus sign (-), multiplication sign (*), division sign (/), and percent sign (%). These operators can be used in SELECT statements.

Example:

```
*|select avg(latency)/100 , sum(latency)/count(1)
```

Mathematical calculation functions

Log Service supports the following mathematical calculation functions.

Function	Description
`abs(x)`	Returns the absolute values of the values in the x field.
`cbrt(x)`	Returns the cube roots of the values in the x field.
`ceiling(x)`	Returns the rounded-up nearest integers of the values in the x field.
`cosine_similarity(x,y)`	Returns the cosine similarity between the sparse vectors x and y.
`degrees`	Converts angles in radians to degrees.
`e()`	Returns the Euler's number.
`exp(x)`	Returns Euler's number raised to the power of the values in the x field.
`floor(x)`	Returns the rounded-down nearest integers of the values in the x field.
`from_base(string,radix)`	Returns the radix number representation of a string.
`ln(x)`	Returns the natural logarithm of x.
`log2(x)`	Returns the base 2 logarithm of x.
`log10(x)`	Returns the base 10 logarithm of x.

Function	Description
`log(x,b)`	Returns the base b logarithm of x.
`pi()`	Returns the constant Pi.
`pow(x,b)`	Returns x raised to the power of b.
`radians(x)`	Converts angle x in degrees to radians.
`rand()`	Returns a random number.
`random(0,n)`	Returns a random number from 0 to n (exclusive).
`round(x)`	Returns x rounded to the nearest integer.
`round(x,y)`	Returns x rounded to y decimal places. For example, round(1.012345,2) = 1.01.
`sqrt(x)`	Returns the square root of x.
`to_base(x,radix)`	Returns the radix number representation of x.
`truncate(x)`	Returns x rounded to integer by dropping digits after the decimal point.
`acos(x)`	Returns the arc cosine of x.
`asin(x)`	Returns the arc sine of x.
`atan(x)`	Returns the arc tangent of x.
`atan2(y,x)`	Returns the arc tangent of y/x.
`cos(x)`	Returns the cosine of x.
`sin(x)`	Returns the sine of x.
`cosh(x)`	Returns the hyperbolic cosine of x.
`tan(x)`	Returns the tangent of x.
`tanh(x)`	Returns the hyperbolic tangent of x.
`infinity()`	Returns the value representing positive infinity.
`is_infinity(x)`	Determines whether x is infinite.
`is_finity(x)`	Determines whether x is finite.
`is_nan(x)`	Determines whether x is not-a-number.

28.1.4.8.7. String functions

This topic describes string functions that Log Service supports for log data search and analytics.

This following table lists the functions and their descriptions.

Function	Description
`chr(x)`	Converts an integer to an ASCII character. For example, the result of `chr(65)` is `A`.
`codepoint (x)`	Converts an ASCII character to a code point of the integer type. For example, the result of `codepoint('A')` is `65`.
`length(x)`	Returns the length of a string.
`levenshtein_distance(string1, string2)`	Returns the Levenshtein distance of string1 and string2.
`lower(string)`	Converts all uppercase characters in a string into lowercase characters.
`lpad(string, size, padstring)`	Pads a string to the specified size. If the length of the string is shorter than the specified size, padstring is used to left pad the string. If the length of the string is longer than the specified size, the string is truncated with the specified size.
`rpad(string, size, padstring)`	Right pads a `string` with the specified padding. The implementation is similar to that of the lpad function.
`ltrim(string)`	Removes whitespace characters from the left side of a string.
`replace(string, search)`	Removes all occurrences of a substring search from a string.
`replace(string, search,rep)`	Replaces all occurrences of a substring search in a string with another substring rep.
`reverse(string)`	Reverses a string.
`rtrim(string)`	Removes whitespace characters from the right side of a string.
`split(string,delimeter,limit)`	Splits a string based on the specified delimiter and returns an array with the maximum number of elements at limit. The index of the first element in the array is 1.
`split_part(string,delimeter,offset)`	Splits a string based on a delimiter into an array of substrings and returns the element with the index specified by the offset parameter.
`split_to_map(string, entryDelimiter, keyValueDelimiter) → map<varchar, varchar>`	Splits a string based on the entryDelemiter into multiple entries, each of which is then split based on the keyValueDelimiter into a key and value. This function returns a map.
`position(substring IN string)`	Returns the position of the first occurrence of the specified substring in a string.
`strpos(string, substring)`	Returns the position of the first occurrence of the specified substring in a string. Positions start with 1. If the substring is found, 0 is returned.

Function	Description
`substr(string, start)`	Returns a substring from the start position. Positions start with 1.
`substr(string, start, length)`	Returns a substring of a specified length from start position. Positions start with 1. The length parameter specifies the length of the substring returned.
`trim(string)`	Removes leading and trailing whitespace characters from a string.
`upper(string)`	Converts all lowercase characters in a string into uppercase characters.
`concat(string,string...)`	Concatenates multiple strings into a single string.
`hamming_distance (string1,string2)`	Returns the Hamming distance of string1 and string2.

Note Strings must be enclosed in single quotation marks ('). Double quotation marks (") are used to enclose field names. For example, `a='abc'` indicates `field a = string 'abc'`, and `"a"="abc"` indicates `field a = field abc`.

28.1.4.8.8. Date and time functions

This topic describes the available time functions, date functions, interval functions, and a time series padding function in Log Service. You can use these functions when you analyze data.

Date and time data types

- Unix timestamp: specifies the number of seconds that have elapsed since 1970-01-01 00:00:00 UTC. The value is in the format of an integer. For example, `1512374067` indicates `Mon Dec 4 15:54:27 CST 2017`. The `__time__` field in every log entry is of this type.
- Timestamp: specifies the date and time in the format of a string. For example, `2017-11-01 13:30:00`.

Date functions

The following table lists the commonly used date functions that are supported in Log Service.

Function	Description	Example
`current_date`	Returns the current date.	`latency>100| select current_date`
`current_time`	Returns the current time.	`latency>100| select current_time`
`current_timestamp`	Returns the current timestamp. This function is equivalent to the combination of the current_date and current_time functions.	`latency>100| select current_timestamp`
`current_timezone()`	Returns the current time zone.	`latency>100| select current_timezone()`

Function	Description	Example
`from_iso8601_timestamp(string)`	Parses an ISO 8601 formatted string into a timestamp that specifies the time zone.	`latency>100| select from_iso8601_timestamp(iso8601)`
`from_iso8601_date(string)`	Parses an ISO 8601 formatted string into a date.	`latency>100| select from_iso8601_date(iso8601)`
`from_unixtime(unixtime)`	Parses a Unix timestamp into a timestamp.	`latency>100| select from_unixtime(1494985275)`
`from_unixtime(unixtime,string)`	Parses a Unix timestamp into a timestamp based on the time zone that is specified by the string parameter.	`latency>100| select from_unixtime (1494985275,'Asia/Shanghai')`
`localtime`	Returns the local time.	`latency>100| select localtime`
`localtimestamp`	Returns the local timestamp.	`latency>100| select localtimestamp`
`now()`	Returns the current date and time. This function is equivalent to the `current_timestamp` function.	N/A
`to_unixtime(timestamp)`	Parses a timestamp into a Unix timestamp.	`*| select to_unixtime('2017-05-17 09:45:00.848 Asia/Shanghai')`

Time functions

The following table lists the time functions that you can use in Log Service to parse time in the formats supported in MySQL, such as %a, %b, and %y.

Function	Description	Example
`date_format(timestamp, format)`	Formats a timestamp in the specified format.	`latency>100 | select date_format (date_parse('2017-05-17 09:45:00','%Y-%m-%d %H:%i:%S'), '%Y-%m-%d')`
`date_parse(string, format)`	Parses a formatted string into a timestamp.	`latency>100 | select date_format (date_parse(time,'%Y-%m-%d %H:%i:%S'), '%Y-%m-%d')`

Formats

Format	Description
%a	The week day in abbreviation, such as Sun and Sat.
%b	The month in abbreviation, such as Jan and Dec.
%c	The month in the numeric format. Valid values: 1 to 12.

Format	Description
%D	The day of the month with a suffix, such as 0th, 1st, 2nd, and 3rd.
%d	The day of the month in the numeric format. Valid values: 01 to 31.
%e	The day of the month in the numeric format. Valid values: 1 to 31.
%H	The hour that applies the 24-hour clock convention. Valid values: 00 to 23.
%h	The hour that applies the 12-hour clock convention. Valid values: 01 to 12.
%I	The hour that applies the 12-hour clock convention. Valid values: 1 to 12.
%i	The minute in the numeric format. Valid values: 00 to 59.
%j	The day of the year. Valid values: 001 to 366.
%k	The hour. Valid values: 0 to 23.
%l	The hour. Valid values: 1 to 12.
%M	The month. Valid values: January to December.
%m	The month in the numeric format. Valid values: 01 to 12.
%p	The abbreviation that indicates the morning or afternoon. Valid values: a.m. and p.m..
%r	The time that applies the 12-hour clock convention: `hh:mm:ss AM/PM`.
%S	The second. Valid values: 00 to 59.
%s	The second. Valid values: 00 to 59.
%T	The time that applies the 24-hour clock convention, formatted in `hh:mm:ss`.
%U	The week of the year. Sunday is the first day of a week. Valid values: 00 to 53.
%u	The week of the year. Monday is the first day of a week. Valid values: 00 to 53.
%V	The week of the year. Sunday is the first day of a week. This format is used together with %X. Valid values: 01 to 53.
%v	The week of the year. Monday is the first day of a week. This format is used in combination with %x. Valid values: 01 to 53.
%W	The day of the week. Valid values: Sunday to Saturday.
%w	The day of the week. Valid values: 0 to 6. The value 0 indicates Sunday.
%Y	The year in the 4-digit format.
%y	The year in the 2-digit format.
%%	Escapes the second percent sign (%).

Truncation functions

Log Service supports a truncation function, which can truncate a time by the second, minute, hour, day, month, or year. Typically, this function is used for time-based analytics.

- Syntax

```
date_trunc(unit, x)
```

- Parameters

  The value of the x parameter can be a timestamp or Unix timestamp.

  The following table lists the values of the unit parameter and the responses when the x parameter is set to `2001-08-22 03:04:05.000`.

Unit	Response
second	2001-08-22 03:04:05.000
minute	2001-08-22 03:04:00.000
hour	2001-08-22 03:00:00.000
day	2001-08-22 00:00:00.000
week	2001-08-20 00:00:00.000
month	2001-08-01 00:00:00.000
quarter	2001-07-01 00:00:00.000
year	2001-01-01 00:00:00.000

- Example

  The date_trunc function is applicable only to analytics at a fixed time interval. To implement analytics at a flexible interval, for example, every 5 minutes, you need to use a GROUP BY clause according to the mathematical modulus method.

```
* | SELECT count(1) as pv,  __time__ - __time__% 300 as minute5 group by minute5 limit 100
```

  In the preceding statement, `%300` indicates that modulo and truncation are performed every 5 minutes.

  The following example shows how to use the date_trunc function:

```
*|select  date_trunc('minute' ,  __time__)  as t,
       truncate (avg(latency) ) ,
       current_date
       group by   t
       order by t  desc
       limit 60
```

Interval functions

Interval functions perform interval-related calculation. For example, you can use interval functions to add or subtract an interval based on a date, or calculate the interval between two dates.

Function	Description	Example

Function	Description	Example
`date_add (unit, value, timestamp)`	Adds an interval `value` of the `unit` type to a `timestamp`. To subtract an interval, use a negative `value`.	`date_add('day', -7, '2018-08-09 00:00:00')`: indicates seven days before August 9.
`date_diff(unit, timestamp1, timestamp2)`	Returns the time difference between `timestamp1` and `timestamp2` expressed in terms of `unit`.	`date_diff('day', '2018-08-02 00:00:00', '2018-08-09 00:00:00') = 7`

The following table lists the values of the unit parameter that are supported by the interval functions.

Value	Description
millisecond	The millisecond.
second	The second.
minute	The minute.
hour	The hour.
day	The day.
week	The week.
month	The month.
quarter	The quarter, namely, three months.
year	The year.

Time series padding function

The time series padding function is used to pad time series and corresponding data.

> **Note** This function must be used in combination with the `group by time order by time` clause. When used together, the `order by` clause does not support the `desc` sorting method.

- Syntax

```
time_series(time_column, window, format, padding_data)
```

- Parameters

Parameter	Description
time_column	The name of the time field in a log entry. The default field name is `__time__`. The field value is of the LONG or TIMESTAMP type.
window	The time window for a data query. It is composed of a number and a unit. Unit: s (seconds), m (minutes), H (hours), and d (days). For example, 2h, 5m, or 3d.
format	The MySQL time format displayed.

Parameter	Description
padding_data	The content to be added for a time point. Valid values: ○ 0: adds 0. ○ null: adds null. ○ last: adds the value corresponding to the last time point. ○ next: adds the value corresponding to the next time point. ○ avg: adds the average value of the last and next values.

- Example

  The following statement is used to format data every 2 hours:

```
* | select time_series(__time__, '2h', '%Y-%m-%d %H:%i:%s', '0')  as stamp, count(*) as num from log group by stamp order by stamp
```

28.1.4.8.9. URL functions

This topic describes the syntax of URL functions and provides examples.

URL functions extract fields from standard URLs. A standard URL is described as follows:

```
[protocol:][//host[:port]][path][? query][#fragment]
```

Common URL functions

Function	Description	Example	
		Statement	Response
`url_extract_fragment(url)`	Extracts the fragment identifier from a URL and returns the fragment identifier of the VARCHAR type.	`*| select url_extract_fragment('https://sls.console.aliyun.com/#/project/dashboard-demo/categoryList')`	`/project/dashboard-demo/categoryList`
`url_extract_host(url)`	Extracts the host information from a URL and returns the host information of the VARCHAR type.	`*|select url_extract_host('http://www.aliyun.com/product/sls')`	`www.aliyun.com`
`url_extract_parameter(url, name)`	Extracts the value of the name parameter in the query from a URL and returns the value of the VARCHAR type.	`*|select url_extract_parameter('http://www.aliyun.com/product/sls?userid=testuser','userid')`	`testuser`
`url_extract_path(url)`	Extracts the path from a URL and returns the path of the VARCHAR type.	`*|select url_extract_path('http://www.aliyun.com/product/sls?userid=testuser')`	`/product/sls`
`url_extract_port(url)`	Extracts the port number from a URL and returns the port number of the BIGINT type.	`*|select url_extract_port('http://www.aliyun.com:80/product/sls?userid=testuser')`	`80`

Function	Description	Example	
		Statement	Response
`url_extract_protocol(url)`	Extracts the protocol from a URL and returns the protocol of the VARCHAR type.	`*|select url_extract_protocol('http://www.aliyun.com:80/product/sls?userid=testuser')`	`http`
`url_extract_query(url)`	Extracts the query string from a URL and returns the query string of the VARCHAR type.	`*|select url_extract_query('http://www.aliyun.com:80/product/sls?userid=testuser')`	`userid=testuser`
`url_encode(value)`	Encodes a URL.	`*|select url_encode('http://www.aliyun.com:80/product/sls?userid=testuser')`	`http%3a%2f%2fwww.aliyun.com%3a80%2fproduct%2fsls%3fuserid%3dtestuser`
`url_decode(value)`	Decodes a URL.	`*|select url_decode('http%3a%2f%2fwww.aliyun.com%3a80%2fproduct%2fsls%3fuserid%3dtestuser')`	`http://www.aliyun.com:80/product/sls?userid=testuser`

28.1.4.8.10. Regular expression functions

This topic describes the available regular expression functions. You can use these functions when you query and analyze data in Log Service.

A regular expression function parses a string and returns the required substrings.

The following table lists common regular expression functions.

Function	Description	Example
`regexp_extract_all(string, pattern)`	Returns an array where each element is a substring that matches the regular expression. These substrings derive from the specified string.	The returned result of `*| SELECT regexp_extract_all('5a 67b 890m', '\d+')` is `['5','67','890']`. The returned result of `*|SELECT regexp_extract_all('5a 67a 890m', '(\d+)a')` is `['5a','67a']`.
`regexp_extract_all(string, pattern, group)`	Returns an array where each element is a part of a substring that matches the regular expression. This part is the content in the group parameter value of the `()` of a substring that derives from the specified string.	The returned result of `*| SELECT regexp_extract_all('5a 67a 890m', '(\d+)a',1)` is `['5','67']`.
`regexp_extract(string, pattern)`	Returns the first substring of the specified string that matches the regular expression.	The returned result of `*|SELECT regexp_extract('5a 67b 890m', '\d+')` is `'5'`.

Function	Description	Example
`regexp_extract(string, pattern,group)`	Returns a part of the first substring that matches the regular expression. This part is the content in the group parameter value of the `()` of the substring that derives from the specified string.	The returned result of `*|SELECT regexp_extract('5a 67b 890m', '(\d+)([a-z]+)',2)` is `'a'`.
`regexp_like(string, pattern)`	Returns a Boolean value. If the string and its substrings cannot match the regular expression, the value False is returned.	The returned result of `*|SELECT regexp_like('5a 67b 890m', '\d+m')` is True.
`regexp_replace(string, pattern, replacement)`	Replaces the substrings of the specified string that match the regular expression with the value of the replacement parameter.	The returned result of `*|SELECT regexp_replace('5a 67b 890m', '\d+','a')` is `'aa ab am'`.
`regexp_replace(string, pattern)`	Removes the substrings of the specified string that match the regular expression. This function is equivalent to `regexp_replace(string,patterm,'')`.	The returned result of `*|SELECT regexp_replace('5a 67b 890m', '\d+')` is `'a b m'`.
`regexp_split(string, pattern)`	Returns an array where each element is a substring of the specified string that is split based on the regular expression.	The returned result of `*|SELECT regexp_split('5a 67b 890m', '\d+')` is `['a','b','m']`.

28.1.4.8.11. JSON functions

JSON functions can convert a string into a JSON type and extract JSON fields. The two major JSON data types are map and array. If a string cannot be converted to a value of the JSON type, null value is returned.

For information about how to expand JSON data into multiple rows, see UNNEST function.

The following table lists the JSON functions that Log Service supports:

Function	Description	Example
`json_parse(string)`	Converts a string to a JSON-formatted data.	`SELECT json_parse('[1, 2, 3]')`: returns a JSON array.
`json_format(json)`	Converts JSON-formatted data to a string.	`SELECT json_format(json_parse('[1, 2, 3]'))`: returns a string.
`json_array_contains(json, value)`	Determines whether a value exists in a JSON array or in a string that contains a JSON array.	`SELECT json_array_contains(json_parse('[1, 2, 3]'), 2)` or `SELECT json_array_contains('[1, 2, 3]', 2)`

Function	Description	Example
`json_array_get(json_array, index)`	Retrieves the element at the specified index in the JSON array. This function is equivalent to `json_array_contains`.	`SELECT json_array_get('["a", "b", "c"]', 0): returns 'a'`
`json_array_length(json)`	Returns the length of the JSON array.	`SELECT json_array_length('[1, 2, 3]'): returns 3`
`json_extract(json, json_path)`	Extracts a value from a JSON object and returns a JSON object. The json_path expression works in a similar manner to `$.store.book[0].title`.	`SELECT json_extract(json, '$.store.book')`
`json_extract_scalar(json, json_path)`	Returns a string. This function works in a similar manner to `json_extract`).	N/A
`json_size(json,json_path)`	Retrieves the length of a JSON object or array.	`SELECT json_size('[1, 2, 3]'): returns 3.`

28.1.4.8.12. Type conversion functions

Type conversion functions convert the data type of a specified value or column in a query.

You can use the index attribute feature of Log Service to set the data type of a field to LONG, DOUBLE, TEXT, or JSON. You can also query fields of various data types, including BIGINT, DOUBLE, VARCHAR, and TIMESTAMP. To query fields of a specific data type, you can use type conversion functions to convert the data type configured in an index into the data type that you use in a query.

Syntax

Note We recommend that you use the try_cast() function if a log contains dirty data. Otherwise, a query may fail due to the dirty data.

- Convert the data type of a column of values or a specific value into the specified type in a query. If the data type of a value fails to be converted, the query is terminated.

```
cast([key|value] AS type)
```

- Convert the data type of a column of values or a specific value into the specified type in a query. If the data type of a value fails to be converted, NULL is returned for the value, and the query continues.

```
try_cast([key|value] AS type)
```

Parameter	Description
key	The key of a field whose value data type is to be converted.
value	The field value whose data type is to be converted into the specified type.

Example

- To convert the numeric value 123 to a value of the VARCHAR type, use the following statement:

```
cast(123 AS varchar)
```

- To convert the data type of the uid field values to the VARCHAR type, use the following statement:

```
cast(uid AS varchar)
```

28.1.4.8.13. IP functions

This topic describes the syntax of IP functions and provides examples.

IP functions can identify whether an IP address is an intranet or Internet IP address. IP functions can also identify the country, province, and city where an IP address resides. For information about geohash functions, see Geography functions.

Function	Description	Example
`ip_to_domain(ip)`	Identifies whether an IP address is an intranet or Internet IP address. This function returns intranet or internet.	`SELECT ip_to_domain(ip)`
`ip_to_country(ip)`	Identifies the country where an IP address resides.	`SELECT ip_to_country(ip)`
`ip_to_province(ip)`	Identifies the province where an IP address resides.	`SELECT ip_to_province(ip)`
`ip_to_city(ip)`	Identifies the city where an IP address resides.	`SELECT ip_to_city(ip)`
`ip_to_geo(ip)`	Identifies the longitude and latitude of the city where an IP address resides. The result is returned in the format of `latitude, longitude`.	`SELECT ip_to_geo(ip)`
`ip_to_city_geo(ip)`	Identifies the longitude and latitude of the city where an IP address resides. Each city has only one longitude and latitude. The result is returned in the format of `latitude, longitude`.	`SELECT ip_to_city_geo(ip)`
`ip_to_provider(ip)`	Identifies the network service provider that assigns an IP address.	`SELECT ip_to_provider(ip)`
`ip_to_country(ip,'en')`	Identifies the country where an IP address resides. The function returns a country code.	`SELECT ip_to_country(ip,'en')`
`ip_to_country_code(ip)`	Identifies the country where an IP address resides. The function returns a country code.	`SELECT ip_to_country_code(ip)`
`ip_to_province(ip,'en')`	Identifies the province where an IP address resides.	`SELECT ip_to_province(ip,'en')`
`ip_to_city(ip,'en')`	Identifies the city where an IP address resides.	`SELECT ip_to_city(ip,'en')`

Example

- To query the number of requests that are not sent from an intranet, run the following statement:

```
* | SELECT count(1) where ip_to_domain(ip)! ='intranet'
```

- To query the top 10 provinces from which requests are sent, run the following statement:

```
* | SELECT count(1) as pv, ip_to_province(ip) as province GROUP BY province order by pv desc limit
10
```

Sample response

```
[
    {
        "__source__": "",
        "__time__": "1512353137",
        "province": "Zhejiang",
        "pv": "4045"
    }, {
        "__source__": "",
        "__time__": "1512353137",
        "province": "Shanghai",
        "pv": "3727"
    }, {
        "__source__": "",
        "__time__": "1512353137",
        "province": "Beijing",
        "pv": "954"
    }, {
        "__source__": "",
        "__time__": "1512353137",
        "province": "intranet IP address",
        "pv": "698"
    }, {
        "__source__": "",
        "__time__": "1512353137",
        "province": "Guangdong",
        "pv": "472"
    }, {
        "__source__": "",
        "__time__": "1512353137",
        "province": "Fujian",
        "pv": "71"
    }
]
```

The response contains an intranet IP address. You can use the SELECT statement to filter requests that are sent from the IP address.

- To query the top 10 provinces from which intranet requests are sent, run the following statement:

```
* | SELECT count(1) as pv, ip_to_province(ip) as province WHERE ip_to_domain(ip) ! = 'intranet'  G
ROUP BY province ORDER BY pv desc limit 10
```

- To query the average request latency, the maximum request latency, and the request with the maximum latency from each country, run the following statement:

```
* | SELECT AVG(latency),MAX(latency),MAX_BY(requestId, latency) ,ip_to_country(ip) as country grou
p by country limit 100
```

- To query the average latency of requests supported by each network service provider, run the following statement:

```
* | SELECT AVG(latency) , ip_to_provider(ip) as provider group by provider limit 100
```

- To query the longitude and latitude of the city to which an IP address belongs and show the city on a map, run the following statement:

```
* | SELECT count(1) as pv , ip_to_geo(ip) as geo group by geo order by pv desc
```

The following table shows the format of the result.

pv	geo
100	35.3284,-80.7459

28.1.4.8.14. GROUP BY syntax

This topic describes the GROUP BY syntax.

GROUP BY statements support multiple columns. A GROUP BY statement allows you to specify a column alias in a SELECT statement to as the corresponding KEY.

Example:

```
method:PostLogstoreLogs |select avg(latency),projectName,date_trunc('hour',__time__) as hour   group by projectName,hour
```

The hour alias indicates the third SELECT column `date_trunc('hour',__time__)`. This improves the performance of complicated queries.

The GROUP BY statement supports the GROUPING SETS, CUBE, and ROLLUP clauses.

Example:

```
method:PostLogstoreLogs |select avg(latency)   group by cube(projectName,logstore)
method:PostLogstoreLogs |select avg(latency)   group by GROUPING SETS ( ( projectName,logstore), (projectName,method))
method:PostLogstoreLogs |select avg(latency)   group by rollup(projectName,logstore)
```

Examples

- Use GROUP BY based on time

  Each log has a built-in time column named `__time__`. When the analytics feature is enabled on one of the columns, the statistics of the time column are included.

  The `date_trunc` function can truncate the time column to minute, hour, day, month, and year. The `date_trunc` function accepts an aligned unit and a column of the Unix timestamp type, such as `__time__`.

  - PV statistics per hour and per minute

```
* | SELECT count(1) as pv , date_trunc('hour',__time__) as hour group by hour order by hour limit 100
* | SELECT count(1) as pv , date_trunc('minute',__time__) as minute group by minute order by minute limit 100
```

> **Note** 100 specifies that up to 100 rows can be retrieved. If a LIMIT clause is not specified, up to 10 rows of data are retrieved by default.

- date_trunc functions are available only for statistics at a fixed time interval. For statistics based on flexible time dimensions, for example, every 5 minutes, run a GROUP BY statement based on the mathematical modulus method.

  ```
  * | SELECT count(1) as pv,  __time__ - __time__% 300 as minute5 group by minute5 limit 100
  ```

  In the preceding statement, `%300` indicates that the time is truncated in mod every 5 minutes.

- Retrieve non-aggregation columns from a GROUP BY statement

  In standard SQL, if a GROUP BY statement is used during the SELECT operation, Log Service selects only the raw data of the column specified in the GROUP BY statement or performs aggregation on any columns.

  For example, the following statement is invalid. Log Service cannot determine which row of b to return during the GROUP BY operation based on a, because b is not a GROUP BY column.

  ```
  *|select a, b , count(c) group by a
  ```

  Instead, you can use the `arbitrary()` function to return b.

  ```
  *|select a, arbitrary(b), count(c) group by a
  ```

28.1.4.8.15. Window functions

This topic describes the syntax for window functions.

Window functions are used to perform calculations across rows of a log. Common SQL aggregate functions calculate the results of only one row or aggregate all rows into one row for calculation. Window functions support cross-row calculation and fill the calculation results in each row.

Syntax for window functions is

```
SELECT key1, key2, value,
       rank() OVER (PARTITION BY key2
                    ORDER BY value DESC) AS rnk
FROM orders
ORDER BY key1,rnk
```

The important part is

```
rank() OVER (PARTITION BY  KEY1 ORDER BY KEY2 DESC)
```

rank() is an aggregate function. You can use any functions in analysis syntax or the function listed in this topic. PARTITION BY indicates the buckets based on which values are calculated.

Special aggregate functions used in windows

Function	Description
rank()	Returns the rank of a value within a group of values. The rank is one plus the number of preceding rows that are not peers of the current row.
row_number()	Returns a unique, sequential number for each row.
first_value(x)	Returns the first value of the window. In most cases, the function is used to obtain the maximum value after the values of the window are sorted.

Function	Description
last_value(x)	Returns the last value of the window. In most cases, the function is used to obtain the minimum value after the values of the window are sorted.
nth_value(x, offset)	Returns the value at the specified offset from the beginning of the window.
lead(x,offset,defaut_value)	Returns the value at offset rows after the current row in the window. If the target row does not exist, the default_value is returned.
lag(x,offset,defaut_value)	Returns the value at offset rows after the current row in the window. If the target row does not exist, the default_value is returned.

Example

- Rank the salaries of employees in their respective departments

```
* | select department, persionId, sallary , rank() over(PARTITION BY department order by sallary d
esc) as sallary_rank  order by department,sallary_rank
```

Results

department	persionId	sallary	sallary_rank
dev	john	9000	1
dev	Smith	8000	2
dev	Snow	7000	3
dev	Achilles	6000	4
Marketing	Blan Stark	9000	1
Marketing	Rob Stark	8000	2
Marketing	Sansa Stark	7000	3

- Calculate the salaries of employees as percentages in their respective departments

```
* | select department, persionId, sallary *1.0 / sum(sallary) over(PARTITION BY department ) as sa
llary_percentage
```

Results

department	persionId	sallary	sallary_percentage
dev	john	9,000	0.3
dev	Smith	8,000	0.26
dev	Snow	7000	0.23
dev	Achilles	6000	0.2

department	persionId	sallary	sallary_percentage
Marketing	Blan Stark	9000	0.375
Marketing	Rob Stark	8000	0.333
Marketing	Sansa Stark	7000	0.29

- Calculate the daily UV increase over the previous day

```
* | select day ,uv, uv *1.0 /(lag(uv,1,0) over() ) as diff_percentage from
(
select approx_distinct(ip) as uv, date_trunc('day',__time__) as day from log group by day order by
day asc
)
```

Results

day	uv	diff_percentage
2017-12-01 00:00:00	100	null
2017-12-02 00:00:00	125	1.25
2017-12-03 00:00:00	1,500	1.2
2017-12-04 00:00:00	175	1.16
2017-12-05 00:00:00	2,000	1.14
2017-12-06 00:00:00	225	1.125
2017-12-07 00:00:00	250	1.11

28.1.4.8.16. HAVING syntax

This topic describes the HAVING syntax.

The LogSearch/Analytics feature of Log Service supports the standard SQL HAVING clause. The HAVING clause is used with the GROUP BY statement to filter GROUP BY results.

Example:

```
method :PostLogstoreLogs |select avg(latency),projectName group by projectName  HAVING avg(latency) >
100
```

Difference between HAVING and WHERE clauses

The HAVING clause is used to filter the aggregation and calculation results after you run the GROUP BY statement. The WHERE clause is used to filter the raw data during the aggregation calculation.

Example

Calculate the average rainfall of each province where the temperature is higher than 10°C, and only show the provinces with average rainfall greater than 100 mL in the final results:

```
* | select avg(rain) ,province where temperature > 10 group by province having avg(rain) > 100
```

28.1.4.8.17. ORDER BY syntax

This topic describes the ORDER BY syntax.

The ORDER BY keyword is used to sort output results. You can sort output results based on only one column.

- Syntax format

```
order by column name [desc|asc]
```

- Example

```
method :PostLogstoreLogs |select avg(latency) as avg_latency,projectName group by projectName
HAVING avg(latency) > 5700000
order by avg_latency desc
```

28.1.4.8.18. LIMIT syntax

The LIMIT clause is used to limit the number of returned rows.

Syntax formats

Log Service supports the following LIMIT syntax formats:

- Reads only the first N rows:

```
limit N
```

- Reads N rows starting from the S-th row:

```
limit S , N
```

> **Note**
>
> - If you use the LIMIT clause to paginate results, the final results rather than the intermediate results of the SQL query are obtained.
> - You cannot apply the LIMIT clause to subqueries. For example, the following statement is not supported:
>
>   ```
>   * | select count(1) from ( select distinct(url) from limit 0,1000)
>   ```
>
> - If you use the LIMIT clause for pagination, the offset value cannot exceed 1,000,000. For example, in the `limit S , N` clause, the sum of S and N cannot exceed 1,000,000, and the value of N cannot exceed 10,000.

Example

- To obtain the first 100 rows of results, run the following statement.

```
* | select distinct(url) from log limit 100
```

- To obtain a total of 1,000 results from row 0 to row 999, run the following statement.

```
* | select distinct(url) from log limit 0,1000
```

- To obtain a total of 1,000 results from row 1,000 to row 1,999, run the following statement:

```
* | select distinct(url) from log limit 1000,1000
```

28.1.4.8.19. Syntax for CASE statements and if() functions

This topic describes the syntax for CASE statements and if() functions.

CASE statements are used to classify continuous data. For example, you can use the following CASE statement to extract information from http_user_agent and classify the information into two types: Android and iOS.

```
SELECT
 CASE
 WHEN http_user_agent like '%android%' then 'android'
 WHEN http_user_agent like '%ios%' then 'ios'
 ELSE 'unknown' END
 as http_user_agent,
    count(1) as pv
    group by  http_user_agent
```

Examples

- Calculate the ratio of requests whose status code is 200 to all requests

```
* | SELECT
 sum(
 CASE
 WHEN status =200 then 1
 ELSE 0 end
 ) *1.0 / count(1) as status_200_percentage
```

- Calculate the distribution of latencies

```
* | SELECT `
 CASE
 WHEN latency < 10 then 's10'
 WHEN latency < 100 then 's100'
 WHEN latency < 1000 then 's1000'
 WHEN latency < 10000 then 's10000'
 else 's_large' end
 as latency_slot,
 count(1) as pv
 group by latency_slot
```

Syntax for if() functions

An if() function works in the same way as a CASE statement does.

```
CASE
     WHEN condition THEN true_value
     [ ELSE false_value ]
 END
```

- if(condition, true_value)

  If the condition is true, the true_value column is returned. Otherwise, null is returned.

- if(condition, true_value, false_value)

  If the condition is true, the true_value column is returned. Otherwise, the false_value column is returned.

Syntax for coalesce() functions

A coalesce() function returns the first non-null value from multiple columns.

```
COALESCE (value1, value2 [,...])
```

Syntax for the nullif() function

If value1 is equal to value2, null is returned. Otherwise, value1 is returned.

```
nullif(value1, value2)
```

Syntax for the try() function

The try() function catches underlying exceptions, such as division by zero errors, and returns null.

```
try(expression)
```

28.1.4.8.20. Nested subqueries

This describes how to use nested subqueries when you query logs.

You can use nested queries to perform more complicated queries.

Nested queries differ from non-nested queries in the need for specifying the FROM clause in the SQL statement. You must specify the `from log` keyword in each SQL statement to read raw data from logs.

Example:

```
* | select sum(pv) from
(
select count(1) as pv from log group by method
)
```

28.1.4.8.21. Array functions

This topic describes the syntax of array functions. It also provides examples that show how to use these functions.

Function	Description	Example
Subscript operator []	The subscript operator [] is used to obtain an element in the array.	N/A
array_distinct	Returns the distinct elements in the array.	N/A
array_intersect(x, y)	Returns the intersection of the x and y arrays.	N/A
array_union(x, y) → array	Returns the union of the x and y arrays.	N/A
array_except(x, y) → array	Returns the subtraction of the x and y arrays.	N/A

Function	Description	Example
array_join(x, delimiter, null_replacement) → varchar	Joins string arrays with the delimiter into a string and replaces null values with null_replacement. **Note** The maximum size of the returned result of this array_join function is 1 KB. If the returned result exceeds 1 KB, the extra data will be truncated.	N/A
array_max(x) → x	Returns the maximum value in the x array.	N/A
array_min(x) → x	Returns the minimum value in the x array.	N/A
array_position(x, element) → bigint	Returns the subscript of the element in the x array. The subscript starts from 1. The value 0 is returned if no subscript is found.	N/A
array_remove(x, element) → array	Removes the element from the array.	N/A
array_sort(x) → array	Sorts the array and moves null values to the end.	N/A
cardinality(x) → bigint	Returns the array size.	N/A
concat(array1, array2, ..., arrayN) → array	Concatenates arrays.	N/A
contains(x, element) → boolean	Returns true if the x array contains the specified element.	N/A
filter(array, function) → array	For more information about this Lambda function, see the filter() function in Lambda functions.	N/A
flatten(x) → array	Flattens an array(array(T)) to an array(T) by concatenating the contained arrays.	N/A
reduce(array, initialState, inputFunction, outputFunction) → x	For more information, see the reduce() function in Lambda functions.	N/A
reverse(x) → array	Returns an array that has the reversed order of the x array.	N/A
sequence(start, stop) → array	Generates a sequence of elements from start to stop. The difference between elements is 1.	N/A
sequence(start, stop, step) → array	Generates a sequence of elements from start to stop. The difference between elements is step.	N/A

Function	Description	Example
sequence(start, stop, step) → array	Generates a sequence of timestamps from start to stop. The difference between timestamps is step. The type of step can be either INTERVAL DAY TO SECOND or INTERVAL YEAR TO MONTH.	N/A
shuffle(x) → array	Shuffles the array.	N/A
slice(x, start, length) → array	Returns a subset of the x array starting from the start value with the specified length.	N/A
transform(array, function) → array	For more information, see the transform() function in Lambda functions.	N/A
zip(array1, array2[, ...]) → array	Merges the specified arrays. The M-th element of the N-th argument will be the N-th field of the M-th output element.	`SELECT zip(ARRAY[1, 2], ARRAY['1b', null, '3b']); — [ROW(1, '1b'), ROW(2, null), ROW(null, '3b')]`
zip_with(array1, array2, function) → array	For more information, see the zip_with() function in Lambda functions.	N/A
array_agg (key)	An aggregate function that returns an array from values in the key column.	`* | select array_agg(key)`
array_transpose(array[array[*x*,*y*,*z*], array[*a*,*b*,*c*]])	Returns a new matrix by transposing the values of the previous matrix from rows to columns.	N/A

28.1.4.8.22. Binary string functions

This topic describes the syntax of binary string functions. It also provides examples that show how to use these functions.

Data of the VARBINARY type is different from data of the VARCHAR type.

Function	Description
Concatenation operator (‖)	The result of `a || b` is `ab`.
length(binary) → bigint	Returns the length in binary.
concat(binary1, ..., binaryN) → varbinary	Connects the binary strings, which is equivalent to ‖.
to_base64(binary) → varchar	Converts a binary string to a Base64 string.
from_base64(string) → varbinary	Converts a Base64 string to a binary string.
to_base64url(binary) → varchar	Converts a string to a URL-safe Base64 string.
from_base64url(string) → varbinary	Converts a URL-safe Base64 string to a binary string.

Function	Description
to_hex(binary) → varchar	Converts a binary string to a hexadecimal string.
from_hex(string) → varbinary	Converts a hexadecimal string to a binary string.
to_big_endian_64(bigint) → varbinary	Convert a number to a binary string in big endian mode.
from_big_endian_64(binary) → bigint	Converts a binary string in big endian mode to a number.
md5(binary) → varbinary	Calculates the MD5 value of a binary string.
sha1(binary) → varbinary	Calculates the SHA1 value of a binary string.
sha256(binary) → varbinary	Calculates the SHA256 hash value of a binary string.
sha512(binary) → varbinary	Calculate the SHA512 value of a binary string.
xxhash64(binary) → varbinary	Calculates the xxhash64 value of a binary string.

28.1.4.8.23. Bitwise operations

This topic describes the syntax for bitwise operations. It also provides examples that show how to use these operations.

Function	Description	Example

bit_count(x, bits) → bigint	Count the number of 1 in the binary expression of x.	`SELECT bit_count(9, 64); — 2`
		`SELECT bit_count(9, 8); — 2`
		`SELECT bit_count(-7, 64); — 62`
		`SELECT bit_count(-7, 8); — 6`

bitwise_and(x, y) → bigint	Perform the AND operation on x and y in the binary form.	N/A
bitwise_not(x) → bigint	Calculate the opposite values of all bits of x in the binary form.	N/A
bitwise_or(x, y) → bigint	Perform the OR operation on x and y in the binary form.	N/A
bitwise_xor(x, y) → bigint	Perform the XOR operation on x and y in the binary form.	N/A

28.1.4.8.24. Interval-valued comparison and periodicity-valued comparison functions

Log Service allows you to use interval-valued comparison and periodicity-valued comparison functions to query and analyze log data.

You can use the functions to compare the value for one period with that for a previous period.

Function	Description	Example
`compare(value, time_window)`	This function compares the value calculated for the current period with that calculated for the period before time_window. The data type of the values to be compared is Double or Long. The time_window parameter is measured in seconds. This function returns an array. Possible return values include the value for the current period, the value for the period before time_window, and the ratio of the current value to the value before time_window.	`*|select compare( pv , 86400) from (select count(1) as pv from log)`
`compare(value, time_window1, time_window2)`	This function compares the current value with the values for periods before time_window1 and time_window2. The comparison results are in the JSON array format, where the values must be returned in the following order: [current value, value before time_window1, value before time_window2, current value/value before time_window1, current value/value before time_window2].	`* | select compare(pv, 86400, 172800) from ( select count(1) as pv from log)`
`compare(value, time_window1, time_window2, time_window3)`	This function compares the value for the current period with the values for periods before time_window1, time_window2, and time_window3. The comparison results are in the JSON array format, where the values must be returned in the following order: [current value, value before time_window1, value before time_window2, value before time_window3, current value/value before time_window1, current value/value before time_window2, current value/value before time_window3].	`* | select compare(pv, 86400, 172800,604800) from ( select count(1) as pv from log)`

Function	Description	Example
`ts_compare(value, time_window)`	This function compares the value for the current period with the values for periods before `time_window1` and `time_window2` and returns a JSON array. The comparison results are in the JSON array format, where the values must be returned in the following order: [current value, value before time_window1, current value/value before time_window1, Unix timestamp that indicates the start time of the previous period]. This function is used to compare time series values. You must specify the GROUP BY keyword for the time column in SQL statements.	For example, `* | select t, ts_compare(pv, 86400 ) as d from(select date_trunc('minute',__time__ ) as t, count(1) as pv from log group by t order by t ) group by t` specifies that the function compares the calculation result of every minute in the current period with that of every minute in the last period. The comparison result is `d:[1251.0,1264.0, 0.9897151898734177, 1539843780.0,1539757380.0]t:2018-10-19 14:23:00.000` .

Examples

- Calculate the ratio of the PV for an hour on a day to that for the same time period on a previous day.

  The start time is 2018-07-25 14:00:00, and the end time is 2018-07-25 15:00:00.

  Statement for query and analysis:

  ```
  * | select compare( pv , 86400) from (select count(1) as pv from log)
  ```

  In the preceding statement, 86400 indicates 86,400 seconds before the current period.

  Return results:

  ```
  [9.0,19.0,0.47368421052631579]
  ```

  In the preceding results,

  - 9.0 is the PV for the period from 2018-07-25 14:00:00 to 2018-07-25 15:00:00.
  - 19.0 is the PV for the period from 2018-07-24 14:00:00 to 2018-07-24 15:00:00.
  - 0.47368421052631579 is the ratio of the PV for the current period to that for a previous period.

  If you want to expand the array into three columns of numbers, the analysis statement is

  ```
  * | select diff[1],diff[2],diff[3] from(select compare( pv , 86400) as diff from (select count(1) as pv from log))
  ```

- Calculate the PV ratio for every minute of the current hour to that in the same time period as the day before, and output the results in a line chart.

  i. Calculate the PV ratio for every minute of the current hour to that in the same time period as the day before. The start time is 2018-07-25 14:00:00, and the end time is 2018-07-25 15:00:00.

  Statement for query and analysis:

  ```
  *| select t, compare( pv , 86400) as diff from (select count(1) as pv, date_format(from_unixtime(__time__), '%H:%i') as t from log group by t) group by t order by t
  ```

  Return results:

t	diff
14:00	[9520.0,7606.0,1.2516434393899554]
14:01	[8596.0,8553.0,1.0050274757395066]
14:02	[8722.0,8435.0,1.0340248962655603]
14:03	[7499.0,5912.0,1.2684370771312586]

In the preceding table, t indicates the time in the format of `Hour:Minute`. The contents of the diff column are included in an array that contains the following values:

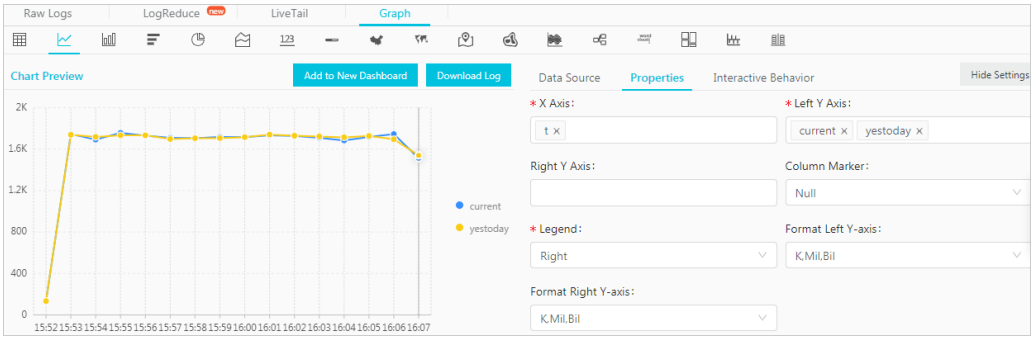
- The PV value of the current period.
- The PV value of the previous period.
- The ratio of the PV value for the current period to that for the previous period.

ii. To show the query results in a line chart, use the following statement:

```
*|select t, diff[1] as current, diff[2] as yestoday, diff[3] as percentage from(select t, compare( pv , 86400) as diff from (select count(1) as pv, date_format(from_unixtime(__time__), '%H:%i') as t from log group by t) group by t order by t)
```

The two lines indicate the PV values of a day and the day before.

Line chart



28.1.4.8.25. Comparison functions and operators

This topic describes the comparison functions and operators in Log Service. You can use these functions and operators to query and analyze log data.

Comparison functions and operators

A comparison function compares two parameter values of any comparable data types, such as INTEGER, BIGINT, DOUBLE, and TEXT.

Comparison operators

A comparison operator is used to compare two values. If the statement is true, TRUE is returned. Otherwise, FALSE is returned.

Operator	Description
<	Less than
>	Greater than

Operator	Description
<=	Less than or equal to
>=	Greater than or equal to
=	Equal to
<>	Not equal to
! =	Not equal to

Range operator BETWEEN

The BETWEEN operator determines whether a value falls in a specified closed interval.

- If the value falls in the specified closed interval, TRUE is returned. Otherwise, FALSE is returned.

  Example: `SELECT 3 BETWEEN 2 AND 6;` . The statement is true, and TRUE is returned.

  The preceding statement is equivalent to `SELECT 3 >= 2 AND 3 <= 6;` .
- The BETWEEN operator can be put behind the NOT operator to test whether a value falls out of a specified closed interval.

  Example: `SELECT 3 NOT BETWEEN 2 AND 6;` . The statement is false, and FALSE is returned.

  The preceding statement is equivalent to `SELECT 3 < 2 OR 3 > 6;` .
- If any of the three values is NULL, NULL is returned.

IS NULL and IS NOT NULL

The IS NULL and IS NOT NULL operators test whether a value is NULL.

IS DISTINCT FROM and IS NOT DISTINCT FROM

These operators are similar to the EQUAL TO and NOT EQUAL TO operators. However, IS DISTINCT FROM and IS NOT DISTINCT FROM can determine whether a NULL value exists.

Examples:

```
SELECT NULL IS DISTINCT FROM NULL; -- false
SELECT NULL IS NOT DISTINCT FROM NULL; -- true
```

The DISTINCT operator compares parameter values under multiple conditions, as described in the following table.

a	b	a = b	a <> b	a DISTINCT b	a NOT DISTINCT b
1	1	TRUE	FALSE	FALSE	TRUE
1	2	FALSE	TRUE	TRUE	FALSE
1	NULL	NULL	NULL	TRUE	FALSE
NULL	NULL	NULL	NULL	FALSE	TRUE

GREATEST and LEAST

These operators are used to obtain the maximum or minimum value from a row of field values.

Example:

```
select greatest(1,2,3) -- Returns 3.
```

Quantified comparison predicates: ALL, ANY, and SOME

The ALL, ANY, and SOME quantifiers can be used to determine whether a parameter value meets specified conditions.

- ALL is used to determine whether a parameter value meets all conditions. If the statement is true, TRUE is returned. Otherwise, FALSE is returned.
- ANY is used to determine whether a parameter value meets a condition. If the statement is true, TRUE is returned. Otherwise, FALSE is returned.
- SOME is used to determine whether a parameter value meets a condition. SOME is equivalent to ANY.
- ALL, ANY, and SOME must immediately follow comparison operators.

ALL and ANY support comparison under multiple conditions, as described in the following table.

Expression	Description
A = ALL (...)	Returns TRUE if A matches all values.
A <> ALL (...)	Returns TRUE if A does not match a value.
A < ALL (...)	Returns TRUE if A is smaller than the smallest value.
A = ANY (...)	Returns TRUE if A is equal to a value. This statement is equivalent to A IN (...).
A <> ANY (...)	Returns TRUE if A does not match a value.
A < ANY (...)	Returns TRUE if A is smaller than the largest value.

Examples:

```
SELECT 'hello' = ANY (VALUES 'hello', 'world'); -- true
SELECT 21 < ALL (VALUES 19, 20, 21); -- false
SELECT 42 >= SOME (SELECT 41 UNION ALL SELECT 42 UNION ALL SELECT 43); -- true
```

28.1.4.8.26. Lambda functions

This topic describes Lambda functions and provides some examples. You can use Lambda functions to analyze log data in Log Service

Lambda expressions

Lambda expressions use the arrow operator `->`.

Examples:

```
x -> x + 1
(x, y) -> x + y
x -> regexp_like(x, 'a+')
x -> x[1] / x[2]
x -> IF(x > 0, x, -x)
x -> COALESCE(x, 0)
x -> CAST(x AS JSON)
x -> x + TRY(1 / 0)
```

Most MySQL expressions can be used in Lambda functions.

filter(array<T>, function<T, boolean>) → ARRAY<T>

Returns an array whose elements are filtered from the specified array based on the Lambda expression.

Examples:

```
SELECT filter(ARRAY [], x -> true); -- []
SELECT filter(ARRAY [5, -6, NULL, 7], x -> x > 0); -- [5, 7]
SELECT filter(ARRAY [5, NULL, 7, NULL], x -> x IS NOT NULL); -- [5, 7]
```

map_filter(map<K, V>, function<K, V, boolean>) → MAP<K,V>

Returns a map whose elements are filtered based on the Lambda expression. The map is generated from the map function.

Examples:

```
SELECT map_filter(MAP(ARRAY[], ARRAY[]), (k, v) -> true); -- {}
SELECT map_filter(MAP(ARRAY[10, 20, 30], ARRAY['a', NULL, 'c']), (k, v) -> v IS NOT NULL); -- {10 ->
a, 30 -> c}
SELECT map_filter(MAP(ARRAY['k1', 'k2', 'k3'], ARRAY[20, 3, 15]), (k, v) -> v > 10); -- {k1 -> 20, k3
-> 15}
```

reduce(array<T>, initialState S, inputFunction<S, T, S>, outputFunction<S, R>) → R

The reduce function starts from the initial state, traverses each element in the array, and then calls inputFunction(S,T) to generate a new state. After all the elements in the array are traversed and the final state is generated, the reduce function calls outputFunction to assign the final state value to the result R and output the result. The procedure is described as follows:

1. Start from the initial state S.
2. Traverse each element T.
3. Calculate inputFunction(S,T) to generate a new state S.
4. Repeat steps 2 and 3 until the last element is traversed and has a new state.
5. Turn the final state S into the final result R.

Examples:

```
SELECT reduce(ARRAY [], 0, (s, x) -> s + x, s -> s); -- 0
SELECT reduce(ARRAY [5, 20, 50], 0, (s, x) -> s + x, s -> s); -- 75
SELECT reduce(ARRAY [5, 20, NULL, 50], 0, (s, x) -> s + x, s -> s); -- NULL
SELECT reduce(ARRAY [5, 20, NULL, 50], 0, (s, x) -> s + COALESCE(x, 0), s -> s); -- 75
SELECT reduce(ARRAY [5, 20, NULL, 50], 0, (s, x) -> IF(x IS NULL, s, s + x), s -> s); -- 75
SELECT reduce(ARRAY [2147483647, 1], CAST (0 AS BIGINT), (s, x) -> s + x, s -> s); -- 2147483648
SELECT reduce(ARRAY [5, 6, 10, 20], -- calculates arithmetic average: 10.25
              CAST(ROW(0.0, 0) AS ROW(sum DOUBLE, count INTEGER)),
              (s, x) -> CAST(ROW(x + s.sum, s.count + 1) AS ROW(sum DOUBLE, count INTEGER)),
              s -> IF(s.count = 0, NULL, s.sum / s.count));
```

transform(array<T>, function<T, U>) → ARRAY<U>

This Lambda function traverses each element in an array to generate a new result U.

Examples:

```
SELECT transform(ARRAY [], x -> x + 1); -- []
SELECT transform(ARRAY [5, 6], x -> x + 1); -- [6, 7] -- Increments each element by 1.
SELECT transform(ARRAY [5, NULL, 6], x -> COALESCE(x, 0) + 1); -- [6, 1, 7]
SELECT transform(ARRAY ['x', 'abc', 'z'], x -> x || '0'); -- ['x0', 'abc0', 'z0']
SELECT transform(ARRAY [ARRAY [1, NULL, 2], ARRAY[3, NULL]], a -> filter(a, x -> x IS NOT NULL)); --
[[1, 2], [3]]
```

zip_with(array<T>, array<U>, function<T, U, R>) → array<R>

This Lambda function merges two arrays and generates the element R in the new array based on element T and element U.

Examples:

```
SELECT zip_with(ARRAY[1, 3, 5], ARRAY['a', 'b', 'c'], (x, y) -> (y, x)) --Transposes the elements of
the two arrays to generate a new array. Result: [['a', 1], ['b', 3],['c', 5]]
SELECT zip_with(ARRAY[1, 2], ARRAY[3, 4], (x, y) -> x + y); -- Result: [4, 6]
SELECT zip_with(ARRAY['a', 'b', 'c'], ARRAY['d', 'e', 'f'], (x, y) -> concat(x, y)) -- Concatenates t
he elements of the two arrays to generate a new string. Result: ['ad', 'be', 'cf']
```

28.1.4.8.27. Logical functions

This topic describes the available logical functions in Log Service. You can use these functions to query and analyze log data.

Logical operators

Operator	Description	Example
AND	The result is TRUE if both values are TRUE.	a AND b
OR	The result is TRUE if either value is TRUE.	a OR b
NOT	The result is TRUE if the value is FALSE.	NOT a

Effect of NULL on logical operators

The following tables list the truth values when the values of a and b are TRUE, FALSE, and NULL, respectively.

Truth table 1

a	b	a AND b	a OR b
TRUE	TRUE	TRUE	TRUE
TRUE	FALSE	FALSE	TRUE
TRUE	NULL	NULL	TRUE
FALSE	TRUE	FALSE	TRUE
FALSE	FALSE	FALSE	FALSE
FALSE	NULL	FALSE	NULL

a	b	a AND b	a OR b
NULL	TRUE	NULL	TRUE
NULL	FALSE	FALSE	NULL
NULL	NULL	NULL	NULL

Truth table 2

a	NOT a
TRUE	FALSE
FALSE	TRUE
NULL	NULL

28.1.4.8.28. Field aliases

This topic describes how to specify an alias for a field and provides some examples.

A field name in an SQL statement must start with letters and contain digits and underscores (_).

If you have configured a field name that does not conform to the SQL standard (such as User-Agent), you must specify an alias for the field on the field index configuration page. The alias takes effect only for the duration of the SQL statement. The data is still stored under the original field name. You must specify the original name when you perform a search.

You can also specify an alias for a field in an SQL statement if the original name is long.

Sample aliases

Original field name	Alias
User-Agent	ua
User.Agent	ua
123	col
abceefghijklmnopqrstuvw	a

28.1.4.8.29. JOIN operations between Logstores and Relational Database Service (RDS) tables

This topic describes how to join Logstores in Log Service with RDS tables for queries and store the query results in RDS tables.

Procedure

1. Create a VPC.

   Create an RDS instance and specify the VPC to host the RDS instance. Then the VPC ID and the RDS instance ID are obtained.

2. Configure a whitelist for the RDS instance.

Add the following CIDR blocks to the whitelist: `100.104.0.0/16`, `11.194.0.0/16`, and `11.201.0.0/16`

3. Create an external store

   Run the following statement to create an external store. Replace the parameter values based on your business needs.

```
{
"externalStoreName":"storeName",
"storeType":"rds-vpc",
"parameter":
   {
   "region":"cn-qingdao",
   "vpc-id":"vpc-m5eq4irc1pucp*******"
   "instance-id":"i-m5eeo2whsn*******"
   "host":"localhost",
   "port":"3306",
   "username":"root",
   "password":"****",
   "db":"scmc"
   "table":"join_meta"
   }
}
```

   Parameters

Parameter	Description
region	The region where your RDS instance resides.
vpc-id	The ID of the VPC where your RDS instance resides.
instance-id	The ID of the RDS instance.
host	The ID of the ECS instance that is used to access the RDS instance.
port	The port of the ECS instance that is used to access the RDS instance.
username	The username that is used to log on to the RDS instance.
password	The password that is used to log on to the RDS instance.
db	The name of the database.
table	The name of the table with which the Logstore is joined.

   Note You can join a Logstore with an RDS table that resides only in the China (Beijing), China (Qingdao), and China (Hangzhou) regions.

4. JOIN query.

   Log on to the Log Service console. In the **Search & Analyze** search box, run a JOIN statement.

   Supported JOIN syntax:

   - INNER JOIN

- LEFT JOIN
- RIGHT JOIN
- FULL JOIN

```
[ INNER ] JOIN
LEFT [ OUTER ] JOIN
RIGHT [ OUTER ] JOIN
FULL [ OUTER ] JOIN
```

> **Note**
>
> - You can join Logstores only to external tables.
> - In the JOIN statement, you must first specify a Logstore before specifying an external store.
> - You must specify the name of the external store instead of the name of an RDS table. The external store name automatically changes into the combination of the RDS database name and the name of the RDS table that you want to join with the Logstore.

Sample JOIN statement:

```
method:postlogstorelogs | select count(1) , histogram(logstore) from log  l join join_meta m o
n l.projectid = cast( m.ikey as varchar)
```

5. Store the query results to the RDS table.

   You can use the INSERT statement to insert the query results into the RDS table.

```
method:postlogstorelogs | insert into method_output  select cast(methodasvarchar(65535)),count
(1)fromloggroupbymethod
```

Sample Python script:

```
# encoding: utf-8
from __future__ import print_function
from aliyun.log import *
from aliyun.log.util import base64_encodestring
from random import randint
import time
import os
from datetime import datetime
    endpoint = os.environ.get('ALIYUN_LOG_SAMPLE_ENDPOINT', 'cn-chengdu.log.aliyuncs.com')
    accessKeyId = os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSID', '')
    accessKey = os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSKEY', '')
    logstore = os.environ.get('ALIYUN_LOG_SAMPLE_LOGSTORE', '')
    project = "ali-yunlei-chengdu"
    client = LogClient(endpoint, accessKeyId, accessKey, token)
## Create an external store
    res = client.create_external_store(project,ExternalStoreConfig("rds_store","region","rds-vpc","vpc id","instance-id","instance-ip","port","username","password","db","table"));
    res.log_print()
    ## Obtain external store details
    res = client.get_external_store(project,"rds_store");
    res.log_print()
    res = client.list_external_store(project,"");
    res.log_print();
    # Perform the JOIN operation.
    req = GetLogStoreLogsRequest(project,logstore,From,To,"","select count(1) from  "+ logstore +"  s join  meta m on  s.projectid = cast(m.ikey as varchar)");
    res = client.get_logs(req)
    res.log_print();
     # Store query results to the RDS table
    req = GetLogStoreLogsRequest(project,logstore,From,To,"," insert into rds_store select count(1) from  "+ logstore );
    res = client.get_logs(req)
    res.log_print();
```

28.1.4.8.30. Geospatial functions

This topic describes the available geospatial functions in Log Service. You can use these functions to query and analyze log data.

Concept of geometry

Geospatial functions support geometries in the well-known text (WKT) format.

Geometry formats

Geometry	WKT format
Point	`POINT (0 0)`
LineString	`LINESTRING (0 0, 1 1, 1 2)`
Polygon	`POLYGON ((0 0, 4 0, 4 4, 0 4, 0 0), (1 1, 2 1, 2 2, 1 2, 1 1))`
MultiPoint	`MULTIPOINT (0 0, 1 2)`

Geometry	WKT format
MultiLineString	`MULTILINESTRING ((0 0, 1 1, 1 2), (2 3, 3 2, 5 4))`
MultiPolygon	`MULTIPOLYGON (((0 0, 4 0, 4 4, 0 4, 0 0), (1 1, 2 1, 2 2, 1 2, 1 1)), ((-1 -1, -1 -2,`
GeometryCollection	`GEOMETRYCOLLECTION (POINT(2 3), LINESTRING (2 3, 3 4))`

Constructors

Constructor description

Function	Description
ST_Point(double, double) → Point	Returns a geometry point instance with the specified coordinate values.
ST_LineFromText(varchar) → LineString	Returns a geometry LineString instance from a WKT representation.
ST_Polygon(varchar) → Polygon	Returns a geometry polygon instance from a WKT representation.
ST_GeometryFromText(varchar) → Geometry	Returns a geometry instance from a WKT representation.
ST_AsText(Geometry) → varchar	Returns the WKT representation of a geometry.

Operations

Function	Description
ST_Boundary(Geometry) → Geometry	Returns the closure of the combinatorial boundary of a geometry.
ST_Buffer(Geometry, distance) → Geometry	Returns the geometry that represents all points whose distance from the specified geometry is shorter than or equal to the specified distance.
ST_Difference(Geometry, Geometry) → Geometry	Returns the geometry value that represents the point set difference of the specified geometries.
ST_Envelope(Geometry) → Geometry	Returns the bounding rectangular polygon of a geometry.
ST_ExteriorRing(Geometry) → Geometry	Returns a line string that represents the exterior ring of the input polygon.
ST_Intersection(Geometry, Geometry) → Geometry	Returns the geometry value that represents the point set intersection of two geometries.
ST_SymDifference(Geometry, Geometry) → Geometry	Returns the geometry value that represents the point set symmetric difference of two geometries.

Relationship tests

Function	Description
ST_Contains(Geometry, Geometry) → boolean	Returns True if and only if no points of the second geometry lie in the exterior of the first geometry, and at least one point of the interior of the first geometry lies in the interior of the second geometry. Returns False if points of the second geometry are on the boundary of the first geometry.
ST_Crosses(Geometry, Geometry) → boolean	Returns True if the specified geometries share some, but not all, interior points in common.
ST_Disjoint(Geometry, Geometry) → boolean	Returns True if the specified geometries do not spatially intersect.
ST_Equals(Geometry, Geometry) → boolean	Returns True if the specified geometries represent the same geometry.
ST_Intersects(Geometry, Geometry) → boolean	Returns True if the specified geometries spatially intersect in two dimensions.
ST_Overlaps(Geometry, Geometry) → boolean	Returns True if the specified geometries share space in the same dimension, but are not completely contained by each other.
ST_Relate(Geometry, Geometry) → boolean	Returns True if the first geometry is spatially related to the second geometry.
ST_Touches(Geometry, Geometry) → boolean	Returns True if the specified geometries have at least one point in common, but their interiors do not intersect.
ST_Within(Geometry, Geometry) → boolean	Returns True if the first geometry is completely inside the second geometry. Returns False if the two geometries have points in common at the boundaries.

Accessors

Function	Description
ST_Area(Geometry) → double	Returns the two-dimensional Euclidean area of a geometry.
ST_Centroid(Geometry) → Geometry	Returns the point value that is the mathematical centroid of a geometry.
ST_CoordDim(Geometry) → bigint	Returns the coordinate dimension of a geometry.
ST_Dimension(Geometry) → bigint	Returns the inherent dimension of a geometry object, which must be less than or equal to the coordinate dimension.
ST_Distance(Geometry, Geometry) → double	Returns the minimum two-dimensional Cartesian distance (based on spatial ref) between two geometries in projected units.
ST_IsClosed(Geometry) → boolean	Returns True if the start and end points of the linestring are coincident.

Function	Description
ST_IsEmpty(Geometry) → boolean	Returns True if the specified geometry is an empty geometry, such as geometry collection, polygon, and point.
ST_IsRing(Geometry) → boolean	Returns True if and only if the line is closed and simple.
ST_Length(Geometry) → double	Returns the length of a LineString or multi-LineString by using Euclidean measurement on a two-dimensional plane (based on spatial ref) in projected units.
ST_XMax(Geometry) → double	Returns the X maximum of the bounding box of the geometry.
ST_YMax(Geometry) → double	Returns the Y maximum of the bounding box of the geometry.
T_XMin(Geometry) → double	Returns the X minimum of the bounding box of the geometry.
ST_YMin(Geometry) → double	Returns the Y minimum of the bounding box of the geometry.
ST_StartPoint(Geometry) → point	Returns the first point of a geometry LineString instance.
ST_EndPoint(Geometry) → point	Returns the last point of a geometry LineString instance.
ST_X(Point) → double	Returns the X coordinate of a point.
ST_Y(Point) → double	Returns the Y coordinate of a point.
ST_NumPoints(Geometry) → bigint	Returns the number of points in a geometry.
ST_NumInteriorRing(Geometry) → bigint	Returns the cardinality of the collection of interior rings of a polygon.

28.1.4.8.31. Geography functions

This topic describes the syntax of geography functions and provides some examples.

For information about functions that identify the country, province, city, ISP, and the longitude and latitude of a specified IP address, see IP functions.

Geography functions

Function	Description	Example
geohash(string)	Returns the geohash value of the specified geographical location. The geographical location is represented by a string in the format of "latitude, longitude". The values for latitude and longitude are separated by a comma.	`select geohash('34.1,120.6')= 'wwjcbrdnzs'`

Function	Description	Example
geohash(lat,lon)	Returns the geohash value of the specified geographical location. The geographical location is represented by two parameters that indicate the latitude and longitude.	`select geohash(34.1,120.6)= 'wwjcbrdnzs'`

28.1.4.8.32. JOIN syntax

The JOIN operation joins multiple tables by using one or more fields in the tables. You can join a Logstore created in Log Service with the Logstore itself, with another Logstore, or with an RDS table. This topic describes how to join different Logstores.

Procedure

1. Download the latest version of the SDK for Python.
2. Call the GetProjectLogs operation to query logs.

Sample SDK

```
#! /usr/bin/env python
#encoding: utf-8
import time,sys,os
from aliyun.log.logexception import LogException
from aliyun.log.logitem import LogItem
from aliyun.log.logclient import LogClient
from aliyun.log.getlogsrequest import GetLogsRequest
from aliyun.log.getlogsrequest import GetProjectLogsRequest
from aliyun.log.putlogsrequest import PutLogsRequest
from aliyun.log.listtopicsrequest import ListTopicsRequest
from aliyun.log.listlogstoresrequest import ListLogstoresRequest
from aliyun.log.gethistogramsrequest import GetHistogramsRequest
from aliyun.log.index_config import *
from aliyun.log.logtail_config_detail import *
from aliyun.log.machine_group_detail import *
from aliyun.log.acl_config import *
if __name__=='__main__':
    token = None
    endpoint = "http://cn-hangzhou.log.aliyuncs.com"
    accessKeyId  = 'LTAIvKy7U'
    accessKey='6gXLNTLyCfdsfwrewrfhdskfdsfuiwu'
    client = LogClient(endpoint, accessKeyId, accessKey,token)
    logstore = "meta"
    # In the query statements, specify two Logstores, the query time ranges of both Logstores, and th
e key that you want to use to join the two Logstores.
    req = GetProjectLogsRequest(project,"select count(1) from sls_operation_log  s join  meta m on s.
__date__ >'2018-04-10 00:00:00' and s.__date__ < '2018-04-11 00:00:00' and m.__date__ >'2018-04-23 00
:00:00' and m.__date__ <'2018-04-24 00:00:00' and s.projectid = cast(m.ikey as varchar)");
    res = client.get_project_logs(req)
    res.log_print();
    exit(0)
```

Note For more information about the JOIN syntax and examples, see Join.

28.1.4.8.33. UNNEST function

This topic describes the UNNEST function.

Scenarios

Log data is typically stored as primitive data types, such as string or number. In certain scenarios, log data may include complex data types, such as arrays, maps, and JSON objects. The UNNEST function can be used to transform complex data types into rows of primitive data types. This simplifies query and analysis.

Example:

```
__source__:  1.1.1.1
__tag__:__hostname__:  vm-req-170103232316569850-tianchi111932.tc
__topic__:  TestTopic_4
array_column:  [1,2,3]
double_column:  1.23
map_column:  {"a":1,"b":2}
text_column: Product
```

The values of the `array_column` field are arrays. To obtain the sum of elements of all `array_column` field values, you must traverse all elements of every array.

UNNEST function

Syntax	Description
`unnest( array) as table_alias(column_name)`	Expands an array into multiple rows. The column name of these rows is `column_name`.
`unnest(map) as table(key_name, value_name)`	Expands a map into multiple rows. `key_name` specifies the column name of the keys, and `value_name` specifies the column name of the values.

Note The UNNEST function is used to expand arrays or maps. If you want to expand a string, you must transform the string into a JSON object, and then convert the JSON object into an array or map. To do this, you can use the `cast(json_parse(array_column) as array(bigint))` function.

Traverse every element of an array

Expands an array into multiple rows by using the following SQL SELECT statement:

```
* | select  array_column, a  from log, unnest( cast( json_parse(array_column)  as array(bigint) ) )
as  t(a)
```

The UNNEST function `unnest( cast( json_parse(array_column) as array(bigint) ) ) as t(a)` expands the array into multiple rows. The rows are stored in a derived table referenced as t, with the column referenced as a.

- Calculate the sum of the elements in an array:

  ```
  * | select  sum(a)  from log, unnest( cast( json_parse(array_column)  as array(bigint) ) ) as
  t(a)
  ```

- Perform a GROUP BY operation on all elements of an array:

  ```
  * | select  a, count(1)  from log, unnest( cast( json_parse(array_column)  as array(bigint) )
  ) as  t(a)  group by a
  ```

Traverse every key and value of a map

- Traverse every key and value of a map:

```
* | select  map_column , a,b    from log, unnest( cast( json_parse(map_column)   as map(varchar, bigint) ) ) as  t(a,b)
```

- Perform a GROUP BY operation on all keys of a map:

```
* | select   key,  sum(value)    from log, unnest( cast( json_parse(map_column)   as map(varchar, bigint) ) ) as  t(key,value)    GROUP  BY  key
```

Visualize the query results of the histogram and numeric_histogram functions.

- histogram

  The histogram function works in a similar manner to the count group by syntax. For more information about the histogram function, see Map functions.

  In most cases, the histogram function returns a JSON object. The following is an example:

```
* | select histogram(method)
```

  You can use the UNNEST function to expand JSON data into multiple rows. Then the data can be visualized. The following is an example:

```
* | select  key , value  from( select histogram(method) as his from log) , unnest(his ) as t(key,value)
```

- numeric_histogram

  The numeric_histogram function assigns a column of numeric values into multiple bins. This function is equivalent to a GROUP BY operation that is performed on a numeric value column. For more information about the syntax of the numeric_histogram function, see Approximate functions.

```
* | select numeric_histogram(10,Latency)
```

  Use the following SELECT statement to visualize the result:

```
* |  select key,value from(select numeric_histogram(10,Latency) as his from log) , unnest(his) as t(key,value)
```

28.1.4.9. Machine learning syntax and functions

28.1.4.9.1. Overview

The machine learning feature of Log Service supports multiple algorithms and calling methods. You can use SELECT statements and machine learning functions to analyze the characteristics of a field or fields within a period of time.

Log Service offers multiple time series analysis algorithms to help you implement time series prediction, time series anomaly detection, time series decomposition, and multi-time series clustering. The algorithms are compatible with standard SQL statements. This greatly simplifies the use of the algorithms and improves the troubleshooting efficiency.

Features

- Supports various smooth operations on single-time series data.
- Supports algorithms related to the prediction, anomaly detection, change point detection, inflection point

detection, and multi-period estimation of single-time series data.

- Supports decomposition operations on single-time series data.
- Supports various clustering algorithms of multi-time series data.
- Supports multi-field pattern mining (based on the sequence of numeric data or text).

Limits

- The specified time series data must be sampled based on the same interval.
- The specified time series data cannot contain data repeatedly sampled from the same time point.

Item	Description
Processing capacity of time-series data	Data can be collected from a maximum of 150,000 consecutive time points. If the data volume exceeds the processing capacity, you must aggregate the data or reduce the sampling amount.
Clustering capacity of the density-based clustering algorithm	A maximum of 5,000 time series curves, each of which cannot contain more than 1,440 time points.
Clustering capacity of the hierarchical clustering algorithm	A maximum of 2,000 time series curves, each of which cannot contain more than 1,440 time points.

Machine learning functions

Type	Function	Description
Smooth functions	ts_smooth_simple	Uses the Holt Winters algorithm to smooth time series data.
	ts_smooth_fir	Uses the finite impulse response (FIR) filter to smooth time series data.
	ts_smooth_iir	Uses the infinite impulse response (IIR) filter to smooth time series data.
Multi-period estimation functions	ts_period_detect	Forecasts time series data by period.
Change point detection functions	ts_cp_detect	Finds intervals with different statistical characteristics from time series data. The interval endpoints are change points.
	ts_breakout_detect	Finds the time points when statistics steeply increases or decreases from time series data.
Maximum value detection function	ts_find_peaks	Finds the local maximum value of time series data in a specified window.
	ts_predicate_simple	Uses default parameters to model time series data and performs simple time series prediction and anomaly detection.
	ts_predicate_ar	Uses an autoregressive (AR) model to model time series data and performs simple time series prediction and anomaly detection.

Type	Function	Description
Prediction and anomaly detection functions	ts_predicate_arma	Uses an autoregressive moving average (ARMA) model to model time series data and performs simple time series prediction and anomaly detection.
	ts_predicate_arima	Uses an autoregressive integrated moving average (ARIMA) model to model time series data and performs simple time series prediction and anomaly detection.
	ts_regression_predict	Accurately predicts the trend for a single periodic time series with a certain tendency.
Time series decomposition function	ts_decompose	Uses the Seasonal and Trend decomposition using Loess (STL) algorithm to decompose time series data.
Time series clustering functions	ts_density_cluster	Uses a density-based clustering method to cluster multiple pieces of time series data.
	ts_hierarchical_cluster	Uses a hierarchical clustering method to cluster multiple pieces of time series data.
	ts_similar_instance	Queries curves that are similar to a specified curve.
Frequent pattern statistics function	pattern_stat	Mines representative combinations of attributes among the given multi-attribute field samples to obtain the frequent pattern in statistical patterns.
Differential pattern statistics function	pattern_diff	Finds the pattern that causes differences between two collections under specified conditions.
Root cause analysis function	rca_kpi_search	When a time series metric is abnormal, you can use the root cause analysis function to analyze the dimension attributes that result in the abnormal metric in a timely manner.
Correlation analysis functions	ts_association_analysis	Quickly finds the metrics that are correlated with a specified metric among multiple observed metrics in the system.
ts_similar	Quickly finds the metrics that are correlated with specified time series data among multiple observed metrics in the system.	
Kernel density estimation function	kernel_density_estimation	Uses the smooth peak function to fit the observed data points, thus simulating the real probability distribution curve.

28.1.4.9.2. Smooth functions

This topic describes the smooth functions that you can use to smooth and filter specified time series curves. Filtering is the first step to discover the shapes of time series curves.

Functions

Function	Description
ts_smooth_simple	Uses the Holt-Winters algorithm to filter time series data. This function is the default smooth function.
ts_smooth_fir	Uses a finite impulse response (FIR) filter to filter time series data.
ts_smooth_iir	Uses an infinite impulse response (IIR) filter to filter time series data.

ts_smooth_simple

- Syntax:

```
select ts_smooth_simple(x, y)
```

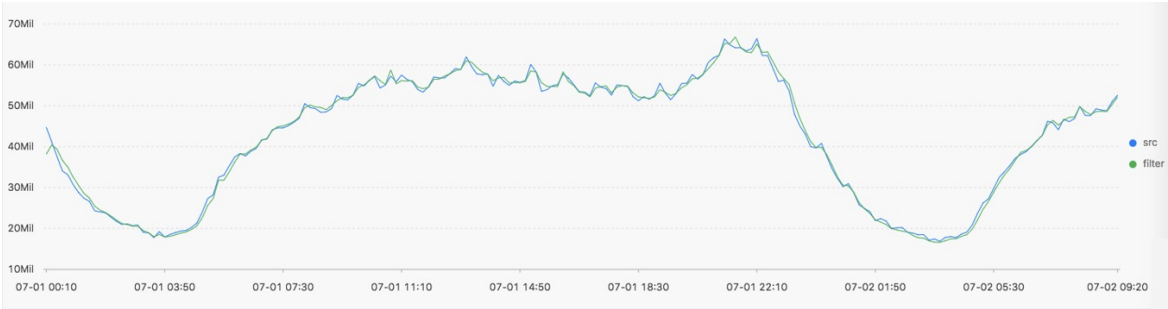
- The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	The Unix timestamp of the time series data. Unit: seconds.
y	The sequence of numeric data at each specified time point.	-

- Example
  - The search and analytic statement is shown as follows:

```
* | select ts_smooth_simple(stamp, value) from ( select __time__ - __time__ % 120 as stamp, avg(
v) as value from log GROUP BY stamp order by stamp )
```

  - The following figure shows the response.



- The following table lists the display items.

Item		Description
Horizontal axis	unixtime	The Unix timestamp of time series data. Unit: seconds.
Vertical axis	src	The unfiltered data.
	filter	The filtered data.

ts_smooth_fir

- Syntax:

- If you cannot determine filter parameters, use built-in window parameters in the following statement:

```
select ts_smooth_fir(x, y,winType,winSize)
```

- If you can determine filter parameters, you can specify the parameters as needed in the following statement:

```
select ts_smooth_fir(x, y,array[])
```

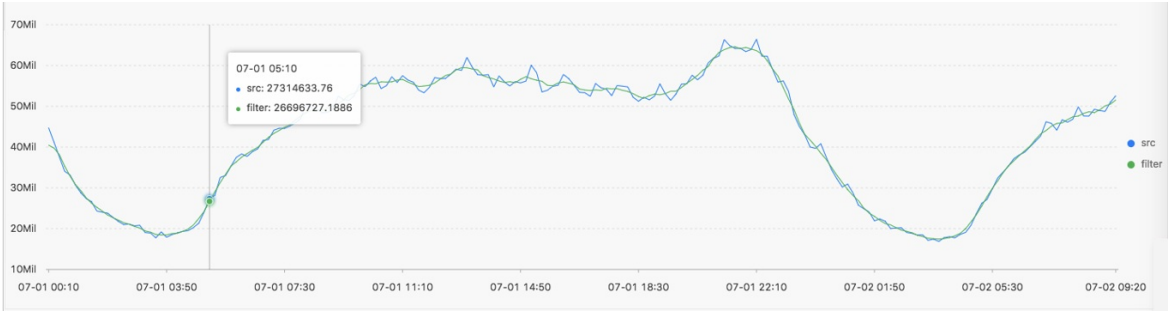
- The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	-
winType	The type of window used for filtering.	Valid values: ○ rectangle: rectangle window. ○ hanning: hanning window ○ hamming: hamming window. ○ blackman: blackman window. **Note** We recommend that you select the rectangle window for better display effects.
winSize	The length of the filtering window.	The value is of the LONG type. Valid values: 2 to 15.
array[]	The parameter used for FIR filtering.	The value is an array where the sum of elements is 1. For example, array[0.2, 0.4, 0.3, 0.1].

- Example 1
  - The search and analytic statement is shown as follows:

```
* | select ts_smooth_fir(stamp, value, 'rectangle', 4) from ( select __time__ - __time__ % 120 a
s stamp, avg(v) as value from log GROUP BY stamp order by stamp )
```

  - The following figure shows the response.

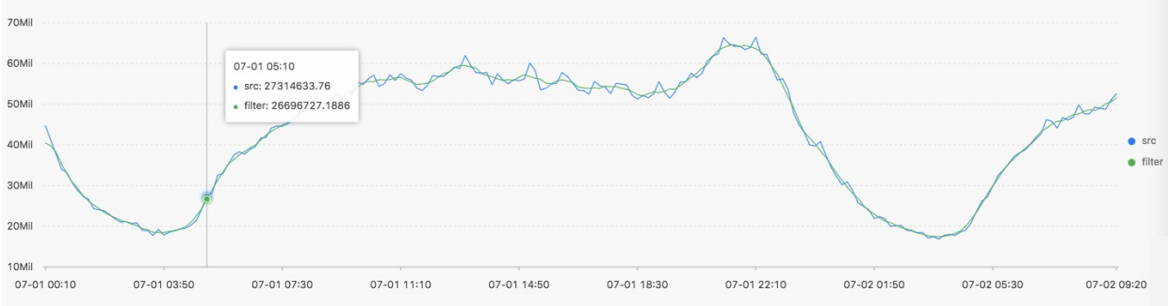


- Example 2

- The search and analytic statement is shown as follows:

```
* | select ts_smooth_fir(stamp, value, array[0.2, 0.4, 0.3, 0.1]) from ( select __time__ - __time__ % 120 as stamp, avg(v) as value from log GROUP BY stamp order by stamp )
```

- The following figure shows the response.



- The following table lists the display items.

Item		Description
Horizontal axis	unixtime	The Unix timestamp of the time series data. Unit: seconds.
Vertical axis	src	The unfiltered data.
	filter	The filtered data.

ts_smooth_iir

- Syntax:

```
select ts_smooth_iir(x, y, array[], array[] )
```

- The following table lists the parameters of the function.

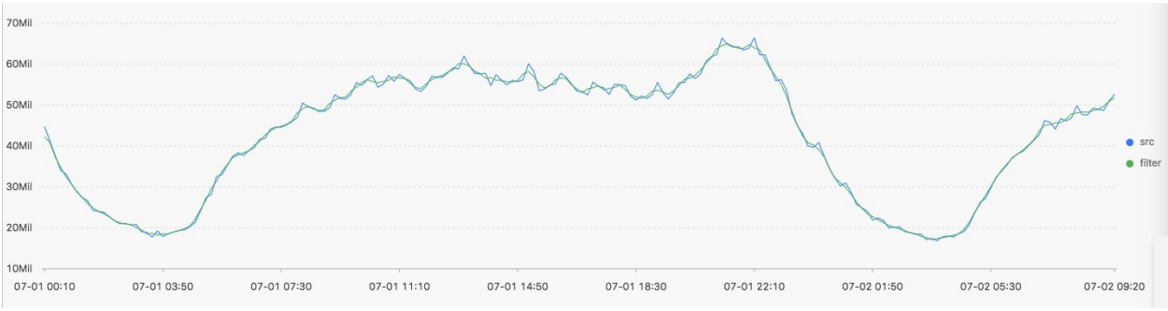
Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	-
array[]	The parameter used for IIR filtering in terms of x_i.	The value is an array where the sum of elements is 1. The length of the array ranges from 2 to 15. For example, array[0.2, 0.4, 0.3, 0.1].
array[]	The parameter used for IIR filtering in terms of y_{i-1}.	The value is an array where the sum of elements is 1. The length of the array ranges from 2 to 15. For example, array[0.2, 0.4, 0.3, 0.1].

- Example

- The search and analytic statement is shown as follows:

```
* | select ts_smooth_iir(stamp, value, array[0.2, 0.4, 0.3, 0.1], array[0.4, 0.3, 0.3]) from ( select __time__ - __time__ % 120 as stamp, avg(v) as value from log GROUP BY stamp order by stamp )
```

- The following figure shows the response.



- The following table lists the display items.

Item		Description
Horizontal axis	unixtime	The Unix timestamp of the time series data. Unit: seconds.
Vertical axis	src	The unfiltered data.
	filter	The filtered data.

28.1.4.9.3. Multi-period estimation functions

This topic describes the multi-period estimation functions that are supported by Log Service. You can use the functions to estimate the periods of time series data in different time intervals. You can also extract the periods by performing a series of operations such as Fourier transform (FT).

Functions

Function	Description
ts_period_detect	Estimates the periods of time series data that is distributed in different time intervals.
ts_period_classify	Uses FT to calculate the periodicity of specified time series curves. This function can be used to identify periodic curves.

ts_period_detect

Syntax:

```
select ts_period_detect(x,y,minPeriod,maxPeriod)
```

The following table lists the parameters of the function.

Parameter	Description	Value

Parameter	Description	Value
x	The time sequence. The points in time along the horizontal axis are sorted in ascending order.	Each point is a UNIX timestamp. Unit: seconds.
y	The sequence of numeric data at each specified point in time.	-
minPeriod	The ratio of the minimum length of the estimated period to the total length of the time series data.	The value must be a decimal number. Value range: (0, 1].
maxPeriod	The ratio of the maximum length of the estimated period to the total length of the time series data. **Note** The value of the *maxPeriod* parameter must be greater than the value of the *minPeriod* parameter.	The parameter value must be a decimal number. Value range: (0, 1].

Example:

- Query statement

```
* | select ts_period_detect(stamp, value, 0.2, 1.0) from ( select __time__ - __time__ % 120 as stamp, avg(v) as value from log GROUP BY stamp order by stamp )
```

- Result

The following table lists the display items.

Display item	Description
period_id	An array with a length of 1. The element in the array indicates the sequence number of the period. The array [0] indicates the original time series curve.
time_series	The sequence of timestamps.
data_series	The sequence of data at each timestamp. • If the value of period_id is 0, the returned data is the original time series data. • If the value of period_id is not 0, the data returned is filtered time series data.

ts_period_classify

Syntax:

```
select ts_period_classify(stamp,value,instanceName)
```

The following table lists the parameters.

Parameter	Description	Value
stamp	The time sequence. The points in time along the horizontal axis are sorted in ascending order.	Each point in time is a UINX timestamp. Unit: seconds.
value	The sequence of numeric data at each specified point in time.	-
instanceName	The name of the time series curve.	-

Example:

- The following query statement is executed:

```
* and h : nu2h05202.nu8 | select ts_period_classify(stamp, value, name) from log
```

- Query result

line_name	prob	type
asg-2z6qjn6zf5ewg188pg5	1.0	-1.0
asg-bp1j8snc92p6v5pptgpj	0.07203669207039314	0.0
asg-wz99hse7u4ubopo5dt9o	0.0	0.0
asg-bp18oqni0gq96vy85te4	0.05590892692207093	0.0

The following table lists the display items.

Display item	Description
line_name	An array with a length of 1. The element in the array indicates the sequence number of the period. The array [0] indicates the original time series curve.
prob	The ratio of the primary period length to the length of the time series curve. Value range: [0, 1]. You can set the value to 0.15 when you perform a test.
type	The type of the curve. Valid values: -1, -2, and 0. • The value -1 indicates that the length of the time series curve is too short (less than 64 points). • The value -2 indicates the time series curve has a high fault rate (the fault rate exceeds 20%). • The value 0 indicates the time series curve is periodic.

28.1.4.9.4. Change point detection functions

This topic describes the change point detection functions in Log Service. You can use the functions to detect the change points in time series data.

The change point detection functions can detect the following two kinds of change points:

- Statistics feature changes within a specified period of time
- Anomalies in time series data

Functions

Function	Description
ts_cp_detect	Finds intervals in which data has different statistics features. The interval endpoints are change points.
ts_breakout_detect	Finds the time points at which data experiences dramatic changes.

ts_cp_detect

Syntax:

- If you cannot specify an appropriate time window size, use the following syntax. The default window size used in the function is 10.

```
select ts_cp_detect(x, y, samplePeriod)
```

- To adjust the effect specific to your business environment, you can specify the minSize parameter in the following function.

```
select ts_cp_detect(x, y, minSize)
```

The following table lists the parameters of the function.

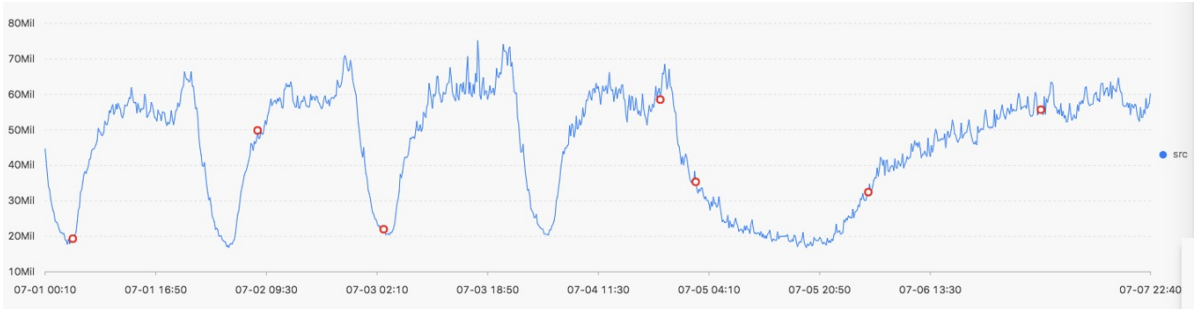
Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	-
minSize	The minimum length of time series data in a continuous interval.	The minimum value is 3 and the maximum value cannot exceed ten percent of the length of the specified time series data.

Example:

- The search and analytic statement is shown as follows:

```
* | select ts_cp_detect(stamp, value, 3) from (select __time__ - __time__ % 10 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

- The following figure shows the response.



The following table lists the display items.

Display item		Description
Horizontal axis	unixtime	The Unix timestamp of time series data, measured in seconds, for example, 1537071480.
Vertical axis	src	The unfiltered data, such as 1956092.7647745228.
	prob	The probability that a time point is a change point. Valid values: 0 to 1.

ts_breakout_detect

Syntax:

```
select ts_breakout_detect(x, y, winSize)
```

The following table lists the parameters of the function.

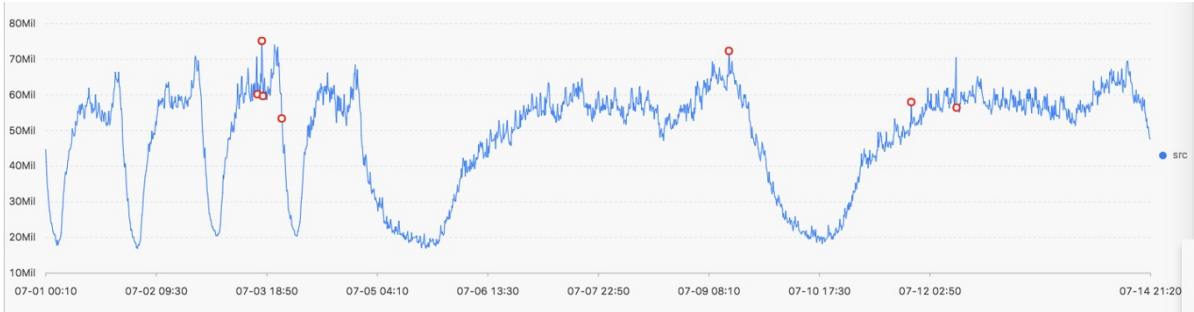
Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	-
winSize	The minimum length of time series data in a continuous interval.	The minimum value is 3 and the maximum value cannot exceed ten percent of the length of the specified time series data.

Example:

- The search and analytic statement is shown as follows:

```
* | select ts_breakout_detect(stamp, value, 3) from (select __time__ - __time__ % 10 as stamp, avg
(v) as value from log GROUP BY stamp order by stamp)
```

- The following figure shows the response.



The following table lists the display items.

Display item		Description
Horizontal axis	unixtime	The Unix timestamp of time series data, measured in seconds, for example, 1537071480.
	src	The unfiltered data, such as 1956092.7647745228.

Vertical axis Display item		Description
	prob	The probability that a time point is a change point. Valid values: 0 to 1.

28.1.4.9.5. Maximum value detection function

This topic describes the available maximum value detection function in Log Service. You can use the functions to find the local maximum value of time series data in a specified window.

ts_find_peaks

Syntax:

```
select ts_find_peaks(x, y, winSize)
```

The following table lists the parameters of the function.

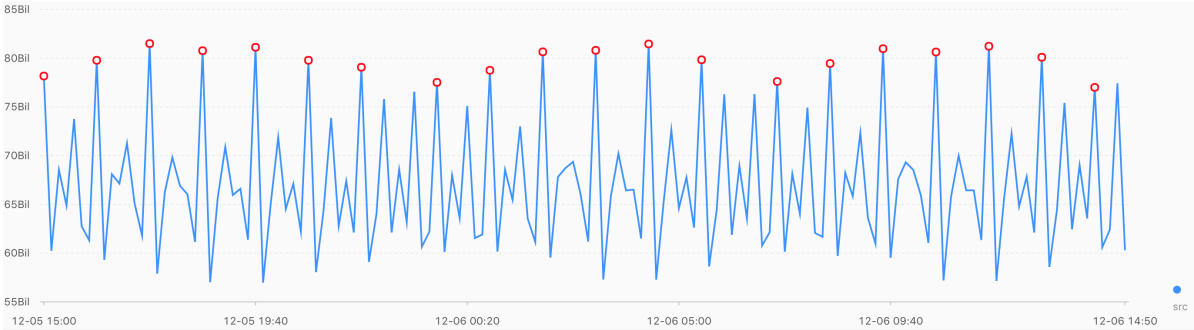
Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	-
winSize	The minimum length of the detection window.	The value of the parameter is of the LONG type, ranging from 1 to the length of time series data. We recommend that you set this parameter to ten percent of the actual data length.

Example:

- The search and analytic statement is shown as follows:

```
* and h : nu2h05202.nu8 and m: NET |  select ts_find_peaks(stamp, value, 30) from (select __time__
- __time__ % 10 as stamp, avg(v) as value from log GROUP  BY  stamp order by stamp)
```

- The following figure shows the response.



The following table lists the display items.

Display item		Description
Horizontal axis	unixtime	The Unix timestamp of time series data, measured in seconds, for example, 1537071480.

Display item		Description
Vertical axis	src	The unfiltered data, such as 1956092.7647745228.
	peak_flag	Indicates whether the numeric value at the time point is the maximum value. Valid values: 1.0 and 0.0. • 1.0: The numeric value at the time point is the maximum value. • 0.0: The numeric value at the time point is not the maximum value.

28.1.4.9.6. Prediction and anomaly detection functions

Prediction and anomaly detection functions predict the trend of time series curves and identify the Ksigma and quantiles of the errors between a predicted curve and an actual curve. You can use the functions to detect anomalies.

Functions

Function	Description
ts_predicate_simple	Uses default parameters to model time series data and performs prediction and anomaly detection on time series data.
ts_predicate_ar	Uses an autoregressive (AR) model to model time series data and performs prediction and anomaly detection on time series data.
ts_predicate_arma	Uses an autoregressive moving average (ARMA) model to model time series data and performs prediction and anomaly detection on time series data.
ts_predicate_arima	Uses an autoregressive integrated moving average (ARIMA) model to model time series data and performs prediction and anomaly detection on time series data.
ts_regression_predict	Accurately predicts the trend for a periodic time series curve. Scenario: This function can be used to predict metering data, network traffic, financial data, and different business data that follows certain rules.
ts_anomaly_filter	Filters the anomalies detected from multiple time series curves based on the custom anomaly mode. The anomalies are detected during the anomaly detection. This function helps you find abnormal curves in a timely manner.

ts_predicate_simple

Syntax:

```
select ts_predicate_simple(x, y, nPred, isSmooth)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.

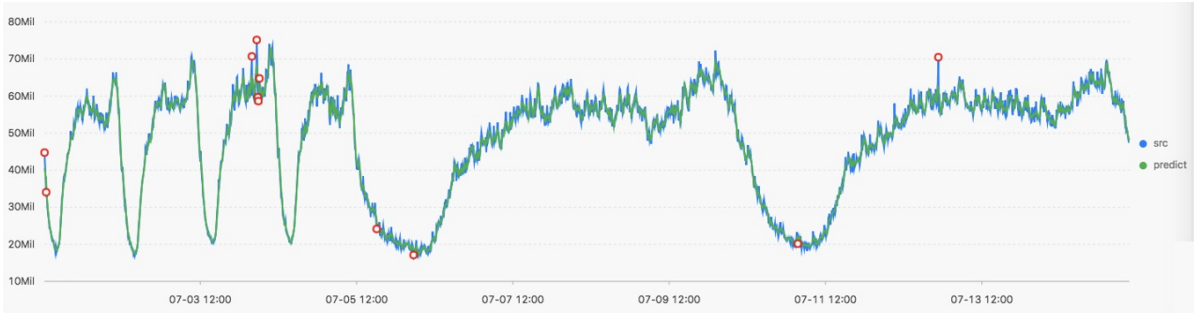
Parameter	Description	Value
y	The sequence of numeric data at each specified time point.	N/A
nPred	The number of points for prediction.	The value is of the LONG data type and must be equal to or greater than 1.
isSmooth	Specifies whether to filter the raw data.	The value is of the Boolean type. The default value is True, which indicates to filter raw data.

Example:

- A search and analytic statement is shown as follows:

```
* | select ts_predicate_simple(stamp, value, 6) from (select __time__ - __time__ % 60 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

- The following figure shows the response.



The following table lists the display items.

Display item		Description
Horizontal axis	unixtime	The Unix timestamp of the data. Unit: seconds.
Vertical axis	src	The raw data.
	predict	The predicted data.
	upper	The upper limit of the prediction. The confidence level is 0.85. This value cannot be modified.
	lower	The lower limit of the prediction. The confidence level is 0.85. This value cannot be modified.
	anomaly_prob	The probability that the point is an anomaly. Valid values: [0, 1].

ts_predicate_ar

Syntax:

```
select ts_predicate_ar(x, y, p, nPred, isSmooth)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	N/A
p	The order of the AR model.	The value is of the LONG data type. Valid values: [2, 8].
nPred	The number of points for prediction.	The value is of the LONG data type. Valid values: [1, 5 × *p*].
isSmooth	Specifies whether to filter the raw data.	The value is of the Boolean type. The default value is true, which indicates to filter raw data.

An example search and analytic statement is shown as follows:

```
* | select ts_predicate_ar(stamp, value, 3, 4) from (select __time__ - __time__ % 60 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

Note The response is similar to that of the ts_predicate_simple function. For more information, see the response of the ts_predicate_simple function.

ts_predicate_arma

Syntax:

```
select ts_predicate_arma(x, y, p, q, nPred, isSmooth)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	N/A
p	The order of the AR model.	The value is of the LONG data type. Valid values: [2, 100].
q	The order of the ARMA model.	The value is of the LONG data type. Valid values: [2, 8].
nPred	The number of points for prediction.	The value is of the LONG data type. Valid values: [*p*, 5p].
isSmooth	Specifies whether to filter the raw data.	The value is of the Boolean type. The default value is true, which indicates to filter raw data.

An example search and analytic statement is shown as follows:

```
* | select ts_predicate_arma(stamp, value, 3, 2, 4) from (select __time__ - __time__ % 60 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

Note The response is similar to that of the ts_predicate_simple function. For more information, see the response of the ts_predicate_simple function.

ts_predicate_arima

Syntax:

```
select ts_predicate_arima(x,y, p, d, q, nPred, isSmooth)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	N/A
p	The order of the AR model.	The value is of the LONG data type. Valid values: [2, 8].
d	The order of the ARIMA model.	The value is of the LONG data type. Valid values: [1, 3].
q	The order of the ARMA model.	The value is of the LONG data type. Valid values: [2, 8].
nPred	The number of points for prediction.	The value is of the LONG type. Valid values: [*p*, 5p].
isSmooth	Specifies whether to filter the raw data.	The value is of the Boolean type. The default value is True, which indicates to filter raw data.

An example search and analytic statement is shown as follows:

```
* | select ts_predicate_arima(stamp, value, 3, 1, 2, 4) from (select __time__ - __time__ % 60 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

Note The response is similar to that of the ts_predicate_simple function. For more information, see the response of the ts_predicate_simple function.

ts_regression_predict

Syntax:

```
select ts_regression_predict(x, y, nPred, algotype,processType)
```

The following table lists the parameters of the function.

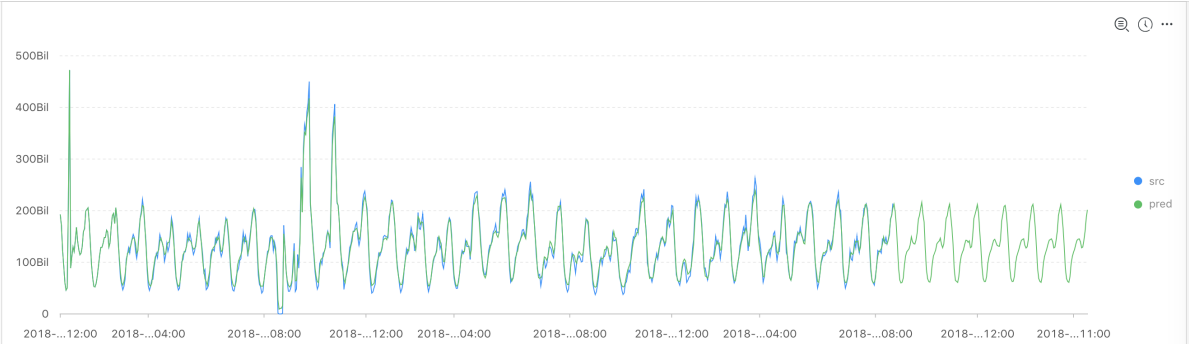
Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	N/A
nPred	The number of points for prediction.	The value is of the LONG data type. Valid values: [1, 500].
algotype	The algorithm type for prediction.	Valid values: • origin: uses the Gradient Boosted Regression Tree (GBRT) algorithm for prediction. • forest: uses the GBRT algorithm for prediction based on the trend component decomposed by Seasonal and Trend decomposition using Loess (STL), and then uses the additive model to sum up the decomposed components and obtains the predicted data. • linear: uses the Linear Regression algorithm for prediction based on the trend components decomposed by STL, and then uses the additive model to sum up the decomposed components and obtains the predicted data.
processType	Specifies whether to preprocess the data.	Valid values: • 0: no additional data preprocessing is performed. • 1: removes abnormal data before prediction.

Example:

- A search and analytic statement is shown as follows:

```
* and h : nu2h05202.nu8 and m: NET |  select ts_regression_predict(stamp, value, 200, 'origin') fr
om (select __time__ - __time__ % 60 as stamp, avg(v) as value from log GROUP  BY  stamp order by s
tamp)
```

- The following figure shows the response.



The following table lists the display items.

Display item		Description
Horizontal axis	unixtime	The Unix timestamp of the data. Unit: seconds.

Display item		Description
Vertical axis	src	The raw data.
	predict	The predicted data.

ts_anomaly_filter

Syntax:

```
select ts_anomaly_filter(lineName, ts, ds, preds, probs, nWatch, anomalyType)
```

The following table lists the parameters of the function.

Parameter	Description	Value
lineName	The name of each curve. The value is of the VARCHAR data type.	N/A
ts	The time sequence of the curve, which indicates the time of the current curve. The parameter value is an array of time points of the DOUBLE data type sorted in the ascending order.	N/A
ds	The actual value sequence of the curve. The parameter value is an array of data points with the same length as the ts parameter value.	N/A
preds	The predicted value sequence of the curve. The parameter value is an array of data points with the same length as the ts parameter value.	N/A
probs	The sequence of anomaly detection results of the curve. The parameter value is an array of data points with the same length as the ts parameter value.	N/A
nWatch	The number of the recently observed actual values on the curve. The value is of the LONG data type. The value must be smaller than the number of time points on the curve.	N/A
anomalyType	The type of anomaly to be filtered. The value is of the LONG data type.	Valid values: • 0: all anomalies. • 1: positive anomalies. • -1: negative anomalies.

Example:

- A search and analytic statement is shown as follows:

```
* | select res.name, res.ts, res.ds, res.preds, res.probs
     from (
         select ts_anomaly_filter(name, ts, ds, preds, probs, cast(5 as bigint), cast(1 as bigint)
) as res
       from (
         select name, res[1] as ts, res[2] as ds, res[3] as preds, res[4] as uppers, res[5] as low
ers, res[6] as probs
     from (
         select name, array_transpose(ts_predicate_ar(stamp, value, 10)) as res
         from (
           select name, stamp, value from log where name like '%asg-%') group by name)) );
```

- The following figure shows the response.

```
| name                     | ts                                                                | ds          |
preds     | probs       |
| ------------------------ | ----------------------------------------------------------------- | ----------- |
--------- | ----------- |
| asg-bp1hylzdi2wx7civ0ivk | [1.5513696E9, 1.5513732E9, 1.5513768E9, 1.5513804E9] | [1,2,3,NaN] |
[1,2,3,4] | [0,0,1,NaN] |
```

28.1.4.9.7. Time series decomposition function

The time series decomposition function decomposes time series curves into curves that reveal the trend and periodicity of curves.

ts_decompose

Syntax:

```
select ts_decompose(x, y)
```

The following table lists the parameters of the function.

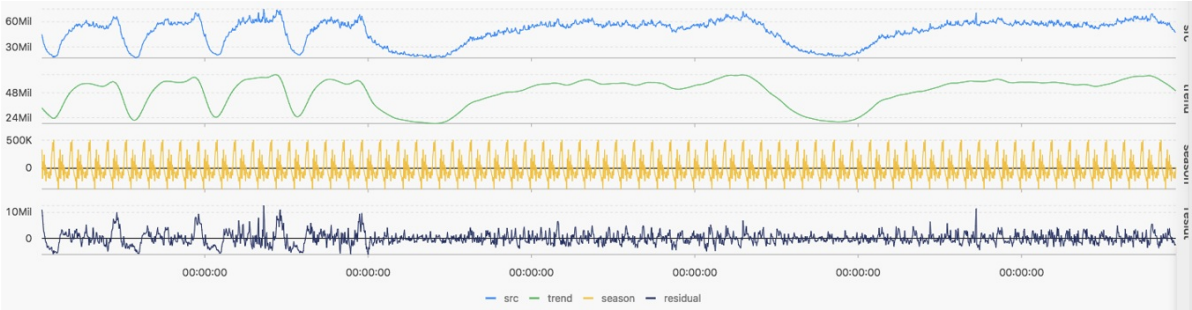
Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	N/A

Example:

- A search and analytic statement is shown as follows:

```
* | select ts_decompose(stamp, value) from (select __time__ - __time__ % 60 as stamp, avg(v) as va
lue from log GROUP BY stamp order by stamp)
```

- The following figure shows the response.



The following table lists the display items.

Display item		Description
Horizontal axis	unixtime	The Unix timestamp of the data. Unit: seconds.
Vertical axis	src	The raw time series data.
	trend	The decomposed data that indicates the trend of the time series data.
	season	The decomposed data that indicates the periodicity of the time series data.
	residual	The residual data decomposed from the time series data.

28.1.4.9.8. Time series clustering functions

You can use time series clustering functions to cluster multiple time series and obtain different curve shapes. Then, you can find the cluster center and identify curves with shapes that are different from other curve shapes in the cluster in a timely manner.

Functions

Function	Description
ts_density_cluster	Uses a density-based clustering method to cluster multiple time series.
ts_hierarchical_cluster	Uses a hierarchical clustering method to cluster multiple time series.
ts_similar_instance	Queries time series curves that are similar to a specified time series curve.

ts_density_cluster

Syntax:

```
select ts_density_cluster(x, y, z)
```

The following table lists the parameters of the function.

Parameter	Description	Value

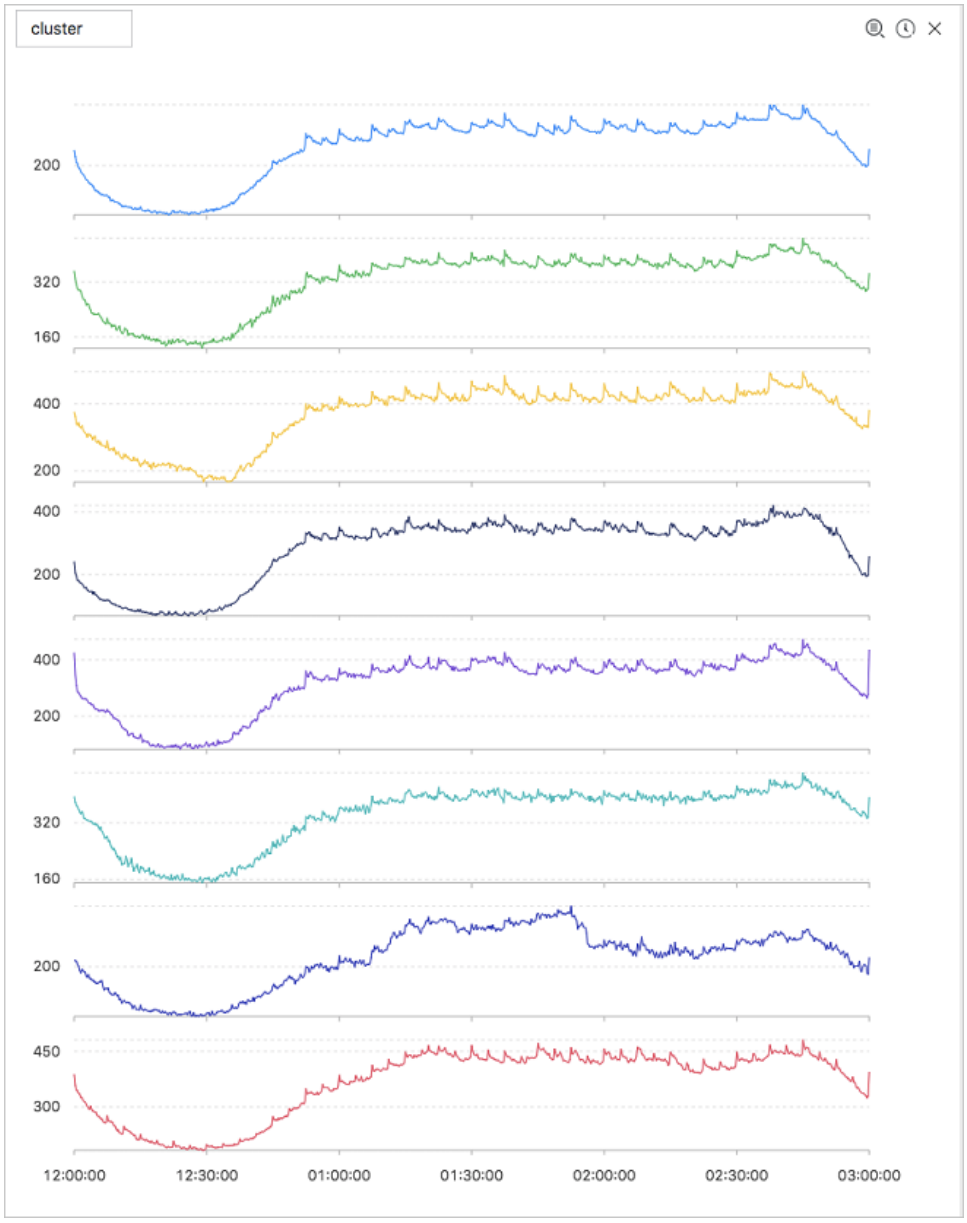
Parameter	Description	Value
x	The time sequence. The points in time along the horizontal axis are sorted in ascending order.	Each point in time is a UNIX timestamp. Unit: seconds.
y	The sequence of numeric data that corresponds to a specified point in time.	-
z	The name of the curve corresponding to the data at a specified point in time.	The value is of the string type, for example, machine01.cpu_usr.

Example

- The query statement:

```
* and (h: "machine_01" OR h: "machine_02" OR h : "machine_03") | select ts_density_cluster(stamp, metric_value,metric_name ) from ( select __time__ - __time__ % 600 as stamp, avg(v) as metric_value, h as metric_name from log GROUP BY stamp, metric_name order BY metric_name, stamp )
```

- Output result



The following table lists the display items.

Display item	Description
cluster_id	The category of the cluster. The value -1 indicates that the cluster is not categorized in any cluster center.
rate	The proportion of instances in the cluster.
time_series	The timestamp sequence of the cluster center.
data_series	The data sequence of the cluster center.
instance_names	The instances that are included in the cluster center.
sim_instance	The name of an instance in the cluster.

ts_hierarchical_cluster

Syntax:

```
select ts_hierarchical_cluster(x, y, z)
```

The following table lists the parameters of the function.

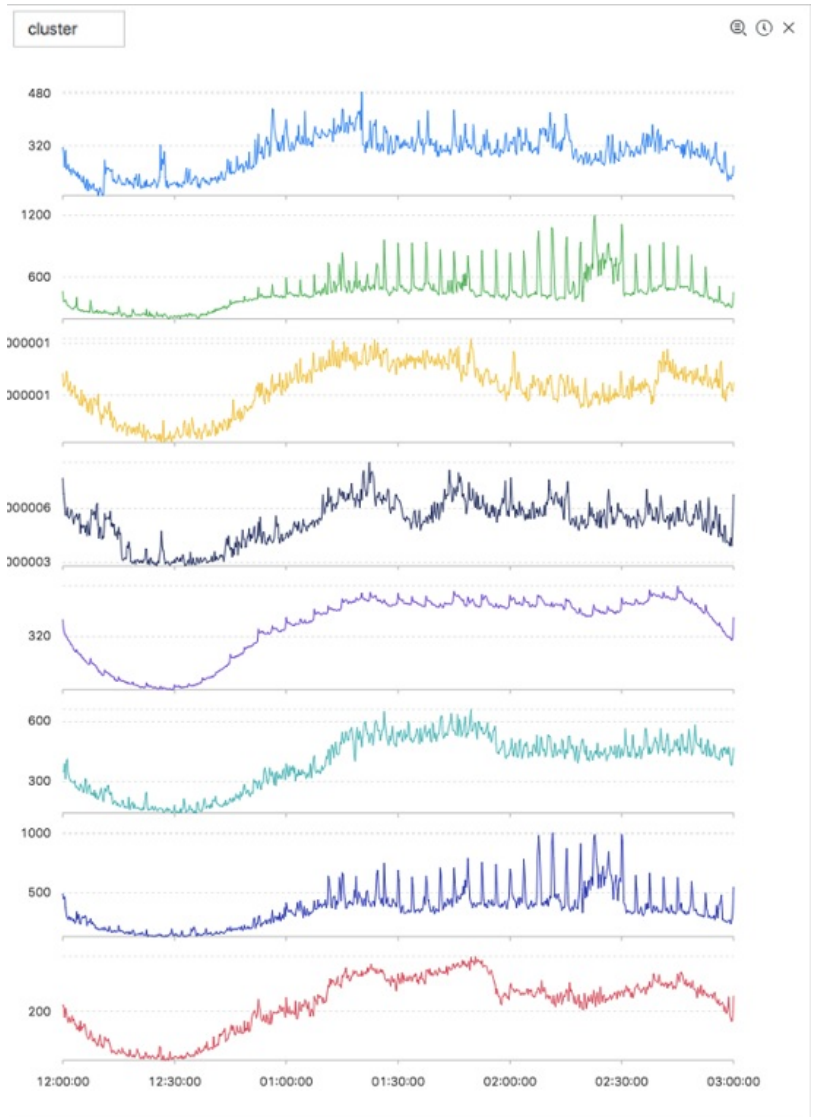
Parameter	Description	Value
x	The time sequence. The points in time along the horizontal axis are sorted in ascending order.	Each point in time is a UNIX timestamp. Unit: seconds.
y	The sequence of numeric data that corresponds to a specified point in time.	-
z	The name of the curve corresponding to the data at a specified point in time.	The value is of the string type, for example, machine01.cpu_usr.

Examples

- The query statement:

```
* and (h: "machine_01" OR h: "machine_02" OR h : "machine_03") | select ts_hierarchical_cluster(stamp, metric_value, metric_name) from ( select __time__ - __time__ % 600 as stamp, avg(v) as metric_value, h as metric_name from log GROUP BY stamp, metric_name order BY metric_name, stamp )
```

- Output result



The following table lists the display items.

Display item	Description
cluster_id	The category of the cluster. The value -1 indicates that the cluster is not categorized in any cluster center.
rate	The proportion of instances in the cluster.
time_series	The timestamp sequence of the cluster center.
data_series	The data sequence of the cluster center.
instance_names	The instances that are included in the cluster center.
sim_instance	The name of an instance in the cluster.

ts_similar_instance

Syntax:

```
select ts_similar_instance(x, y, z, instance_name, topK, metricType)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The points in time along the horizontal axis are sorted in ascending order.	Each point in time is a UNIX timestamp. Unit: seconds.
y	The sequence of numeric data that corresponds to a specified point in time.	-
z	The name of the curve corresponding to the data at a specified point in time.	The value is of the string type, for example, machine01.cpu_usr.
instance_name	The name of a specified curve to be queried.	The value is of the string type, for example, machine01.cpu_usr. **Note** The curve to be queried must be an existing one.
topK	The maximum number of curves that are similar to the specified curve can be returned.	-
metricType	`{'shape', 'manhattan', 'euclidean'}`. The metric used to measure the similarity between time series curves.	-

The query statement:

```
* and m: NET and m: Tcp and (h: "nu4e01524.nu8" OR  h: "nu2i10267.nu8" OR  h : "nu4q10466.nu8") | sel
ect ts_similar_instance(stamp, metric_value, metric_name, 'nu4e01524.nu8' ) from ( select __time__ -
__time__ % 600 as stamp, sum(v) as metric_value, h as metric_name from log GROUP BY stamp, metric_nam
e order BY  metric_name, stamp )
```

The following table lists the display items.

Display item	Description
instance_name	The list of metrics that are similar to the specified metric.
time_series	The timestamp sequence of the cluster center.
data_series	The data sequence of the cluster center.

28.1.4.9.9. Frequent pattern statistics function

The frequent pattern statistics function combines representative attributes in a specified multi-attribute field sample.

pattern_stat

Syntax:

```
select pattern_stat(array[col1, col2, col3], array['col1_name', 'col2_name', 'col3_name'], array[col5
, col6], array['col5_name', 'col6_name'], support_score, sample_ratio)
```

The following table lists the parameters of the function.

Parameter	Description	Value
array[col1, col2, col3]	A column of character values.	An array of values, for example, array[clientIP, sourceIP, path, logstore].
array['col1_name', 'col2_name', 'col3_name']	The field names of the character values.	An array of field names, for example, array['clientIP', 'sourceIP', 'path', 'logstore'].
array[col5, col6]	A column of numeric values.	An array of values, for example, array[Inflow, OutFlow].
array['col5_name', 'col6_name']	The field names of the numeric values.	An array of field names, for example, array['Inflow', 'OutFlow'].
support_score	The support ratio of samples for pattern mining.	The value is of the DOUBLE data type. Value range: (0,1].
sample_ratio	The sampling ratio. The default value is 0.1, which indicates that only 10% of the total samples are used.	The value is of the DOUBLE data type. Value range: (0,1].

Example:

- Query statement

```
* | select pattern_stat(array[ Category, ClientIP, ProjectName, LogStore, Method, Source, UserAgent ], array[ 'Category', 'ClientIP', 'ProjectName', 'LogStore', 'Method', 'Source', 'UserAgent' ], array[ InFlow, OutFlow ], array[ 'InFlow', 'OutFlow' ], 0.45, 0.3) limit 1000
```

- Display item

Display item	Description
count	The number of samples in the current pattern.
support_score	The score of the current pattern. The score indicates the degree to which the current pattern is supported.
pattern	The content of the pattern. The pattern is organized in the format that is defined by the query conditions.

28.1.4.9.10. Differential pattern statistics function

The differential pattern statistics function analyzes differential patterns of specified multi-field samples based on the specified condition. It helps you identify the causes of the differences under the current condition in a timely manner.

pattern_diff

Syntax:

```
select pattern_diff(array_char_value, array_char_name, array_numeric_value, array_numeric_name, condition, supportScore,posSampleRatio,negSampleRatio )
```

The following table lists the parameters of the function.

Parameter	Description	Value
array_char_value	A column of values of the character data type.	An array of values, for example, array[clientIP, sourceIP, path, logstore].
array_char_name	The field names of the values of the character data type.	An array of field names, for example, array['clientIP', 'sourceIP', 'path', 'logstore'].
array_numeric_value	A column of values of the numeric data type.	An array of values, for example, array[Inflow, OutFlow].
array_numeric_name	The field names of the values of the numeric data type.	An array of field names, for example, array[originflow', 'OutFlow'].
condition	The condition for filtering data. The value True indicates positive samples, and the value False indicates negative samples.	For example, Latency <= 300.
supportScore	The support ratio of positive and negative samples for pattern mining.	The value is of the DOUBLE data type. Valid values: (0,1].
posSampleRatio	The sampling ratio of positive samples. The default value is 0.5, indicating that 50% of positive samples are collected.	The value is of the DOUBLE data type. Valid values: (0,1].
negSampleRatio	The sampling ratio of negative samples. The default value is 0.5, indicating that 50% of positive samples are collected.	The value is of the DOUBLE data type. Valid values: (0,1].

Example:

- A search and analytic statement is shown as follows:

```
* | select pattern_diff(array[ Category, ClientIP, ProjectName, LogStore, Method, Source, UserAgent ], array[ 'Category', 'ClientIP', 'ProjectName', 'LogStore', 'Method', 'Source', 'UserAgent' ], array[ InFlow, OutFlow ], array[ 'InFlow', 'OutFlow' ], Latency > 300, 0.2, 0.1, 1.0) limit 1000
```

- Display item

Display item	Description
possupport	The support ratio of positive samples for the mined patterns.
posconfidence	The confidence level of the mined patterns in positive samples.
negsupport	The support ratio of negative samples for the mined patterns.
diffpattern	The content of the mined patterns.

28.1.4.9.11. Root cause analysis function

Log Service provides the alert and analytics features that help you quickly analyze data and locate anomalies of specific subdimensions of a metric. You can use the root cause analysis function to analyze the subdimension attributes that result in anomalies of the monitoring metric.

rca_kpi_search

Syntax

```
select rca_kpi_search(varchar_array, name_array, real, forecast, level)
```

The following table lists the parameters of the function.

Parameter	Description	Value
varchar_array	The subdimension attributes.	The parameter value is formatted in an array, for example, array[col1, col2, col3].
name_array	The subdimension attribute names.	The parameter value is formatted in an array, for example, array['col1', 'col2', 'col3'].
real	The actual value of each subdimension attribute specified by the varchar_array parameter.	The parameter value is of the DOUBLE data type. Valid values: all real numbers.
forecast	The predicted value of each subdimension attribute specified by the varchar_array parameter.	The parameter value is of the DOUBLE data type. Valid values: all real numbers.
level	The number of subdimension attributes identified in the returned root cause set. The value 0 indicates that all root causes that are found are returned.	The parameter value is of the LONG data type. Valid values: [0, number of analyzed subdimensions]. The number of analyzed subdimensions is the length of the array specified by the varchar_array parameter.

Example:

- The search and analytic statement is shown as follows:

  Use a subquery to obtain the actual value and predicted value of each subdimension attribute, and then call the rca_kpi_search function to analyze the root causes of anomalies.

```
* not Status:200 |
select rca_kpi_search(
 array[ ProjectName, LogStore, UserAgent, Method ],
 array[ 'ProjectName', 'LogStore', 'UserAgent', 'Method' ], real, forecast, 1)
from (
select ProjectName, LogStore, UserAgent, Method,
 sum(case when time < 1552436040 then real else 0 end) * 1.0 / sum(case when time < 1552436040
then 1 else 0 end) as forecast,
 sum(case when time >=1552436040 then real else 0 end) *1.0 / sum(case when time >= 1552436040
then 1 else 0 end) as real
 from (
select __time__ - __time__ % 60 as time, ProjectName, LogStore, UserAgent, Method, COUNT(*) as rea
l
from log GROUP by time, ProjectName, LogStore, UserAgent, Method )
GROUP BY ProjectName, LogStore, UserAgent, Method limit 100000000)
```

- The following figure shows the response.

The following figure shows the structured response.

```
{
  "rcSets": [
    {
      "rcItems": [
        {
          "kpi": [("attr": "xxx", "val": "xxx")],
          "nleaf": 100,
          "change": 0.524543,
          "score": 0.1454543
        }
      ]
    }
  ]
}
```

The following table lists the display items.

Display item	Description
rcSets	The root cause sets. Each value of this parameter is an array.
rcItems	A specific root cause set.
kpi	A specific item in the root cause set. Each item is formatted in an array where each element is a JSON object. The attr parameter indicates the subdimension name, and the val parameter indicates the attribute name under the subdimension.
nleaf	The number of leaf nodes that an item (KPI) in the root cause set covers in the original data. **Note** Leaf node: the log entry that contains the finest-grained attribute information.
change	The ratio of anomalies of leaf nodes in a KPI to the total anomalies in the root cause set that occurred at the same time point.
score	The abnormality score of the current KPI. Valid values: [0, 1].

The response is formatted in a JSON object as follows:

```
{
  "rcSets": [
  {
    "rcItems": [
    {
      "kpi": [
      {
        "attr": "country",
        "val": "*"
      },
      {
        "attr": "province",
        "val": "*"
      },
      {
        "attr": "provider",
        "val": "*"
      },
      {
        "attr": "domain",
        "val": "download.huya.com"
      },
      {
        "attr": "method",
        "val": "*"
      }
      ],
      "nleaf": 119,
      "change": 0.3180687806279939,
      "score": 0.14436007709620113
    }
    ]
  }
  ]
}
```

28.1.4.9.12. Correlation analysis functions

You can use a correlation analysis function to find the metrics that are correlated with a specified metric or time series data among multiple observed metrics in the system.

Functions

Function	Description
ts_association_analysis	Quickly finds the metrics that are correlated with a specified metric among multiple observed metrics in the system.
ts_similar	Quickly finds the metrics that are correlated with specified time series data among multiple observed metrics in the system.

ts_association_analysis

Syntax

```
select ts_association_analysis(stamp, params, names, indexName, threshold)
```

The following table lists the parameters of the function.

Parameter	Description	Value
stamp	The Unix timestamp of the LONG data type.	-
params	The metrics to be analyzed, formatted in an array where each element is of the DOUBLE data type.	The parameter value is formatted in an array where each element is of the DOUBLE data type. For example, Latency, QPS, and NetFlow.
names	The names of the metrics to be analyzed.	The parameter value is formatted in an array where each element is of the VARCHAR data type. For example, Latency, QPS, and NetFlow.
indexName	The name of the target metric.	The parameter value is of the VARCHAR data type, for example, Latency.
threshold	The threshold of correlation between the metrics to be analyzed and the target metric.	The parameter value is of the DOUBLE data type. Valid values: [0, 1].

Response

- name: the name of the metric that meets the specified correlation condition with the target metric.
- score: the value of correlation between the returned metric and the target metric. Valid values: [0, 1].

Sample statement

```
* | select ts_association_analysis(
              time,
              array[inflow, outflow, latency, status],
              array['inflow', 'outflow', 'latency', 'status'],
              'latency',
              0.1) from log;
```

Sample response

```
| results               |
| --------------------- |
| ['latency', '1.0']    |
| ['outflow', '0.6265'] |
| ['status', '0.2270']  |
```

ts_similar

Syntax 1

```
select ts_similar(stamp, value, ts, ds)
select ts_similar(stamp, value, ts, ds, metricType)
```

The following table lists the parameters of the function.

Parameter	Description	Value
stamp	The Unix timestamp of the LONG data type.	-
value	The value of the metric to be analyzed. The parameter value is of the DOUBLE data type.	-
ts	The time sequence of the specified time series curve. The parameter value is formatted in an array where each element is of the DOUBLE data type.	-
ds	The sequence of numeric data of the specified time series curve.	-
metricType	The type of correlation between the measured curves. The parameter value is of the VARCHAR data type.	Valid values: SHAPE, RMSE, PEARSON, SPEARMAN, R2, and KENDALL

Syntax 2

```
select ts_similar(stamp, value, startStamp, endStamp, step, ds)
select ts_similar(stamp, value, startStamp, endStamp, step, ds, metricType )
```

The following table lists the parameters of the function.

Parameter	Description	Value
stamp	The Unix timestamp of the LONG data type.	-
value	The value of the metric to be analyzed. This parameter is of the DOUBLE data type.	-
startStamp	The start timestamp of the specified time series curve. The parameter value is of the LONG data type.	-
endStamp	The end timestamp of the specified time series curve. The parameter value is of the LONG data type.	-
step	The time interval between two adjacent data points in a time series. The parameter value is of the LONG data type.	-
ds	The sequence of numeric data of the specified time series curve. The parameter is formatted in an array where each element is of the DOUBLE data type.	-

Parameter	Description	Value
metricType	The type of correlation between the measured curves. The parameter value is of the VARCHAR data type.	Valid values: SHAPE, RMSE, PEARSON, SPEARMAN, R2, and KENDALL

- Response

  score: the correlation between the analyzed metric and the specified time series curve. Valid values: [-1, 1].

- Sample statement

```
* | select vhost, metric, ts_similar(time, value, 1560911040, 1560911065, 5, array[5.1,4.0,3.3,5.6
,4.0,7.2], 'PEARSON') from log  group by vhost, metric;
```

- Sample response

```
| vhost  | metric          | score               |
| ------ | --------------- | ------------------- |
| vhost1 | redolog         | -0.3519082537204182  |
| vhost1 | kv_qps          | -0.15922168009772697 |
| vhost1 | file_meta_write | NaN                 |
```

28.1.4.9.13. Kernel density estimation function

Kernel density estimation (KDE) is a non-parametric way to estimate the probability density function of a random variable.

The Kernel density estimation function uses the smooth peak function to fit the observed data points. In this way, the function simulates the real probability distribution curve.

- Syntax

```
select kernel_density_estimation(bigint stamp, double value, varchar kernelType)
```

- Parameters

Parameter	Description
stamp	The Unix timestamp of observed data. Unit: second.
value	The observed value.
kernelType	○ box: rectangle window. ○ epanechniov: Epanechnikov curve. ○ gausener: Gaussian curve.

- Response

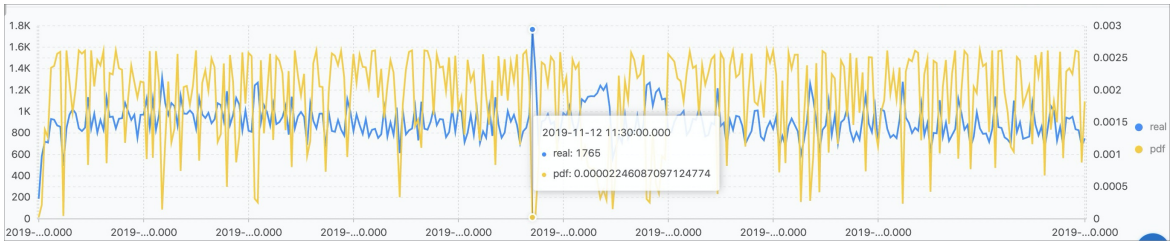
Display item	Description
unixtime	The Unix timestamp of observed data.
real	The observed value.
pdf	The probability of each observed data point.

- Example

- Sample statement

```
* |
select
    date_trunc('second', cast(t1[1] as bigint)) as time, t1[2] as real, t1[3] as pdf from (
        select kernel_density_estimation(time, num, 'gaussian') as res from (
            select __time__ - __time__ % 10 as time, COUNT(*) * 1.0 as num from log group by tim
e order by time)
        ), unnest(res) as t(t1)  limit 1000
```

- Response



28.1.4.10. Advanced analysis

28.1.4.10.1. Optimize queries

This topic describes how to optimize queries to improve query efficiency.

You can use the following methods to optimize queries:

- Increase the number of shards.
- Reduce the query time range and data volume.
- Repeat queries multiple times.
- Optimize the SQL statement for queries.

Increase the number of shards

More shards represent more computing resources and faster computing speed. You can increase the number of shards to ensure that the average number of log entries to be scanned in each shard does not exceed 50 million. You can increase the number of shards by splitting shards. For more information, see Split a shard.

> **Note** Splitting shards incurs more fees and only accelerates queries of new data. Existing data is still stored in old shards.

Reduce the query time range and data volume

- The larger the time range, the slower the query. If you query data within a year or a month, data is computed by day. To facilitate computing, you can reduce the query time range.
- The larger the data volume, the slower the query. Reduce the amount of data to be queried as much as possible.

Repeat queries multiple times

If you find that the result of a query is inaccurate, you can repeat the query multiple times. The underlying acceleration mechanism ensures that each query uses the previous query result to analyze data. In this way, multiple queries make the query result more accurate.

Optimize the SQL statement for queries

A time-consuming query statement has the following characteristics:

- Performs the GROUP BY operation on string-type columns.
- Performs the GROUP BY operation on more than five fields.
- Includes operations that generates strings.

You can use the following methods to optimize a query statement:

- Avoid operations that generate strings if possible.
  - If you use the date_format function to generate a formatted timestamp, the query is inefficient.

    ```
    * | select date_format(from_unixtime(__time__) , '%H_%i') as t, count(1) group by t
    ```

  - If you use the substr() function, strings are generated. We recommend that you use the date_trunc or time_series function in a query statement.
- Avoid performing the GROUP BY operation on string-formatted columns if possible.

  Performing the GROUP BY operation on strings may result in a large number of hash calculations, which account for more than 50% of total calculations. Examples:

  ```
  * | select count(1) as pv , date_trunc('hour',__time__) as time group by time
  * | select count(1) as pv , from_unixtime(__time__-__time__%3600) as time group by __time__-__time__%3600
  ```

  Both query 1 and query 2 count the number of log entries per hour. However, query 1 converts the time into a string, for example, 2017-12-12 00:00:00, and then performs the GROUP BY operation on this string. Query 2 calculates the on-the-hour time value, performs the GROUP BY operation on the result, and then converts the value into a string. Query 1 is less efficient than query 2 because query 1 needs to hash strings.
- List fields alphabetically based on the initial letter when performing the GROUP BY operation on multiple columns.

  For example, you need to query 100 million users who are from 13 provinces.

  ```
  Fast: * | select province,uid,count(1)groupby province,uid
  Slow: * | select province,uid,count(1)groupby uid,province
  ```

- Use estimating functions.

  Estimating functions provide stronger performance than accurate calculation. In estimation, accuracy is compromised to an acceptable extent for fast calculation.

  ```
  Fast: * |select approx_distinct(ip)
  Slow: * | select count(distinct(ip))
  ```

- Specify only required columns in the SQL statement if possible.

  You can specify all columns in the search statement. In the SQL statement, specify only required columns if possible. This will speed up calculation.

  ```
  Fast: * |select a,b c
  Slow: * |select *
  ```

- Place columns that do not need to be grouped in an aggregate function if possible.

  For example, a user ID is associated with a username. Therefore, you can execute the Group By operation on user IDs to analyze data.

  ```
  Fast: * | select userid, arbitrary(username), count(1)groupby userid
  Slow: * | select userid, username, count(1)groupby userid,username
  ```

- Avoid using the IN operator if possible.

If possible, avoid using the IN clause in SQL statements. Instead, use the OR clause.

```
Fast: key : a or key :b or key:c | select count(1)
Slow: * | select count(1) where key in ('a','b')
```

28.1.4.10.2. Use cases

This topic provides some use cases of log data analysis.

Trigger an alert when the error rate exceeds 40% over the last 5 minutes

Calculate the percentage of 500 Internal Server Error every minute. An alert is triggered when the error rate exceeds 40% over the last 5 minutes.

```
status:500 | select __topic__, max_by(error_count,window_time)/1.0/sum(error_count) as error_ratio, sum(error_count) as total_error  from (
select __topic__, count(*) as error_count , __time__ - __time__ % 300  as window_time  from log group by __topic__, window_time
)
group by __topic__  having  max_by(error_count,window_time)/1.0/sum(error_count)   > 0.4  and sum(error_count) > 500 order by total_error desc limit 100
```

Calculate the amount of transferred data and configure alerts

Calculate the amount of transferred data every minute. An alert is triggered when transferred data plunges. Transferred data counted in the last minute does not cover a full minute. The `(max(time) - min(time))` clause is used for normalization to count the average traffic per minute.

```
* | SELECT SUM(inflow) / (max(__time__) - min(__time__))  as inflow_per_minute, date_trunc('minute',__time__)  as minute group by minute
```

Calculate the average latency of traffic data in different sizes

Distribute traffic data to multiple bins based on the data size and calculate the average latency of the data in the bins.

```
* | select avg(latency) as latency , case when originSize < 5000 then 's1' when originSize < 20000 then 's2' when originSize < 500000 then 's3' when originSize < 100000000 then 's4' else 's5' end as os group by os
```

Retrieve the percentages of different results

List the number and the percentage of each result for different departments. This query includes subqueries and window functions. The `sum(c) over()` clause indicates the sum of values in all rows.

```
* |  select  department, c*1.0/ sum(c) over ()  from(select  count(1) as c, department  from log group by department)
```

Count the number of log entries that meet the query condition

To count the number of URLs based on their characteristics, you can use the CASE WHEN clause or the COUNT_IF clause. The latter clause is simpler.

```
* | select  count_if(uri like '%login') as login_num, count_if(uri like '%register') as register_num, date_format(date_trunc('minute', __time__), '%m-%d %H:%i') as time  group by time order by time limit 100
```

28.1.4.10.3. Time field conversion examples

During search and analytics, you often need to process time fields in log data, such as converting a timestamp to another time format. This topic uses some examples to describe how to convert time fields.

A log entry may include multiple time fields, for example:

- `__time__`: the time that you specify when you use the API or SDK to write log data. This field can be used for log data shipping, search, and analytics.
- Original time field in log data: the field that records the time when the log data is generated. This field is in raw logs.

Time fields in different formats are difficult to read. To simplify the read process, you can convert the time format during search and analytics. For example, you can perform the following conversions:

1. Convert __time__ to a timestamp
2. Display __time__ in a specified format
3. Convert a timestamp to a specified format

Convert __time__ to a timestamp

You can use the from_unixtime function to convert the `__time__` field to a timestamp.

```
* | select from_unixtime(__time__)
```

Display __time__ in a specified format

To display the `__time__` field in the format of `YYYY-MM-DD HH:MM:SS`, you can use the date_format function.

```
* | select date_format(__time__, '%Y-%m-%d %H:%i:%S')
```

Convert the time in a log to a specified format

To convert the time field in a log to the specified format (`YYYY-MM-DD HH:MM:SS`) and perform the GROUP BY operation on the `YYYY-MM-DD` part, you can use the date_format function.

- Sample log entry

```
__topic__:
body_byte_sent:  307

- Example SQL statement

```
* | select date_format (date_parse(time,'%Y-%m-%d %H:%i:%S'), '%Y-%m-%d') as day, count(1) as uv g
roup by day order by day asc
```

28.1.4.11. Visual analysis

28.1.4.11.1. Analysis graph

28.1.4.11.1.1. Overview

All search and analytics results can be rendered by using visualized charts.

Prerequisites

- The index feature is enabled and configured. The analytics switches are turned on. For more information, see Enable the index feature and configure indexes for a Logstore.
- An analytic statement is included in a query statement. You cannot use charts to show query results if you do not include an analytic statement in your query statement.

Precautions

When multiple search and analytic statements are being executed in sequence, the **Value Column**, **X Axis**, or **Y Axis** information cannot automatically change based on the search and analytic statement. The X and Y axis information may remain the same as the last search and analytic statement. If this happens, the query results of the current search and analytic statement cannot be automatically displayed in a chart. If the following messages are returned, configure parameters on the **Properties** tab based on the current search and analytic statement:

- The currently selected dimensions are not in the queried results. Check and configure the attributes.
- X-Axis or Y-Axis is not available. Check and configure the attributes.

Chart configurations

On the **Graph** tab, various charts are provided to show query results. You can select a type of chart from the chart bar to show results.

- On the **Graph** tab, you can view the **Chart Preview** and **Data Preview** of query results of the current search and analytic statement. **Chart Preview** is the preview of the query results that are displayed in the specified type of chart. **Data Preview** displays the query results in a table.
- On the **Graph** tab on the right, you can configure the following chart properties:
  - **Data Source**: used to set placeholder variables. For example, you configure the drill-down event of Chart A to redirect to the dashboard where Chart B is located. The placeholder variable you configured for Chart B is the same as the variable that you click to trigger the drill-down event. Then the placeholder variable is replaced with the variable you click to trigger the drill-down event and the search and analytic statement of Chart B is executed. For more information, see Drill-down analysis.

    This feature is applicable to scenarios where you configure drill-down events to redirect to targeted dashboards.
  - **Properties**: used to configure the display properties of a chart, including the X axis, left and right Y axes, margins, font size and other properties. The properties vary with different type of charts.

    This feature is applicable to all search and analytics scenarios.
  - **Interactive Behavior**: used to configure drill-down events for a chart. After you configure a drill-down event for the chart, you can click the variable value in the chart to trigger the specified drill-down event. For more information, see Drill-down analysis.

    This feature is applicable to triggering drill-down events for charts.

28.1.4.11.1.2. Display query results on a table

Tables are used to sort and display data for quick reference and analysis. All query results that match specified query statements can be rendered into visualized charts. By default, the query results are displayed in a table.

Components

- Table header
- Row
- Column

Where:

- The number of columns can be specified by using a `SELECT` statement.
- The number of rows is calculated based on the number of log entries in a specified time range. The default clause is `LIMIT 100`.

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, data is displayed in a table by default. You do not need to click the  icon.
3. On the **Properties** tab, configure the properties of the table.

Properties

Parameter	Description
Items per Page	The number of log entries to return on each page.
Zebra Striping	Specifies whether to display the query results in a zebra-striped table.
Transpose Rows and Columns	Specifies whether to transpose rows and columns.
Hide Reserved Fields	Specifies whether to hide reserved fields.
Disable Sorting	Specifies whether to disable the sorting feature.
Disable Search	Specifies whether to disable the search feature.
Highlight Settings	The rules for highlighting rows or columns that conform to specified rules.

28.1.4.11.1.3. Display query results on a line chart

A line chart is used to analyze the value changes of fields based on an ordered data type. In most cases, this analysis is based on a specified time range.

You can use a line chart to analyze the following change characteristics of field values over a specified period:

- Increment or decrement
- Increment or decrement rate
- Increment or decrement pattern, for example, periodicity
- Peak value and trough value

Line charts are used to analyze field value changes over a time period. You can also use a line chart to analyze the value changes of multiple fields in multiple lines over the same time period. Then, you can analyze the relationships between the different fields. For example, the values of multiple fields can display positive, negative, or inverse trends.

Components

- X-axis
- Left Y-axis
- Right Y-axis (optional)
- Data point
- Line of trend change
- Legend

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, click the  icon.
3. On the **Properties** tab, configure the properties of the line chart.

> **Note** In a line chart, each line must contain more than two data points. Otherwise, the data trend cannot be analyzed. We recommend that you select five or fewer lines in a line chart.

Properties

Parameter	Description
X Axis	The sequential data. In most cases, time series is selected.
Left Y Axis	The numeric data. You can select one or more fields for the left Y-axis.
Right Y Axis	The numeric data. You can select one or more fields for the right Y-axis. The layer of the right Y-axis is higher than that of the left Y-axis.
Column Marker	The column on the left or right Y-axis. The column is selected as a histogram.
Legend	The position where the legend is located in the chart. Valid values: Top, Bottom, Left, and Right.
Format Left Y-axis	The format in which data selected for the left Y-axis and right Y-axis is displayed.
Format Right Y-axis	
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

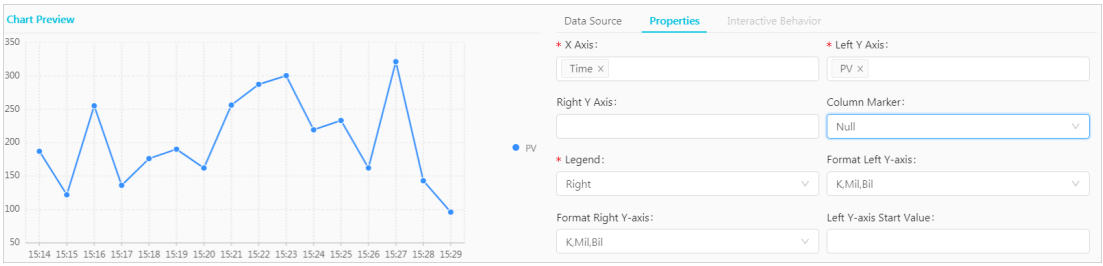
Example of a line chart

To query the page views (PVs) of the IP address `10.0.192.0` in the last 24 hours, execute the following query statement:

```
remote_addr: 10.0.192.0 | select date_format(date_trunc('hour', __time__), '%m-%d %H:%i')
as time, count(1) as PV group by time order by time limit 1000
```

Select `time` for the X-axis, `PV` for the left Y-axis, and Bottom for Legend. Adjust the margins based on your business requirements.

Line chart



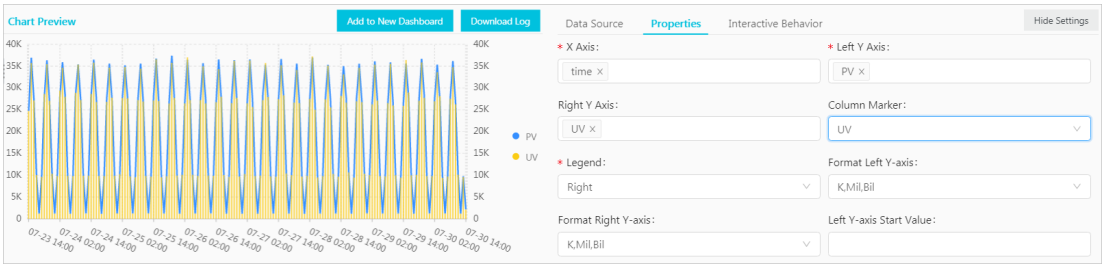
Example of a dual Y-axis line chart

To query the PVs and unique visitors (UVs) in the last 24 hours, execute the following query statement:

```
* | select date_format(date_trunc('hour', __time__), '%m-%d %H:%i') as time, count(1) as PV, approx_d
istinct(remote_addr) as UV group by time order by time limit 1000
```

Select `time` for the X-axis, `PV` for the left Y-axis, `UV` for the right Y-axis, and `PV` for Column Marker.

Dual Y-axis line chart



28.1.4.11.1.4. Display query results on a column chart

A column chart uses vertical or horizontal bars to present categorical values. Compared with a line chart, a column chart does not display ordered data, but provides a method to count the number of values in each category.

Components

- X-axis (horizontal)
- Y-axis (vertical)
- Rectangular bar
- Legend

By default, column charts in Log Service use vertical bars. Each rectangular bar has a fixed width and a variable height that indicates a value. You can use a grouped column chart to display the data if multiple columns of data are mapped to the Y-axis.

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click

Search & Analyze.

2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the column chart.

> **Note** Column charts can be used to display query results if the number of returned log entries is less than 20. You can use a `LIMIT` clause to control the number of rectangular bars. Analysis results may not be clearly displayed if the chart contains a large number of rectangular bars. In addition, we recommend that you select less than five fields for the Y-axis.

Properties

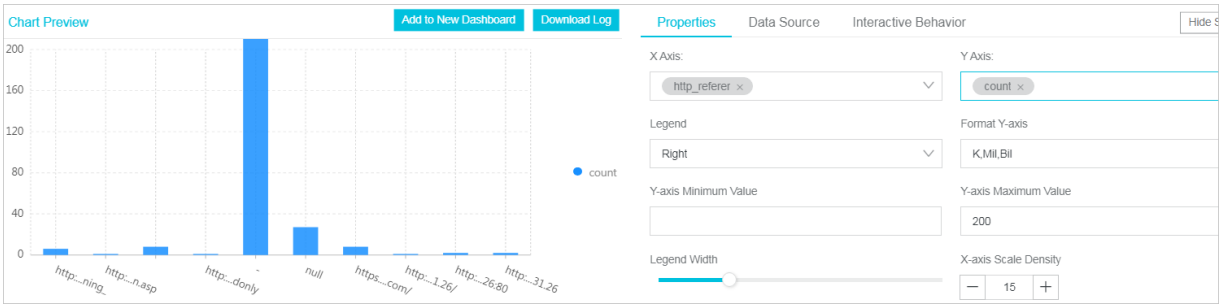
Parameter	Description
X Axis	The categorical data.
Y Axis	The numeric data. You can select one or more fields for the Y-axis.
Legend	The position where the legend is located in the chart. Valid values: Top, Bottom, Left, and Right.
Format	The format in which data is displayed on the Y-axis.
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

Example of a simple column chart

To query the number of visits for each `http_referer` in the specified time range, execute the following query statement:

```
* | select  http_referer, count(1) as count group by http_referer
```

Select `http_referer` for X-axis and `count` for Y-axis.



Example of a grouped column chart

To query the number of requests and the average bytes for each `http_referer` in the specified time range, execute the following statement:

```
* | select  http_referer, count(1) as count, avg(body_bytes_sent) as avg group by http_referer
```

Select `http_referer` for X-axis. Select `count` and `avg` for Y-axis.

28.1.4.11.1.5. Display query results on a bar chart

A bar chart is a horizontal column chart that is used to analyze the top N values of fields. A bar chart is configured in a similar way to a column chart.

Components

- X-axis (vertical)
- Y-axis (horizontal)
- Rectangular bar
- Legend

Each rectangular bar has a fixed height and a variable width. The variable width indicates a value. You can use a grouped bar chart to display the data if multiple columns of data are mapped to the Y-axis.

Procedure

1.
2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the bar chart.

> **Note**
>
> - Bar charts can be used to display query results if 20 or fewer log entries are returned. You can use the `LIMIT` clause to control the number of rectangular bars. Analysis results may not be clearly displayed if the chart contains a large number of rectangular bars. You can use the `ORDER BY` clause to analyze the top N values of fields. We recommend that you map less than five columns of data to the Y-axis.
> - You can use a grouped bar chart to display query results. However, the values represented by each rectangular bar in a group must be positively or negatively associated with each other.

Properties

Parameters

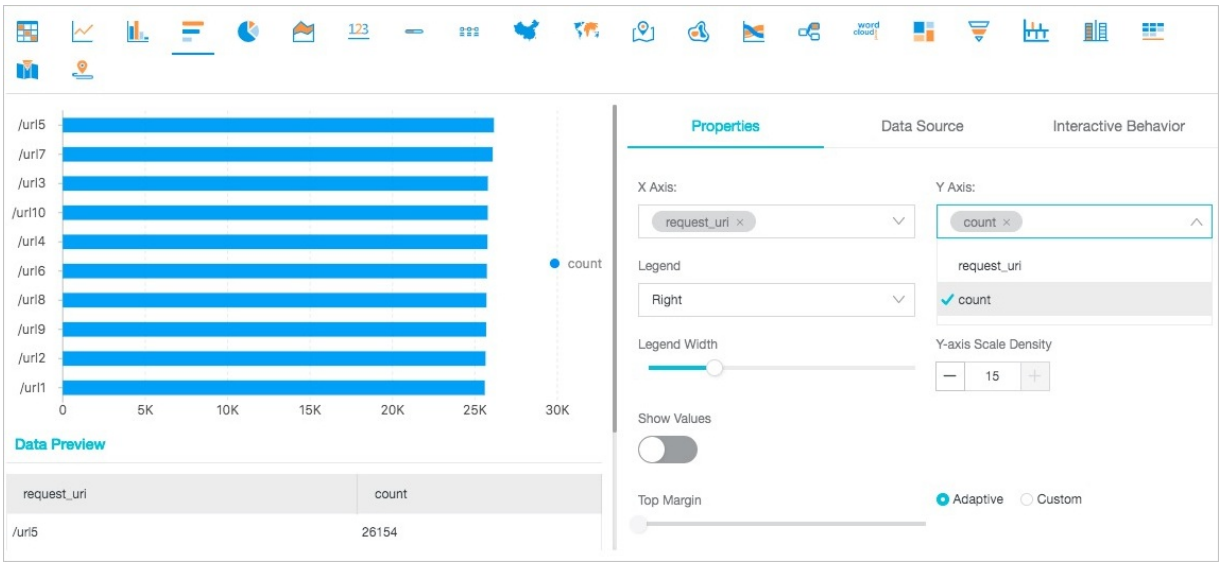
Parameter	Description
X Axis	The categorical data.
Y Axis	The numeric data. You can select one or more fields for the Y-axis.

Parameter	Description
Legend	The position where the legend is located in the chart. Valid values: Top, Bottom, Left, and Right.
Format X-axis	The format in which data is displayed on the X-axis.
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

Examples

To analyze the top 10 visited request URIs (`request_uri`), execute the following query statement:

```
* | select  request_uri, count(1) as count group by request_uri order by count desc limit 10
```



28.1.4.11.1.6. Display query results on a pie chart

A pie chart is used to indicate the percentages of different data types and compare different data types based on the arc length of each slice.

Components

- Segment
- Percentage in the text format
- Legend

Types

Log Service provides three types of pie charts: a standard pie chart, donut chart, and polar area chart.

- Standard pie chart

  A standard pie chart is divided into multiple segments based on the percentages of various field values. The entire chart displays all field values. Each segment displays the percentage and the numeric value of a field. The sum of percentages from all segments is equal to 100%.

- Donut chart

A donut chart is a standard pie chart with a hollow center. A donut chart has the following benefits:

- In addition to the information that a standard pie chart displays, a donut chart displays the total number of occurrences of all field values.
- You can view the differences between the number of occurrences of the same value in two charts based on the ring length. This is more intuitive than comparing two standard pie charts.

- Polar area chart

  A polar area chart is a column chart in the polar coordinate system. Each category of field values is represented by a segment with the same radian. The radius of a segment indicates the number of occurrences of a field value. Compared with a standard pie chart, a polar area chart has the following benefits:

  - Standard pie charts are suitable to display query results if 10 or fewer log entries are returned. Polar area charts are suitable for displaying query results if the number of returned log entries ranges from 10 to 30.
  - The area is the square of a radius. Therefore, the display of the polar area chart enlarges the differences among multiple types of data. This is best suited for a comparison of similar values.
  - A circle can be used to display a periodic pattern. Therefore, you can use a polar area chart to analyze value change characteristics in specified periods, such as weeks and months.

Procedure

1.
2. On the **Graph** tab, click the  icon.
3. On the **Properties** tab, configure the properties of the pie chart.

> **Note**
>
> - Donut charts and standard pie charts can be used to display query results if less than 10 log entries are returned. You can use a `LIMIT` clause to control the number of segments. Analysis results may not be clearly displayed if the chart contains a large number of segments of different colors.
> - We recommend that you use a polar area chart or column chart if the number of returned log entries exceeds 10.

Properties

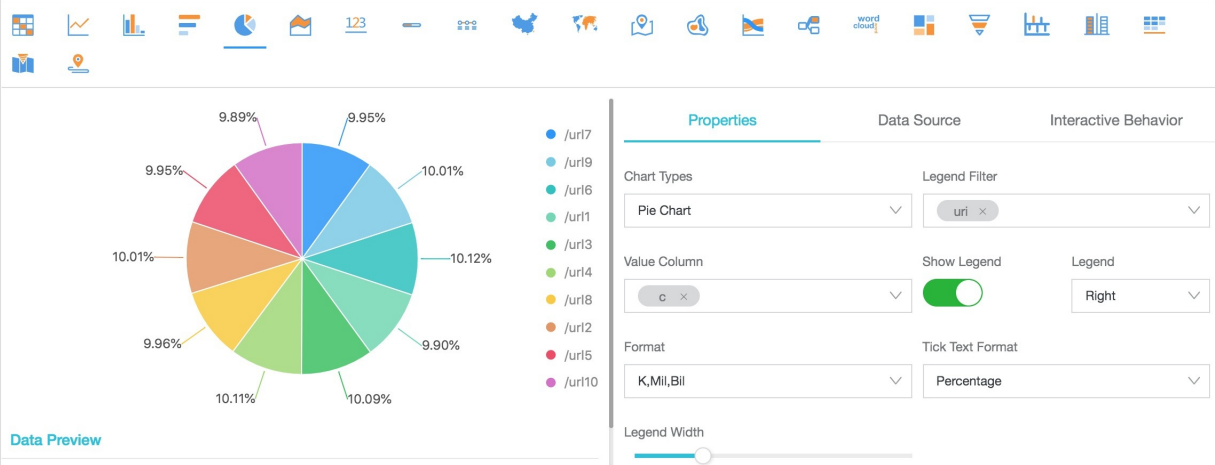
Parameter	Description
Chart Types	The type of the chart. Valid values: Pie Chart, Donut Chart, and Polar Area Chart. Default value: Pie Chart.
Legend Filter	The categorical data.
Value Column	The values that correspond to different types of data.
Show Legend	Specifies whether to show the legend.
Legend	The position where the legend is located in the chart. Valid values: Top, Bottom, Left, and Right. You can configure this parameter only after you turn on the Show Legend switch.
Format	The format in which data is displayed.
Tick Text Format	The format of the tick.

Parameter	Description
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

Example of a standard pie chart

To analyze the percentages of the `request_uri` field values, execute the following query statement:

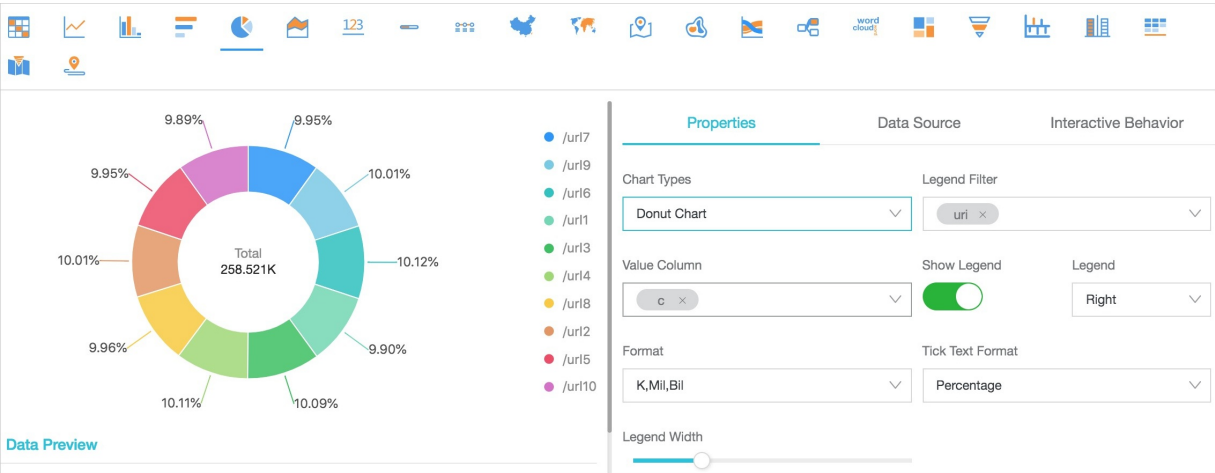
```
* | select requestURI as uri , count(1) as c group by uri limit 10
```



Example of a donut chart

To analyze the percentages of the `request_uri` field values, execute the following query statement:

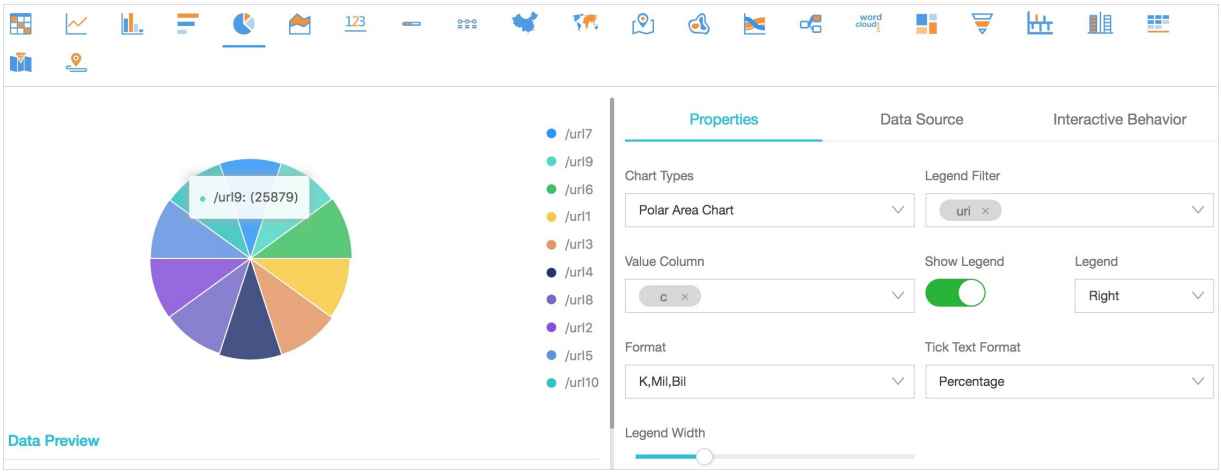
```
* | select requestURI as uri , count(1) as c group by uri limit 10
```



Example of a polar area chart

To analyze the percentages of the `request_uri` field values, execute the following query statement:

```
* | select requestURI as uri , count(1) as c group by uri limit 10
```



28.1.4.11.1.7. Display query results on an area chart

An area chart is built based on a line chart. The colored section between a line and the axis is an area. The color is used to highlight the trend. Similar to a line chart, an area chart shows the numeric value changes over a specified time period to highlight the overall data trend. Both the line chart and the area chart display the trend and relationship between numeric values instead of displaying specific values.

Components

- X-axis (horizontal)
- Y-axis (vertical)
- Area segment

Procedure

1.
2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the area chart.

> **Note** In an area chart, a single area segment must contain more than two data points. Otherwise, the data trend cannot be analyzed. We recommend that you select five or fewer area segments in an area chart.

Properties

Parameter	Description
X Axis	The sequential data. In most cases, time series is selected.
Y Axis	The numeric data. You can select one or more fields for the Y-axis.
Legend	The position where the legend is located in the chart. Valid values: Top, Bottom, Left, and Right.
Format	The format in which data is displayed.

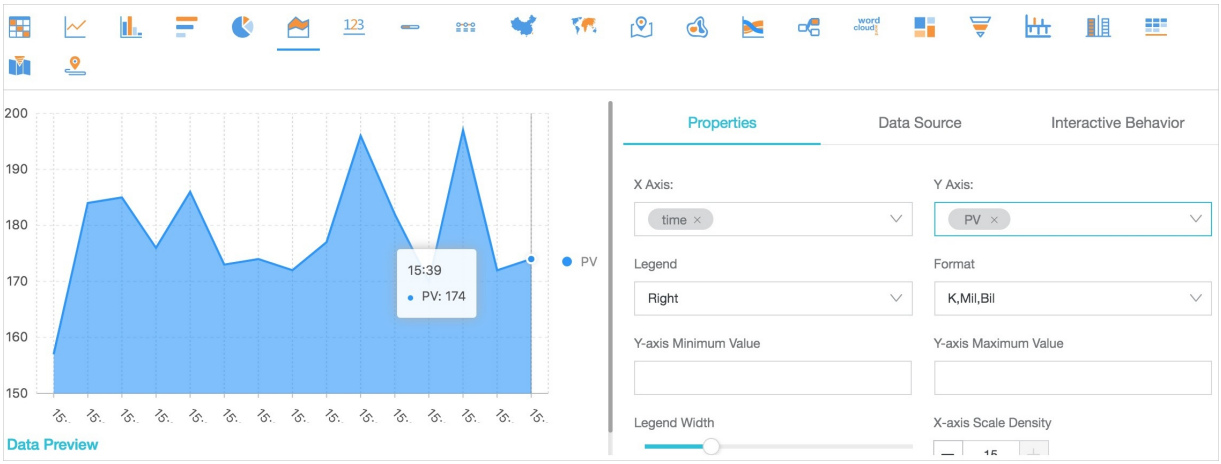
Parameter	Description
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

Example of a simple area chart

To query the page views (PVs) of the IP address `10.0.192.0` in the last 24 hours, execute the following query statement:

```
remote_addr: 10.0.192.0 | select date_format(date_trunc('hour', __time__), '%m-%d %H:%i') as time, co
unt(1) as PV group by time order by time limit 1000
```

Select `time` for the X-axis and `PV` for the Y-axis.



Example of a cascade chart

```
* | select date_format(date_trunc('hour', __time__), '%m-%d %H:%i') as time, count(1) as PV, approx_d
istinct(remote_addr) as UV group by time order by time limit 1000
```

Select `time` for the X-axis. Select `PV` and `UV` for the Y-axis.

28.1.4.11.1.8. Display query results on a single value chart

A single value chart displays a single value.

Single value charts have the following types:

- Rectangle Frame: shows a general value.
- Dial: shows the difference between the current value and the specified threshold value.
- Compare Numb Chart: shows the SQL query results of interval-valued comparison and periodicity-valued comparison functions. For more information about the analytic syntax, see Interval-valued comparison and periodicity-valued comparison functions.

Rectangle Frame is selected by default. A rectangle frame is the most basic method to display data at a specified point. In most cases, it is used to show the key information at a specified point in time. To display a proportional metric, you can select Dial.

Components

- Numeric value
- Chart type

Procedure

1.
2. On the **Graph** tab, click the 123 icon.
3. On the **Properties** tab, configure the properties of the single value chart.

> **Note** Log Service normalizes data in numeric value-based charts. For example, `230000` is normalized to `230K`. You can include Mathematical calculation functions in query statements to customize numeric formats.

Properties

- The following table lists the parameters of a rectangle frame.

Parameter	Description
Chart Types	The type of the chart. Select Rectangle Frame.
Value Column	The value displayed in the chart. By default, data in the first row of the specified column is displayed.
Unit	The unit of data.
Unit Font Size	The font size of the unit. You can drag the slider to adjust the font size. Valid values: 10 to 100. Unit: pixels.
Description	The description of the value.
Description Font Size	The font size of the value description. You can drag the slider to adjust the font size. Valid values: 10 to 100. Unit: pixels.
Format	The format in which data is displayed.
Font Size	The font size of the value. You can drag the slider to adjust the font size. Valid values: 10 to 100. Unit: pixels.
Font Color	The color of the value, unit, and description in the chart. You can use the default color or select a color.

Parameter	Description
Background Color	The color of the background. You can use the default color or select another color.

- The following table describes the parameters of a dial.

Parameter	Description
Chart Types	The type of the chart. Select **Dial** to display query results on a dial.
Actual Value	The actual value in the chart. By default, data in the first row of the specified column is displayed.
Unit	The unit of the value on the dial.
Font Size	The font size of the value and unit. Valid values: 10 to 100. Unit: pixels.
Description	The description of the value.
Description Font Size	The font size of the value description. You can drag the slider to adjust the font size. Valid values: 10 to 100. Unit: pixels.
Dial Maximum	The maximum value of the scale in the dial. Default value: 100.
Maximum Value Column	The maximum value in the specified column. If you turn on the Use Query Results switch, **Dial Maximum** is replaced by Maximum Value Column. Then, you can select the maximum value from query results for this parameter.
Use Query Results	If you turn on the Use Query Results switch, Dial Maximum is replaced by Maximum Value Column. Then, you can select the maximum value from query results for this parameter.
Format	The format in which data is displayed.
Colored Regions	The number of segments that divide the dial. Each segment is displayed in a different color. Valid values: 2, 3, 4, and 5. Default value: 3.
Region Max Value	The maximum value of the scale in each colored segment of the dial. By default, the maximum value in the last segment is the maximum value on the dial. You do not need to specify this value. **Note** A dial is evenly divided into three colored segments by default. If you change the value of **Colored Regions**, Region Max Value is not automatically adjusted. You can manually set the maximum value for each colored segment based on your business requirements.
Font Color	The color of the value on the dial.
Region	The colored segments that divide the dial. A dial is evenly divided into three segments by default. The segments are displayed in blue, yellow, and red. If you set **Colored Regions** to a value greater than 3, the added segments are displayed in blue by default. You can change the color of each segment.

Parameter	Description
Show Title	Specifies whether to display the title of a dial when you add the dial to a dashboard. The **Show Title** feature can show or hide the title of the dial on the dashboard page. This switch is turned off by default. If you turn on the Show Title switch, the title of the dial is not displayed on the current page. You must create or modify a dashboard and view the title on the dashboard page.

- The following table lists the parameters of a compare numb chart.

Parameter	Description
Chart Types	The type of the single value chart. If you select Compare Numb Chart, query results are displayed on a compare numb chart.
Show Value	The value that is displayed in the center of the compare numb chart. In most cases, this value is set to the statistical result that is calculated by the related comparison function in the specified time range.
Compare Value	The value that is compared with the threshold. Set the value to the result of the comparison between the statistical results calculated by the related comparison function in the specified time range and the previously specified time range.
Font Size	The font size of the show value. Valid values: 10 to 100. Unit: pixels.
Unit	The unit of the show value.
Unit Font Size	The font size of the unit for the show value. Valid values: 10 to 100. Unit: pixels.
Compare Unit	The unit of the compare value.
Compare Font Size	The font size of the compare value and unit. Valid values: 10 to 100. Unit: pixels.
Description	The description of the show value and its growth trend.
Description Font Size	The font size of the description. Valid values: 10 to 100. Unit: pixels.
Trend Comparison Threshold	The value that is used to measure the variation trend of the compare value. For example, the compare value is -1. ◦ If you set **Trend Comparison Threshold** to 0, a down arrow that indicates a value decrease is displayed on the page. ◦ If you set **Trend Comparison Threshold** to -1, it indicates that the value remains unchanged. The system does not display the trend on the page. ◦ If you set **Trend Comparison Threshold** to -2, an up arrow that indicates a value increase is displayed on the page.
Format	The format in which data is displayed.
Font Color	The color of the show value and its description.
Growth Font Color	The font color of the compare value that is greater than the threshold.

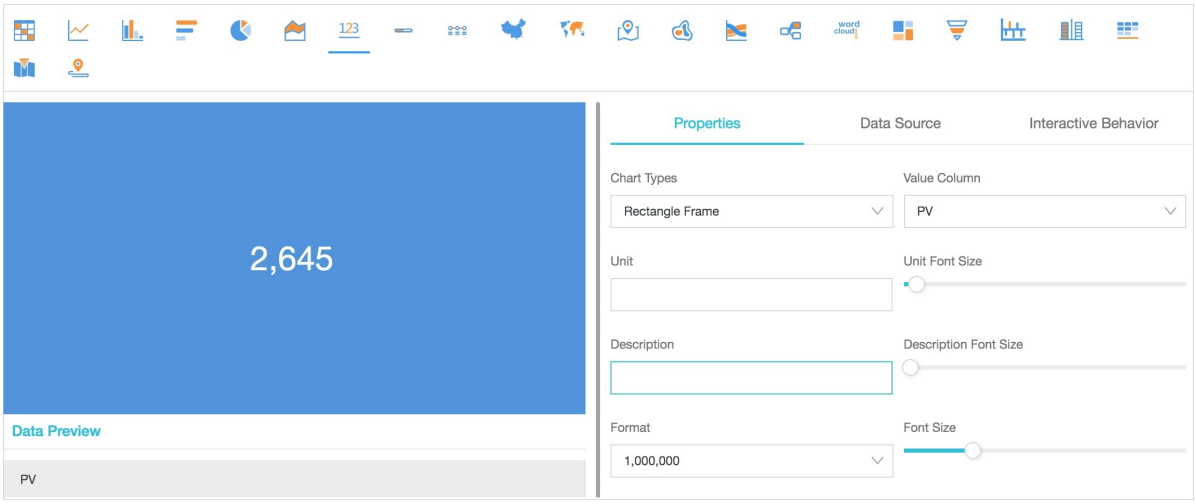
Parameter	Description
Growth Background Color	The background color displayed when the compare value is greater than the threshold.
Decrease Font Color	The font color displayed when the compare value is less than the threshold.
Decrease Background Color	The background color displayed when the compare value is less than the threshold.
Equal Background Color	The background color displayed when the compare value is equal to the threshold.

Examples

To view the number of access requests, execute the following query statements:

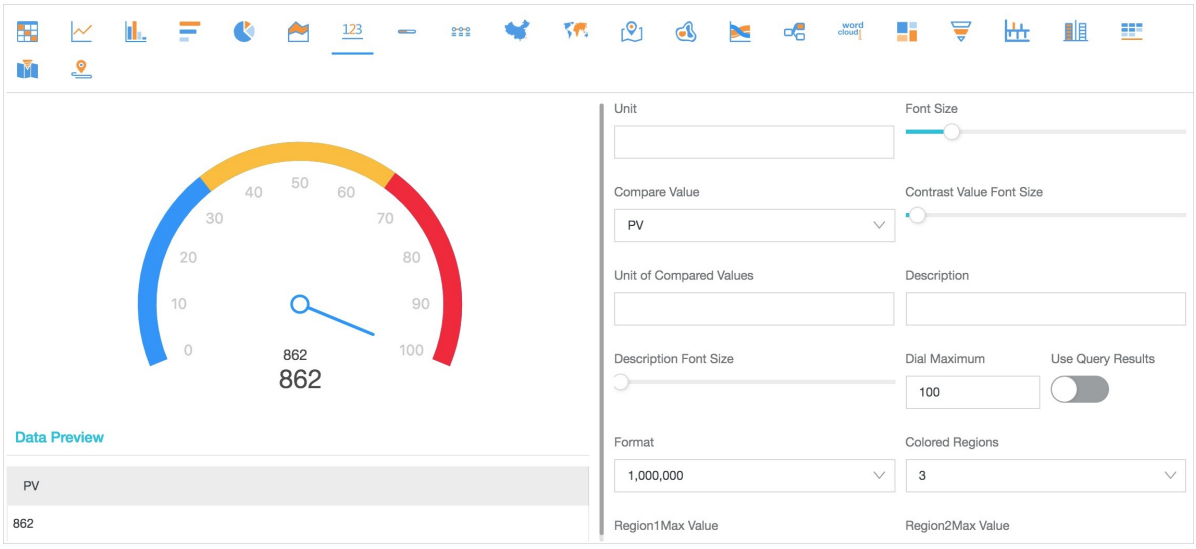
- Rectangle frame

```
* | select count(1) as pv
```



- Dial

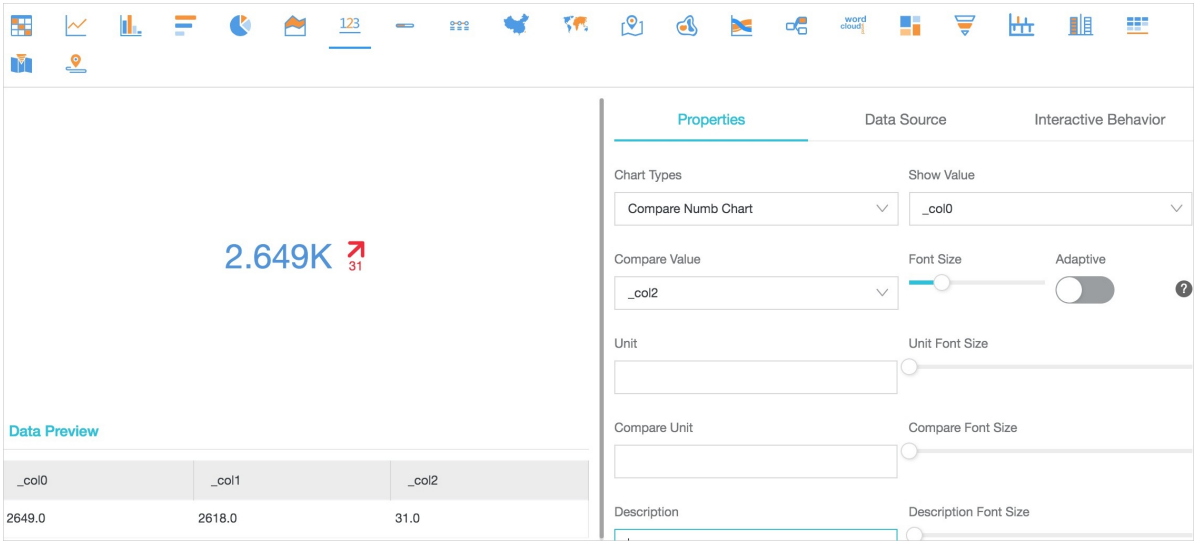
```
* | select count(1) as pv
```



- Compare numb chart

  To view and compare the access requests for today and yesterday, execute the following query statement:

```
* | select diff[1],diff[2], diff[1]-diff[2] from (select compare( pv , 86400) as diff from (select count(1) as pv from log))
```



28.1.4.11.1.9. Display query results on a progress bar

The progress bar shows the percentage of the actual value of a field to the maximum value of the field. You can configure the properties of the progress bar to adjust its style and set display rules.

Components

- Actual value
- Unit (optional)
- Total value

Procedure

1.
2. On the **Graph** tab, click to select the progress bar.
3. Configure the properties of the progress bar.

Properties

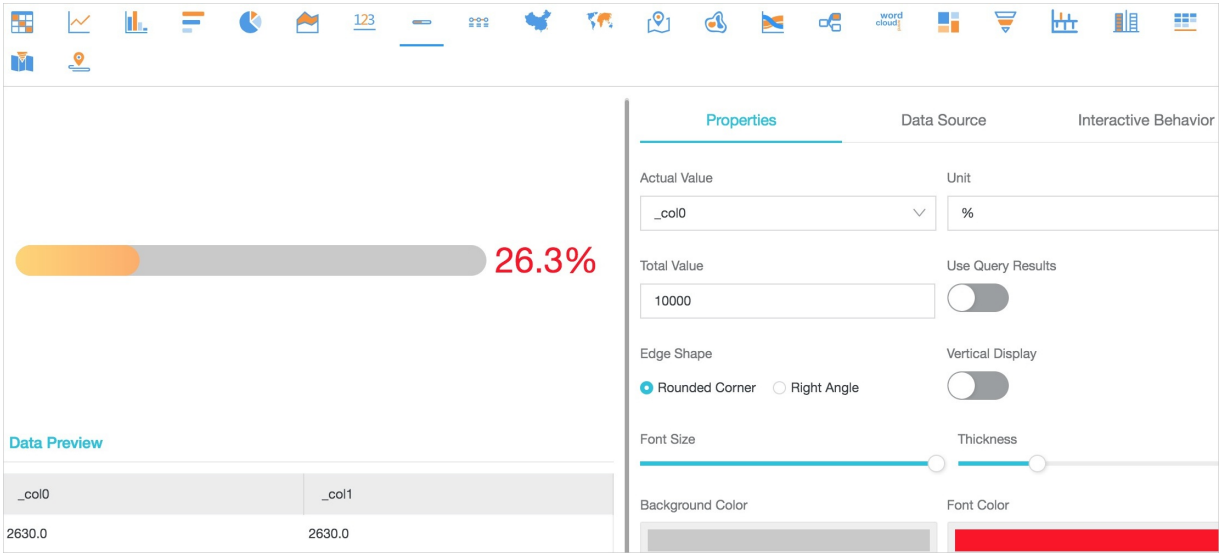
Parameter	Description
Actual Value	The actual value in the chart. By default, data in the first row of the specified column is displayed.
Unit	The unit of the value in the progress bar.
Total Value	The maximum value indicated by the progress bar. Default value: 100.

Parameter	Description
Maximum Value Column	The maximum value in the specified column. If you turn on the **Use Query Results** switch, **Total Value** is replaced by **Maximum Value Column**. Then, you can select the maximum value from the query results for this parameter.
Use Query Results	If you turn on the Use Query Results switch, Total Value is replaced by Maximum Value Column. Then, you can select the maximum value from the query results for this parameter.
Edge Shape	The edge shape of the progress bar.
Vertical Display	Specifies whether to display the progress bar in vertical display mode.
Font Size	The font size of the value in the progress bar.
Thickness	The thickness of the progress bar.
Background Color	The background color of the progress bar.
Font color	The font color of the value in the progress bar.
Default Color	The default color of the progress bar.
Color Display Mode	The display mode of the progress bar.
Start Color	The start color of the progress bar. This parameter is available if **Gradient** is selected for **Color Display Mode**.
End Color	The end color of the progress bar. This parameter is available if **Gradient** is selected for **Color Display Mode**.
Display Color	The display color of the progress bar. This parameter is available if **Display by Rule** is selected for **Color Display Mode**. **Note** The value of **Actual Value** is compared with that of **Threshold** based on the condition specified by **Operator**. If the actual value matches the condition specified by **Operator**, the progress bar is displayed in the color specified by Display Color. Otherwise, the progress bar is displayed in the default color.
Operator	The condition that is used to specify the color of the progress bar. This parameter is available if **Display by Rule** is selected for **Color Display Mode**.
Threshold	The threshold that is used to specify the color of the progress bar. This parameter is available if **Display by Rule** is selected for **Color Display Mode**.

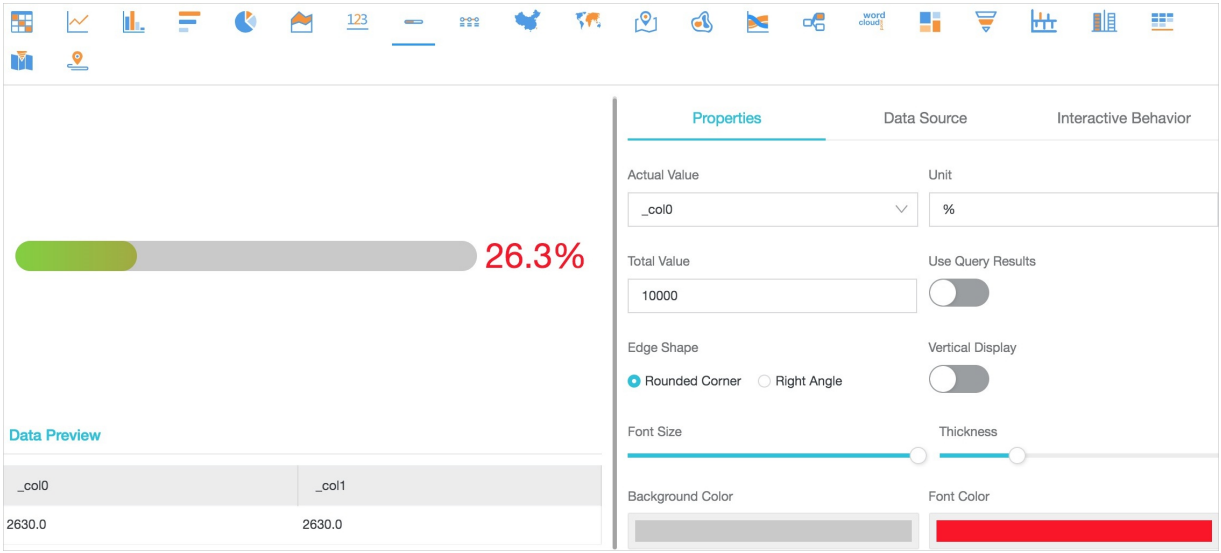
Examples

To view the percentage of a metric or the proportion of data, you can execute the following query statement:

```
* | select diff[1],diff[2] from (select compare( pv , 86400) as diff from (select count(1) as pv from log))
```



If you select **Display by Rule** for Color Display Mode, colors are dynamically displayed based on the specified rule. If the conditions of a rule are not matched, the default color is displayed.



28.1.4.11.1.10. Display query results on a map

You can color and mark a map to display geographic data. Log Service provides three types of maps: map of China, world map, and AMap. The display modes of an AMap include the anchor point and heat map. You can include specific functions in query statements to display analysis results as maps.

Components

- Map canvas
- Color area

Properties

Parameter	Description
Location information	The location information that is recorded in logs. The information is displayed in one of the following dimensions based on the map type: • Provinces (Map of China) • Country (World Map) • Longitude/Latitude (AMap)
Value Column	The data volume of the location information.

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
   - To display query results on a map of China, include the `ip_to_province` function in a query statement.
   - To display query results on a world map, include the `ip_to_country` function in a query statement.
   - To display query results on an AMap, include the `ip_to_geo` function in a query statement.
2. On the **Graph** tab, click the icon.
3. Configure the properties of the map.

Map of China

To display query results on a map of China, you can execute the following query statement that includes the `ip_to_province` function:

- SQL statement

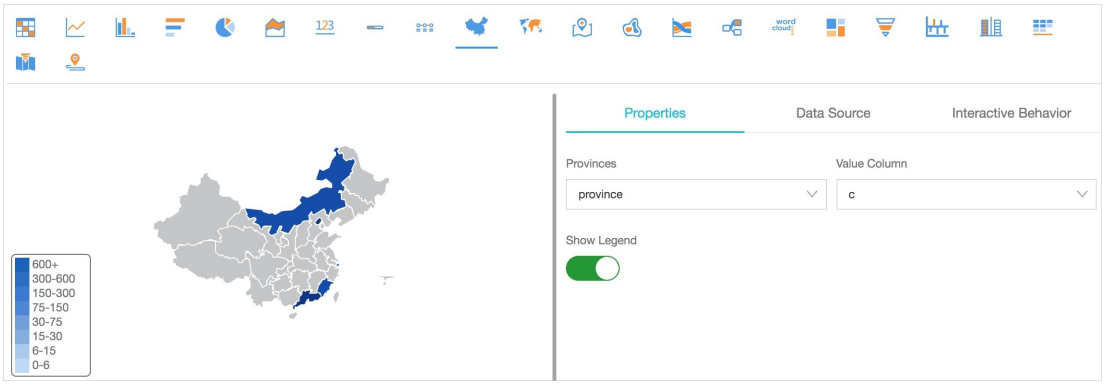
```
* | select  ip_to_province(remote_addr) as address, count(1) as count group by address order by co
unt desc limit 10
```

- Dataset

address	count
Guangdong	163
Zhejiang	110
Fujian	107
Beijing	89
Chongqing	28
Heilongjiang	19

Select address for *Provinces* and count for *Value Column*.

Map of China



World Map

To display query results in a world map, you can execute the following query statement that includes the `ip_to_country` function:

- SQL statement

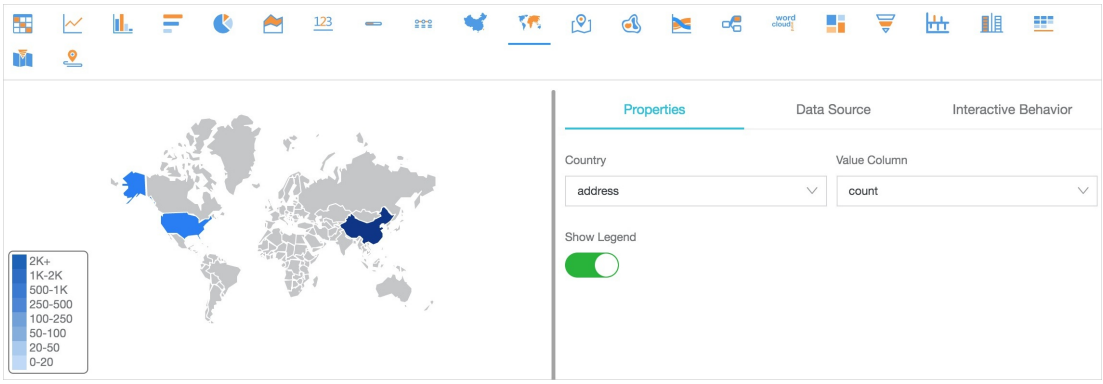
```
* | select  ip_to_country(remote_addr) as address, count(1) as count group by address order by cou
nt desc limit 10
```

- Dataset

address	count
China	8354
United States	142

Select address for *Country* and count for *Value Column*.

World Map



AMap

To display query results on an AMap, you can execute the following query statement that includes the `ip_to_geo` function. The address column in the dataset contains the latitude and longitude values, which are separated by a comma (,). If the longitude and latitude values are contained in two separate columns named lng and lat, you can use the `concat('lat', ',', lng')` function to combine the two columns into one column.

- SQL statement

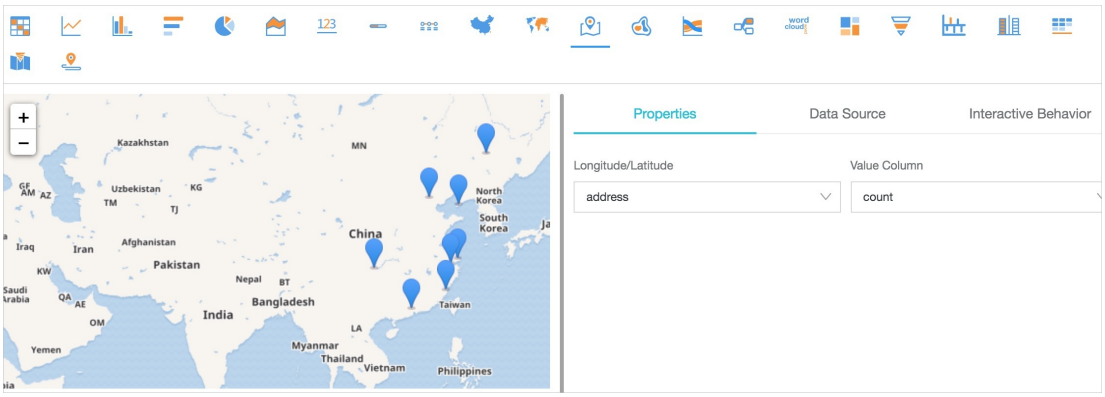
```
* | select  ip_to_geo(remote_addr) as address, count(1) as count group by address order by count d
esc limit 10
```

- Dataset

address	count
39.9289,116.388	771
39.1422,117.177	724
29.5628,106.553	651
30.2936,120.161420	577
26.0614,119.306	545
34.2583,108.929	486

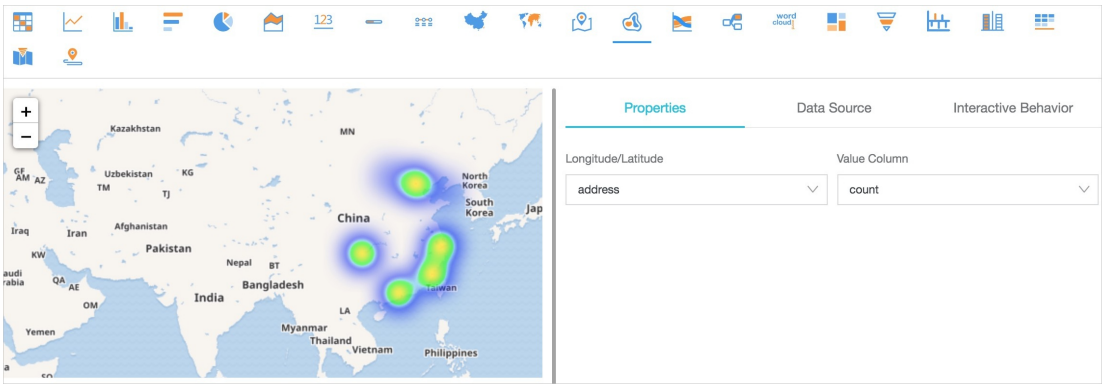
Select address for *Longitude/Latitude* and count for *Value Column*.

AMap: Anchor points



By default, the display mode of the anchor points is returned. If the anchor points are densely distributed on the map, you can switch the display mode to heat map.

AMap: Heat map



28.1.4.11.1.11. Flow chart

The flow chart, also known as ThemeRiver, is a stacked area chart around a central axis. The banded branches with different colors indicate different categorical data. The band width indicates the numeric value. The time information of the data is mapped to the X-axis by default. A flow chart can display the data of three parameters.

You can select the line chart or column chart for the Chart Types parameter. The column chart is stacked by default. Each category of data starts from the top of the last column of categorical data.

Components

- X-axis (horizontal)
- Y-axis (vertical)
- Band

Procedure

1.
2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the flow chart.

Properties

Parameter	Description
Chart Types	The type of the chart. Valid values: Line Chart, Area Chart, and Column Chart. Default value: Line Chart.
X Axis	The sequential data. In most cases, time series is selected.
Y Axis	The numeric data. You can configure one or more fields on the Y-axis.
Aggregate Column	The field information required to be aggregated as the third point for comparison.
Legend	The position where the legend is located in the chart. Valid values: Top, Bottom, Left, and Right.
Format	The format in which data is displayed.
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

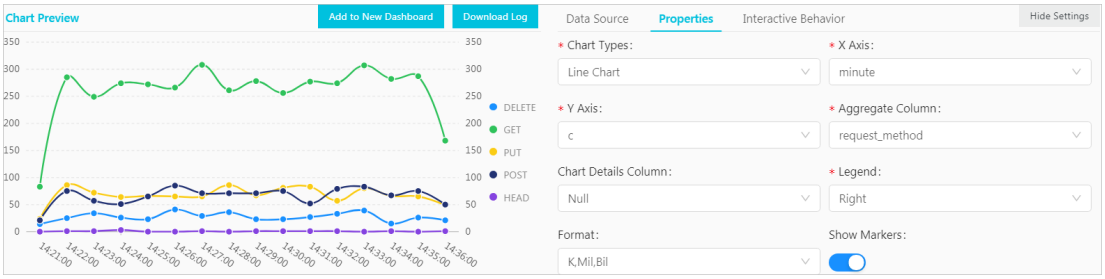
Examples

The flow chart is suitable to display data of three parameters, including the time, categories, and numeric values. In this example, you can execute the following query statement:

```
* | select date_format(from_unixtime(__time__ - __time__% 60), '%H:%i:%S') as minute, count(1) as c, request_method group by minute, request_method order by minute asc limit 100000
```

Select `minute` for the X-axis, `c` for the Y-axis, and `request_method` for Aggregate Column.

Flow chart



28.1.4.11.1.12. Display query results in a Sankey diagram

A Sankey diagram is a specific type of flow chart. It is used to describe the flow from one set of values to another set of values.

Sankey diagrams are applicable to scenarios such as network traffic flows. A Sankey diagram contains the values of three fields: `source`, `target`, and `value`. The `source` and `target` fields describe the source and target nodes and the `value` field describes the flows from the `source` node to the `target` node.

Features

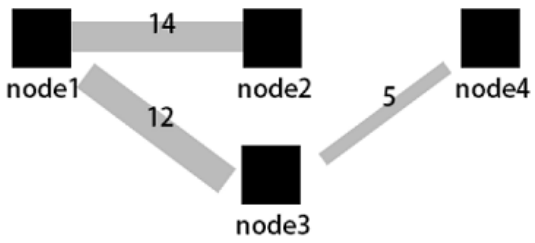
A Sankey diagram has the following features:

- The start flow is equal to the end flow. The overall width of all main edges is equal to the total sum of all branch edges. This allows you to manage and maintain a balanced flow of all traffic.
- The edge width in a row represents the traffic distribution in a specific status. The edge width in a row represents the distribution of traffic.
- The width of an edge between two nodes represents the flow volume of a status.

The following table lists the data that can be displayed in a Sankey diagram.

source	target	value
node1	node2	14
node1	node3	12
node3	node4	5
...	...	...

The following figure shows the data relationships in a Sankey diagram.



Components

- Node
- Edge

Procedure

1.
2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the Sankey diagram.

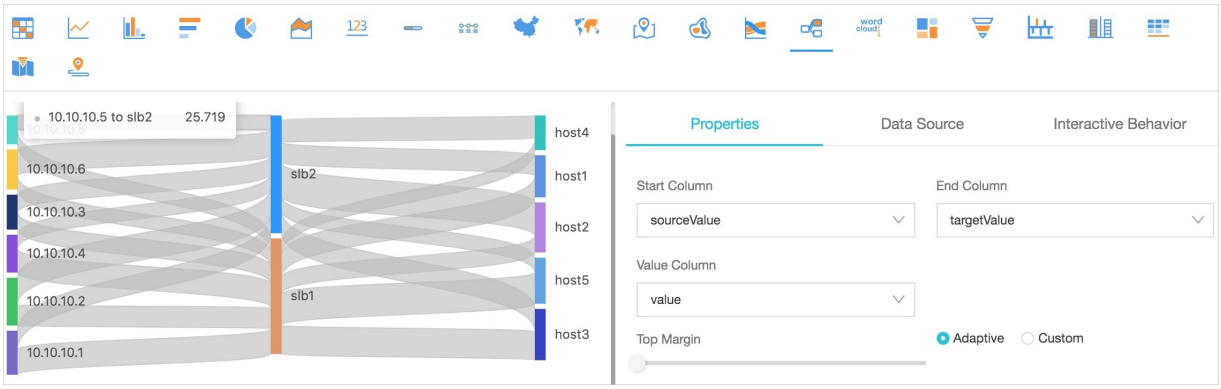
Properties

Parameter	Description
Start Column	The start node.
End Column	The end node.
Value Column	The value that indicates the flow volume from the start node to the end node.
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

Example of a Sankey diagram

If a log entry contains the `source`, `target`, and `value` fields, you can use a Nested subqueries statement to obtain the sum of all `steamValue` values.

```
* | select sourceValue, targetValue, sum(streamValue) as streamValue from (select sourceValue, target
Value,
 streamValue, __time__ from log group by  sourceValue, targetValue, streamValue, __time__ order by __
time__ desc) group by sourceValue,
 targetValue
```



28.1.4.11.1.13. Display query results on a word cloud

A word cloud visualizes text data. It is a cloud-like and colored image that consists of words. You can use a word cloud to display a large amount of text data. The font size or color of a word indicates the significance of the word. This allows you to identify the most significant words in an efficient way.

Components

The words in a word cloud are sorted.

Procedure

1.
2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the word cloud.

Properties

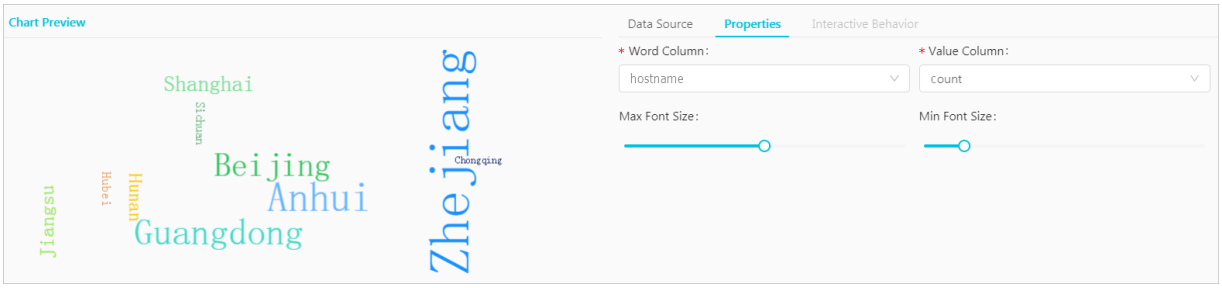
Parameter	Description
Word Column	The words to be displayed.
Value Column	The numeric value that corresponds to a word.
Font Size	The font size of a word. • The minimum font size ranges from 10 pixels to 24 pixels. • The maximum font size ranges from 50 pixels to 80 pixels.

Examples

To query the distribution of hostnames in NGINX logs, execute the following query statement:

```
* | select domain, count(1) as count group by domainorder by count desc limit 1000
```

Select `hostname` for Word Column and `count` for Value Column.



28.1.4.11.1.14. Display query results on a treemap chart

A treemap chart includes multiple rectangles that represent the data volume. A larger rectangle area represents a larger proportion of the categorical data.

Components

Sorted rectangles

Procedure

1.
2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the treemap chart.

Properties

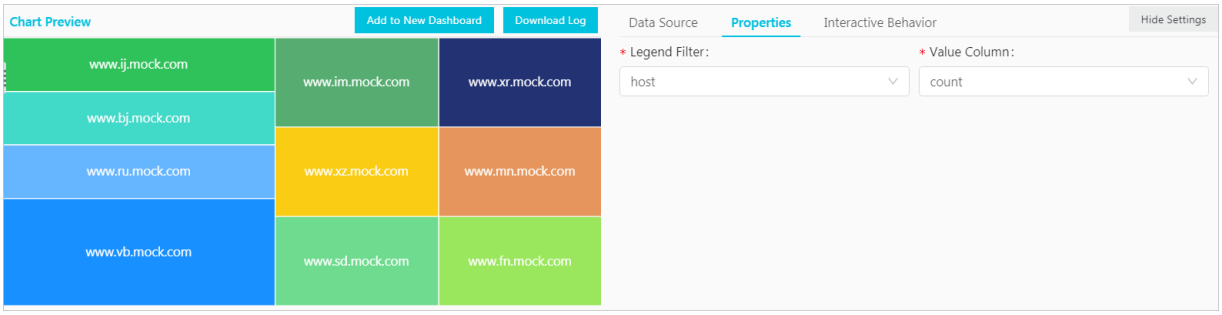
Parameter	Description
Legend Filter	The field that includes categorical data.
Value Column	The numeric value of a field. A greater field value represents a larger rectangle area.

Examples

To query the distribution of hostnames in NGINX logs, execute the following query statement:

```
* | select hostname, count(1) as count group by hostname order by count desc limit 1000
```

Select **hostname** for `Legend Filter` and **count** for `Value Column`.



28.1.4.11.2. Dashboard

28.1.4.11.2.1. Overview

A dashboard provided by Log Service is a platform where you can analyze data in real time. You can add multiple charts to a dashboard for data analysis. Each chart is a visualized search and analytic statement.

A dashboard allows you to view the charts of multiple search and analytic statements at one time. When you open or refresh the dashboard, the statements of the charts run automatically.

After you add a chart to a dashboard, you can configure Drill-down analysis for the chart. Then you can click the chart on the dashboard to further analyze data and obtain more fine-grained analysis results.

Limits

- You can create a maximum of 50 dashboards for a project.
- Each dashboard can contain a maximum of 50 analysis charts.

Features

A dashboard has two modes: display mode and edit mode.

- Configure the display mode of a dashboard

  In the display mode, you can configure multiple display settings on the dashboard page.

  - Dashboard: You can specify the time range, the automatic refresh interval, full screen, and the display mode of the title for the dashboard, configure alerts for all charts on the dashboard, and filter chart data based on the Configure and use a filter on a dashboard of a Logstore.
  - Chart: You can view the analysis details of a specified chart, specify the time range and configure alerts for the chart, download logs and the chart, and check whether drill-down analysis is configured for the chart.

- Edit mode

  In the edit mode, you can change the configurations of the dashboard and charts.

  - Dashboard: You can use a dashboard as a canvas and add Markdown chart, custom charts, text, icons, and other chart elements to the dashboard. You can also add lines between chart elements that are self-adaptive to the positions of the charts. You can also add Configure and use a filter on a dashboard of a Logstore, which can be used to filter chart data in the display mode. In addition, you can configure display gridlines to help arrange chart elements such as icons in an orderly manner.
  - Chart: You can also edit a chart on the dashboard. You can modify the statement, properties, and interactive behavior such as drill-down analysis of the chart.

28.1.4.11.2.2. Create and delete a dashboard

This topic describes how to create and delete a dashboard in a Logstore. In the Log Service console, you can run a query statement and visualize the query result in a chart. After you complete the configurations of the chart, you can add the chart to a dashboard. Each dashboard can display up to 50 charts, which support multiple formats and custom settings.

Prerequisites

The indexing feature of the Logstore is enabled and configured. For more information, see Enable the index feature and configure indexes for a Logstore.

Create a dashboard

1. Log on to the Log Service console.
2. Click a project name.
3. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
4. Enter a query statement in the search box, and then click **Search & Analyze**.
5. On the **Graph** tab that appears, configure the chart properties on the **Properties** tab.
6. (Optional)Set a placeholder variable.

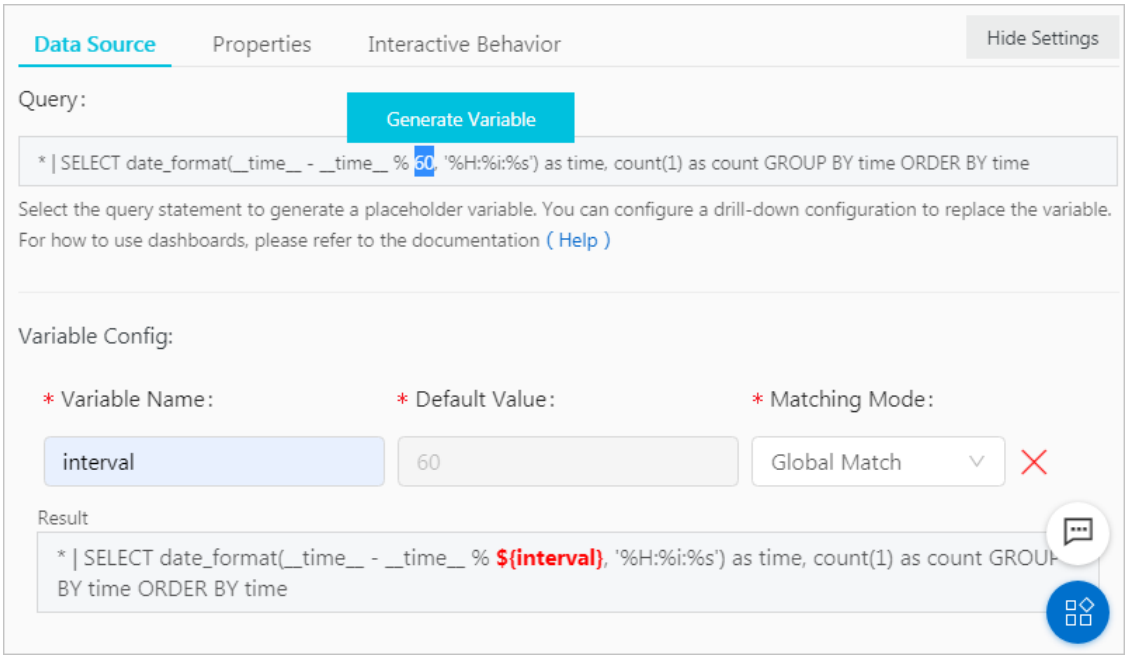
   For example, you have configured a drill-down event for another chart. This drill-down event redirects you to the current dashboard. You have also specified a placeholder variable for the query statement of the preceding chart. When you click a chart value to trigger the drill-down event, you are redirected to the current dashboard. The placeholder variable is replaced by the chart value and the current dashboard is refreshed by the new query statement. For more information, see Drill-down analysis.

   i. Click the **Data Source** tab, and then select a part of the query statement in the **Query** field.

   ii. Click **Generate Variable** to generate a placeholder variable.

iii. Set the parameters in the **Variable Config** section.

Parameter	Description
Variable Name	The name of the placeholder variable. If the name of the placeholder variable is the same as the variable specified in the chart, the placeholder variable is replaced with the chart value when the drill-down event is triggered.
Default Value	The default value of the placeholder variable in the current dashboard.
Matching mode	You can select Global Match or Exact Match.
Result	The query statement that contains the specified variable.



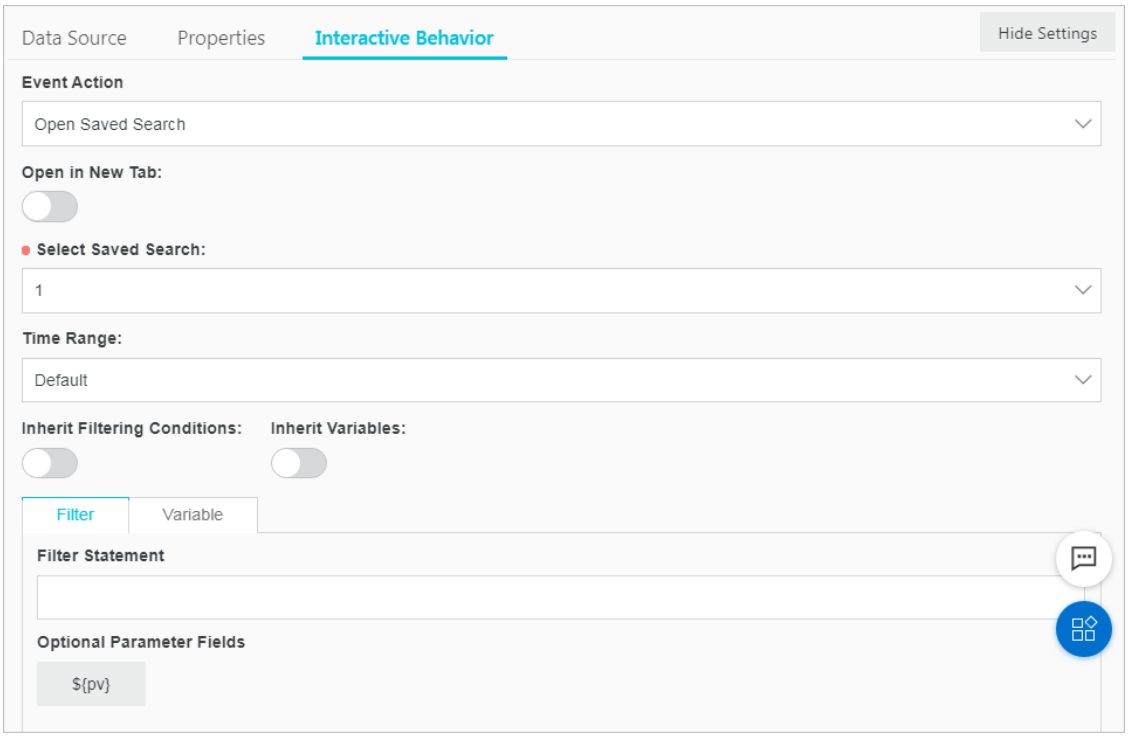
7. Configure a drill-down event.

   After you configure a drill-down event, you can click the chart on the dashboard for a more detailed analysis. For example, you can be redirected to another dashboard or a saved search. For more information, see Drill-down analysis.

   i. Click the **Interactive Behavior** tab.

   ii. Select an **Event Action**.

iii. Set the parameters of the selected event action.



8. Click **Add to New Dashboard** and specify the dashboard name and chart name.

Parameter	Description
Operation	◦ **Add to Existing Dashboard**: Add the chart to an existing dashboard. ◦ **Create Dashboard**: Create a dashboard and then add the chart to the dashboard.
Dashboards	Select an existing dashboard name. **Note** This parameter is required only when you set the **Operation** parameter to **Add to Existing Dashboard**.
Dashboard Name	Enter a dashboard name. **Note** This parameter is required only when you set the **Operation** parameter to **Create Dashboard**.
Chart Name	Enter a name for the current chart. The chart name is displayed as the chart title in the dashboard.

9. Click **OK**.

You can add multiple charts to a dashboard.

Delete a dashboard

You can delete a dashboard if you no longer need it. However, you cannot recover a deleted dashboard.

1. Log on to the Log Service console, and then click the destination project name.

2. In the left-side navigation pane, click the **Dashboard** icon.
3. Click the icon next to the dashboard that you want to delete, and then select **Delete**.

28.1.4.11.2.3. Configure the display mode of a dashboard

This topic describes how to configure the display mode of a dashboard. By default, you can view all charts in a dashboard in the display mode. When you configure the display mode, you can add chart elements, enable automatic refresh, and set the title display mode.

Set a query time range for a dashboard of a Logstore

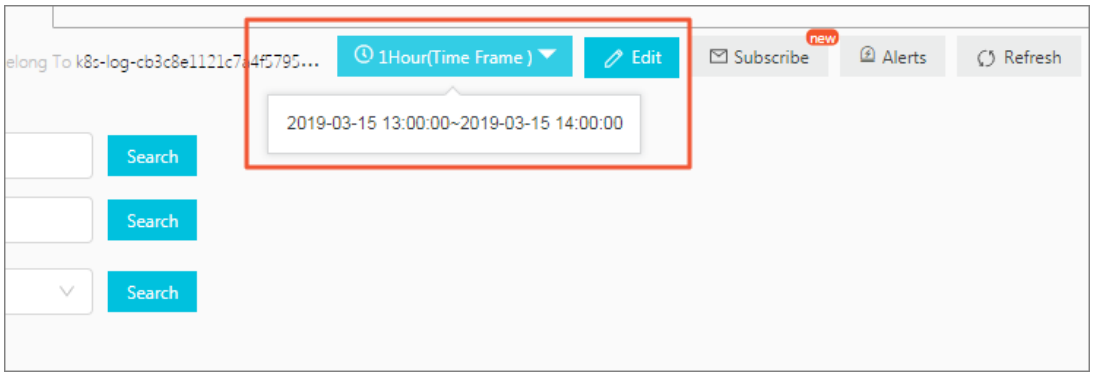
By default, all charts in a dashboard use the query time range that is set for the dashboard. For more information about how to set a query time range for a single chart, see Set a query time range for a chart.

> **Note** On the dashboard page, you can click **Time Range** to specify a time range for a query. The specified query time range is used only for the current query. The next time you open the dashboard, the system will display the analysis results in the default query time range.

1. Log on to the Log Service console.
2. Click a project name.
3. In the left-side navigation pane, click the **Dashboard** icon.
4. Click the icon next to the dashboard, and then select **Details** from the drop-down list.
5. Click **Time Range** to set a time range.

   You can set one of the following time ranges:

   - Relative: queries log data obtained in a time range of 1 minute, 5 minutes, 15 minutes, or other time ranges that end with the current time, accurate to the second. For example, if the current time is 19:20:31 and you select 1Hour as the relative time, the charts on the dashboard display the analysis results of the log data queried from 18:20:31 to 19:20:31.
   - Time Frame: If you select or customize a time range less than one hour (for example, 1 minute, 5 minutes, and 15 minutes), log data obtained in the time range that ends with the current time is queried, accurate to the minute. If you select or customize a time range greater than one hour, log data obtained on the hour before the current time is queried. For example, if the current time is 19:20:31 and you select 1Hour as the time frame, the charts on the dashboard display the analysis results of the log data queried from 18:00:00 to 19:00:00.
   - Custom: queries log data obtained in a specified time range.
6. Move the pointer over the **Time Range** button to confirm the specified time range.



Switch to the edit mode

Click **Edit** to switch to the edit mode of the dashboard. In the edit mode, you can add Markdown chart, custom charts, text, icons, and other chart elements to the dashboard. For more information, see Edit mode.

Set alerts

On the dashboard page, choose **Alerts > Create** to create an alert. Choose **Alerts > Modify** to modify an alert. An alert must be associated with one or more charts.

For more information, see Configure alerts.

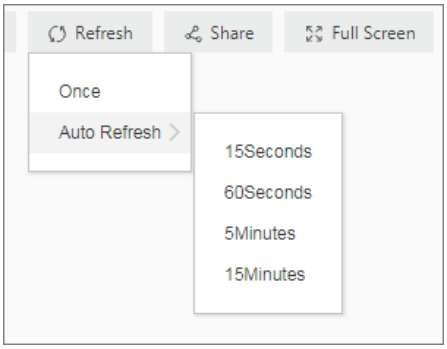
Set a refresh method

You can manually refresh the dashboard, or set an automatic refresh interval for the dashboard.

- To manually refresh the dashboard, choose **Refresh > Once**.
- To set an automatic refresh interval for the dashboard, choose **Refresh > Auto Refresh**, and then select an interval.

  The **Auto Refresh** interval can be 15 seconds, 60 seconds, 5 minutes, or 15 minutes.

> **Note** If your browser is inactive, the automatic refresh interval may be inaccurate.



Share a dashboard

To share a dashboard with authorized users, click **Share** to copy the link of the dashboard page and then send the link to the users. The shared dashboard page uses the settings of the dashboard at the time of sharing. The settings include the time range of charts and chart title format.

> **Note** Before you share the dashboard with other users, you must grant relevant permissions to them.

Display a dashboard in full screen

Click **Full Screen**. Then the charts on a dashboard are displayed in full screen.

Set the chart title format

On the dashboard page, click **Title Configuration**. Available title formats include:

- Single-line Title and Time Display
- Title Only
- Time Only

Reset the query time range

To restore the default query time ranges of all charts on the dashboard, click **Reset Time**.

Select chart view

- View analysis details of a chart

To view analysis details of a chart, move the pointer over the More icon in the upper-right corner of the chart, and then select **View Analysis Details**. The corresponding Search & Analysis page appears, showing the query statement and property settings.

- Set the query time range for a chart

  To set the query time range for a chart, move the pointer over the More icon in the upper-right corner of the chart, and then select **Select Time Range**. The settings are valid only for the current chart.

- Set an alert for a chart

  To set an alert for a chart, move the pointer over the More icon in the upper-right corner of the chart, and then select **Create Alert**. For more information, see Configure alerts.

- Download log analysis results of a chart

  To download analysis results of a chart, move the pointer over the More icon in the upper-right corner of the chart, and then select **Download Log**.

- Download a chart

  To download a chart, move the pointer over the More icon in the upper-right corner of the chart, and then select **Download Chart**.

- Check whether a drill-down event is configured for a chart

  To check whether a drill-down event is configured for a chart, move the pointer over the More icon in the upper-right corner of the chart. Then, check the color of the hand icon at the bottom of the shortcut menu. If the icon is red, a drill-down event is configured for the chart. If the icon is gray, no drill-down event is configured for the chart.

> **Note** Different charts in a dashboard have different shortcut menus. For example, you cannot use the shortcut menu of a custom chart or Markdown chart to view analysis details because they are not analysis charts.

28.1.4.11.2.4. Edit mode

You can click the Edit button on the dashboard page to enter the edit mode. Then you can change the configurations of the dashboard and charts on the dashboard.

- Dashboard:
  - You can modify the dashboard name in the upper-left corner of the page.
  - You can use a dashboard as a canvas and add Markdown chart, custom charts, text, icons, and other chart elements to the dashboard.
  - You can add lines between chart elements. The lines are adaptive to the positions of the charts.
  - You can add a filter to the dashboard. Then you can filter chart data in the display mode. For more information, see Configure and use a filter on a dashboard of a Logstore.
  - In addition, you can configure display grid lines to arrange chart elements such as icons in order.
  - You can use the menu bar to manage the chart property settings on the dashboard. For example, you can perform the add, delete, and cancel operations on a chart. You can also configure the size and location of a chart and move a chart to the top or bottom of the dashboard.
- Chart: You can edit a chart on the dashboard. For example, you can modify the statement, properties, and interactive behavior such as drill-down analysis of a chart.

> **Note** All changes to the dashboard take effect only after you click **Save** in the upper-right corner of the page.

Chart elements

In the edit mode of a dashboard, you can add the following chart elements:

- Common icons

  Log Service allows you to display common icons on a dashboard page. You can drag an icon from the menu bar and drop the icon to a specified position.

- Text

  You can drag the text icon from the menu bar and drop the icon to a specified position. Double-click the text box to modify the text.

- Markdown chart

  You can add a Markdown chart to a dashboard and edit the chart with the Markdown syntax.

  Drag the Markdown icon from the menu bar and drop the icon to a specified position. Select **Edit** from the More icon. Then you can set the Markdown content.

- Filter

  You can add a filter to a dashboard. Then you can add search conditions or replace placeholder variables in query statements.

  Click the filter icon in the dashboard menu bar. On the page that appears, configure the filter based on your needs. By default, the filter is in the upper-left corner of the dashboard page. To modify the settings of a filter, you can select **Edit** on the More icon in the upper-right corner of the page.

- Customize SVG

  You can upload a Scalable Vector Graphics (SVG) file to a dashboard. Click the SVG icon in the menu bar. On the page that appears, click the box or drag an SVG file to the box to upload the file.

  > **Note** The size of an SVG file cannot exceed 10 KB.

- Customize image's HTTP link

  You can upload the HTTP link of an image to a dashboard. Click the Customize image's HTTP link icon in the menu bar. On the page that appears, enter the HTTP link of an image and click **OK**.

Layout

In the edit mode, all charts and chart elements are placed on a canvas. You can drag and scale each chart, except for the lines. The horizontal width of a chart is up to 1,000 units. Each unit is equal to `current browser width/1,000`. The vertical height is unlimited and each unit is equal to 1 pixel. Before you arrange a chart on the dashboard, you can click **Display gridlines** to better arrange the position of the chart and the spacing between charts.

You can perform the following operations to arrange a chart on the dashboard:

- Adjust the position of a chart
  - You can drag a chart and drop the chart to a specified position.
  - After you specify a chart, you can click **L** and **T** to adjust the chart position.
- Adjust the width and height of a chart
  - After you specify a chart, you can drag the chart in the lower-right corner to resize the chart.
  - After you specify a chart, you can also specify the **W** and **H** parameters to resize the chart.
- Add lines to connect charts

  You can add a directional line between two charts. When you adjust the position and size of the charts, the line automatically moves to display the relative position between the two charts.

After you select a chart, four squares appear on the border of the chart. These squares indicate the starting point of the connection line. Press and hold one square, and the area where the end point of the connection line is automatically displayed. Move the pointer to this position to connect the two charts.

- You can move a chart to the top or bottom of the dashboard. After you select a chart, you can use the menu bar to move the chart to the top or bottom.

Chart configurations

In the edit mode of a dashboard, you can perform the following operations on chart elements:

- Edit: modifies the query statement, properties, and interactive behavior such as drill-down analysis of a chart.
  i. In the upper-right corner of the dashboard page, click **Edit**.
  ii. Find the target chart and choose > **Edit**.
  iii. Modify the query statement of the chart, **Properties**, **Data Source**, or **Interactive Behavior**.
  iv. Click **Preview**, and then click **OK**.
  v. In the upper-right corner of the dashboard page, click **Save**.
- Copy: creates a copy of the specified chart and retains all configurations.
  i. In the upper-right corner of the dashboard page, click **Edit**.
  ii. Find the target chart and choose > **Copy**.
  iii. Drag the chart copy and drop it to a specified position, and then set the top margin, left margin, and size of the copy.
  iv. In the upper-right corner of the dashboard page, click **Save**.
- Delete: deletes the specified chart from the dashboard.
  i. In the upper-right corner of the dashboard page, click **Edit**.
  ii. Find the target chart and choose > **Delete**.
  iii. In the upper-right corner of the dashboard page, click **Save**.

28.1.4.11.2.5. Drill-down analysis

This topic describes how to configure drill-down analysis for a chart of a Logstore. When you add a chart to a dashboard, you can modify the configurations in the drill-down list to obtain deeper data analysis results.

Prerequisites

- The index feature of the Logstore is enabled and configured. For more information, see Enable the index feature and configure indexes for a Logstore.
- A saved search, a dashboard, and a custom link to which you want to be redirected are configured.
- A placeholder variable is specified in the saved search or the query statement of a chart added to a dashboard to which you are redirected if you want to add a variable. For more information, see Saved search and Create and delete a dashboard.

Context

Drilling is essential for data analysis. This feature allows you to analyze data in a fine-grained or coarse-grained way. This feature includes drill-up and drill-down analysis. You can implement drill-down analysis to gain a deeper insight into data and make a better decision.

Log Service supports drill-down analysis of the following charts: tables, line charts, column charts, bar charts, pie charts, individual value plots, area charts, and treemap charts.

Procedure

1. Log on to the Log Service console.
2. Click the target project name.
3. Click the icon next to the name of the Logstore, and then select **Search & Analysis** from the drop-down list.
4. Enter a query statement in the search box, set a time range, and then click **Search & Analyze**.
5. On the **Graph** tab that appears, select a **chart type**, and then configure the parameters on the **Properties** tab of the chart.
6. Click the **Interactive Behavior** tab. On this tab, configure the **Event Action** for drill-down analysis.
   - **Disable**: disables drill-down analysis.
   - **Open Logstore**: sets the drill-down event to open a Logstore.

     If you configure a filter statement on the Interactive Behavior tab, the filter statement automatically fills the Search & Analyze search box of the redirected Logstore page when you click a value on the chart.

Parameter	Description
Select Logstore	The name of the Logstore to which you want to be redirected.
Open in New Tab	If you turn on this switch, the specified Logstore is opened on a new tab when the interactive behavior is triggered.
Time Range	The query time range of the Logstore to which you are redirected. Valid values: ■ **Default**: The default time range (15 minutes, accurate to the second) is used for a query statement of the redirected Logstore. ■ **Inherit table time**: The time range that a statement queries in the redirected Logstore is the time range specified for the chart when the event is triggered. ■ Relative: The time range that a statement queries in the redirected Logstore is accurate to the second. ■ Time Frame: The time range that a statement queries in the redirected Logstore is accurate to the minute, hour, or day. Default value: **Default**.
Inherit Filtering Conditions	If you turn on the **Inherit Filtering Conditions** switch, the filtering conditions added to the dashboard are synchronized to a query statement of the specified Logstore. The filtering conditions are added before the query statement by using the logical `AND` operator.
Filter	Enter a **Filter Statement** on the **Filter** tab. The filter statement can contain the **Optional Parameter Fields**. If you configure a filter statement on the **Filter** tab, the **filter statement** automatically fills the Search & Analyze search box of the redirected Logstore page when you click a chart value on the dashboard.

   - **Open Saved Search**: sets the drill-down event to execute a saved search.

     You can configure variables and a filter statement for a chart at the same time. When you click a value on the chart:

     ■ If you configure a variable for the chart, the variable value that you click replaces the placeholder variable that you have configured for the saved search and the saved search is executed for drill-down analysis.

- If you configure a filter statement, the filter statement is added to the saved search to which you are redirected.

Parameter	Description
Select Saved Search	The name of the saved search to which you want to be redirected. For more information about how to configure a saved search, see Saved search.
Open in New Tab	If you turn on this switch, the specified saved search is opened on a new tab when the interactive behavior is triggered.
Time Range	The time range of the saved search to which you want to be redirected. Valid values: ■ **Default**: The default time range (15 minutes, accurate to the second) is used for the saved search to which you are redirected. ■ **Inherit table time**: The time range of the saved search is the query time range of the chart that you configure on the dashboard. ■ Relative: The time range of the saved search is accurate to the second. ■ Time Frame: The time range of the saved search is accurate to the minute, hour, or day. Default value: **Default**.
Inherit Filtering Conditions	If you turn on the **Inherit Filtering Conditions** switch, the filtering conditions added on the dashboard are synchronized to the saved search of the specified Logstore. The filtering conditions are added before the saved search by using the logical `AND` operator.
Filter	Click the **Filter** tab, and then enter a **Filter Statement**. The filter statement can contain the **Optional Parameter Fields**. If you configure a filter statement on the **Filter** tab, the **Filter Statement** is added to the saved search when you click a chart value on the dashboard.
Variable	Click the **Variable** tab, click **Add Variable**, and then set the following parameters: ■ **Replace Variable Name**: the variable that triggers the drill-down event. When you click this variable, you are redirected to the specified saved search. ■ **Replace the value in the column**: the column where the value that you want to replace data with is located. To process multiple columns, you can specify the current column and other columns. The current column is the column on which you want to perform drill-down analysis. Specify the current column in the **Replace the value in the column** field. Other columns can be the fields in the chart for which you configure drill-down analysis. If the variable name of the saved search is the same as the added variable, the variable of the saved search is replaced with the chart value that triggers the drill-down event. This helps you use the saved search for analysis in an efficient way. **Note** ■ If you add a variable for drill-down analysis, you must first configure a placeholder variable for the saved search to which you want to be redirected. ■ You can add up to five placeholder variables for a saved search.

- **Open Dashboard**: sets the drill-down event to open a dashboard.

Analysis charts on a dashboard are visualized query results. When you click a chart value on the source dashboard:

- If you configure a variable for the chart and set a placeholder variable for the chart on the destination dashboard to which you want to be redirected, the placeholder variable is replaced with the chart value that you click.
- If you configure a filter statement, the filter statement is added to the query statement of the chart on the destination dashboard.

Parameter	Description
Select Dashboard	The name of the dashboard to which you want to be redirected. For more information, see Create and delete a dashboard.
Open in New Tab	If you turn on this switch, the specified dashboard is opened on a new tab when interactive behavior is triggered.
Time Range	Set the time range for the dashboard to which you want to be redirected. Valid values: ■ **Default**: After you are redirected to the dashboard by clicking a chart value on the current dashboard, the selected dashboard uses its original time range. ■ **Inherit table time**: After you are redirected to the selected dashboard, the time range of the chart on the selected dashboard is the time range of the chart specified on the source dashboard when the event is triggered. ■ Relative: After you are redirected to the selected dashboard, set the time range of the selected dashboard to the specified relative time. ■ Time Frame: After you are redirected to the selected dashboard set the time range of the selected dashboard to the specified time frame. Default value: **Default**.
Inherit Filtering Conditions	If you turn on the **Inherit Filtering Conditions** switch, the filtering conditions added on the current dashboard are synchronized to the dashboard to which you are redirected. The filtering conditions are added before the query statement by using the logical `AND` operator.
Filter	Click the **Filter** tab, and then enter a **Filter Statement**. The filter statement can contain the **Optional Parameter Fields**. If you have set the **Filter**, a filtering condition is added to the selected dashboard when you click a chart value on the current dashboard. The filtering condition is the specified **Filter Statement**.

Parameter	Description
Variable	Click the **Variable** tab, click **Add Variable**, and then set the following parameters: ■ **Replace Variable Name**: the variable that triggers drill-down analysis. When you click this variable, you are redirected to the selected dashboard. ■ **Replace the value in the column**: the column where the value that you want to replace data with is located. To process multiple columns, you can specify the **Default Column** and other columns. The **Default Column** is the current column on which you want to perform drill-down analysis. Other columns can be fields in the chart for which you configure drill-down analysis. If the variable in the query statement of the chart on the selected dashboard is the same as the added variable, the variable is replaced with the chart value that triggers the drill-down event. This changes the query statement of the chart on the selected dashboard. **Note** ■ If you add a variable for drill-down analysis, you must first configure a placeholder in the query statement for the selected dashboard to which you want to be redirected. ■ You can add up to five variables.

- **Custom HTTP Link**: sets the drill-down event to open a custom HTTP link.

  The path in the HTTP link is the path of the destination file in the server. When you add optional parameter fields to the path and click the chart value on the dashboard, the added parameter fields are replaced with the chart value. At the same time, you are redirected to the new HTTP link.

Parameter	Description
Enter Link	The destination address to which you want to be redirected.
Optional Parameter Fields	By clicking an optional parameter variable, you can replace a part of the HTTP link with the chart value that triggers a drill-down event.

7. Click **Add to New Dashboard** and set the dashboard name and chart name.

Example

You want to store collected NGINX access logs in a Logstore named accesslog, display the relevant analysis results on a dashboard named RequestMethod, and display the page view (PV) changes over time on a dashboard named destination_drilldown. You can configure drill-down analysis for the table of request methods, add the table to the RequestMethod dashboard, and then configure the drill-down event that redirects you to the destination_drilldown dashboard. When you click a request method on the table on the RequestMethod dashboard, you are redirected to the destination_drilldown dashboard. Then you can view the PV changes on the dashboard.

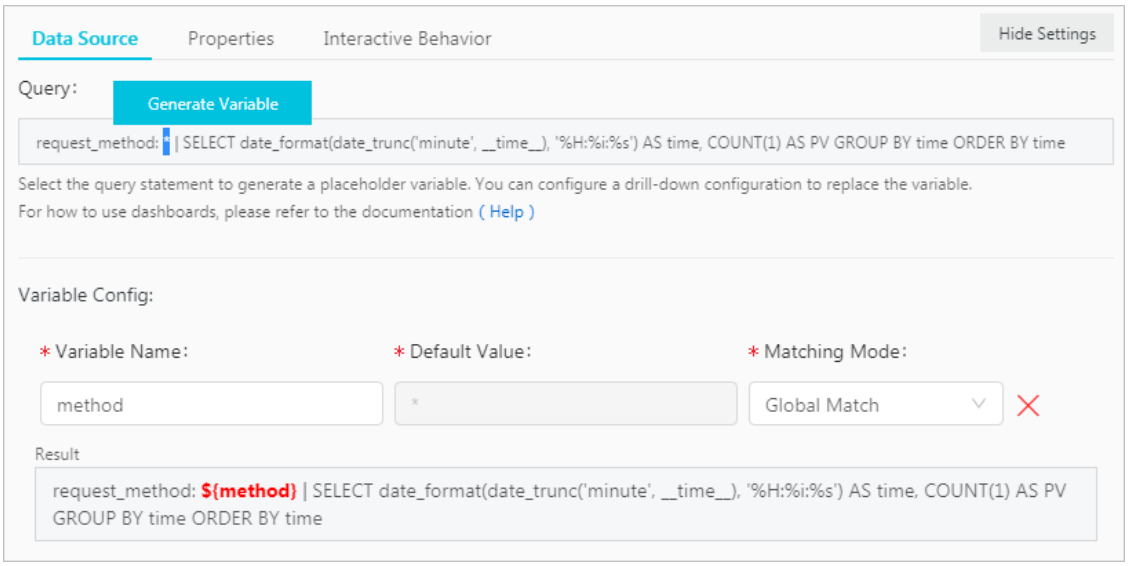
1. Set the dashboard to which you want to be redirected.
   i. Filter log data by request method and analyze how the PV of each request method changes over time.

      The query statement is shown as follows:

```
request_method: * | SELECT date_format(date_trunc('minute', __time__), '%H:%i:%s') AS time, C
OUNT(1) AS PV GROUP BY time ORDER BY time
```

ii. Use a line chart to display the query result and add the line chart to the dashboard named destination_drilldown.

Before you add the line chart to the dashboard, specify the asterisk (`*`) to generate a placeholder variable and set the variable name to method. If the variable name of another chart for which you configure drill-down analysis is method, when you click the variable value on the chart to trigger drill-down analysis, the asterisk (`*`) is replaced with the value that you click and the query statement of the line chart is performed.



2. Configure drill-down analysis for a chart and add the chart to the dashboard.

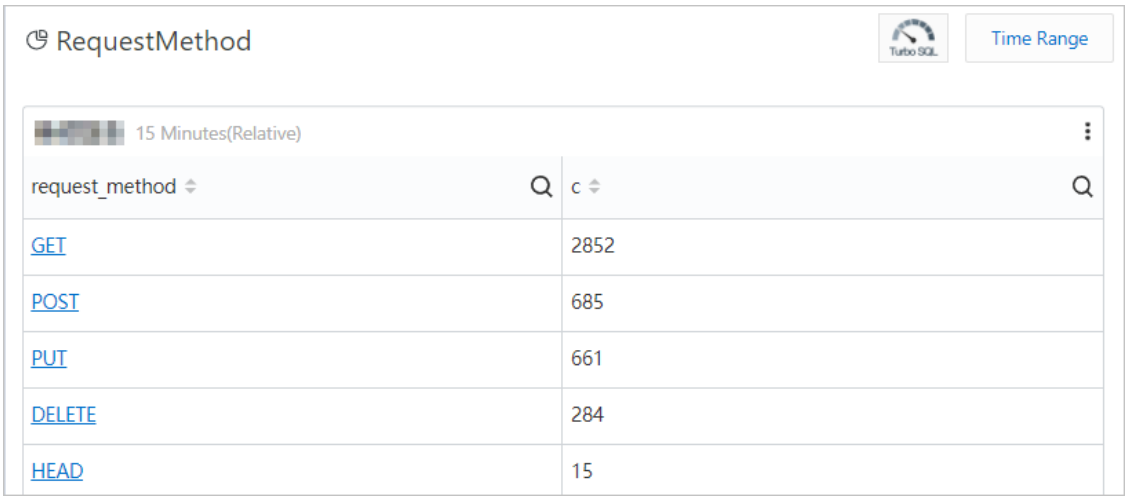
i. On the Search & Analysis page, enter a SQL statement to query the number of NGINX access log entries of each request method, and display the result in a table.

The query statement is shown as follows:

```
*|SELECT request_method, COUNT(1) AS c GROUP BY request_method ORDER BY c DESC LIMIT 10
```

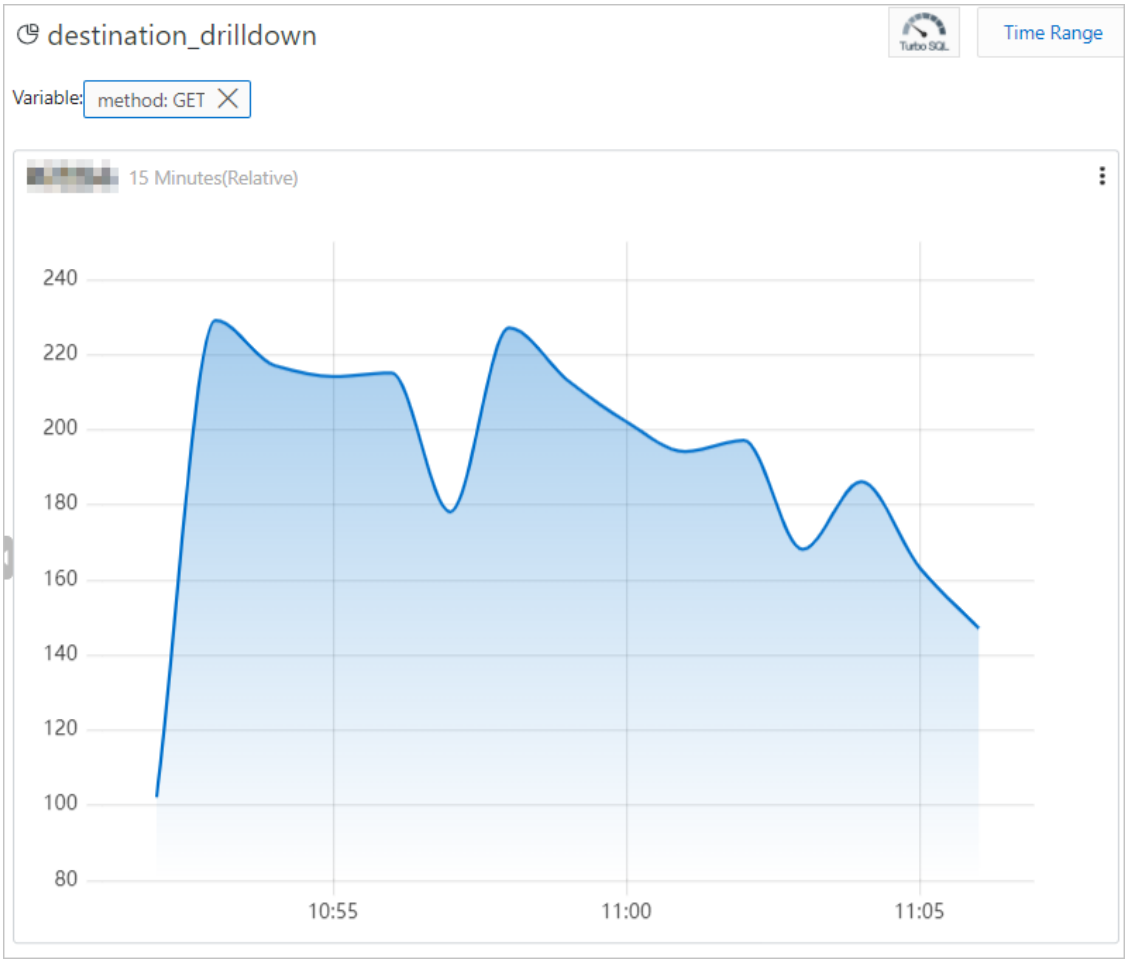
ii. Configure drill-down analysis for the `request_method` column in the table.

iii. Click the GET request on the RequestMethod dashboard.



iv. Redirected to the destination_drilldown dashboard.

You are redirected to the dashboard configured in step . The asterisk (`*`) in the query statement is replaced with `GET` . The dashboard shows how the PV of the GET request changes over time.



28.1.4.11.2.6. Configure and use a filter on a dashboard of a Logstore

This topic describes how to configure and use a filter on a dashboard of a Logstore. Filters help you refine search results or replace placeholder variables with specified values.

Prerequisites

- The index feature of the Logstore is enabled and configured. For more information, see Enable the index feature and configure indexes for a Logstore.
- A dashboard is created. For more information, see Create and delete a dashboard. A placeholder variable is specified for charts on the dashboard if the filter type is set to Replace Variable.

Context

Each chart on a dashboard is a visualized query statement. When you configure a filter on a dashboard, the specified filtering condition or variables apply to all charts on the dashboard. You can configure the following two types of filters:

- Filter: Add key-value pairs as a filtering condition before the query statement `[search query]` . The new query statement is `key:value AND [search query]` , which means to search the result of the original query

statement for log entries that contain `key:value`. For the **Filter** type, you can select or enter multiple key-value pairs. When you select multiple key-value pairs as filtering conditions, the logical `OR` operator is used between the pairs.

- Replace Variable: Specify a variable. If the dashboard contains a chart configured with the same placeholder variable, the placeholder variable in the query statement of the chart is replaced with the selected value.

Components

Each filter chart has one or more filters. Each filter consists of the following two components:

- The key, which indicates a filter operation.
- The values of the key.

Procedure

1. Log on to the Log Service console.
2. Click a project name.
3. In the left-side navigation pane, click the **Dashboard** icon.
4. In the dashboard list, click the name of the target dashboard.
5. On the dashboard page, click **Edit** to enter the edit mode.
6. Click the icon, and then set the filter parameters. Click **OK**.

Parameters of a filter

Parameter	Description
Filter Name	The name of the filter.
Display Settings	Valid values: ○ Title: specifies to add a title for a filter. You can turn on the Title switch to add a title for a filter. ○ Border: specifies to add borders for a filter. You can turn on the Border switch to add borders for a filter. ○ Background: specifies to add a white background for a filter. You can turn on the Background switch to add a white background for a filter.
Type	The filter type. Valid values: ○ If you select **Filter**, a List Item is a value of a key that is used to filter the results of a query statement. You can set multiple values for a key. After the filter takes effect, you can select one or more values on the dashboard to filter query results based on your needs. ○ If you select **Replace Variable**, a List Item is the value that replaces a specified variable. You can set multiple values for a variable. After the filter takes effect, you can select one or more values on the dashboard to filter query results based on your needs.

Parameter	Description
Key	◦ For the **Filter** type, the **Key** parameter specifies the key in the filtering condition. ◦ For the **Replace Variable** type, the **Key** parameter specifies the variable. **Note** The variable must be the same as the placeholder variable that you specified for charts. Otherwise, the placeholder variable cannot be replaced.
Alias	The alias of the key. This parameter is available only when you select **Filter**. After you set an alias for a key, the alias is displayed in the filter on the dashboard.
Global filter	This switch indicates whether to filter the specified values in all fields. This switch is turned off by default. The switch is available only when you select the **Filter** type. ◦ To filter the specified values in all fields, turn on the **Global filter** switch. ◦ To filter the specified values in specified keys, turn off the **Global filter** switch.
Static List Items	The values of the key that is used as a filtering condition. Click the **plus sign** and enter a value for the key in the text box.
Add Dynamic List Item	The dynamic value of the key retrieved by running the specified query statement. Turn on the **Add Dynamic List Item** switch, select a Logstore, and turn on the Inherit Filtering Conditions switch (specifies whether to include the filtering condition in the query statement). Enter a query statement in the search box, specify a time range, and then click **Search** to preview the dynamic values.

Examples

You can use a filter to modify the query statements of charts on a dashboard and replace placeholder variables in the charts on the dashboard. Each chart represents a query statement in the format of `[search query] | [sql query]`. The filter query is appended to the original query statement to filter data.

- If the filter type is Filter, the key-value pairs to be filtered are added before `[search query]` to form a new query statement by using the logical `AND` operator. The new query statement is `key:value AND [search query]`.
- If the filter type is Replace Variable, the filter queries all charts that contain the specified placeholder variables on the dashboard and replaces the placeholder variables with the selected `values`.

Example 1: Use different time granularities to analyze logs

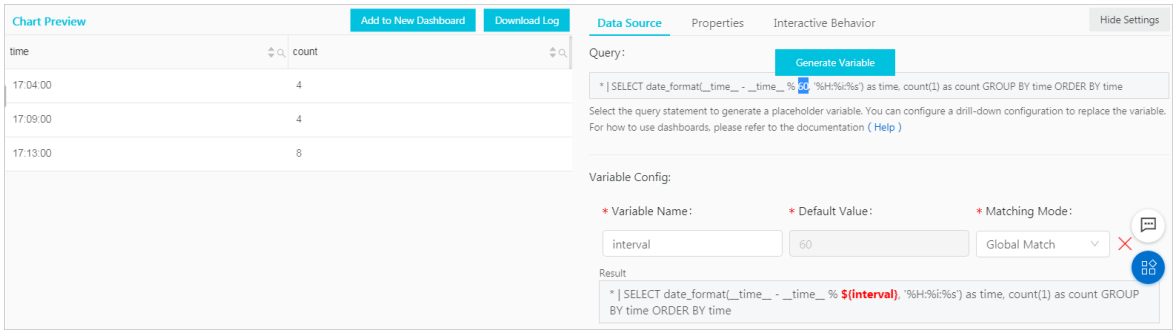
After you collect NGINX access logs, you need to query and analyze these logs in real time.

You can use a query statement to view the number of page views (PVs) per minute. However, if you want to view the number of PVs per second, you must modify the value of `__time__ - __time__ % 60` in the query statement. To simplify this operation, you can use a filter to replace variables in the query statement.

1. Use the following query statement to view the number of PVs per minute:

```
* | SELECT date_format(__time__ - __time__ % 60, '%H:%i:%s') as time, count(1) as count GROUP BY time ORDER BY time
```

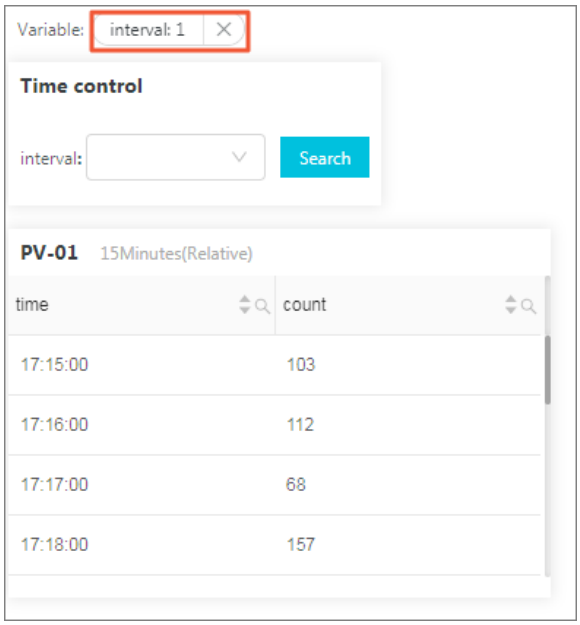
2. Add the chart to a dashboard, and select `60` generate a variable with the name `interval`.



3. Add a filter on the dashboard page.
   - **Type**: Select **Replace Variable**.
   - **Key**: Enter `interval`.
   - **Static List Items**: Add `1` and `120` as values of the key. The default unit is seconds.
4. In the Filter section of the dashboard, select `1` from the Interval drop-down list to view statistics by second.

   The following statement shows the query statement after the placeholder variable is replaced:

```
* | SELECT date_format(__time__ - __time__ % 1, '%H:%i:%s') as time, count(1) as count GROUP BY time ORDER BY time
```



Example 2: Switch between request methods

You can add dynamic values to a filter to dynamically switch between request methods. In example 1, the query statement starts with an asterisk (`*`), which means no condition is set to filter the query results and all logs are queried. You can add another filter to view the PV data of different request `methods`.

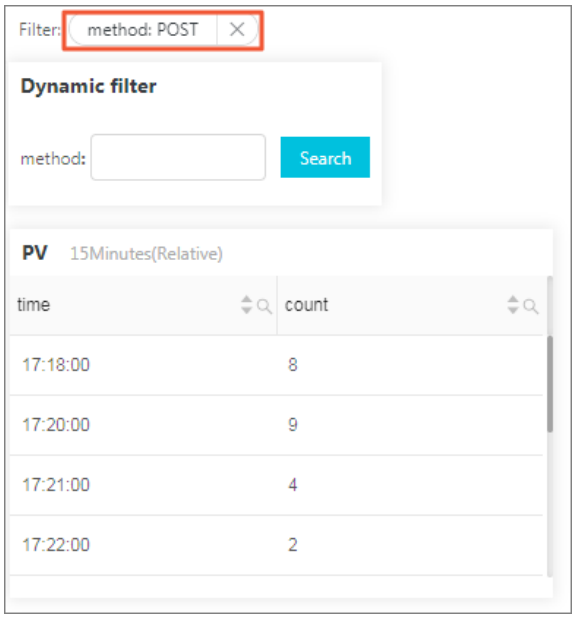
1. Add a filter on the dashboard and turn on the **Add Dynamic List Item** switch.

   Set the parameters as follows:
   - **Type**: Select Filter.
   - **Key**: Enter `method`.
   - **Select Logstore**: Select the Logstore to which the dashboard belongs.
   - **Add Dynamic List Item**: Enter a query statement to obtain the relevant dynamic values, and then click OK.

2. In the Filter section of the dashboard, select `POST` from the method drop-down list.

   Only the PV data whose `method` is `POST` is displayed in the chart. The query statement is changed as follows:

```
(*) and (method: POST) | SELECT date_format(__time__ - __time__ % 60, '%H:%i:%s') as time, count(
1) as count GROUP BY time ORDER BY time
```



28.1.4.11.2.7. Markdown chart

Log Service allows you to add a Markdown chart to a dashboard. In the Markdown chart, you can insert images, links, videos, and other elements to make your dashboard page more intuitive.

Context

You can create different Markdown charts based on your business needs. Markdown charts can make a dashboard more informative. You can insert text such as background information, chart description, notes, extension information, and custom images in a Markdown chart. You can also insert saved searches or dashboard links of other projects to redirect to other query pages.

Scenarios

You can insert links in a Markdown chart to redirect to other dashboard pages of the current project. You can also insert an image corresponding to each link for better recognition. In addition, you can use a Markdown chart to describe parameters of analysis charts.

Procedure

1. Log on to the Log Service console.
2. Click the destination project name.
3. In the left-side navigation pane, click the **Dashboard** icon.
4. In the dashboard list, click the name of the destination dashboard.
5. In the upper-right corner of the dashboard page, click **Edit** to enter the edit mode.
6. In edit mode, drag the Markdown icon from the menu bar to the specified location to create a Markdown chart.
7. Click the created Markdown chart, find the More icon in the upper-right corner of the chart, and click **edit**.

Parameter	Description
Chart Name	The name of the Markdown chart.
Show Border	Specifies whether to show the borders of a Markdown chart. You can turn on the **Show Border** switch to show the borders of a Markdown chart.
Show Title	Specifies whether to show the title of a Markdown chart. You can turn on the **Show Title** switch to show the title of a Markdown chart.
Show Background	Specifies whether to show the background of a Markdown chart. You can turn on the **Show Background** switch to show the background of a Markdown chart.
Query Binding	Specifies whether to bind a query statement to a Markdown chart. You can turn on the **Query Binding** switch and bind a query statement to a Markdown chart. Then, query results are dynamically displayed in the Markdown chart.

8. (Optional)Bind a query statement.
   i. Select the destination Logstore and enter a query statement in the search box. A query statement consists of a search statement and an analytic statement in the format of `search statement|analytic statement`.
   ii. On the Search & Analysis page, click **15 Minutes(Relative)** to set the time range for the query.
   iii. Click **Search** to display the first values of the returned query result.
   iv. Click the plus sign next to a field to insert the corresponding query result to **Markdown Content**.
9. Edit **Markdown Content**.

   Enter Markdown content in the **Markdown content** column. Then, data preview is displayed in real time in the **Show Chart** column on the right. You can modify the Markdown content based on the data preview.

Modify a Markdown chart

- Modify the location and size of a Markdown chart
  i. Click **Edit** in the upper-right corner of the **Dashboard** page.
  ii. Drag the Markdown icon to the specified location on the dashboard and drag the lower-right corner of the chart to adjust its size.
  iii. Click **Save** in the upper-right corner of the dashboard page to save the modification.
- Modify the title of a Markdown chart
  i. Click **Edit** in the upper-right corner of the **Dashboard** page.
  ii. Click the specified Markdown chart, find the More icon in the upper-right corner of the chart, and click **Edit**.
  iii. Enter a new title in the **Chart name** field and then click **OK**.
  iv. Click **Save** in the upper-right corner of the dashboard page. In the dialog box that appears, click **OK**.
- Modify the content of a Markdown chart
  i. Click **Edit** in the upper-right corner of the **Dashboard** page.
  ii. Click the specified Markdown chart, find the More icon in the upper-right corner of chart, and then click **Edit**.
  iii. Modify the chart content, and then click **OK**.
  iv. Click **Save** in the upper-right corner of the dashboard page. In the dialog box that appears, click **OK**.
- Delete a Markdown chart
  i. Click **Edit** in the upper-right corner of the **Dashboard** page.

ii. Click the specified Markdown chart, find the More icon in the upper-right corner of chart, and then click **Delete**.

iii. Click **Save** in the upper-right corner of the dashboard page. In the dialog box that appears, click **OK**.

28.1.5. Alerts

28.1.5.1. Overview

Log Service enables you to configure alerts for charts on a dashboard to monitor the service status in real time.

You can configure alerts on the **Search & Analysis** page of a Logstore or on a **Dashboard** page. When you configure an alert, you must configure the alert name, trigger condition, notification method, and other parameters. After you Configure alerts, Log Service checks the query results on the dashboard at an interval and sends an alert notification if the check results meet the specified conditions. In this way, Log Service facilitates real-time monitoring of the service status.

Limits

Item	Description
Associated charts	The number of charts that can be associated with an alert ranges from 1 to 3.
String	If the length of a string exceeds 1,024 characters, only the first 1,024 characters are computed during a query.
Conditional expression	• The conditional expression must be 1 to 128 characters in length. • The conditional expression is evaluated based on the first 100 log entries returned for a query. • The conditional expression can be evaluated up to 1,000 times. If the conditional expression is not matched, the alert is not triggered.
Search Period	The time range of each query statement cannot exceed 24 hours.

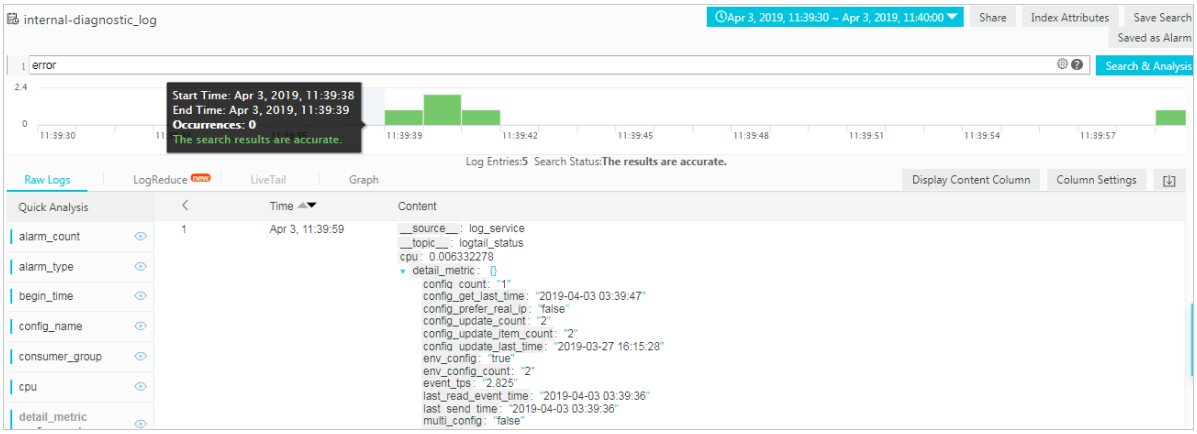
Query statement in an alert

An alert is configured based on analysis charts on a dashboard. An analysis chart is a visualized query result of a query statement. A query statement can include a search statement and an analytic statement.

- If you use only a search statement for a query, log data that matches the search condition is returned.
- If you include search and analytic statements for a query, log data that matches the search condition is analyzed before being returned.
- Search statement

  For example, you want to query the data that contains "error" information in the last 15 minutes. The search statement is error. A total of 154 log entries are retrieved. Each log entry consists of key-value pairs. You can set an alert rule for the value of a key.

  > **Note** If over 100 log entries are returned for a query, only the first 100 log entries are used for evaluating the conditions set in an alert. An alert is triggered when any of the first 100 log entries returned meets the conditions.

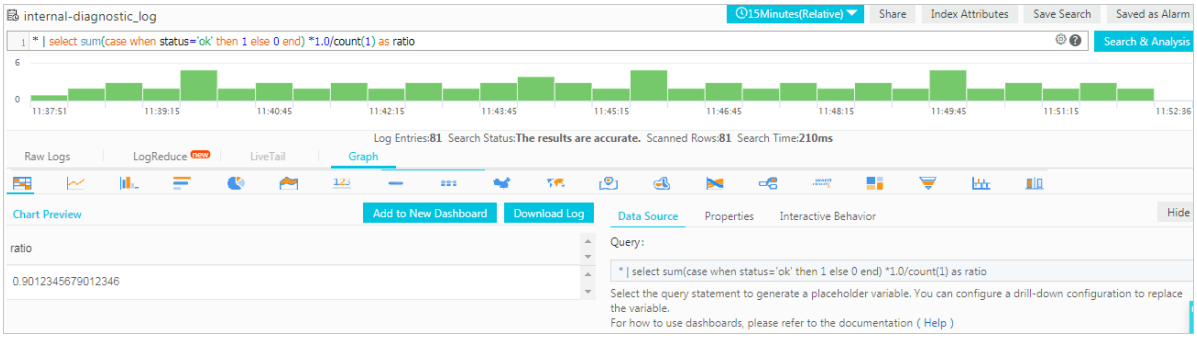


- Search and analytic statement

For example, the following statement queries the ratio of log entries whose status field value is ok to all log entries. For more information about query syntax, see Query syntax.

```
* | select sum(case when status='ok' then 1 else 0 end) *1.0/count(1) as ratio
```

If you set the trigger condition of an alert to `ratio < 0.9`, the alert is triggered when the ratio of log entries whose status field value is ok to all log entries is less than 90%.



28.1.5.2. Configure an alarm

28.1.5.2.1. Configure alerts

Log Service allows you to configure alerts on the Search & Analysis page of a Logstore or on a dashboard page. If the trigger condition of an alert is met, the alert is triggered and a notification is sent to specified recipients.

Prerequisites

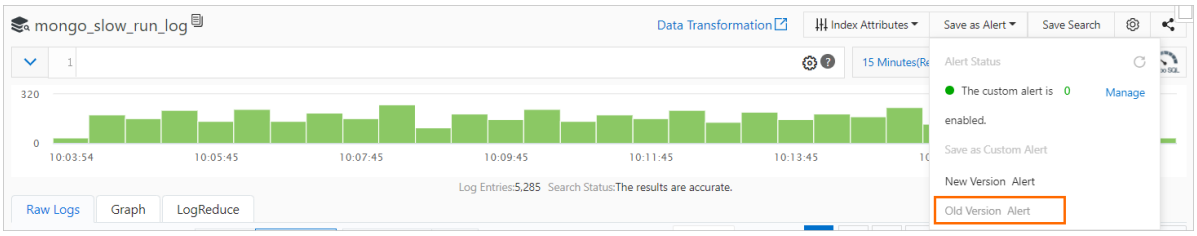
- Log data is collected.
- The indexing feature is enabled and indexes are configured. For more information, see Enable the index feature and configure indexes for a Logstore.

Context

Alerts are configured based on analysis charts. When you view an analysis chart, you can add the chart to a dashboard and configure an alert for the chart. You can also configure an alert for the existing charts on a dashboard.

- Create a chart and configure an alert for the chart

  You can save the results of a query statement as a chart on a dashboard, and configure an alert for the chart. When you configure an alert on the Search & Analysis page, you must specify the name of the dashboard on which the chart is saved and the chart name.



- Configure an alert for existing charts on a dashboard.

  You can configure an alert for one or more charts on a dashboard at a time. When you configure an alert for multiple charts, you can specify a conditional expression for each chart and combine the conditional expressions into the trigger condition for the alert.

This topic describes how to configure an alert for existing charts on a dashboard.

> **Note** If an alert is configured for a chart on a dashboard and you update the search and analytic statement of the chart, you must update the search and analytic statement in the alert configuration. For more information, see Modify an alert.

For information about example alert configurations, see FAQ about alerts.

Procedure

1. Log on to the Log Service console.
2. In the Projects section, click the name of the project in which you want to create a Logstore.
3. In the left-side navigation pane, click the **Dashboard** icon.
4. Click the target dashboard name.
5. In the upper-right corner of the dashboard, choose **Alerts > Create**.
6. In the Create Alert wizard, configure an alert and click **Next**.

   The following table describes the configuration parameters of an alert.

Parameter	Description
Alert Name	The name of the alert. The name must be 1 to 64 characters in length.
Associated Chart	The chart that is associated with the alert. The **Search Period** parameter specifies the time range of log data that Log Service reads when you query data. You can select a relative time or a time frame. For example, if you set **Search Period** to 15 minutes (relative) and start the query at 14:30:06, Log Service reads the log data that was written from 14:15:06 to 14:30:06. If you set **Search Period** to 15 minutes (time frame) and start the query at 14:30:06, Log Service reads the log data that was written from 14:15:00 to 14:30:00. To associate the alert with multiple charts, you must separately add and configure the charts. The number before the chart name indicates the sequence number of the chart in the alert configuration. You can use the sequence number to associate a chart in the trigger condition.
Frequency	The time interval at which Log Service executes the alert.
Trigger Condition	The conditional expression that determines whether to trigger the alert. If the condition is met, Log Service sends an alert notification based on the specified **Check Frequency** and **Notification Interval**. For example, you can enter `pv%100 > 0 && uv > 0` in the Trigger Condition field. **Note** In the conditional expression, you can use `$sequence number` to differentiate charts. For example, you can use `$0` to identify the chart whose sequence number is 0.
Advanced	

Parameter	Description
Notification Trigger Threshold	If the number of times that the trigger condition is met exceeds this threshold and the specified **Notification Interval** elapses, Log Service sends an alert notification to the specified recipients. The default value of **Notification Trigger Threshold** is 1. This value indicates that each time the specified **Trigger Condition** is met, Log Service checks **Notification Interval** to determine whether to send notifications. You can set a custom value. This way, Log Service sends an alert notification to the specified recipient only after the trigger condition is met multiple times. For example, if you set the value to 100, Log Service checks **Notification Interval** only after the trigger condition is met 100 times. If the **Notification Trigger Threshold** and **Notification Interval** are reached, Log Service sends an alert notifications to the specified recipients. The overall count is then reset to zero. If Log Service fails to check log data due to exceptions such as network failures, the overall count does not change.
Notification Interval	The time interval at which Log Service sends an alert notification. If the number of times that the trigger condition is met exceeds the specified **Notification Trigger Threshold** and the specified notification interval elapses, Log Service sends an alert notification to the specified recipients. If you set this parameter to 5 minutes, you can receive up to one alert notification every 5 minutes. The default value is No Interval. **Note** You can use the Notification Trigger Threshold and Notification Interval parameters to control the number of alert notifications that you receive.

7. Set the notification method.

   Notifications can be sent to a custom webhook address in a specified format. To use this notification method, you must set the **Request URL**, **Request Method**, and **Request Content** parameters. For more information, see Notification methods.

   - **Request URL**: a custom webhook address, for example, https://webhook.com/notify.
   - **Request Method**: the request method. Request methods include GET, PUT, POST, DELETE, and OPTIONS.
   - **Request Content**: the content of the notification. The content must be 1 to 500 characters in length. Template variables are supported.
8. Click **OK**.

28.1.5.2.2. Grant permissions on alerts to a RAM user

This topic describes how to grant a RAM user the permissions to enable the alerting feature.

Context

Grant a RAM user the permissions only to create and modify alerts. Create a custom authorization policy, and apply the policy to the RAM user. For more information, see Procedure in this topic.

Procedure

1.
2. Create a RAM role.
3. Create a permission policy.

Use the following policy and replace the `<Project name>` with the actual project name.

```
{
  "Version": "1",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "log:CreateLogStore",
        "log:CreateIndex",
        "log:UpdateIndex"
      ],
      "Resource": "acs:log:*:*:project/<Project name>/logstore/internal-alert-history"
    },
    {
      "Effect": "Allow",
      "Action": [
        "log:CreateDashboard",
        "log:CreateChart",
        "log:UpdateDashboard"
      ],
      "Resource": "acs:log:*:*:project/<Project name>/dashboard/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "log:*"
      ],
      "Resource": "acs:log:*:*:project/<Project name>/job/*"
    }
  ]
}
```

4. Create a user.
5. Create a RAM user group.
6. Add a RAM user to a RAM user group
7. Grant permissions to a RAM role.

28.1.5.2.3. Notification methods

This topic describes the available notification methods that you can configure for an alert in Log Service.

WebHook-Custom

You can set the notification method to WebHook-Custom. When an alert is triggered, Log Service sends an alert notification to a specified webhook URL by using a specified method.

> **Note** The timeout period of the **WebHook-Custom** notification method is five seconds. If no response is received within five seconds after a notification request is sent, the notification request is deemed to be failed.

1. Configure an alert in the Log Service console. For more information, see Configure alerts. Select **WebHook-Custom** from the Notifications drop-down list.
2. Enter your custom webhook URL in the **Request URL** field. Select a **Request Method**.
3. (Optional)Click **Add Request Headers** to add request header fields.

   By default, the request header contains the field `Content-Type: application/json;charset=utf-8`. You

can add request header fields based on your business needs.

4. Enter the notification content in the **Request Content** field.

   When an alert is triggered, Log Service sends the specified notification content to the custom webhook URL by using the specified method.

5. Click **Submit**.

Template variables

You must set **Content** for each notification method. In the notification content, you can reference some template variables in the ${fieldName} format for the alert. When sending an alert notification, Log Service replaces the template variables referenced in the **Content** field with real values. For example, it replaces ${Project} with the name of the project to which the alert belongs.

> **Note** You must reference valid variables. If a referenced variable does not exist or is invalid, Log Service processes the variable as a null string. If the value of a referenced variable is of the object type, the value is converted and displayed as a JSON string.

The following table lists all the supported variables and reference methods.

Variable	Description	Example	Reference example
Aliuid	The ID of the Apsara Stack tenant account to which the project belongs.	1234567890	The alert configured by the user ${Aliuid} is triggered.
Project	The project to which the alert belongs.	my-project	The alert configured in the project ${Project} is triggered.
AlertID	The unique ID of the alert.	0fdd88063a611aa114938f9371daeeb6-1671a52eb23	The ID of the alert is ${AlertID}.
AlertName	The name of the alert, which must be unique in a project.	alert-1542111415-153472	The alert ${AlertName} is triggered.
AlertDisplayName	The display name of the alert.	My alert	The alert ${AlertDisplayName} is triggered.
Condition	The conditional expression that triggers the alert. Each variable in the conditional expression is replaced with the value that triggers the alert. The value is enclosed in brackets [].	[5] > 1	The conditional expression that triggers the alert is ${Condition}.
RawCondition	The original conditional expression that triggers the alert. Variables in the conditional expression are not replaced.	count > 1	The original conditional expression that triggers the alert is ${RawCondition}.
Dashboard	The name of the dashboard with which the alert is associated.	mydashboard	The alert is associated with the dashboard ${Dashboard}.
DashboardUrl	The URL of the dashboard with which the alert is associated.	https://sls.console.aliyun.com/next/project/myproject/dashboard/mydashboard	The URL of the dashboard associated with the alert is ${DashboardUrl}.

Variable	Description	Example	Reference example
FireTime	The time when the alert is triggered.	2018-01-02 15:04:05	The alert is triggered at ${FireTime}.
FullResultUrl	The URL used to query the history records that an alert rule was executed.	https://sls.console.aliyun.com/next/project/my-project/logsearch/internal-alert-history?endTime=1544083998&queryString=AlertID%3A9155ea1ec10167985519fccede4d5fc7-1678293caad&queryTimeType=99&startTime=1544083968	Click ${FullResultUrl} to view details.

Variable	Description	Example	Reference example

Results	The parameters and results of each log data query. The value is of the array type. For information about parameters in the Results field, see Fields in alert log entries.
	
	Note A maximum of 100 alert notifications can be sent.
		<pre>[
		  {
		    "EndTime": 1542507580,
		    "FireResult": {
		      "__time__": "1542453580",
		      "count": "0"
		    },
		    "LogStore": "test-logstore",
		    "Query": "* | SELECT COUNT(*) as count",
		    "RawResultCount": 1,
		    "RawResults": [
		      {
		        "__time__": "1542453580",
		        "count": "0"
		      }
		    ],
		    "StartTime": 1542453580
		  }
		]</pre>
			The first query starts at ${Results[0].StartTime} and ends at ${Results[0].EndTime}. The alert has been triggered ${Results[0].FireResult.count} times.
			
			Note In this example, the number 0 indicates the sequence number of the chart or the search and analytic statement. For more information, see How can I check the sequence number of a chart?

28.1.5.3. Modify and view an alarm

28.1.5.3.1. Modify an alert

This topic describes how to modify an alert. After you create an alert, you can modify the alert and then update the alert. To modify an alert associated with a search statement, you can directly modify the search statement.

Precautions

- You can modify only search statements with which alerts are associated. You cannot modify search statements to search and analytic statements, which are in the format of `search statement|analytic statement`.

  For example, after you associate the `request_method: GET` statement with an alert, you can modify the statement to `error`, but you cannot modify the statement to `error| select count(1) as c`.
- To modify an alert, you can click **Modify Settings** on the **Alert Overview** page, or choose **Alerts > Modify** on the associated dashboard.

Modify the search statement associated with an alert

If you associate a search statement with an alert, you can modify the search statement to modify the alert.

1. Log on to the Log Service console.
2. Click a project name.
3. In the left-side navigation pane, click the **Dashboard** icon.
4. In the dashboard list, click the name of the target dashboard.
5. On the dashboard, choose **Alerts > Modify**.
6. Find the search statement, and then click  .

   You can modify only search statements with which alerts are associated. You cannot modify search statements to search and analytic statements, which are in the format of `search statement|analytic statement`.
7. On the dialog box that appears, enter a new search statement, click **Preview**, and then click **OK** after the search statement is verified.
8. Modify other parameters specific to your environment, such as **Frequency** and **Trigger Condition**, and then click **Next**.
9. Set the notification method, and then click **Submit**.

Modify the chart associated with an alert

After you create an alert, you can modify the chart associated with the alert to modify the alert.

1. In the dashboard list, click the name of the target dashboard.
2. On the dashboard, choose **Alerts > Modify**.
3. Find the **Associated Chart**, and then click  next to **Query**.
4. On the dialog box that appears, enter a new query statement, click **Preview**, and then click **OK** after the query statement is verified.
5. Modify other parameters specific to your environment, such as **Frequency** and **Trigger Condition**, and then click **Next**.
6. Set the notification method.
7. Click **Submit**. The new settings take effect immediately.

28.1.5.3.2. View history alerts

This topic describes how to view history alerts in the Log Service console. Log Service records alerts as log data and creates a dashboard to display alert details.

View history alerts in the Logstore

When you create an alert, Log Service creates a Logstore named **internal-alert-history** for the project to which the alert belongs. A log entry is generated and written to the Logstore each time the alert rule is executed, regardless of whether the alert is triggered. For more information about the fields in the log entry, see Fields in alert log entries.

> **Note** The Logstore does not incur fees and cannot be deleted or modified. Each alert log entry is retained in the Logstore for seven days.

1. Log on to the Log Service console.
2. Click a project name.
3. Click the icon next to the **internal-alert-history** Logstore, and then select **Search & Analysis**.
4. On the page that appears, query alert log entries based on your needs.

View history alerts on the dashboard

After you create an alert, Log Service creates a dashboard named **internal-alert-analysis** for the project to which the alert belongs. The dashboard displays the statistics of all previous alerts, including the number of triggered alerts, percentage of successful alerts and notifications, and top 10 alerts whose alert rules are executed.

> **Note** The dashboard cannot be deleted or modified.

1. In the left-side navigation pane, click the **Dashboard** icon.
2. Click **Alert History Statistics** to open the dashboard page.

   On the **Alert History Statistics** dashboard, the details of history alerts are displayed, including whether the alerts are triggered, why the alerts are triggered, error information, and other information.

28.1.5.3.3. Manage an alert

This topic describes how to manage an alert after you create the alert.

Context

You can disable, enable, modify, and delete the alert, or view the details of the alert such as the update time.

View the details of an alert

1. Log on to the Log Service console.
2. Click a project name.
3. In the left-side navigation pane, click the **Alerts** icon.
4. In the alert list, click the name of the target alert.

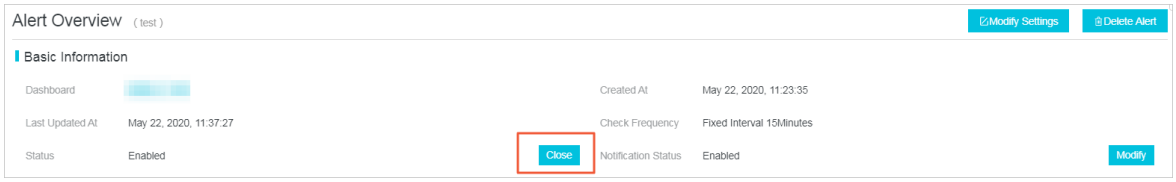
   On the **Alert Overview** page, you can view the details of the alert, such as the dashboard, creation time, last update time, check frequency, alert status, and notification status.

Disable and enable an alert

After you create an alert, you can disable or enable the alert. If you disable an alert, Log Service no longer checks the alert or send alert notifications.

1. In the left-side navigation pane, click the **Alerts** icon.
2. In the alert list, click the name of the target alert.

   On the **Alert Overview** page, click **Enable** or **Close** in the **Alert Status** field.

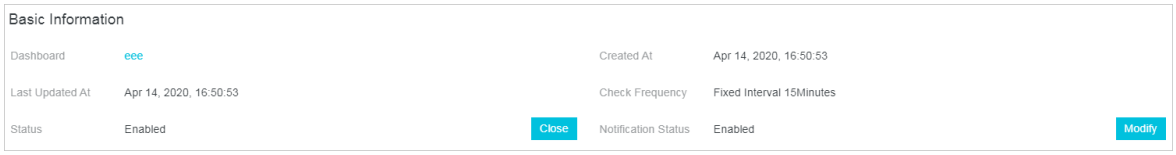


Disable and enable alert notifications

You can disable notifications of enabled alerts. After you disable notifications of an alert, alert notifications are not sent even if the trigger condition is met.

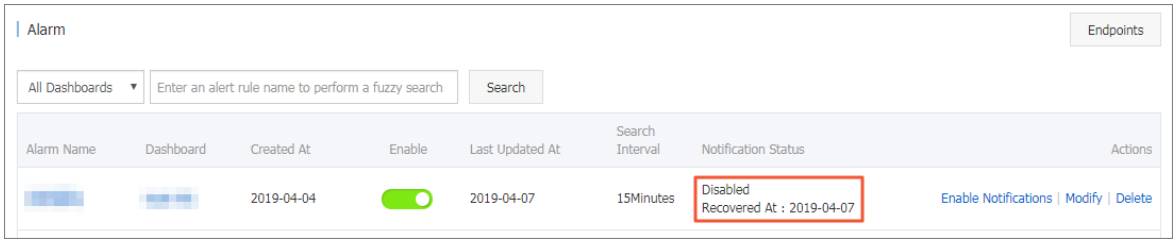
1. In the left-side navigation pane, click the **Alerts** icon.
2. In the alert list, click the name of the target alert.

   On the **Alert Overview** page, click **Modify** in the **Notification Status** field.



3. Set the time range for which notifications are disabled, and then click **Confirm**.

   After you disable alert notifications, you can view the time when alert notifications resume in the **Notification Status** field. You can click **Modify** in the **Notification Status** field to manually resume alert notifications.



Delete an alert

You cannot recover a deleted alert. Proceed with caution when you delete an alert.

1. In the left-side navigation pane, click the **Alerts** icon.
2. In the alert list, click the name of the target alert.
3. On the **Alert Overview** page, click **Delete Alert**.
4. In the dialog box that appears, click **OK**.

28.1.5.4. Relevant syntax and fields for reference

28.1.5.4.1. Conditional expression syntax of an alert

This topic describes how to configure a conditional expression for an alert in Log Service. An alert is triggered if the conditional expression configured for the alert is met.

In determining whether the conditional expression of an alert is met, the results of query statements configured for the alert are used as the inputs and the log fields in the conditional expression are used as the variables. If the conditional expression is met, the alert is triggered.

Limits

- Negative numbers must be enclosed with parentheses (), for example, x +(-100)<100.
- Numeric data is treated as 64-bit floating-point numbers. If a comparison is performed, errors may occur.
- A variable can contain only letters and digits and must start with a letter.
- A conditional expression can be up to 128 characters in length.
- A conditional expression can be evaluated up to 1,000 times. If an alert is configured for multiple charts and the conditional expression of the alert is not met after 1,000 times of evaluation, the alert is not triggered.
- A maximum of three charts can be associated with an alert.
- An alert is triggered if and only if the Boolean value of its conditional expression is true. For example, the result of the expression 100+100 is 200, which cannot trigger the alert.
- `true`, `false`, `$`, and `.` are reserved and cannot be used as variables.

Basic syntax

The following table lists the syntax supported in a conditional expression.

Syntax	Description	Examples
Basic operators	Supports the addition operator (+), subtraction operator (-), multiplication operator (*), division operator (/), and modulus operator (%).	x*100+y>200 x%10>5
Comparison operators	Supports eight comparison operators, including the greater than operator (>), greater than or equal to operator (>=), less than operator (<), less than or equal to operator (<=), equal to operator (==), not equal to operator (! =), match operator (=~), and mismatch operator (! ~). **Note** • Backslashes (/) must be escaped. • Regular expressions support the RE2 syntax.	x >= 0 x < 100 x <= 100 x == 100 x == "foo" Regular expression: x =~ "\\w +"
Logical operators	Supports the logical operators AND (&&) and OR (||).	x >=0&&y <=100 x > 0 || y > 0
Logical negation	Supports the logical negation operator (!).	!(a < 1 && a > 100)

Syntax	Description	Examples
Numeric constants	Numeric constants are processed as 64-bit floating-point numbers.	x > 100
String constants	String constants are formatted in a string enclosed in single quotation marks ('').	foo == 'string'
Boolean constants	Supports true and false.	(x > 100) == true
Parentheses	Parentheses () can be used to enforce precedence order.	x*(y+100)>100
contains function	Determines whether a substring is included in a string. For example, if the result of the contains(field, 'xxxx') function is true, the field string includes the xxxx substring.	contains(foo, 'hello')

Conditional expression for results of multiple query statements

- Syntax

  If you configure an alert for multiple charts, the variables in a conditional expression must be prefixed. In this way, you can specify from which query result to obtain the corresponding values of the variables when it evaluates your expression. The format is `$N.fieldname`, where N is the sequence number of the query statement. You can configure up to three query statements in an alert. Therefore the value range of N is 0 to 2. For example, $0.foo indicates to obtain the value of the foo field returned from the first query statement. If you configure one query statement in an alert, you do not need to specify the prefix.

  > **Note** How can I view the sequence number of a query statement?
  >
  > In the Alert Configuration step, the **Associated Chart** parameter specifies the sequence number of each query statement (chart). The first query statement is numbered 0, the second query statement is numbered 1, and the third statement is numbered 2.

- Evaluate a conditional expression

  If multiple query results are returned, the variables specified in the conditional expression determine how to use the results to evaluate the conditional expression. For example, if you configure three query statements in an alert, x, y, and z log entries are returned when you execute each of the three statements. The conditional expression that you configure for the alert is $0.foo > 100 && $1.bar < 100. Then the first two query results are used to evaluate the conditional expression. A maximum of **x × y** times of evaluation (or 1,000 if x × y is greater than 1,000) is performed. If the conditional expression is met within the maximum times of evaluation, true is returned. Otherwise, false is returned.

Operations

> **Note**
>
> - 64-bit floating-point numbers are used in a conditional expression.
> - Each string constant must be enclosed in single quotation marks ('') or double quotation marks (""), for example, 'string', and "string".
> - Boolean values include true and false.

Operator	Operation		
	Operation between variables	Operation between non-string constants and variables	Operation between string constants and variables
Basic operators, including the addition operator (+), subtraction operator (-), multiplication operator (*), division operator (/), and modulus operator (%)	The left and right operands are converted to numbers before being operated.		Unsupported.
Comparison operators, including the greater than operator (>), greater than or equal to operator (>=), less than operator (<), less than or equal to operator (<=), equal to operator (==), not equal to operator (! =)	Operations are performed based on the following priorities: 1. The left and right operands are converted to numbers before being operated based on the numerical order. If the conversion fails, 2. operands are operated based on the alphabetical order of strings.	The left and right operands are converted to numbers before being operated based on the numerical order.	The left and right operands are operated based on the alphabetical order of strings.
Regular expression match operator (=~) and regular expression mismatch operator (! ~)	The left and right operands are operated based on the alphabetical order of strings.	Unsupported.	The left and right operands are operated based on the alphabetical order of strings.
Logical operators, including AND (&&) and OR (||)	These two operators cannot be directly used on the fields in query results. The left and right operands must be sub-expressions, and the values of the sub-expressions are of the Boolean type.		
Logical negation (!)	This operator cannot be directly used on the fields in query results. The left and right operands must be sub-expressions, and the values of the sub-expressions are of the Boolean type.		

Operator	Operation		
	Operation between variables	Operation between non-string constants and variables	Operation between string constants and variables
contains function	The left and right operands are operated based on the alphabetical order of strings.	Unsupported.	The left and right operands are operated based on the alphabetical order of strings.
Parentheses ()	Parentheses () enforce precedence order.		

28.1.5.4.2. Fields in alert log entries

After you configure an alert, Log Service automatically creates a Logstore to store log entries that are generated when alert rules are executed and notifications are sent. This topic describes fields in alert log entries.

Fields

Field	Description	Example
AlertDisplayName	The display name of an alert.	Test alert rules
AlertID	The unique ID of an alert.	0fdd88063a611aa114938f9371daeeb6-1671a52eb23
AlertName	The unique name of an alert in a project.	alert-1542111415-153472
Condition	The conditional expression configured for an alert.	$0.count > 1
Dashboard	The dashboard associated with an alert.	my-dashboard
FireCount	The cumulative times that an alert has been triggered since the last notification was sent.	1
Fired	Indicates whether an alert was triggered. Valid values: true and false.	true
LastNotifiedAt	The time when the last notification was sent. The time is displayed in a Unix timestamp.	1542164541
NotifyStatus	The status of a notification. Valid values: • Success: indicates that a notification was successfully sent. • Failed: indicates that a notification failed to be sent. • NotNotified: indicates that no notification was sent. • PartialSuccess: indicates that the notification sending partially succeeded.	Success

Field	Description	Example
Reason	The reason that a notification failed to be sent or no notification was sent.	result type is not bool

Results	The parameters and results of each log data query. The value is of the array type. For information about parameters in the Results field, see Parameters in the Result field.	<pre>[
		  {
		  "EndTime": 1542334900,
		  "FireResult": null,
		  "LogStore": "test-logstore",
		  "Query": "* | select count(1) as count",
		  "RawResultCount": 1,
		  "RawResults": [
		  {
		  "__time__": "1542334840",
		  "count": "0"
		  }
		  ],
		  "StartTime": 1542334840
		  }
		]</pre>

Status	The execution result of an alert. Valid values: Success and Failed.	Success

Parameters in the Result field

Parameter	Description	Example
Query	The query statement that is configured in an alert.	* | select count(1) as count
LogStore	The target Logstore of a query.	my-logstore
StartTime	The time when a query starts.	2019-01-02 15:04:05
StartTimeTs	The time when a query starts. The time is in the Unix timestamp format.	1542334840
EndTime	The time when a query ends.	2019-01-02 15:19:05
EndTimeTs	The time when a query ends. The time is in the Unix timestamp format. The actual query time range is `[StartTime, EndTime)`.	1542334900

Parameter	Description	Example

RawResults	The raw query result. The parameter value is formatted in an array where each element is a log entry. The maximum length of the array is 100.	<pre>[
		  {
		  "__time__": "1542334840",
		  "count": "0"
		  }
		]</pre>

RawResultsAsKv	The query result that is formatted in key-value pairs. **Note** This parameter can only be used as a template variable. It is not saved to a Logstore.	[foo:0]
RawResultCount	The number of log entries that are returned in the RawResults parameter.	1

FireResult	The log entry that records the triggering of an alert. If an alert is not triggered, the parameter value is null.	<pre>{
		  "__time__": "1542334840",
		  "count": "0"
		}</pre>

FireResultAsKv	The log entry that records the triggering of an alert, formatted in key-value pairs. **Note** This parameter can only be used as a template variable. It is not saved to a Logstore.	[foo:0]

28.1.6. Real-time consumption

28.1.6.1. Overview

Log Service allows you to consume log data by using multiple methods.

After data is collected to LogHub, you can consume the log data by using two methods. The following table describes the methods.

Method	Scenarios	Timeliness	Retention period
Real-time consumption (LogHub)	Real-time computing	Real time	Custom

Method	Scenarios	Timeliness	Retention period
Indexing and query (LogSearch)	Online query of hot data	Real time	Custom

Real-time consumption

LogHub allows you to pull log data and consume the data in real time. The following procedure describes how log data in a shard is consumed:

1. Obtain a cursor based on the start time and end time of data consumption.
2. Read log data based on the cursor and step parameters and return the position of the next cursor.
3. Move the cursor to continuously consume log data.

- Consume log data by using an SDK

  You can use Log Service SDKs in multiple programming languages such as Java, Python, and Go to consume log data.

- Consume log data by using consumer groups

  Log Service provides an advanced method that allows you to consume logs by using consumer groups. A consumer group is a lightweight computing framework that allows multiple consumers to consume data from a Logstore at the same time. The consumers in a consumer group are automatically allocated shards. Data is consumed in order based on the time when it is written to the Logstore. In addition, the consumers can use checkpoints to resume consumption from a breakpoint. You can use consumer group SDKs in multiple programming languages such as Go, Python, and Java to consume log data.

- Log consumption by using real-time stream processing systems
  - Use Spark Streaming clients to consume log data.
  - Use Storm spouts to consume log data.
  - Use Flink Connector to consume log data.

- Log consumption by using open-source services

  Use Flume to consume log data and import log data to Hadoop file system (HDFS) instances.

Log search and analytics

- You can query log data in the Log Service console.
- You can also query log data by using an SDK or the API of Log Service. Log Service provides an HTTP-based RESTful API. You can call all log query API operations that are provided by Log Service.

28.1.6.2. Consume log data

Log Service provides SDKs in various programming languages, such as Java, Python, and Go. You can use an SDK to consume log data.

Use an SDK to consume log data

The following example shows how to use the SDK for Java to consume log data in a shard:

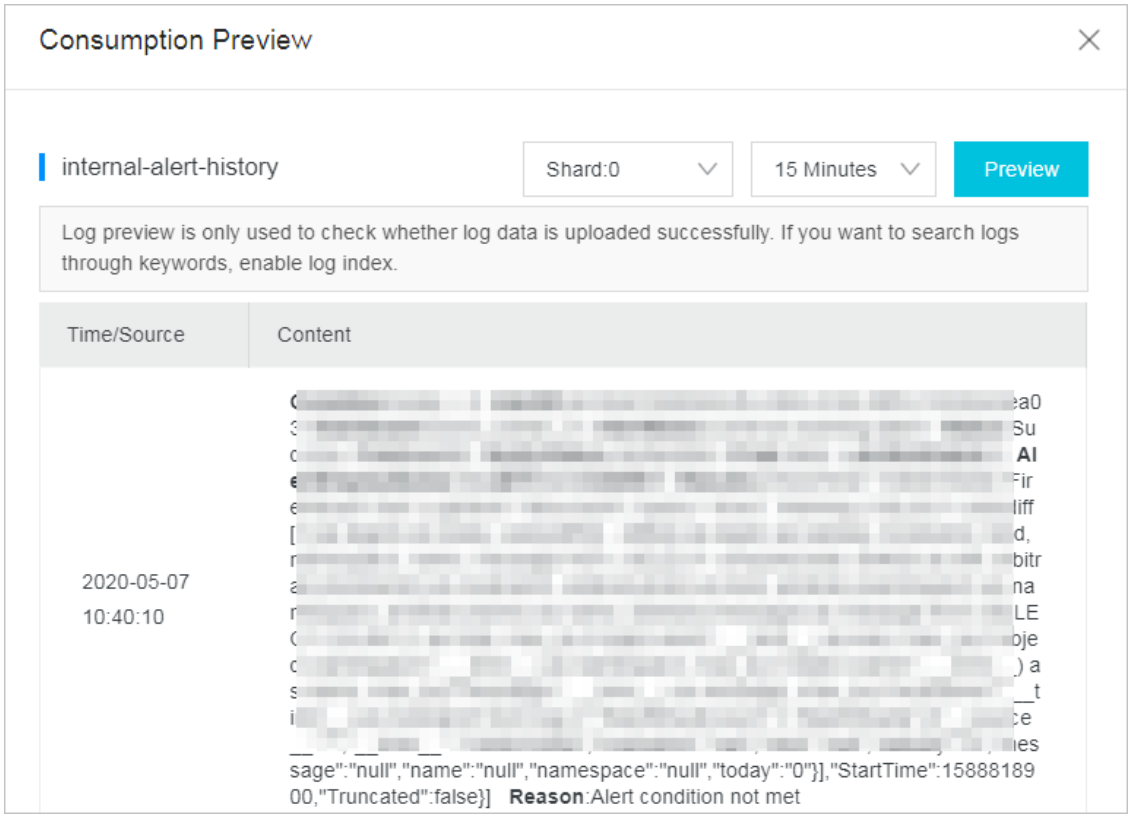
```
Client client = new Client(host, accessId, accessKey);
    String cursor = client.GetCursor(project, logStore, shardId, CursorMode.END).GetCursor();
    System.out.println("cursor = " +cursor);
    try {
      while (true) {
        PullLogsRequest request = new PullLogsRequest(project, logStore, shardId, 1000, cursor);
        PullLogsResponse response = client.pullLogs(request);
        System.out.println(response.getCount());
        System.out.println("cursor = " + cursor + " next_cursor = " + response.getNextCursor());
        if (cursor.equals(response.getNextCursor())) {
            break;
                }
        cursor = response.getNextCursor();
        Thread.sleep(200);
      }
    }
    catch(LogException e) {
      System.out.println(e.GetRequestId() + e.GetErrorMessage());
    }
```

Preview log data in the Log Service console

Log preview is a way of log data consumption. To preview log data that is stored in a Logstore in the Log Service console, perform the following steps:

1. Log on to the Log Service console.
2. In the Projects section, click the target project.
3. In the Logstore list, find the target Logstore, click the icon next to the Logstore, and then select **Consumption Preview**.
4. In the Consumption Preview dialog box, select a shard, set a time range, and then click **Preview**.

   The log preview page displays the log data of the first 10 packets in the specified time range.



28.1.6.3. Consumption by consumer groups

28.1.6.3.1. Use consumer groups to consume log data

Log consumption by using consumer groups

Consumer groups allow you to focus on the business logic during log data consumption. You do not need to consider factors such as Log Service implementation, load balancing among consumers, and failovers that may be introduced when you use an SDK to consume log data.

Terms

The following table describes the terms of consumer groups and consumers.

Term	Description
consumer group	A consumer group consists of multiple consumers. Each consumer in a consumer group consumes different data in a Logstore.
consumer	The consumers in a consumer group consume data from specified data sources. Each consumer name in a consumer group must be unique.

A Logstore has multiple shards. A consumer library allocates shards to consumers in a consumer group based on the following principles:

- Each shard can be allocated to one consumer.
- Each consumer can consume data from multiple shards.

After a new consumer joins a consumer group, the shards allocated to the consumer group are reallocated to each consumer for load balancing. The reallocation is based on the preceding principles and cannot be viewed by users.

A consumer library stores checkpoints. This allows consumers to resume consumption from a breakpoint and avoid repetitive consumption after a program fault is resolved.

Procedure

Log consumption by using consumer groups is implemented in Java or Python. The following procedure takes Java as an example to describe how consumer groups consume log data.

1. Add Maven dependencies.

```
<dependency>
  <groupId>com.google.protobuf</groupId>
  <artifactId>protobuf-java</artifactId>
  <version>2.5.0</version>
</dependency>
<dependency>
  <groupId>com.aliyun.openservices</groupId>
  <artifactId>loghub-client-lib</artifactId>
  <version>0.6.16</version>
</dependency>
```

2. Create a file named main.java.

```
import com.aliyun.openservices.loghub.client.ClientWorker;
import com.aliyun.openservices.loghub.client.config.LogHubConfig;
import com.aliyun.openservices.loghub.client.exceptions.LogHubClientWorkerException;
public class Main {
    // The endpoint of Log Service.
    private static String sEndpoint = "cn-hangzhou.log.aliyuncs.com";
    // The name of a Log Service project.
    private static String sProject = "ali-cn-hangzhou-sls-admin";
    // The name of a Logstore.
    private static String sLogstore = "sls_operation_log";
    // The name of a consumer group.
    private static String sConsumerGroup = "consumerGroupX";
    // The AccessKey pair of an Apsara Stack tenant account or RAM user that is used to consume d
ata.
    private static String sAccessKeyId = "";
    private static String sAccessKey = "";
    public static void main(String[] args) throws LogHubClientWorkerException, InterruptedExcepti
on {
        // The second parameter is the consumer name. Each consumer name in a consumer group must
be unique. However, the names of consumer groups can be the same. When different consumers start
multiple processes on multiple servers to consume the data of a Logstore, you can use a server IP
address to identify a consumer. The ninth parameter maxFetchLogGroupSize indicates the maximum nu
mber of log groups that are retrieved from the server at a time. Valid values: 1 to 1000. You can
use the default value or specify a value based on your requirements.
        LogHubConfig config = new LogHubConfig(sConsumerGroup, "consumer_1", sEndpoint, sProject,
sLogstore, sAccessKeyId, sAccessKey, LogHubConfig.ConsumePosition.BEGIN_CURSOR);
        ClientWorker worker = new ClientWorker(new SampleLogHubProcessorFactory(), config);
        Thread thread = new Thread(worker);
        // The ClientWorker instance automatically runs after the thread is executed and extends
the Runnable interface.
        thread.start();
        Thread.sleep(60 * 60 * 1000);
        // The shutdown function of the ClientWorker instance is called to exit the consumption i
nstance. The associated thread is  automatically stopped.
        worker.shutdown();
        // Multiple asynchronous tasks are generated when the ClientWorker instance is running. W
e recommend that you wait for 30 seconds to ensure that all running tasks exit after shutdown.
        Thread.sleep(30 * 1000);
    }
}
```

3. Create a file named SampleLogHubProcessor.java.

```
import com.aliyun.openservices.log.common.FastLog;
import com.aliyun.openservices.log.common.FastLogContent;
import com.aliyun.openservices.log.common.FastLogGroup;
import com.aliyun.openservices.log.common.FastLogTag;
import com.aliyun.openservices.log.common.LogGroupData;
import com.aliyun.openservices.loghub.client.ILogHubCheckPointTracker;
import com.aliyun.openservices.loghub.client.exceptions.LogHubCheckPointException;
import com.aliyun.openservices.loghub.client.interfaces.ILogHubProcessor;
import com.aliyun.openservices.loghub.client.interfaces.ILogHubProcessorFactory;
import java.util.List;
public class SampleLogHubProcessor implements ILogHubProcessor {
    private int shardId;
    // Record the last persistent checkpoint time.
    private long mLastCheckTime = 0;
    public void initialize(int shardId) {
        this.shardId = shardId;
    }
```

```
    }
    // The main logic of data consumption. All exceptions must be captured and cannot be thrown.
    public String process(List<LogGroupData> logGroups,
                          ILogHubCheckPointTracker checkPointTracker) {
        // Display the retrieved data.
        for (LogGroupData logGroup : logGroups) {
            FastLogGroup flg = logGroup.GetFastLogGroup();
            System.out.println(String.format("\tcategory\t:\t%s\n\tsource\t:\t%s\n\ttopic\t:\t%s\
n\tmachineUUID\t:\t%s",
                    flg.getCategory(), flg.getSource(), flg.getTopic(), flg.getMachineUUID()));
            System.out.println("Tags");
            for (int tagIdx = 0; tagIdx < flg.getLogTagsCount(); ++tagIdx) {
                FastLogTag logtag = flg.getLogTags(tagIdx);
                System.out.println(String.format("\t%s\t:\t%s", logtag.getKey(), logtag.getValue(
)));
            }
            for (int lIdx = 0; lIdx < flg.getLogsCount(); ++lIdx) {
                FastLog log = flg.getLogs(lIdx);
                System.out.println("--------\nLog: " + lIdx + ", time: " + log.getTime() + ", Get
ContentCount: " + log.getContentsCount());
                for (int cIdx = 0; cIdx < log.getContentsCount(); ++cIdx) {
                    FastLogContent content = log.getContents(cIdx);
                    System.out.println(content.getKey() + "\t:\t" + content.getValue());
                }
            }
        }
        long curTime = System.currentTimeMillis();
        // Write checkpoints to the server every 30 seconds. If a ClientWorker instance does not
respond within 30 seconds,
        // a new ClientWorker instance consumes data starting from the last checkpoint. A small a
mount of duplicate data may exist.
        if (curTime - mLastCheckTime > 30 * 1000) {
            try {
                // If the parameter is set to true, checkpoints are synchronized to the server im
mediately. If the parameter is set to false, checkpoints are  locally cached. The default synchro
nization interval of checkpoints is 60 seconds.
                checkPointTracker.saveCheckPoint(true);
            } catch (LogHubCheckPointException e) {
                e.printStackTrace();
            }
            mLastCheckTime = curTime;
        }
        return null;
    }
    // The ClientWorker instance calls this function upon exit. You can perform a cleanup.
    public void shutdown(ILogHubCheckPointTracker checkPointTracker) {
        // Save consumption breakpoints to the server.
        try {
            checkPointTracker.saveCheckPoint(true);
        } catch (LogHubCheckPointException e) {
            e.printStackTrace();
        }
    }
}
class SampleLogHubProcessorFactory implements ILogHubProcessorFactory {
    public ILogHubProcessor generatorProcessor() {
        // Generate a consumption instance.
        return new SampleLogHubProcessor();
    }
}
```

> **Note** Run the preceding code to display all data in a Logstore. If you want multiple consumers to consume data from the same Logstore, you can modify the code based on the comments. You can use the same consumer group name and different consumer names to start new consumption processes.

Limits and troubleshooting

You can create a maximum of 10 consumer groups for each Logstore. The `ConsumerGroupQuotaExceed` error is reported if the number of consumer groups exceeds 10.

We recommend that you configure Log4j for the consumer program to throw error messages within consumer groups. This improves the troubleshooting efficiency. If you save the log4j.properties file to the resources directory and run the program, the following error message appears:

```
[WARN ] 2018-03-14 12:01:52,747 method:com.aliyun.openservices.loghub.client.LogHubConsumer.sampleLog
Error(LogHubConsumer.java:159)
com.aliyun.openservices.log.exception.LogException: Invalid loggroup count, (0,1000]
```

The following example is a typical log4j. properties configuration file:

```
log4j.rootLogger = info,stdout
log4j.appender.stdout = org.apache.log4j.ConsoleAppender
log4j.appender.stdout.Target = System.out
log4j.appender.stdout.layout = org.apache.log4j.PatternLayout
log4j.appender.stdout.layout.ConversionPattern = [%-5p] %d{yyyy-MM-dd HH:mm:ss,SSS} method:%l%n%m%n
```

Advanced operations

The preceding code is suitable for log consumption in common scenarios. This section describes how to perform advanced operations in other scenarios.

- Consume data that is logged from a certain time point

  LoghubConfig in the preceding code has two constructors:

  ```
  // The value of the consumerStartTimeInSeconds parameter is a UNIX timestamp representing the numb
  er of seconds that have elapsed since 00:00:00 on January 1, 1970, 00:00:00 UTC.
  public LogHubConfig(String consumerGroupName,
                      String consumerName,
                      String loghubEndPoint,
                      String project, String logStore,
                      String accessId, String accessKey,
                      int consumerStartTimeInSeconds);
  // The position parameter is an enumeration variable. LogHubConfig.ConsumePosition.BEGIN_CURSOR in
  dicates that the consumption starts from the earliest data. LogHubConfig.ConsumePosition.END_CURSO
  R indicates that the consumption starts from the latest data.
  public LogHubConfig(String consumerGroupName,
                      String consumerName,
                      String loghubEndPoint,
                      String project, String logStore,
                      String accessId, String accessKey,
                      ConsumePosition position);
  ```

  You can use different constructors based on your requirements. However, if a checkpoint is stored on the server, you must start data consumption from this checkpoint.

- Reset a checkpoint

In scenarios such as data padding or repeated computing, you may need to set the consumption position to a time point for a consumer group. Then data consumption is started from the consumption position. To set the consumption position, you can use either one of the following two methods:

- Delete the consumer group.
  a. Stop the consumption processes.
  b. Delete the consumer group from the Log Service console.
  c. Modify the code to specify the start time point for data consumption.
  d. Restart the consumption processes.
- Use an SDK to reset the start time point of data consumption for the consumer group.
  a. Stop the consumption processes.
  b. Use an SDK to modify the checkpoint.
  c. Restart the consumption processes.

```
public static void updateCheckpoint() throws Exception {
        Client client = new Client(host, accessId, accessKey);
        long timestamp = Timestamp.valueOf("2017-11-15 00:00:00").getTime() / 1000;
        ListShardResponse response = client.ListShard(new ListShardRequest(project, logStore));
        for (Shard shard : response.GetShards()) {
            int shardId = shard.GetShardId();
            String cursor = client.GetCursor(project, logStore, shardId, timestamp).GetCursor();
            client.UpdateCheckPoint(project, logStore, consumerGroup, shardId, cursor);
        }
    }
```

Use a RAM user to access consumer groups

Before you use a RAM user to access consumer groups, you must grant relevant permissions to the RAM user. For more information, see Grant permissions to a RAM role.

The following table lists the actions you can perform as a RAM user.

Action	Resource
log:GetCursorOrData	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*
log:CreateConsumerGroup	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*/consumergroup/*
log:ListConsumerGroup	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*/consumergroup/*
log:ConsumerGroupUpdateCheckPoint	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*/consumergroup/*${consumerGroupName}*
log:ConsumerGroupHeartBeat	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*/consumergroup/*${consumerGroupName}*
log:UpdateConsumerGroup	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*/consumergroup/*${consumerGroupName}*
log:GetConsumerGroupCheckPoint	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*/consumergroup/*${consumerGroupName}*

For example, a project named project-test resides in the China (Hangzhou) region. The ID of the Apsara Stack tenant account to which the project belongs is 1234567. The name of the Logstore to be consumed is logstore-test and the consumer group name is consumergroup-test. To allow a RAM user to access the consumer group, you must grant the following permissions to the RAM user:

```
{
  "Version": "1",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "log:GetCursorOrData"
      ],
      "Resource": "acs:log:cn-hangzhou:1234567:project/project-test/logstore/logstore-test"
    },
    {
      "Effect": "Allow",
      "Action": [
        "log:CreateConsumerGroup",
        "log:ListConsumerGroup"
      ],
      "Resource": "acs:log:cn-hangzhou:1234567:project/project-test/logstore/logstore-test/consumergroup/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "log:ConsumerGroupUpdateCheckPoint",
        "log:ConsumerGroupHeartBeat",
        "log:UpdateConsumerGroup",
        "log:GetConsumerGroupCheckPoint"
      ],
      "Resource": "acs:log:cn-hangzhou:1234567:project/project-test/logstore/logstore-test/consumergroup/consumergroup-test"
    }
  ]
}
```

28.1.6.3.2. View the status of a consumer group

This topic describes how to use the console, API, and SDK to view the status of a consumer group. Log data consumption by using consumer groups is an advanced real-time data consumption method provided by Log Service. Automatic load balancing is implemented among multiple consumption instances. Spark Streaming and Storm use consumer groups as the basic mode to consume log data.

View the consumption progress in the console

1. Log on to the Log Service console.
2. In the Projects section, click the target project.
3. Find the target Logstore, and choose > **Data Consumption**.
4. Click the consumer group whose data consumption progress you want to view. The data consumption progress of each shard in the Logstore is displayed.

Use an API or SDK to view the data consumption progress

The following example uses the SDK for Java to describe how to call API operations to view the data consumption progress.

```
package test;
import java.util.ArrayList;
import com.aliyun.openservices.log.Client;
import com.aliyun.openservices.log.common.Consts.CursorMode;
import com.aliyun.openservices.log.common.ConsumerGroup;
import com.aliyun.openservices.log.common.ConsumerGroupShardCheckPoint;
import com.aliyun.openservices.log.exception.LogException;
public class ConsumerGroupTest {
    static String endpoint = "";
    static String project = "";
    static String logstore = "";
    static String accesskeyId = "";
    static String accesskey = "";
    public static void main(String[] args) throws LogException {
        Client client = new Client(endpoint, accesskeyId, accesskey);
        //Query all consumer groups of this Logstore. If no consumer group exists, the length of cons
umerGroups is 0.
        ArrayList<ConsumerGroup>  consumerGroups;
        try{
            consumerGroups = client.ListConsumerGroup(project, logstore).GetConsumerGroups();
        }
        catch(LogException e){
            if(e.GetErrorCode() == "LogStoreNotExist")
                System.out.println("this logstore does not have any consumer group");
            else{
                //internal server error branch
            }
            return;
        }
        for(ConsumerGroup c: consumerGroups){
            //Print consumer group properties, including the name, heartbeat timeout, and whether dat
a is consumed in order.
            System.out.println("Name: " + c.getConsumerGroupName());
            System.out.println("Heartbeat timeout: " + c.getTimeout());
            System.out.println("Consumption in order: " + c.isInOrder());
            for(ConsumerGroupShardCheckPoint cp: client.GetCheckPoint(project, logstore, c.getConsume
rGroupName()).GetCheckPoints()){
                System.out.println("shard: " + cp.getShard());
                //Format the returned time. The time is a long integer that is accurate to millisecon
ds.
                System.out.println("The last time when data was consumed: " + cp.getUpdateTime());
                System.out.println("Consumer name: " + cp.getConsumer());
                String consumerPrg = "";
                if(cp.getCheckPoint().isEmpty())
                    consumerPrg = "Consumption not started";
                else{
                    //The UNIX timestamp. Unit: seconds. Format the output value of the timestamp.
                    try{
                        int prg = client.GetPrevCursorTime(project, logstore, cp.getShard(), cp.getCh
eckPoint()).GetCursorTime();
                        consumerPrg = "" + prg;
                    }
                    catch(LogException e){
                        if(e.GetErrorCode() == "InvalidCursor")
                            consumerPrg = "Invalid. The previous consumption time has exceeded the re
tention period of the data in the Logstore.";
                        else{
```

```
                        else{
                            //internal server error
                            throw e;
                        }
                    }
                }
                System.out.println("Consumption progress: " + consumerPrg);
                String endCursor = client.GetCursor(project, logstore, cp.getShard(), CursorMode.END)
.GetCursor();
                int endPrg = 0;
                try{
                    endPrg = client.GetPrevCursorTime(project, logstore, cp.getShard(), endCursor).Ge
tCursorTime();
                }
                catch(LogException e){
                    //do nothing
                }
                //The UNIX timestamp. Unit: seconds. Format the output value of the timestamp.
                System.out.println("The time when the last data entry was received: " + endPrg);
            }
        }
    }
}
```

28.1.6.4. Use LogHub Storm to consume log data

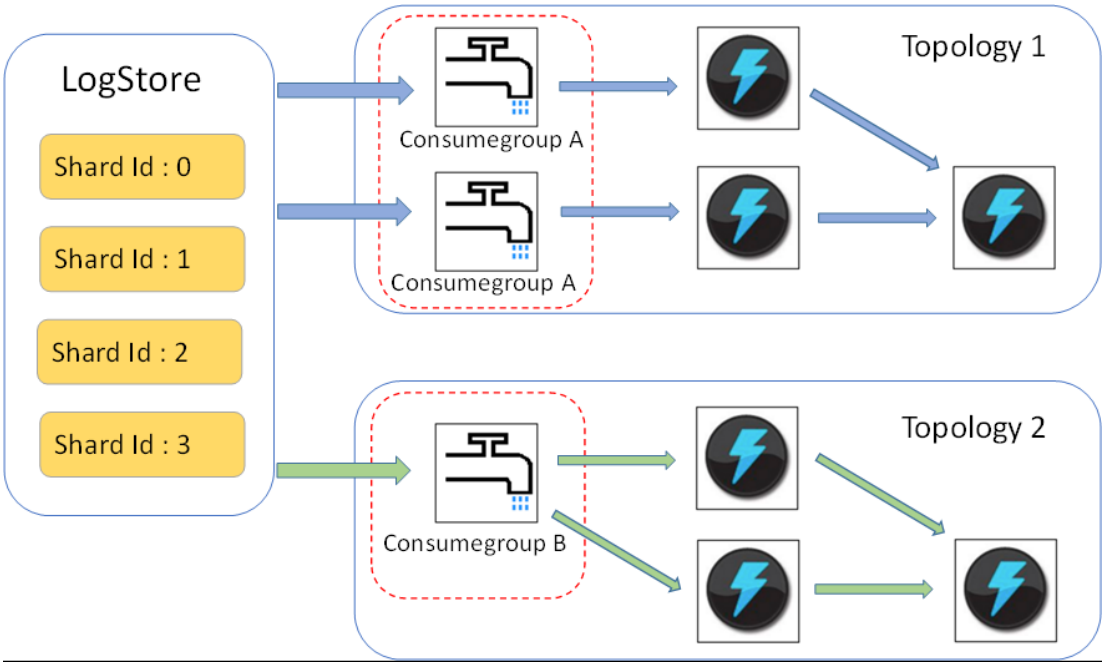
Log Service provides efficient and reliable log collection and consumption channels. You can use Logtail or the SDK to collect log data in real time. After logs are collected to LogHub, you can use Apache Spark Streaming, Apache Storm, and other real-time computation systems to consume the log data.

To reduce the consumption cost of LogHub data, Log Service provides LogHub Storm spouts for Storm users to read data from LogHub in real time.

Basic architecture and flowchart

- LogHub Storm spouts are enclosed in the boxes with red dashed lines. Each Storm topology has a group of spouts that read data from a Logstore. Spouts in different topologies are independent of each other.
- Each topology is identified by a unique LogHub consumer group name. Spouts in the same topology use a consumer library to achieve load balancing and automatic failover.
- Spouts read data from LogHub in real time, send data to bolts in the same topology, and then save consumption checkpoints to the LogHub server on a regular basis.

  Basic architecture and flowchart



Limits

- You can create up to 10 consumer groups to consume log data from a Logstore. If a consumer group is no longer in use, you can call the DeleteConsumerGroup operation of the SDK for Java to delete the consumer group.
- We recommend that the number of spouts be equal to the number of shards in a Logstore. This is because a single spout may be unable to process a large amount of data in multiple shards.
- If the data volume in a shard exceeds the processing capacity of a single spout, you can split the shard to reduce its data volume.
- LogHub spouts and bolts must use the ack method to check whether log data is successfully sent from spouts to bolts and whether the data is successfully processed by the bolts.

Examples

- Use the following code to create spouts and construct a topology:

```
     public static void main( String[] args )
    {
        String mode = "Local"; // Specify to use the local test mode.
           String conumser_group_name = ""; // Specify a unique consumer group name for each topol
ogy. The name cannot be an empty string. It must be 3 to 63 characters in length and can contain l
owercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase
letter or digit.
        String project = ""; // Specify the project in Log Service.
        String logstore = ""; // Specify the Logstore in Log Service.
        String endpoint = ""; // Specify the endpoint of Log Service.
        String access_id = ""; // Specify the AccessKey ID of the user.
        String access_key = "";
        // Configure a LogHub Storm spout.
        LogHubSpoutConfig config = new LogHubSpoutConfig(conumser_group_name,
                endpoint, project, logstore, access_id,
                access_key, LogHubCursorPosition.END_CURSOR);
        TopologyBuilder builder = new TopologyBuilder();
        // Create a LogHub Storm spout.
        LogHubSpout spout = new LogHubSpout(config);
        // You can create the same number of spouts as that of shards in a Logstore in actual busi
ness scenarios.
```

```
        builder.setSpout("spout", spout, 1);
        builder.setBolt("exclaim", new SampleBolt()).shuffleGrouping("spout");
        Config conf = new Config();
        conf.setDebug(false);
        conf.setMaxSpoutPending(1);
        // Configure the serialization method of LogGroupData by using the LogGroupDataSerializSer
ializer class if Kryo is used to serialize and deserialize data.
        Config.registerSerialization(conf, LogGroupData.class, LogGroupDataSerializSerializer.clas
s);
        if (mode.equals("Local")) {
            logger.info("Local mode...") ;
            LocalCluster cluster  = new LocalCluster();
            cluster.submitTopology("test-jstorm-spout", conf, builder.createTopology());
            try {
                Thread.sleep(6000 * 1000);    //waiting for several minutes
            } catch (InterruptedException e) {
                // TODO Auto-generated catch block
                e.printStackTrace();
            }
            cluster.killTopology("test-jstorm-spout");
            cluster.shutdown();
        } else if (mode.equals("Remote")) {
            logger.info("Remote mode...");
            conf.setNumWorkers(2);
            try {
                StormSubmitter.submitTopology("stt-jstorm-spout-4", conf, builder.createTopology()
);
            } catch (AlreadyAliveException e) {
                // TODO Auto-generated catch block
                e.printStackTrace();
            } catch (InvalidTopologyException e) {
                // TODO Auto-generated catch block
                e.printStackTrace();
            }
        } else {
            logger.error("invalid mode: " + mode);
        }
    }
}
```

- Use the following example code of bolts to consume log data and display the content of each log entry:

```
public class SampleBolt extends BaseRichBolt {
    private static final long serialVersionUID = 4752656887774402264L;
    private static final Logger logger = Logger.getLogger(BaseBasicBolt.class);
    private OutputCollector mCollector;
    @Override
    public void prepare(@SuppressWarnings("rawtypes") Map stormConf, TopologyContext context,
            OutputCollector collector) {
        mCollector = collector;
    }
    @Override
    public void execute(Tuple tuple) {
        String shardId = (String) tuple
                .getValueByField(LogHubSpout.FIELD_SHARD_ID);
        @SuppressWarnings("unchecked")
        List<LogGroupData> logGroupDatas = (ArrayList<LogGroupData>) tuple.getValueByField(LogHubS
pout.FIELD_LOGGROUPS);
        for (LogGroupData groupData : logGroupDatas) {
            // Each log group consists of one or more log entries.
            LogGroup logGroup = groupData.GetLogGroup();
            for (Log log : logGroup.getLogsList()) {
                StringBuilder sb = new StringBuilder();
                // Each log entry has a time field and other key-value pairs.
                int log_time = log.getTime();
                sb.append("LogTime:").append(log_time);
                for (Content content : log.getContentsList()) {
                    sb.append("\t").append(content.getKey()).append(":")
                            .append(content.getValue());
                }
                logger.info(sb.toString());
            }
        }
        // Spouts must use the ack method to indicate whether data has been successfully sent to b
olts.
        // In addition, bolts must use the ack method to indicate whether data is successfully pro
cessed by the bolts.
        mCollector.ack(tuple);
    }
    @Override
    public void declareOutputFields(OutputFieldsDeclarer declarer) {
        //do nothing
    }
}
```

Maven

Use the following code to add Maven dependencies for Storm versions earlier than Storm 1.0 (for example, Storm 0.9.6):

```
<dependency>
  <groupId>com.aliyun.openservices</groupId>
  <artifactId>loghub-storm-spout</artifactId>
  <version>0.6.6</version>
</dependency>
```

Use the following code to add Maven dependencies for Storm 1.0 and later versions:

```
<dependency>
  <groupId>com.aliyun.openservices</groupId>
  <artifactId>loghub-storm-1.0-spout</artifactId>
  <version>0.1.3</version>
</dependency>
```

28.1.6.5. Use Flume to consume log data

This topic describes how to use Flume to consume log data. You can use the aliyun-log-flume plug-in to connect LogHub of Log Service to Flume, and then write and consume log data.

The aliyun-log-flume plug-in connects LogHub to Flume. When LogHub is connected to Flume, you can connect Log Service to other systems such as HDFS and Kafka through Flume. The aliyun-log-flume plug-in provides the Sink and Source methods to connect Log Service to Flume.

- Sink: uses Flume to read data from other data sources and then writes data to LogHub.
- Source: uses Flume to consume LogHub data and then writes data to other systems.

LogHub Sink

You can use the Sink method to transmit data from other data sources to LogHub through Flume. Data can be parsed into the following two formats:

- SIMPLE: writes a Flume event to LogHub as a field.
- DELIMITED: delimits a Flume event with delimiters, parses an event into fields based on the configured column names, and then writes the fields to LogHub.

The following table lists the parameters you can configure when you use the Sink method to read data.

Parameter	Required	Description
type	Yes	Valid value: com.aliyun.loghub.flume.sink.LoghubSink.
endpoint	Yes	The endpoint of Log Service.
project	Yes	The name of the project.
logstore	Yes	The name of the Logstore.
accessKeyId	Yes	The AccessKey ID of your Apsara Stack tenant account.
accessKey	Yes	The AccessKey secret of your Apsara Stack tenant account.
batchSize	No	The number of log entries that are written to LogHub at a time. Default value: 1000.
maxBufferSize	No	The maximum size of the queue in the buffer. Default value: 1000.

Parameter	Required	Description
serializer	No	The serialization format of log data. Valid values: • **DELIMITED**: Data is parsed into the DELIMITED format. If you set this parameter to DELIMITED, you must set the columns parameter. • **SIMPLE**: Data is parsed into the SIMPLE format. This is the default value. • Custom **serializer**: Data is parsed into a custom serialization format. If you set this parameter to a custom serializer, you must specify the full name of the class.
columns	No	The configured column names. You must set this parameter if you set the serializer parameter to **DELIMITED**. Separate multiple columns with commas (,). Ensure that the columns are sorted in the same order as those of the log data.
separatorChar	No	The delimiter, which must be a single character. You can set this parameter if you set the serializer parameter to **DELIMITED**. Default value: `,`.
quoteChar	No	The quote character. You can set this parameter if you set the serializer parameter to **DELIMITED**. Default value: `""`.
escapeChar	No	The escape character. You can set this parameter if you set the serializer parameter to **DELIMITED**. Default value: `""`.
useRecordTime	No	Specifies whether to use the value of the timestamp field as the time when log data is written to Log Service. The default value false indicates that the current time is used.

Loghub Source

You can use the Source method to ship data from LogHub to other data systems through Flume. Data can be output in the following two formats:

- DELIMITED: writes delimited log data to Flume.
- JSON: writes JSON-formatted log data to Flume.

The following table lists the parameters you can configure when you use the Source method to read data.

Parameter	Required	Description
type	Yes	Valid value: com.aliyun.loghub.flume.source.LoghubSource.
endpoint	Yes	The endpoint of Log Service.
project	Yes	The name of the project.
logstore	Yes	The name of the Logstore.
accessKeyId	Yes	The AccessKey ID of your Apsara Stack tenant account.

Parameter	Required	Description
accessKey	Yes	The AccessKey secret of your Apsara Stack tenant account.
heartbeatIntervalMs	No	The heartbeat interval between the Flume client and LogHub. Unit: milliseconds. Default value: 30000.
fetchIntervalMs	No	The interval for pulling data from LogHub. Unit: milliseconds. Default value: 100.
fetchInOrder	No	Specifies whether to consume log data in the order that log data was generated. Default value: false.
batchSize	No	The number of log entries that are read at a time. Default value: 100.
consumerGroup	No	The name of the consumer group that reads data. The name is randomly generated.
initialPosition	No	The start point from which data is read. Valid values: begin, end, and timestamp. Default value: begin. **Note** If a checkpoint exists on the server, the checkpoint is used.
timestamp	No	The Unix timestamp. You must set this parameter if you set the initialPosition parameter to **timestamp**. Unix timestamp.
deserializer	Yes	The deserialization format of log data. Valid values: • **DELIMITED**: Data is parsed into the DELIMITED format. This is the default value. If you set this parameter to DELIMITED, you must set the columns parameter. • **JSON**: Data is parsed into the JSON format. • Custom **deserializer**: Data is parsed into a custom deserialization format. If you set this parameter to a custom deserializer, you must specify the full name of the class.
columns	No	The configured column names. You must set this parameter if you set the deserializer parameter to **DELIMITED**. Separate multiple columns with commas (,). Ensure that the columns are sorted in the same order as those of the log data.
separatorChar	No	The delimiter, which must be a single character. You can set this parameter if you set the deserializer parameter to **DELIMITED**. Default value: `,`.
quoteChar	No	The quote character. You can set this parameter if you set the deserializer parameter to **DELIMITED**. Default value: `""`.
escapeChar	No	The escape character. You can set this parameter if you set the deserializer parameter to **DELIMITED**. Default value: `""`.

Parameter	Required	Description
appendTimestamp	No	Specifies whether to append the timestamp as a field to the end of each log entry. You can set this parameter if you set the deserializer parameter to **DELIMITED**. Default value: false.
sourceAsField	No	Specifies whether to add the log source as a field named __source__. You can set this parameter if you set the deserializer parameter to **JSON**. Default value: false.
tagAsField	No	Specifies whether to add the log tags as a field with the field name __tag__: {tag names}. You can set this parameter if you set the deserializer parameter to **JSON**. Default value: false.
timeAsField	No	Specifies whether to add the log time as a field named __time__. You can set this parameter if you set the deserializer parameter to **JSON**. Default value: false.
useRecordTime	No	Specifies whether to use the value of the timestamp field as the time when log data is read from Log Service. The default value false indicates that the current time is used. Default value: false.

28.1.6.6. Use open source Flink to consume log data

Log Service provides the flink-log-connector plug-in to connect with Flink. This topic describes how to integrate the flink-log-connector plug-in with Flink to consume log data.

Prerequisites

- An AccessKey pair, a Log Service project, and a Logstore are created.
- If you log on to Log Service with a RAM user, relevant permissions to access a Logstore are granted to a RAM user. For more information, see Grant permissions to a RAM role.

Context

The flink-log-collector plug-in includes flink-log-consumer and flink-log-producer.

- The flink-log-consumer plug-in reads data from Log Service. This plug-in supports the exactly-once semantics and load balancing among shards.
- The flink-log-producer plug-in writes data into Log Service. When you use the flink-log-producer plug-in, you must add the following Maven dependencies to a project:

```
<dependency>
   <groupId>com.aliyun.openservices</groupId>
   <artifactId>flink-log-connector</artifactId>
   <version>0.1.13</version>
</dependency>
<dependency>
   <groupId>com.google.protobuf</groupId>
   <artifactId>protobuf-java</artifactId>
   <version>2.5.0</version>
</dependency>
```

Log Consumer

The flink-log-consumer plug-in can consume the log data of a Logstore in Log Service. The exactly-once semantics is achieved during log consumption. The flink-log-consumer plug-in detects the change of the number of shards in a Logstore. This increases efficiency.

Each Flink subtask consumes data of some shards in a Logstore. If shards in a Logstore are split or merged, the shards consumed by the subtask also change.

When you use the flink-log-consumer plug-in to consume data from Log Service, you can call the following API operations:

- GetCursorOrData

  You can call this operation to pull log data from a shard. Frequent API requests may exceed the read speed and IOPS limits of the shard. You can specify the ConfigConstants.LOG_FETCH_DATA_INTERVAL_MILLIS and ConfigConstants.LOG_MAX_NUMBER_PER_FETCH parameters to control the interval of API requests and number of log entries pulled in each request.

  ```
  configProps.put(ConfigConstants.LOG_FETCH_DATA_INTERVAL_MILLIS, "100");
  configProps.put(ConfigConstants.LOG_MAX_NUMBER_PER_FETCH, "100");
  ```

- ListShards

  You can call this operation to view all shards in a Logstore and the status of each shard. If the shards are frequently split and merged, you can adjust the call interval to detect the changes in the number of shards.

  ```
  // Call the ListShards operation once every 30 seconds.
  configProps.put(ConfigConstants.LOG_SHARDS_DISCOVERY_INTERVAL_MILLIS, "30000");
  ```

- CreateConsumerGroup

  You can call this operation to create a consumer group to synchronize checkpoints. This operation can be called only when consumption progress monitoring is enabled.

- ConsumerGroupUpdateCheckPoint

  You can call this operation to synchronize snapshots of Flink to a consumer group.

The following table lists the Apsara Stack resources required for RAM users to call the preceding API operations.

API	Alibaba Resource Name (ARN)
GetCursorOrData	`acs:log:${regionName}:${projectOwnerAliUid}:project/${projectName}/logstore/${logstoreName}`
ListShards	`acs:log:${regionName}:${projectOwnerAliUid}:project/${projectName}/logstore/${logstoreName}`
CreateConsumerGroup	`acs:log:${regionName}:${projectOwnerAliUid}:project/${projectName}/logstore/${logstoreName}/consumergroup/*`
ConsumerGroupUpdateCheckPoint	`acs:log:${regionName}:${projectOwnerAliUid}:project/${projectName}/logstore/${logstoreName}/consumergroup/${consumerGroupName}`

For more information, see Grant permissions to a RAM role.

1. Configure startup parameters.

   The following example shows how to consume log data. The java.util.Properties class is used as the configuration tool. You can find all constants to be configured in the ConfigConstants class.

```
Properties configProps = new Properties();
// Specify the endpoint of Log Service.
configProps.put(ConfigConstants.LOG_ENDPOINT, "cn-hangzhou.log.aliyuncs.com");
// Specify the AccessKey pair.
configProps.put(ConfigConstants.LOG_ACCESSSKEYID, "");
configProps.put(ConfigConstants.LOG_ACCESSKEY, "");
// Specify the project.
configProps.put(ConfigConstants.LOG_PROJECT, "ali-cn-hangzhou-sls-admin");
// Specify the Logstore.
configProps.put(ConfigConstants.LOG_LOGSTORE, "sls_consumergroup_log");
// Specify the start position to consume logs.
configProps.put(ConfigConstants.LOG_CONSUMER_BEGIN_POSITION, Consts.LOG_END_CURSOR);
// Specify the data deserialization method.
RawLogGroupListDeserializer deserializer = new RawLogGroupListDeserializer();
final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
DataStream<RawLogGroupList> logTestStream = env.addSource(
        new FlinkLogConsumer<RawLogGroupList>(deserializer, configProps));
```

Note The number of subtasks in the Flink Streaming is independent of the number of shards in a Logstore. If the number of shards is greater than that of subtasks, each subtask consumes multiple shards exactly once. If the number of shards is less than that of subtasks, some subtasks are idle until new shards are generated.

2. Specify the start consumption position.

   The flink-log-consumer plug-in enables you to specify the start consumption position of log data in a shard. By specifying the ConfigConstants.LOG_CONSUMER_BEGIN_POSITION parameter, you can start data consumption from the earliest, latest, or a specific time point. The flink-log-connector plug-in also allows a consumer group to resume consumption from a specific position. Valid values:

   - Consts.LOG_BEGIN_CURSOR: The consumption starts from the earliest data.
   - Consts.LOG_END_CURSOR: The consumption starts from the latest data.
   - Consts.LOG_FROM_CHECKPOINT: The consumption starts from a checkpoint that is stored in a specific consumer group. You can use the ConfigConstants.LOG_CONSUMERGROUP parameter to specify the consumer group.
   - UnixTimestamp: a string of the INTEGER data type. The timestamp is the number of seconds that have elapsed since 00:00:00 January 1, 1970. The value indicates that data in a shard is consumed from this time point.

   You can use the following code to specify a start consumption position:

   ```
   configProps.put(ConfigConstants.LOG_CONSUMER_BEGIN_POSITION, Consts.LOG_BEGIN_CURSOR);
   configProps.put(ConfigConstants.LOG_CONSUMER_BEGIN_POSITION, Consts.LOG_END_CURSOR);
   configProps.put(ConfigConstants.LOG_CONSUMER_BEGIN_POSITION, "1512439000");
   configProps.put(ConfigConstants.LOG_CONSUMER_BEGIN_POSITION, Consts.LOG_FROM_CHECKPOINT);
   ```

   Note If you have configured consumption resumption from a state backend of Flink when you start a Flink job, the flink-log-connector plug-in uses checkpoints stored in the state backend.

3. (Optional)Configure consumption progress monitoring.

   The flink-log-consumer plug-in enables you to configure consumption progress monitoring. Consumption progress indicates the real-time consumption position of each shard. These positions are indicated by timestamps. For more information, see View the status of a consumer group.

   ```
   configProps.put(ConfigConstants.LOG_CONSUMERGROUP, "your consumer group name");
   ```

> **Note** This configuration item is optional. If you specify this configuration item and no consumer group exists, the flink-log-consumer plug-in creates a consumer group. Snapshots in the flink-log-consumer plug-in are automatically synchronized to the consumer group of Log Service, and you can view the consumption progress of the flink-log-consumer plug-in in the Log Service console.

4. Configure consumption resumption and the exactly-once semantics.

   If the checkpointing feature of Flink is enabled, the flink-log-consumer plug-in periodically stores the consumption progress of each shard. When a job fails, Flink restores the flink-log-consumer plug-in and starts to consume data from the latest checkpoint.

   While you configure the checkpointing period, the maximum amount of data to be re-consumed when a failure occurs is defined. You can use the following code to configure the checkpointing period:

   ```
   final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
   // Configure the exactly-once semantics.
   env.getCheckpointConfig().setCheckpointingMode(CheckpointingMode.EXACTLY_ONCE);
   // Store checkpoints every five seconds.
   env.enableCheckpointing(5000);
   ```

   For more information about the Flink checkpoints, see Checkpoints in the Flink documentation.

Log Producer

The flink-log-producer plug-in writes data into Log Service.

> **Note** The flink-log-producer plug-in supports the Flink at-least-once semantics. If a job fails, data written into Log Service may be duplicated but never lost.

When you use the flink-log-producer plug-in to writes data to Log Service, you can call the following API operations:

- PostLogStoreLogs
- ListShards

The following table lists the Apsara Stack resources required for RAM users to call the preceding API operations.

API	ARN
PostLogStoreLogs	`acs:log:${regionName}:${projectOwnerAliUid}:project/${projectName}/logstore/${logstoreName}`
ListShards	`acs:log:${regionName}:${projectOwnerAliUid}:project/${projectName}/logstore/${logstoreName}`

For more information about RAM users and how to authorize RAM users, see Grant permissions to a RAM role.

1. Initialize the flink-log-producer plug-in.

i. Configure startup parameters for the flink-log-producer plug-in.

The initialization process for the flink-log-producer plug-in is similar to that for the flink-log-consumer plug-in. The following code shows the available parameters that you can configure for the flink-log-producer plug-in. You can use the default values of these parameters. You can also specify the parameters based on your needs.

```
// The number of I/O threads used to send data. Default value: 8.
ConfigConstants.LOG_SENDER_IO_THREAD_COUNT
// The time it takes to send the data after log data is cached. Default value: 3000.
ConfigConstants.LOG_PACKAGE_TIMEOUT_MILLIS
// The number of logs in the cached package. Default value: 4096.
ConfigConstants.LOG_LOGS_COUNT_PER_PACKAGE
// The size of the cached package. Default value: 3 Mbits.
ConfigConstants.LOG_LOGS_BYTES_PER_PACKAGE
// The total memory size that the job can use. Default value: 100 Mbits.
ConfigConstants.LOG_MEM_POOL_BYTES
```

> **Note** These parameters are optional. You can use their default values.

ii. Reload LogSerializationSchema to define the method of serializing data into RawLogGroup.

To use the hash key to specify the shard for data writes, you can use the LogPartitioner method to generate the hash key for the data.

Example:

```
FlinkLogProducer<String> logProducer = new FlinkLogProducer<String>(new SimpleLogSerializer()
, configProps);
logProducer.setCustomPartitioner(new LogPartitioner<String>() {
      // Generate a 32-bit hash value.
      public String getHashKey(String element) {
          try {
              MessageDigest md = MessageDigest.getInstance("MD5");
              md.update(element.getBytes());
              String hash = new BigInteger(1, md.digest()).toString(16);
              while(hash.length() < 32) hash = "0" + hash;
              return hash;
          } catch (NoSuchAlgorithmException e) {
          }
          return  "00000000000000000000000000000000000000000000000000000000000000000000";
      }
  });
```

> **Note** The LogPartitioner method is optional. If you do not configure this method, data is randomly written into a shard.

2. Run the following code and write the generated strings to Log Service.

```
// Serialize data into the format of raw log groups.
class SimpleLogSerializer implements LogSerializationSchema<String> {
    public RawLogGroup serialize(String element) {
        RawLogGroup rlg = new RawLogGroup();
        RawLog rl = new RawLog();
        rl.setTime((int)(System.currentTimeMillis() / 1000));
        rl.addContent("message", element);
        rlg.addLog(rl);
        return rlg;
    }
}
public class ProducerSample {
    public static String sEndpoint = "cn-hangzhou.log.aliyuncs.com";
    public static String sAccessKeyId = "";
    public static String sAccessKey = "";
    public static String sProject = "ali-cn-hangzhou-sls-admin";
    public static String sLogstore = "test-flink-producer";
    private static final Logger LOG = LoggerFactory.getLogger(ConsumerSample.class);
    public static void main(String[] args) throws Exception {
        final ParameterTool params = ParameterTool.fromArgs(args);
        final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment
();
        env.getConfig().setGlobalJobParameters(params);
        env.setParallelism(3);
        DataStream<String> simpleStringStream = env.addSource(new EventsGenerator());
        Properties configProps = new Properties();
        // Specify the endpoint of Log Service.
        configProps.put(ConfigConstants.LOG_ENDPOINT, sEndpoint);
        // Specify the AccessKey pair to access Log Service.
        configProps.put(ConfigConstants.LOG_ACCESSSKEYID, sAccessKeyId);
        configProps.put(ConfigConstants.LOG_ACCESSKEY, sAccessKey);
        // Specify the project to which logs are written.
        configProps.put(ConfigConstants.LOG_PROJECT, sProject);
        // Specify the Logstore to which logs are written.
        configProps.put(ConfigConstants.LOG_LOGSTORE, sLogstore);
        FlinkLogProducer<String> logProducer = new FlinkLogProducer<String>(new SimpleLogSerializ
er(), configProps);
        simpleStringStream.addSink(logProducer);
        env.execute("flink log producer");
    }
    // Simulate log generation.
    public static class EventsGenerator implements SourceFunction<String> {
        private boolean running = true;
        @Override
        public void run(SourceContext<String> ctx) throws Exception {
            long seq = 0;
            while (running) {
                Thread.sleep(10);
                ctx.collect((seq++) + "-" + RandomStringUtils.randomAlphabetic(12));
            }
        }
        @Override
        public void cancel() {
            running = false;
        }
    }
}
```

28.1.6.7. Use Logstash to consume log data

Log Service allows you to use SDKs developed in various languages and various stream computing systems to consume log data. In addition, Log Service allows you to use Logstash to consume log data. You can configure the Logstash input plug-in to read log data from Log Service and write the data to other systems, such as Kafka and Hadoop Distributed File System (HDFS).

Features

- **Distributed collaborative consumption**: Multiple servers can be configured to consume log data from a Logstore at the same time.
- **High performance**: If you use consumer groups written in Java to consume log data, the consumption speed of a CPU core can reach up to 20 MB/s.
- **High reliability**: Log Service saves the consumption progress. This mechanism enables automatic resumption of log consumption from the last checkpoint after a consumption exception is solved.
- **Automatic load balancing**: Shards are automatically allocated based on the number of consumers in a consumer group. The shards are reallocated if consumers join or leave the consumer group.

28.1.6.8. Use Spark Streaming to consume log data

This topic describes how to use Spark Streaming to consume log data. After logs are collected to Log Service, you can use the Spark SDK provided by Log Service to process log data in Spark Streaming.

The Spark SDK supports two consumption modes: Receiver and Direct.

The Maven dependency is as follows:

```
<dependency>
  <groupId>com.aliyun.emr</groupId>
  <artifactId>emr-logservice_2.11</artifactId>
  <version>1.7.2</version>
</dependency>
```

Receiver mode

In the Receiver mode, a consumer group consumes data from Log Service and temporarily stores the data in Spark Executor. After a Spark Streaming job is started, it reads and processes data from Spark Executor. For more information, see Use consumer groups to consume log data. Each log entry is returned as a JSON string. The consumer group periodically saves checkpoints to Log Service. You do not need to update checkpoints.

- Example code

```
import org.apache.spark.storage.StorageLevel
import org.apache.spark.streaming.aliyun.logservice.LoghubUtils
import org.apache.spark.streaming.{ Milliseconds, StreamingContext}
import org.apache.spark.SparkConf
object TestLoghub {
  def main(args: Array[String]): Unit = {
    if (args.length < 7) {
      System.err.println(
        """Usage: TestLoghub <project> <logstore> <loghub group name> <endpoint>
          |         <access key id> <access key secret> <batch interval seconds>
        """.stripMargin)
      System.exit(1)
    }
    val project = args(0)
    val logstore = args(1)
    val consumerGroup = args(2)
    val endpoint = args(3)
    val accessKeyId = args(4)
    val accessKeySecret = args(5)
    val batchInterval = Milliseconds(args(6).toInt * 1000)
    def functionToCreateContext(): StreamingContext = {
      val conf = new SparkConf().setAppName("Test Loghub")
      val ssc = new StreamingContext(conf, batchInterval)
      val loghubStream = LoghubUtils.createStream(
        ssc,
        project,
        logstore,
        consumerGroup,
        endpoint,
        accessKeyId,
        accessKeySecret,
        StorageLevel.MEMORY_AND_DISK)
      loghubStream.checkpoint(batchInterval * 2).foreachRDD(rdd =>
        rdd.map(bytes => new String(bytes)).top(10).foreach(println)
      )
      ssc.checkpoint("hdfs:///tmp/spark/streaming") // set checkpoint directory
      ssc
    }
    val ssc = StreamingContext.getOrCreate("hdfs:///tmp/spark/streaming", functionToCreateContext
_)
    ssc.start()
    ssc.awaitTermination()
  }
}
```

- Parameter description

Parameter	Type	Description
project	String	The project in Log Service.
logstore	String	The Logstore in Log Service.
consumerGroup	String	The name of the consumer group.
endpoint	String	The endpoint of the region to which the project belongs.

Parameter	Type	Description
accessKeyId	String	The AccessKey ID used to access Log Service.
accessKeySecret	String	The AccessKey secret used to access Log Service.

- Notes

  In the Receiver mode, data loss may occur in some cases. To avoid data loss, you can turn on the Write-Ahead Logs switch, which is supported in Spark 1.2 and later versions. For more information, visit Spark Streaming Programming Guide.

Direct mode

In the Direct mode, no consumer group is required. API operations are called to request data from Log Service. Compared with the Receiver mode, the Direct mode has the following benefits:

- Simplified parallelism. The number of Spark partitions is the same as the number of shards in a Logstore. You can split shards to improve the parallelism of tasks.
- Increased efficiency. You no longer need to turn on the Write-Ahead Logs switch to prevent data loss.
- Exactly-once semantics. Data is read directly from Log Service. Checkpoints are submitted after the task is successful. In some cases, data may be repeatedly consumed if the task is not ended due to unexpected exit of Spark.

You must configure the ZooKeeper service when you use the Direct mode. You must set a checkpoint directory in ZooKeeper to store intermediate state data. If you want to re-consume data after restarting a task, you must delete the directory from ZooKeeper and change the name of the consumer group.

- Example code

```
import com.aliyun.openservices.loghub.client.config.LogHubCursorPosition
import org.apache.spark.SparkConf
import org.apache.spark.streaming.{ Milliseconds, StreamingContext}
import org.apache.spark.streaming.aliyun.logservice.{ CanCommitOffsets, LoghubUtils}
object TestDirectLoghub {
  def main(args: Array[String]): Unit = {
    if (args.length < 7) {
      System.err.println(
        """Usage: TestDirectLoghub <project> <logstore> <loghub group name> <endpoint>
          |         <access key id> <access key secret> <batch interval seconds> <zookeeper host:p
ort=localhost:2181>
        """.stripMargin)
      System.exit(1)
    }
    val project = args(0)
    val logstore = args(1)
    val consumerGroup = args(2)
    val endpoint = args(3)
    val accessKeyId = args(4)
    val accessKeySecret = args(5)
    val batchInterval = Milliseconds(args(6).toInt * 1000)
    val zkAddress = if (args.length >= 8) args(7) else "localhost:2181"
    def functionToCreateContext(): StreamingContext = {
      val conf = new SparkConf().setAppName("Test Direct Loghub")
      val ssc = new StreamingContext(conf, batchInterval)
      val zkParas = Map("zookeeper.connect" -> zkAddress,
        "enable.auto.commit" -> "false")
      val loghubStream = LoghubUtils.createDirectStream(
        ssc,
        project,
        logStore,
        consumerGroup,
        accessKeyId,
        accessKeySecret,
        endpoint,
        zkParas,
        LogHubCursorPosition.END_CURSOR)
      loghubStream.checkpoint(batchInterval).foreachRDD(rdd => {
        println(s"count by key: ${rdd.map(s => {
          s.sorted
          (s.length, s)
        }).countByKey().size}")
        loghubStream.asInstanceOf[CanCommitOffsets].commitAsync()
      })
      ssc.checkpoint("hdfs:///tmp/spark/streaming") // set checkpoint directory
      ssc
    }
    val ssc = StreamingContext.getOrCreate("hdfs:///tmp/spark/streaming", functionToCreateContext
_)
    ssc.start()
    ssc.awaitTermination()
  }
}
```

- Parameter description

Parameter	Type	Description
project	String	The project in Log Service.
logstore	String	The Logstore in Log Service.
consumerGroup	String	The name of the consumer group (only used to save consumption checkpoints).
endpoint	String	The endpoint of the region to which the project belongs.
accessKeyId	String	The AccessKey ID used to access Log Service.
accessKeySecret	String	The AccessKey secret used to access Log Service.
zkAddress	String	The endpoint of ZooKeeper.

- Parameter settings

  In the Direct mode, you must specify the number of log entries that are consumed in each shard in each batch. Otherwise, the data reading process cannot be ended. You can throttle the transmission rate of a single batch by setting the two parameters listed in the following table.

Parameter	Description	Default value
spark.loghub.batchGet.step	The number of log groups returned for a single request.	100
spark.streaming.loghub.maxRatePerShard	The maximum number of log entries that are read in a shard.	10,000

  The number of log entries processed in each batch is calculated as follows: `number of shards x max(spark.loghub.batchGet.step x n x number of log entries in a log group, spark.streaming.loghub.maxRatePerShard x duration)`.

  - n: the number of requests required to increase the returned rows to `spark.streaming.loghub.maxRatePerShard x duration`.
  - duration: the interval between batch processing. Unit: milliseconds.

  If you need to combine multiple data streams, the number of shards refers to the total number of shards in all Logstores.

  - Example

    For example, the number of shards is 100. Each log group contains 50 log entries. Batches are processed at an interval of two seconds. If you want to process 20,000 log entries in each batch, use the following configurations:

    - `spark.loghub.batchGet.step: 4`
    - `spark.streaming.loghub.maxRatePerShard: 100`

    If each log group contains 60 log entries and you want to process 20,000 log entries in each batch, 24,000 log entries will be processed based on the preceding configurations (`60 x 4 x 100 = 24,000`).

- Accurate transmission rate throttling

  A smaller `spark.loghub.batchGet.step` value increases the accuracy of throttling and the number of requests. We recommend that you count the average number of log entries contained in a log group and then set the preceding two parameters.

28.1.6.9. Use Realtime Compute to consume log data

You can use Realtime Compute (Blink) to create a schema for Log Service data and consume the data.

Log Service stores streaming data. Therefore, Realtime Compute can use the streaming data as input data. In Log Service, each log entry contains multiple fields and each field is a key-value pair. The following example is a sample log entry:

```
__source__:  11.85.123.199
__tag__:__receive_time__:  1562125591
__topic__:  test-topic
a:  1234
b:  0
c:  hello
```

You can use the following data definition language (DDL) statement to create a table in Realtime Compute:

```
create table sls_stream(
  a int,
  b int,
  c varchar
) with (
  type ='sls',
  endPoint ='<your endpoint>',
  accessId ='<your access key id>',
  accessKey ='<your access key>',
  startTime = '2017-07-05 00:00:00',
  project ='ali-cloud-streamtest',
  logStore ='stream-test',
  consumerGroup ='consumerGroupTest1'
);
```

Attribute fields

Realtime Compute can extract fields from log content. In addition, Realtime Compute can extract three attribute fields and custom tag fields, such as `__receive_time__`. The following table lists the three attribute fields.

Attribute fields

Field name	Description
`__source__`	The source of the log entry.
`__topic__`	The topic of the log entry.
`__timestamp__`	The time when the log entry is generated.

To extract the preceding fields, you must add HEADERs in the DDL statement. For example:

```
create table sls_stream(
  __timestamp__ bigint HEADER,
  __receive_time__ bigint HEADER
  b int,
  c varchar
) with (
  type ='sls',
  endPoint ='<your endpoint>',
  accessId ='<your access key id>',
  accessKey ='<your access key>',
  startTime = '2017-07-05 00:00:00',
  project ='ali-cloud-streamtest',
  logStore ='stream-test',
  consumerGroup ='consumerGroupTest1'
);
```

Parameters in the WITH clause

The following table describes the parameters in the WITH clause.

Parameter	Required	Description
endPoint	Yes	The endpoint of Log Service.
accessId	Yes	The AccessKey ID of the Apsara Stack tenant account or RAM user that is used to access Log Service.
accessKey	Yes	The AccessKey secret of the Apsara Stack tenant account or RAM user that is used to access Log Service.
project	Yes	The name of the project in Log Service.
logStore	Yes	The name of the Logstore in Log Service.
consumerGroup	No	The name of the consumer group.
startTime	No	The time when Realtime Compute starts to consume data.
heartBeatIntervalMills	No	The heartbeat interval of the client that consumes log data. Unit: seconds. Default value: 10.
maxRetryTimes	No	The maximum number of retries to read data. Default value: 5.
batchGetSize	No	The number of log groups that are read at a time. Default value: 10. If the version of Blink is 1.4.2 or later, the default value is 100 and the maximum value is 1000.

Parameter	Required	Description
columnErrorDebug	No	Specifies whether to enable debugging. If debugging is enabled, log entries that fail to be parsed are displayed. Default value: `false`.

Field type mapping

All log fields in Log Service are of the string type. The following table lists the mapping between the type of Log Service fields and the type of Realtime Compute fields. We recommend that you declare the mapping in a data definition language (DDL) statement.

Data type of Log Service	Data type of Realtime Compute
STRING	VARCHAR

If you specify another data type to convert Log Service data, an automatic conversion attempt is performed. For example, you can specify *BIGINT* as the data type to convert the string "1000" and specify *timestamp* as the data type to convert the string "2018-01-12 12:00:00".

> **Note**
> - Blink versions earlier than 2.2.0 do not support shard scaling. If you split or merge shards when a job is reading data from a Logstore, the job fails and cannot continue. In this case, you must restart the job.
> - No versions of Blink allow you to delete or recreate a Logstore whose log data is being consumed.
> - For Blink version 1.6.0 and earlier, if you specify *consumerGroup* to consume log data from a Logstore that contains a large number of shards, the read performance may be affected.
> - When you create a schema, Log Service data cannot be converted to data of the map type.
> - Fields whose values are empty are set to *null*.
> - Unordered field conversions are supported. However, we recommend that you convert the fields in the same order as the fields in the schema.
> - The *batchGetSize* parameter specifies the number of log groups that are obtained based on the *logGroup* parameter. If the size of each log entry and the value of the *batchGetSize* parameter are both large, garbage collection (GC) of data in the memory may frequently occur.

Precautions

- If no new data is written to a shard, the overall latency of a job increases. In this case, you need to modify the number of concurrent tasks in the job to the number of shards from which data is read and written.
- We recommend that you set the number of concurrent tasks in a job to the same as the number of shards. Otherwise, data may be filtered out when the job reads historical data from two shards at significantly different speeds.
- To extract fields in tags such as `__tag__:__hostname__` and `__tag__:__path__`, you can delete the __tag__: prefix and use the method of extracting attribute fields.

  > **Note** This type of data cannot be extracted during debugging. We recommend that you use the local debugging method and the print method to display data in logs.

28.1.7. RAM

28.1.7.1. Overview

Resource Access Management (RAM) is a resource access control service provided by Apsara Stack.

You can use RAM to manage users, including employees, systems, and applications. You can also use RAM to grant users permissions to access resources.

RAM provides the following features:

- RAM Role

  To authorize a cloud service in a level-1 organization to use other resources in the organization, you must create a RAM role. This role specifies the operations that the cloud service can perform on the resources.

  Only system administrators and level-1 organization administrators can create RAM roles.

- User group

  You can create multiple RAM users for an organization and grant the users different permissions on the same cloud resources in the organization.

  You can create RAM user groups to classify and authorize RAM users within your Apsara Stack tenant account. This simplifies the management of RAM users and their permissions.

  You can create RAM policies to grant permissions to different user groups.

28.1.7.2. Create a RAM role

To authorize a cloud service in a level-1 organization to use other resources in the organization, you must create a RAM role. This role specifies the operations that the cloud service can perform on the resources.

Procedure

1. Log on to the Apsara Uni-manager Management Console as an administrator.

   For more information, see Log on to the Log Service console.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Roles**.
4. In the upper-right corner of the page, click **Create RAM Role**.
5. On the **Roles - Create RAM Role** page that appears, set the **Role Name** and **Description** parameters.
6. Click **Create**.

28.1.7.3. Create a user

This topic describes how an administrator creates a user and assigns a role to the user. The role varies based on the cloud resources that the user needs to access.

Procedure

1.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Users**.
4. On the **Users** page, click **Create**.
5. In the dialog box that appears, set the parameters based on your requirements.

Parameter	Description
Username	The username.
Display Name	The display name of the user.

Parameter	Description
Roles	The role that you want to assign to the user.
Organization	The organization to which the user belongs.
Logon Policy	The logon policy that restricts the logon time and IP address of the user. If you do not specify this parameter, the default policy is attached to the created user.
Mobile Number	The mobile phone number of the user. If you need to send text messages about the usage and requests for resources to the mobile phone number, make sure that the specified mobile phone number is correct.
Landline Number	Optional. The landline number of the user.
Email	The email address of the user. If you need to send emails about the usage and requests for resources to the email address, make sure that the specified email address is correct.
DingTalk Key	Optional. The DingTalk key.
Notify User by SMS	Specifies whether to send text messages about the usage and requests for resources to the specified mobile phone number.
Notify User by Email	Specifies whether to send emails about the usage and requests for resources to the specified email address.
Notify User by DingTalk	Specifies whether to send messages about the usage and requests for resources to the specified DingTalk user.

6. Click **OK**.

28.1.7.4. Create a RAM user group

This topic describes how to create a RAM user group in an organization and grant permissions to RAM users in the RAM user group.

Prerequisites

An organization is created.

Context

The relationships between RAM user groups and RAM users:

- A RAM user group can contain zero or more RAM users.
- A RAM user does not need to belong to a RAM user group.
- You can add a RAM user to multiple RAM user groups.

The relationships between RAM user groups and organizations:

- A RAM user group belongs to only one organization.
- You can create multiple RAM user groups in an organization.

The relationships between RAM user groups and RAM roles:

- Only one RAM role can be assigned to each RAM user group.
- A RAM role can be assigned to multiple RAM user groups.
- When a RAM role is assigned to a RAM user group, the permissions that the RAM role has are automatically

granted to RAM users in the RAM user group.

The relationships between RAM user groups and resource sets:

- You can add zero or more user groups to a resource set.
- A user group can be added to multiple resource sets.

Procedure

1.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **User Groups**.
4. In the upper-right corner of the page, click **Create User Group**.
5. In the dialog box that appears, set the **User Group Name** and **Organization** parameters.
6. Click **OK**.

28.1.7.5. Add a RAM user to a RAM user group

This topic describes how to add a RAM user to a RAM user group.

Procedure

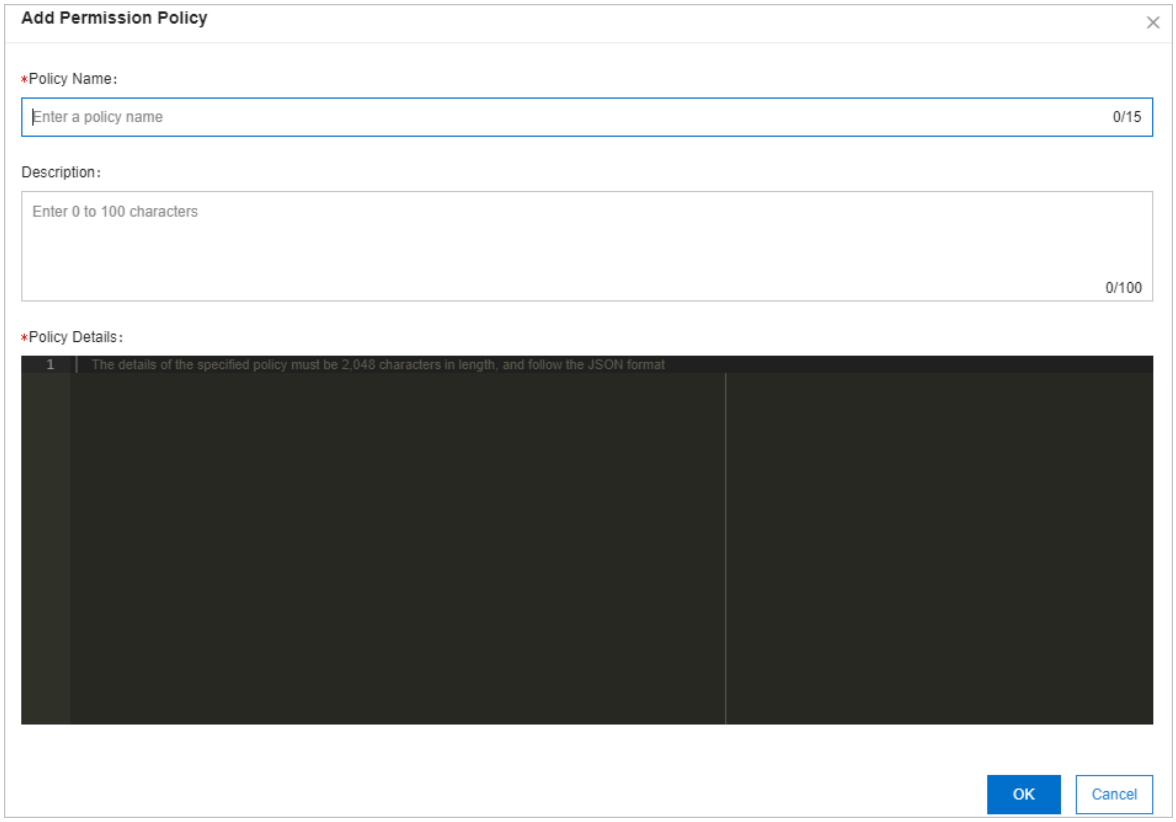
1.
2. In the top navigation bar, click **Enterprise**.
3.
4. Find the user group to which you want to add a RAM user, and click **Add User** in the **Actions** column.
5. In the dialog box that appears, select a RAM user from the left pane, and click the right arrow to move the RAM user to the right pane.
6. Click **OK**.

28.1.7.6. Create a permission policy

If you want to use a cloud service to access the resources of other cloud services, you must create a permission policy for a RAM role. Then, the policy is automatically attached to the RAM user group to which the RAM role is assigned.

Procedure

1.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Roles**.
4. In the list of role names, find the RAM role for which you want to create a permission policy and choose **More > Modify**.
5. Click **Permissions**.
6. Click **Add Permission Policy**.
7. In the **Add Permission Policy** dialog box, enter the policy information.



For more information about how to specify the policy information, see Use custom policies to grant RAM user the required permissions.

28.1.7.7. Grant permissions to a RAM role

This topic describes how to grant permissions to a RAM role. After a RAM role is granted permissions, the RAM users in the associated RAM user group inherit the permissions.

Procedure

1.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Roles**.
4.
5. On the **Permissions** tab, click **Select Existing Permission Policy**.
6. In the **Select Existing Permission Policy** dialog box, select a permission policy and click **OK**.

   If no policies are available, create a policy. For more information, see Create a permission policy.

28.1.7.8. Use custom policies to grant RAM user the required permissions

This topic describes how to use custom Resource Access Management (RAM) policies to grant RAM users the required permissions. You can grant permissions to the RAM users under your Apsara Stack tenant account.

Context

For data security, we recommend that you follow the principle of least privilege (PoLP) when you grant permissions to RAM users. You must grant the read-only permission on the project list to RAM users. Otherwise, the RAM users cannot view the projects in the project list.

Use the RAM console to grant permissions to a RAM user

- The read-only permission on projects

  For example, you can use your Apsara Stack tenant account to grant RAM users the following permissions:

  - The permission to view the list of projects that belong to the Apsara Stack tenant account
  - The permission to read specific projects

  Use the following policy:

```
{
   "Version": "1",
   "Statement": [
     {
       "Action": ["log:ListProject"],
       "Resource": ["acs:log:*:*:project/*"],
       "Effect": "Alow"
      },
     {
       "Action": [
         "log:Get*",
         "log:List*"
       ],
       "Resource": "acs:log:*:*:project/<The name of the project>/*",
       "Effect": "Allow"
     }
   ]
 }
```

- The permission to read a Logstore, save searches, and use saved searches.

  For example, you can use your Apsara Stack tenant account to grant RAM users the following permissions:

  - The permission to view the project list of the Apsara Stack tenant account
  - The permission to read a Logstore, save searches, and use saved searches

  Use the following policy:

```
{
  "Version": "1",
  "Statement": [
    {
      "Action": [
        "log:ListProject"
      ],
      "Resource": "acs:log:*:*:project/*",
      "Effect": "Allow"
    },
    {
      "Action": [
        "log:List*"
      ],
      "Resource": "acs:log:*:*:project/<The name of the project>/logstore/*",
      "Effect": "Allow"
    },
    {
      "Action": [
        "log:Get*",
        "log:List*"
      ],
      "Resource": [
        "acs:log:*:*:project/<The name of the project>/logstore/<The name of the Logstore>"
      ],
      "Effect": "Allow"
    },
    {
      "Action": [
        "log:List*"
      ],
      "Resource": [
        "acs:log:*:*:project/<The name of the project>/dashboard",
        "acs:log:*:*:project/<The name of the project>/dashboard/*"
      ],
      "Effect": "Allow"
    },
    {
      "Action": [
        "log:Get*",
        "log:List*",
        "log:Create*"
      ],
      "Resource": [
        "acs:log:*:*:project/<The name of the project>/savedsearch",
        "acs:log:*:*:project/<The name of the project>/savedsearch/*"
      ],
      "Effect": "Allow"
    }
  ]
}
```

Note In the policy, a value of the Resource attribute that does not end with an asterisk (*) indicates the exact resource. A value that ends with an asterisk (*) indicates all resources that match the value.

- The permission to read a Logstore and view all saved searches and dashboards in a project

  For example, you can use your Apsara Stack tenant account to grant a RAM user the following permissions:

- The permission to view the project list of the Apsara Stack tenant account
- The permission to read a Logstore and view all saved searches and dashboards in a project

Use the following policy:

```
{
  "Version": "1",
  "Statement": [
    {
      "Action": [
        "log:ListProject"
      ],
      "Resource": "acs:log:*:*:project/*",
      "Effect": "Allow"
    },
    {
      "Action": [
        "log:List*"
      ],
      "Resource": "acs:log:*:*:project/<The name of the project>/logstore/*",
      "Effect": "Allow"
    },
    {
      "Action": [
        "log:Get*",
        "log:List*"
      ],
      "Resource": [
        "acs:log:*:*:project/<The name of the project>/logstore/<The name of the Logstore>"
      ],
      "Effect": "Allow"
    },
    {
      "Action": [
        "log:Get*",
        "log:List*"
      ],
      "Resource": [
        "acs:log:*:*:project/<The name of the project>/dashboard",
        "acs:log:*:*:project/<The name of the project>/dashboard/*"
      ],
      "Effect": "Allow"
    },
    {
      "Action": [
        "log:Get*",
        "log:List*"
      ],
      "Resource": [
        "acs:log:*:*:project/<The name of the project>/savedsearch",
        "acs:log:*:*:project/<The name of the project>/savedsearch/*"
      ],
      "Effect": "Allow"
    }
  ]
}
```

Grant RAM users the permissions that are required to call Log Service operations

- The permission to write data to a project

  To grant RAM users only the permission to write data to a project, use the following policy:

```
{
  "Version": "1",
  "Statement": [
    {
      "Action": [
        "log:Post*"
      ],
      "Resource": "acs:log:*:*:project/<The name of the project>/*",
      "Effect": "Allow"
    }
  ]
}
```

- The permission to consume data of a project

  To grant RAM users only the permission to consume data of a project, use the following policy:

```
{
  "Version": "1",
  "Statement": [
    {
      "Action": [
        "log:ListShards",
        "log:GetCursorOrData",
        "log:GetConsumerGroupCheckPoint",
        "log:UpdateConsumerGroup",
        "log:ConsumerGroupHeartBeat",
        "log:ConsumerGroupUpdateCheckPoint",
        "log:ListConsumerGroup",
        "log:CreateConsumerGroup"
      ],
      "Resource": "acs:log:*:*:project/<The name of the project>/*",
      "Effect": "Allow"
    }
  ]
}
```

- The permission to consume data of a Logstore

  To grant RAM users only the permission to consume data of a Logstore, use the following policy:

```
{
  "Version": "1",
  "Statement": [
    {
      "Action": [
        "log:ListShards",
        "log:GetCursorOrData",
        "log:GetConsumerGroupCheckPoint",
        "log:UpdateConsumerGroup",
        "log:ConsumerGroupHeartBeat",
        "log:ConsumerGroupUpdateCheckPoint",
        "log:ListConsumerGroup",
        "log:CreateConsumerGroup"
      ],
      "Resource": [
        "acs:log:*:*:project/<The name of the project>/logstore/<The name of the Logstore>",
        "acs:log:*:*:project/<the name of the project>/logstore/<the name of the Logstore>/*"
      ],
      "Effect": "Allow"
    }
  ]
}
```

28.1.8. FAQ

28.1.8.1. Log collection

28.1.8.1.1. How do I troubleshoot Logtail collection errors?

If the Logtail preview page is blank or "No Data" is displayed on the query page, perform the following steps:

Procedure

1. Check whether Log Service receives heartbeats from the server group.

   You can view the Logtail heartbeat status in the Log Service console. For more information, see View the status of a server group.

   If the heartbeat status is OK, go to the next step. If the heartbeat status is FAIL, proceed with further troubleshooting. For more information, see What can I do if no heartbeat packet is received from a Logtail client?.

2. Check whether the Logtail configuration is created.

   If the heartbeat status of Logtail is OK, check whether the Logtail configuration is created. Make sure that the path and name of monitored logs match the files that are stored on the server. The path can be a full path or a path that includes wildcards.

3. Make sure that the Logtail configuration is applied to the server group.

   Check whether the target Logtail configuration is applied to the server group. For more information, see Manage server group configurations.

4. Check collection errors.

   If Logtail is configured correctly, check whether new logs are generated in real time. Logtail only collects incremental log data. Logtail does not read log files in which no log is generated. If a log file is updated but the updates cannot be queried in Log Service, you can diagnose the problem as follows:

   - View logs of the Logtail client

The client logs include key INFO logs, all WARNING logs, and all ERROR logs. To view complete error information in real time, check the following client logs:

- Linux: */usr/local/ilogtail/ilogtail.LOG*.
- Linux: */usr/local/ilogtail/logtail_plugin.LOG*. The file contains the logs such as HTTP logs, MySQL binary logs, and MySQL query results.
- 64-bit Windows: *C:\Program Files (x86)\Alibaba\Logtail\logtail_*.log*.
- 32-bit Windows: *C:\Program Files\Alibaba\Logtail\logtail_*.log*.

- Check whether the log volume exceeds the limit.

  To collect large volumes of logs, you may need to modify the Logtail startup parameters for higher log collection throughput. For more information, see Set Logtail startup parameters.

28.1.8.1.2. What can I do if Log Service does not receive heartbeats from a Logtail client?

If Log Service does not receive heartbeats from a Logtail client, perform the steps that are described in the topic to troubleshoot the problem.

Context

After Logtail is installed on a server, the Logtail client sends heartbeats to Log Service. If the status page of the machine group shows that Log Service does not receive heartbeats from a Logtail client, it indicates that the Logtail client is not installed or disconnected from the server.

Step 1: Check whether Logtail is installed

Use the following method to check whether Logtail is installed:

- On a Linux server, run the following command:

  ```
  sudo /etc/init.d/ilogtaild status
  ```

  If the command returns `ilogtail is running`, it indicates that Logtail is installed. The following script shows an example command and response:

  ```
  [root@****************~]# sudo /etc/init.d/ilogtaild status
  ilogtail is running
  ```

- On a Windows server:
  i. Press Win+R. In the Run dialog box, enter services.msc and click **OK**.
  ii. In the **Services** window, check the status of the LogtailDaemon and LogtailWorker services. If the services are in the Running state, it indicates that Logtail is installed.

If Logtail is not installed, install it. For more information, see Install Logtail in Linux or Install Logtail in Windows. Ensure that the Log Service endpoint in the Logtail installation command corresponds to the region to which the Log Service project belongs. If Logtail is running, go to the next step.

Step 2: Check the Log Service endpoint in the Logtail installation command

When you install Logtail, you must specify a Log Service endpoint based on the region to which the Log Service project belongs. If the endpoint is incorrect or the Logtail installation command is invalid, Log Service cannot receive heartbeats from the Logtail client.

You can view the Log Service endpoint and installation method in the Logtail configuration file named *ilogtail_config.json*. The file is stored in the following path:

- Linux: */usr/local/ilogtail/ilogtail_config.json*

- 64-bit Windows: *C:\Program Files (x86)\Alibaba\Logtail\ilogtail_config.json*
- 32-bit Windows: *C:\Program Files\Alibaba\Logtail\ilogtail_config.json*

In the Logtail configuration file, check the value of the `config_server_address` parameter. This parameter specifies the Log Service endpoint. Then, check whether the Logtail client can connect to Log Service based on the endpoint. For example, if the endpoint that is recorded in the Logtail configuration file is `logtail.cn-qingdao-env25-d01.sls-pub.inter.env25.shuguang.com`, you can run the following command to check the connection:

- Linux:

```
curl logtail.cn-qingdao-env25-d01.sls-pub.inter.env25.shuguang.com
```

- Windows:

```
telnet logtail.cn-qingdao-env25-d01.sls-pub.inter.env25.shuguang.com 80
```

If the Log Service endpoint in the Logtail installation command is incorrect, re-install Logtail. For more information, see Install Logtail in Linux or Install Logtail in Windows.

If the Log Service endpoint in the Logtail installation command is correct, go to the next step.

Step 3: Check the server IP addresses in the machine group

The server IP address that is obtained by a Logtail client must be configured in the machine group. Otherwise, Log Service cannot receive heartbeats or collect logs from the Logtail client. Logtail uses the following methods to obtain the IP address of a server:

- If the server is not bound with a hostname, Logtail obtains the IP address of the first network interface controller (NIC) card of the server.
- If the server is bound with a hostname, Logtail obtains the IP address that corresponds to the hostname. You can view the hostname and IP address in the */etc/hosts* file.

> **Note** You can run the **hostname** command to query the hostname.

Perform the following steps to check whether the server IP address that is obtained by the Logtail client is configured in the machine group.

1. Check the server IP address that is obtained by Logtail.

   The `ip` field in the *app_info.json* file indicates the server IP address that is obtained by Logtail. The file is stored in the following path:

   - Linux: */usr/local/ilogtail/app_info.json*
   - 64-bit Windows: *C:\Program Files (x86)\Alibaba\Logtail\app_info.json*
   - 32-bit Windows: *C:\Program Files\Alibaba\Logtail\app_info.json*

   > **Note**
   > - If the `ip` field in the `app_info.json` file is empty, Logtail cannot work. In this case, you must configure an IP address for the server and restart Logtail.
   > - The `app_info.json` file is used only to record information. If you modify the IP address in the file, the server IP address obtained by Logtail is not updated.

2. Check the server IP addresses in the machine group.

   Log on to the Log Service console. In the **Projects** section, click the project to which the machine group belongs. In the left-side navigation pane, click the **Machine Groups** icon. In the **Machine Groups** pane, click the machine group. In the **Machine Group Status** section of the **Machine Group Settings** page, check the server IP addresses.

If no server IP address in the machine group is the same as the IP address that is obtained by Logtail, perform the following step to modify the IP address configurations in the Log Service console:

- If a server IP address in the machine group is incorrect, change the IP address to the IP address that is obtained by Logtail. Then, check the heartbeat status 1 minute after you save the change.
- If you have modified the IP address of the server where Logtail is installed (for example, the */etc/hosts* file is modified), restart Logtail. After Logtail obtains the new server IP address, set a server IP address in the machine group to the value of the `ip` field in the `app_info.json` file.

You can use the following method to restart Logtail:

- On a Linux server, run the following commands:

```
sudo /etc/init.d/ilogtaild stop
sudo /etc/init.d/ilogtaild start
```

- On a Windows server:

  Press Win+R. In the Run dialog box, enter services.msc and click OK. In the **Services** window, find and restart the LogtailWorker service.

28.1.8.1.3. How do I query the local log collection statuses?

You can use Logtail to query the health status of Logtail and log collection statuses. The statuses help you troubleshoot log collection issues and customize status monitoring for log collection.

Instructions

After a Logtail client that supports the status query feature is installed, you can query the local log collection statuses by running commands on the client. For more information about how to install Logtail, see Install Logtail in Linux.

You can run the `/etc/init.d/ilogtaild -h` command on the client to check whether a client supports the feature of querying the local log collection status. If the command output includes the `logtail insight, version` keyword, it indicates that the client supports the status query feature.

```
/etc/init.d/ilogtaild -h
Usage: ./ilogtaild { start | stop (graceful, flush data and save checkpoints) | force-stop | status |
-h for help}$
logtail insight, version : 0.1.0
commond list :
       status all [index]
             get logtail running status
       status active [--logstore | --logfile] index [project] [logstore]
             list all active logstore | logfile. if use --logfile, please add project and logstore. d
efault --logstore
       status logstore [--format=line | json] index project logstore
             get logstore status with line or json style. default --format=line
       status logfile [--format=line | json] index project logstore fileFullPath
             get log file status with line or json style. default --format=line
       status history beginIndex endIndex  project logstore [fileFullPath]
             query logstore | logfile history status.
index :   from 1 to 60. in all, it means last $(index) minutes; in active/logstore/logfile/history, i
t means last $(index)*10 minutes
```

The following table describes the commands that are supported by Logtail:

Command	Function	Maximum time range that can be queried	Time window
all	Queries the status of Logtail.	Last 60 minutes	1 minute
active	Queries the active Logstores that are collecting logs and the active log files from which logs are being collected.	Last 600 minutes	10 minutes
logstore	Queries the collection status of a Logstore.	Last 600 minutes	10 minutes
logfile	Queries the collection status of a log file.	Last 600 minutes	10 minutes
history	Queries the collection status of a Logstore or log file in the query time window.	Last 600 minutes	10 minutes

Note

- The `index` parameter in the preceding commands indicates the index of the time window. Valid values: 1 to 60. The index of the latest time window is 1 and the time window ends at the current system time. If you specify a 1-minute time window, the status in the past interval of `(index, index-1]` minutes is returned. If you specify a 10-minute time window, the status in the past interval of `(10*index, 10*(index-1)]` minutes is returned.
- All commands in the preceding table is the subcommands of the status command.

Command all

Command syntax

```
/etc/init.d/ilogtaild status all [ index ]
```

Note The all command is used to query the status of Logtail. The index parameter is optional. Default value: 1.

Examples

```
/etc/init.d/ilogtaild status all 1
ok
/etc/init.d/ilogtaild status all 10
busy
```

Response

Status	Description	Priority	Troubleshooting
ok	Logtail is running as expected.	N/A	No action is required.

Status	Description	Priority	Troubleshooting
busy	The collection speed is high, and Logtail is running as expected.	N/A	No action is required.
many_log_files	A large number of log files are being collected by Logtail.	Low	You can check the Logtail configuration for log files that do not need to be collected.
process_block	The process of log parsing is blocked.	Low	You can check whether a large number of logs are generated in a short time. If you use the all command for multiple times and the returned value is always process_block, you can modify the limit of CPU usage or the limit of concurrent packet sending.
send_block	The process of sending log packets is blocked.	High	You can check whether a large number of logs are generated in a short time and the network connection is stable. If you use the all command for multiple times and the returned value is always send_block, you can modify the limit of CPU usage or the limit of concurrent packet sending.

Command active

Command syntax

```
/etc/init.d/ilogtaild status active [--logstore] index
 /etc/init.d/ilogtaild status active --logfile index project-name logstore-name
```

Note

- You can use the `active [--logstore] index` command to query all active Logstores. The `--logstore` parameter is optional.
- The command `active --logfile index project-name logstore-name` is used to query all active log files in the Logstore of a project.
- The active command is used to query log files. We recommend that you query active Logstores before querying active log files in the Logstores.

Examples

```
/etc/init.d/ilogtaild status active 1
sls-zc-test : release-test
sls-zc-test : release-test-ant-rpc-3
sls-zc-test : release-test-same-regex-3
/etc/init.d/ilogtaild status active --logfile 1 sls-zc-test release-test
/disk2/test/normal/access.log
```

Response

- If you run the `active --logstore index` command, the names of the active Logstores are returned in the following format: `project-name : logstore-name`. If you run the command `active --logfile index project-name logstore-name`, the paths of active log files are returned.

- The status of the inactive Logstores or inactive log files in the query time window is not returned.

Command logstore

Command syntax

```
/etc/init.d/ilogtaild status logstore [--format={line|json}] index project-name logstore-name
```

> **Note**
>
> - The logstore command is used to query the collection status of the specified project and Logstore in the LINE or JSON format.
> - The default value of the `--format=` parameter is `--format=line`, which indicates that the status is returned in the LINE format. Noted that the `--format=` parameter is placed after the `logstore` parameter.
> - If the Logstore specified in the preceding command does not exist or is not active in the query time window, an empty response in LINE format or the `null` value in the JSON format is returned.

Examples

```
/etc/init.d/ilogtaild status logstore 1 sls-zc-test release-test-same
time_begin_readable : 17-08-29 10:56:11
time_end_readable : 17-08-29 11:06:11
time_begin : 1503975371
time_end : 1503975971
project : sls-zc-test
logstore : release-test-same
status : ok
config : ##1.0##sls-zc-test$same
read_bytes : 65033430

   "time_end" : 1503975971,
   "time_end_readable" : "17-08-29 11:06:11"
}
```

Response

Parameter	Description	Unit

Parameter	Description	Unit
status	The status of the Logstore.For information about Logstore statuses and actions that are required to deal with each status, see the following table.	N/A
time_begin_readable	The time when logs become readable.	N/A
time_end_readable	The time when logs become unreadable.	N/A
time_begin	The time when statistics collection starts.	Unix timestamp in seconds
time_end	The time when statistics collection ends.	Unix timestamp in seconds
project	The name of the project.	N/A
logstore	The name of the Logstore.	N/A
config	The name of the Logtail configuration, which is globally unique. The format of the name is `##1.0##` + project + `$` + config.	N/A
read_bytes	The amount of the log data that is read in the query time window.	Byte
parse_success_lines	The number of the log lines that are parsed in the query time window.	Line
parse_fail_lines	The number of the log lines that fail to be parsed in the query time window.	Line
last_read_time	The last time when logs are read in the query time window.	Unix timestamp in seconds
read_count	The number of times that the log file is read in the query time window.	Times
avg_delay_bytes	The average of difference between the actual file size and the offset generated when reading log data each time in the query time window.	Byte
max_unsend_time	The maximum period of time for which an unsent packet waits in the sending queue. An unsent packet refers to a packet that has not been sent at the end of the query time window. If no packets exist in the queue, the value is 0.	Unix timestamp in seconds

Parameter	Description	Unit
min_unsend_time	The minimum period of time for which an unsent packet waits in the sending queue. Unsent packets refer to packets that have not been sent at the end of the query time window. If no packets exist in the queue, the value is 0.	Unix timestamp in seconds
max_send_success_time	The maximum period of time when a packet waited in the sending queue.	Unix timestamp in seconds
send_queue_size	The number of the unsent packets in the sending queue at the end of the query time window.	Number of packets
send_network_error_count	The number of the packets that cannot be sent due to network errors in the query time window.	Number of packets
send_network_quota_count	The number of the packets that cannot be sent due to quota limit in the query time window.	Number of packets
send_network_discard_count	The number of the packets that are discarded due to data errors or lack of permissions.	Number of packets
send_success_count	The number of the packets that are sent in the query time window.	Number of packets
send_block_flag	Indicates whether the sending queue is blocked at the end of the query time window.	N/A
sender_valid_flag	Indicates whether the sender flag of the Logstore is valid. The value true indicates that the sender flag is valid. The value false indicates that the sender flag is invalid and disabled because of a network error or quota error.	N/A

Logstore statuses

Status	Description	Troubleshooting
ok	Logtail is running as expected.	No action is required.
process_block	The process of log parsing is blocked.	You can check whether a large number of logs are generated in a short time. If you use the all command for multiple times and the returned value is always process_block, you can Set Logtail startup parametersmodify the limit of CPU usage or of concurrent packet sending.
parse_fail	Logtail fails to parse logs.	You can check whether the format of logs is consistent with that you set in the Logtail configuration.

Status	Description	Troubleshooting
send_block	The process of sending log packets is blocked.	You can check whether a large number of logs are generated in a short time and the network connection is stable. If you use the all command for multiple times and the returned value is always send_block, you can Set Logtail startup parametersmodify the limit of CPU usage or of concurrent packet sending.

Command logfile

Command syntax

```
/etc/init.d/ilogtaild status logfile [--format={line|json}] index project-name logstore-name fileFullPath
```

Note

- The logfile command is used to query the collection status of the specified log files in the LINE or JSON format.
- The default value of the `--format=` parameter is `--format=line`, which indicates that the status is returned in the LINE format.
- If the log file specified in the command does not exist or is not active in the query time window, an empty response in the LINE format or the `null` value in the JSON format is returned.
- The `--format` parameter is placed after the `logfile` parameter.
- The value of the `filefullpath` parameter must be the full path of the log file.

Examples

```
/etc/init.d/ilogtaild status logfile 1 sls-zc-test release-test-same /disk2/test/normal/access.log
time_begin_readable : 17-08-29 11:16:11
time_end_readable : 17-08-29 11:26:11
time_begin : 1503976571
time_end : 1503977171
project : sls-zc-test
logstore : release-test-same
status : ok
config : ##1.0##sls-zc-test$same
file_path : /disk2/test/normal/access.log
file_dev : 64800
file_inode : 22544456
file_size_bytes : 17154060
file_offset_bytes : 17154060
read_bytes : 65033430
parse_success_lines : 230615
parse_fail_lines : 0
last_read_time : 1503977170
read_count : 667
avg_delay_bytes : 0
/etc/init.d/ilogtaild status logfile --format=json 1 sls-zc-test release-test-same /disk2/test/normal
/access.log
{
   "avg_delay_bytes" : 0,
   "config" : "##1.0##sls-zc-test$same",
   "file_dev" : 64800,
   "file_inode" : 22544456,
   "file_path" : "/disk2/test/normal/access.log",
   "file_size_bytes" : 17154060,

   "time_end_readable" : "17-08-29 11:26:11"
}
```

Response

Parameter	Description	Unit
status	The collection status of the log file in the query time window. For more information, see the status parameter in the Command logstore section.	N/A
time_begin_readable	The time when logs become readable.	N/A

Parameter	Description	Unit
time_end_readable	The time when logs become unreadable.	N/A
time_begin	The time when statistics collection starts.	Unix timestamp in seconds
time_end	The time when statistics collection ends.	Unix timestamp in seconds
project	The name of the project.	N/A
logstore	The name of the Logstore.	N/A
file_path	The path of the log file.	N/A
file_dev	The ID of the device from which the log file is collected.	N/A
file_inode	The inode of the log file.	N/A
file_size_bytes	The size of the log file that is last scanned in the query time window.	Byte
read_offset_bytes	The parsing offset of the log file.	Byte
config	The name of the Logtail configuration, which is globally unique. The format of the name is `##1.0##` + project + `$` + config.	N/A
read_bytes	The amount of the log data that is read in the query time window.	Byte
parse_success_lines	The number of the log lines that are parsed in the query time window.	Line
parse_fail_lines	The number of the log lines that fail to be parsed in the query time window.	Line
last_read_time	The last time when logs are read in the query time window.	Unix timestamp in seconds
read_count	The number of times that the log file is read in the query time window.	Times
avg_delay_bytes	The average of difference between the actual file size and the offset generated when reading log data each time in the query time window.	Byte

Command history

Command syntax

```
/etc/init.d/ilogtaild status history beginIndex endIndex project-name logstore-name [fileFullPath]
```

> **Note**
>
> - The history command is used to query the collection status of a Logstore or log file in the query time window.
> - The `beginIndex` and `endIndex` parameters specify the start and end indexes of the range of time windows that you want to query. You must ensure that `beginIndex <= endIndex`.
> - The `fileFullPath` parameter is optional. If you specify the path of a log file, the collection status of the log file is queried. If the path is not specified, the collection status of the Logstore is queried.

Examples

```
/etc/init.d/ilogtaild status history 1 3 sls-zc-test release-test-same /disk2/test/normal/access.log
        begin_time          status      read  parse_success  parse_fail      last_read_time  read_cou
nt  avg_delay    device     inode  file_size  read_offset
 17-08-29 11:26:11              ok   62.12MB         231000           0   17-08-29 11:36:11         6
71         0B     64800  22544459    18.22MB      18.22MB

92         0B           0             0            0              0           302       false
true   70-01-01 08:00:00   70-01-01 08:00:00   17-08-29 10:56:10
```

Response

- The collection status of the Logstore or log file in each query time window is listed in a line.
- For more information about response parameters, see the Command `logstore` and Command `logfile` sections.

Response status codes

Success code

If parameters that you specify in a command is valid (even if the queried Logstore or log file is not found), the code 0 is returned. The following section provides two examples:

```
/etc/init.d/ilogtaild status logfile --format=json 1 error-project error-logstore /no/this/file
null
echo $?
0
/etc/init.d/ilogtaild status all
ok
echo $?
0
```

Error codes

If a non-zero code is returned, it indicates that an error occurs. The following table describes the possible non-zero codes.

Code	Description	Message	Troubleshooting
10	The command is invalid or required parameters in the command are not specified.	`invalid param, use -h for help.`	You can run the `-h` command for help.
1	The value of the index parameter is not in the range from 1 to 60.	`invalid query interval`	You can run the `-h` command for help.
1	The collection status in the specified query time window cannot be queried.	`query fail, error: $(error)` . For more information, visit errno.	The startup time of Logtail is earlier than the query time window. Otherwise, you can submit a ticket for help.
1	The start time of querying is out of the query time window.	`no match time interval, please check logtail status`	You can check whether Logtail is running. If yes, you can submit a ticket for help.
1	No logs exist in the specified query time window.	`invalid profile, maybe logtail restart`	You can check whether Logtail is running. If yes, you can submit a ticket for help.

Examples

```
/etc/init.d/ilogtaild status nothiscmd
invalid param, use -h for help.
echo $?
10
/etc/init.d/ilogtaild status/all 99
invalid query interval
echo $?
1
```

Scenarios

You can query the overall status of Logtail, and specific metrics by querying the collection status during collection. You can customize a mechanism to monitor the log collection status based on the queried information.

Monitor the status of Logtail

You can monitor the status of Logtail by using the `all` command.

For example, you can run the command every minute to query Logtail status. If the `process_block`, `send_block` or `send_error` value is returned for 5 consecutive minutes, an alert is triggered.

You can adjust the alert duration and monitoring scope based on the priorities of the collected log files.

Monitor the log collection status

You can monitor the log collection status of a Logstore by using the `logstore` command.

For example, you can run the `logstore` command every 10 minutes to query the collection status of the Logstore. If the value of the `avg_delay_bytes` parameter exceeds 1 MB (1024 × 1024 bytes) or the value of the `status` parameter is not `ok`, an alert is triggered.

You can adjust the alert threshold for the `avg_delay_bytes` metric based on the size of data that is generated during the log collection.

Check whether Logtail has finished collecting log files

You can check whether Logtail has finished collecting log files by using the `logfile` command.

After Logtail stops collecting log files, you can run the `logfile` command every 10 minutes to query the status of the log file. If the value of the `read_offset_bytes` parameter is the same as that of the `file_size_bytes` parameter, it indicates that the log file is collected.

Troubleshoot log collection issues

If log collection latency occurs on a server, you can use the `history` command to query the status history of log collection.

1. The value of the `send_block_flag` parameter is true.This indicates that the log collection is blocked because of unstable network connections.
   - If the value of the `send_network_quota_count` parameter is greater than 0, split shards in the Logstore. For more information, see Split a shard.
   - If the value of the `send_network_error_count` parameter is greater than 0, check the network connections.
   - If no network error occurs, adjust the limit of concurrent packet sending and data transfer speed of Logtail.
2. The parameters related to packet sending are set to appropriate values. However, the value of the `avg_delay_bytes` parameter is large.
   - Use the value of the `read_bytes` parameter to calculate the average speed of parsing logs, and then determine whether a large amount of data is transferred during log collection based on the average speed.
   - Adjust the resource usage limits for Logtail.
3. The value of the `parse_fail_lines` parameter is greater than 0.

   Check whether the regular expression can match all required log fields as expected.

28.1.8.1.4. How do I test a regular expression?

If you select the full regex mode when you configure Logtail to collect and parse text logs, you must specify a regular expression based on your sample log entries. This topic describes how to test a regular expression.

Context

To test a regular expression that you have specified in the Log Service console, you can click **Validate** in the console and check the results as follows:

- For the regular expression that matches the first line of logs, check whether the regular expression can match the expected number of log entries.
- For the fields extracted by the regular expression, check whether the value of each field meets your expectations.

If you want to validate more items and test a regular expression, you can use online tools such as regex101.com and regextester.com. You can copy and paste the regular expression that is generated by Log Service to an online tool, and specify a sample log entry as the test string.

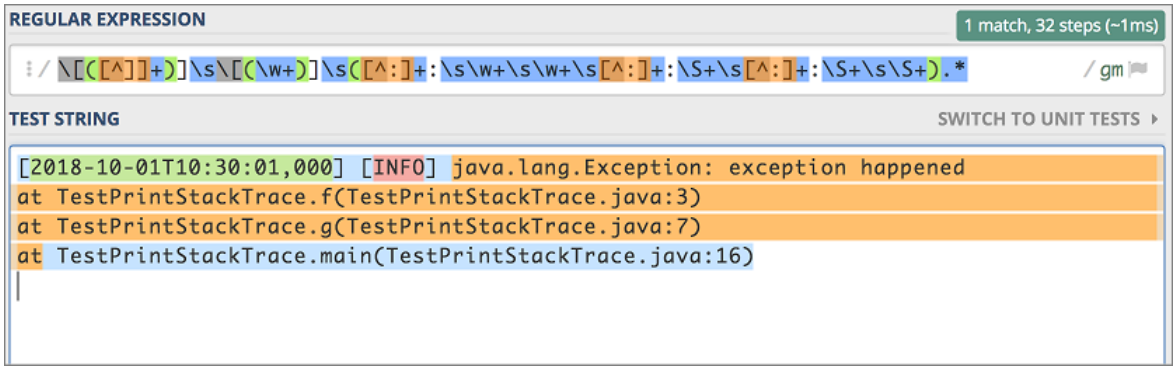
If you use the full regex mode, Log Service automatically generates a regular expression based on a sample log entry. However, the regular expression may fail to match the message field in multi-line log entries as expected. The following example describes how to use the regex101.com tool to test the regular expression.

Procedure

1. Copy the generated regular expression.
2. Visit the regex101.com website.
3. Paste the regular expression in the **REGULAR EXPRESSION** field.

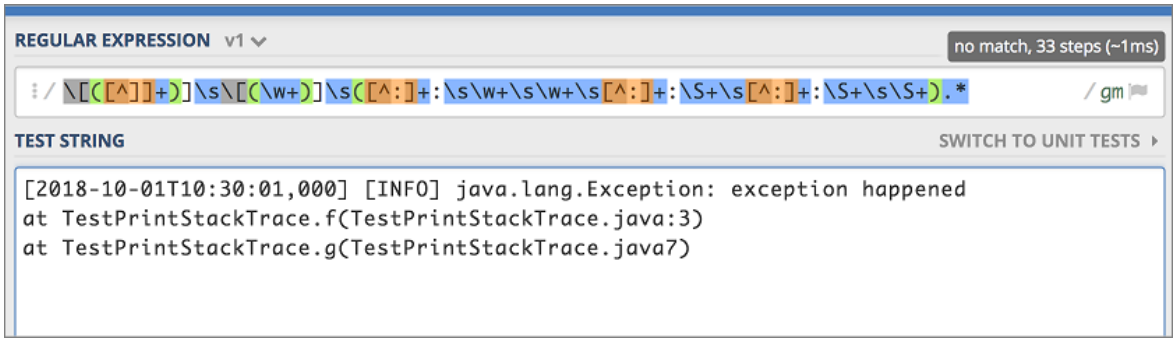
   On the right side of the page, you can view the explanation of the regular expression.
4. In the **TEST STRING** field, paste a log sample entry.

   In the following figure, the log contents that are included in the message field are highlighted in orange, and the log contents that are not included are highlighted in blue. The figure shows that the substring following the `at` word is not included in the `message` field. Therefore, this regular expression does not match fields in the sample log entry as expected and cannot be used to collect log data.



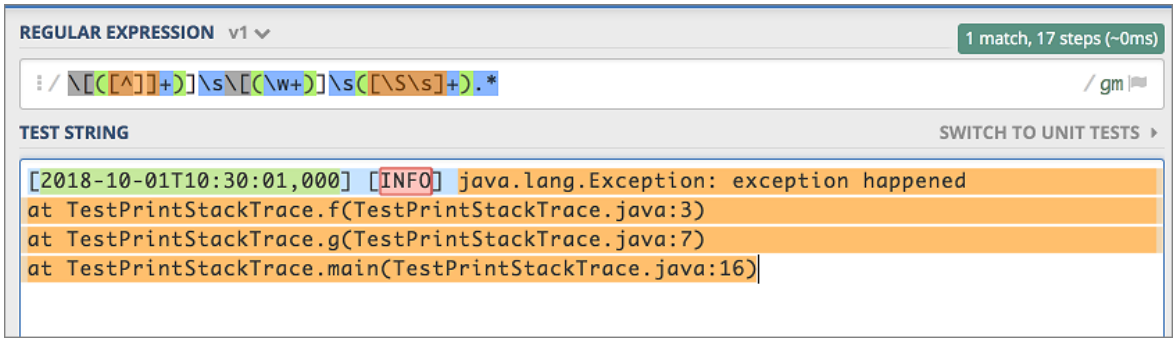
5. Check whether the regular expression can match fields in a sample log entry with two colons as expected.

   The following figure shows that the regular expression fails to match fields in the sample log entry as expected.

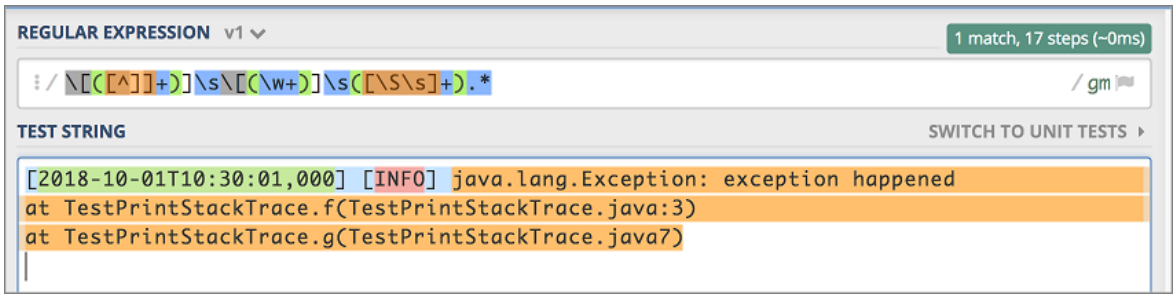


6. Replace the last subexpression in the regular expression with `[\S\s]+`, and check whether the regular expression can match fields in the sample log entries as expected.

   The following figure shows how the modified regular expression matches the substring following the `at` word.



The following figure shows how the modified regular expression matches the sample log entry with two colons.



You can follow the preceding instructions to test your regular expression. After you validate the regular expression, you can apply it to a Logtail configuration.

28.1.8.1.5. How do I optimize regular expressions?

You can optimize regular expressions to improve the Logtail performance.

When you optimize regular expressions, we recommend that you follow these rules:

- Use precise characters

  We recommend that you do not use the wildcard characters `.*` in a regular expression to match fields in log entries. Using wildcard characters may lead to mismatches and low matching performance. For example, if a field that you want to match only consists of letters, use `[A-Za-z]`.

- Use appropriate quantifiers

  We recommend that you do not use plus signs (+) or asterisks (*). For example, you can use `\d` instead of `\d+` or `\d{1,3}` to match the IP address.

- Test and modify regular expressions

  You can visit the **regex101.com** website to test and modify a regular expression to decrease the time required to match log entries.

28.1.8.1.6. How do I use the full regex mode to collect log entries in multiple formats?

The full regex mode requires that log entries to be collected be in the same format. Therefore, if you want to collect log entries that are in multiple formats, you must use the schema-on-write or schema-on-read solution.

Taking Java logs as an example, the following section lists the types of error log entry and normal log entry.

- Multi-line WARNING log entries
- Simple text INFO log entries
- Key-value DEBUG log entries

```
[2018-10-01T10:30:31,000] [WARNING] java.lang.Exception: another exception happened
    at TestPrintStackTrace.f(TestPrintStackTrace.java:3)
    at TestPrintStackTrace.g(TestPrintStackTrace.java:7)
    at TestPrintStackTrace.main(TestPrintStackTrace.java:16)
[2018-10-01T10:30:32,000] [INFO] info something
[2018-10-01T10:30:33,000] [DEBUG] key:value key2:value2
```

To collect log entries of these types, you can use the following solutions:

- Schema-on-write: To extract log fields, you must apply multiple Logtail configurations with different regular expressions to a log file.

  > **Note** However, Logtail cannot apply multiple Logtail configurations directly to the same log file. Therefore, you must set up multiple symbolic links for the directory in which the log file resides. Each Logtail configuration applies to a symbolic link to collect log entries in a specific format.

- Schema-on-read: you can use a common regular expression to collect log entries in different formats.

  For example, if you want to collect log entries in multiple formats, you can configure a regular expression that matches the time and log level fields as the first line, and specify the rest of the log entries as the log message. If you want to parse the message, create an index for the message, specify a regular expression to extract log messages, and then extract target fields.

  > **Note** We recommend that you use this solution only for scenarios in which tens of millions of log entries are collected, or fewer.

28.1.8.1.7. How do I set the time format for logs?

You must be familiar with the following rules before setting the time format for logs in Logtail configurations.

- The unit of the timestamp in Log Service is seconds. Therefore, you cannot set the unit as milliseconds or microseconds.
- You only need to set the time field. Other parameters are not required.

The following section lists commonly used formats:

```
Custom1 2017-12-11 15:05:07
%Y-%m-%d %H:%M:%S
Custom2 [2017-12-11 15:05:07.012]
[%Y-%m-%d %H:%M:%S
RFC822     02 Jan 06 15:04 MST
%d %b %y %H:%M
RFC822Z    02 Jan 06 15:04 -0700
%d %b %y %H:%M
RFC850      Monday, 02-Jan-06 15:04:05 MST
%A, %d-%b-%y %H:%M:%S
RFC1123     Mon, 02 Jan 2006 15:04:05 MST
%A, %d-%b-%y %H:%M:%S
RFC3339     2006-01-02T15:04:05Z07:00
%Y-%m-%dT%H:%M:%S
RFC3339Nano 2006-01-02T15:04:05.999999999Z07:00
%Y-%m-%dT%H:%M:%S
```

28.1.8.1.8. How do I configure non-printable characters in a sample log?

This topic describes how to configure non-printable characters in a sample log entry.

Context

Log Service allows you to specify a non-printable character as the delimiter or quote to collect logs. Non-printable characters are those whose decimal ASCII codes are in the range of 1 to 31 and 127. If you want to specify a non-printable character as the delimiter or quote, you must find the hexadecimal ASCII code of this character and enter this character in the following format: `0x` *the hexadecimal ASCII code of the non-printable character*. For example, a sample log entry is `123456780`. You can set 0x01 as the delimiter and 0x02 as the quote, and then enter a non-printable character 0x01 between the digits 5 and 6.

Procedure

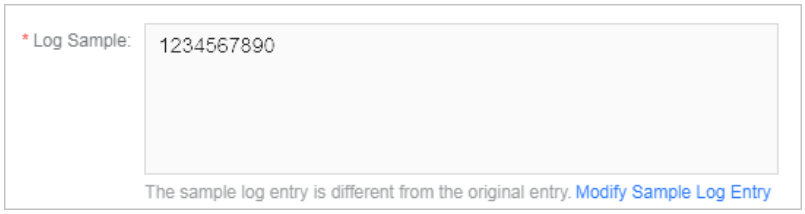
1. Log on to the Log Service console.
2. Right-click the blank space on the browser and select **Inspect** from the shortcut menu.
3. Click the **Console** tab on the page that appears.
4. Enter `"\x01"` in the code editor and press Enter.
5. Copy the returned result.

   A non-printable character is enclosed in quotation marks (").

6. Paste the returned result between the digits 5 and 6.

7. Delete the quotation marks between the digits 5 and 6.

   Then, a non-printable character is configured in a sample log entry.



28.1.8.1.9. How do I troubleshoot errors during container log collection?

Perform the steps that are described in this topic to troubleshoot an error that occurs when you use Logtail to collect logs from common containers or containers in a Kubernetes cluster.

Related O&M operations

- Log on to a Logtail container
- View the operational logs of Logtail
- Ignore the stdout logs of a Logtail container
- View the status of Log Service components in a Kubernetes cluster
- View the version number, IP address, and startup time of Logtail

Troubleshoot an error if Log Service does not receive heartbeats from Logtail clients

Perform the following steps to check whether Logtail is installed:

1. In the machine group, count the number of the servers whose heartbeat status is OK.
   i. Log on to the Log Service console.
   ii. Click the project to which the machine group belongs.
   iii. In the left-side navigation pane, click **Machine Groups**.
   iv. In the **Machine Groups** pane, click the name of the machine group.
   In the **Machine Group Status** section, count the number of the servers whose heartbeat status is **OK**.
2. Count the number of worker nodes in the cluster.
   Run the `kubectl get node | grep -v master` command to query the work nodes in the cluster. Count the number of the work nodes that are returned.

```
$kubectl get node | grep -v master
NAME                                STATUS    ROLES     AGE       VERSION
cn-hangzhou.i-bp17enxc2us3624wexh2   Ready     <none>    238d      v1.10.4
cn-hangzhou.i-bp1ad2b02jtqd1shi2ut   Ready     <none>    220d      v1.10.4
```

3. Check whether the number of servers whose heartbeat status is **OK** in the machine group is equal to the number of worker nodes in the cluster. Troubleshoot the error based on the check result.
   - The number of servers whose heartbeat status is OK is equal to the number of worker nodes. This means that the heartbeat status of all of the servers in the machine group is **Failed**.
     - If Logtail is installed into a common container, check whether the values of the *${your_region_name}*, *${your_aliyun_user_id}*, and *${your_machine_group_user_defined_id}* parameters are correct. For information about how to set these parameters, see Collect standard Docker logs.
     - If Logtail is installed into a container in a Container Service for Kubernetes cluster, submit a ticket.
     - If Logtail is installed into a container in a user-created Kubernetes cluster, check whether the values of the *{your-project-suffix}*, *{regionId}*, *{aliuid}*, *{access-key-id}*, and *{access-key-secret}* parameters are correct. If the value of a parameter is incorrect, run the `helm del --purge alibaba-log-controller` command to delete the installation package and re-install Logtail. For information about how to set these parameters, see Collect Kubernetes logs.
   - The number of servers whose heartbeat status is OK is less than the number of worker nodes.

a. Check whether you used a YAML file to manually deploy a DaemonSet.

   Run the `kubectl get po -n kube-system -l k8s-app=logtail` command to perform the check. If the command returns pod information, it indicates that you manually deployed a DaemonSet by using a YAML file.

b. Download the latest version of the Logtail DaemonSet template.

c. Set the *${your_region_name}*, *${your_aliyun_user_id}*, and *${your_machine_group_name}* parameters to the values that are specific to your environment.

d. Run the `kubectl apply -f ./logtail-daemonset.yaml` command to update the DaemonSet YAML file.

Submit a ticket if the error persists.

Troubleshoot an error if Log Service collects no logs from containers

If no log is displayed in the **Consumption Preview** pane or on the **Search & Analysis** page of a Logstore, it indicates that Log Service does not collect logs from the machine group of the Logstore. Check the status of the containers that correspond to the servers in the machine group. If the containers are working as expected, perform the following steps to troubleshoot the error:

1. Check the heartbeat status of the servers in the machine group.
2. Check whether the parameter settings in the Logtail configuration files are correct.

   Check whether the values of the IncludeLabel, ExcludeLabel, IncludeEnv, and ExcludeEnv parameters in the Logtail collection configuration files meet your requirements.

   > **Note** The `IncludeLabel` or `ExcludeLabel` parameter specifies whether to include or exclude the container images to which specified labels are attached. You can retrieve a list of container image labels by running the docker inspect command. The labels are not the labels that are defined by using Kubernetes. To check whether the parameter settings are correct in a Logtail configuration file, delete the IncludeLabel, ExcludeLabel, IncludeEnv, and ExcludeEnv parameters from the file. If Log Service can collect logs from the containers after the parameters are deleted, it indicates that the settings of the parameters are incorrect.

3. Check other items.

   Log Service does not collect logs from containers in the following scenarios:

   - Log files are not updated.
   - The log files of a container are stored in locations that are neither the default storage nor a storage attached to the container.

Log on to a Logtail container

- Common container
  i. Run the `docker ps | grep logtail` command on the host to search for the Logtail container.
  ii. Run the `docker exec -it ****** bash` command to log on to the container.

```
$docker ps | grep logtail
223fbd3ed2a6e        registry.cn-hangzhou.aliyuncs.com/log-service/logtail
"/usr/local/ilogta..."   8 days ago          Up 8 days                                  logtail-iba
$docker exec -it 223fbd3ed2a6e bash
```

- Container in a Kubernetes cluster
  i. Run the `kubectl get po -n kube-system | grep logtail` command to search for the pod where the Logtail container resides.
  ii. Run the `kubectl exec -it -n kube-system ****** bash` command to log on to the pod.

```
$kubectl get po -n kube-system | grep logtail
logtail-ds-g5wgd                                        1/1       Running    0          8d
logtail-ds-slpn8                                        1/1       Running    0          8d
$kubectl exec -it -n kube-system logtail-ds-g5wgd bash
```

View the operational logs of Logtail

The operational logs of Logtail are saved in the files named *ilogtail.LOG* and *logtail_plugin.LOG* under the */usr/local/ilogtail/* directory of a Logtail container.

1. Log on to a Logtail container.
2. Open the */usr/local/ilogtail/* directory.

   ```
   cd /usr/local/ilogtail
   ```

3. View the *ilogtail.LOG* and *logtail_plugin.LOG* files.

   ```
   cat ilogtail.LOG
   cat logtail_plugin.LOG
   ```

Ignore the stdout logs of a Logtail container

The standard output (stdout) logs of a Logtail container are useless for troubleshooting. Ignore the following stdout logs:

```
start umount useless mount points, /shm$|/merged$|/mqueue$
umount: /logtail_host/var/lib/docker/overlay2/3fd0043af174cb0273c3c7869500fbe2bdb95d13b1e110172ef57fe
840c82155/merged: must be superuser to unmount
umount: /logtail_host/var/lib/docker/overlay2/d5b10aa19399992755de1f85d25009528daa749c1bf8c16edff44be
ab6e69718/merged: must be superuser to unmount
umount: /logtail_host/var/lib/docker/overlay2/5c3125daddacedec29df72ad0c52fac800cd56c6e880dc4e8a640b1
e16c22dbe/merged: must be superuser to unmount
......
xargs: umount: exited with status 255; aborting
umount done
start logtail
ilogtail is running
logtail status:
ilogtail is running
```

View the status of Log Service components in a Kubernetes cluster

Run the `helm status alibaba-log-controller` command to view the status of Log Service components in a Kubernetes cluster.

View the version number, IP address, and startup time of Logtail

View the information in the *app_info.json* file under the */usr/local/ilogtail/* directory of the Logtail container. For example, you can run the following command to view the content of the file:

```
kubectl exec logtail-ds-gb92k -n kube-system cat /usr/local/ilogtail/app_info.json
{
   "UUID" : "",
   "hostname" : "logtail-gb92k",
   "instance_id" : "0EBB2B0E-0A3B-11E8-B0CE-0A58AC140402_10.10.10.10_1517810940",
   "ip" : "10.10.10.10",
   "logtail_version" : "0.16.2",
   "os" : "Linux; 3.10.0-693.2.2.el7.x86_64; #1 SMP Tue Sep 12 22:26:13 UTC 2017; x86_64",
   "update_time" : "2018-02-05 06:09:01"
}
```

28.1.8.2. Log search and analysis

28.1.8.2.1. FAQ about log query

This topic describes the common issues that may occur when you query log data in the Log Service console. It also includes solutions to these issues.

How do I identify the source server from which Logtail collects logs during a query?

If a server group uses IP addresses as its identifier when logs are collected by using Logtail, servers in the server group are distinguished from one another by internal IP addresses. When querying logs, you can use the hostname and custom IP address to identify the source server from which logs are collected.

For example, you can use the following statement to count the times different hostnames appear in logs:

> **Note** You must enable the index feature for the Logstore and enable the statistics feature for the __tag__:__hostname__ field in advance.

```
* | select "__tag__:__hostname__" , count(1) as count group by "__tag__:__hostname__"
```

How do I query IP addresses in logs?

You can use the exact match method to query IP addresses in logs. For example, you can specify IP addresses to query log data that includes or excludes the specified IP addresses. However, you cannot use the partial match method to query log data related to specified IP addresses. This is because decimal points contained in an IP address are not default delimiters in Log Service. If you want to use the partial match method, you can configure the decimal point as a delimiter for indexes. For example, you can use the SDK to download data and then use regular expressions or the string.indexof method in the code.

For example, you use the following statement to query projects that meet the specified conditions.

```
not ip:121.42.0 not status:200 not 360jk not DNSPod-Monitor not status:302 not jiankongbao
        not 301 and status:403
```

The retrieved log data still contains 121.42.0.x. An IP address such as 121.42.0.x is taken as a word in Log Service. To include or filter out 121.42.0.x in the query result, you must specify 121.42.0.x in the query statement. If you specify 121.42.0 in the query statement, you cannot retrieve log data that includes or excludes the keyword.

How do I query log data by using a keyword that contains a whitespace character?

If you use a keyword that contains a whitespace character to query log data, log data that contains the part of the keyword on the left or right of the whitespace character is retrieved. You can enclose the keyword that contains a whitespace character in double quotation marks (""). Then the entire enclosed content is regarded as a keyword to query the log data that you expect.

For example, you want to query log data that contains the keyword `POS version` from the following log data:

```
post():351]: device_id: BTAddr : B6:xF:xx:65:xx:A1 IMEI : 35847xx2
2xx81x9 WifiAddr : 4c:xx:0e:xx:4e:xx | user_id: bb07263xxd2axx43xx9exxe
a26e39e5f POS version:903
```

If you use `POS version` as the keyword, log data that contains `POS` and `version` is retrieved. This result does not meet your expectations. If you use `"POS version"` as the keyword, log data that contains the keyword `POS version` is retrieved.

How do I use two query conditions to query log data?

You can enter two query conditions at one time to query log data that you want.

For example, you want to query log data whose status field value is neither OK nor Unknown in a Logstore. You can use the `not OK not Unknown` statement to retrieve the expected result.

How can I query collected logs in Log Service?

You can use one of the following methods to query logs in Log Service:

- Use the Log Service console.
- Use the SDK.
- Use the Restful API.

28.1.8.2.2. What can I do if no log data is retrieved?

When you use the log search and analytics feature of Log Service to query data, you may not retrieve the data you want. In this case, you can troubleshoot the problem as follows:

Log collection failure

If log data fails to be collected by Log Service, the target log data cannot be queried. Check whether log data is available on the consumption preview page of the target Logstore.

If data is available, log data is collected by Log Service.

If data is unavailable, possible causes are as follows:

- The log source does not generate log data.

  In this case, no logs can be sent to Log Service. Check your log source.

- Logtail has no heartbeat.

  On the **Server Group Settings** page, check whether the relevant server has a heartbeat in the Server Group Status section. If it has no heartbeat, troubleshoot the problem. For more information, see What can I do if no heartbeat packet is received from a Logtail client?

- The monitoring file is not written in real time.

  If the monitoring file is written in real time, you can open the */usr/local/ilogtail/ilogtail.LOG* file to view the error message. Common error messages are as follows:

  - parse delimiter log fail: The error message is returned because an error has occurred when Log Service collects logs in the delimiter mode.
  - parse regex log fail: The error message is returned because an error has occurred when Log Service collects logs in the regex mode.

Delimiter setting errors

View the configured delimiters. Check whether you can use a keyword to query log data after the log content is split by using a delimiter. For example, the default delimiters `, ; = ( ) [ ] { } ? @ & < > / : '` are used. If a log entry contains abc"defg,hij, it is split into abc"defg and hij. In this case, you cannot retrieve this log entry by searching for abc.

Fuzzy match is also supported. For more information, see Query syntax.

> **Note**
>
> - To save your indexing cost, Log Service has optimized the index feature. If you configure an index for a field, full-text indexing is ineffective for the key of this field. For example, an index is configured for a log field whose key is message, and a whitespace character is used as a delimiter. To use a whitespace character as a delimiter, put it in the middle of delimiters that you have configured for an index. You can retrieve the log entries that contain "message: this is a test message" by searching for the key-value-pair-formatted keyword message:this. However, if you use the keyword this to query the log entries, you cannot retrieve the data because an index is configured for the message field and full-text indexing is ineffective.
> - You can create indexes or modify existing indexes. However, new or modified indexes take effect only for new data.
>
>   You can click Index Attributes to check whether the configured delimiters meet the requirements.

Other reasons

If log data is available, modify the time range of the query and try again. Log Service allows you to preview log data in real time. Due to a maximum latency of one minute, we recommend that you query log data at least one minute after logs are generated.

28.1.8.2.3. What are the differences between log consumption and log search and analytics?

Both the log consumption and log search and analytics features provided by Log Service need to read log data. The log consumption feature provides log collection and distribution channels. In contrast, the log search and analytics feature allows you to query log data.

Both the log consumption and log search and analytics features need to read log data:

Log collection and consumption (LogHub): provides public channels for log collection and distribution. It reads and writes full data in first-in, first-out (FIFO) order, which is similar to Kafka.

- Each Logstore has one or more shards. Data is written to a random shard.
- You can read multiple log entries at a time from a specified shard based on the order in which the log entries were written to the shard.
- You can set the start position (cursor) to pull log entries from shards based on the time when Log Service receives the log entries.

Log search and analytics: enables you to set conditions to search and analyze large amounts of log data based on LogHub.

- This feature allows you to search for required data based on query conditions.
- This feature allows you to include a combination of Boolean keywords AND, NOT, and OR and SQL statements in a query.
- This feature is independent of shards.

The following table lists the differences between the log search and analytics feature and the LogHub feature.

Feature	Log search and analytics (LogSearch)	LogHub
Search by keyword	Supported.	Not supported.
Data read (a small amount of data)	Fast.	Fast.
Data read (full data)	Slow. LogSearch reads 100 log entries in 100 milliseconds. This method is not recommended.	Fast. LogHub reads 1 MB of log data in 10 milliseconds. This method is recommended.
Data read by topic	Yes.	No. Data is identified only by shard.
Data read by shard	No. Data in all shards of a Logstore is queried.	Yes. You need to specify a shard each time to read data.
Price	Relatively high.	Low.
Scenario	Monitoring, problem investigation, and analysis.	Full data processing scenarios, such as stream computing and batch processing.

28.1.8.2.4. How do I resolve common errors returned in log data queries?

Common errors returned in log data queries are as follows:

line 1:44: Column 'my_key_field' cannot be resolved;please add the column in the index attribute

- Cause

  The `my_key_field` key cannot be included in the query statement because it does not exist.

- Solution

  In the upper-right corner of the Search & Analysis page, click Index Attributes to create an index for this field and enable the statistics feature for this field.

Column 'xxxxline' not in GROUP BY clause;please add the column in the index attribute

- Cause

  You use the GROUP BY clause and include a non-aggregated field in a SELECT statement. However, this field is not specified in the GROUP BY clause. For example, the key1 field in the `select key1, avg(latency) group by key2` statement is not specified in the GROUP BY clause.

- Solution

  An example correct statement is `select key1,avg(latency) group by key1,key2`.

sql query must follow search query,please read syntax doc

- Cause

  You do not include a filtering condition in a query statement, for example, `select ip,count(*) group by ip`.

- Solution

  An example correct statement is `*|select ip,count(*) group by ip`.

please read syntax document,and make sure all related fields are indexed. error after select .error detail:line 1:10: identifiers must not start with a digit; surround the identifier with double quotes

- Cause

  The column name or variable name referenced in an SQL statement starts with a number and does not comply with the rules.

- Solution

  Change the name so the name starts with a letter.

please read syntax document,and make sure all related fields are indexed. error after select .error detail:line 1:9: extraneous input '' expecting

- Cause

  Misspelled words exist in the query statement.

- Solution

  Correct the misspelled words.

key (category) is not config as key value config,if symbol : is in your log,please wrap : with quotation mark "

- Cause

  No index is configured for the category field. It cannot be used in a query statement.

- Solution

  Configure an index for this field in the index attributes. For more information, see Enable the index feature and configure indexes for a Logstore.

Query exceeded max memory size of 3GB

- Cause

  The size of memory used by the current query exceeds 3 GB. The common cause is that a large number of values are still returned in the query result after you use the GROUP BY clause to remove duplicates.

- Solution

  Reduce the number of keys specified in the GROUP BY clause.

ErrorType:ColumnNotExists.ErrorPosition,line:0,column:1.ErrorMessage:line 1:123: Column '__raw_log__' cannot be resolved; it seems __raw_log__ is wrapper by ";if __raw_log__ is a string ,not a key field, please use '__raw_log__'

- Cause

  The `my_key_field` key cannot be included in the query statement because it does not exist.

- Solution

  In the upper-right corner of the Search & Analysis page, click Index Attributes to create an index for this field and enable the statistics feature for this field.

28.1.8.2.5. Why data queries are inaccurate?

This topic describes the causes for inaccurate data queries. It also includes solutions to these issues.

When you search and analyze log data, the message **The results are inaccurate** may prompt in the console. This indicates that the returned result is inaccurate because some log data in a Logstore was not queried.

Possible causes include:

The time range for queries is excessive.

- Cause

  The time range for a query is excessively wide, for example, three months or a year. In this case, Log Service cannot scan all log data generated within this time period for one query.

- Solution

  Narrow down the query time range and perform multiple queries.

Query statements are complex.

- Cause

  The query statement is exceedingly complex or contains multiple frequently used words. In this case, Log Service cannot scan all related log data or read the query results at one time.

- Solution

  Narrow down the query scope and perform multiple queries.

The SQL computing needs to read an excessively large amount of data.

- Cause

  The SQL computing needs to read an excessively large amount of data. In this case, query results are likely to become inaccurate. A maximum of 1 GB of data can be read from each shard. For example, if the SQL computing needs to read strings from multiple columns, which exceed the threshold data volume, inaccurate query results will be returned.

- Solution

  Narrow down the query scope and perform multiple queries.

28.1.8.2.6. How do I configure indexes for historical log data?

You cannot directly configure indexes for historical log data in Log Service. To configure indexes for historical log data, you can use DataWorks or the command line interface (CLI) to move data into another Logstore.

Indexes take effect on log data that is collected after the indexes are configured. You cannot use indexes to search and analyze historical log data. To configure indexes for historical log data, you can use either of the following two methods:

- Configure indexes in a new Logstore and then use DataWorks to move data into the Logstore.

  After you configure indexes in a new Logstore, you can use DataWorks to move historical log data from the Logstore where it is stored to the new Logstore. Then you can use the configured indexes to search and analyze the data.

- After you configure indexes in a new Logstore, you can use the CLI to export historical log data from the Logstore where it is stored to the new Logstore.

> **Note** The preceding two methods copy historical log data and then export the data into a Logstore. They do not change or delete the data.

28.1.8.3. Alarm

28.1.8.3.1. FAQ about alerts

This topic describes the common issues that may occur when you configure alerts in the Log Service console. It also includes solutions to these issues.

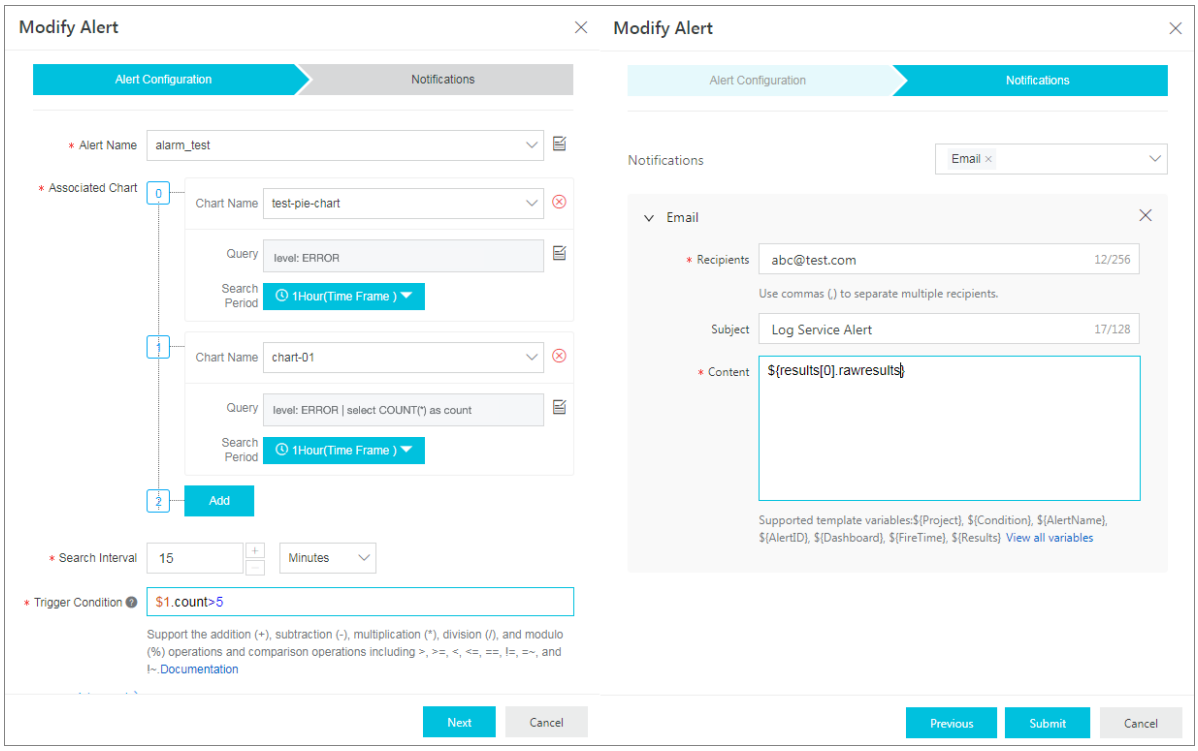
How can I include the raw error log entries in the notification content?

- Issue

  More than five error log entries were generated in the past five minutes, which triggered an alert. How can I include the raw error log entries in notifications that were sent when the alert was triggered?

- Solution
  - Associated query statements
    - Number 0: `level:ERROR`
    - Number 1: `level:ERROR | select COUNT(*) as count`
  - Trigger condition: `$1.count > 5`
  - Notification content: `${results[0].rawresults}`

- Configuration examples



29.Apsara Stack DNS

29.1. User Guide

29.1.1. What is Apsara Stack DNS?

Apsara Stack DNS is a service that runs on Apsara Stack to resolve domain names. You can configure rules to map domain names to IP addresses. Apsara Stack DNS then distributes domain name requests from clients to cloud resources, business systems on your internal networks, or the business resources of Internet service providers (ISPs).

Apsara Stack DNS provides DNS resolution in VPCs. You can perform the following operations on your VPC by using Apsara Stack DNS:

- Manage internal domain names.
- Manage DNS records of internal domain names.
- Manage forwarding configurations.
- Manage recursive resolution configurations.

29.1.2. User roles and permissions

Role	Permission
System administrator	A user of this role has read, write, and execute permissions on all level-1 organization resources, global resources, and system configurations.
Level-1 organization administrator	A user of this role has read, write, and execute permissions on level-1 organization resources to which the user belongs, but does not have permissions on level-1 organization resources, global resources, or system configurations to which other users belong.
Lower-level organization administrator	A user of this role does not have permissions on Apsara Stack DNS. The user does not have permissions on level-1 organization resources to which the user belongs, and does not have permissions on level-1 organization resources, global resources, or system configurations to which other users belong.
Resource user	A user of this role does not have permissions on Apsara Stack DNS. The user does not have permissions on level-1 organization resources to which the user belongs, and does not have permissions on level-1 organization resources, global resources, or system configurations to which other users belong.
Other roles	A user of this role does not have permissions on Apsara Stack DNS. The user does not have permissions on level-1 organization resources to which the user belongs, and does not have permissions on level-1 organization resources, global resources, or system configurations to which other users belong.

29.1.3. Log on to the Apsara Stack DNS console

This topic describes how to log on to the Apsara Stack DNS console by using Google Chrome.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 10 to 32 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Log On**.
4. In the top navigation bar, choose **Products > Networking > Apsara Stack DNS**.

29.1.4. Internal DNS resolution management

Internal DNS resolution management allows you to manage global internal domain names, global forwarding configurations, and global recursive resolution configurations that you have created in Apsara Stack.

29.1.4.1. Global internal domain names

29.1.4.1.1. Overview

All the operations of this feature require administrator privileges.

29.1.4.1.2. View an internal domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domains > Global Internal Domains**.
3. In the **Domain Name** search box, enter the domain name that you want to view.
4. Click **Search**.

   The search result is displayed.

29.1.4.1.3. Add a domain name

This topic describes how to add a domain name in the Apsara Uni-manager Management Console.

Procedure

1. Log on to the Apsara Stack DNS console.

2. In the left-side navigation pane, choose **Internal Domain Names > Internal Domain**.
3. Click **Add Domain Name**.
4. In the dialog box that appears, set **Internal Domain**.
5. Click **OK**.

29.1.4.1.4. Add a description for a domain name

This topic describes how to add a description for a domain name in the Apsara Uni-manager Management Console.

Context

You can add a description for a domain name to help you easily identify it. For example, you can add a hostname or internal system information to describe a domain name.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Internal Domain**.
3. Find the domain name for which you want to add a description, click the  icon in the Actions column, and then select **Description**.
4. In the dialog box that appears, enter a description.
5. Click **OK**.

29.1.4.1.5. Delete a domain name

This topic describes how to delete a domain name in the Apsara Uni-manager Management Console.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Internal Domain**.
3. Find the domain name that you want to delete, click the  icon in the **Actions** column, and then select **Delete**.
4. In the message that appears, click **OK**.

29.1.4.1.6. Delete multiple domain names

This topic describes how to delete unnecessary domain names at a time in the Apsara Uni-manager Management Console.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Internal Domain**.
3. Select one or more domain names that you want to delete and click **Delete** in the upper-right corner.
4. In the message that appears, click **OK**.

29.1.4.1.7. Configure DNS records

This topic describes how to configure DNS records in the Apsara Uni-manager Management Console.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Internal Domain**.
3. Find the domain name for which you want to configure DNS records, click the icon in the Actions column, and then select **Configure DNS Records**.
4. In the upper-right corner of the **Configure DNS Records** page, click **Add DNS Record**.
5.

29.1.4.1.8. View a resolution policy

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domains > Global Internal Domains**.
3. Find the target domain name, click the icon in the Actions column, and then select **Configure DNS Records**.
4. On the page that appears, select the domain name for which you want to configure DNS records, and click **Weight** in the **Resolution Policy** column.
5. On the page that appears, view the details of **Resolution Policy**.

29.1.4.2. Global forwarding configurations

29.1.4.2.1. Global forwarding domain names

29.1.4.2.1.1. Overview

All operations of this feature require administrator privileges.

Apsara Stack DNS forwards specific domain names to other DNS servers for resolution.

Two forwarding modes are available: forward all requests without recursion and forward all requests with recursion.

- Forward all requests without recursion: Only a specified DNS server is used to resolve domain names. If the specified DNS server cannot resolve the domain names or the request times out, a message is returned to the DNS client to indicate that the query failed.
- Forward all requests with recursion: A specified DNS server is preferentially used to resolve domain names. If the specified DNS server cannot resolve the domain names, the local DNS is used instead.

29.1.4.2.1.2. View global forwarding domain names

This topic describes how to view global forwarding domain names in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global**

Forwarding Domains.

3. In the **Domain Name** search box, enter the domain name that you want to query and click **Search**.

29.1.4.2.1.3. Add a domain name

This topic describes how to add a domain name in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Forwarding Domains**.
3. Click **Add Domain Name**.
4. In the dialog box that appears, configure *Global Forwarding Domain*, *Forwarding Mode*, and *Forwarder IP Addresses*. Then, click **OK**.

29.1.4.2.1.4. Add a description for a domain name

This topic describes how to add a description for a domain name in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Context

You can add a description for a domain name to help you easily identify it. For example, you can describe a domain name by using a hostname or internal system information.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Forwarding Domains**.
3. Select the domain name for which you want to add a description, click  in the Actions column, and then select **Description** from the shortcut menu.
4. In the dialog box that appears, enter a description and click **OK**.

29.1.4.2.1.5. Modify the forwarding configurations of a domain name

This topic describes how to modify the forwarding configurations of a domain name in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Forwarding Domains**.
3. Find the domain name whose forwarding configurations you want to modify, click the  icon in the Actions column, and then select **Modify**.
4. In the dialog box that appears, change the value of *Forwarding Mode* or *Forwarder IP Addresses*, and click **OK**.

29.1.4.2.1.6. Delete a domain name

This topic describes how to delete a domain name in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Forwarding Domains**.
3. Find the domain name that you want to delete, click the icon in the Actions column, and then select **Delete**.
4. In the message that appears, click **OK**.

29.1.4.2.1.7. Delete multiple domain names

This topic describes how to delete multiple domain names at the same time in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Domains > Forwarding Settings > Global Forwarding Domains**.
3. Select one or more domain names that you want to delete and click **Delete** in the upper-right corner of the domain name list.
4. In the message that appears, click **OK**.

29.1.4.2.2. Global default forwarding configurations

29.1.4.2.2.1. Enable default forwarding

This topic describes how to enable default forwarding in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Default Forwarding**.
3. Click the icon in the Actions column and select **Enable**.
4. In the dialog box that appears, configure *Default Forwarding Mode* and *Forwarder IP Addresses*. Then, click **OK**.

   Make sure that Enable Default Forwarding is set to ON.

29.1.4.2.2.2. Modify default forwarding configurations

This topic describes how to modify default forwarding configurations in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Default Forwarding**.
3. Click the icon in the Actions column and select **Modify**.
4. In the dialog box that appears, configure *Forwarding Mode* and *Forwarder IP Addresses*. Then, click **OK**.

29.1.4.2.2.3. Disable default forwarding

This topic describes how to disable default forwarding in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Default Forwarding**.
3. Click the icon in the Actions column and select **Disable**.
4. In the message that appears, click **OK**.

29.1.4.3. Global recursive resolution

29.1.4.3.1. Enable global recursive resolution

Prerequisites

You have administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. Choose **Internal Domains > Global Recursive Resolution**.
3. Click the icon in the Actions column and select **Enable**.
4. In the dialog box that appears, click **OK**.

29.1.4.3.2. Disable global recursive resolution

Prerequisites

You have administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. Choose **Internal Domains > Global Recursive Resolution**.
3. Click the icon in the Actions column and select **Disable**.

4. In the dialog box that appears, click **OK**.

29.1.5. PrivateZone (DNS Standard Edition only)

The PrivateZone feature allows you to create VPC-specific tenant domain names. You can bind the domain names to VPCs as required to achieve tenant isolation.

29.1.5.1. Tenant internal domain name

29.1.5.1.1. View a domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. In the **Domain Name** search box, enter the domain name that you want to view.
4. Click Search.

   The search result is displayed.

29.1.5.1.2. Add a domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Click **Add Domain Name**.
4. In the dialog box that appears, set *Tenant Internal Domain Name*.
5. Click **OK**.

29.1.5.1.3. Bind an organization to a VPC

Tenant domain names are isolated based on VPCs. To ensure that the DNS forwarding configurations take effect, you must bind the organization of domain names to a VPC.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Find the target domain name, click the  icon in the Actions column, and select **Associate VPCs**.
4. Select one or more VPCs from the list of VPCs to Select, click the right arrow to add them to the list of VPCs Selected, and then click **OK**.

29.1.5.1.4. Unbind a domain name from a VPC

This topic describes how to unbind a domain name from a VPC.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.

3. Find the target domain name and click the number in the **VPCs Associated** column.
4. On the **VPCs Associated** page, find the target VPC, click the icon in the **Actions** column, and then select **Disassociate**.

   Make sure that the unbound VPC is no longer displayed on the VPCs Associated page.

29.1.5.1.5. Add a description for a domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Find the target domain name, click the icon in the Actions column, and then select **Description**.
4. In the dialog box that appears, enter a description.
5. Click **OK**.

29.1.5.1.6. Delete a domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Find the target domain name, click the icon in the Actions column, and then select **Delete**.
4. In the message that appears, click **OK**.

29.1.5.1.7. Delete multiple domain names

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Select one or more domain names that you want to delete and click **Delete** in the upper-right corner.
4. In the message that appears, click **OK**.

29.1.5.1.8. Configure DNS records

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Find the target domain name, click the icon in the Actions column, and then select **Configure DNS Records**.
4. In the upper-right corner of the **Configure DNS Records** page, click **Add DNS Record**.
5. In the **Add DNS Record** dialog box, configure *Host*, *Type*, *TTL*, *Resolution Policy*, and *Record Set*. Then, click **OK**.

The following tables describe the types of DNS records.

- A record

Resolution policy	Formatting rule
None	You can enter up to 100 unique IPv4 addresses, each in a separate row. Make sure that the IPv4 addresses are valid. Example: ■ 192.168.1.1 ■ 192.168.1.2 ■ 192.168.1.3
Weight	You can enter up to 100 unique IPv4 addresses, each in a separate row. Format: ■ [IPv4 address] [Weight] (The IPv4 address and weight are separated with a space.) ■ Make sure that the IPv4 addresses are valid. ■ The weight value is an integer ranging from 0 to 999. A larger value indicates a greater weight. Example: ■ 192.168.1.1 20 ■ 192.168.1.1 30 ■ 192.168.1.1 50

- AAAA record

Resolution policy	Formatting rule
None	You can enter up to 100 unique IPv6 addresses, each in a separate row. Make sure that the IPv6 addresses are valid. Example: ■ 2400:3200::6666 ■ 2400:3200::6688 ■ 2400:3200::8888
Weight	You can enter up to 100 unique IPv6 addresses, each in a separate row. Format: ■ [IPv6 address] [Weight] (The IPv6 address and weight are separated with a space.) ■ Make sure that the IPv6 addresses are valid. ■ The weight value is an integer ranging from 0 to 999. A larger value indicates a greater weight. Example: ■ 2400:3200::6666 20 ■ 2400:3200::6688 20 ■ 2400:3200::8888 60

- CNAME record

Resolution policy	Formatting rule
None	You can enter only one domain name. The domain name must be a fully qualified domain name (FQDN) that ends with a dot (.). It must be 1 to 255 characters in length. Example: www.example.com.
Weight	You can enter up to 100 unique domain names, each in a separate row. Format: ■ [Domain name] [Weight] (The domain name and weight are separated with a space.) ■ The domain name must be an FQDN that ends with a period (.). It must be 1 to 255 characters in length. ■ The weight value is an integer ranging from 0 to 999. A larger value indicates a greater weight. Example: ■ www1.example.com. 20 ■ www2.example.com. 20 ■ www3.example.com. 60

- MX record

Resolution policy	Formatting rule
None	You can enter 100 unique email server hostnames, each in a separate row. Format: ■ [Priority] [Email server hostname] (The priority and hostname are separated with a space.) ■ The priority value is an integer ranging from 0 to 999. A smaller value indicates a higher priority. ■ The email server hostname must be an FQDN that ends with a period (.). It must be 1 to 255 characters in length. Example: ■ 10 mailserver1.example.com. ■ 20 mailserver2.example.com.

- TXT record

Resolution policy	Formatting rule
None	You can enter up to 100 unique character strings, each in a separate row. A string must be 1 to 255 characters in length. No row can be left blank. Example: "v=spf1 ip4:192.168.0.1/16 ip6:2001::1/96 ~all"

- PTR record

Resolution policy	Formatting rule
None	You can enter up to 100 unique domain names, each in a separate row. The DNS server address must be an FQDN that ends with a period (.). It must be 1 to 255 characters in length. Example: ■ www1.example.com. ■ www2.example.com. ■ www3.example.com.

- SRV record

Resolution policy	Formatting rule
None	You can enter up to 100 unique application server hostnames, each in a separate row. Format: ■ [Priority] [Weight] [Port number] [Application server hostname] (Every two items are separated with a space.) ■ The priority value is an integer ranging from 0 to 999. A smaller value indicates a higher priority. ■ The weight value is an integer ranging from 0 to 999. A larger value indicates a greater weight. ■ The port number is an integer ranging from 0 to 65535. It indicates the TCP or UDP port used for network communications. ■ The application server hostname must be an FQDN that ends with a period (.). It must be 1 to 255 characters in length. Example: ■ 1 10 8080 www1.example.com. ■ 2 20 8081 www2.example.com.

- NAPTR record

Resolution policy	Formatting rule

Resolution policy	Formatting rule
None	You can enter up to 100 unique NAPTR record values, each in a separate row. Format: ■ [Serial number] [Priority] [Flag] [Service information] [Regular expression] [Substitute domain name] (Every two items are separated with a space.) ■ The serial number is an integer ranging from 0 to 999. A smaller value indicates a higher priority. ■ The priority value is an integer ranging from 0 to 999. A smaller value indicates a higher priority. If two records have the same serial number, the one with a higher priority takes effect first. ■ The flag value can be left blank or be a character from A to Z, a to z, or 0 to 9. It is not case-sensitive and must be enclosed in double quotation marks (""). ■ The service information can be left blank or be a string of 1 to 32 characters. It must start with a letter and be enclosed in double quotation marks (""). ■ The regular expression can be left blank or be a string of 1 to 255 characters enclosed in double quotation marks (""). ■ The substitute domain name must be an FQDN that ends with a period (.). It must be 1 to 255 characters in length. Example: ■ 100 50 "S" "Z3950+I2L+I2C" "" _z3950._tcp.example.com. ■ 100 50 "S" "RCDS+I2C" "" _rcds._udp.example.com. ■ 100 50 "S" "HTTP+I2L+I2C+I2R" "" _http._tcp.example.com.

- CAA record

Resolution policy	Formatting rule
None	You can enter up to 100 unique CAA records, each in a separate row. Format: ■ [Certificate authority flag] [Certificate property tag] [Authorization information] (Every two items are separated with a space.) ■ The certification authority flag is an integer ranging from 0 to 255. ■ The certificate property tag can be issue, issuewild, or iodef. ■ The authorization information must be 1 to 255 characters in length and enclosed in double quotation marks (""). Example: ■ 0 issue "caa.example.com" ■ 0 issuewild ";" ■ 0 iodef "mailto:example@example.com"

- NS record

Resolution policy	Formatting rule

Resolution policy	Formatting rule
None	You can enter up to 100 unique DNS server addresses, each in a separate row. The DNS server address must be an FQDN that ends with a period (.). It must be 1 to 255 characters in length. Wildcard domain names are not allowed. Example: ■ ns1.example.com. ■ ns2.example.com.

6. After you add DNS records, perform the following operations as required:
   - Add a description for a DNS record.

     Find the target DNS record, click the icon in the Actions column, and then select **Description**. In the dialog box that appears, enter a description and click **OK**.
   - Delete a DNS record.

     Find the target DNS record, click the icon in the Actions column, and then select **Delete**. In the message that appears, click **OK**.
   - Modify a DNS record.

     Find the target DNS record, click the icon in the Actions column, and then select **Modify**. In the dialog box that appears, modify the required parameters and click **OK**.
   - Delete multiple DNS records.

     Select the DNS records that you want to modify and click **Delete** in the upper-right corner. In the message that appears, click **OK**.

29.1.5.1.9. View a resolution policy

This topic describes how to view the details of a resolution policy.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Find the target domain name, click the icon in the Actions column, and then select Configure DNS Records.
4. View the resolution policy in the DNS Records list.

29.1.5.2. Tenant forwarding configurations

29.1.5.2.1. Tenant forwarding domain names

29.1.5.2.1.1. View a tenant forwarding domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. In the **Domain Name** search box, enter the domain name that you want to view.
4. Click **Search**.

   The search result is displayed.

29.1.5.2.1.2. Add a tenant forwarding domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Click **Add Domain Name**.
4. In the dialog box that appears, configure parameters such as *Domain Name*, *Forwarding Mode*, and *Forwarder IP Addresses*.

Parameter	Description
Domain Name	The domain name, which must meet the following formatting rules: ○ The domain name must be 1 to 255 characters in length. This includes the period (.) at the end of the domain name. ○ The domain name can contain multiple domain name segments that are separated with periods (.). A domain name segment must be 1 to 63 characters in length. It cannot contain consecutive periods (.) or be left blank. ○ The domain name can only contain letters (a to z, A to Z), digits (0 to 9), hyphens (-), and underscores (_). ○ The domain name must start with a letter, digit, or underscore (_) and end with a letter, digit, or period (.). ○ The domain name is not case-sensitive. The system saves the domain name in lowercase letters. ○ The period (.) at the end of the domain name is optional. The system adds a period (.) to the end of the domain name.
Forwarding Mode	For both domain name-based forwarding and default forwarding, the following two forwarding modes are supported: ○ Forward All Requests without Recursion: forwards DNS requests to the target DNS server. If the target DNS server cannot resolve the domain names, a message is returned to the DNS client indicating that the query failed. ○ Forward All Requests with Recursion: A specified DNS server is preferentially used to resolve domain names. If the specified DNS server cannot resolve the domain names, the local DNS is used instead. If you enter internal IP addresses in the Forwarder IP Addresses field, unexpected results may occur during recursive resolution. For example, a domain name used for internal network services may be resolved to a public IP address.
Forwarder IP Addresses	A list of destination IP addresses. **Note** Multiple IP addresses are separated with semicolons (;).

5. Click **OK**.

29.1.5.2.1.3. Bind an organization to a VPC

Tenant domain names are isolated based on VPCs. You must bind the organization of domain names to a VPC before the DNS forwarding configurations can take effect.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Find the target domain name, click the  icon in the Actions column, and then select **Associate VPCs**.
4. Select one or more VPCs from the list of VPCs to Select, click the right arrow to add them to the list of VPCs Selected, and then click **OK**.

29.1.5.2.1.4. Unbind a domain name from a VPC

This topic describes how to unbind a domain name from a VPC.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Find the target domain name and click the number in the **VPCs Associated** column.
4. On the VPCs Associated page, find the target VPC, click the  icon in the Actions column, and then select **Disassociate**.

   Make sure that the unbound VPC is no longer displayed on the VPCs Associated page.

29.1.5.2.1.5. Modify the forwarding configurations of a domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Find the target domain name, click the  icon in the Actions column, and then select **Modify**.
4. In the dialog box that appears, change the value of **Forwarding Mode** or **Forwarder IP Addresses**.
5. Click **OK**.

29.1.5.2.1.6. Add a description for a tenant forwarding domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Find the target domain name, click the  icon in the Actions column, and then select **Description**.
4. In the dialog box that appears, enter a description.
5. Click **OK**.

29.1.5.2.1.7. Delete a tenant forwarding domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Find the target domain name, click the  icon in the Actions column, and then select **Delete**.
4. In the message that appears, click **OK**.

29.1.5.2.1.8. Delete multiple tenant forwarding domain names

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Select one or more domain names that you want to delete and click **Delete** in the upper-right corner.
4. In the message that appears, click **OK**.

29.1.5.2.2. Tenant default forwarding configurations

29.1.5.2.2.1. View default forwarding configurations

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.

29.1.5.2.2.2. Add a default forwarding configuration

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Click **Add Settings**.
4. In the dialog box that appears, configure parameters such as *Forwarding Mode* and *Forwarder IP Addresses*.

Parameter	Description
Forwarding Mode	For both domain name-based forwarding and default forwarding, the following two forwarding modes are available: ○ Forward All Requests without Recursion: Only a specified DNS server is used to resolve domain names. If the specified DNS server cannot resolve the domain names, a message is returned to the DNS client to indicate that the query failed. ○ Forward All Requests with Recursion: A specified DNS server is preferentially used to resolve domain names. If the specified DNS server cannot resolve the domain names, a local DNS server is used instead. If you enter internal IP addresses in the Forwarder IP Addresses field, unexpected results may occur during recursive resolution. For example, a domain name used for internal network services may be resolved to a public IP address.
Forwarder IP Addresses	A list of destination IP addresses. **Note** Multiple IP addresses are separated with semicolons (;).

5. Click **OK**.

29.1.5.2.2.3. Bind an organization to a VPC

Tenant domain names are isolated based on VPCs. You must bind the organization of domain names to a VPC before the DNS forwarding configurations can take effect.

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Find the target organization, click the  icon in the Actions column, and then select **Associate VPCs**.
4. Select one or more VPCs from the list of VPCs to Select, click the right arrow to add them to the list of VPCs Selected, and then click **OK**.

29.1.5.2.2.4. Unbind a domain name from a VPC

This topic describes how to unbind a domain name from a VPC.

Procedure

1. Log on to the Apsara Stack DNS console.

2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Find the target domain name and click the number in the **VPCs Associated** column.
4. On the VPCs Associated page, find the target VPC, click the icon in the Actions column, and then select **Disassociate**.

   Make sure that the unbound VPC is no longer displayed on the VPCs Associated page.

29.1.5.2.2.5. Modify a default forwarding configuration

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Find the target organization, click the icon in the Actions column, and then select **Modify**.
4. In the dialog box that appears, change the value of **Forwarding Mode** or **Forwarder IP Addresses**.
5. Click **OK**.

29.1.5.2.2.6. Add a default forwarding configuration

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Find the target organization, click the icon in the Actions column, and then select **Description**.
4. In the dialog box that appears, enter **Description**.
5. Click **OK**.

29.1.5.2.2.7. Delete a default forwarding configuration

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.

3. Find the target organization, click the  icon in the Actions column, and then select **Delete**.
4. In the dialog box that appears, click **OK**.

29.1.5.2.2.8. Delete multiple default forwarding configurations

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Select one or more domain names that you want to delete and click **Delete** in the upper-right corner.
4. In the message that appears, click **OK**.

29.1.6. Internal Global Traffic Manager (internal GTM Standard Edition only)

Internal Global Traffic Manager (GTM) supports multi-cloud disaster recovery for domain names of customers. This feature manages traffic loads between multiple Apsara Stack networks.

29.1.6.1. Scheduling instance management

29.1.6.1.1. Scheduling Instance

The Scheduling Instance tab displays all existing scheduling instances. You can add, delete, modify, and configure scheduling instances on this tab. When you create a scheduling instance, you must associate an address pool and scheduling domain with the instance.

29.1.6.1.1.1. Create a scheduling instance

After you create a scheduling instance, you can associate the scheduling instance with a scheduling domain and address pool.

1. In the left-side navigation pane, choose **Internal Global Traffic Manager** > **Scheduling Instances** > Scheduling Instance.

2. Click **Create Scheduling Instance** in the upper-right corner of the instance list.

3. In the dialog box that appears, configure Scheduling Instance Name, CNAME Access Domain Name, and Global TTL. Then, click **OK**.

29.1.6.1.1.2. Modify a scheduling instance

1. In the left-side navigation pane, choose **Internal Global Traffic Manager** > **Scheduling Instances** > Scheduling Instance.

2. Find the instance that you want to modify and click **Modify** in the Actions column.

3. Modify the parameter settings as prompted and click **OK**.

29.1.6.1.1.3. Configure a scheduling instance

You can add, delete, modify, and query access policies of scheduling instances.

Create an access policy for a scheduling instance

1. Log on to the Apsara Stack DNS console and choose Recursion Configurations > Scheduling Instances > Scheduling Instance. Find the target scheduling instance and click Configure in the Actions column. On the Access Policy Configuration page, click Create Access Policy in the upper-right corner of the page.

2. In the dialog box that appears, enter the required information and click OK.

Modify the access policy of a scheduling instance

1. On the Access Policy Configuration page, find the target access policy and click Modify in the Actions column.

2. In the dialog box that appears, modify the configurations and click OK.

Delete the access policy of a scheduling instance

1. On the Access Policy Configuration page, find the target access policy and click Delete in the Actions column.

2. In the dialog box that appears, click OK after you verify that the displayed information is correct.

29.1.6.1.1.4. Delete a scheduling instance

1. Log on to the Apsara Stack DNS console and choose Recursion Configurations > Scheduling Instances > Scheduling Instance.

2. Find the target instance and click Delete in the Actions column.

3. In the dialog box that appears, click OK.

Note: After you delete the instance, its configuration data is also deleted.

29.1.6.1.2. Address Pool

The Address Pool tab allows you to manage address pools. You can associate address pools with scheduling instances. The address pools are classified into three types: IPv4 address pool, IPv6 address pool, and domain name address pool. The load balancing policy of an address pool can be set to polling or weight.

29.1.6.1.2.1. Create an address pool

1. In the left-side navigation pane, choose **Internal Global Traffic Manager > Scheduling Instances > Address Pool**.

2. Click **Create Address Pool** in the upper-right corner of the address pool list.

3. Configure **Address Pool Name**, **Address Type**, **Load Balancing Policy**, and **Address List**. Then, click **OK**.

29.1.6.1.2.2. Modify the configurations of an address pool

1. In the left-side navigation pane, choose **Internal Global Traffic Manager > Scheduling Instances > Address Pool**.

2. Find the address pool whose configurations you want to modify and click **Modify** in the Actions column.

3. In the dialog box that appears, modify the configurations as required and click **OK**.

29.1.6.1.2.3. Delete an address pool

1. Log on to the Apsara Stack DNS console and choose Recursion Configurations > Scheduling Instances > Address Pool.

2. Find the target address pool and click Delete in the Actions column.

3. In the dialog box that appears, click OK after you verify that the displayed information is correct.

29.1.6.1.3. Scheduling Domain

The Scheduling Domain tab allows you to add, delete, and query scheduling domains.

You can log on to the Apsara Stack DNS console and choose Internal Global Traffic Manager > Scheduling Instances > Scheduling Domain to go to the scheduling domain list.

29.1.6.1.3.1. Create a scheduling domain

1. Log on to the Apsara Stack DNS console and choose Recursion Configurations > Scheduling Instances > Scheduling Domain. Then, click Create Scheduling Domain in the upper-right corner of the scheduling domain list.

2. In the dialog box that appears, enter the custom domain name and click OK.

29.1.6.1.3.2. Add a description for a scheduling domain

1. In the left-side navigation pane, choose Internal Global Traffic Manager > Scheduling Instances > Scheduling Domain.

2. Find the scheduling domain for which you want to add a description and click Edit in the Actions column.

3. In the dialog box that appears, add a description in the Edit field and click OK.

29.1.6.1.3.3. Delete a scheduling domain

1. In the left-side navigation pane, choose Internal Global Traffic Manager > Scheduling Instances > Scheduling Domain.

2. Find the scheduling domain that you want to delete and click Delete in the Actions column.

3. In the message that appears, click OK after you verify that the displayed information is correct.

29.1.6.2. Scheduling line management

29.1.6.2.1. IP Address Line Configuration

The IP Address Line Configuration tab allows you to define lines based on IP addresses. The lines are used to group request sources to achieve intelligent load balancing.

29.1.6.2.1.1. Add a line

1. In the left-side navigation pane, choose **Internal Global Traffic Manager** > **Scheduling Line Management** > IP Address Line Configuration.

2. Click **Add Line** in the upper-right corner of the line list.

3. In the dialog box that appears, configure the parameters as prompted and click **OK**.

29.1.6.2.1.2. Sort lines

1. In the left-side navigation pane, choose **Internal Global Traffic Manager** > **Scheduling Line Management** > IP Address Line Configuration.

2. Find the line whose sequence you want to change and click **Sort** in the Actions column.

3. Specify Sort Behavior as prompted and click **OK**.

29.1.6.2.1.3. Modify the configurations of a line

1. In the left-side navigation pane, choose **Internal Global Traffic Manager** > **Scheduling Line Management** > IP Address Line Configuration.
2. Find the line whose configurations you want to modify and click **Modify** in the Actions column.
3. Modify the configurations as prompted and click **OK**.

29.1.6.2.1.4. Delete a line

1. In the left-side navigation pane, choose **Internal Global Traffic Manager** > **Scheduling Line Management** > **IP Address Line Configuration**.
2. Find the line that you want to delete and click **Delete** in the Actions column.
3. In the message that appears, click **OK**.

29.1.6.3. Data synchronization management

Data synchronization management is used to synchronize Global Traffic Manager (GTM) data between clouds.

29.1.6.3.1. Synchronization cluster management

Synchronization clusters involve two operations: **Set Emergency Group** and **Merge GTM Control Domain**.

You can perform the following operations to go to the synchronization cluster management page:

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Global Traffic Manager**.
3. On the page that appears, click the **Data Synchronization** tab.

Set Emergency Group

You can select some service instances to form a cluster to provide services.

- Enable the emergency group feature: If the synchronization cluster is abnormal, click **Set Emergency Group**. In the Set Emergency Group dialog box, turn on Emergency Group Switch, select available service instances to form an emergency group, and then click **OK**.
- Disable the emergency group feature: If the synchronization cluster is restored to normal, click **Set Emergency Group**. In the Set Emergency Group dialog box, turn off the Emergency Group Switch and click **OK**.

Merge GTM Control Domain

In multi-cloud scenarios, you can click **Merge GTM Control Domain** and enter the IP address of the leader service instance of the merged Global Traffic Manager (GTM) control domain to form a large synchronization cluster.

View the status of the synchronization cluster

You can view the status of the synchronization cluster on the Synchronization Cluster Management tab.

View the service instances in the synchronization cluster

You can view the following information of the service instances in the current synchronization cluster:

Instance IP Address, Instance Role, Status, Latest Synchronization Log ID, IP Address, and Instance Description.

You can also perform the following operations to switch the role of a service instance in the synchronization cluster from follower to leader:

1. Find the service instance with the follower role and click **Switch Primary** in the Actions column.

2. In the message that appears, click **OK**.
