Instance monitoring is divided into resource monitoring and engine monitoring. Engine monitoring metrics are classified into metrics at the instance level and metrics at the database level. When some engine monitoring metrics are abnormal, you can directly check the metrics of each database to locate the database with performance problems. The following table describes the metrics of these two types in details.

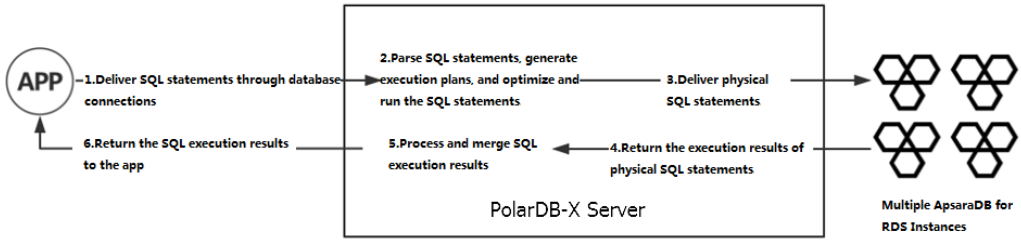
Monitoring item	Category	Description	Data collection cycle	Data retention period	Description
CPU Utilization (%)	Resource monitoring	The average CPU utilization of server nodes.	1 minute	3 days	-
Memory Usage (%)	Resource monitoring	The memory usage of JVM Old Generation on server nodes.	1 minute	3 days	Memory usage fluctuations are normal.
Inbound Traffic (Kbps)	Resource monitoring	The total inbound network traffic of server nodes.	1 minute	3 days	Inbound network traffic is generated when ApsaraDB RDS for MySQL returns data to .
Outbound Traffic (Kbps)	Resource monitoring	The total outbound network traffic of server nodes.	1 minute	3 days	Outbound network traffic is generated when a instance sends a physical SQL statement to an AparaDB RDS for MySQL instance or a instance returns data to an application.

Monitoring item	Category	Description	Data collection cycle	Data retention period	Description
Logical QPS	Engine monitoring	The total number of SQL statements processed per second on server nodes.	5 seconds	7 days	-
Physical QPS	Engine monitoring	The total number of SQL operations sent from server nodes to ApsaraDB RDS for MySQL per second.	5 seconds	7 days	One logical SQL statement can be partitioned into multiple physical SQL statements.
Logical RT (ms)	Engine monitoring	The average response time (RT) for processing each SQL statement by .	5 seconds	7 days	If a logical SQL statement is partitioned into physical SQL statements for delivery, the logical RT of the SQL statement contains the RT of the physical SQL statements.
Physical RT (ms)	Engine monitoring	The average RT for transmitting SQL statements from to ApsaraDB RDS for MySQL.	5 seconds	7 days	-
Connections	Engine monitoring	The total number of connections established between an application and .	5 seconds	7 days	The connections from to ApsaraDB RDS for MySQL are not included.
Active Threads	Engine monitoring	The number of threads that are used by to run SQL statements.	5 seconds	7 days	-

13.1.4.9.3. How metrics work

Before analyzing metrics, you need to understand the execution process of SQL statements on .

SQL execution flowchart



In the entire SQL execution process, the execution status of steps 2 through 4 is reflected in various metrics of .

- In step 2, SQL parsing, optimization, and execution consume CPU resources. A more complex SQL statement (with a complex structure or ultra-long length) consumes more CPU resources. You can run the **TRACE** command to trace the SQL execution process. You can see the time consumed by an SQL statement during optimization. The longer time consumed indicates a higher CPU utilization.
- In step 3, the delivery and execution of physical SQL statements consume I/O resources. You can analyze the execution status of physical SQL statements based on metrics such as logical queries per second (QPS), physical QPS, logical response time (RT), and physical RT. For example, if the physical QPS is low and the physical RT is high, the current ApsaraDB RDS for MySQL instance is processing SQL statements very slowly. You need to check the performance of the ApsaraDB RDS for MySQL instance.
- In step 5, the SQL execution results are processed and integrated. These operations convert the execution results of physical SQL statements. In most cases, only SQL metadata is converted, which consumes few resources. However, the CPU utilization is high for steps such as `heap sort`. For more information about how to determine the consumption of SQL statements at this stage, see Details about a low SQL statement.

13.1.4.9.4. Prevent performance problems

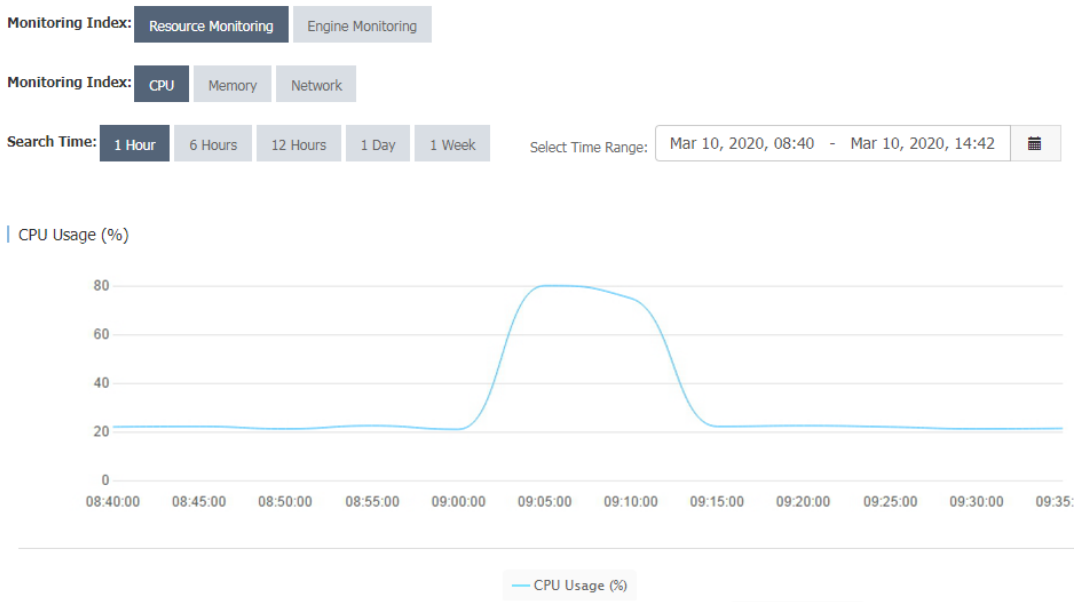
13.1.4.9.4.1. Example 1: PolarDB-X CPU utilization

Performance metrics change with the system business traffic.

The following describes the CPU utilization in two common cases:

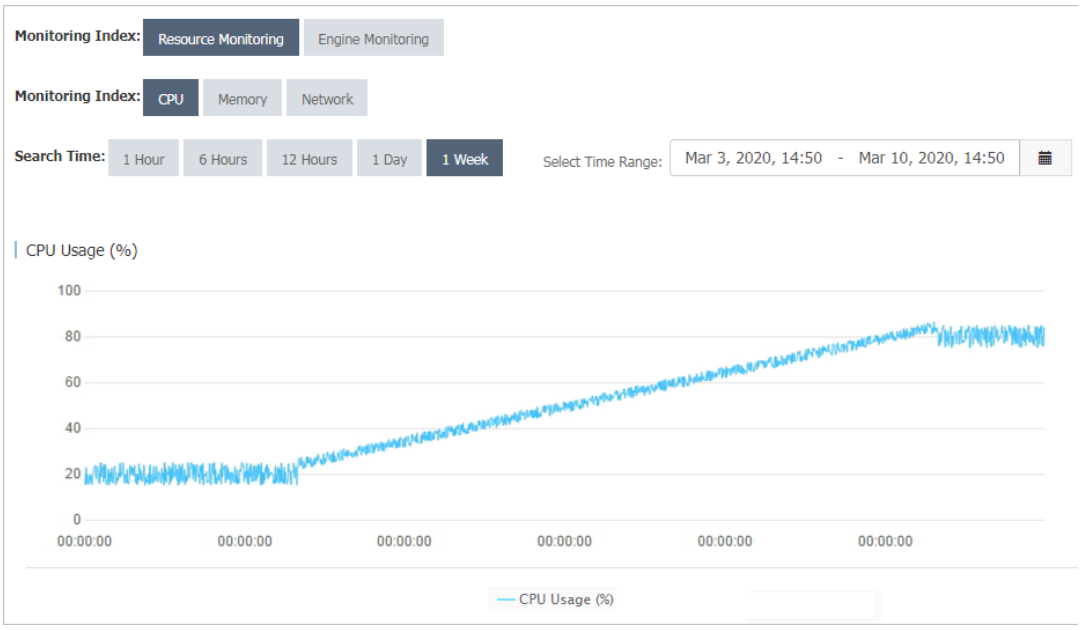
- An application has a shopping spree activity at 09:00 every morning. Therefore, the traffic of the system increases significantly at this time point. According to the monitoring data, the CPU utilization of the instance increased from 20% to about 80% from about 09:00, with the traffic peak lasting about 10 minutes.

  CPU utilization-1



- The system traffic keeps increasing with an application until it reaches a plateau. The monitored CPU utilization of the instance also reflects this change.

  CPU utilization-2



When the load on the instance changes with the business, you must pay close attention to the changes in metrics. If the CPU utilization exceeds the threshold, you must upgrade the specifications to alleviate the performance pressure.

You can set alert rules for instances in the console. When the average CPU utilization exceeds the preset threshold, the system sends short messages to the corresponding contacts. You can set the CPU utilization threshold as needed. We recommend that you set it to 80%.

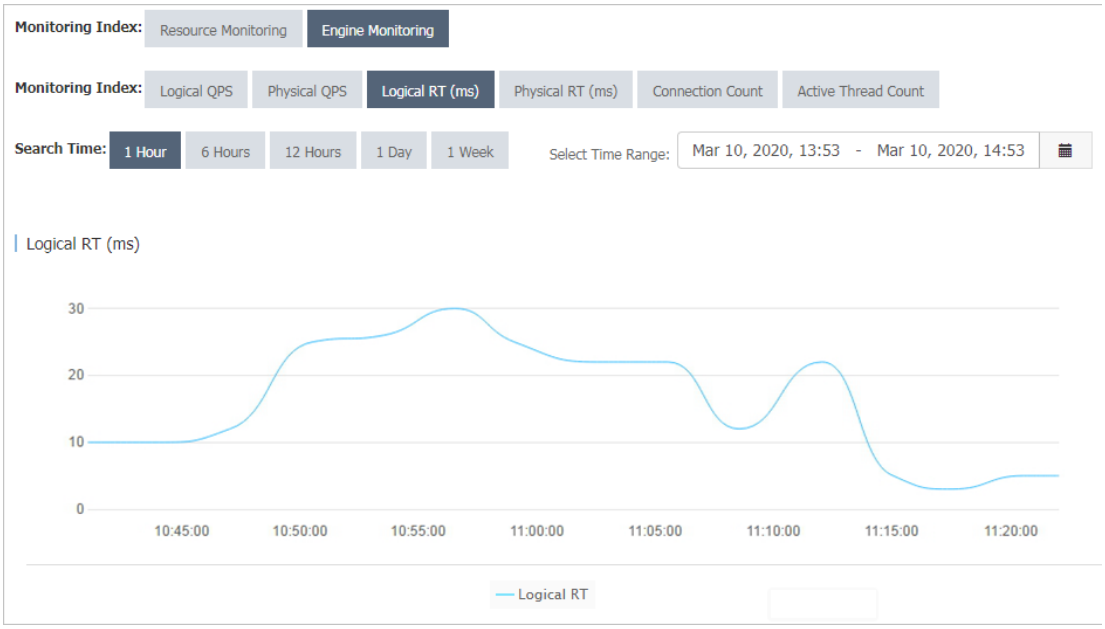
13.1.4.9.4.2. Example 2: Logical RT and physical RT

You can observe the difference between the logical response time (RT) and physical RT.

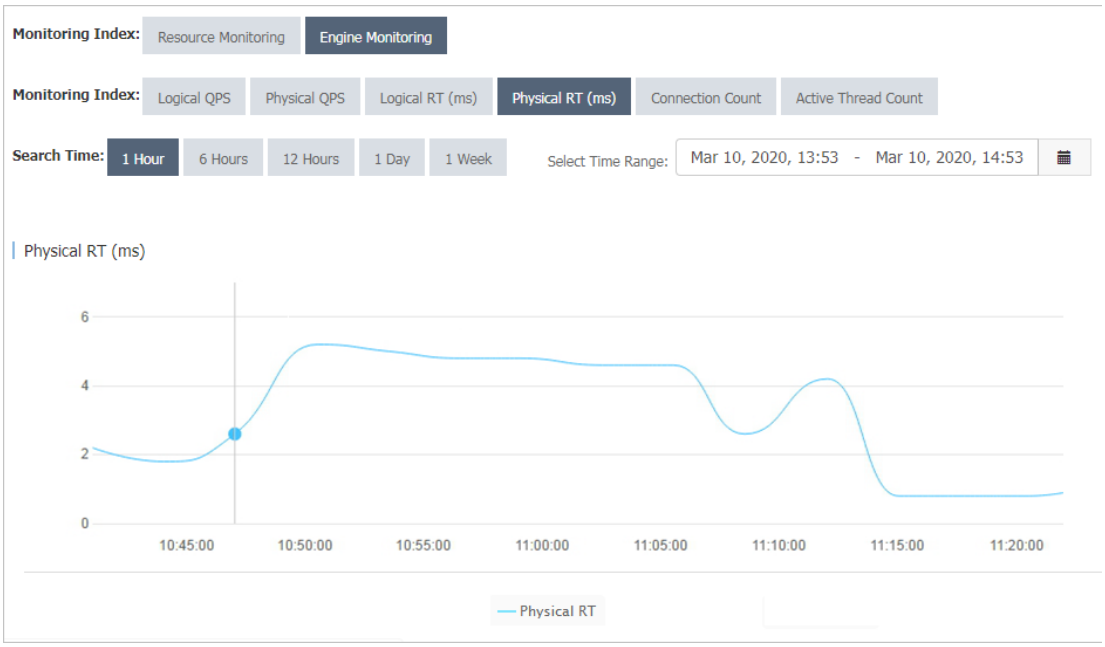
Logical RT refers to the time from when a instance receives a logical SQL statement to when it returns data to an application. Physical RT refers to the time from when a instance sends a physical SQL statement to an ApsaraDB RDS for MySQL instance to when it receives the data returned by the ApsaraDB RDS for MySQL instance.

If a logical SQL statement is partitioned into one or more physical SQL statements, the logical RT is greater than or equal to the physical RT. Ideally, performs only a few operations on the data returned by ApsaraDB RDS for MySQL. Therefore, logical RT is slightly longer than physical RT. Under special circumstances, physical SQL queries are run fast, while logical SQL queries take a long time to run. In this case, the logical RT and physical RT are as follows.

Logical RT



Physical RT



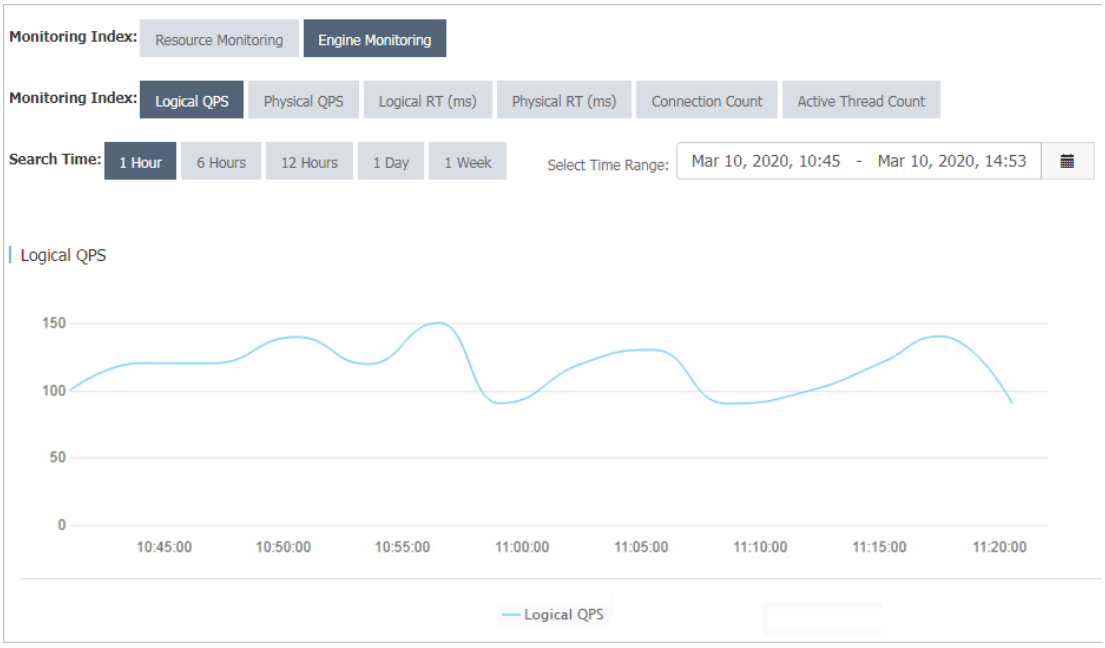
As shown in the preceding figures, the change trends of logical RT and physical RT in the two monitoring charts are basically the same, while logical RT fluctuates between 10 ms and 20 ms and physical RT fluctuates between 2 ms and 5 ms. This means that has a heavy load, which can be solved by upgrading the configuration. If both the logical RT and physical RT are high, you can upgrade the ApsaraDB RDS for MySQL configuration or optimize SQL statements on the ApsaraDB RDS for MySQL instance.

13.1.4.9.4.3. Example 3: Logical QPS and physical QPS

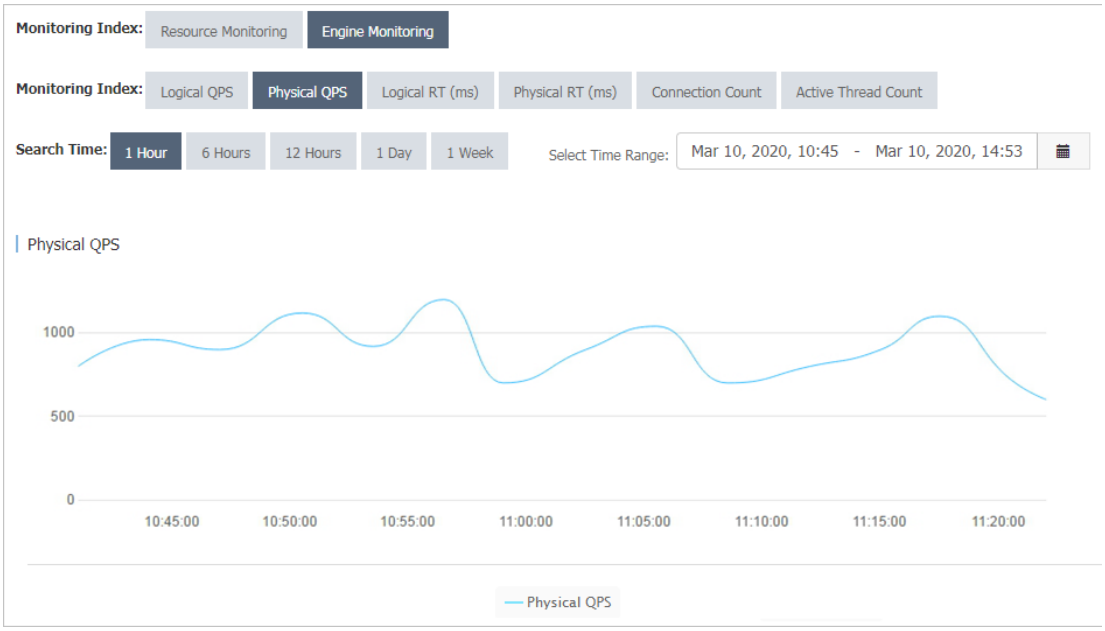
You can observe the difference between the logical queries per second (QPS) and physical QPS.

According to the monitoring data, the logical QPS and physical QPS have the same trends, but the difference between the two is relatively large and in a certain proportion.

Logical QPS



Physical QPS



As shown in the preceding figures, logical QPS fluctuates between 80 and 150, and physical QPS fluctuates between 700 and 1,200.

The reason is that generates physical SQL statements based on logical SQL statements. The ratio of logical SQL statements to physical SQL statements is not necessarily 1:1. For example, a logical table is created by using the following statement:

```
CREATE TABLE drds_user
(id int,
name varchar(30))
dbpartition by hash(id);
```

When the query condition contains the database shard key, pushes the logical SQL statement down to the ApsaraDB RDS for MySQL instance for execution. According to the execution plan, the number of physical SQL statements is 1:

```
mysql> explain select name from drds_user where id = 1;
+----------------------------+-------------------------------------------------------------------------------
-+---------+
| GROUP_NAME                 | SQL
| PARAMS |
+----------------------------+-------------------------------------------------------------------------------
-+---------+
|     SANGUAN_BSQT_0001_RDS | select `drds_user`.`name` from `drds_user` where (`drds_user`.`id` = 1)
| {}     |
+----------------------------+-------------------------------------------------------------------------------
-+---------+
```

When the query does not contain the database shard key, partitions the logical SQL statement into multiple physical SQL statements. The following execution plan shows that there are eight physical SQL statements:

```
mysql> explain select name from drds_user where name = 'LiLei';
+----------- ---------------+-------------------------------------------------------------------------------
---------+---------+
| GROUP_NAME                 | SQL
| PARAMS |
+----------------------------+-------------------------------------------------------------------------------
---------+---------+
| SANGUAN_BSQT_0001_RDS     | select `drds_user`.`name` from `drds_user` where (`drds_user`.`name` =
'LiLei') | {}     |
| SANGUAN_BSQT_0001_RDS     | select `drds_user`.`name` from `drds_user` where (`drds_user`.`name` =
'LiLei') | {}     |
| SANGUAN_BSQT_0001_RDS     | select `drds_user`.`name` from `drds_user` where (`drds_user`.`name` =
'LiLei') | {}     |
| SANGUAN_BSQT_0001_RDS     | select `drds_user`.`name` from `drds_user` where (`drds_user`.`name` =
'LiLei') | {}     |
| SANGUAN_BSQT_0001_RDS     | select `drds_user`.`name` from `drds_user` where (`drds_user`.`name` =
'LiLei') | {}     |
| SANGUAN_BSQT_0001_RDS     | select `drds_user`.`name` from `drds_user` where (`drds_user`.`name` =
'LiLei') | {}     |
| SANGUAN_BSQT_0001_RDS     | select `drds_user`.`name` from `drds_user` where (`drds_user`.`name` =
'LiLei') | {}     |
| SANGUAN_BSQT_0001_RDS     | select `drds_user`.`name` from `drds_user` where (`drds_user`.`name` =
'LiLei') | {}     |
+----------------------------+-------------------------------------------------------------------------------
---------+---------+
8 rows in set (0.06 sec)
```

Logical or physical QPS indicates the total number of logical or physical SQL statements processed per unit of time. When most SQL statements in the system contain the shard key, the ratio of logical QPS to physical QPS is close to 1:1. If the difference between the logical and physical QPS is too large, many SQL statements of the current application do not contain the shard key. In this case, check the SQL statements of the application to improve performance.

13.1.4.9.4.4. Example 4: High memory usage

The overly high memory usage of the instance is mostly caused by the large number of SQL queries in your application and the overlarge result set that is returned. If the memory usage of your instance remains at about 100%, perform the Restart a PolarDB-X instance operations to locate and optimize the slow SQL queries of your application.

13.1.4.10. View the instance version

You can view the instance version in two ways.

View the instance version in the console

1.
2.
3.
4. In the **Configuration Information** section, view the value of **Current Version**.

View the instance version by using the *version()* function

Connect to the instance through the MySQL command line and run the `SELECT version()` statement to view the version of the instance.

```
mysql> select version();
+----------------------------+
| VERSION()                  |
+----------------------------+
| 5.6.29-TDDL-5.1.28-1320920  |
+----------------------------+
1 row in set (0.00 sec)
```

In the preceding statement, 5.1.28-1320920 indicates the version of the instance.

13.1.5. Account management

13.1.5.1. Terms

This topic describes the terms of the account and permission system.

The usage of the account and permission system in is the same as that in MySQL. PolarDB-X supports statements such as `GRANT`, `REVOKE`, `SHOW GRANTS`, `CREATE USER`, `DROP USER`, and `SET PASSWORD`. Currently, PolarDB-X allows you to grant permissions at the database and table levels, but does not allow you to grant permissions at the global or column level.

For more information about the MySQL account and permission system, see MySQL official documentation.

Notice Accounts created by using `CREATE USER` in only exist in the instance and will not be synchronized to the backend ApsaraDB RDS for MySQL instances.

Account

An account is specified by the user name and hostname in the username@'host' format. Accounts with the same user name but different hostnames are different accounts. For example, lily@30.9.73.96 and lily@30.9.73.100 are two different accounts, and their passwords and permissions may be different.

After a database is created in the console, the system automatically creates two system accounts for the database: administrator account and read-only account. These two accounts are built-in accounts. You cannot delete them or modify their permissions.

- The administrator account name is the same as the database name. For example, if the database name is easydb, the administrator account name is easydb.
- The read-only account name is the database name suffixed with _RO. For example, if the database name is easydb, the read-only account name is easydb_RO.

Assume that the dreamdb and andordb databases are available. According to the preceding rules, the dreamdb database contains the dreamdb administrator account and the dreamdb_RO read-only account, while the andordb database contains the andordb administrator account and the andordb_RO read-only account.

Account rules

- Each administrator account has all permissions.
- Only the administrator account can create accounts and grant permissions. Other accounts can only be created and granted permissions by the administrator account.
- The administrator account is bound to a database and does not have permissions on other databases. It can only access the bound database, and cannot grant permissions of other databases to an account. For example, the easydb administrator account can only connect to the easydb database, and can only grant permissions of the easydb database or tables in the easydb database to an account.
- A read-only account has only the SELECT permission.

User name rules

- User names are case-insensitive.
- A user name must be 4 to 20 characters in length.
- A user name must start with a letter.
- A user name can contain letters and digits.

Password rules

- A password must be 6 to 20 characters in length.
- A password can contain letters, digits, and special characters (@ # $ % ^ & + =).

Hostname matching rules

- A hostname must be an IP address. It can contain underscores (_) and wildcards (%). A underscore (_) indicates a character and a wildcard (%) indicates no or more characters. Quote hostnames that contain wildcards with single quotations marks ('), for example, `lily@'30.9. %.%'` and `david@'%'`.
- If there are two user names that can be used to log on to the system, the user name with the longest prefix (the longest IP segment excluding wildcards) prevails. For example, if the `david@'30.9.12_.234'` and `david@'30.9.1%.234'` user names are available in the system, use `david@'30.9.12_.234'` to log on from the 30.9.127.234 host as david.
- When you enable the Virtual Private Cloud (VPC) access feature for a host, the IP address of the host changes. To avoid invalid configurations in the account and permission system, set the hostname to `'%'` to match any IP address.

Permission support

Permission support by level

- Global permission (not supported currently)
- Database-level permission (supported)
- Table-level permission (supported)
- Column-level permission (not supported currently)
- Subprogram-level permission (not supported currently)

Permissions

Currently, eight table-associated basic permissions are supported: `CREATE`, `DROP`, `ALTER`, `INDEX`, `INSERT`, `DELETE`, `UPDATE`, and `SELECT`.

- The `TRUNCATE` statement requires the table-level DROP permission.
- The `REPLACE` statement requires the table-level INSERT and DELETE permissions.
- `CREATE INDEX` and `DROP INDEX` statements are supported.
- The `CREATE SEQUENCE` statement requires the database-level CREATE permission.
- The `DROP SEQUENCE` statement requires the database-level DROP permission.
- The `ALTER SEQUENCE` statement requires the database-level ALTER permission.
- The `INSERT ON DUPLICATE UPDATE` statement requires the table-level INSERT and UPDATE permissions.

Permission rules

- Permissions are bound to an account (`username@'host'`) rather than a user name (`username`).
- An error occurs if the table does not exist during authorization.
- The database permissions in descending order are as follows: global permissions (not supported currently), database-level permissions, table-level permissions, and column-level permissions (not supported currently). A granted higher-level permission overwrites a lower-level permission. If you remove the higher-level permission, the lower-level permission is also removed.
- USAGE authorization is not supported.

13.1.5.2. Create an account

This topic describes how to create a account in the console and by using SQL statements.

Create an account in the console

1.
2.
3.
4.
5. On the **Account Management** page, click **Create Account** in the upper-right corner.
6. Configure the following parameters.

Parameter	Description
Database Account	Enter the account name. The account name must meet the following requirements: ○ The name must be 4 to 20 characters in length. ○ The name must start with a letter and end with a letter or digit. ○ The name can contain letters, digits, and underscores (_).

Parameter	Description
New Password	Enter an account password. The password must meet the following requirements: ○ The password must be 8 to 32 characters in length. ○ The password must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. ○ Special characters include ! @#$%^&*()_+-=
Confirm New Password	Enter the password again.
Authorization Databases	You can grant permissions on one or multiple databases to the account. i. Select one or more databases in the left-side section, and click **Add** to add them to the right-side section. ii. In the right-side section, select **Read/Write**, **Read-only**, **DDL Only**, or **DML Only**. **Note** You can also grant permissions on multiple authorized databases by clicking **Set All to Read-only**, **Set All to DDL Only**, **Set All to DML Only**, or **Set All to Read/Write** in the upper-right corner of the right-side section. The button in the upper-right corner changes as you click it. For example, after you click **Set All to Read-only**, the button is changed to **Set All to DDL Only**.

Create an account in the command line

Syntax rules:

```
CREATE USER user_specification [, user_specification] ...
  user_specification: user [ auth_option ]
  auth_option: IDENTIFIED BY 'auth_string'
```

Examples:

Create an account with the user name lily and password 123456, which can be used to log on only from 30.xx.xx.96.

```
CREATE USER lily@30.xx.xx.96 IDENTIFIED BY '123456';
```

Create an account named david with no password, which can be used to log on from any host.

```
CREATE USER david@'%';
```

13.1.5.3. Reset the password

When using , you can reset the password of your database account in the console or by using the command line.

Note

- Accounts with ROOT permissions cannot be deleted or modified.
- For data security, we recommend that you change your password periodically.

Reset the password in the console

1.
2.
3.
4.
5. Find the target account, and click **Reset Password**.
6. In the **Reset Account Password** dialog box, set **New Password** and **Confirm New Password**.

   > **Note** The password must meet the following requirements:
   > - The password must be 8 to 32 characters in length.
   > - The password must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters.
   > - Special characters include ! @#$%^&*()_+-=

7. After you confirm that the password is correct, click **OK**.

Reset the password in the command line

Syntax rules:

```
SET PASSWORD FOR user = password_option
password_option: {
    PASSWORD('auth_string')
}
```

Examples:

Change the password of the account lily@30.xx.xx.96 to 123456.

```
SET PASSWORD FOR lily@30.xx.xx.96 = PASSWORD('123456')
```

13.1.5.4. Modify account permissions

You can modify the account permissions of your instances at any time when using .

Precautions

- Privileged accounts cannot be modified.
- In the console, you can only grant data manipulation language (DML), data definition language (DDL), read-only, and read/write permissions to standard accounts. To grant more permissions, use the command line.

Modify account permissions in the console

1.
2.
3.
4.
5. Find the target account and click **Modify Permission**.
6. In the **Modify Permissions** dialog box, **grant** or **remove** the permissions on one or more databases to or from the account.

- Authorize a database:

  Select one or more databases in the left-side section, and click **Add** to add them to the right-side section.

- Remove an authorized database:

  Select one or more databases in the right-side section, and click **Remove** to remove them. The removed databases are displayed in the left-side section.

- Modify permissions of an authorized database:

  In the right-side section, select **Read/Write**, **Read-only**, **DDL Only** or **DML Only**.

  > **Note** You can also grant permissions on multiple authorized databases by clicking **Set All to Read-only**, **Set All to DDL Only**, **Set All to DML Only**, or **Set All to Read/Write** in the upper-right corner of the right-side section.
  >
  > The button in the upper-right corner changes as you click it. For example, after you click **Set All to Read-only**, the button is changed to **Set All to DDL Only**.

7. After the configuration is complete, click **OK**.

GRANT statements

Syntax rules:

```
GRANT
    priv_type[, priv_type] ...
    ON priv_level
    TO user_specification [, user_specification] ...
    [WITH GRANT OPTION]
priv_level: {
  | db_name.*
  | db_name.tbl_name
  | tbl_name
}
user_specification:
    user [ auth_option ]
auth_option: {
    IDENTIFIED BY 'auth_string'
}
```

> **Notice**
>
> - If the account in the GRANT statement does not exist and no IDENTIFIED BY information is provided, an error message indicating that the account does not exist is returned.
> - If the account specified in the GRANT statement does not exist but the IDENTIFIED BY information is provided, the account is created and granted with the specified permission.

For example, in the easydb database, create an account named david, which can be used to log on from any host and has all the permissions on easydb.

Method 1: Create an account and then grant permissions to the account.

```
CREATE USER david@'%' IDENTIFIED BY 'your#password';
GRANT ALL PRIVILEGES ON easydb.* to david@'%';
```

Method 2: Create an account and grant permissions to the account by using one statement.

```
GRANT ALL PRIVILEGES ON easydb.* to david@'%' IDENTIFIED BY 'your#password';
```

In the easydb database, create an account named hanson, which can be used to log on from any host and has all the permissions on the easydb.employees table.

```
GRANT ALL PRIVILEGES ON easydb.employees to hanson@'%' IDENTIFIED BY 'your#password';
```

In the easydb database, create an account named hanson, which can be used to log on only from 192.xx. xx.10 and has the INSERT and SELECT permissions on the easydb.emp table.

```
GRANT INSERT,SELECT ON easydb.emp to hanson@'192.xx.xx.10' IDENTIFIED BY 'your#password';
```

In the easydb database, create a read-only account named actro, which can be used to log on from any host.

```
GRANT SELECT ON easydb.* to actro@'%' IDENTIFIED BY 'your#password';
```

REVOKE statements

Syntax rules:

- Delete the permissions at a certain level from an account. The permission level is specified by priv_level.

```
REVOKE
    priv_type
      [, priv_type] ...
    ON priv_level
    FROM user [, user] ...
```

- Delete all permissions of the account at the database and table levels.

```
REVOKE ALL PRIVILEGES, GRANT OPTION
    FROM user [, user] ...
```

Examples:

Delete the CREATE, DROP, and INDEX permissions from hanson@'%' on the easydb.emp table.

```
REVOKE CREATE,DROP,INDEX ON easydb.emp FROM hanson@'%';
```

Delete all permissions from the account lily@30.xx.xx.96.

```
REVOKE ALL PRIVILEGES,GRANT OPTION FROM lily@30.xx.xx.96;
```

Notice GRANT OPTION must be added to the statement for compatibility with MySQL.

SHOW GRANTS statements

Syntax rules:

```
SHOW GRANTS[FOR user@host];
```

Query all permissions:

```
SHOW GRANTS;
```

Query the permissions of an account:

```
SHOW GRANTS FOR user@host;
```

13.1.5.5. Delete an account

You can delete an account in the Cloud Native Distributed Database PolarDB-X (PolarDB-X) console or by using the command line.

Delete an account in the console

> **Note** You can only delete standard accounts that are created in the console.

1.
2.
3.
4.
5. Find the target account and click **Delete**.
6. In the **Delete Account** dialog box, click **OK**.

Delete an account by using the command line

Syntax rules:

```
DROP USER user [, user] ...
```

Examples:

Delete the account lily@30.xx.xx.96:

```
DROP USER lily@30.xx.xx.96;
```

13.1.6. Database management

13.1.6.1. Create a database

After you create a instance, create a database that runs on one or more ApsaraDB RDS for MySQL instances.

Prerequisites

- An ApsaraDB RDS for MySQL instance is created in the same department of the instance.
- The permissions on Resource Access Management (RAM) resources are granted. For more information about how to grant permissions, see *RAM management* in *Apsara Uni-manager user guide*.

1. Log on to the PolarDB-X console.
2. Find the target instance in the instance list.
3. Click the target instance ID or choose **More** > **Manage** from the Actions column of the instance to access the **Basic Information** page.
4. On the **Basic Information** page, click **Create Database** in the upper-right corner.
5. In the **Enter Basic Information** step, configure the following parameters:

Parameter	Description
Partition Mode	Select **Horizontal Partition**.
Database Name	Enter a custom name for the database. The name must meet the following requirements: ○ The name must be 2 to 24 characters in length. ○ The name must start with a letter and end with a letter or a digit. ○ The name can contain lowercase letters, digits, and underscores (_). ○ The name must be unique on the instance.
Character Set	Select utf8, gbk, latin1, or utf8mb4.
DRDS Link Password	Set the password for the database in . The password must meet the following requirements: ○ The password must be 8 to 30 characters in length. ○ The password must contain at least three of the following types: uppercase letters, lowercase letters, digits, and underscores (_).
Confirm Password	Enter the password again.

6. Click **Next**.
7. In the **Select RDS Instance** step, select **Buy New RDS Instance** or **Use Existing RDS Instance**.
   i. **Buy New RDS Instance**: Click the **Buy New RDS Instance** tab.
   ii. Set **Storage Type**, **Series**, **Instance Specifications**, **Storage Capacity**, **Availability Zone**, and **Quantity**.
   iii. Click **Next**.
   i. **Use Existing RDS Instance**: Click the **Use Existing RDS Instance** tab.
   ii. In the left-side section, click the ApsaraDB RDS for MySQL instances that you want to add.
   iii. Click > to add the selected instances to the **Selected RDS Instances** section on the right side.
   iv. Click **Next**.
8. After the precheck is successful in the **Precheck** step, click **Next**.

   > **Note** If the precheck fails, fix the issue based on the instructions on the page.

9. In the **Preview** step, click **Next**. Wait until the database is created.

13.1.6.2. View a database

After the database is created, you can view the basic information of the database in database management in the console.

Procedure

1.
2.
3.
4.
5. Find the target database, and click **Manage**. The **Basic Information** page of the database appears.

> **Note** On the **Basic Information** page, you can delete the database or reset the password.

What's next

is fully compatible with the MySQL protocol. You can use **Command Line URL** on the MySQL client to connect to the instance and enter the user name and password to log on to the database. When using the MySQL client, note the following points:

> **Note**
> - Some MySQL clients of earlier versions have limits on the user name length, which cannot be more than 16 characters. The database name and user name are the same. If the database name exceeds 16 characters, an error is reported.
> - When using the MySQL client, you must add the `-c` parameter to the hint command. In , HINT is implemented by using annotations. If the `-c` parameter is not added, the annotation is lost and the hint is lost.

13.1.6.3. Perform smooth scale-out

When the underlying storage of the logical database reaches the physical bottleneck, for example, when the remaining disk space is about 30%, you can smoothly scale it out to improve the performance. The smooth scale-out process is divided into four steps: configuration > migration > switchover > cleanup.

Configuration

> **Note** In smooth scale-out, ApsaraDB RDS for MySQL instances are added, and some source database shards are migrated to the new ApsaraDB RDS for MySQL instances. In this way, the overall data storage capacity is increased and the number of requests that a single ApsaraDB RDS for MySQL instance needs to process is reduced.

1.
2.
3.
4.
5. Find the target database, and click **Manage**. The **Basic Information** page of the database appears.
6. In the left-side navigation pane, choose **Configuration and Management > Scale-out Management**.
7. In the upper-right corner of the **Scale-out Management** page, click **Scale Out**.
8. Select **Smooth Scale-out**, and then click **Next**.
9. After all prechecks are passed on the **Precheck** page, click **Next**.

   > **Note** If a precheck fails, rectify the configuration as prompted.

10. On the **Select RDS Instance** page, you can click the **Buy New RDS Instance** or **Use Existing RDS Instance** tab.
    i. **Buy New RDS Instance**: Click the **Buy New RDS Instance** tab.
    ii. Set **Storage Type**, **Edition**, and **Storage Capacity**.
    iii. Click **Next**.
    i. **Use Existing RDS Instance**: Click the **Use Existing RDS Instance** tab.
    ii. Click the ApsaraDB RDS for MySQL instances to be added on the left.

iii. Click > to move the selected instances to the **Selected RDS Instances** section on the right.

iv. Click **Next**.

11. On the **Preview** page, click **Start Scale-out**.

> **Note** By default, the console evenly distributes the physical database shards to the ApsaraDB RDS for MySQL instances you added. You can also manually add or delete physical database shards to or from the new ApsaraDB RDS for MySQL instances.

12. Click the icon in the upper-right corner to view the details of the scale-out task.

Migration

Some physical database shards are migrated during smooth scale-out.

The migration does not change the data in the source database, and therefore it does not affect online services. Before the switchover, you can cancel the smooth scale-out operation through a rollback.

> **Note**
> - This is because before the switchover, the current scale-out operation does not have a real impact on the data in the source database.
> - During scale-out, the binary log files of the source ApsaraDB RDS for MySQL instance are not cleaned, which may result in insufficient disk space. Therefore, you must reserve sufficient disk space on the source ApsaraDB RDS for MySQL instance. Generally, the remaining disk space should be more than 30%. If the disk space cannot be guaranteed, you can submit a ticket to expand the ApsaraDB RDS for MySQL storage space.
> - To reduce the pressure of read operations on the source ApsaraDB RDS for MySQL instance, perform scale-out when the load on the source ApsaraDB RDS for MySQL instance is low.
> - During the scale-out, do not submit data description language (DDL) tasks in the console or connect to the instance to directly run DDL statements. Otherwise, the scale-out task may fail.
> - Make sure that all tables in the source database have primary keys before scale-out.

After historical data and incremental data are migrated, the migration progress reaches 100%. Then, you can **switch** the read and write traffic to the new ApsaraDB RDS for MySQL instance or **roll back** to cancel this scale-out.

Switchover

The switchover task switches the read and write traffic to the new ApsaraDB RDS for MySQL instance. The whole process takes 3 to 5 minutes. During the switchover process, the service is not affected except for one or two transient disconnections. Perform the switchover during off-peak hours.

1. In the upper-right corner of the **Basic Information** page, click the icon. The **Task Progress** dialog box appears.
2. In the **Task Progress** dialog box, click **Switch Over** and then **OK**.

   During the switchover process, a switchover task is generated and displayed in the Task Progress dialog box.
3. After the switchover is complete, the **Clean Up** button appears in the **Task Progress** dialog box, which means that the switchover task is complete.

Cleanup

In this step, the migrated database shards are deleted from the source ApsaraDB RDS for MySQL instance.

1. After switchover is complete, click **Clean Up** next to the target task.
2. Click **OK**. A cleanup task appears in the Task Progress dialog box.

> Note
> - The cleanup task is an asynchronous task. You can view the execution status in the Task Progress dialog box.
> - After the cleanup task is complete, the smooth scale-out process ends. The new ApsaraDB RDS for MySQL instance becomes the storage node of the logical database.
> - Currently, you can implement smooth scale-out by migrating physical database shards. If no further scale-out is allowed after the number of database shards exceeds the capacity of a single ApsaraDB RDS for MySQL instance, you can submit a ticket to apply for increasing the number of database shards and scaling out the database. In this case, Hash calculation is performed again to reallocate data.
> - The cleanup task deletes database shards that are no longer used after the current scale-out. You can back up the database shards before running the cleanup task.
> - The cleanup operation brings pressure to databases. We recommend that you perform this operation during off-peak hours.

13.1.6.4. View database monitoring information

displays the historical monitoring information of a database in two dimensions: data metrics and query time.

Procedure

1.
2.
3.
4. In the left-side navigation pane, choose **Monitoring and Alerts > Database Monitoring**.
5. Select **Data Indexes** and **Query Time**. Then, the corresponding monitoring information appears.

> Note For more information about instance-level monitoring, see View monitoring information.

13.1.6.5. Set the IP address whitelist

provides the access control function. Only IP addresses in the whitelist of a database can access the database.

Procedure

1.
2.
3.
4.
5.
6. On the **Basic Information** page of the database, choose **Data Security > Whitelist Settings** from the left-side navigation pane.
7. On the Whitelist Settings page, click **Manually Modify**.
8. Enter the IP address that is allowed to access the database, and click **OK**.

> **Note**
> - The whitelist supports the following formats:
>   - IP address, for example, 192.168.1.1.
>   - CIDR IP address, for example, 192.168.1.1/24.
>   - IP address with an asterisk (*) as the wildcard, for example, 192.168.1. *, indicating that access is allowed from any host with an IP address in the range of 192.168.1.1 to 192.168.1.254.
>   - CIDR block, for example, 192.168.1.1-192.168.1.254.
> - If you want to add multiple IP addresses or CIDR blocks, separate them with commas (,) without spaces, for example, 192.168.0.1,172.16.213.9.

13.1.6.6. Delete a database

This topic describes how to delete a database in the Cloud Native Distributed Database PolarDB-X (PolarDB-X) console.

Procedure

1.
2.
3.
4.
5. Find the target database and click **Delete**.

   > **Warning** You cannot recover databases that have been deleted. Exercise caution when you perform this operation.

6. In the **Delete Database** dialog box, click **OK**.

13.1.6.7. Fix database shard connections

Context

When using a instance, you need to access ApsaraDB RDS for MySQL. If the network configuration of the connected ApsaraDB RDS for MySQL instance changes, for example, if the zone is switched or the network type is changed from classic to Virtual Private Cloud (VPC), the network connection between the instance and the ApsaraDB RDS for MySQL instance is broken. As a result, the instance cannot access the ApsaraDB RDS for MySQL instance. In this case, you must manually fix the database shard link in the console to restore the network connection from the instance to the ApsaraDB RDS for MySQL instance.

Procedure

1.
2.
3.
4.
5.
6. In the **Shortcuts** section, click **Fix Database Shard Connections**.
7. In the pop-up window, click **OK**.

13.1.7. Custom control commands

provides a series of auxiliary SQL commands to help you conveniently use .

13.1.7.1. Overview

provides unique auxiliary statements for you to use and maintain .

Syntax description: The identifier provided by the user is in [] and optional content is in (). In addition, this document applies to the current version. If some statements are unavailable, the version is earlier than required.

13.1.7.2. Help statements

This topic describes all the auxiliary SQL commands of and their descriptions.

SHOW HELP statements:

```
mysql> show help;
+----------------------------------------+-------------------------------------------------------+
-----------------------------------------+
| STATEMENT                              | DESCRIPTION                                           |
EXAMPLE                                  |
+----------------------------------------+-------------------------------------------------------+
-----------------------------------------+
| show rule                              | Report all table rule                                 |
|
| show rule from TABLE                   | Report table rule                                     |
show rule from user                      |
| show full rule from TABLE              | Report table full rule                                |
show full rule from user                 |
| show topology from TABLE               | Report table physical topology                        |
show topology from user                  |
| show partitions from TABLE             | Report table dbPartition or tbPartition columns       |
show partitions from user                |
| show broadcasts                        | Report all broadcast tables                           |
|
| show datasources                       | Report all partition db threadPool info               |
|
| show node                              | Report master/slave read status                       |
|
| show slow                              | Report top 100 slow sql                               |
|
| show physical_slow                     | Report top 100 physical slow sql                      |
|
| clear slow                             | Clear slow data                                       |
|
| trace SQL                              | Start trace sql, use show trace to print profiling data |
trace select count(*) from user; show trace |
| show trace                             | Report sql execute profiling info                     |
|
| explain SQL                            | Report sql plan info                                  |
explain select count(*) from user        |
| explain detail SQL                     | Report sql detail plan info                           |
explain detail select count(*) from user |
| explain execute SQL                    | Report sql on physical db plan info                   |
explain execute select count(*) from user |
| show sequences                         | Report all sequences status                           |
|
| create sequence NAME [start with COUNT] | Create sequence                                       |
create sequence test start with 0        |
| alter sequence NAME [start with COUNT]  | Alter sequence                                        |

13.1.7.3. Statements for viewing rules and node topologies

SHOW RULE [FROM tablename]

Usage notes:

- `show rule`: shows the partitioning status of each logical table in a database.
- `show rule from tablename`: shows the partitioning status of a specified logical table in a database.

The following describes the meanings of important columns:

- BROADCAST: indicates whether the table is a broadcast table. 0 indicates "No" and 1 indicates "Yes".
- DB_PARTITION_KEY: indicates the database shard key. If no database shards exist, the parameter value is NULL.
- DB_PARTITION_POLICY: indicates the database sharding policy. Options are Hash and date policies such as YYYYMM, YYYYDD, and YYYYWEEK.
- DB_PARTITION_COUNT: indicates the number of database shards.
- TB_PARTITION_KEY: indicates the table shard key. If no table shards exist, the parameter value is NULL.
- TB_PARTITION_POLICY: indicates the table sharding policy. Options are Hash and date policies such as MM, DD, MMDD, and WEEK.
- TB_PARTITION_COUNT: indicates the number of table shards.

```
mysql> show rule;
+------+--------------+-----------+------------------+---------------------+--------------------+----
--------------+---------------------+--------------------+
| ID   | TABLE_NAME   | BROADCAST | DB_PARTITION_KEY | DB_PARTITION_POLICY | DB_PARTITION_COUNT | TB_
PARTITION_KEY | TB_PARTITION_POLICY | TB_PARTITION_COUNT |
+------+--------------+-----------+------------------+---------------------+--------------------+----
--------------+---------------------+--------------------+
|    0 | dept_manager |         0 |                  | NULL                | 1                  |
| NULL                | 1                   |
|    1 | emp          |         0 | emp_no           | hash                | 8                  | id
| hash                | 2                   |
|    2 | example      |         0 | shard_key        | hash                | 8                  |
| NULL                | 1                   |
+------+--------------+-----------+------------------+---------------------+--------------------+----
--------------+---------------------+--------------------+
3 rows in set (0.01 sec)
```

SHOW FULL RULE [FROM tablename]

You can run this SQL statement to view the sharding rules of logical tables in a database. It displays more detailed information than the SHOW RULE command.

The following describes the meanings of important columns:

- BROADCAST: indicates whether the table is a broadcast table. 0 indicates "No" and 1 indicates "Yes".
- JOIN_GROUP: a reserved field.
- ALLOW_FULL_TABLE_SCAN: indicates whether to allow data querying when no table shard key is specified for database or table sharding. If this parameter is set to True, each physical table is scanned to find data that meets the condition, which is a full table scan.
- DB_NAME_PATTERN: The value 0 between {} in DB_NAME_PATTERN is a placeholder. When the SQL statement is run, this value is replaced by the value of DB_RULES_STR, with the number of digits unchanged. For example, if the value of DB_NAME_PATTERN is SEQ_{0000}_RDS and the value of DB_RULES_STR is [1,2,3,4], four DB_NAME values are generated: SEQ_0001_RDS, SEQ_0002_RDS, SEQ_0003_RDS, and SEQ_0004_RDS.
- DB_RULES_STR: indicates the database sharding rule.
- TB_NAME_PATTERN: The value 0 between {} in TB_NAME_PATTERN is a placeholder. When the SQL statement is run, this value is replaced by the value of TB_RULES_STR, with the number of digits unchanged. For example, if the value of TB_NAME_PATTERN is table_{00} and the value of TB_RULES_STR is [1,2,3,4,5,6,7,8], eight tables are generated: table_01, table_02, table_03, table_04, table_05, table_06, table_07, and table_08.
- TB_RULES_STR: indicates the table sharding rule.
- PARTITION_KEYS: indicates a set of database and table shard keys. When database sharding and table sharding

coexist, the database shard key is placed before the table shard key.

- DEFAULT_DB_INDEX: indicates the database shard in which a single database and a single table are stored.

```
mysql> show full rule;
+------+--------------+-----------+------------+----------------------+-----------------------------
----------------------+-----------------------------------------------------------+-----------------+-----
------------------------------+----------------+-----------------------------------------------------+
| ID   | TABLE_NAME   | BROADCAST | JOIN_GROUP | ALLOW_FULL_TABLE_SCAN | DB_NAME_PATTERN
| DB_RULES_STR                                        | TB_NAME_PATTERN | TB_RULES_STR
| PARTITION_KEYS | DEFAULT_DB_INDEX                                |
+------+--------------+-----------+------------+----------------------+-----------------------------
----------------------+-----------------------------------------------------------+-----------------+-----
------------------------------+----------------+-----------------------------------------------------+
|    0 | dept_manager |         0 | NULL       |                    0 | SEQ_TEST_1487767780814RGKKSE
Q_TEST_WNJG_0000_RDS   | NULL                                                |                 | dept_manager    | NULL
| NULL           | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0000_RDS |
|    1 | emp          |         0 | NULL       |                    1 | SEQ_TEST_1487767780814RGKKSE
Q_TEST_WNJG_{0000}_RDS | ((#emp_no,1,8#).longValue().abs() % 8)              | emp_{0}         | ((#i
d,1,2#).longValue().abs() % 2) | emp_no      id | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0000_RDS |
|    2 | example      |         0 | NULL       |                    1 | SEQ_TEST_1487767780814RGKKSE
Q_TEST_WNJG_{0000}_RDS | ((#shard_key,1,8#).longValue().abs() % 8).intdiv(1) | example         | NULL
| shard_key      | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0000_RDS |

----------------------+-----------------------------------------------------------+-----------------+-----
------------------------------+----------------+-----------------------------------------------------+
3 rows in set (0.01 sec)
```

SHOW TOPOLOGY FROM tablename

You can run this SQL statement to view the topology of a specified logical table, that is, the database shards to which data in the logical table is partitioned and the table shards in each database shard.

```
mysql> show topology from emp;
+------+-----------------------------------------------------+------------+
| ID   | GROUP_NAME                                          | TABLE_NAME |
+------+-----------------------------------------------------+------------+
|    0 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0000_RDS | emp_0      |
|    1 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0000_RDS | emp_1      |
|    2 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0001_RDS | emp_0      |
|    3 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0001_RDS | emp_1      |
|    4 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0002_RDS | emp_0      |
|    5 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0002_RDS | emp_1      |
|    6 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0003_RDS | emp_0      |
|    7 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0003_RDS | emp_1      |
|    8 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0004_RDS | emp_0      |
|    9 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0004_RDS | emp_1      |
|   10 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0005_RDS | emp_0      |
|   11 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0005_RDS | emp_1      |
|   12 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0006_RDS | emp_0      |
|   13 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0006_RDS | emp_1      |
|   14 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0007_RDS | emp_0      |
|   15 | SEQ_TEST_1487767780814RGKKSEQ_TEST_WNJG_0007_RDS | emp_1      |
+------+-----------------------------------------------------+------------+
16 rows in set (0.01 sec)
```

SHOW PARTITIONS FROM tablename

You can run this SQL statement to view the set of database shard keys and table shard keys, which are separated by commas (,). If the final result contains two values, both database sharding and table sharding are performed. The first value is the database shard key and the second value is the table shard key. If only one value is returned, only database sharding is performed. This value is the database shard key.

```
mysql> show partitions from emp;
+-----------+
| KEYS      |
+-----------+
| emp_no,id |
+-----------+
1 row in set (0.00 sec)
```

SHOW BROADCASTS

You can run this SQL statement to view the list of broadcast tables.

```
mysql> show broadcasts;
+------+------------+
| ID   | TABLE_NAME |
+------+------------+
|    0 | brd2       |
|    1 | brd_tbl    |
+------+------------+
2 rows in set (0.01 sec)
```

SHOW DATASOURCES

You can run this SQL statement to view the information about the underlying storage, including the database name, database group name, connection URL, user name, storage type, read/write weight, and connection pool information.

The following describes the meanings of important columns:

- SCHEMA: indicates the database name.
- GROUP: indicates the database group name. Grouping aims to manage multiple groups of databases that have identical data, such as the primary and secondary databases after data replication through ApsaraDB RDS for MySQL. It is mainly used for read/write splitting and primary/secondary switchovers.
- URL: indicates the connection information of the underlying ApsaraDB RDS for MySQL instance.
- TYPE: indicates the type of the underlying storage. Currently, only ApsaraDB RDS for MySQL instances are supported.
- READ_WEIGHT: indicates the read weight of the database. When the primary ApsaraDB RDS for MySQL instance is under a heavy load of many read requests, you can use the read/write splitting function of to distribute the read traffic. automatically identifies the read and write traffic. It directs the write traffic to the primary ApsaraDB RDS for MySQL instance and the read traffic to all ApsaraDB RDS for MySQL instances based on the configured weight.
- WRITE_WEIGHT: indicates the write weight. For more information, see READ_WEIGHT.

```
mysql> show datasources;
+------+----------------------------+-------------------------------------------------+---------------
--------------------------------+-------------------------------------------------------------------------
----------------+-----------+-------+------+------+------+-------------+----------+--------------+-

SHOW NODE

You can run this SQL statement to view the accumulative number of read and write operations and accumulative read/write weights of a physical database.

The following describes the meanings of important columns:

- MASTER_READ_COUNT: indicates the accumulative number of read-only queries processed by the primary

ApsaraDB RDS for MySQL instance.

- SLAVE_READ_COUNT: indicates the accumulative number of read-only queries processed by the secondary ApsaraDB RDS for MySQL instances.
- MASTER_READ_PERCENT: indicates the actual percentage of read-only queries processed by the primary ApsaraDB RDS for MySQL instance, not the configured percentage.
- SLAVE_READ_PERCENT: indicates the actual percentage of read-only queries processed by the secondary ApsaraDB RDS for MySQL instances, not the configured percentage.

> **Note**
> - Read-only queries in transactions are sent to the primary ApsaraDB RDS for MySQL instance.
> - The `MASTER_READ_PERCENT` and `SLAVE_READ_PERCENT` fields indicate the accumulative historical data. After the read/write weight ratio has been changed, these values do not immediately reflect the latest read/write weight ratio, which appears after a long period of time has passed.

```
mysql> show node;
+------+-----------------------------------------------------+------------------+------------------+---
------------------+--------------------+
| ID   | NAME                                                | MASTER_READ_COUNT | SLAVE_READ_COUNT | MA

13.1.7.4. SQL tuning statements

SHOW [FULL] SLOW [WHERE expr] [limit expr]

SQL statements that take more than 1 second to execute are slow SQL statements. Slow logical SQL statements are the slow SQL statements sent from an application to a instance.

- `SHOW SLOW`: You can run this SQL statement to view the 100 slowest logical SQL queries that are recorded since the instance is started or the last time when `CLEAR SLOW` is executed.

  > **Note** The recorded 100 slowest SQL queries are stored in the system. When the PolarDB-X instance is restarted or executes `CLEAR SLOW`, these queries will be discarded.

- `SHOW FULL SLOW`: You can run this SQL statement to view all the slow logical SQL queries that are recorded and persisted to the built-in database of the instance since the PolarDB-X instance is started. The upper limit for the number of records is specified in the specifications of the PolarDB-X instance. The instance scrolls to delete the earliest slow SQL statements. If the specifications of the PolarDB-X instance is 4-core 4 GB, a maximum of 10,000 slow SQL statements can be recorded, including slow logical and physical SQL statements. If the specifications of the PolarDB-X instance is 8-core 8 GB, a maximum of 20,000 slow SQL statements can be recorded, including slow logical and physical SQL statements. The same rule applies to other specifications.

The following describes the meanings of important columns:

- HOST: the IP address of the host from which the SQL statement is sent.
- START_TIME: the time when the SQL statement starts to be executed.
- EXECUTE_TIME: the time when the SQL statement is executed.
- AFFECT_ROW: For data manipulation language (DML) statements, this parameter indicates the number of affected rows. For query statements, this parameter indicates the number of returned records.

```
mysql> show slow where execute_time > 1000 limit 1;
+-----------+---------------------+--------------+------------+-----------+
| HOST      | START_TIME          | EXECUTE_TIME | AFFECT_ROW | SQL       |
+-----------+---------------------+--------------+------------+-----------+
| 127.0.0.1 | 2016-03-16 13:02:57 |         2785 |          7 | show rule |
+-----------+---------------------+--------------+------------+-----------+
1 row in set (0.02 sec)
```

SHOW [FULL] PHYSICAL_SLOW [WHERE expr] [limit expr]

SQL statements that take more than 1 second to execute are slow SQL statements. Slow logical SQL statements are the slow SQL statements sent from an application to a instance.

- `SHOW SLOW`: You can run this SQL statement to view the 100 slowest logical SQL queries that are recorded since the instance is started or the last time when `CLEAR SLOW` is executed.

  > **Note** The recorded 100 slowest SQL queries are stored in the system. When the PolarDB-X instance is restarted or executes `CLEAR SLOW`, these queries will be discarded.

- `SHOW FULL SLOW`: You can run this SQL statement to view all the slow logical SQL queries that are recorded and persisted to the built-in database of the instance since the PolarDB-X instance is started. The upper limit for the number of records is specified in the specifications of the PolarDB-X instance. The instance scrolls to delete the earliest slow SQL statements. If the specifications of the PolarDB-X instance is 4-core 4 GB, a maximum of 10,000 slow SQL statements can be recorded, including slow logical and physical SQL statements. If the specifications of the PolarDB-X instance is 8-core 8 GB, a maximum of 20,000 slow SQL statements can be recorded, including slow logical and physical SQL statements. The same rule applies to other specifications.

The following describes the meanings of important columns:

- GROUP_NAME: the name of the group to which the database that executes the SQL statement belongs.
- START_TIME: the time when the SQL statement starts to be executed.
- EXECUTE_TIME: the time when the SQL statement is executed.
- AFFECT_ROW: For data manipulation language (DML) statements, this parameter indicates the number of affected rows. For query statements, this parameter indicates the number of returned records.

```
mysql> show physical_slow;
+----------------+-----------------------------------+--------------------+--------------+----------
--------+------------------------+----------------------+------------+-----------------+
| GROUP_NAME     | DBKEY_NAME                        | START_TIME         | EXECUTE_TIME | SQL_EXECU
TE_TIME | GETLOCK_CONNECTION_TIME | CREATE_CONNECTION_TIME | AFFECT_ROW | SQL             |
+----------------+-----------------------------------+--------------------+--------------+----------
--------+------------------------+----------------------+------------+-----------------+
| TDDL5_00_GROUP | db218249098_sqa_zmf_tddl5_00_3309 | 2016-03-16 13:05:38 |         1057 |
1011 |                      0 |                      0 |          1 | select sleep(1) |
+----------------+-----------------------------------+--------------------+--------------+----------
--------+------------------------+----------------------+------------+-----------------+
1 row in set (0.01 sec)
```

CLEAR SLOW

You can run this SQL statement to clear the 100 slowest logical SQL queries and the 100 slowest physical SQL queries that are recorded since the instance is started or the last time when `CLEAR SLOW` is executed.

> **Note** Both `SHOW SLOW` and `SHOW PHYSICAL_SLOW` can be executed to display the 100 slowest SQL statements. If `CLEAR SLOW` has not been executed for a long time, these SQL statements may have been recorded a long time ago. Therefore, after SQL tuning statements are executed, we recommend that you execute `CLEAR SLOW`. After the system runs for a while, check the tuning results of slow SQL statements.

```
mysql> clear slow;
Query OK, 0 rows affected (0.00 sec)
```

EXPLAIN SQL

You can run this SQL statement to view the execution plan of a specified SQL statement in the . Note that this SQL statement is not truly executed.

Example:

You can run this SQL statement to view the execution plan of the SQL `select * from doctest` statement. The doctest table is stored in database shards according to values in the id column. According to the execution plan, the SQL statement will be routed to each database shard for execution, and the execution results will be aggregated.

```
mysql> explain select * from doctest;
+-----------------------------------------------+-------------------------------------+---------+
| GROUP_NAME                                    | SQL                                 | PARAMS |
+-----------------------------------------------+-------------------------------------+---------+
| DOCTEST_1488704345426RCUPDOCTEST_CAET_0000_RDS | select `doctest`.`id` from `doctest` | {}     |
| DOCTEST_1488704345426RCUPDOCTEST_CAET_0001_RDS | select `doctest`.`id` from `doctest` | {}     |
| DOCTEST_1488704345426RCUPDOCTEST_CAET_0002_RDS | select `doctest`.`id` from `doctest` | {}     |
| DOCTEST_1488704345426RCUPDOCTEST_CAET_0003_RDS | select `doctest`.`id` from `doctest` | {}     |
| DOCTEST_1488704345426RCUPDOCTEST_CAET_0004_RDS | select `doctest`.`id` from `doctest` | {}     |
| DOCTEST_1488704345426RCUPDOCTEST_CAET_0005_RDS | select `doctest`.`id` from `doctest` | {}     |
| DOCTEST_1488704345426RCUPDOCTEST_CAET_0006_RDS | select `doctest`.`id` from `doctest` | {}     |
| DOCTEST_1488704345426RCUPDOCTEST_CAET_0007_RDS | select `doctest`.`id` from `doctest` | {}     |
+-----------------------------------------------+-------------------------------------+---------+
8 rows in set (0.00 sec)
```

You can run this SQL statement to view the execution plan of the SQL `select * from doctest where id = 1` statement. The doctest table is stored in database shards according to values in the id column. According to the execution plan, the PolarDB-X instance will calculate a specified database shard based on the shard key, which is id, directly route the SQL statement to the database shard, and aggregate the execution results.

```
mysql> explain select * from doctest where id = 1;
+-------------------------------------------------+-------------------------------------------------
-------------+---------+
| GROUP_NAME                                      | SQL
| PARAMS |
+-------------------------------------------------+-------------------------------------------------
-------------+---------+
| DOCTEST_1488704345426RCUPDOCTEST_CAET_0001_RDS | select `doctest`.`id` from `doctest` where (`docte
st`.`id` = 1) | {}     |
+-------------------------------------------------+-------------------------------------------------
-------------+---------+
1 row in set (0.01 sec)
```

EXPLAIN DETAIL SQL

You can run this SQL statement to view the execution plan of a specified SQL statement in the . Note that this SQL statement is not truly executed.

```
mysql> explain detail select * from doctest where id = 1;
+-------------------------------------------------+-------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------+---------+
| GROUP_NAME                                      | SQL
| PARAMS |
+-------------------------------------------------+-------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------+---------+
| DOCTEST_1488704345426RCUPDOCTEST_CAET_0001_RDS | Query from doctest as doctest
    keyFilter:doctest.id = 1
    queryConcurrency:SEQUENTIAL
    columns:[doctest.id]
    tableName:doctest
    executeOn:DOCTEST_1488704345426RCUPDOCTEST_CAET_0001_RDS
 | NULL   |
+-------------------------------------------------+-------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------+---------+
1 row in set (0.02 sec)
```

EXPLAIN EXECUTE SQL

You can run this SQL statement to view the execution plan of underlying storage. This statement is equivalent to the MySQL EXPLAIN statement.

```
mysql> explain execute select * from tddl_mgr_log limit 1;
+----+-------------+--------------+------+---------------+------+---------+------+------+-------+
| id | select_type | table        | type | possible_keys | key  | key_len | ref  | rows | Extra |
+----+-------------+--------------+------+---------------+------+---------+------+------+-------+
|  1 | SIMPLE      | tddl_mgr_log | ALL  | NULL          | NULL | NULL    | NULL |    1 | NULL  |
+----+-------------+--------------+------+---------------+------+---------+------+------+-------+
1 row in set (0.07 sec)
```

TRACE SQL and SHOW TRACE

You can run these SQL statements to view the execution results of an SQL statement. Note that you must use TRACE SQL and SHOW TRACE together. The difference between TRACE SQL and EXPLAIN SQL is that TRACE SQL is truly executed.

For example, you can run these statements to view the execution results of the select 1 statement.

```
mysql> trace select 1;
+---+
| 1 |
+---+
| 1 |
+---+
1 row in set (0.03 sec)
mysql> show trace;
+------+----------+----------------+----------------------------------+---------------+-------------
-------------+------+-----------+---------+
| ID   | TYPE     | GROUP_NAME     | DBKEY_NAME                       | TIME_COST(MS) | CONNECTION_T
IME_COST(MS) | ROWS | STATEMENT | PARAMS |
+------+----------+----------------+----------------------------------+---------------+-------------
-------------+------+-----------+---------+
|    0 | Optimize | DRDS           | DRDS                             | 3             | 0.00
|    0 | select 1  | NULL   |
|    1 | Query    | TDDL5_00_GROUP | db218249098_sqa_zmf_tddl5_00_3309 | 7             | 0.15
|    1 | select 1  | NULL   |
+------+----------+----------------+----------------------------------+---------------+-------------
-------------+------+-----------+---------+
2 rows in set (0.01 sec)
```

CHECK TABLE tablename

You can run this SQL statement to check a data table. This SQL statement is mainly used when a table failed to be created by using a data definition language (DDL) statement.

- If the data table is a table shard, this SQL statement allows you to check whether any underlying physical table shard is missing and whether the columns and indexes of the underlying physical table are consistent.
- If the data table is a single-database non-partition table, this SQL statement allows you to check whether this table exists.

```
mysql>  check table tddl_mgr_log;
+------------------------+-------+----------+----------+
| TABLE                  | OP    | MSG_TYPE | MSG_TEXT |
+------------------------+-------+----------+----------+
| TDDL5_APP.tddl_mgr_log | check | status   | OK       |
+------------------------+-------+----------+----------+
1 row in set (0.56 sec)
mysql> check table tddl_mg;
+-------------------+-------+----------+----------------------------------------+
| TABLE             | OP    | MSG_TYPE | MSG_TEXT                               |
+-------------------+-------+----------+----------------------------------------+
| TDDL5_APP.tddl_mg | check | Error    | Table 'tddl5_00.tddl_mg' doesn't exist |
+-------------------+-------+----------+----------------------------------------+
1 row in set (0.02 sec)
```

SHOW TABLE STATUS [LIKE 'pattern' | WHERE expr]

You can run this SQL statement to obtain the information about a table. This command aggregates the data of all underlying physical table shards.

The following describes the meanings of important columns:

- NAME: indicates the name of the table.
- ENGINE: indicates the storage engine of the table.
- VERSION: indicates the version of the storage engine of the table.
- ROW_FORMAT: indicates the format of the rows in the table. Valid values include Dynamic, Fixed, and Compressed. The value Dynamic indicates that the row length is variable, for example, is a VARCHAR or BLOB field. The value Fixed indicates that the row length is constant, for example, is a CHAR or INTEGER field.
- ROWS: indicates the number of rows in the table.
- AVG_ROW_LENGTH: indicates the average number of bytes in each row.
- DATA_LENGTH: indicates the data volume of the entire table, in bytes.
- MAX_DATA_LENGTH: indicates the maximum volume of data that can be stored in the table.
- INDEX_LENGTH: indicates the size of the disk space occupied by indexes.
- CREATE_TIME: indicates the time when the table was created.
- UPDATE_TIME: indicates the time when the table was last updated.
- COLLATION: indicates the default character set and character sorting rule of the table.
- CREATE_OPTIONS: indicates all the other options specified when the table was created.

```
mysql> show table status like 'multi_db_multi_tbl';
+--------------------+--------+---------+------------+------+----------------+-------------+---------
--------+--------------+-----------+----------------+----------------------+-------------+----------
--+-----------------+----------+----------------+---------+
| NAME               | ENGINE | VERSION | ROW_FORMAT | ROWS | AVG_ROW_LENGTH | DATA_LENGTH | MAX_DATA
_LENGTH | INDEX_LENGTH | DATA_FREE | AUTO_INCREMENT | CREATE_TIME          | UPDATE_TIME | CHECK_TIM
E | COLLATION       | CHECKSUM | CREATE_OPTIONS | COMMENT |
+--------------------+--------+---------+------------+------+----------------+-------------+---------
--------+--------------+-----------+----------------+----------------------+-------------+----------
--+-----------------+----------+----------------+---------+

13.1.7.5. Statistics query statements

SHOW [FULL] STATS

You can run this SQL statement to view the overall statistics of a Distributed Relational Database Service (DRDS) instance. The statistics are instantaneous values. Note that the results of `DRDS SHOW FULL STATS` vary with the version of the DRDS instance.

The following describes the meanings of important columns:

- QPS: the number of queries per second (QPS) sent from an application to the DRDS instance. These queries are

usually called logical QPS.

- RDS_QPS: the number of QPS sent from the DRDS instance to an ApsaraDB RDS for MySQL instance. These queries are usually called physical QPS.
- ERROR_PER_SECOND: the total number of errors that occur on the DRDS instance per second. These errors include various errors such as SQL syntax errors, primary key conflicts, system errors, and connectivity errors.
- VIOLATION_PER_SECOND: the number of conflicts that occur on primary keys or unique keys per second.
- MERGE_QUERY_PER_SECCOND: the number of queries processed on multiple tables through database sharding and table sharding per second.
- ACTIVE_CONNECTIONS: the number of active connections to the DRDS instance.
- CONNECTION_CREATE_PER_SECCOND: the number of connections that are created for the DRDS instance per second.
- RT(MS): the time to respond to an SQL query sent from an application to the DRDS instance. This response time (RT) is usually called logical RT.
- RDS_RT(MS): the time to respond to an SQL query sent from the DRDS instance to an ApsaraDB RDS for MySQL instance. This RT is usually called physical RT.
- NET_IN(KB/S): the amount of inbound traffic of the DRDS instance per second.
- NET_OUT(KB/S): the amount of outbound traffic of the DRDS instance per second.
- THREAD_RUNNING: the number of threads that are running in the DRDS instance.
- HINT_USED_PER_SECOND: the number of SQL queries that contain hints and are processed by the DRDS instance per second.
- HINT_USED_COUNT: the total number of SQL queries that contain hints and have been processed by the DRDS instance since startup.
- AGGREGATE_QUERY_PER_SECCOND: the number of aggregate SQL queries processed by the DRDS instance per second.
- AGGREGATE_QUERY_COUNT: the total number of aggregate SQL queries that have been processed by the DRDS instance.
- TEMP_TABLE_CREATE_PER_SECCOND: the number of temporary tables created in the DRDS instance per second.
- TEMP_TABLE_CREATE_COUNT: the total number of temporary tables that have been created in the DRDS instance since startup.
- MULTI_DB_JOIN_PER_SECCOND: the number of multi-database JOIN queries processed by the DRDS instance per second.
- MULTI_DB_JOIN_COUNT: the number of multi-database JOIN queries that have been processed by the DRDS instance since startup.

SHOW DB STATUS

You can run this SQL statement to view the capacity and performance information of a physical database, which is also called a database shard. All the returned values indicate the real-time information. The capacity information is obtained from the ApsaraDB RDS for MySQL system table, and therefore may be different from the actual capacity information.

The following describes the meanings of important columns:

- NAME: the internal tag that represents a logical database corresponding to the database shard. The value is different from the name of the logical database.
- CONNECTION_STRING: the information about a connection from the DRDS instance to the database shard.
- PHYSICAL_DB: the name of the database shard. The `TOTAL` row indicates the total amount of capacity of all the database shards corresponding to the logical database.
- SIZE_IN_MB: the size of the space occupied by the data in the database shard. Unit: MB
- RATIO: the ratio of the data volume of the database shard to the total data volume of the current logical database.

- THREAD_RUNNING: the number of threads that are running in the ApsaraDB RDS for MySQL instance to which the physical database belongs. The meaning of this parameter is the same as that of the THREAD_RUNNING parameter returned by the MySQL `SHOW GLOBAL STATUS` command. For more information, see MySQL Documentation.

```
mysql> show db status;

SHOW FULL DB STATUS [LIKE {tablename}]

You can run this SQL statement to view the capacity and performance information of a table shard in a physical database, which is also called a database shard. All the returned values indicate the real-time information. The capacity information is obtained from the ApsaraDB RDS for MySQL system table, and therefore may be different from the actual capacity information.

The following describes the meanings of important columns:

- NAME: the internal tag that represents a logical database corresponding to the database shard. The value is different from the name of the logical database.
- CONNECTION_STRING: the information about a connection from the DRDS instance to the database shard.
- PHYSICAL_DB: the name of the database shard. If the LIKE keyword is used for filtering in the statement, the TOTAL row indicates the total amount of capacity of the database shard. If the LIKE keyword is not used for filtering in the statement, the TOTAL row indicates the total amount of capacity of all database shards.
- PHYSICAL_TABLE: the name of the table shard in the database shard. If the LIKE keyword is used for filtering in the statement, the TOTAL row indicates the total amount of capacity of the table shard. If the LIKE keyword is not used for filtering in the statement, the TOTAL row indicates the total amount of capacity of all table shards in the database shard.
- SIZE_IN_MB: the size of the space occupied by the data in the database shard. Unit: MB
- RATIO: the ratio of the data volume of the table shard to the total data volume of all the table shards obtained through filtering.
- THREAD_RUNNING: the number of threads that are running in the ApsaraDB RDS for MySQL instance to which the physical database belongs. The meaning of this parameter is the same as that of the THREAD_RUNNING

parameter returned by the MySQL `SHOW GLOBAL STATUS` command. For more information, see MySQL Documentation.

13.1.7.6. SHOW PROCESSLIST and KILL commands

> **Note**
>
> - If the version of is 5.1.28-1408022 or later, support the SHOW PROCESSLIST and KILL commands for both logical and physical connections. For more information, see this topic.
> - If the version of is earlier than 5.1.28-1408022, support the SHOW PROCESSLIST and KILL commands only for physical connections. For more information, see SHOW PROCESSLIST and KILL commands in earlier versions.

SHOW PROCESSLIST command

In a instance, you can run the `SHOW PROCESSLIST` command to view information such as connections to the instance and SQL statements that are being executed in the PolarDB-X instance.

Syntax

```
SHOW [FULL] PROCESSLIST
```

Examples

```
mysql> SHOW PROCESSLIST\G
     ID: 1971050
   USER: admin
   HOST: 111.111.111.111:4303
     DB: drds_test
COMMAND: Query
   TIME: 0
  STATE:
   INFO: show processlist
1 row in set (0.01 sec)
```

The following describes the meanings of the fields in the result set:

- ID: the ID of the connection. The value is a long-type number.
- USER: the name of the user who sets up the connection.
- HOST: the IP address and port number of the host that sets up the connection.
- DB: the name of the database accessed by the connection.
- COMMAND: the usage state of the connection. Currently, this field can be set to the following values:
  - Query: the current connection is executing an SQL statement.
  - Sleep: the current connection is idle.
- TIME: the duration when the connection is in the current state:
  - When the value of COMMAND is Query, this field indicates how long the SQL statement has been being executed on the connection.
  - When the value of COMMAND is Sleep, this field indicates how long the connection has been in the idle state.
- STATE: currently, no meaning has been assigned for this field. The value is constantly empty.
- INFO:

- When the value of COMMAND is Query, this field indicates the content of the SQL statement that is being executed on the connection. If the FULL parameter is not specified, a maximum of the first 30 characters of the SQL statement are returned. If the FULL parameter is specified, a maximum of the first 1000 characters of the SQL statement are returned.
- When the value of COMMAND is other values, this field is meaningless and left empty.

SHOW PHYSICAL_PROCESSLIST command

In a instance, you can run the SHOW PHYSICAL_PROCESSLIST command to view information about all the SQL statements that are being executed on underlying ApsaraDB RDS for MySQL instances.

Syntax

```
SHOW [FULL] PHYSICAL_PROCESSLIST
```

When an SQL statement is excessively long, the responses of the `SHOW PHYSICAL_PROCESSLIST` command may be truncated. In this case, you can run the `SHOW FULL PHYSICAL_PROCESSLIST` command to obtain the complete SQL statement.

The meaning of each column in the responses is equivalent to that in the responses of the `SHOW PROCESSLIST` command. For more information, see SHOW PROCESSLIST Syntax.

> **Note** Different from ApsaraDB RDS for MySQL, the instance returns a string instead of a number in the ID column of a physical connection.

```
mysql> SHOW PHYSICAL_PROCESSLIST\G
*************************** 1. row ***************************
           ID: 0-0-521414
         USER: tddl5
           DB: tddl5_00
      COMMAND: Query
         TIME: 0
        STATE: init
         INFO: show processlist
*************************** 2. row ***************************
           ID: 0-0-521570
         USER: tddl5
           DB: tddl5_00
      COMMAND: Query
         TIME: 0
        STATE: User sleep
         INFO: /*DRDS /88.88.88.88/b67a0e4d8800000/ */ select sleep(1000)
2 rows in set (0.01 sec)
```

KILL command

The KILL command is used to terminate an SQL statement that is being executed.

The instance connects to an ApsaraDB RDS for MySQL instance by using the username created by the instance on the ApsaraDB RDS for MySQL instance. Therefore, if you directly connect to the ApsaraDB RDS for MySQL instance, you do not have the permission to run the KILL command on a request initiated by the instance.

To terminate an SQL statement that is being executed on the instance, you must use tools such as the MySQL command line and to connect to the instance, and then run the KILL command on the instance.

Syntax

```
KILL PROCESS_ID | 'PHYSICAL_PROCESS_ID' | 'ALL'
```

The KILL command can be used in the following ways:

- Run `KILL PROCESS_ID` to terminate a specified logical SQL statement.

  The PROCESS_ID parameter is obtained from the ID column in the responses of the `SHOW [FULL] PROCESSLIST` command.

  Running the `KILL PROCESS_ID` command in the instance will terminate both logical and physical SQL statements that are being executed on this connection, and disconnect this connection.

  The instance does not support the `KILL QUERY` command.

- Run `KILL 'PHYSICAL_PROCESS_ID'` to terminate a specified physical SQL statement.

  The PHYSICAL_PROCESS_ID parameter is obtained from the ID column in the responses of the `SHOW PHYSICAL_PROCESS_ID` command.

  > **Note** The PHYSICAL_PROCESS_ID column is a string instead of a number. Therefore, the PHYSICAL_PROCESS_ID parameter must be enclosed in single quotation marks (') in the KILL command.

  Examples:

  ```
  mysql> KILL '0-0-521570';
  Query OK, 0 rows affected (0.01 sec)
  ```

- Run `KILL 'ALL'` to terminate all the physical SQL statements that are executed by the instance in the current logical database.

  When the underlying ApsaraDB RDS for MySQL instance is overloaded due to some SQL statements, you can use the `KILL 'ALL'` command to terminate all the physical SQL statements that are being executed in the current logical database.

  All physical SQL statements indicated by PROCESS that meet the following conditions can be terminated by running `KILL 'ALL'`:

  - The value of the User parameter for the physical SQL statement indicated by PROCESS is a username created by the instance in the ApsaraDB RDS for MySQL instance.
  - The physical SQL statement indicated by PROCESS is executing a query. In other words, the value of COMMAND is Query.

13.1.7.7. SHOW PROCESSLIST and KILL commands in earlier versions

> **Note**
>
> - If the version of is 5.1.28-1408022 or later, support the SHOW PROCESSLIST and KILL commands for both logical and physical connections. For more information, see SHOW PROCESSLIST and KILL commands.
> - If the version of is earlier than 5.1.28-1408022, only supports the SHOW PROCESSLIST and KILL commands for physical connections. For more information, see this topic.

SHOW PROCESSLIST command

In a instance, you can run the `SHOW PROCESSLIST` command to view information about all the SQL statements that are being executed on the ApsaraDB RDS for MySQL instances.

Syntax

```
SHOW [FULL] PROCESSLIST
```

When an SQL statement is excessively long, the responses of the `SHOW PROCESSLIST` command may be truncated. In this case, you can run the `SHOW FULL PROCESSLIST` command to obtain the complete SQL statement.

The meaning of each column in the responses is equivalent to that in the responses of the `SHOW PROCESSLIST` statement. For more information, see SHOW PROCESSLIST Syntax.

```
mysql> SHOW PROCESSLIST\G
*************************** 1. row ***************************
           ID: 0-0-521414
         USER: tddl5
           DB: tddl5_00
      COMMAND: Query
         TIME: 0
        STATE: init
         INFO: show processlist
    ROWS_SENT: NULL
ROWS_EXAMINED: NULL
    ROWS_READ: NULL
*************************** 2. row ***************************
           ID: 0-0-521570
         USER: tddl5
           DB: tddl5_00
      COMMAND: Query
         TIME: 0
        STATE: User sleep
         INFO: /*DRDS /88.88.88.88/b67a0e4d8800000/ */ select sleep(1000)
    ROWS_SENT: NULL
ROWS_EXAMINED: NULL
    ROWS_READ: NULL
2 rows in set (0.01 sec)
```

KILL

You can execute the KILL statement to terminate an SQL statement that is being executed.

The instance connects to an ApsaraDB RDS for MySQL instance by using the username created by the instance on the ApsaraDB RDS for MySQL instance. Therefore, if you directly connect to the ApsaraDB RDS for MySQL instance, you are not authorized to execute the KILL statement to terminate a request initiated by the instance.

To terminate an SQL statement that is being executed on the instance, you must use tools to connect to the instance. You can use tools such as the MySQL command line and . Then, execute the KILL statement on the instance.

Syntax

```
KILL 'PROCESS_ID' | 'ALL'
```

The KILL command can be used in the following ways:

- Run `KILL 'PROCESS_ID'` to terminate a specified SQL statement.

  The PROCESS_ID parameter is obtained from the ID column in the responses of the `SHOW PROCESSLIST` command.

> **Note** Different from ApsaraDB RDS for MySQL, the instance returns a string instead of a number in the ID column. Therefore, the PROCESS_ID parameter must be enclosed in single quotation marks (') in the KILL command.

Examples

```
mysql> KILL '0-0-521570';
Query OK, 0 rows affected (0.01 sec)
```

- Run `KILL 'ALL'` to terminate all the SQL statements executed by the instance in the current logical database.

  When the underlying ApsaraDB RDS for MySQL instance is overloaded due to several SQL statements, you can use the `KILL 'ALL'` command to terminate all the SQL statements that are being executed in the current logical database.

  All SQL statements indicated by PROCESS that meet the following conditions can be terminated by running `KILL 'ALL'`:

  - The value of the User parameter for the physical SQL statement indicated by PROCESS is a username created by the instance in the ApsaraDB RDS for MySQL instance.
  - The physical SQL statement indicated by PROCESS is executing a query, which means that the value of COMMAND is Query.

  instances in earlier versions do not support the `KILL 'ALL'` command. An error will be reported if this command is being executed in these instances. To resolve this problem, you can upgrade the version of the instance.

13.1.8. Custom hints

> **Note** This topic is applicable to 5.3 and later. For earlier versions, see PolarDB-X 5.2 hints.

13.1.8.1. Introduction to hints

As a supplement to the SQL syntax, hints play a critical role in relational databases. They allow you to influence execution plans of SQL statements by using relevant syntax, to specially optimize the SQL statements. also provides special hint syntax.

For example, if you know the target data is stored in table shards in certain database shards and you need to route the SQL statement directly to the database shards for execution, you can use custom hints provided by .

```
SELECT /*+TDDL:node('node_name')*/ * FROM table_name;
```

In the preceding SQL statement, the part between `/*` and `*/`, namely, `+TDDL:node('node_name')`, is a hint. The hint specifies the ApsaraDB RDS for MySQL database shard where the SQL statement is to be executed.

> **Note**
> - hints can be in the formats of `/*+TDDL:hint_command*/` and `/! +TDDL:hint_command*/`.
> - In the MySQL command-line client, if you need to run an SQL statement that contains a hint in the format of `/*+TDDL:hint_command*/`, add the `-c` parameter to the logon command, because hints are based on the MySQL Comment Syntax. Otherwise, the client deletes the hint and then sends the SQL statement to the server for execution, which causes the hint to fail to take effect. For more information, see MySQL Client Options.

PolarDB-X hint syntax

Basic syntax

```
/*+TDDL: hint_command [hint_command ...] */
/! +TDDL: hint_command [hint_command ...] */
```

hints are based on the MySQL Comment Syntax. The hint statements are located between `/*` and `*/` or between `/!` and `*/`, and must begin with `+TDDL:`. The `hint_command` parameter indicates a hint command related to the specific operation. Multiple `hint_command` parameters are separated by spaces.

Examples

```
# Query the names of physical tables in each database shard.
/*+TDDL:scan()*/SHOW TABLES;
# Route the query to database shard 0000 of a read-only ApsaraDB RDS for MySQL instance.
/*+TDDL:node(0) slave()*/SELECT * FROM t1;
```

In the example, `/*+TDDL:scan()*/` and `/*+TDDL:node(0) slave()*/` are hints that begin with `+TDDL:`. The `scan()`, `node(0)`, and `slave()` functions are hint commands. Hint commands are separated by spaces.

- Use one hint in an SQL statement:

  allows you to use hints in data manipulation language (DML), data definition language (DDL), and data access language (DAL) statements. The following describes the syntax in detail.

  - For all statements that support hints, you can specify a hint at the beginning of the statements, for example:

    ```
    /*+TDDL: ... */ SELECT ...
    /*+TDDL: ... */ INSERT ...
    /*+TDDL: ... */ REPLACE ...
    /*+TDDL: ... */ UPDATE ...
    /*+TDDL: ... */ DELETE ...
    /*+TDDL: ... */ CREATE TABLE ...
    /*+TDDL: ... */ ALTER TABLE ...
    /*+TDDL: ... */ DROP TABLE ...
    /*+TDDL: ... */ SHOW ...
    ...
    ```

  - For DML statements, you can specify a hint behind the first keyword of the statements, for example:

    ```
    SELECT /*+TDDL: ... */  ...
    INSERT /*+TDDL: ... */  ...
    REPLACE /*+TDDL: ... */  ...
    UPDATE /*+TDDL: ... */  ...
    DELETE /*+TDDL: ... */  ...
    ...
    ```

    Note Different hints may be applicable to different syntaxes. For more information about the applicable syntaxes, see the documentation of hint commands.

- Use multiple hint commands in an SQL statement:

  allows you to use multiple hint commands in SQL statements that contain hints.

  ```
  SELECT /*+TDDL:node(0) slave()*/ ... ;
  ```

  has the following limitations on the use of multiple hint commands:

```
# A single SQL statement cannot contain multiple hint statements.
SELECT /*+TDDL:node(0)*/ /*+TDDL:slave()*/ ... ;
# An SQL statement that contains a hint cannot contain duplicate hint commands.
SELECT /*+TDDL:node(0) node(1)*/ ... ;
```

PolarDB-X hint classification

hints are classified into the following major categories according to operation types:

- Read/write splitting
- Specify a timeout period for an SQL statement
- Specify a database shard to run an SQL statement
- Scan all or some of database shards and table shards

13.1.8.2. Read/write splitting

provides transparent read/write splitting at the application layer. Data synchronization between primary and read-only ApsaraDB RDS for MySQL instances has a delay of several milliseconds. If you need to read changed data immediately after the primary ApsaraDB RDS for MySQL instance is changed, you must ensure that the SQL statement for reading data is routed to the primary ApsaraDB RDS for MySQL instance. To meet this demand, provides custom hints for read/write splitting, to route SQL statements to a specified primary or read-only ApsaraDB RDS for MySQL instance.

> **Note** This topic is applicable to 5.3 and later. For earlier versions, see Read/write splitting.

Syntax

```
/*+TDDL:
    master()
    | slave()
*/
```

With this custom hint, you can specify whether to run an SQL statement on a primary or read-only ApsaraDB RDS for MySQL instance. With the custom hint `/*+TDDL:slave()*/`, if a primary ApsaraDB RDS for MySQL instance is configured with multiple read-only ApsaraDB RDS for MySQL instances, the instance randomly selects a read-only ApsaraDB RDS for MySQL instance based on its weight, to run the SQL statement.

> **Note**
> - hints can be in the formats of `/*+TDDL:hint_command*/` and `/! +TDDL:hint_command*/`.
> - In the MySQL command-line client, you may need to execute an SQL statement that contains a hint in the format of `/*+TDDL:hint_command*/`. In this case, add the `-c` parameter to the logon command. Otherwise, the client deletes the hint before it sends the SQL statement to the server for execution because the hint is in the format of a MySQL comment. In this case, the hint fails to take effect. For more information, see MySQL Client Options.

Examples

- Specify a primary ApsaraDB RDS for MySQL instance to run an SQL statement:

```
SELECT /*+TDDL:master()*/ * FROM table_name;
```

After the custom hint `/*+TDDL:master()*/` is added behind the first keyword in the SQL statement, this SQL statement is routed to the primary ApsaraDB RDS for MySQL instance for execution.

- Specify a read-only ApsaraDB RDS for MySQL instance to run an SQL statement:

```
SELECT /*+TDDL:slave()*/ * FROM table_name;
```

After the custom hint `/*+TDDL:slave()*/` is added behind the first keyword in the SQL statement, this SQL statement is randomly routed to a read-only ApsaraDB RDS for MySQL instance based on the allocated weight.

Note

- The custom hints for read-write splitting are only applicable to read SQL statements for non-transactional data. SQL statements for transactional data and write SQL statements are still routed to the primary ApsaraDB RDS for MySQL instance for execution.
- The hint `/*+TDDL:slave()*/` allows you to route the SQL statement randomly to a read-only ApsaraDB RDS for MySQL instance based on the configured weight for execution. If no read-only ApsaraDB RDS for MySQL instance is available, no error is reported. Instead, the primary ApsaraDB RDS for MySQL instance is selected to run the SQL statement.

13.1.8.3. Specify a timeout period for an SQL statement

In , the SQL statements for instances and ApsaraDB RDS for MySQL instances are timed out after 900 seconds (which can be adjusted) by default. However, for some slow SQL statements, the execution duration may exceed 900 seconds. For these slow SQL statements, provides a custom hint to adjust their timeout periods. You can use this custom hint to adjust the SQL execution duration as needed.

> **Note** This topic is applicable to 5.3 and later. For earlier versions, see Specify a timeout period for an SQL statement.

Syntax

The syntax of the hint for specifying a timeout period for an SQL statement is as follows:

```
/*+TDDL:SOCKET_TIMEOUT(time)*/
```

The `SOCKET_TIMEOUT` parameter is measured in milliseconds. With this custom hint, you can adjust the timeout period for the SQL statement based on business requirements.

> **Note**
> - hints can be in the formats of `/*+TDDL:hint_command*/` and `/! +TDDL:hint_command*/`.
> - In the MySQL command-line client, you may need to execute an SQL statement that contains a hint in the format of `/*+TDDL:hint_command*/`. In this case, add the `-c` parameter to the logon command. Otherwise, the client deletes the hint before it sends the SQL statement to the server for execution because the hint is in the format of a MySQL comment. In this case, the hint fails to take effect. For more information, see MySQL Client Options.

Examples

Set the timeout period of an SQL statement to 40 seconds:

```
/*+TDDL:SOCKET_TIMEOUT(40000)*/SELECT * FROM t_item;
```

> **Note** A longer timeout period causes database resources to be occupied for a longer period of time. If excessive SQL statements are executed over a long time within the same period, a large number of database resources may be consumed. This will make users unable to use PolarDB-X properly. In this case, we need to use this custom hint to optimize the SQL statements that take a long time to execute.

13.1.8.4. Specify a database shard to run an SQL statement

When running SQL commands in a instance, you may find that some SQL statements are not supported by the instance. In this case, you can use the `NODE HINT` provided by , to route the SQL statements to one or more database shards for execution. In addition, if you need to query the data in a specified database shard or the data in a specified table shard in a known database shard, you can use the `NODE HINT` to directly route the SQL statement to the database shard for execution.

> **Note** This topic is applicable to 5.3 and later. For earlier versions, see Specify a database shard to run an SQL statement.

Syntax

The `NODE HINT` allows you to specify a database shard by using a shard name, to run the SQL statement in the database shard. A shard name uniquely identifies a database shard in a instance. You can run the SHOW NODE statement to obtain the shard name.

Specify a database shard by using a shard name, to run an SQL statement

This custom hint allows you to specify one or more database shards to run an SQL statement.

> **Note** If the hint for specifying a database shard is used in an INSERT statement that contains a sequence for the target table, the sequence will not take effect. For more information, see Limits and precautions for sequences.

- Specify one database shard to run an SQL statement:

  ```
  /*+TDDL:node('node_name')*/
  ```

  Specifically, `node_name` indicates the shard name. This hint enables you to route the SQL statement to the database shard specified by `node_name`.

- Specify multiple database shards to run an SQL statement:

  ```
  /*+TDDL:node('node_name'[,'node_name1','node_name2'])*/
  ```

  You can specify multiple shard names in the parameters and route the SQL statement to multiple database shards for execution. Separate multiple shard names with commas (,).

Note

- When this custom hint is used, the instance directly routes the SQL statement to the specified database shards for execution. Therefore, the specified shard names in the SQL statement must correspond to existing database shards.
- The `NODE HINT` can be used in data manipulation language (DML), data definition language (DDL), and data access language (DAL) statements.
- hints can be in the formats of `/*+TDDL:hint_command*/` and `/! +TDDL:hint_command*/`.
- In the MySQL command-line client, you may need to execute an SQL statement that contains a hint in the format of `/*+TDDL:hint_command*/`. In this case, add the `-c` parameter to the logon command. Otherwise, the client deletes the hint before it sends the SQL statement to the server for execution because the hint is in the format of a MySQL comment. In this case, the hint fails to take effect. For more information, see MySQL Client Options.

Examples

The following shows the responses of the SHOW NODE statement for a logical database named `drds_test` in a instance.

```
mysql> SHOW NODE\G
*************************** 1. row ******************
                ID: 0
              NAME: DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0000_RDS
  MASTER_READ_COUNT: 212
   SLAVE_READ_COUNT: 0
MASTER_READ_PERCENT: 100%
 SLAVE_READ_PERCENT: 0%
*************************** 2. row ******************
                ID: 1
              NAME: DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0001_RDS
  MASTER_READ_COUNT: 29
   SLAVE_READ_COUNT: 0

8 rows in set (0.02 sec)
```

As you can see, each database shard has the `NAME` attribute, which indicates the shard name corresponding to the database shard. Each shard name uniquely corresponds to one database shard name. For example, the shard name `DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0003_RDS` corresponds to the database shard name `drds_test_vtla_0003`. Therefore, after obtaining the shard name, you can use the hint to specify the corresponding database shard to run the SQL statement.

- Specify database shard 0 to run an SQL statement:

```
SELECT /*TDDL:node('DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0000_RDS')*/ * FROM table_name;
```

- Specify multiple database shards to run an SQL statement:

```
SELECT /*TDDL:node('DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0000_RDS','DRDS_TEST_1473471355140LR
PRDRDS_TEST_VTLA_0006_RDS')*/ * FROM table_name;
```

  This SQL statement will be executed in the database shards whose shard names are `DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0000_RDS` and `DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0006_RDS`.

- View the execution plan of an SQL statement in database shard 0:

```
/*TDDL:node('DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0000_RDS')*/ EXPLAIN SELECT * FROM table_na
me;
```

13.1.8.5. Scan all or some of database shards and table shards

In addition to routing an SQL statement to one or more database shards for execution, provides the `SCAN HINT` to scan all or some of database shards and table shards. With the `SCAN HINT`, you can route an SQL statement to each database shard at a time. For example, you can view all the table shards in a specified database shard or view the data volume of each physical table of a specified logical table.

> **Note** This topic is applicable to 5.3 and later. For earlier versions, see Scan all database shards and table shards.

With the SCAN HINT, you can specify the following SQL execution manners:

- Run an SQL statement in all table shards in all database shards.
- Run an SQL statement in all table shards in a specified database shard.
- Run an SQL statement in the specified table shard in the specified database shard by calculating the name of the physical table based on conditions.
- Run an SQL statement in the specified table shard in the specified database shard by explicitly specifying the name of the physical table.

The `SCAN HINT` can be used in data manipulation language (DML) statements, data definition language (DDL) statements, and some data access language (DAL) statements.

> **Note**
>
> - hints can be in the formats of `/*+TDDL:hint_command*/` and `/! +TDDL:hint_command*/`.
> - In the MySQL command-line client, you may need to execute an SQL statement that contains a hint in the format of `/*+TDDL:hint_command*/`. In this case, add the `-c` parameter to the logon command. Otherwise, the client deletes the hint before it sends the SQL statement to the server for execution because the hint is in the format of a MySQL comment. In this case, the hint fails to take effect. For more information, see MySQL Client Options.

Syntax

```
# SCAN HINT
# Route an SQL statement to all table shards in all database shards.
SCAN()
# Route an SQL statement to all table shards in a specified database shard.
SCAN(NODE="node_list")               # Specify the database shard.
# Route an SQL statement to the specified table shard in the specified database shard by calculating
the name of the physical table based on conditions.
SCAN(
  [TABLE=]"table_name_list"          # Specify the name of the logical table.
  , CONDITION="condition_string"     # Calculate the names of physical databases based on the content
of TABLE and CONDITION.
  [, NODE="node_list"] )             # Filter the results obtained based on the content of CONDITION,
to retain only the results of the specified physical database.
# Route an SQL statement to the specified table shard in the specified database shard by explicitly s
pecifying the name of the physical table.
SCAN(
  [TABLE=]"table_name_list"          # Specify the name of the logical table.
  , REAL_TABLE=("table_name_list")   # Specify the name of the physical table. The same physical tabl
e names are applied to all physical databases.
  [, NODE="node_list"] )             # Filter the results obtained based on the content of CONDITION,
to retain only the results of the specified physical database.
# Specify physical table names or logical table names.
table_name_list:
    table_name [, table_name]...
# Specify physical databases by using GROUP_KEY and GROUP_INDEX, which can be obtained by running the
SHOW NODE statement.
node_list:
    {group_key | group_index} [, {group_key | group_index}]...
# Run an SQL WHERE statement. When using this syntax, you must specify conditions for each table, for
example, t1.id = 2 and t2.id = 2.
condition_string:
    where_condition
```

Examples

- Run the following SQL statement in all table shards in all database shards:

  ```
  SELECT /*+TDDL:scan()*/ COUNT(1) FROM t1
  ```

  After this statement is executed, the SQL statement is routed to all the physical tables corresponding to the logical table `t1`, and the result sets are merged and returned.

- Run the following SQL statement in all table shards in specified database shards:

  ```
  SELECT /*+TDDL:scan(node='0,1,2')*/ COUNT(1) FROM t1
  ```

  After this statement is executed, all physical tables corresponding to the logical table `t1` in database shards 0000, 0001, and 0002 are calculated, the SQL statement is routed to the physical tables, and the result sets are merged and returned.

- Run the following SQL statement in specified table shards based on conditions:

  ```
  SELECT /*+TDDL:scan('t1', condition='t1.id = 2')*/ COUNT(1) FROM t1
  ```

  After this statement is executed, all physical tables that correspond to the logical table `t1` and meet the conditions are calculated, the SQL statement is routed to the physical tables, and the result sets are merged and returned.

- Run the following SQL JOIN statement in the specified table shards based on conditions:

```
SELECT /*+TDDL:scan('t1, t2', condition='t1.id = 2 and t2.id = 2')*/ * FROM t1 a JOIN t2 b ON a.id
= b.id WHERE b.name = "test"
```

After this statement is executed, all physical tables that correspond to the logical tables `t1` and `t2` and meet the conditions are calculated, the SQL statement is routed to the physical tables, and the result sets are merged and returned.

> **Notice** Before using this custom hint, you must ensure that the logical tables t1 and t2 are partitioned into the same number of database shards and the same number of table shards. Otherwise, the database shards calculated by the instance based on the conditions are different, and an error will be returned.

- Run the following SQL statement in the specified table shards in database shards by explicitly specifying the names of the physical tables:

```
SELECT /*+TDDL:scan('t1', real_table=("t1_00", "t1_01"))*/ COUNT(1) FROM t1
```

After this statement is executed, the SQL statement is routed to the table shards `t1_00``t1_01` in all database shards, and the result sets are merged and returned.

- Run the following SQL JOIN statement in the specified table shards in database shards by explicitly specifying the names of the physical tables:

```
SELECT /*+TDDL:scan('t1, t2', real_table=("t1_00,t2_00", "t1_01,t2_01"))*/ * FROM t1 a JOIN t2 b O
N a.id = b.id WHERE b.name = "test";
```

After this statement is executed, the SQL statement is routed to the table shards `t1_00`, `t2_00`, `t1_01`, and `t2_01` in all database shards, and the result sets are merged and returned.

13.1.8.6. INDEX HINT

- supports global secondary indexes. The INDEX hint allows you to obtain query results from a specified GSI.
- The INDEX hint takes effect only for SQL SELECT statements.

> **Note** This custom hint is applicable to only MySQL 5.7 and later and 5.4.1 and later.

Syntax

```
# FORCE INDEX
tbl_name [[AS] alias] [index_hint]
index_hint:
    FORCE INDEX({index_name})
# INDEX()
/*+TDDL:
    INDEX({table_name | table_alias}, {index_name})
*/
```

INDEX hint can be used in two ways:

- `FORCE INDEX()`: This syntax is the same as that of MySQL FORCE INDEX.
- `INDEX()`: In this syntax, a global secondary index is specified using a table name (or alias) and an index name. This hint does not take effect in the following cases:
  - The query does not contain the specified table name or alias.
  - The specified global secondary index is not in the specified table.

> **Note**
> - hints can be in the formats of `/*+TDDL:hint_command*/` and `/! +TDDL:hint_command*/`.
> - In the MySQL command-line client, you may need to execute an SQL statement that contains a hint in the format of `/*+TDDL:hint_command*/`. In this case, add the `-c` parameter to the logon command. Otherwise, the client deletes the hint before it sends the SQL statement to the server for execution because the hint is in the format of a MySQL comment. In this case, the hint fails to take effect. For more information, see MySQL Client Options.

Examples

```
CREATE TABLE t_order (
 `id` bigint(11) NOT NULL AUTO_INCREMENT,
 `order_id` varchar(20) DEFAULT NULL,
 `buyer_id` varchar(20) DEFAULT NULL,
 `seller_id` varchar(20) DEFAULT NULL,
 `order_snapshot` longtext DEFAULT NULL,
 `order_detail` longtext DEFAULT NULL,
 PRIMARY KEY (`id`),
 GLOBAL INDEX `g_i_seller`(`seller_id`) dbpartition by hash(`seller_id`),
 UNIQUE GLOBAL INDEX `g_i_buyer` (`buyer_id`) COVERING(`seller_id`, `order_snapshot`)
  dbpartition by hash(`buyer_id`) tbpartition by hash(`buyer_id`) tbpartitions 3
) ENGINE=InnoDB DEFAULT CHARSET=utf8 dbpartition by hash(`order_id`);
```

Specify the global secondary index `g_i_seller` by using FORCE INDEX in the FROM clause:

```
 SELECT a.*, b.order_id
   FROM t_seller a
     JOIN t_order b FORCE INDEX(g_i_seller) ON a.seller_id = b.seller_id
   WHERE a.seller_nick="abc";
```

Specify the global secondary index `g_i_buyer` by using INDEX+table alias:

```
/*+TDDL:index(a, g_i_buyer)*/ SELECT * FROM t_order a WHERE a.buyer_id = 123
```

13.1.9. PolarDB-X 5.2 hints

13.1.9.1. Introduction to hints

As a supplement to the SQL syntax, hints play a critical role in relational databases. They allow you to affect execution plans of SQL statements by using relevant syntax, to specially optimize the SQL statements.

Overview of PolarDB-X hints

provides special hint syntax.

For example, if you know the target data is stored in table shards in certain database shards and you need to route the SQL statement directly to the database shards for execution, you can use custom hints provided by .

```
/! TDDL:NODE IN('node_name', ...) */SELECT * FROM table_name;
```

In the preceding SQL statement, the part between `/!` and `*/`, namely, `TDDL:node in('node_name', ...)`, is a hint. The hint specifies the ApsaraDB RDS for MySQL database shard where the SQL statement is to be executed.

> **Note**
> - hints can be in the formats of `/*+TDDL:hint_command*/` and `/! +TDDL:hint_command*/`.
> - In the MySQL command-line client, you may need to execute an SQL statement that contains a hint in the format of `/*+TDDL:hint_command*/`. In this case, add the `-c` parameter to the logon command. Otherwise, the client deletes the hint before it sends the SQL statement to the server for execution because the hint is in the format of a MySQL comment. In this case, the hint fails to take effect. For more information, see MySQL Client Options.

PolarDB-X hint syntax

Basic syntax:

```
/! TDDL:hint command*/
```

hints are based on MySQL Comment Syntax. Therefore, an SQL statement that contains a hint is located between `/!` and `*/`, and must begin with `TDDL:`. The `hint command` indicates a hint command related to the specific operation. For example, a hint is added to the following SQL statement to display the name of each database shard.

```
/! TDDL:SCAN*/SHOW TABLES;
```

In this SQL statement, `/! TDDL:SCAN*/` is the hint that begins with `TDDL:`, and `SCAN` is a hint command.

13.1.9.2. Read/write splitting

provides transparent read/write splitting at the application layer. Data synchronization between primary and read-only ApsaraDB RDS for MySQL instances has a delay of several milliseconds. If you need to read changed data immediately after the primary ApsaraDB RDS for MySQL instance is changed, you must ensure that the SQL statement for reading data is routed to the primary ApsaraDB RDS for MySQL instance. To meet this demand, provides custom hints for read/write splitting, to route SQL statements to a specified primary or read-only ApsaraDB RDS for MySQL instance.

Syntax

```
/! TDDL:MASTER|SLAVE*/
```

With this custom hint, you can specify whether to run an SQL statement on a primary or read-only ApsaraDB RDS for MySQL instance. With the custom hint `/!TDDL:SLAVE*/`, if a primary ApsaraDB RDS for MySQL instance is configured with multiple read-only ApsaraDB RDS for MySQL instances, the instance randomly selects a read-only ApsaraDB RDS for MySQL instance based on its weight, to run the SQL statement.

> **Note**
> - hints can be in the formats of `/*+TDDL:hint_command*/` and `/! +TDDL:hint_command*/`.
> - In the MySQL command-line client, you may need to execute an SQL statement that contains a hint in the format of `/*+TDDL:hint_command*/`. In this case, add the `-c` parameter to the logon command. Otherwise, the client deletes the hint before it sends the SQL statement to the server for execution because the hint is in the format of a MySQL comment. In this case, the hint fails to take effect. For more information, see MySQL Client Options.

Examples

- Specify a primary ApsaraDB RDS for MySQL instance to run an SQL statement:

```
/! TDDL:MASTER*/SELECT * FROM table_name;
```

After the custom hint `/! TDDL:MASTER*/` is added at the beginning of the SQL statement, this SQL statement is routed to the primary ApsaraDB RDS for MySQL instance for execution.

- Specify a read-only ApsaraDB RDS for MySQL instance to run an SQL statement:

```
/! TDDL:SLAVE*/SELECT * FROM table_name;
```

After the custom hint `/! TDDL:SLAVE*/` is added at the beginning of the SQL statement, this SQL statement is randomly routed to a read-only ApsaraDB RDS for MySQL instance based on the allocated weight.

Considerations

- The custom hints for read/write splitting are only applicable to read SQL statements for non-transactional data. SQL statements for transactional data and write SQL statements are still routed to the primary ApsaraDB RDS for MySQL instance.
- When you use the `/*+TDDL:slave()*/` hint, the instance routes the SQL statement randomly to a read-only ApsaraDB RDS for MySQL instance based on the allocated weight. If no read-only ApsaraDB RDS for MySQL instance is available, no error is reported. Instead, the primary ApsaraDB RDS for MySQL instance is selected to execute the SQL statement.

13.1.9.3. Prevent the delay from a read-only ApsaraDB RDS for MySQL instance

Normally, if you have configured a read-only ApsaraDB for RDS instance for the primary ApsaraDB RDS for MySQL instance of a logical database in a instance and set read traffic for both the primary and read-only ApsaraDB RDS for MySQL instances, routes SQL statements to the primary and read-only ApsaraDB RDS for MySQL instances based on the read/write ratio. However, if asynchronous data replication between the primary and read-only ApsaraDB RDS for MySQL instances has a high delay, an error is reported or error results are returned when PolarDB-X routes the SQL statements to the read-only ApsaraDB RDS for MySQL instance.

To address this issue, the PolarDB-X instance provides a custom hint to cut off the delay of the read-only instance. Specifically, based on the maximum delay of primary/secondary replication, PolarDB-X determines whether to route the SQL statement to the primary or the read-only ApsaraDB RDS for MySQL instance.

Syntax

```
/! TDDL:SQL_DELAY_CUTOFF=time*/
```

With this custom hint, you can specify the value of `SQL_DELAY_CUTOFF`. When the value of SQL_DELAY (primary/secondary replication delay of ApsaraDB RDS for MySQL) for the read-only ApsaraDB RDS for MySQL instance reaches or exceeds the value of `time` (which is measured in seconds), the SQL statement is routed to the primary ApsaraDB RDS for MySQL instance.

> **Note**
>
> - hints can be in the formats of `/*+TDDL:hint_command*/` and `/! +TDDL:hint_command*/`.
> - In the MySQL command-line client, you may need to execute an SQL statement that contains a hint in the format of `/*+TDDL:hint_command*/`. In this case, add the `-c` parameter to the logon command. Otherwise, the client deletes the hint before it sends the SQL statement to the server for execution because the hint is in the format of a MySQL comment. In this case, the hint fails to take effect. For more information, see MySQL Client Options.

Examples

- Set the primary/secondary replication delay to 5 seconds:

```
/! TDDL:SQL_DELAY_CUTOFF=5*/SELECT * FROM table_name;
```

  In this SQL statement, the value of `SQL_DELAY_CUTOFF` is set to 5. Therefore, when the value of `SQL_DELAY` for the read-only ApsaraDB RDS for MySQL instance reaches or exceeds 5 seconds, the SQL statement is routed to the primary ApsaraDB RDS for MySQL instance.

- Use the custom hint for delay cutoff with other custom hints:

```
/! TDDL:SLAVE AND SQL_DELAY_CUTOFF=5*/SELECT * FROM table_name;
```

  The custom hint for cutting off the delay of the read-only ApsaraDB RDS for MySQL instance can be used with other hints. By default, the SQL query request is routed to a read-only ApsaraDB RDS for MySQL instance. However, when the primary/secondary replication delay reaches or exceeds 5 seconds, the SQL query request is routed to the primary ApsaraDB RDS for MySQL instance.

13.1.9.4. Specify a timeout period for an SQL statement

In , the SQL statements for instances and ApsaraDB RDS for MySQL instances are timed out after 900 seconds (which can be adjusted) by default. However, for some slow SQL statements, the execution duration may exceed 900 seconds. For these slow SQL statements, provides a custom hint to adjust their timeout periods. You can use this custom hint to adjust the SQL execution duration as needed.

Syntax

The syntax of the hint for specifying a timeout period for an SQL statement is as follows:

```
/! TDDL:SOCKET_TIMEOUT=time*/
```

The `SOCKET_TIMEOUT` parameter is measured in milliseconds. With this custom hint, you can adjust the timeout period for the SQL statement based on business requirements.

> **Note**
> - hints can be in the formats of `/*+TDDL:hint_command*/` and `/! +TDDL:hint_command*/`.
> - In the MySQL command-line client, you may need to execute an SQL statement that contains a hint in the format of `/*+TDDL:hint_command*/`. In this case, add the `-c` parameter to the logon command. Otherwise, the client deletes the hint before it sends the SQL statement to the server for execution because the hint is in the format of a MySQL comment. In this case, the hint fails to take effect. For more information, see MySQL Client Options.

Examples

Set the timeout period of an SQL statement to 40 seconds:

```
/! TDDL:SOCKET_TIMEOUT=40000*/SELECT * FROM t_item;
```

> **Note** A longer timeout period causes database resources to be occupied for a longer period of time. If excessive SQL statements are executed over a long time within the same period, a large number of database resources may be consumed. This will make users unable to use PolarDB-X properly. In this case, we need to use this custom hint to optimize the SQL statements that take a long time to execute.

13.1.9.5. Specify a database shard to run an SQL statement

When running SQL commands in a instance, you may find that some SQL statements are not supported by the instance. In this case, you can use the custom hint provided by to route the SQL statements to one or more database shards for execution. In addition, if you need to query the data in a specified database shard or the data in a specified table shard, you can use the custom hint to directly route the SQL statement to the database shard for execution.

Syntax

This custom hint allows you to specify a database shard by using a shard name or the value of the database shard key, to run an SQL statement in the database shard. A shard name uniquely identifies a database shard in a instance. You can run the `SHOW NODE` command to obtain the shard name.

> **Note** If the hint for specifying a database shard is used in an INSERT statement that contains a sequence for the target table, the sequence will not take effect. For more information, see Limits and precautions for sequences.

- Specify a database shard by using a shard name, to run an SQL statement

  This custom hint allows you to specify one or more database shards to run an SQL statement.

  - Specify one database shard to run an SQL statement:

    ```
    /! TDDL:NODE='node_name'*/
    ```

    Specifically, `node_name` indicates the shard name. This hint enables you to route the SQL statement to the database shard specified by `node_name`.

  - Specify multiple database shards to run an SQL statement:

    ```
    /! TDDL:NODE IN ('node_name'[,'node_name1','node_name2'])*/
    ```

    The `IN` keyword is used to specify multiple shard names. This custom hint allows you to route the SQL statement to multiple database shards. Separate multiple shard names with commas (,).

    > **Note** When this custom hint is used, the instance directly routes the SQL statement to the specified database shards for execution. Therefore, the specified shard names in the SQL statement must correspond to existing database shards.

- Specify a database shard by using the value of the database shard key, to run an SQL statement

  ```
  /! TDDL:table_name.partition_key=value [and table_name1.partition_key=value1]*/
  ```

  In this hint, `table_name` indicates the name of a logical table, and this table is a partitioned table. In addition, `partition_key` indicates a shard key, and `value` indicates the value specified for the shard key. In this custom hint, you can use the `and` keyword to specify the shard keys of multiple partitioned tables. When this hint is used, the instance calculates the database shards and table shards where the SQL statement is to be executed, and routes the SQL statement to the corresponding database shards.

Note

- hints can be in the formats of `/*+TDDL:hint_command*/` and `/! +TDDL:hint_command*/`.
- In the MySQL command-line client, you may need to execute an SQL statement that contains a hint in the format of `/*+TDDL:hint_command*/`. In this case, add the `-c` parameter to the logon command. Otherwise, the client deletes the hint before it sends the SQL statement to the server for execution because the hint is in the format of a MySQL comment. In this case, the hint fails to take effect. For more information, see MySQL Client Options.

Examples

The following shows the responses of the `SHOW NODE` statement for a logical database named `drds_test` in a instance.

```
mysql> SHOW NODE\G
*************************** 1. row ******************
                ID: 0
              NAME: DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0000_RDS
  MASTER_READ_COUNT: 212
   SLAVE_READ_COUNT: 0
MASTER_READ_PERCENT: 100%
 SLAVE_READ_PERCENT: 0%
*************************** 2. row ******************
                ID: 1
              NAME: DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0001_RDS
  MASTER_READ_COUNT: 29
   SLAVE_READ_COUNT: 0
MASTER_READ_PERCENT: 100%
 SLAVE_READ_PERCENT: 0%
*************************** 3. row ******************
                ID: 2
              NAME: DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0002_RDS
  MASTER_READ_COUNT: 29
   SLAVE_READ_COUNT: 0
MASTER_READ_PERCENT: 100%
 SLAVE_READ_PERCENT: 0%
*************************** 4. row ******************
                ID: 3
              NAME: DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0003_RDS
  MASTER_READ_COUNT: 29

```

As you can see, each database shard has the `NAME` attribute, which indicates the shard name corresponding to the database shard. Each shard name uniquely corresponds to one database shard name. For example, the shard name `DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0003_RDS` corresponds to the database shard name `drds_test_vtla_0003`. Therefore, after obtaining the shard name, you can use the hint to specify the corresponding database shard to run the SQL statement.

- Specify database shard 0 to run an SQL statement:

```
/! TDDL:NODE='DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0000_RDS'*/SELECT * FROM table_name;
```

- Specify multiple database shards to run an SQL statement:

```
/! TDDL:NODE  IN('DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0000_RDS','DRDS_TEST_1473471355140LRPR
DRDS_TEST_VTLA_0006_RDS')*/SELECT * FROM table_name;
```

  This SQL statement will be executed in the database shards whose shard names are `DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0000_RDS` and `DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0006_RDS`.

- View the execution plan of an SQL statement in a specified database shard:

```
/! TDDL:NODE='DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0000_RDS'*/EXPLAIN SELECT * FROM table_nam
e;
```

  After this SQL statement is executed, the execution plan of the `SELECT` statement in the database shard corresponding to the shard name `DRDS_TEST_1473471355140LRPRDRDS_TEST_VTLA_0000_RDS` will be returned.

- Specify a database shard by using the value of the database shard key, to run an SQL statement:

  does not support subqueries in the `SET` clause of an `UPDATE` statement, because a shard key must be specified for `UPDATE` statements in . To address this issue, provides a custom hint to route the statement to a database shard for execution.

  For example, the following shows the CREATE TABLE statement for creating two logical tables t1 and t2, which are partitioned into table shards in database shards:

```
CREATE TABLE `t1` (
    `id` bigint(20) NOT NULL,
    `name` varchar(20) NOT NULL,
    `val` varchar(20) DEFAULT NULL,
    PRIMARY KEY (`id`)
  ) ENGINE=InnoDB DEFAULT CHARSET=utf8 dbpartition by hash(`id`) tbpartition by hash(`name`) tbpar
titions 3
  CREATE TABLE `t2` (
    `id` bigint(20) NOT NULL,
    `name` varchar(20) NOT NULL,
    `val` varchar(20) DEFAULT NULL,
    PRIMARY KEY (`id`)
  ) ENGINE=InnoDB DEFAULT CHARSET=utf8 dbpartition by hash(`id`) tbpartition by hash(`name`) tbpar
titions 3
```

  The following SQL statement is to be executed for the two tables:

```
UPDATE t1 SET val=(SELECT val FROM t2 WHERE id=1) WHERE id=1;
```

  If this statement is directly executed in a instance, an error will be returned indicating that this statement is not supported. In this case, you can add the hint to this SQL statement before submitting it to the instance for execution. The SQL statements are as follows:

```
/! TDDL:t1.id=1 and t2.id=1*/UPDATE t1 SET val=(SELECT val FROM t2 WHERE id=1) WHERE id=1;
```

This statement will be routed to database shards of `t1`, with the `id` of the database shards being 1. You can run the following `EXPLAIN` command to view the execution plan of this SQL statement:

```
  mysql> explain /! TDDL:t1.id=1 and t2.id=1*/UPDATE t1 SET val=(SELECT val FROM t2 WHERE id=1) WH
ERE id=1\G
  *************************** 1. row ***************************
  GROUP_NAME: TEST_DRDS_1485327111630IXLWTEST_DRDS_IGHF_0001_RDS
         SQL: UPDATE `t1_2` AS `t1` SET `val` = (SELECT val FROM `t2_2` AS `t2` WHERE `id` = 1) WH
ERE `id` = 1
      PARAMS: {}
  *************************** 2. row ***************************
  GROUP_NAME: TEST_DRDS_1485327111630IXLWTEST_DRDS_IGHF_0001_RDS
         SQL: UPDATE `t1_1` AS `t1` SET `val` = (SELECT val FROM `t2_1` AS `t2` WHERE `id` = 1) WH
ERE `id` = 1
      PARAMS: {}
  *************************** 3. row ***************************
  GROUP_NAME: TEST_DRDS_1485327111630IXLWTEST_DRDS_IGHF_0001_RDS
         SQL: UPDATE `t1_0` AS `t1` SET `val` = (SELECT val FROM `t2_0` AS `t2` WHERE `id` = 1) WH
ERE `id` = 1
      PARAMS: {}
  3 rows in set (0.00 sec)
```

According to the result set of the `EXPLAIN` command, the SQL statement is rewritten into three statements, which are then routed to the database shards for execution. You can further specify a table shard by using the value of the table shard key, to narrow the execution scope of the SQL statement to a specified table shard.

```
  mysql> explain /! TDDL:t1.id=1 and t2.id=1 and t1.name='1'*/UPDATE t1 SET val=(SELECT val FROM t
2 WHERE id=1) WHERE id=1\G
  *************************** 1. row ***************************
  GROUP_NAME: TEST_DRDS_1485327111630IXLWTEST_DRDS_IGHF_0001_RDS
         SQL: UPDATE `t1_1` AS `t1` SET `val` = (SELECT val FROM `t2_1` AS `t2` WHERE `id` = 1) WH
ERE `id` = 1
      PARAMS: {}
  1 row in set (0.00 sec)
```

Note Before using this custom hint, you must ensure that the logical tables t1 and t2 are partitioned into the same number of database shards and the same number of table shards. Otherwise, the database shards calculated by the instance based on the conditions are different, and an error will be returned.

13.1.9.6. Scan all database shards and table shards

In addition to routing an SQL statement to one or more database shards for execution, provides a custom hint to allow you to scan all database shards and table shards. With this custom hint, you can route an SQL statement to each database shard at a time. For example, you can use this custom hint to view all the table shards in a specified database shard. In addition, you can use this custom hint to view the data volume of table shards in each database shard corresponding to a specified logical table.

Syntax

With this hint, you can route an SQL statement to all database shards for execution and route an SQL statement to all database shards to perform an operation on a specified logical table.

- Route an SQL statement to all database shards for execution:

```
/! TDDL:SCAN*/
```

- Perform an operation on a specified logical table:

```
/! TDDL:SCAN='table_name'*/
```

The `table_name` parameter indicates the name of a logical table in the logical database of a instance. This custom hint is provided for table shards in database shards. Ensure that the value of `table_name` is the name of a table shard in database shards.

> **Note**
> - hints can be in the formats of `/*+TDDL:hint_command*/` and `/! +TDDL:hint_command*/`.
> - In the MySQL command-line client, you may need to execute an SQL statement that contains a hint in the format of `/*+TDDL:hint_command*/`. In this case, add the `-c` parameter to the logon command. Otherwise, the client deletes the hint before it sends the SQL statement to the server for execution because the hint is in the format of a MySQL comment. In this case, the hint fails to take effect. For more information, see MySQL Client Options.

Examples

- View the data volume of a specified broadcast table in each database shard:

```
/! TDDL:SCAN*/SELECT COUNT(1) FROM table_name
```

In this SQL statement, `table_name` indicates a broadcast table. This hint causes the PolarDB-X instance to route the SQL statement to each database shard for execution. Therefore, the result sets include the total data volume of the broadcast table `table_name` in all database shards. This statement allows you to conveniently check whether the data of a broadcast table is normal.

- Scan a single-database non-partition logical table:

```
/! TDDL:SCAN*/SELECT COUNT(1) FROM table_name
```

This hint causes the PolarDB-X instance to route the SQL `select count(1) from table_name` statement to each database shard for execution. The `table_name` parameter indicates a logical table in a logical database of a instance. Before using this hint, ensure that each database shard contains the table shard `table_name`. In other words, the table shard `table_name` is a logical table that is only partitioned into database shards, but not partitioned into table shards. Otherwise, an error that indicates that the table is not found will be returned.

- Scan a partitioned logical table in database shards:

```
/! TDDL:SCAN='table_name'*/SELECT COUNT(1) FROM table_name
```

When executing this statement, the instance first calculates all the database shards and table shards corresponding to the logical table `table_name`, and then generates a COUNT clause for each table shard in each database shard.

- View the execution plans of all database shards:

```
/! TDDL:SCAN='table_name'*/EXPLAIN SELECT * FROM table_name;
```

13.1.10. Distributed transactions

13.1.10.1. Distributed transactions based on MySQL 5.7

> **Note**
> - When you use MySQL 5.7 or later and 5.3.4 or later, XA distributed transactions are automatically enabled. The user experience of the XA distributed transactions is the same as that of single-database transactions in MySQL. No special commands are required to enable XA distributed transactions.
> - When you use MySQL and a PolarDB-X instance in other versions, see Distributed transactions based on MySQL 5.6.

How it works

When you use MySQL 5.7 or later, the instance processes distributed transactions based on the XA protocol by default.

Use method

The user experience of distributed transactions in a instance is the same as that of single-database transactions in MySQL, for example, in terms of the following commands:

- `SET AUTOCOMMIT=0` : Start a transaction.
- `COMMIT` : Commit the current transaction.
- `ROLLBACK` : Roll back the current transaction.

If the SQL statement in a transaction involves only a single shard, the instance routes the transaction directly to the ApsaraDB RDS for MySQL instance as a single-database transaction. If the SQL statement in the transaction is to modify the data of multiple shards, the instance automatically upgrades the current transaction to a distributed transaction.

13.1.10.2. Distributed transactions based on MySQL 5.6

How it works

The XA protocol for MySQL 5.6 is not mature. Therefore, the instance independently implements two-phase commit (2PC) transaction policies for distributed transactions. When you use MySQL 5.7 or later, we recommend that you use XA transaction policies.

> **Note** The distributed transactions described in this topic are intended for users who use MySQL 5.6 or earlier than 5.3.4. When you use MySQL 5.7 or later and a instance in 5.3.4 or later, see Distributed transactions based on MySQL 5.7.

Use method

If a transaction involves multiple database shards, you must declare the current transaction as a distributed transaction. If a transaction involves only a single database shard, you do not need to enable distributed transactions, but can process the transaction as a single-database transaction in MySQL. No additional operations are required.

To enable distributed transactions, do as follows:

After transactions are enabled, run `SET drds_transaction_policy = '...'` .

To enable 2PC transactions in the MySQL command-line client, run the following statements:

```
SET AUTOCOMMIT=0;
SET drds_transaction_policy = '2PC'; -- We recommend that you use MySQL 5.6 to run this command.
.... -- Here, you can run your business SQL statement.
COMMIT; -- You can alternatively write ROLLBACK.
```

To enable 2PC transactions by using the Java database connectivity (JDBC) API, write the code as follows:

```
conn.setAutoCommit(false);
try (Statement stmt = conn.createStatement()) {
    stmt.execute("SET drds_transaction_policy = '2PC'");
}
// ... Here, you can run your business SQL statement.
conn.commit(); // You can alternatively write rollback().
```

FAQ

Q: How can I use distributed transactions in the Spring framework?

A: If you enable transactions by using the Spring `@Transactional` annotation, you can enable distributed transactions by extending the transaction manager.

Sample code:

```
import org.springframework.jdbc.datasource.DataSourceTransactionManager;
import org.springframework.transaction.TransactionDefinition;
import javax.sql.DataSource;
import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;
public class DrdsTransactionManager extends DataSourceTransactionManager {
    public DrdsTransactionManager(DataSource dataSource) {
        super(dataSource);
    }
    @Override
    protected void prepareTransactionalConnection(Connection con, TransactionDefinition definition) t
hrows SQLException {
        try (Statement stmt = con.createStatement()) {
            stmt.executeUpdate("SET drds_transaction_policy = '2PC'"); // A 2PC transaction is used a
s an example.
        }
    }
}
```

After that, instantiate the preceding class in the Spring configuration. For example, you can write the code as follows:

```
<bean id="drdsTransactionManager" class="my.app.DrdsTransactionManager">
     <property name="dataSource" ref="yourDataSource" />
</bean>
```

To enable distributed transactions for a class, you can add the `@Transactional("drdsTransactionManager")` annotation.

13.1.11. DDL operations

13.1.11.1. DDL statements

The data definition language (DDL) statement CREATE TABLE in a Distributed Relational Database Service (DRDS) instance is similar to that in a MySQL database, and is extended based on the syntax in a MySQL database. To create a table shard in a DRDS instance, you must specify the table sharding manner and the database sharding manner in the `drds_partition_options` parameter. The valid values include `DBPARTITION BY` , `TBPARTITION BY` , `TBPARTITIONS` , and `BROADCAST` .

Currently, you can run a DDL statement in the following ways:

- Run the DDL statement through the MySQL command-line client, for example, by using MySQL command lines, Navicat, or MySQL Workbench.
- Connect to the specified DRDS instance by using program code and then call the DDL statement for execution.

For the syntax of the CREATE TABLE statement in a MySQL database, see MySQL CREATE TABLE Statement.

13.1.11.2. CREATE TABLE statement

13.1.11.2.1. Overview

This topic describes the syntax, clauses, parameters, and basic methods for creating a table by using a data definition language (DDL) statement.

> **Note** instances do not allow you to directly create a database by using a DDL statement. To create a database, you can Log on to the PolarDB-X console. For the information about how to create a database, see Create a database.

Syntax

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    (create_definition,...)
    [table_options]
    [drds_partition_options]
    [partition_options]
drds_partition_options:
    DBPARTITION BY
        HASH([column])
        [TBPARTITION BY
            { HASH(column)
            | {MM|DD|WEEK|MMDD}(column)}
          [TBPARTITIONS num]
        ]
```

Clauses and parameters for database and table sharding

- `DBPARTITION BY hash(partition_key)` : This parameter specifies the shard key and the sharding algorithm for database sharding. Database sharding by time is not supported.
- `TBPARTITION BY { HASH(column) | {MM|DD|WEEK|MMDD}(column)` : (Optional) This parameter specifies the method of mapping data to a physical table. The value is the same as that of DBPARTITION BY by default.
- `TBPARTITIONS num` : (Optional) This parameter specifies the number of physical tables to be created in each database shard. The default value is 1. If no table sharding is required, you do not need to specify this parameter.

13.1.11.2.2. Create a single-database non-partition table

This topic describes how to create a single-database non-partition table.

Create a single-database non-partition table

```
CREATE TABLE single_tbl(
  id int,
  name varchar(30),
  primary key(id)
);
```

According to the node topology of the logical table, you can see that a single-database non-partition logical table is created in database 0.

```
mysql> show topology from single_tbl;
+------+--------------------------------------------------------------------+------------+
| ID   | GROUP_NAME                                                         | TABLE_NAME |
+------+--------------------------------------------------------------------+------------+
|    0 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0000_RDS | single_tbl |
+------+--------------------------------------------------------------------+------------+
1 row in set (0.01 sec)
```

Specify parameters

You can also specify the `select_statement` parameter when creating a a single-database non-partition table. If you need to create table shards, you cannot specify this parameter.

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    [(create_definition,...)]
    [table_options]
    [partition_options]
    select_statement
```

For example, you can run the following statement to create a single-database non-partition table single_tbl2 to store the data from the single_tbl table. In this case, no sharding is required.

```
CREATE TABLE single_tbl2(
  id int,
  name varchar(30),
  primary key(id)
) select * from single_tbl;
```

13.1.11.2.3. Create a non-partition table in database shards

This topic describes how to create a non-partition table in database shards.

Assume that eight database shards have been created. You can run the following command to create a non-partition table in the database shards by calculating the hash function based on the userId shard key.

```
CREATE TABLE multi_db_single_tbl(
  id int,
  name varchar(30),
  primary key(id)
) dbpartition by hash(id);
```

According to the node topology of the logical table, you can see that a table shard is created in each database shard. In other words, the table is only distributed to database shards.

```
mysql> show topology from multi_db_single_tbl;
+------+-------------------------------------------------------------------+---------------------+
| ID   | GROUP_NAME                                                        | TABLE_NAME          |
+------+-------------------------------------------------------------------+---------------------+
|    0 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0000_RDS | multi_db_single_tbl |
|    1 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0001_RDS | multi_db_single_tbl |
|    2 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0002_RDS | multi_db_single_tbl |
|    3 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0003_RDS | multi_db_single_tbl |
|    4 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0004_RDS | multi_db_single_tbl |
|    5 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0005_RDS | multi_db_single_tbl |
|    6 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0006_RDS | multi_db_single_tbl |
|    7 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0007_RDS | multi_db_single_tbl |
+------+-------------------------------------------------------------------+---------------------+
8 rows in set (0.01 sec)
```

13.1.11.2.4. Create table shards in database shards

This topic describes how to create table shards in database shards in different sharding manners.

- Use HASH for sharding
- Use RANGE_HASH for sharding
- Use date functions for sharding

In the following examples, it is assumed that eight database shards have been created.

Use HASH for sharding

Create a table that is split into table shards in database shards, with each database shard containing three physical tables. The database sharding process is calculating the hash function by using id as the shard key, and the table sharding process is calculating the hash function by using bid as the shard key. Specifically, a hash operation is performed on the data of the table based on the id column, to distribute the data to multiple database shards. Then, a hash operation is performed on the data in each database shard based on the bid column, to distribute the data to the three physical tables.

```
CREATE TABLE multi_db_multi_tbl(
  id int auto_increment,
  bid int,
  name varchar(30),
  primary key(id)
) dbpartition by hash(id) tbpartition by hash(bid) tbpartitions 3;
```

According to the node topology of the logical table, you can see that three table shards are created in each database shard.

```
mysql> show topology from multi_db_multi_tbl;
+------+-------------------------------------------------------------------+-----------------------+
| ID   | GROUP_NAME                                                        | TABLE_NAME            |
+------+-------------------------------------------------------------------+-----------------------+
|    0 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0000_RDS | multi_db_multi_tbl_00 |
|    1 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0000_RDS | multi_db_multi_tbl_01 |
|    2 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0000_RDS | multi_db_multi_tbl_02 |
|    3 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0001_RDS | multi_db_multi_tbl_03 |
|    4 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0001_RDS | multi_db_multi_tbl_04 |
|    5 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0001_RDS | multi_db_multi_tbl_05 |
|    6 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0002_RDS | multi_db_multi_tbl_06 |
|    7 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0002_RDS | multi_db_multi_tbl_07 |
|    8 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0002_RDS | multi_db_multi_tbl_08 |
|    9 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0003_RDS | multi_db_multi_tbl_09 |
|   10 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0003_RDS | multi_db_multi_tbl_10 |
|   11 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0003_RDS | multi_db_multi_tbl_11 |
|   12 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0004_RDS | multi_db_multi_tbl_12 |
|   13 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0004_RDS | multi_db_multi_tbl_13 |
|   14 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0004_RDS | multi_db_multi_tbl_14 |
|   15 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0005_RDS | multi_db_multi_tbl_15 |
|   16 | SANGUAN_TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0005_RDS | multi_db_multi_tbl_16 |

According to the sharding rule of the logical table, you can see that both database sharding and table sharding are running the hash function, except that the database shard key is id and the table shard key is bid.

```
mysql> show rule from multi_db_multi_tbl;
+------+--------------------+-----------+------------------+---------------------+-------------------
-+------------------+---------------------+--------------------+
| ID   | TABLE_NAME         | BROADCAST | DB_PARTITION_KEY | DB_PARTITION_POLICY | DB_PARTITION_COUNT

Use RANGE_HASH for sharding

- Requirements

  The shard key must be a character or a number.

- Routing method

  Calculate a hash value based on the last N digits of any shard key, and then calculate the route by using RANGE_HASH. The number N is the third parameter in the function. For example, during calculation of the RANGE_HASH(COL1, COL2, N) function, COL1 is preferentially selected and then truncated to obtain the last N digits for calculation. If COL1 does not exist, COL2 is selected and truncated for calculation.

- Scenarios

  RANGE_HASH is applicable to scenarios where two shard keys are used for sharding but only the values of one shard is used for SQL query. Assume that a DRDS database is partitioned into eight physical databases. Our customer has the following requirements:

  i. The order table of each service needs to be split into database shards by buyer ID and order ID.

  ii. The query is executed based on either the buyer ID or order ID as the condition.

  In this case, you can run the following DDL statement to create the order table:

```
create table test_order_tb (
           id int,
           seller_id varchar(30) DEFAULT NULL,
           order_id varchar(30) DEFAULT NULL,
           buyer_id varchar(30) DEFAULT NULL,
           create_time datetime DEFAULT NULL,
           primary key(id)
   ) ENGINE=InnoDB DEFAULT CHARSET=utf8 dbpartition by RANGE_HASH(buyer_id, order_id, 10) tbpartit
ion by RANGE_HASH(buyer_id, order_id, 10) tbpartitions 3;
```

> **Note**
>
> - Neither of the two shard keys can be modified.
> - Data insertion fails if the two shard keys point to different database shards or table shards.

Use date functions for sharding

In addition to using the hash function as the sharding algorithm, you can also use the date functions MM, DD, WEEK, and MMDD as the table sharding algorithms. For more information, see the following examples.

- Create a table and then split the table into table shards in database shards. The database sharding process is calculating the hash function by using userId as the shard key, and the table sharding process is calculating DAY_OF_WEEK through the WEEK(actionDate) function and then splitting the table into table shards based on the actionDate column, with one week counted as seven days.

  For example, if the value in the actionDate column is 2017-02-27, which is on Monday, the value obtained by calculating the WEEK(actionDate) function is 2. In this case, the record is stored in table shard 2, because 2 % 7 = 2. This table shard is located in a database shard and is named user_log_2. For another example, if the value in the actionDate column is 2017-02-26, which is on Sunday, the value obtained by calculating the WEEK(actionDate) function is 1. In this case, the record is stored in table shard 1, because 1 % 7 = 1. This table shard is located in a database shard and is named user_log_1.

```
CREATE TABLE user_log(
userId int,
name varchar(30),
operation varchar(30),
actionDate DATE
) dbpartition by hash(userId) tbpartition by WEEK(actionDate) tbpartitions 7;
```

  According to the node topology of the logical table, you can see that seven table shards are created in each database shard, because one week is counted as seven days in the function. The responses are very long, and therefore are omitted by using an ellipsis (...).

```
mysql> show topology from user_log;

```

According to the specified database and table shard key parameters, you can see the specific physical table in the specific physical database to which the SQL statement is routed.

View the route of the SQL statement

- Create a table that is split into table shards in database shards. The database sharding process is calculating the hash function by using userId as the shard key, and the table sharding process is calculating MONTH_OF_YEAR through the MM(actionDate) function and then splitting the table into table shards based on

the actionDate column, with one year counted as 12 months.

For example, if the value in the actionDate column is 2017-02-27, the value obtained by calculating the MM(actionDate) function is 02. In this case, the record is stored in table shard 02, because 02 % 12 = 02. This table shard is located in a database shard and is named user_log_02. For another example, if the value in the actionDate column is 2016-12-27, the value obtained by calculating the MM(actionDate) function is 12. In this case, the record is stored in table shard 00, because 12 % 12 = 00. This table shard is located in a database shard and is named user_log_00.

```
CREATE TABLE user_log2(
userId int,
name varchar(30),
operation varchar(30),
actionDate DATE
) dbpartition by hash(userId) tbpartition by MM(actionDate) tbpartitions 12;
```

According to the node topology of the logical table, you can see that 12 table shards are created in each database shard, because one year is counted as 12 months in the function. The responses are very long, and therefore are omitted by using an ellipsis (...).

```
mysql> show topology from user_log2;

248 rows in set (0.01 sec)
```

According to the sharding rule of the logical table, you can see that the database sharding process is calculating the hash function by using userId as the shard key, and the table sharding process is calculating the DD function by using actionDate as the shard key.

```
mysql> show rule from user_log3;
+------+------------+-----------+------------------+---------------------+--------------------+---
--------------+---------------------+--------------------+
| ID   | TABLE_NAME | BROADCAST | DB_PARTITION_KEY | DB_PARTITION_POLICY | DB_PARTITION_COUNT | TB
_PARTITION_KEY | TB_PARTITION_POLICY | TB_PARTITION_COUNT |
+------+------------+-----------+------------------+---------------------+--------------------+---
--------------+---------------------+--------------------+
|    0 | user_log3  |         0 | userId           | hash                | 8                  | ac
tionDate       | dd                  | 31                 |
+------+------------+-----------+------------------+---------------------+--------------------+---
--------------+---------------------+--------------------+
1 row in set (0.01 sec)
```

- Create a table that is split into table shards in database shards. The database sharding process is calculating the hash function by using userId as the shard key, and the table sharding process is calculating DAY_OF_YEAR % 365 through the MMDD(actionDate) tbpartitions 365 function and then splitting the table into 365 physical tables, with one year counted as 365 days.

  For example, if the value in the actionDate column is 2017-02-27, the value obtained by calculating the MMDD(actionDate) function is 58. In this case, the record is stored in table shard 58. This table shard is located in a database shard and is named user_log_58.

  ```
  CREATE TABLE user_log4(
  userId int,
  name varchar(30),
  operation varchar(30),
  actionDate DATE
  ) dbpartition by hash(userId) tbpartition by MMDD(actionDate) tbpartitions 365;
  ```

  According to the node topology of the logical table, you can see that 365 table shards are created in each database shard, because one year is counted as 365 days in the function. The responses are very long, and therefore are omitted by using an ellipsis (...).

```
mysql> show topology from user_log4;

```

13.1.11.2.5. Use the primary key as the shard key

When no shard key is specified for the sharding algorithm, the system uses the primary key as the shard key by default. The following illustrates how to use the primary key as the database shard key and the table shard key.

Use the primary key as the database shard key

```
CREATE TABLE prmkey_tbl(
id int,
name varchar(30),
primary key(id)
) dbpartition by hash();
```

Use the primary key as the database shard key and the table shard key

```
CREATE TABLE prmkey_multi_tbl(
id int,
name varchar(30),
primary key(id)
) dbpartition by hash() tbpartition by hash() tbpartitions 3;
```

13.1.11.2.6. Create a broadcast table

The BROADCAST clause is used to specify a broadcast table to be created. A broadcast table is replicated to each database shard and data consistency is ensured between the database shards by using a synchronization mechanism with a delay of several seconds. This feature allows you to route a JOIN operation from a Cloud Native Distributed Database PolarDB-X (PolarDB-X) instance to an underlying ApsaraDB RDS for MySQL instance to prevent the JOIN operation from being performed in multiple databases. Overview describes how to optimize SQL statements by using broadcast tables.

The following is an example statement for creating a broadcast table:

```
CREATE TABLE brd_tbl(
  id int,
  name varchar(30),
  primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8 BROADCAST;
```

13.1.11.2.7. Other attributes of the MySQL CREATE TABLE statement

When creating table shards in database shards, you can also specify other attributes of the table shards in the MySQL CREATE TABLE statement. For example, you can specify other attributes as follows:

```
CREATE TABLE multi_db_multi_tbl(
  id int,
  name varchar(30),
  primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8 dbpartition by hash(id) tbpartition by hash(id) tbpartitions 3;
```

13.1.11.3. ALTER TABLE statement

The syntax of the ALTER TABLE statement used to modify a table is as follows:

```
ALTER [ONLINE|OFFLINE] [IGNORE] TABLE tbl_name
    [alter_specification [, alter_specification] ...]
    [partition_options]
```

In a Distributed Relational Database Service (DRDS) instance, you can use this data definition language (DDL) statement to perform routine DDL operations, such as adding a column, adding an index, and modifying a data definition. For more information about the syntax, see MySQL CREATE TABLE Statement.

> **Note** If you need to modify a table shard, you are not allowed to modify the shard key.

- Add a column:

```
ALTER TABLE user_log
  ADD COLUMN idcard varchar(30);
```

- Add an index:

```
ALTER TABLE user_log
  ADD INDEX idcard_idx (idcard);
```

- Delete an index:

```
ALTER TABLE user_log
  DROP INDEX idcard_idx;
```

- Modify a field:

```
ALTER TABLE user_log
  MODIFY COLUMN idcard varchar(40);
```

13.1.11.4. DROP TABLE statement

The syntax of the DROP TABLE statement used to delete a table is as follows:

```
DROP [TEMPORARY] TABLE [IF EXISTS]
    tbl_name [, tbl_name] ...
    [RESTRICT | CASCADE]
```

The DROP TABLE statement in a Distributed Relational Database Service (DRDS) instance is the same as the DROP TABLE statement in a MySQL database. After the statement is executed, the system automatically deletes the corresponding physical table. For more information about the syntax, see MySQL DROP TABLE Statement.

For example, you can run the following statement to delete the user_log table:

```
DROP TABLE user_log;
```

13.1.11.5. FAQ about DDL statements

What can I do if an error occurs during table creation?

Data definition language (DDL) statements in a instance are processed in a distributed manner. If an error occurs, the structures of all table shards are inconsistent from each other. Therefore, you need to perform manual cleanup.

Perform the following steps:

1. Check the basic error descriptions provided by the instance, such as syntax errors. If the error message is too

long, the system will prompt you to call the SHOW WARNINGS command to view the failure cause of each database shard.

2. Run the SHOW TOPOLOGY command to view the topology of physical tables.

```
SHOW TOPOLOGY FROM multi_db_multi_tbl;
+------+-----------------+-----------------------+
| ID   | GROUP_NAME      | TABLE_NAME            |
+------+-----------------+-----------------------+
|    0 | corona_qatest_0 | multi_db_multi_tbl_00 |
|    1 | corona_qatest_0 | multi_db_multi_tbl_01 |
|    2 | corona_qatest_0 | multi_db_multi_tbl_02 |
|    3 | corona_qatest_1 | multi_db_multi_tbl_03 |
|    4 | corona_qatest_1 | multi_db_multi_tbl_04 |
|    5 | corona_qatest_1 | multi_db_multi_tbl_05 |
|    6 | corona_qatest_2 | multi_db_multi_tbl_06 |
|    7 | corona_qatest_2 | multi_db_multi_tbl_07 |
|    8 | corona_qatest_2 | multi_db_multi_tbl_08 |
|    9 | corona_qatest_3 | multi_db_multi_tbl_09 |
|   10 | corona_qatest_3 | multi_db_multi_tbl_10 |
|   11 | corona_qatest_3 | multi_db_multi_tbl_11 |
+------+-----------------+-----------------------+
12 rows in set (0.21 sec)
```

3. Run the `CHECK TABLE tablename` command to check whether the logical table has been created. For example, the following response indicates that a physical table corresponding to the logical table multi_db_multi_tbl failed to be created.

```
mysql> check table multi_db_multi_tbl;
+-------------------------------------------------+-------+----------+---------------------------
-----------------------------------------------+
| TABLE                                           | OP    | MSG_TYPE | MSG_TEXT
|
+-------------------------------------------------+-------+----------+---------------------------
-----------------------------------------------+
| andor_mysql_qatest. multi_db_multi_tbl | check | Error    | Table 'corona_qatest_0. multi_db_mu
lti_tbl_02' doesn't exist |
+-------------------------------------------------+-------+----------+---------------------------
-----------------------------------------------+
1 row in set (0.16 sec)
```

4. Continue to create or delete the table in idempotent mode to create or delete the remaining physical tables.

```
CREATE TABLE IF NOT EXISTS table1
(id int, name varchar(30), primary key(id))
dbpartition by hash(id);
DROP TABLE IF EXISTS table1;
```

What can I do if I failed to create an index or add a column?

The method for handling the failure in creating an index or adding a column is similar to that for the failure in creating a table. For more information, see Handle DDL exceptions.

13.1.11.6. DDL functions for sharding

13.1.11.6.1. Overview

is a database service that supports both database sharding and table sharding.

Support for database sharding and table sharding

The following table lists the support for database sharding and table sharding in data definition language (DDL) sharding functions.

Sharding function	Description	Support for database sharding	Support for table sharding
HASH	Performs a simple modulus operation.	Yes	Yes
UNI_HASH	Performs a simple modulus operation.	Yes	Yes
RIGHT_SHIFT	Shifts the value to the right.	Yes	Yes
RANGE_HASH	Performs double hashing.	Yes	Yes
MM	Performs hashing by month.	No	Yes
DD	Performs hashing by date.	No	Yes
WEEK	Performs hashing by week.	No	Yes
MMDD	Performs hashing by month and date.	No	Yes
YYYYMM	Performs hashing by year and month.	Yes	Yes
YYYYWEEK	Performs hashing by year and week.	Yes	Yes
YYYYDD	Performs hashing by year and date.	Yes	Yes
YYYYMM_OPT	Performs optimized hashing by year and month.	Yes	Yes
YYYYWEEK_OPT	Performs optimized hashing by year and week.	Yes	Yes
YYYYDD_OPT	Performs optimized hashing by year and date.	Yes	Yes

Note When using database sharding and table sharding in , note the following:

- In a instance, the sharding method of a logical table is defined jointly by a sharding function and a shard key. The sharding function contains the number of shards to be created and the routing algorithm. The shard key also specifies the MySQL data type of the shard key.
- When the database sharding function is the same as the table sharding function and the database shard key is the same as the table shard key in a instance, the same sharding method is used for database sharding and table sharding. This allows the instance to uniquely locate one physical table in a physical database based on the value of the shard key.
- If the database sharding method and the table sharding method of a logical table are different and an SQL query does not contain both database shard key and table shard key, the instance scans all database shards or all table shards when processing the SQL query.

Support for data types of PolarDB-X DDL sharding functions

Different DDL sharding functions support different data types. The following table lists the support for various data types in sharding functions (√ indicates supported and × indicates not supported).

Support for data types in DDL sharding functions

Sharding function	BIGINT	INT	MEDIUMINT	SMALLINT	TINYINT	VARCHAR	CHAR	DATE	DATETIME	TIMESTAMP	Other types
HASH	√	√	√	√	√	√	√	×	×	×	×
UNI_HASH	√	√	√	√	√	√	√	×	×	×	×
RANGE_HASH	√	√	√	√	√	√	√	×	×	×	×
RIGHT_SHIFT	√	√	√	√	√	×	×	×	×	×	×
MM	×	×	×	×	×	×	×	√	√	√	×
DD	×	×	×	×	×	×	×	√	√	√	×
WEEK	×	×	×	×	×	×	×	√	√	√	×
MMDD	×	×	×	×	×	×	×	√	√	√	×
YYYYMM	×	×	×	×	×	×	×	√	√	√	×
YYYYWEEK	×	×	×	×	×	×	×	√	√	√	×
YYYYDD	×	×	×	×	×	×	×	√	√	√	×
YYYYMM_OPT	×	×	×	×	×	×	×	√	√	√	×
YYYYWEEK_OPT	×	×	×	×	×	×	×	√	√	√	×
YYYYDD_OPT	×	×	×	×	×	×	×	√	√	√	×

Syntax description for PolarDB-X DDL sharding functions

is compatible with the CREATE TABLE statement in MySQL, and additionally provides the `drds_partition_options` keyword to support database sharding and table sharding:

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    (create_definition,...)
    [table_options]
    [drds_partition_options]
    [partition_options]
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    [(create_definition,...)]
    [table_options]
    [drds_partition_options]
    [partition_options]
    select_statement
drds_partition_options:
    DBPARTITION BY
        { {HASH|YYYYMM|YYYYWEEK|YYYYDD|YYYYMM_OPT|YYYYWEEK_OPT|YYYYDD_OPT}([column])}
        [TBPARTITION BY
            { {HASH|MM|DD|WEEK|MMDD|YYYYMM|YYYYWEEK|YYYYDD|YYYYMM_OPT|YYYYWEEK_OPT|YYYYDD_OPT}(column
)}
          [TBPARTITIONS num]
        ]
```

13.1.11.6.2. HASH

Requirements

- The shard key must be an integer or a string.
- This sharding function has no requirements on the version of a Distributed Relational Database Service (DRDS)

instance. It supports all DRDS instances by default.

Routing method

When the HASH function is run by using different shard keys for database sharding and table sharding, perform the remainder operation on the value of the database shard key based on the number of database shards. If the value of the shard key is a string, the string is converted to a hash value before route calculation. For example, HASH('8') is equivalent to 8 % D, where D indicates the number of database shards.

When the UNI_HASH function is run by using the same shard key for both database sharding and table sharding, perform the remainder operation on the value of the shard key based on the total number of table shards. For example, assume that two database shards are created, each database shard contains four table shards, table shards 0 to 3 are stored in database shard 0, and table shards 4 to 7 are stored in database shard 1. If a key value is 15, the key value 15 is distributed to table shard 7 in database shard 1, because 15 % (2 x 4) = 7.

Scenarios

- HASH is applicable when database sharding is implemented by user ID or order ID.
- HASH is also applicable when the shard key is a string.

Examples

If you need to create a non-partition table in database shards by using the HASH function based on the ID column, you can use the following CREATE TABLE statement:

```
create table test_hash_tb (
    id int,
    name varchar(30) DEFAULT NULL,
    create_time datetime DEFAULT NULL,
    primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8 dbpartition by HASH(ID);
```

Notes

The HASH is a simple modulus operation. The output distribution of the HASH function can be even only when the values in the shard column are evenly distributed.

13.1.11.6.3. UNI_HASH

Requirements

- The shard key must be an integer or a string.
- The version of the instance must be 5.1.28-1508068 or later. For more information about the release notes, see View the instance version.

Routing method

When the UNI_HASH function is used for database sharding, perform a remainder operation on the value of the database shard key based on the number of database shards. If the value of the shard key is a string, the string is converted to a hash value before route calculation. For example, HASH('8') is equivalent to 8 % D, where D indicates the number of database shards.

When the UNI_HASH function is run by using the same shard key for both database sharding and table sharding, perform the remainder operation on the value of the database shard key based on the number of database shards first (this step is different from that in the HASH function). Then, the data is evenly distributed to the table shards in the database shard.

Scenarios

- UNI_HASH is applicable when database sharding is implemented by user ID or order ID.

- UNI_HASH is also applicable when the shard key is an integer or a string.
- UNI_HASH can be used when the following conditions are met: Two logical tables need to be partitioned into different numbers of table shards in database shards based on the same shard key. In addition, the two tables are frequently joined by using a JOIN statement based on the shard key.

Comparison with HASH

When you use the UNI_HASH function to create a non-partition table in database shards, the routing method is the same as that used in the HASH function. Specifically, the route is calculated by performing the remainder operation on the key value of the database shard key based on the number of database shards.

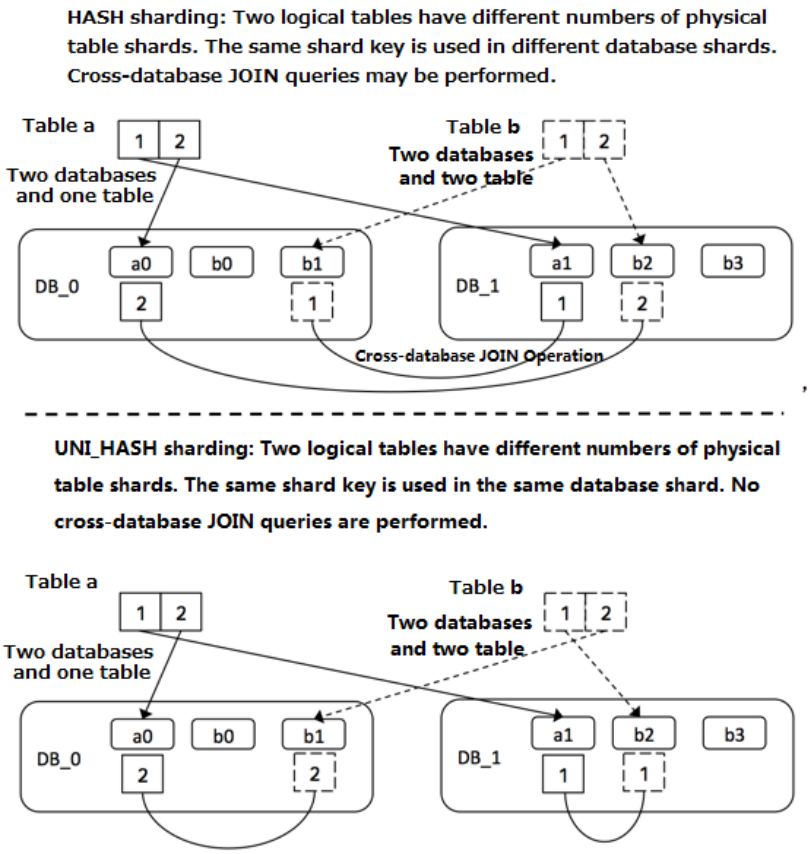
When the UNI_HASH function is run by using the same shard key for both database sharding and table sharding, as the number of table shards changes, the database shard route calculated based on the same key value may also change.

When the UNI_HASH function is run by using the same shard key for both database sharding and table sharding, the database shard route calculated based on the same key value is always the same regardless of the number of table shards.

If two logical tables need to be partitioned into different table shards in database shards based on the same shard key, when the two tables are joined by using the HASH function based on the shard key, multi-database join may occur. However, when the two tables are joined by using the UNI_HASH function based on the shard key, multi-database join does not occur.

Assume that you have two database shards and two logical tables, and each database shard in logical table a stores one table shard and each database shard in logical table b stores two table shards. The following figures separately show the results of a JOIN query for logical tables a and b after the HASH function is used for sharding and the results of a JOIN query for logical tables a and b after the HASH function is used for sharding.

Comparison between HASH and UNI_HASH



Examples

If you need to create four table shards in each database shard by using the UNI_HASH function based on the ID column, you can run the following CREATE TABLE statement:

```
create table test_hash_tb (
    id int,
    name varchar(30) DEFAULT NULL,
    create_time datetime DEFAULT NULL,
    primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
dbpartition by UNI_HASH(ID)
tbpartition by UNI_HASH(ID) tbpartitions 4;
```

Precautions

The UNI_HASH is a simple modulus operation. The output distribution of the UNI_HASH function can be even only when the values in the shard column are evenly distributed.

13.1.11.6.4. RIGHT_SHIFT

Requirements

- The shard key must be an integer.
- The version of the instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Routing method

Shift the value of the database shard key to the right by a specified number of binary digits, and then perform the remainder operation on the obtained integer based on the number of database shards or table shards. In particular, you can specify the number of shifted digits by running a data definition language (DDL) statement.

Scenarios

RIGHT_SHIFT is applicable to improve the evenness of the hash results when the lower-digit parts of most shard key values are very similar to each other but the higher-digit parts vary greatly.

Assume that four shard key values are available: 12340000, 12350000, 12460000, and 12330000. The four lower digits of the four values are all 0000. Directly hashing the values of the shard keys outputs poor results. However, if you run the RIGHT_SHIFT(shardKey, 4) statement to shift the values of the shard keys to the right by four digits, to obtain 1234, 1235, 1246, and 1233, the hashing results are improved.

Examples

If you need to use the ID column as a shard key and shift the values of the ID column to the right by four binary digits to obtain hash values, you can run the following CREATE TABLE statement:

```
create table test_hash_tb (
    id int,
    name varchar(30) DEFAULT NULL,
    create_time datetime DEFAULT NULL,
    primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
dbpartition by RIGHT_SHIFT(id, 4)
tbpartition by RIGHT_SHIFT(id, 4) tbpartitions 2;
```

Precautions

The number of shifted digits cannot exceed the number of digits occupied by the integer.

13.1.11.6.5. RANGE_HASH

Requirements

- The shard key must be a character or a number.
- The version of the instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Routing method

Calculate the hash value based on the last N digits of any shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes the route computing. The number N is the third parameter in the function.

For example, during calculation of the RANGE_HASH(COL1, COL2, N) function, COL1 is preferentially selected and then truncated to obtain the last N digits for calculation. If COL1 does not exist, COL2 is selected and truncated for calculation.

Scenarios

RANGE_HASH is applicable to scenarios where a table needs to be partitioned by two shard keys but query is performed only based on the value of one shard key.

Examples

Assume that a database is partitioned into eight physical databases. Our customer has the following requirements:

The order table of a business needs to be partitioned into database shards by buyer ID and order ID. The query is executed based on either the buyer ID or order ID as the condition.

In this case, you can run the following DDL statement to create the order table:

```
create table test_order_tb (
    id int,
    buyer_id varchar(30) DEFAULT NULL,
    order_id varchar(30) DEFAULT NULL,
    create_time datetime DEFAULT NULL,
    primary key(id)
    ) ENGINE=InnoDB DEFAULT CHARSET=utf8
    dbpartition by RANGE_HASH(buyer_id,order_id, 10)
    tbpartition by RANGE_HASH (buyer_id,order_id, 10) tbpartitions 3;
```

Precautions

- Neither of the two shard keys can be modified.
- Data insertion fails if the two shard keys point to different database shards or table shards.

13.1.11.6.6. MM

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- MM is only applicable to table sharding.
- The version of the instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Routing method

Perform the remainder operation based on the month that corresponds to the time value of the database shard key to obtain the table shard subscript.

Scenarios

MM can be used to partition tables by month. The table shard name indicates a specific month.

Examples

Assume that we need to perform database sharding by ID, perform table sharding for the create_time column by month, and map every month to a physical table. The data definition language (DDL) statement is as follows:

```
create table test_mm_tb (
    id int,
    name varchar(30) DEFAULT NULL,
    create_time datetime DEFAULT NULL,
    primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
dbpartition by HASH(id)
tbpartition by MM(create_time) tbpartitions 12;
```

Precautions

When you partition tables with MM, ensure that each database shard has no more than 12 table shards because a year has 12 months.

13.1.11.6.7. DD

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- DD is only applicable to table sharding.
- The version of the instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Routing method

Perform the remainder operation based on the day of the month that corresponds to the time value of the database shard key to obtain the table shard subscript.

Scenarios

DD can be used to partition tables based on a specified number of days in a month, that is, a date. The subscript of the table shard name indicates the day in a month. A month has 31 days at most.

Examples

Assume that we need to perform database sharding by ID, perform table sharding for the create_time column by day, and map every day to a physical table. The data definition language (DDL) statement is as follows:

```
create table test_dd_tb (
    id int,
    name varchar(30) DEFAULT NULL,
    create_time datetime DEFAULT NULL,
    primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
dbpartition by HASH(id)
tbpartition by DD(create_time) tbpartitions 31;
```

Precautions

When you partition tables with DD, ensure that each database shard has no more than 31 table shards because a month has 31 days at most.

13.1.11.6.8. WEEK

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- WEEK is only applicable to table sharding.
- The version of the instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Routing method

Perform the remainder operation based on the day of a week that corresponds to the time value of the database shard key to obtain the table shard subscript.

Scenarios

WEEK can be used to partition tables based on days in a week. The subscript of the table shard name corresponds to each day of a week, from Monday to Sunday.

Examples

Assume that we need to perform database sharding by ID, perform table sharding for the create_time column by week, and map every day of a week (from Monday to Sunday) to a physical table. The data definition language (DDL) statement is as follows:

```
create table test_week_tb (
    id int,
    name varchar(30) DEFAULT NULL,
    create_time datetime DEFAULT NULL,
    primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
dbpartition by HASH(name)
tbpartition by WEEK(create_time) tbpartitions 7;
```

Precautions

When you partition tables with WEEK, ensure that each database shard has no more than seven table shards because a week has seven days.

13.1.11.6.9. MMDD

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- MMDD is only applicable to table sharding.
- The version of the instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Routing method

Perform the remainder operation based on the number of days in a year that corresponds to the time value of the database shard key to obtain the table sharding subscript.

Scenarios

MMDD can be used to partition tables based on the number of days in a year that corresponds to a date in that year. The subscript of the table shard name indicates the day in that year, with a maximum of 366 days in a year.

Examples

Assume that we need to perform database sharding by ID, create tables for the create_time column by date (month-day), and map every day of a year to a physical table. The data definition language (DDL) statement is as follows.

```
create table test_mmdd_tb (
    id int,
    name varchar(30) DEFAULT NULL,
    create_time datetime DEFAULT NULL,
    primary key(id)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
dbpartition by HASH(name)
tbpartition by MMDD(create_time) tbpartitions 365;
```

Precautions

When you partition tables with MMDD, ensure that each database shard has no more than 366 table shards because a year has 366 days at most.

13.1.11.6.10. YYYYMM

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The version of the instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Routing method

Calculate the hash value based on the year and months of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.

For example, YYYYMM('2012-12-31 12:12:12') is equivalent to (2012 x 12 + 12) % D, where D indicates the number of database shards.

Scenarios

YYYYMM can be used to partition databases by year and month. We recommend that you use YYYYMM with tbpartition YYYYMM(ShardKey).

Assume that a database is partitioned into eight physical databases. Our customer has the following requirements:

- Perform database sharding for a service by year and month.
- Distribute data from every month within two years to a separate table shard.
- Distribute a query with the database and table shard keys to a physical table shard of a physical database shard.

The preceding requirements can be met by using YYYYMM. For the requirement of distributing data from every month within two years to a table shard (that is, one table shard stores the data of one month), create at least 24 physical table shards because a year has 12 months. Create three physical table shards for each database shard because the instance contains eight database shards. The data definition language (DDL) statement is as follows.

```
create table test_yyyymm_tb (
        id int,
        name varchar(30) DEFAULT NULL,
        create_time datetime DEFAULT NULL,
        primary key(id)
    ) ENGINE=InnoDB DEFAULT CHARSET=utf8
    dbpartition by YYYYMM(create_time)
    tbpartition by YYYYMM(create_time) tbpartitions 3;
```

Precautions

- YYYYMM does not support distributing data from every month in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle over months (for example, a cycle exists between 2012-03 and 2013-03), data from the same month may be routed to the same database or table shard, depending on the actual number of table shards.

13.1.11.6.11. YYYYWEEK

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The version of the instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Routing method

Calculate the hash value based on the year and weeks of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.

For example, YYYYWEEK('2012-12-31 12:12:12') is equivalent to (2013 x 52 + 1) % D, with the date 2012-12-31 falling on the first week of 2013, where D indicates the number of database shards.

Scenarios

YYYYWEEK can be used to partition databases by year and the number of weeks in a year. We recommend that you use YYYYWEEK with tbpartition YYYYWEEK(ShardKey).

Assume that a database is partitioned into eight physical databases. Our customer has the following requirements:

- Perform database sharding for a service by year and by week.
- Distribute data from every week within two years to a separate table shard.
- Distribute a query with the database and table shard keys to a physical table shard of a physical database shard.

The preceding requirements can be met by using YYYYWEEK. For the requirement of distributing data from every week within two years to a table shard (that is, one table shard stores the data of one week), create at least 106 physical table shards because a year has roughly 53 weeks (rounded). Create 14 physical table shards for each database shard because the instance contains eight database shards (14 x 8 = 112 > 106). We recommend that the number of table shards be an integer multiple of the number of database shards. The data definition language (DDL) statement is as follows:

```
create table test_yyyymm_tb (
        id int,
        name varchar(30) DEFAULT NULL,
        create_time datetime DEFAULT NULL,
        primary key(id)
    ) ENGINE=InnoDB DEFAULT CHARSET=utf8
    dbpartition by YYYYWEEK(create_time)
    tbpartition by YYYYWEEK(create_time) tbpartitions 14;
```

Precautions

- YYYYWEEK does not support distributing data from every week in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle over weeks (for example, a cycle exists between the first week of 2012 and the first week of 2013), data from the same week after a cycle may be routed to the same database shard or table shard, depending on the actual number of table shards.

13.1.11.6.12. YYYYDD

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The version of the instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Routing method

Calculate the hash value based on the year and days of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.

For example, YYYYDD('2012-12-31 12:12:12') is equivalent to (2012 x 366 + 365) % D, with 2012-12-31 as the 365th day of 2012, where D indicates the number of database shards.

Scenarios

Database sharding is performed by year and the number of days in a year. We recommend that you use YYYYDD with tbpartition YYYYDD(ShardKey).

Assume that a database is partitioned into eight physical databases. Our customer has the following requirements:

- Perform database sharding for a service by year and day.
- Distribute data from every week within two years to a separate table shard.
- Distribute a query with the database and table shard keys to a physical table shard of a physical database shard.

The preceding requirements can be met by using YYYYDD. For the requirement of distributing data from every day within two years to a table shard (that is, one table shard stores the data of one day), create at least 732 physical table shards because a year has up to 366 days. Create 92 physical table shards for each database shard because the instance contains eight database shards (732/8 = 91.5, rounded to 92). We recommend that the number of table shards be an integer multiple of the number of database shards. The data definition language (DDL) statement is as follows:

```
create table test_yyyydd_tb (
        id int,
        name varchar(30) DEFAULT NULL,
        create_time datetime DEFAULT NULL,
        primary key(id)
    ) ENGINE=InnoDB DEFAULT CHARSET=utf8
    dbpartition by YYYYDD(create_time)
    tbpartition by YYYYDD(create_time) tbpartitions 92;
```

Precautions

- YYYYDD does not support distributing data from every day in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle of a specific date (for example, a cycle exists between 2012-03-01 and 2013-03-01), data from the same date may be routed to the same database shard or table shard, depending on the actual number of table shards.

13.1.11.6.13. YYYYMM_OPT

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The year and month of user data increase naturally over time, rather than randomly.
- The version of the instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Optimizations

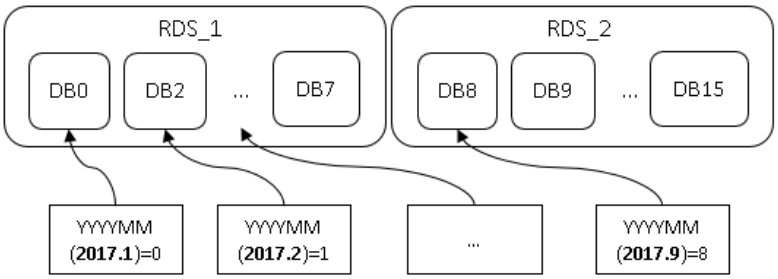
Compared with YYYYMM, YYYYMM_OPT maintains the even distribution of data among ApsaraDB RDS for MySQL instances as the timeline increases.

For example, assume that two ApsaraDB RDS for MySQL instances are attached to a instance, with 16 database shards. DB0 to DB7 shards are located on one ApsaraDB RDS for MySQL instance, and DB8 to DB15 shards are located on the other ApsaraDB RDS for MySQL instance.

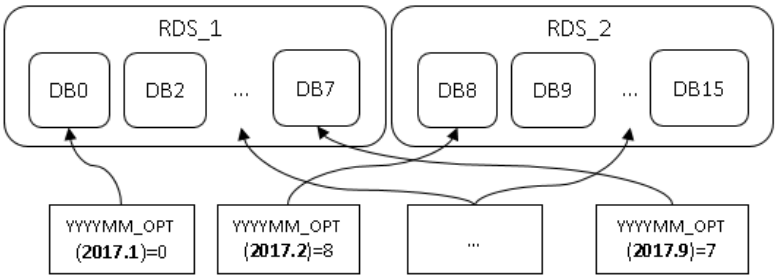
The following figure shows the mappings when YYYYMM and YYYYMM_OPT are used for database sharding, respectively.

Comparison between YYYYMM and YYYYMM_OPT

As the time goes on linearly, YYYYMM fills data in ApsaraDB for RDS instances in sequence (data is first distributed to the database shards of RDS_1, then to the database shards of RDS_2, and then to the database shards of RDS_1 again).



YYYYMM_OPT evenly distributes data between ApsaraDB for RDS instances as the time goes on (data is alternately distributed between RDS_1 and RDS_2, so that the data size of the two RDS instances is balanced).



- YYYYMM_OPT distributes data evenly to each ApsaraDB RDS for MySQL instance, helping to maximize the performance of each ApsaraDB RDS for MySQL instance.
- How to choose between YYYYMM and YYYYMM_OPT:
  - YYYYMM_OPT can be used to distribute data evenly to each ApsaraDB RDS for MySQL instance if the time of service data generation increases sequentially and the data volume does not differ much between the time points.
  - YYYYMM is applicable if the time of data generation increases randomly rather than sequentially.

Routing method

- Calculate the hash value based on the year and months of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.
- The hash calculation based on the database and table shard key considers the data distribution among the ApsaraDB RDS for MySQL instances that connect to the instances.

Scenarios

- Databases and tables need to be partitioned by year and month, respectively.
- Data must be evenly distributed to each ApsaraDB RDS for MySQL instance that connects to the instance.
- The time of the shard key increases sequentially rather than randomly, and the data volume is relatively average from month to month. For example, the number of monthly journal logs increases every month, and the log data is not concentrated on the same ApsaraDB RDS for MySQL instance.

Precautions

- YYYYMM_OPT does not support distributing data from every month in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle over months (for example, a cycle exists between 2012-03 and 2013-03), data from the same month may be routed to the same database or table shard, depending on the actual number of table shards.

13.1.11.6.14. YYYYWEEK_OPT

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The version of the instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Optimizations

- Compared with YYYYWEEK, YYYYWEEK_OPT maintains the even distribution of data among ApsaraDB RDS for MySQL instances as the timeline increases. The effect is similar to YYYYMM_OPT.
- YYYYWEEK_OPT distributes data evenly to each ApsaraDB RDS for MySQL instance, helping to maximize the performance of each ApsaraDB RDS for MySQL instance.
- How to choose between YYYYWEEK and YYYYWEEK_OPT:
  - YYYYWEEK_OPT can be used to distribute data evenly to each ApsaraDB RDS for MySQL instance if the time of service data increases sequentially and the data volume does not differ much between time points.
  - YYYYWEEK is applicable if the time of data generation increases randomly rather than sequentially.

Routing method

- Calculate the hash value based on the year and weeks of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.
- The hash calculation based on the database and table shard key considers the data distribution among the ApsaraDB RDS for MySQL instances that connect to the instances.

Scenarios

- Databases and tables are partitioned by year and week, respectively.
- Data must be evenly distributed to each ApsaraDB RDS for MySQL instance that connects to the instance.
- The time of the shard key increases sequentially rather than randomly, and the data volume is relatively average from week to week. For example, the number of weekly journal logs increases every week, and the log data is not concentrated on the same ApsaraDB RDS for MySQL instance.

Precautions

- YYYYWEEK_OPT does not support distributing data from every week in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle over weeks (for example, a cycle exists between the first week of 2012 and the first week of 2013), data from the same week after a cycle may be routed to the same database shard or table shard, depending on the actual number of table shards.

13.1.11.6.15. YYYYDD_OPT

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The version of the instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Optimizations

- Compared with YYYYDD, YYYYDD_OPT maintains the even distribution of data among ApsaraDB RDS for MySQL instances as the timeline increases. The effect is similar to YYYYMM_OPT.
- YYYYDD_OPT distributes data evenly to each ApsaraDB RDS for MySQL instance, helping to maximize the performance of each ApsaraDB RDS for MySQL instance.
- How to choose between YYYYDD and YYYYDD_OPT:
  - YYYYDD_OPT can be used to distribute data evenly to each ApsaraDB RDS for MySQL instance if the time of service data generation increases sequentially and the data volume does not differ much between time points.
  - YYYYDD is applicable if the time of data generation increases randomly rather than sequentially.

Routing method

- Calculate the hash value based on the year and days of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.
- The hash calculation based on the database and table shard key considers the data distribution among the ApsaraDB RDS for MySQL instances that connect to the instances.

Scenarios

- Databases and tables need to be partitioned by year and by day, respectively.
- Data must be evenly distributed to each ApsaraDB RDS for MySQL instance that connects to the instance.
- The time of the shard key increases sequentially rather than randomly, and the data volume is relatively average from day to day. For example, the number of daily journal logs increases every day, and the log data is not concentrated on the same ApsaraDB RDS for MySQL instance.

Precautions

- YYYYDD_OPT does not support distributing data from every day in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle of a specific date (for example, a cycle exists between 2012-03-01 and 2013-03-01), data from the same date may be routed to the same database shard or table shard, depending on the actual number of table shards.

13.1.12. Automatic protection of important SQL statements

In Distributed Relational Database Service (DRDS), the data manipulation language (DML) statements are the same as MySQL statements.

We recommend that you include the shard key in the **SELECT** and **UPDATE** statements of DRDS. The **INSERT** statement of DRDS must include the shard key and a non-empty key value.

By default, DRDS disables full-table deletion and updating to avoid misoperation.

The following statements are prohibited by default:

- A DELETE statement without the WHERE or LIMIT condition
- An UPDATE statement without the WHERE or LIMIT condition

If you need to perform full-table deletion or update, you can temporarily skip this limit by using the following hint:

```
HINT: /! TDDL:FORBID_EXECUTE_DML_ALL=false*/
```

Examples

- Full-table deletion is intercepted by default.

```
mysql> delete from tt;
ERR-CODE: [TDDL-4620][ERR_FORBID_EXECUTE_DML_ALL] Forbid execute DELETE ALL or UPDATE ALL sql. Mor
e: [http://middleware.alibaba-inc.com/faq/faqByFaqCode.html?faqCode=TDDL-4620]
```

  The operation is successful if the following hint is added:

```
mysql> /! TDDL:FORBID_EXECUTE_DML_ALL=false*/delete from tt;
Query OK, 10 rows affected (0.21 sec)
```

- Full-table update is intercepted by default.

```
mysql> update tt set id = 1;
ERR-CODE: [TDDL-4620][ERR_FORBID_EXECUTE_DML_ALL] Forbid execute DELETE ALL or UPDATE ALL sql. Mor
e: [http://middleware.alibaba-inc.com/faq/faqByFaqCode.html?faqCode=TDDL-4620]
```

  The operation is successful if the following HINT is added:

```
mysql> /! TDDL:FORBID_EXECUTE_DML_ALL=false*/update tt set id = 1;
Query OK, 10 rows affected (0.21 sec)
```

- This limit does not apply to DELETE or UPDATE statements that contain the WHERE or LIMIT condition.

```
mysql> delete from tt where id = 1;
Query OK, 1 row affected (0.21 sec)
```

13.1.13. PolarDB-X sequence

13.1.13.1. Overview

A Distributed Relational Database Service (DRDS) sequence is a 64-digit number that corresponds to the signed BIGINT type in MySQL. It is used to create a globally unique and sequentially incremental numeric sequence, such as the values of primary key columns and unique index columns.

DRDS sequences are used in the following two ways:

- Explicit sequences are created and maintained by using sequence-specific data definition language (DDL) syntax and can be used independently. The sequence value can be acquired by using `select seq.nextval;`, in which `seq` indicates the sequence name.
- Implicit sequences are used to automatically fill in primary keys with AUTO_INCREMENT defined and are automatically maintained by DRDS.

> **Notice** DRDS creates implicit sequences only after AUTO_INCREMENT is defined for partitioned tables and broadcast tables. This is not the case for non-partition tables. The AUTO_INCREMENT value of a non-partition table is created by ApsaraDB RDS for MySQL.

Types and features of DRDS sequences

Currently, three types of DRDS sequences are supported.

Type (abbreviation)	Globally unique	Consecutive	Monotonically increasing	Monotonically increasing within the same connection	Non-single point	Data type	Readability
Group sequence (GROUP)	Yes	No	No	Yes	Yes	All integer types	High
Time-based sequence (TIME)	Yes	No	Monotonically increasing at the macro level and non-monotonically increasing at the micro level	Yes	Yes	Only BIGINT is supported	Low
Simple sequence (SIMPLE)	Yes	Yes	Yes	Yes	No	All integer types	High

Concepts:

- **Consecutive:** If the current value is n, the next value must be n + 1. If the next value is not n + 1, it is nonconsecutive.
- **Monotonically increasing:** If the current value is n, the next value must be a number greater than n.
- **Single point:** The risk of single point of failure exists.
- **Monotonically increasing at the macro level and non-monotonically increasing at the micro level:** An example of this is `1, 3, 2, 4, 5, 7, 6, 8, ...`

Group sequence (GROUP, used by default)

Features

A group sequence is a globally unique sequence with natural numeric values, which are not necessarily consecutive or monotonically increasing. If the sequence type is not specified, DRDS uses the group sequence type by default.

- **Advantages:** A group sequence is globally unique and provides excellent performance, preventing single point of failure.
- **Disadvantages:** A group sequence may contain nonconsecutive values, which may not necessarily start from the initial value and do not cycle.

Implementation

The values of a group sequence are created by multiple nodes to ensure high availability. The values in a segment are nonconsecutive if the values are not all used, such as in the case of disconnection.

Time-based sequence

Features

A time-based sequence consists of **a timestamp, node ID, and serial number**. It is globally unique and automatically increments at the macro level. Value updates are database-independent and not persistently stored in databases. Only names and types are stored in databases. This delivers good performance to time-based sequences, which create values like 776668092129345536, 776668098018148352, 776668111578333184, and 776668114812141568.

> Notice **Sequence values must be of the BIGINT type** when used in the auto-increment columns of tables.

- **Advantages:** Time-based sequences are globally unique with good performance.
- **Disadvantages:** The values of a time-based sequence are nonconsecutive. The START WITH, INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE parameters are invalid for time-based sequences.

Simple sequence

Features

Only simple sequences support the START WITH, INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE parameters.

- **Advantages:** Simple sequences are globally unique and monotonically increasing with consecutive values.
- **Disadvantages:** Simple sequences are prone to single point of failure, poor performance, and bottlenecks. Use them with caution.

Implementation

Each sequence value must be persistently stored.

Scenarios

Group sequences, time-based sequences, and simple sequences are globally unique and can be used in **primary key columns** and **unique index columns**.

- We recommend that you use **group sequences**.
- Use only simple sequences for services that strongly depend on consecutive sequence values. Pay attention to sequence performance.
- We recommend that you use time-based sequences if you have high requirements for sequence performance, the amount of data inserted to tables is small, and large sequence values are acceptable. Time-based sequences are CPU-bound with no requirements on computing lock, database dependence, or persistent storage.

The following example shows how to create a sequence with an initial value of 100000 and a step of 1.

- A **simple sequence** creates globally unique, consecutive, and monotonically increasing values, such as 100000, 100001, 100002, 100003, 100004, ..., 200000, 200001, 200002, 200003... The values of a simple sequence are persistently stored. Even after services are restarted upon a single point of failure, values are still created consecutively from the breakpoint. However, simple sequences have poor performance because each value is persistently stored once it is created.
- A **group sequence** may create values like 200001, 200002, 200003, 200004, 100001, 100002, 100003...

> Notice
>
> - The initial value of a group sequence is not necessarily the same as the START WITH value (which is 100000 in this example) but is invariably greater than this value. In this example, the initial value is 200001.
> - A group sequence is globally unique but may contain nonconsecutive values, which may occur when a node is faulty or the connection that only uses partial values is closed. The group sequence in this example contains nonconsecutive values because the values between 200004 and 100001 are missing.

- A **time-based sequence** may create values like 776668092129345536, 776668098018148352, 776668111578333184, 776668114812141568...

13.1.13.2. Explicit sequence usage

This topic describes how to use data definition language (DDL) statements to create, modify, delete, and query sequences and how to acquire the values of explicit sequences.

Create a sequence

Syntax:

```
CREATE [ GROUP | SIMPLE | TIME ] SEQUENCE <name>
[ START WITH <numeric value> ] [ INCREMENT BY <numeric value> ]
[ MAXVALUE <numeric value> ] [ CYCLE | NOCYCLE ]
```

Parameters:

Parameter	Description	Applicable To
START WITH	The initial sequence value. If it is not set, the default value is 1.	Simple sequence and group sequence
INCREMENT BY	The increment (or interval value or step) of each sequence increase. If it is not set, the default value is 1.	Simple sequence
MAXVALUE	The maximum sequence value. If it is not specified, the default value is the maximum value of the signed BIGINT type.	Simple sequence
CYCLE or NOCYCLE	Indicates whether to repeat the sequence value which starts from the value specified by START WITH after the sequence value reaches the maximum value. If it is not specified, the default value is NOCYCLE.	Simple sequence

> **Note**
>
> - If the sequence type is not specified, the group sequence type is used by default.
> - The INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE parameters are invalid for group sequences.
> - The START WITH, INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE parameters are invalid for time-based sequences.
> - Group sequences are nonconsecutive. The START WITH parameter only provides reference for group sequences. **The initial group sequence value is not necessarily the same as but is greater than the value of START WITH.**

Example 1: Create a group sequence.

- Method 1:

```
mysql> CREATE SEQUENCE seq1;
Query OK, 1 row affected (0.27 sec)
```

- Method 2:

```
mysql> CREATE GROUP SEQUENCE seq1;
Query OK, 1 row affected (0.27 sec)
```

Example 2: Create a time-based sequence.

```
mysql> CREATE TIME SEQUENCE seq1;
Query OK, 1 row affected (0.27 sec)
```

Example 3: Create a simple sequence with an initial value of 1000, step of 2, and maximum value of 99999999999, which does not repeat after increasing to the maximum value.

```
mysql> CREATE SIMPLE SEQUENCE seq2 START WITH 1000 INCREMENT BY 2 MAXVALUE 99999999999 NOCYCLE;
Query OK, 1 row affected (0.03 sec)
```

Modify a sequence

Distributed Relational Database Service (DRDS) allows you to modify sequences in the following ways:

- For simple sequences, change the values of START WITH, INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE.
- For group sequences, change the value of START WITH.
- Convert the sequence type to another.

Syntax:

```
ALTER SEQUENCE <name> [ CHANGE TO GROUP | SIMPLE | TIME ]
START WITH <numeric value> [ INCREMENT BY <numeric value> ]
[ MAXVALUE <numeric value> ] [ CYCLE | NOCYCLE ]
```

Parameters:

Parameter	Description	Applicable To
START WITH	The initial sequence value. If it is not set, the default value is 1.	Simple sequence and group sequence
INCREMENT BY	The increment (or interval value or step) of each sequence increase. If it is not set, the default value is 1.	Simple sequence
MAXVALUE	The maximum sequence value. If it is not specified, the default value is the maximum value of the signed BIGINT type.	Simple sequence
CYCLE or NOCYCLE	Indicates whether to repeat the sequence value which starts from the value specified by START WITH after the sequence value reaches the maximum value. If it is not specified, the default value is NOCYCLE.	Simple sequence

> **Note**
>
> - Group sequences are nonconsecutive. The START WITH parameter only provides reference for group sequences. **The initial group sequence value is not necessarily the same as but is greater than the value of START WITH.**
> - If you set START WITH when modifying a simple sequence, the START WITH value takes effect immediately. The following sequence value starts from the new START WITH value. For example, if you change the START WITH value to 200 when the sequence value increases to 100, the following sequence value starts from 200.
> - Before changing the START WITH value, you need to analyze the existing sequence values and the speed of creating sequence values to avoid conflicts. Do not change the START WITH value unless necessary.

Example: Change the initial value, step, and maximum value of the simple sequence named seq2 to 3000, 5, and 1000000 respectively, and set CYCLE.

```
mysql> ALTER SEQUENCE seq2 START WITH 3000 INCREMENT BY 5 MAXVALUE 1000000 CYCLE;
Query OK, 1 row affected (0.01 sec)
```

Convert the sequence type to another

- Use the `CHANGE TO <sequence_type>` clause of `ALTER SEQUENCE`.
- If the `CHANGE TO` clause of `ALTER SEQUENCE` is specified, add the `START WITH` parameter to prevent duplicate values. This parameter is optional if `CHANGE TO` is not specified.

Example: Convert a group sequence to a simple sequence.

```
mysql> ALTER SEQUENCE seq1 CHANGE TO SIMPLE START WITH 1000000;
Query OK, 1 row affected (0.02 sec)
```

Delete a sequence

Syntax:

```
DROP SEQUENCE <name>
```

Example:

```
mysql> DROP SEQUENCE seq3;
Query OK, 1 row affected (0.02 sec)
```

Query sequences

Syntax:

```
SHOW SEQUENCES
```

Example: The TYPE column lists the sequence types in the abbreviated form.

```
mysql> SHOW SEQUENCES;
+------------+---------------------+-------------+------------+---------------------+-------+-------
-+
| NAME       | VALUE               | INCREMENT_BY | START_WITH | MAX_VALUE           | CYCLE | TYPE
|
+------------+---------------------+-------------+------------+---------------------+-------+-------
-+
| AUTO_SEQ_1 | 91820513            | 1            | 91820200   | 9223372036854775807 | N     | SIMPLE
|
| AUTO_SEQ_4 | 91820200            | 2            | 1000       | 9223372036854775807 | Y     | SIMPLE
|
| seq_test   | N/A                 | N/A          | N/A        | N/A                 | N/A   | TIME
|
| AUTO_SEQ_2 | 100000              | N/A          | N/A        | N/A                 | N/A   | GROUP
|
| AUTO_SEQ_3 | 200000              | N/A          | N/A        | N/A                 | N/A   | GROUP
|
+------------+---------------------+-------------+------------+---------------------+-------+-------
-+
5 rows in set (0.01 sec)
```

Get the sequence value

Syntax:

```
< sequence name >.NEXTVAL
```

Example:

```
SELECT sample_seq.nextVal FROM dual;
+--------------------+
| SAMPLE_SEQ.NEXTVAL |
+--------------------+
|             101001 |
+--------------------+
1 row in set (0.04 sec)
```

You can also write SAMPLE_SEQ.nextVal as a value to the SQL statement:

```
mysql> INSERT INTO some_users (name,address,gmt_create,gmt_modified,intro) VALUES ('sun',SAMPLE_SEQ.n
extVal,now(),now(),'aa');
Query OK, 1 row affected (0.01 sec)
```

Note If you set the AUTO_INCREMENT parameter when creating a table, you do not need to specify an auto-increment column when running the INSERT statement. The auto-increment column is automatically maintained by DRDS.

Acquire the values of sequences in batches

Syntax:

```
SELECT < sequence name >.NEXTVAL FROM DUAL WHERE COUNT = < numeric value >
```

Example:

```
SELECT sample_seq.nextVal FROM dual WHERE count = 10;
+--------------------+
| SAMPLE_SEQ.NEXTVAL |
+--------------------+
|             101002 |
|             101003 |
|             101004 |
|             101005 |
|             101006|
|             101007 |
|             101008 |
|             101009 |
|             101010 |
|             101011 |
+--------------------+
10 rows in set (0.04 sec)
```

13.1.13.3. Implicit sequence usage

After AUTO_INCREMENT is set for a primary key, the primary key is automatically filled in by using a sequence which is maintained by Distributed Relational Database Service (DRDS).

CREATE TABLE

The standard CREATE TABLE syntax is extended to add the sequence type for auto-increment columns. If the type keyword is not specified, the default type is GROUP. The sequence names that are automatically created by DRDS and associated with tables are prefixed with AUTO_SEQ_ and suffixed with the table name.

```
CREATE TABLE <name> (
   <column> ... AUTO_INCREMENT [ BY GROUP | SIMPLE | TIME ],
   <column definition>,
   ...
) ... AUTO_INCREMENT=<start value>
```

SHOW CREATE TABLE

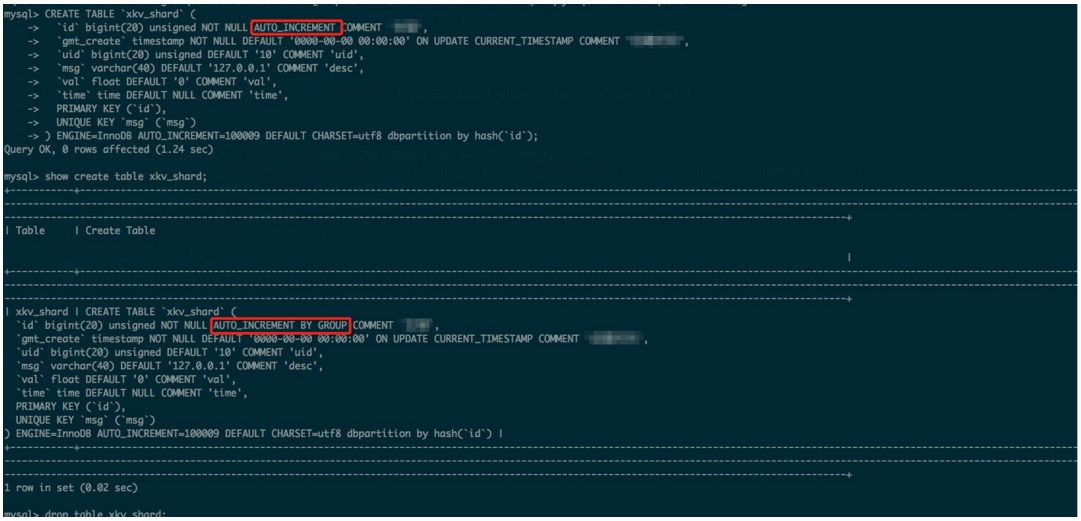
The sequence type is displayed for the auto-increment column of a table shard or broadcast table.

```
SHOW CREATE TABLE <name>
```

Examples

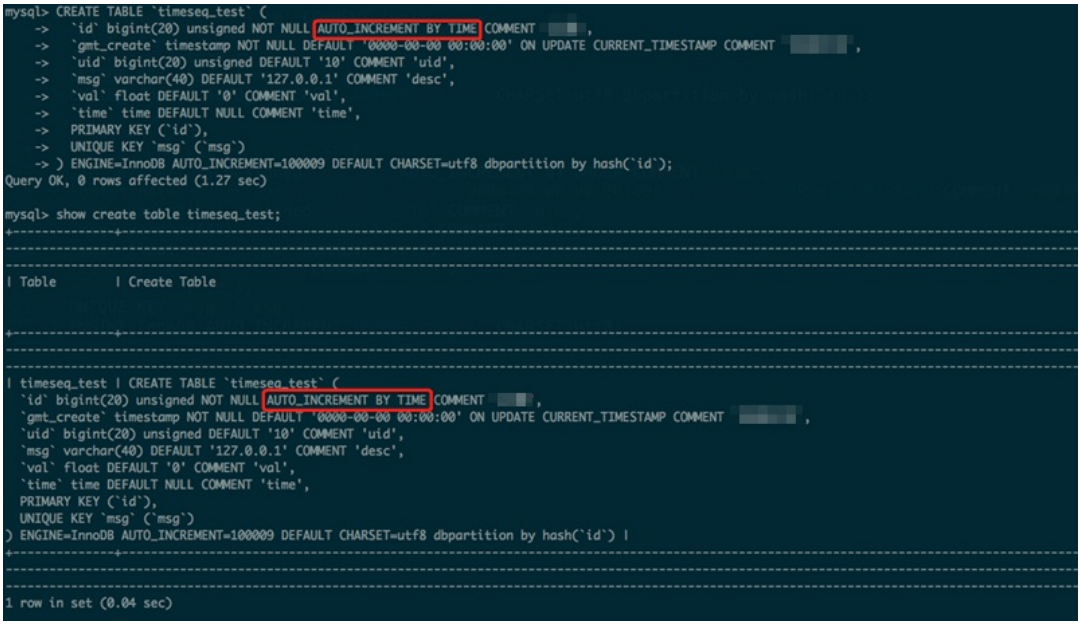
- If AUTO_INCREMENT is set but the sequence type is not specified when a table is created, the group sequence type is used by default.

  Example 1



- When creating a table, set AUTO_INCREMENT and specify a time-based sequence as the primary key value.

  Example 2



ALTER TABLE

Currently, **ALTER TABLE** cannot be used to change the sequence type but can be used to change the initial value. If you want to modify the data of the implicit sequence type in a table, run **SHOW SEQUENCES** to find the names and types of sequences and run **ALTER SEQUENCE** to modify the data.

```
ALTER TABLE <name> ... AUTO_INCREMENT=<start value>
```

Notice Exercise caution when changing the initial value of AUTO_INCREMENT after DRDS sequences are used. You need to analyze the existing sequence values and the speed of creating sequence values to avoid conflicts.

13.1.13.4. Limits and precautions for sequences

This topic describes the limits and precautions for sequences.

Limits and precautions

- When a time-based sequence is used in the auto-increment column of a table, the column must be of the BIGINT type.
- `START WITH` must be set when the sequence is changed to another type.
- When the `INSERT` statement is executed on a database in non-partition mode where only one ApsaraDB RDS for MySQL database is bound or on a database in partition mode that has only one table but no broadcast table, automatically optimizes and sends the statement, and bypasses the part of the optimizer that allocates the sequence value. In this case, `INSERT INTO ... VALUES (seq.nextval, ...)` is not supported. We recommend that you use the ApsaraDB RDS for MySQL auto-increment column feature instead.
- If the hint for a specific database shard is used by the `INSERT` statement such as `INSERT INTO ... VALUES ...` or `INSERT INTO … SELECT…` and the target table uses a sequence, bypasses the optimizer and directly sends the statement so that the sequence does not take effect. The target table creates an ID by using the auto-increment feature of the ApsaraDB RDS for MySQL table.
- The auto-increment ID allocation method for the same table must be kept consistent, which may be based on sequences or the auto-increment column of the ApsaraDB RDS for MySQL. If both of the two allocation methods are used for the same table, duplicate IDs may be created and making location difficult.

Troubleshoot primary key conflicts

Assume that data is directly written to ApsaraDB RDS for MySQL and that the related primary key value is not the sequence value created by . If automatically creates a primary key and writes it to the database, this primary key may conflict with that of the directly written data. This problem can be resolved as follows:

1. View the existing sequences by using the -specified SQL statement. The sequence prefixed with `AUTO_SEQ_` is an implicit sequence. This sequence is generated when a table is created with the `AUTO_INCREMENT` parameter.

```
mysql> SHOW SEQUENCES;
+-------------------------+-------+--------------+------------+-----------+-------+-------+
| NAME                    | VALUE | INCREMENT_BY | START_WITH | MAX_VALUE | CYCLE | TYPE  |
+-------------------------+-------+--------------+------------+-----------+-------+-------+
| AUTO_SEQ_timeseq_test   | N/A   | N/A          | N/A        | N/A       | N/A   | TIME  |
| AUTO_SEQ_xkv_shard_tbl1 | 0     | N/A          | N/A        | N/A       | N/A   | GROUP |
| AUTO_SEQ_xkv_shard      | 0     | N/A          | N/A        | N/A       | N/A   | GROUP |
+-------------------------+-------+--------------+------------+-----------+-------+-------+
3 rows in set (0.04 sec)
```

2. For example, if the t_item table contains conflicts and its primary key is ID, then retrieve the maximum primary key value of this table from :

```
mysql> SELECT MAX(id) FROM t_item;
+-----------+
| max(id)   |
+-----------+
| 8231 |
+-----------+
1 row in set (0.01 sec)
```

3. Update the related value in the sequence table to a value greater than 8231, such as 9000. Then, no error is returned for the auto-increment primary key created by the subsequent INSERT statement.

```
mysql> ALTER SEQUENCE AUTO_SEQ_USERS START WITH 9000;
Query OK, 1 row affected (0.01 sec)
```

13.1.14. Best practices

13.1.14.1. Select a shard key

A shard key is a field for database sharding and table sharding, which is used to create sharding rules during horizontal partitioning. partitions a logical table horizontally into the physical database shards on each ApsaraDB RDS for MySQL instance based on the shard key.

The primary principle of sharding is to identify the business logic-specific subject of data in a table as much as possible and confirm that most (or core) database operations are performed based on this subject. Then, use the subject-related field as the shard key to perform database sharding and table sharding.

The business logic-specific subject is related to business scenarios. The following typical scenarios include business logic-specific subjects that can be used as shard keys:

- User-oriented Internet applications are operated to meet user requirements. Users are the business logic-specific subject and the user-related field can be used as the shard key.
- Seller-oriented e-commerce applications are operated to meet seller requirements. Sellers are the business logic-specific subject and the seller-related field can be used as the shard key.
- Game-oriented applications are operated to meet gamer requirements. Gamers are the business logic-specific subject and the gamer-related field can be used as the shard key.
- Internet of Vehicles (IoV) applications are operated based on vehicle information. Vehicles are the business logic-specific subject and the vehicle-related field can be used as the shard key.
- Tax-oriented applications are operated based on taxpayer information to provide frontend services. Taxpayers are the business logic-specific subject and the taxpayer-related field can be used as the shard key.

In other scenarios, you can also use the appropriate subject of business logic as the shard key.

For example, in a seller-oriented e-commerce application, the following single table must be horizontally partitioned:

```
CREATE TABLE sample_order (
  id INT(11) NOT NULL,
  sellerId INT(11) NOT NULL,
  trade_id INT(11) NOT NULL,
  buyer_id INT(11) NOT NULL,
  buyer_nick VARCHAR(64) DEFAULT NULL,
  PRIMARY KEY (id)
)
```

The sellerId field is used as the shard key because seller is the business logic-specific subject. In the case of database sharding but no table sharding, the distributed data definition language (DDL) statement for table creation is as follows:

```
CREATE TABLE sample_order (
  id INT(11) NOT NULL,
  sellerId INT(11) NOT NULL,
  trade_id INT(11) NOT NULL,
  buyer_id INT(11) NOT NULL,
  buyer_nick VARCHAR(64) DEFAULT NULL,
  PRIMARY KEY (id)
) DBPARTITION BY HASH(sellerId)
```

If no business logic-specific subject can be used as the shard key, use the following methods to select an appropriate shard key:

- Determine the shard key based on the distribution and access of data. Distribute the data in a table to different physical database shards and table shards as evenly as possible. This method is applicable to scenarios with massive analytical queries, in which query concurrency stays at 1.
- Determine the shard key for database sharding and table sharding by combining fields of the numeric (string)

type and time type. This method is applicable to log retrieval.

For example, a log system records all user operations and needs to horizontally partition the following single log table:

```
CREATE TABLE user_log (
  userId INT(11) NOT NULL,
  name VARCHAR(64) NOT NULL,
  operation VARCHAR(128) DEFAULT NULL,
  actionDate DATE DEFAULT NULL
)
```

You can combine the user identifier with the time field to create a shard key for partitioning the table by week. The distributed DDL statement for table creation is as follows:

```
CREATE TABLE user_log (
  userId INT(11) NOT NULL,
  name VARCHAR(64) NOT NULL,
  operation VARCHAR(128) DEFAULT NULL,
  actionDate DATE DEFAULT NULL
) DBPARTITION BY HASH(userId) TBPARTITION BY WEEK(actionDate) TBPARTITIONS 7
```

For more information about shard key selection and table shard forms, see DDL statements.

Notice Avoid using hotspot data as the shard key if possible.

13.1.14.2. Select the number of shards

Distributed Relational Database Service (DRDS) supports horizontal partitioning of databases and tables. By default, eight physical database shards are created on an ApsaraDB for RDS instance, and one or more physical table shards can be created on each physical database shard. The number of table shards is also called the number of shards.

Generally, we recommend that each physical table shard contain no more than 5 million rows of data. Generally, you can estimate the data growth in one to two years. Divide the estimated total data size by the total number of physical database shards, and then divide the result by the recommended maximum data size of 5 million, to obtain the number of physical table shards to be created on each physical database shard:

```
Number of physical table shards in each physical database shard = CEILING(Estimated total data size/(
Number of ApsaraDB for RDS instances x 8)/5,000,000)
```

Therefore, when the calculated number of physical table shards is equal to 1, only database sharding needs to be performed, that is, a physical table shard is created in each physical database shard. If the calculation result is greater than 1, we recommend that you perform both database sharding and table sharding, that is, there are multiple physical table shards in each physical database shard.

For example, if a user estimates that the total data size of a table will be about 0.1 billion rows two years later and the user has four ApsaraDB for RDS instances, then according to the preceding formula:

```
Number of physical table shards in each physical database shard = CEILING(100,000,000/(4 x 8)/5,000,0
00) = CEILING(0.625) = 1
```

If the result is 1, only database sharding is needed, that is, one physical table shard is created in each physical database shard.

If only one ApsaraDB for RDS instance is used in the preceding example, the formula is as follows:

```
Number of physical table shards in each physical database shard = CEILING(100,000,000/(1 x 8)/5,000,000) = CEILING(2.5) = 3
```

If the result is 3, we recommend that you create three physical table shards in each physical database shard.

13.1.14.3. Basic concepts of SQL optimization

Distributed Relational Database Service (DRDS) is an efficient and stable distributed relational database service that processes distributed relational computing. DRDS optimizes SQL statements differently from single-instance relational databases such as MySQL. DRDS focuses on the network I/O overheads in a distributed environment and pushes SQL operations down to the underlying database shards (such as databases on ApsaraDB for RDS instances) for execution, thereby reducing the network I/O overheads and improving the SQL execution efficiency.

DRDS provides commands for obtaining the SQL execution information to help SQL optimization, for example, EXPLAIN commands for obtaining SQL execution plans and TRACE commands for obtaining SQL execution processes and overheads. This topic describes the basic concepts and common commands related to SQL optimization in DRDS.

Execution plan

An SQL execution plan (or execution plan) is a set of ordered operation steps generated to access data. In DRDS, the execution plan is divided into the execution plan at the DRDS layer and the execution plan at the ApsaraDB for RDS layer. Execution plan analysis is an effective way to optimize SQL statements. Through execution plan analysis, you can know whether DRDS or ApsaraDB for RDS has generated optimal execution plans for SQL statements and whether further optimization can be made.

During SQL statement execution, based on the basic information of the SQL statement and related tables, the DRDS optimizer determines on which the database shards the SQL statement should be executed, and the specific SQL statement form, execution policy, and data merging and computing policy for each database shard. This process optimizes SQL statement execution and generates execution plans at the DRDS layer. The execution plan at the ApsaraDB for RDS layer is the native MySQL execution plan.

DRDS provides a set of EXPLAIN commands to display execution plans at different levels or with different levels of detail.

The following table briefly describes the EXPLAIN commands in DRDS.

EXPLAIN command description

Command	Description	Example
EXPLAIN { SQL }	Displays the summary execution plan of SQL statements at the DRDS layer, including the database shards on which the SQL statement is run, physical statements, and general parameters.	EXPLAIN SELECT * FROM test
EXPLAIN DETAIL { SQL }	Displays the detailed execution plans of SQL statements at the DRDS layer, including the statement type, concurrency, returned field information, physical tables, and database groups.	EXPLAIN DETAIL SELECT * FROM test
EXPLAIN EXECUTE { SQL }	Displays the execution plan of the underlying ApsaraDB for RDS instance, which is equivalent to the EXPLAIN statement of MySQL.	EXPLAIN EXECUTE SELECT * FROM test

Execution plans at the DRDS layer

The following table describes the fields in the results returned for a DRDS-layer execution plan.

Description of fields in DRDS-layer execution plans

Field	Description
GROUP_NAME	The name of the DRDS database shard. The suffix identifies the specific database shard. The value is consistent with the result of the SHOW NODE command.
SQL	The SQL statement run on this database shard.
PARAMS	The SQL statement parameters used when DRDS communicates with ApsaraDB for RDS over the Prepare protocol.

The SQL field can be in two forms:

1. If an SQL statement does not contain the following parts, the execution plan is displayed as an SQL statement:
   - Aggregate function involving multiple database shards.
   - Distributed JOIN queries involving multiple shards.
   - Complex subqueries.

   Example:

```
mysql> EXPLAIN SELECT * FROM test;
+-----------------------------------------------+-----------------------------------------------+----
----+
| GROUP_NAME                                    | SQL                                           | PAR
AMS |
+-----------------------------------------------+-----------------------------------------------+----
----+
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0000_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}
|
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0001_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}
|
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0002_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}
|
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0003_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}
|
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0004_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}
|
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0005_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}
|
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0006_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}
|
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0007_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}
|
+-----------------------------------------------+-----------------------------------------------+----
----+
8 rows in set (0.04 sec)
```

   The group names displayed in the GROUP_NAME field can be found in the returned result of SHOW NODE:

```
mysql> SHOW NODE;
+----+-----------------------------------------------+------------------+-----------------+-----
---------------+--------------------+
| ID | NAME                                          | MASTER_READ_COUNT | SLAVE_READ_COUNT | MAST
ER_READ_PERCENT | SLAVE_READ_PERCENT |
+----+-----------------------------------------------+------------------+-----------------+-----
---------------+--------------------+
| 0  | TESTDB_1478746391548CDTCTESTDB_OXGJ_0000_RDS |               69 |               0 | 100%
| 0%                 |
| 1  | TESTDB_1478746391548CDTCTESTDB_OXGJ_0001_RDS |               45 |               0 | 100%
| 0%                 |
| 2  | TESTDB_1478746391548CDTCTESTDB_OXGJ_0002_RDS |               30 |               0 | 100%
| 0%                 |
| 3  | TESTDB_1478746391548CDTCTESTDB_OXGJ_0003_RDS |               29 |               0 | 100%
| 0%                 |
| 4  | TESTDB_1478746391548CDTCTESTDB_OXGJ_0004_RDS |               11 |               0 | 100%
| 0%                 |
| 5  | TESTDB_1478746391548CDTCTESTDB_OXGJ_0005_RDS |                1 |               0 | 100%
| 0%                 |
| 6  | TESTDB_1478746391548CDTCTESTDB_OXGJ_0006_RDS |                8 |               0 | 100%
| 0%                 |
| 7  | TESTDB_1478746391548CDTCTESTDB_OXGJ_0007_RDS |               50 |               0 | 100%
| 0%                 |
+----+-----------------------------------------------+------------------+-----------------+-----
---------------+--------------------+
8 rows in set (0.10 sec)
```

2. Execution plans that cannot be expressed by SQL statements can be expressed by DRDS in custom format.

   Example:

```
mysql> EXPLAIN DETAIL SELECT COUNT(*) FROM test;
+-----------------------------------------------+-----------------------------------+--------+
| GROUP_NAME                                    | SQL                               | PARAMS |
+-----------------------------------------------+-----------------------------------+--------+
| TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0000_RDS | Merge as test
    queryConcurrency:GROUP_CONCURRENT
    columns:[count(*)]
    executeOn: TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0000_RDS
        Query from test as test
            queryConcurrency:SEQUENTIAL
            columns:[count(*)]
            tableName:test
            executeOn: TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0000_RDS
        Query from test as test
            queryConcurrency:SEQUENTIAL
            columns:[count(*)]
            tableName:test
            executeOn: TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0001_RDS
        ... ...
        Query from test as test
            queryConcurrency:SEQUENTIAL
            columns:[count(*)]
            tableName:test
            executeOn: TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0007_RDS
| NULL   |
+-----------------------------------------------+-----------------------------------+--------+
1 row in set (0.00 sec)
```

executeOn in the SQL statement field indicates the database shard on which the SQL statement is run. DRDS finally merges the results returned by the database shards.

Execution plans at the ApsaraDB for RDS layer

The execution plans at the ApsaraDB for RDS layer are the same as the native MySQL execution plan. For more information, see official MySQL documentation.

One DRDS logical table may consist of multiple shards distributed in different database shards. Therefore, you can view the execution plans at the ApsaraDB for RDS layer in multiple ways.

1. View the execution plan of an ApsaraDB for RDS database shard.

   If the query condition contains a shard key, directly run the EXPLAIN EXECUTE command to display the execution plan on the corresponding database shard. Example:

```
mysql> EXPLAIN EXECUTE SELECT * FROM test WHERE c1 = 1;
+----+-------------+-------+-------+---------------+---------+---------+-------+------+-------+
| id | select_type | table | type  | possible_keys | key     | key_len | ref   | rows | Extra |
+----+-------------+-------+-------+---------------+---------+---------+-------+------+-------+
|  1 | SIMPLE      | test  | const | PRIMARY       | PRIMARY | 4       | const |    1 | NULL  |
+----+-------------+-------+-------+---------------+---------+---------+-------+------+-------+
1 row in set (0.04 sec)
```

   Notice If an SQL statement involves multiple shards (for example, its condition does not contain a shard key), the EXPLAIN EXECUTE command returns an execution plan on a random ApsaraDB for RDS database shard.

   To view the execution plan of an SQL statement on a specified database shard, you can use the Hint method. Example:

```
mysql> /! TDDL:node='TESTDB_1478746391548CDTCTESTDB_OXGJ_0000_RDS'*/EXPLAIN SELECT * FROM test;
+----+-------------+-------+------+---------------+------+---------+------+------+-------+
| id | select_type | table | type | possible_keys | key  | key_len | ref  | rows | Extra |
+----+-------------+-------+------+---------------+------+---------+------+------+-------+
|  1 | SIMPLE      | test  | ALL  | NULL          | NULL | NULL    | NULL |    2 | NULL  |
+----+-------------+-------+------+---------------+------+---------+------+------+-------+
1 row in set (0.04 sec)
```

2. View the execution plans of all ApsaraDB for RDS database shards.

   You can run SCAN Hint to display the execution plans of SQL statements on all database shards:

```
mysql> /! TDDL:scan='test'*/EXPLAIN SELECT * FROM test;
+----+-------------+-------+------+---------------+------+---------+------+------+-------+
| id | select_type | table | type | possible_keys | key  | key_len | ref  | rows | Extra |
+----+-------------+-------+------+---------------+------+---------+------+------+-------+
|  1 | SIMPLE      | test  | ALL  | NULL          | NULL | NULL    | NULL |    2 | NULL  |
|  1 | SIMPLE      | test  | ALL  | NULL          | NULL | NULL    | NULL |    3 | NULL  |
+----+-------------+-------+------+---------------+------+---------+------+------+-------+
2 rows in set (0.08 sec)
```

   Notice

   i. In Hint mode, DRDS only replaces the table names in case of database or table sharding, and then directly sends the logical SQL statement to ApsaraDB for RDS for execution. It will not process the result.

   ii. Execution plans obtained by using an EXPLAIN command are generated by static analysis and are not actually executed in databases.

TRACE command

The TRACE command in DRDS can track the SQL execution process and the overheads in each stage. It can be used together with the execution plan to facilitate SQL statement optimization.

The TRACE command contains two related commands: TRACE and SHOW TRACE, which must be used together.

13.1.14.4. SQL optimization methods

13.1.14.4.1. Overview

This topic describes the SQL optimization principles and methods for optimizing different types of SQL statements in .

Basic principles of SQL optimization

In , SQL computing that can be performed by ApsaraDB RDS for MySQL instances is called push-down computing. Push-down computing reduces data transmission, decreases overheads at the network layer and layer, and improves the execution efficiency of SQL statements.

Therefore, the basic principle for SQL statement optimization in is as follows: Push down as many computations as possible to ApsaraDB RDS for MySQL instances.

Push-down computations include:

- JOIN connections
- Filter conditions, such as `WHERE` or `HAVING` conditions
- Aggregate computing, such as `COUNT` and `GROUP BY`
- Sorting, such as `ORDER BY`
- Deduplication, such as `DISTINCT`
- Function computing, such as the `NOW()` function
- Subqueries

> **Notice** The preceding list only describes possible forms of push-down computations. It does not mean that all clauses or conditions or combinations of clauses or conditions can be pushed down for computing.

SQL statements of different types and containing different conditions can be optimized in different ways. The following uses some examples to describe how to optimize SQL statements:

- Single-table SQL optimization
  - Filter condition optimization
  - Optimization of the number of returned rows for a query
  - Grouping and sorting optimization
- JOIN query optimization
  - Optimization of push-down JOIN queries
  - Optimization of distributed JOIN queries
- Subquery optimization

13.1.14.4.2. Single-table SQL optimization

Single-table SQL optimization must follow the following principles:

- Make sure that the SQL statements contain the shard key.
- Use an equivalence condition for the shard key whenever possible.

- If the shard key is an IN condition, the number of values after IN should be as small as possible (far fewer than the number of shards, and remain unchanged as the business grows).
- If SQL statements do not contain a shard key, use only one of DISTINCT, GROUP BY, and ORDER BY in the same SQL statement.

Filter condition optimization

DRDS partitions data horizontally by the shard key. Therefore, the filter condition must contain the shard key as much as possible so that DRDS can push queries down to specific database shards based on the shard key value, to avoid scanning all tables in the DRDS instance.

For example, the shard key of the test table is c1. If the filter condition does not contain this shard key, full table scan is performed:

```
mysql> SELECT * FROM test WHERE c2 = 2;
+----+----+
| c1 | c2 |
+----+----+
|  2 |  2 |
+----+----+
1 row in set (0.05 sec)
```

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT * FROM test WHERE c2 = 2;
+-----------------------------------------------+-----------------------------------------------
-----------------+--------+
| GROUP_NAME                                    | SQL
| PARAMS |
+-----------------------------------------------+-----------------------------------------------
-----------------+--------+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0004_RDS | select `test`.`c1`,`test`.`c2` from `test` where (
`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0007_RDS | select `test`.`c1`,`test`.`c2` from `test` where (
`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0005_RDS | select `test`.`c1`,`test`.`c2` from `test` where (
`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `test`.`c1`,`test`.`c2` from `test` where (
`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0003_RDS | select `test`.`c1`,`test`.`c2` from `test` where (
`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0006_RDS | select `test`.`c1`,`test`.`c2` from `test` where (
`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0000_RDS | select `test`.`c1`,`test`.`c2` from `test` where (
`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0001_RDS | select `test`.`c1`,`test`.`c2` from `test` where (
`test`.`c2` = 2) | {}     |
+-----------------------------------------------+-----------------------------------------------
-----------------+--------+
8 rows in set (0.00 sec)
```

The smaller the value range of the filter condition containing the shard key, the faster the DRDS query speed.

For example, in the query on the test table, the filter condition contains the value range of the shard key c1:

```
mysql> SELECT * FROM test WHERE c1 > 1 AND c1 < 4;
+----+----+
| c1 | c2 |
+----+----+
|  2 |  2 |
|  3 |  3 |
+----+----+
2 rows in set (0.04 sec)
```

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT * FROM test WHERE c1 > 1 AND c1 < 4;
+-----------------------------------------------+-----------------------------------------------------------
-----------------------------------------+--------+
| GROUP_NAME                                    | SQL
| PARAMS |
+-----------------------------------------------+-----------------------------------------------------------
-----------------------------------------+--------+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `test`.`c1`,`test`.`c2` from `test` where (
(`test`.`c1` > 1) AND (`test`.`c1` < 4)) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0003_RDS | select `test`.`c1`,`test`.`c2` from `test` where (
(`test`.`c1` > 1) AND (`test`.`c1` < 4)) | {}     |
+-----------------------------------------------+-----------------------------------------------------------
-----------------------------------------+--------+
2 rows in set (0.00 sec)
```

The equivalence condition is executed faster than the range condition. For example:

```
mysql> SELECT * FROM test WHERE c1 = 2;
+----+----+
| c1 | c2 |
+----+----+
|  2 |  2 |
+----+----+
1 row in set (0.03 sec)
```

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT * FROM test WHERE c1 = 2;
+-----------------------------------------------+-----------------------------------------------------------
-----------------+--------+
| GROUP_NAME                                    | SQL
| PARAMS |
+-----------------------------------------------+-----------------------------------------------------------
-----------------+--------+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `test`.`c1`,`test`.`c2` from `test` where (
`test`.`c1` = 2) | {}     |
+-----------------------------------------------+-----------------------------------------------------------
-----------------+--------+
1 row in set (0.00 sec)
```

In addition, if you want to insert data into a table shard, the inserted field must contain a shard key.

For example, data inserted into the test table contains the shard key c1:

```
mysql> INSERT INTO test(c1,c2) VALUES(8,8);
Query OK, 1 row affected (0.07 sec)
```

Optimization of the number of returned rows for a query

When DRDS runs a query containing **LIMIT** [*offset*,] *row_count*, DRDS actually reads records before *offset* in order and directly discards them. In this way, when the value of *offset* is large, the query is slow even if the value of *row_count* is small. Take the following SQL statement as an example:

```
SELECT *
FROM sample_order
ORDER BY sample_order.id
LIMIT 10000, 2
```

Although only the 10000th and 10001st records are returned, it takes about 12 seconds to run the SQL statement because DRDS actually reads 10,002 records.

```
mysql> SELECT * FROM sample_order ORDER BY sample_order.id LIMIT 10000,2;
+--------------+------------+--------------+--------------+------------+
| id           | sellerId   | trade_id     | buyer_id     | buyer_nick |
+--------------+------------+--------------+--------------+------------+
| 242012755468 | 1711939506 | 242012755467 | 244148116334 | zhangsan   |
| 242012759093 | 1711939506 | 242012759092 | 244148138304 | wangwu     |
+--------------+------------+--------------+--------------+------------+
2 rows in set (11.93 sec)
```

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT * FROM sample_order ORDER BY sample_order.id LIMIT 10000,2;
+------------------+-------------+------------+
| GROUP_NAME       | SQL         | PARAMS     |
+------------------+-------------+------------+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0004_RDS | select `sample_order`.`id`,`sample_order`.`sellerI
d`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order
` order by `sample_order`.`id` asc  limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0007_RDS | select `sample_order`.`id`,`sample_order`.`sellerI
d`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order
` order by `sample_order`.`id` asc  limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0005_RDS | select `sample_order`.`id`,`sample_order`.`sellerI
d`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order
` order by `sample_order`.`id` asc  limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `sample_order`.`id`,`sample_order`.`sellerI
d`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order
` order by `sample_order`.`id` asc  limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0003_RDS | select `sample_order`.`id`,`sample_order`.`sellerI
d`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order
` order by `sample_order`.`id` asc  limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0006_RDS | select `sample_order`.`id`,`sample_order`.`sellerI
d`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order
` order by `sample_order`.`id` asc  limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0000_RDS | select `sample_order`.`id`,`sample_order`.`sellerI
d`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order
` order by `sample_order`.`id` asc  limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0001_RDS | select `sample_order`.`id`,`sample_order`.`sellerI
d`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order
` order by `sample_order`.`id` asc  limit 0,10002 | {}     |
+------------------+-------------+------------+
8 rows in set (0.01 sec)
```

To optimize the preceding SQL statement, find the ID set, and use IN to match the actual records. The modified SQL query is as follows:

```
SELECT *
FROM sample_order o
WHERE o.id IN (
      SELECT id
      FROM sample_order
      ORDER BY id
      LIMIT 10000, 2 )
```

The purpose is to cache IDs in the memory first (on the premise that the number of IDs is small). If the shard key of the sample_order table is an ID, DRDS can also push down such an IN query to different database shards through rule-based calculation, avoiding full table scan and unnecessary network I/O. Check the result of the rewritten SQL query:

```
mysql> SELECT *
    -> FROM sample_order o
    -> WHERE o.id IN ( SELECT id FROM sample_order ORDER BY id LIMIT 10000,2 );
+--------------+------------+--------------+--------------+------------+
| id           | sellerId   | trade_id     | buyer_id     | buyer_nick |
+--------------+------------+--------------+--------------+------------+
| 242012755468 | 1711939506 | 242012755467 | 244148116334 | zhangsan   |
| 242012759093 | 1711939506 | 242012759092 | 244148138304 | wangwu     |
+--------------+------------+--------------+--------------+------------+
2 rows in set (1.08 sec)
```

The execution time is significantly reduced from 12 seconds to 1.08 seconds.

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT *
    -> FROM sample_order o
    -> WHERE o.id IN ( SELECT id FROM sample_order ORDER BY id LIMIT 10000,2 );
+-----------------------------------------------+-----------------------------------------------------
-------------------------------------------------------------------------------+---------+
| GROUP_NAME                                    | SQL
| PARAMS |
+-----------------------------------------------+-----------------------------------------------------
-------------------------------------------------------------------------------+---------+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `o`.`id`,`o`.`sellerId`,`o`.`trade_id`,`o`.
`buyer_id`,`o`.`buyer_nick` from `sample_order` `o` where (`o`.`id` IN (10002)) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0001_RDS | select `o`.`id`,`o`.`sellerId`,`o`.`trade_id`,`o`.
`buyer_id`,`o`.`buyer_nick` from `sample_order` `o` where (`o`.`id` IN (10001)) | {}     |
+-----------------------------------------------+-----------------------------------------------------
-------------------------------------------------------------------------------+---------+
2 rows in set (0.03 sec)
```

Grouping and sorting optimization

In DRDS, if an SQL query must use DISTINCT, GROUP BY, and ORDER BY at the same time, try to ensure that the fields after DISTINCT, GROUP BY, and ORDER BY are the same and the fields are shard keys. In this way, only a small amount of data is returned for the SQL query. This minimizes the network bandwidth consumed by distributed queries and removes the need to retrieve a large amount of data and sort the data in a temporary table, thereby maximizing the system performance.

13.1.14.4.3. JOIN query optimization

JOIN queries in DRDS are classified into push-down JOIN queries and non-push-down JOIN queries (distributed JOIN queries). The optimization policies for these two types of JOIN queries are different.

Optimize push-down JOIN queries

Push-down JOIN queries are classified into the following types:

- JOIN queries between single tables (non-partition tables).
- The tables involved in the JOIN query contain the shard key in the filter condition and use the same sharding algorithm (that is, the data calculated by the sharding algorithm is distributed to the same shard).
- Tables involved in the JOIN query use the shard key as the JOIN condition and use the same sharding algorithm.
- JOIN query between broadcast tables (or small table broadcast) and table shards.

In DRDS, optimize JOIN queries to push-down JOIN queries that can be executed on database shards.

Take a JOIN query between a broadcast table and table shards as an example. The broadcast table is used as the JOIN driving table (the left table in the JOIN query is called the driving table). The DRDS broadcast table stores the same data in each database shard. When the broadcast table is used as the JOIN driving table, the JOIN query between this broadcast table and table shards can be converted into single-database JOIN queries and combined for computing to improve query performance.

For example, a JOIN query is performed on the following three tables, among which the sample_area table is the broadcast table, and the sample_item and sample_buyer tables are table shards. The query execution time is about 15s:

```
mysql> SELECT sample_area.name
    -> FROM sample_item i JOIN sample_buyer b ON i.sellerId = b.sellerId JOIN sample_area a ON b.prov
ince = a.id
    -> WHERE a.id < 110107
    -> LIMIT 0, 10;
+------+
| name |
+------+
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
+------+
10 rows in set (14.88 sec)
```

If you adjust the JOIN query order and move the broadcast table to the farthest left as the JOIN driving table, the JOIN query is pushed down to a single database shard in the DRDS instance:

```
mysql> SELECT sample_area.name
    -> FROM sample_area a JOIN sample_buyer b ON b.province = a.id JOIN sample_item i ON i.sellerId =
b.sellerId
    -> WHERE a.id < 110107
    -> LIMIT 0, 10;
+------+
| name |
+------+
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
|  BJ  |
+------+
10 rows in set (0.04 sec)
```

The query execution time decreases from 15 seconds to 0.04 seconds, which is a significant improvement to the query performance.

> **Notice** The broadcast table achieves data consistency through the synchronization mechanism on database shards, with a latency of several seconds.

Optimize distributed JOIN queries

If a JOIN query cannot be pushed down (that is, the JOIN condition and filter condition do not contain the shard key), DRDS must complete part of the computing in the query. Such a query is a distributed JOIN query.

Tables in a distributed JOIN query are classified into two types based on the data size:

- Small table: A table that contains a small amount of data (less than 100 data records or less data than other tables) that is involved in JOIN computing after filtering.
- Large table: A table that contains a large amount of data (more than 100 data records or more data than other tables) that is involved in JOIN computing after filtering.

In most cases, Nested Loop and its derived algorithms are used in JOIN computing at the DRDS layer. If sorting is required for JOIN queries, the Sort Merge algorithm is used. When the Nested Loop algorithm is used, a smaller data size in the left table in a JOIN query indicates a smaller number of queries performed by DRDS on the right table. If the right table has indexes or contains a small amount of data, the JOIN query is even faster. Therefore, in DRDS, the left table of a distributed JOIN query is called the driving table. To optimize a distributed JOIN query, use a small table as the driving table and set as many filter conditions as possible for the driving table.

Take the following distributed JOIN query as an example. The query takes about 24 seconds:

```
mysql> SELECT t.title, t.price
    -> FROM sample_order o,
    ->      ( SELECT * FROM sample_item i WHERE i.id = 242002396687 ) t
    -> WHERE t.source_id = o.source_item_id AND o.sellerId < 1733635660;
+----------------------------------+--------+
| title                            | price  |
+----------------------------------|--------+
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
+----------------------------------+--------+
10 rows in set (23.79 sec)
```

The preceding JOIN query is an INNER JOIN query, with the actual size of the intermediate data involved in JOIN computing unknown. In this case, perform COUNT() on the o table and t table respectively to obtain the actual data size.

For the o table, o.sellerId < 1733635660 in the WHERE condition is only related to the o table. Then, extract and add it to the COUNT() condition of the o table. The following query result is returned:

```
mysql> SELECT COUNT(*) FROM sample_order o WHERE o.sellerId < 1733635660;
+----------+
| count(*) |
+----------+
|   504018 |
+----------+
1 row in set (0.10 sec)
```

The intermediate result of the o table contains about 500,000 records. Similarly, the t table is a subquery, which can be extracted directly for the COUNT() query:

```
mysql> SELECT COUNT(*) FROM sample_item i WHERE i.id = 242002396687;
+----------+
| count(*) |
+----------+
|        1 |
+----------+
1 row in set (0.01 sec)
```

The intermediate result of the t table contains only one record. Therefore, the o table is a large table and the t table is a small table. Use the small table as the driving table of the distributed JOIN query. The result of the adjusted JOIN query is as follows:

```
mysql> SELECT t.title, t.price
    -> FROM ( SELECT * FROM sample_item i WHERE i.id = 242002396687 ) t,
    ->      sample_order o
    -> WHERE  t.source_id = o.source_item_id AND o.sellerId < 1733635660;
+----------------------------------+--------+
| title                            | price  |
+----------------------------------|--------+
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
+----------------------------------+--------+
10 rows in set (0.15 sec)
```

The query execution time decreases from about 24 seconds to 0.15 seconds, with the query performance significantly improved.

13.1.14.4.4. Subquery optimization

When optimizing an SQL query that contains subqueries, push the subqueries down to database shards as much as possible to reduce the computing workload at the DRDS layer.

For this purpose, you can try two optimization methods:

- Rewrite subqueries into multi-table JOIN queries, and optimize the JOIN queries.
- Use the shard key in the JOIN condition or filter condition so that DRDS can push the query down to a specific database shard to avoid full table scan.

The following subquery is used as an example:

```
SELECT o. *
FROM sample_order o
WHERE NOT EXISTS
     (SELECT sellerId FROM sample_seller s WHERE o.sellerId = s.id)
```

Rewrite the subquery into a JOIN query query:

```
SELECT o. *
FROM sample_order o LEFT JOIN sample_seller s ON o.sellerId = s.id
WHERE s.id IS NULL
```

13.1.14.5. Select connection pools for an application

A database connection pool is used to manage database connections in a centralized manner, so as to improve application performance and reduce database loads.

- **Reuse resources**: Connections can be reused to avoid high performance overheads caused by frequent connection creation and release. Resource reuse can also improve the system stability.

- **Improve the system response efficiency**: After the connection initialization is complete, all requests can directly use the existing connections, which avoids the overheads of connection initialization and release and improves the system response efficiency.
- **Avoid connection leakage**: The connection pool forcibly revokes connections based on the preset de-allocation policy to avoid connection resource leakage.

We recommend that you use a connection pool to connect applications and databases for service operations. For Java programs, we recommend that you use the Druid connection pool.

The following is an example of standard Druid Spring configuration:

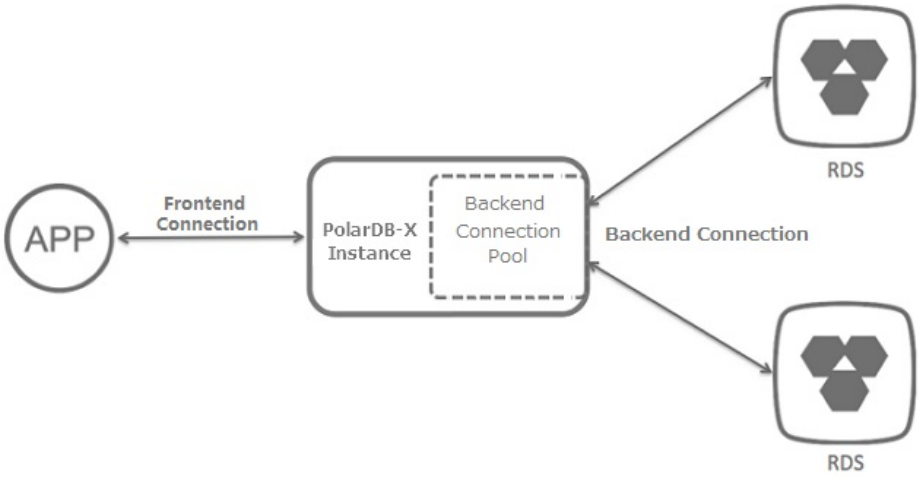
```
    <bean id="dataSource" class="com.alibaba.druid.pool.DruidDataSource" init-method="init" destroy-m
ethod="close">
        <property name="driverClassName" value="com.mysql.jdbc.Driver" />
        <! -- Basic attributes URL, user, and password -->
        <property name="url" value="jdbc:mysql://ip:port/db? autoReconnect=true&amp;rewriteBatchedSta
tements=true&amp;socketTimeout=30000&amp;connectTimeout=3000" />
        <property name="username" value="root" />
        <property name="password" value="123456" />
        <! -- Configure the initial size, minimum value, and maximum value -->
        <property name="maxActive" value="20" />
        <property name="initialSize" value="3" />
        <property name="minIdle" value="3" />
        <! -- maxWait indicates the time-out period for obtaining the connection -->
        <property name="maxWait" value="60000" />
        <! -- timeBetweenEvictionRunsMillis indicates the interval for detecting idle connections to
be closed, in milliseconds -->
        <property name="timeBetweenEvictionRunsMillis" value="60000" />
        <! -- minEvictableIdleTimeMillis indicates the minimum idle time of a connection in the conne
ction pool, in milliseconds-->
        <property name="minEvictableIdleTimeMillis" value="300000" />
        <! -- SQL statement used to check whether connections are available -->
        <property name="validationQuery" value="SELECT 'z'" />
        <! -- Whether to enable idle connection check -->
        <property name="testWhileIdle" value="true" />
        <! -- Whether to check the connection status before obtaining a connection -->
        <property name="testOnBorrow" value="false" />
        <! -- Whether to check the connection status before releasing a connection -->
        <property name="testOnReturn" value="false" />
    </bean>
```

13.1.14.6. Connections to PolarDB-X instances

When an application connects to a instance for operation, there are two types of connections from the perspective of the instance:

- Frontend connection: a connection established by an application to the logical database in the instance.
- Backend connection: a connection established by a node in a instance to a physical database in a backend ApsaraDB RDS for MySQL instance.

  instance connection diagram



Frontend connection

Theoretically, the number of frontend connections is limited by the available memory size and the number of network connections to the nodes of the instance. However, in actual application scenarios, when an application connects to a instance, the nodes of the PolarDB-X instance usually manage a limited number of connections to perform requested operations, and do not maintain a large number of concurrent persistent connections (for example, tens of thousands of concurrent persistent connections). Therefore, the number of frontend connections that a instance can accept can be considered to be unlimited.

Considering that the number of frontend connections is unlimited and a large number of idle connections are allowed, this method applies to scenarios where a large number of servers are deployed and need to maintain their connections to the instance.

> **Note** Although the number of frontend connections is considered as unlimited, operation requests obtained from frontend connections are actually executed by internal threads of the instance through backend connections. Due to the limited number of internal threads and backend connections, the total number of concurrent requests that can be processed by the instance is limited.

Backend connection

Each node of a instance creates a backend connection pool to automatically manage and maintain the backend connections to the physical databases in the ApsaraDB RDS for MySQL instance. Therefore, the maximum number of connections in the backend connection pool of a instance is directly related to the maximum number of connections supported by the ApsaraDB RDS for MySQL instance. You can use the following formula to calculate the maximum number of connections in the backend connection pool of a instance:

```
Maximum number of connections in a backend connection pool of a  instance = FLOOR (Maximum number of connections in an ApsaraDB RDS for MySQL instance/Number of physical database shards in the ApsaraDB RDS for MySQL instance/Number of nodes on the  instance)
```

For example, a user has purchased an ApsaraDB RDS for MySQL instance and a instance of the following types:

- The ApsaraDB RDS for MySQL instance has eight physical database shards, four cores, and 16 GB memory, supporting a maximum number of 4,000 connections.
- The dedicated instance has 32 cores and 32 GB memory, with each node having two cores and 2 GB memory (that is, the instance has 16 nodes).

You can use the following formula to calculate the maximum number of connections in the backend connection pool of the instance:

```
Maximum number of connections in the backend connection pool of the  instance = FLOOR (4000/8/16) = FLOOR (31.25) = 31
```

> **Note**
>
> - The calculation result of the preceding formula is the maximum number of connections in the backend connection pool of the instance. In actual use, to reduce the connection pressure on the ApsaraDB RDS for MySQL instance, the instance adjusts the maximum number of connections in the backend connection pool to make it smaller than the upper limit.
> - We recommend that you create databases in a instance on a dedicated ApsaraDB RDS for MySQL instance. Do not create databases for other applications or instances on the dedicated ApsaraDB RDS for MySQL instance.

Relationship between frontend and backend connections

After an application establishes frontend connections to a instance and sends SQL statement execution requests, the nodes process the requests asynchronously and obtain backend connections through the internal backend connection pool, and then run optimized SQL statements on one or more physical databases.

nodes process requests asynchronously and frontend connections are not bound to backend connections. Therefore, a small number of backend connections can process a large number of requests for short transactions and simple queries from many concurrent frontend connections. This is why you need to focus on the queries per second (QPS) in , rather than the number of concurrent connections.

Although the number of frontend connections is considered to be unlimited, the maximum number of connections maintained in the backend connection pool of a instance is limited. For more information, see "Backend connections." Therefore, note the following points in actual application scenarios:

- Avoid long or large transactions in applications. These transactions occupy many or even all backend connections when they are not committed or rolled back for a long time, which reduces the overall concurrent processing capability and increases the response time (RT).
- Monitor and optimize or remove slow SQL queries run in the instance, to prevent them from occupying too many backend connections. Otherwise, the instance or the ApsaraDB RDS for MySQL instance is under greater processing pressure, which may lead to reduced concurrent processing capability, increased RT, or higher SQL execution failure rate due to execution timeout. For troubleshooting and optimization of slow SQL queries, see Troubleshoot slow SQL statements in PolarDB-X and Overview.
- Under normal use of connections and execution of queries, if the maximum number of connections in the backend connection pool of the instance is reached, contact Customer Services for assistance.

13.1.14.7. Perform instance upgrade

Database performance can be measured by the response time (RT) and queries per second (QPS). RT reflects the performance of a single SQL statement. This type of performance problem can be solved through SQL optimization. upgrade expands the capacity to improve performance, and is suitable for database access services with low latency and high QPS.

The performance of a instance depends on the performance of and ApsaraDB RDS for MySQL. Insufficient performance of any or ApsaraDB RDS for MySQL node can create a bottleneck in the overall performance. This topic describes how to observe the performance metrics of a instance and upgrade the PolarDB-X instance to solve the performance bottleneck. For more information about how to determine the performance of an ApsaraDB RDS for MySQL instance and upgrade the ApsaraDB RDS for MySQL instance, see the ApsaraDB RDS for MySQL documentation.

Determine the performance bottleneck of a instance

The QPS and CPU performance of a instance are in positive correlation. When a instance encounters a performance bottleneck, the CPU utilization of the PolarDB-X instance remains high.

Observe the CPU utilization

1. On the **Basic Information** page of the PolarDB-X instance, choose **Monitoring and Alerts > Instance Monitoring** from the left-side navigation pane.
2. On the Instance Monitoring page, select a monitoring dimension and the corresponding metrics to view details.

If the CPU utilization **exceeds 90%** or **remains above 80%**, the PolarDB-X instance faces a performance bottleneck. If there is no bottleneck for the ApsaraDB RDS for MySQL instance, the current instance specifications cannot meet the QPS performance requirements of the business. In this case, the PolarDB-X instance needs to be upgraded.

For more performance-related service monitoring scenarios and methods for configuring the CPU utilization alert.

Upgrade

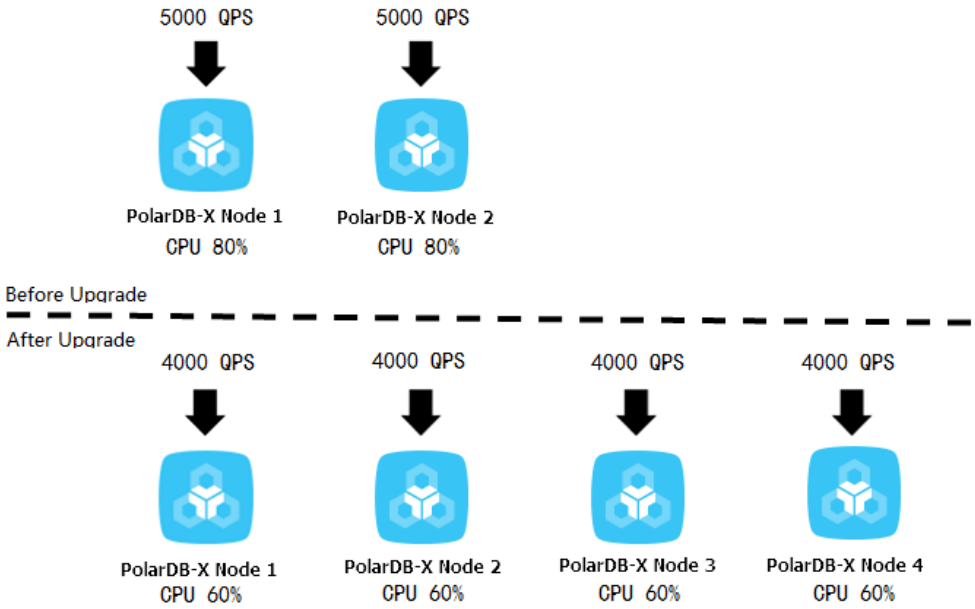
QPS is an important metric for determining whether the instance specifications can meet the business requirements. Each type of instance specifications corresponds to a reference QPS value.

Some special SQL statements require more computing (such as temporary table sorting and aggregate computing) in . In this case, the QPS supported by each instance is lower than the standard value in its type.

upgrade improves the processing performance of a PolarDB-X instance by adding nodes to share the QPS. As nodes are stateless, this upgrade method linearly improves the performance of instances.

For example, service A requires QPS of about 15 thousand. The current instance has a 4-core virtual CPU (vCPU), 4 GB memory, and two nodes, supporting QPS of only 10 thousand. After finding that the CPU utilization of the instance remains high, we upgraded the instance to 8-core vCPU and 8 GB memory, with each node handling about 4,000 QPS. Then, the performance meets service requirements, and the CPU utilization also drops to a reasonable level, as shown in the following figure.

upgrade



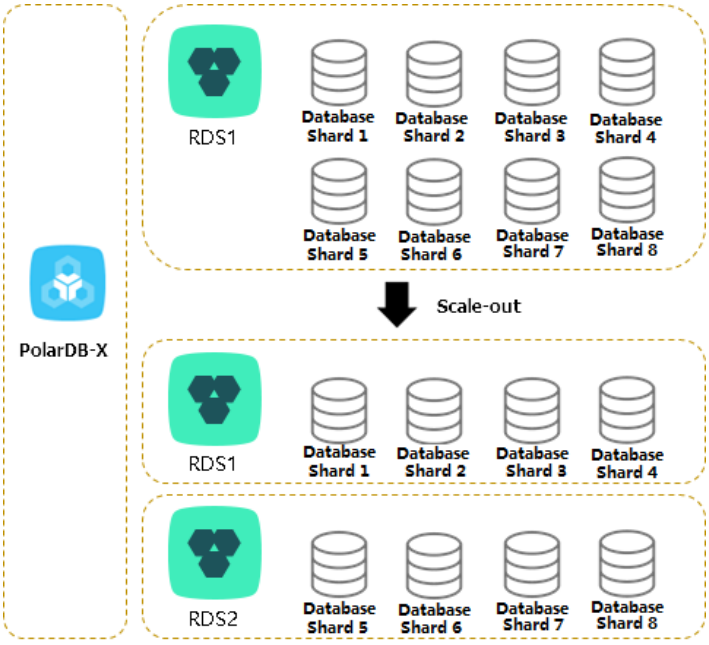
For more information about how to upgrade a PolarDB-X instance, see Change specifications.

13.1.14.8. Perform scale-out

In , smooth scale-out improves the overall performance by increasing the number of ApsaraDB RDS for MySQL instances. You can increase the number of ApsaraDB RDS for MySQL instances through smooth scale-out to increase the database capacity when the following conditions are met: 1. The input/output operations per second (IOPS), CPU utilization, disk space, and other metrics of the ApsaraDB RDS for MySQL instance reach their bottlenecks. 2. The bottlenecks cannot be removed through SQL optimization or ApsaraDB RDS for MySQL upgrade (for example, the disk has been upgraded to the top configuration).

smooth scale-out reduces the pressure on the original ApsaraDB RDS for MySQL instance by migrating database shards to the new ApsaraDB RDS for MySQL instance. For example, before scale-out, all the eight databases are deployed in one ApsaraDB RDS for MySQL instance. After scale-out, the eight databases are deployed in two ApsaraDB RDS for MySQL instances, and the pressure on a single ApsaraDB RDS for MySQL instance is significantly reduced, as shown in the following figure.

scale-out



After multiple scale-out operations, if the number of ApsaraDB RDS for MySQL instances is equal to the number of database shards, you need to create another instance and ApsaraDB RDS for MySQL databases with the expected capacity, and then migrate data to further increase the data capacity. This process is complex. We recommend that you consider the data growth expected in the next two to three years and plan the number of ApsaraDB RDS for MySQL instances properly when creating a database.

Determine whether scale-out is required

You can determine whether smooth scale-out is required based on three ApsaraDB RDS for MySQL metrics: IOPS, CPU utilization, and disk space. You can view these metrics in the ApsaraDB RDS for MySQL console. For more information, see the ApsaraDB RDS for MySQL documentation.

IOPS and CPU utilization

If you find that the IOPS or CPU utilization remains above 80% for a long time or you frequently receive alerts, follow these steps:

1. Optimize SQL statements. Generally, you can solve the high CPU utilization problem by this method.
2. If the problem persists, upgrade the ApsaraDB RDS for MySQL instance. For more information, see the ApsaraDB RDS for MySQL documentation.
3. When the CPU utilization or IOPS exceeds the threshold, you can set read-only databases to share the load on the primary database. However, read/write splitting affects read consistency. For more information, see the Read/write splitting documentation.
4. If the problem persists, scale out the instance.

Disk space

ApsaraDB RDS for MySQL has the following types of disk space:

1. Data space: the space occupied by data. The space usage continues increasing as more data is inserted. We recommend that you keep the remaining disk space above 30%.
2. System file space: the space occupied by shared tables and error log files.
3. Binary log file space: the space occupied by binary logs generated during database operation. The more update transactions there are, the larger the occupied space is.

Whether scale-out is required depends on the data space. When the data space is about to or expected to exceed the disk capacity, you can distribute the data to the databases on multiple ApsaraDB RDS for MySQL instances through scale-out.

Scale-out risks and precautions

scale-out consists of four steps: **configuration > migration > switchover > cleanup**. For more information, see the Perform smooth scale-out documentation.

Note the following points before scale-out:

- To reduce the pressure of read operations on the source ApsaraDB RDS for MySQL instance, perform scale-out when the load on the source ApsaraDB RDS for MySQL instance is low.
- During scale-out, do not submit data definition language (DDL) tasks in the console or connect to the instance to directly run DDL SQL statements. Otherwise, the scale-out task may fail.
- Scale-out requires that the source database table have a primary key. If the source database does not have a primary key, add one first.
- During scale-out, the read and write traffic is switched to the new ApsaraDB RDS for MySQL instance. The switchover process takes three to five minutes. We recommend that you perform a switchover during off-peak hours.
- Scale-out does not affect the instance before the switchover. Therefore, you can cancel the scale-out through rollback before the switchover.
- Scale-out creates pressure on databases. We recommend that you perform this operation during off-peak hours.

13.1.14.9. Troubleshoot slow SQL statements in DRDS

13.1.14.9.1. Details about a low SQL statement

defines an SQL statement that takes more than 1 second to run as a slow SQL statement. Slow SQL statements in are classified into slow logical SQL statements and slow physical SQL statements. In , an SQL statement is run step by step on and ApsaraDB RDS for MySQL nodes. Large execution loss on any node will result in slow SQL statements.

- Slow logical SQL statements are slow SQL statements sent by an application to .
- Slow physical SQL statements are slow SQL statements sent by to ApsaraDB RDS for MySQL.

Syntax

```
SHOW FULL {SLOW | PHYSICAL_SLOW} [WHERE where_condition]
                                 [ORDER BY col_name [ASC | DESC], ...]
                                 [LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

Description

The `SHOW FULL SLOW` command shows slow logical SQL statements, that is, SQL statements sent by an application to .

The result set of the `SHOW FULL SLOW` command contains the following columns:

- TRACE_ID: the unique identifier of the SQL statement. A logical SQL statement and the physical SQL statements generated by the logical SQL statement have the same TRACE_ID. The TRACE_ID is also sent as a comment to ApsaraDB RDS for MySQL.
- HOST: the IP address of the client that sends the SQL statement.

  > **Notice** The client IP address may not be obtained when the network type is Virtual Private Cloud (VPC).

- START_TIME: the time when starts running the SQL statement.
- EXECUTE_TIME: the time consumed by to run the SQL statement.
- AFFECT_ROW: the number of records returned or the number of rows affected by the SQL statement.
- SQL: the statement that is run.

The `SHOW FULL PHYSICAL_SLOW` command shows the slow physical SQL statements, that is, SQL statements sent by to ApsaraDB RDS for MySQL.

The result set of `SHOW FULL PHYSICAL_SLOW` contains the following columns:

- TRACE_ID: the unique identifier of the SQL statement. A logical SQL statement and the physical SQL statements generated by the logical SQL statement have the same TRACE_ID. The TRACE_ID is also sent as a comment to ApsaraDB RDS for MySQL.
- GROUP_NAME: the name of a database group. Grouping aims to manage multiple groups of databases with identical data, such as the primary and secondary databases after data replication through ApsaraDB RDS for MySQL, which are mainly used for read/write splitting and primary/secondary switchover.
- DBKEY_NAME: the name of the database shard on which the SQL statement is run.
- START_TIME: the time when starts running the SQL statement.
- EXECUTE_TIME: the time consumed by to run the SQL statement.
- SQL_EXECUTE_TIME: the time consumed by to call ApsaraDB RDS for MySQL to run this SQL statement.
- GETLOCK_CONNECTION_TIME: the time that takes to get connections from the connection pool. If the value is large, the ApsaraDB RDS for MySQL connections have been exhausted. This is typically due to a large number of slow SQL statements. You can log on to the corresponding ApsaraDB RDS for MySQL instance and run SHOW PROCESSLIST for troubleshooting.
- CREATE_CONNECTION_TIME: the time consumed by to establish a connection to ApsaraDB RDS for MySQL. If the value is large, it is largely because the ApsaraDB RDS for MySQL instance is overloaded or faulty.
- AFFECT_ROW: the number of records returned or the number of rows affected by the SQL statement.
- SQL: the statement that is run.

Example 1

The following example describes how to locate the execution of a slow SQL statement on and between and ApsaraDB RDS for MySQL.

1. You can use certain conditions, such as the execution time and SQL string match, to obtain the specified slow SQL statement:

```
mysql> show full slow where `SQL` like '%select sleep(50)%';
+-----------------+-----------+-------------------------+--------------+------------+------------
------+
| TRACE_ID        | HOST      | START_TIME              | EXECUTE_TIME | AFFECT_ROW | SQL

----------+-------------------------+------------+------------------+
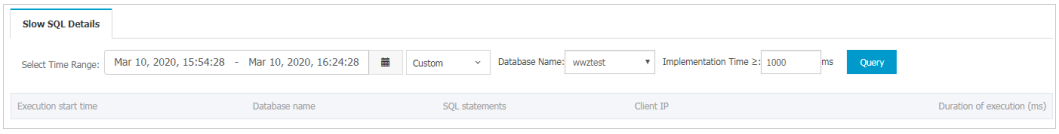
1 row in set (0.01 sec)
```

3. In the SQL statement details and slow SQL statement records of the ApsaraDB RDS for MySQL instance, you can query the execution information of this SQL statement on the ApsaraDB RDS for MySQL instance based on TRACE_ID.

   Slow query logs



Example 2

This example describes how to locate the original SQL statement in based on the slow SQL statement located in ApsaraDB RDS for MySQL.

1. Based on the slow SQL query log in ApsaraDB RDS for MySQL, TRACE_ID of the slow SQL statement is ae0e55660c00000.
2. Based on the TRACE_ID obtained in Step 1, run `SHOW FULL PHYSICAL_SLOW` to obtain the physical execution information of this SQL statement.

```
mysql> show full physical_slow where trace_id = 'ae0e55660c00000';
+-----------------+-----------------------------------------------------+-------------------------
----------------------+-------------------------+--------------+-------------------+--------------
-----------+-------------------------+------------+------------------+
| TRACE_ID        | GROUP_NAME                                          | DBKEY_NAME
| START_TIME              | EXECUTE_TIME | SQL_EXECUTE_TIME | GETLOCK_CONNECTION_TIME | CREATE_CO
NNECTION_TIME | AFFECT_ROW | SQL              |
+-----------------+-----------------------------------------------------+-------------------------
----------------------+-------------------------+--------------+-------------------+--------------
-----------+-------------------------+------------+------------------+
| ae0e55660c00000 | PRIV_TEST_1489167306631PJAFPRIV_TEST_APKK_0000_RDS | rdso6g5b6206sdq832ow_pri
v_test_apkk_0000_nfup | 2017-03-29 19:27:37.308 |        10003 |            10001 |
0 |                     0 |          1 | select sleep(10) |
+-----------------+-----------------------------------------------------+-------------------------
----------------------+-------------------------+--------------+-------------------+--------------
-----------+-------------------------+------------+------------------+
1 row in set (0.02 sec)
```

13.1.14.9.2. Locate slow SQL statements

Generally, you can locate a slow SQL statement in two ways: Obtain historical information about slow SQL statements from slow SQL statement records, or run `SHOW PROCESSLIST` to display the real-time execution information about slow SQL statements.

You can troubleshoot slow SQL statements as follows:

1. Locate slow SQL statements.
2. Locate nodes with performance loss.
3. Troubleshoot the performance loss.

> **Note** During troubleshooting, we recommend that you use the MySQL command line `mysql -hIP -PPORT -uUSER -pPASSWORD -c` to create the connection. Be sure to add `-c` to prevent the MySQL client from filtering out the comments (default operation) and therefore affecting the execution of HINT.

- View slow SQL statement records

  Run the following command to query top 10 slow SQL statements. This command can query logical SQL statements in . One logical SQL statement corresponds to SQL statements of one or more databases or tables of the ApsaraDB RDS for MySQL instance. For more information, see Details about a low SQL statement.

```
mysql> SHOW SLOW limit 10;
+-----------------+--------------+-------------------------+--------------+------------+----------
-----------------------------------------------------+
| TRACE_ID        | HOST         | START_TIME              | EXECUTE_TIME | AFFECT_ROW | SQL
|
+-----------------+--------------+-------------------------+--------------+------------+----------
-----------------------------------------------------+
| ac3133132801001 | xx.xxx.xx.97 | 2017-03-06 15:48:32.330 |       900392 |         -1 | select de
tail_url, sum(price) from t_item group by detail_url;  |
......
+-----------------+--------------+-------------------------+--------------+------------+----------
-----------------------------------------------------+
10 rows in set (0.01 sec)
```

- View real-time SQL execution information

If the execution of an SQL statement is slow in the current server, run **SHOW PROCESSLIST** to view the real-time SQL execution information in the current database. The value in the TIME column indicates how long the current SQL statement has been run.

```
mysql> SHOW PROCESSLIST WHERE COMMAND ! = 'Sleep';
+---------------+-----------+--------------------+-------------+---------+------------------------
-----------------------------------------------+-----------------------------------------------------
-------------------------------------------------+-----------+---------------+-----------+
| ID            | USER      | DB                 | COMMAND     | TIME    | STATE
| INFO
| ROWS_SENT | ROWS_EXAMINED | ROWS_READ |
+---------------+-----------+--------------------+-------------+---------+------------------------
-----------------------------------------------+-----------------------------------------------------
-------------------------------------------------+-----------+---------------+-----------+
| 0-0-352724126 | ifisibhk0 | test_123_wvvp_0000 | Query       |     13  | Sending data
| /*DRDS /42.120.74.88/ac47e5a72801000/ */select `t_item`.`detail_url`,SUM(`t_item`.`price`) from
`t_i |      NULL |          NULL |      NULL |
| 0-0-352864311 | cowxhthg0 | NULL               | Binlog Dump |     17  | Master has sent all bin
log to slave; waiting for binlog to be updated | NULL
|      NULL |          NULL |      NULL |
| 0-0-402714795 | ifisibhk0 | test_123_wvvp_0005 | Alter       |     114 | Sending data
| /*DRDS /42.120.74.88/ac47e5a72801000/ */ALTER TABLE `Persons` ADD `Birthday` date
|      NULL |          NULL |      NULL |
......
+---------------+-----------+--------------------+-------------+---------+------------------------
-----------------------------------------------+-----------------------------------------------------
-------------------------------------------------+-----------+---------------+-----------+
12 rows in set (0.03 sec)
```

The following describes each column:

- ID: the ID of the connection.
- USER: the user name of the database shard in which this SQL statement is run.
- DB: the specified database. If no database is specified, the value is NULL.
- COMMAND: the type of the command being executed. SLEEP indicates an idle connection. For more information about other commands, see MySQL thread information documentation.
- TIME: the elapsed execution time of the SQL statement, in seconds.
- STATE: the current execution status. For more information, see MySQL thread status documentation.
- INFO: the SQL statement being executed. The SQL statement may be too long to be displayed completely. You can derive the complete SQL statement based on information such as service parameters.

In the current example, the following slow SQL statement is identified:

```
ALTER TABLE `Persons` ADD `Birthday` date
```

13.1.14.9.3. Locate nodes with performance loss

When you locate a slow SQL statement in slow SQL statement records or real-time SQL execution information, you can run the TRACE command to trace the running time of the SQL statement in and ApsaraDB RDS for MySQL to locate the bottleneck.

The TRACE command actually runs the SQL statement, records the time consumed on all nodes, and returns the execution result. For more information about TRACE and other control commands, see Help statements.

> **Note** The TRACE command needs to maintain the context information of the connection. Some GUI clients may use connection pools, which results in command exceptions. Therefore, we recommend that you use the MySQL command line to run the TRACE command.

Run the following command for the identified slow SQL statement:

```
mysql> trace select detail_url, sum(distinct price) from t_item group by detail_url;
    +---------------+---------------+
    | detail_url    | sum(price)    |
    +---------------+---------------+
    | www.xxx.com   | 1084326800.00 |
    | www.xx1.com   | 1084326800.00 |
    | www.xx2.com   | 1084326800.00 |
    | www.xx3.com   | 1084326800.00 |
    | www.xx4.com   | 1084326800.00 |
    | www.xx5.com   | 1084326800.00 |
    ......
    +---------------+---------------+
    1 row in set (7 min 2.72 sec)
```

After the TRACE command is run, run SHOW TRACE to view the result. You can identify the bottleneck of the slow SQL statement based on the time consumption of each component.

```
 mysql> SHOW TRACE;
    +------+------------+--------------+-------------------------------------------------------------------+--
----------------------------------------------+---------------+--------------------------+------+------
----------------------------------------------------------------------------------------------------------
-----------------------------------+--------+
    | ID   | TIMESTAMP  | TYPE         | GROUP_NAME                                                        | D

    11 rows in set (0.01 sec)
```

In the returned results of SHOW TRACE, you can determine which node has a long execution time based on the values (in milliseconds) in the TIME_COST column. You can also see the corresponding GROUP_NAME (that is, the or ApsaraDB RDS for MySQL node) and the STATEMENT column information (that is, the SQL statement being executed). By checking whether the value of GROUP_NAME is , you can determine whether the slow node exists in or ApsaraDB RDS for MySQL.

According to the preceding results, the Merge Sorted action on the node and the TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0005_RDS node of ApsaraDB RDS for MySQL take a lot of time.

13.1.14.9.4. Troubleshoot the performance loss

Slow nodes may exist on the or ApsaraDB RDS for MySQL instance. Troubleshoot the fault accordingly after the cause is determined.

Solution for slow nodes

When the `GROUP_NAME` of a slow node is in the instance, check whether time-consuming computing operations such as Merge Sorted, Temp Table Merge, and Aggregate exist during SQL statement execution. If so, rectify it. For more information, see Overview.

Solution for slow ApsaraDB RDS for MySQL nodes

When the slow node is on the ApsaraDB RDS for MySQL instance, check the execution plan of this SQL statement on the ApsaraDB RDS for MySQL instance.

In , you can run `/! TDDL:node={GROUP_NAME}*/ EXPLAIN` to check the SQL execution plan of an ApsaraDB RDS for MySQL instance. The execution plan displays the SQL execution process information, including inter-table association and index information.

The detailed process is as follows:

1. Based on `GROUP_NAME`, assemble the HINT: `/! TDDL:node='TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0005_RDS'*/`.
2. Combine the assembled HINT and the statement prefixed by EXPLAIN to form a new SQL statement and run it. The EXPLAIN command does not actually run. It only displays the execution plan of the SQL statement.

The following example describes how to query the execution plan of the identified slow node.

```
    mysql> /! TDDL:node='TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0005_RDS'*/ EXPLAIN  select
`t_item`.`detail_url`,SUM(distinct `t_item`.`price`) from `t_item` group by `t_item`.`detail_url` ord
er by `t_item`.`detail_url` asc;
    +----+-------------+--------+------+---------------+-----+---------+-----+---------+-----------
--------------------+
    | id | select_type | table  | type | possible_keys | key | key_len | ref | rows    | Extra
|
    +----+-------------+--------+------+---------------+-----+---------+-----+---------+-----------
--------------------+
    |  1 | SIMPLE      | t_item | ALL  | NULL          |NULL | NULL    | NULL| 1322263 | Using tempor
ary; Using filesort |
    +----+-------------+--------+------+---------------+-----+---------+-----+---------+-----------
--------------------+
    1 row in set (0.01 sec)
```

When the preceding SQL statement is run in ApsaraDB RDS for MySQL, the message `Using temporary; Using filesort` is returned. It indicates that low SQL statement execution is caused by improper use of the index. In this case, you can correct the index and run the SQL statement again.

13.1.14.10. Handle DDL exceptions

When you run any data definition language (DDL) commands of , PolarDB-X performs the corresponding DDL operation on all table shards.

Failures can be divided into two types:

1. A DDL statement fails to be executed in a database shard. DDL execution failure in any database shard may result in inconsistent table shard structures.
2. The system does not respond for a long time after a DDL statement is executed. When you perform a DDL statement on a large table, the system may make no response for a long time due to the long execution time of the DDL statement in a database shard.

Execution failures in database shards may occur for various reasons. For example, the table you want to create already exists, the column you want to add already exists, or the disk space is insufficient.

No response for a long time is generally caused by the long execution time of a DDL statement in a database shard. Taking ApsaraDB RDS for MySQL as an example, the DDL execution time depends mostly on whether the operation is an in-place (directly modifying the source table) or copy (copying data in the table) operation. An in-place operation only requires modification of metadata, while a copy operation reconstructs the whole table and also involves log and buffer operations.

To determine whether a DDL operation is an in-place or copy operation, you can view the returned value of "rows affected" after the operation is completed.

Example:

- Change the default value of a column (this operation is very fast and does not affect the table data at all):

```
Query OK, 0 rows affected (0.07 sec)
```

- Add an index (this operation takes some time, but "0 rows affected" indicates that the table data is not replicated):

```
Query OK, 0 rows affected (21.42 sec)
```

- Change the data type of column (this operation takes a long time and reconstructs all data rows in the table):

```
Query OK, 1671168 rows affected (1 min 35.54 sec)
```

Therefore, before executing a DDL operation on a large table, perform the following steps to determine whether the operation is a fast or slow operation:

1. Copy the table structure to generate a cloned table.
2. Insert some data.
3. Perform the DDL operation on the cloned table.
4. Check whether the value of "rows affected" is 0 after the operation is completed. A non-zero value means that this operation reconstructs the entire table. In this case, you need to perform this operation in off-peak hours.

Solution for failures

DDL operations distribute all SQL statements to all database shards for parallel execution. Execution failure on any database shard does not affect the execution on other database shards. In addition, provides the CHECK TABLE command to check the structure consistency of the table shards. Therefore, failed DDL operations can be performed again, and errors reported on database shards on which the operations have been executed do not affect the execution on other database shards. Make sure that all table shards ultimately have the same structure.

Procedure for handling DDL operation failures

1. Run the **CHECK TABLE** command to check the table structure. If the returned result contains only one row and the status is normal, **the table statuses are consistent**. In this case, go to Step 2. Otherwise, go to Step 3.
2. Run the **SHOW CREATE TABLE** command to check the table structure. If the displayed table structure is the same as the expected structure after the DDL statement is run, the DDL statement is run. Otherwise, go to Step 3.
3. Run the **SHOW PROCESSLIST** command to check the statuses of all SQL statements being executed. If any ongoing DDL operations are detected, wait until these operations are completed, and then perform Steps 1 and 2 to check the table structure. Otherwise, go to Step 4.
4. Perform the DDL operation again on . If the **Lock conflict** error is reported, go to Step 5. Otherwise, go to Step 3.
5. Run the **RELEASE DBLOCK** command to release the DDL operation lock, and then go to Step 4.

The procedure is as follows:

1. Check the table structure consistency

   Run the CHECK TABLE command to check the table structure. When the returned result contains only one row and the displayed status is OK, **the table structures are consistent**.

   > **Notice** If no result is returned after you run CHECK TABLE, retry by using the CLI.

```
mysql> check table `xxxx`;
+----------------------------+-------+----------+----------+
| TABLE                      | OP    | MSG_TYPE | MSG_TEXT |
+----------------------------+-------+----------+----------+
| TDDL5_APP.xxxx             | check | status   | OK       |
+----------------------------+-------+----------+----------+
1 row in set (0.05 sec)
```

2. Check the table structure

Run the SHOW CREATE TABLE command to check the table structure. If **table structures are consistent** and **correct**, the DDL statement has been run.

```
mysql> show create table `xxxx`;
+---------+-----------------------------------------------------------------------------------------------
----------------------------+
| Table   | Create Table
|
+---------+-----------------------------------------------------------------------------------------------

PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8 dbpartition by hash(`id`) tbpartition by hash(`id`) tbpartit
ions 3                      |
+---------+-----------------------------------------------------------------------------------------------
----------------------------+
1 row in set (0.05 sec)
```

3. Check the SQL statements being executed.

   If some DDL statement executions are slow and no response is received for a long time, you can run the SHOW PROCESSLIST command to check the status of all SQL statements being executed.

```
mysql> SHOW PROCESSLIST WHERE COMMAND ! = 'Sleep';
+---------------+-----------+--------------------+-------------+---------+-----------------------
-----------------------------------------------+-----------------------------------------------
-----------------------------------------------------+-----------+---------------+-----------+
| ID            | USER      | DB                 | COMMAND     | TIME    | STATE
| INFO
| ROWS_SENT | ROWS_EXAMINED | ROWS_READ |
+---------------+-----------+--------------------+-------------+---------+-----------------------
-----------------------------------------------+-----------------------------------------------

| 0-0-352724126 | ifisibhk0 | test_123_wvvp_0000 | Query       |      15 | Sending data
| /*DRDS /xx.xxx.xx.88/ac47e5a72801000/ */select `t_item`.`detail_url`,SUM(`t_item`.`price`) from
`t_i |      NULL |          NULL |      NULL |
| 0-0-352864311 | cowxhthg0 | NULL               | Binlog Dump |      13 | Master has sent all bi
nlog to slave; waiting for binlog to be updated | NULL
|      NULL |          NULL |      NULL |
| 0-0-402714566 | ifisibhk0 | test_123_wvvp_0005 | Query       |      14 | Sending data
| /*DRDS /xx.xxx.xx.88/ac47e5a72801000/ */select `t_item`.`detail_url`,`t_item`.`price` from `t_i
|      NULL |          NULL |      NULL |
| 0-0-402714795 | ifisibhk0 | test_123_wvvp_0005 | Alter       |     114 | Sending data
| /*DRDS /xx.xxx.xx.88/ac47e5a72801000/ */ALTER TABLE `Persons` ADD `Birthday` date
|      NULL |          NULL |      NULL |
......
+---------------+-----------+--------------------+-------------+---------+-----------------------
-----------------------------------------------+-----------------------------------------------
-----------------------------------------------------+-----------+---------------+-----------+
12 rows in set (0.03 sec)
```

   The value in the TIME column indicates the number of seconds that the command has been executed. If a command execution is too slow, as shown in the figure, you can run the **KILL '0-0-402714795'** command to cancel the slow command.

> **Notice** In , one logical SQL statement corresponds to multiple statements on database shards. Therefore, you may need to kill multiple commands to stop a logical DDL statement. You can determine the logical SQL statement to which a command belongs based on the INFO column in the SHOW PROCESSLIST result set.

4. Handle the lock conflict error

   adds a database lock before performing a DDL operation and releases the lock after the operation. The KILL DDL operation may not release the lock. If you perform the DDL operation again, the following error message will be returned:

   ```
   Lock conflict , maybe last DDL is still running
   ```

   In this case, run **RELEASE DBLOCK** to release the lock. After the command is canceled and the lock is released, run the DDL statement again during off-peak hours or when the service is stopped.

Other problems

Clients cannot display the modified table structures.

To enable some clients to obtain table structures from system tables (such as COLUMNS or TABLES), creates a shadow database in database shard 0 on your ApsaraDB RDS for MySQL instance. The shadow database name must be the same as the name of your logical database. It stores all table structures and other information in the user database.

The client obtains the table structure from the system table of the shadow database. During the processing of DDL exceptions, the table structure may be modified normally in the user database but not in the shadow database due to some reasons. In this case, you need to connect to the shadow database and perform the DDL operation on the table again in the database.

> **Notice** The CHECK TABLE command does not check whether the table structure in the shadow database is consistent with that in the user database.

13.1.14.11. Efficiently scan DRDS data

Distributed Relational Database Service (DRDS) supports efficient data scanning and uses aggregate functions for statistical summary during full table scan.

The following describes common scanning scenarios:

- **Scan of table without database or table shards**: DRDS transmits the original SQL statement to the backend ApsaraDB RDS for MySQL database for execution. In this case, DRDS supports any aggregate functions.
- **Non-full table scan**: DRDS transmits the original SQL statement to each single ApsaraDB RDS for MySQL database for execution. For example, when the shard key in the WHERE clause is Equal, non-full table scan is performed. In this case, DRDS also supports any aggregate functions.
- **Full table scan**: Currently, the supported aggregate functions are COUNT, MAX, MIN, and SUM. In addition, LIKE, ORDER BY, LIMIT, and GROUP BY are also supported during full table scan.S
- **Parallel scan of all table shards**: If you need to export data from all databases, you can run the SHOW command to view the table topology and scan all table shards in parallel. For more information, see the following section.

Traverse tables by using a hint

1. Run the SHOW TOPOLOGY FROM TABLE_NAME command to obtain the table topology.

```
mysql:> SHOW TOPOLOGY FROM DRDS_USERS;
+------+------------------+--------------+
| ID   | GROUP_NAME       | TABLE_NAME   |
+------+------------------+--------------+
|    0 | DRDS_00_RDS      | drds_users   |
|    1 | DRDS_01_RDS      | drds_users   |
+------+------------------+--------------+
2 rows in set (0.06 sec)
```

By default, the non-partition table is stored in database shard 0.

2. Traverse each table for TOPOLOGY.
   i. Run the current SQL statement in database shard 0.

   ```
   /! TDDL:node='DRDS_00_RDS'*/ SELECT * FROM DRDS_USERS;
   ```

   ii. Run the current SQL statement in database shard 1.

   ```
   /! TDDL:node='DRDS_01_RDS'*/ SELECT * FROM DRDS_USERS;
   ```

Notice We recommend that you run `SHOW TOPOLOGY FROM TABLE_NAME` to obtain the latest table topology before each scan.

Parallel scans

DRDS allows you to run mysqldump to export data. However, if you want to scan data faster, you can enable multiple sessions for each table shard to scan tables in parallel.

```
mysql> SHOW TOPOLOGY FROM LJLTEST;
+------+----------------+------------+
| ID   | GROUP_NAME     | TABLE_NAME |
+------+----------------+------------+
|    0 | TDDL5_00_GROUP | ljltest_00 |
|    1 | TDDL5_00_GROUP | ljltest_01 |
|    2 | TDDL5_00_GROUP | ljltest_02 |
|    3 | TDDL5_01_GROUP | ljltest_03 |
|    4 | TDDL5_01_GROUP | ljltest_04 |
|    5 | TDDL5_01_GROUP | ljltest_05 |
|    6 | TDDL5_02_GROUP | ljltest_06 |
|    7 | TDDL5_02_GROUP | ljltest_07 |
|    8 | TDDL5_02_GROUP | ljltest_08 |
|    9 | TDDL5_03_GROUP | ljltest_09 |
|   10 | TDDL5_03_GROUP | ljltest_10 |
|   11 | TDDL5_03_GROUP | ljltest_11 |
+------+----------------+------------+
12 rows in set (0.06 sec)
```

As shown above, the table has four database shards, and each database shard has three table shards. Run the following SQL statement to operate on the table shards of the TDDL5_00_GROUP database:

```
/! TDDL:node='TDDL5_00_GROUP'*/ select * from ljltest_00;
```

Note TDDL5_00_GROUP in HINT corresponds to the GROUP_NAME column in the results of the SHOW TOPOLOGY command. In addition, the table name in the SQL statement is the table shard name.

At this time, you can enable up to 12 sessions (corresponding to 12 table shards respectively) to process data in parallel.

13.1.15. Appendix: PolarDB-X terms

This topic lists common terms of for your reference.

Term	Description	Remarks
	is a distributed database service that was independently developed by Alibaba to solve the bottlenecks of single-instance database services. is compatible with MySQL protocols and syntax. It supports automatic sharding, smooth scale-out, auto scaling, and transparent read/write splitting, and provides O&M capabilities for distributed databases throughout their entire lifecycle.	-
TDDL	Taobao Distributed Data Layer (TDDL) was developed by Alibaba and has become a preferred component for nearly 1,000 core applications of Alibaba.	-
Console	Console is designed for database administrators (DBAs) to isolate resources as required and perform operations, such as instance management, database and table management, read/write splitting configuration, smooth scale-out, monitoring data display, and IP address whitelist.	-
DRDS Manager	DRDS Manager is designed for global O&M personnel and DBAs to manage all resources and monitor the system.	-
Server	Server is the service layer of . Multiple server nodes make up a server cluster to provide distributed database services, including the read/write splitting, routed SQL execution, result merging, dynamic database configuration, and globally unique ID (GUID).	-
Load balancer	server nodes are stateless, and therefore requests can be randomly routed to any server node. The load balancer is used to complete this task. Server Load Balancer (SLB) is used for overall output by Apsara Stack. VIPServer is typically used for Alibaba middleware output.	-
Diamond	Diamond manages the configuration and storage of . It provides the configuration functions for storage, query, and notification. In , Diamond stores the source data of databases, and configuration data including the sharding rules, and switches.	-
Data Replication System	Data Replication System migrates and synchronizes data for . Its core capabilities include full data migration and incremental data synchronization. Its derived features include smooth data import, smooth scale-out, and global secondary index. Data Replication System requires the support of ZooKeeper and Rtools.	-
instance (instance)	A instance consists of multiple server nodes. A instance can contain multiple databases.	-
instance ID (instance ID)	An instance ID uniquely identifies an instance.	-
Number of nodes on a instance	The number of server nodes in a instance.	-

Term	Description	Remarks
VIP	The virtual IP addresses (VIPs) of the load balancer can be classified as: • 1. Public VIP, which is accessible from the Internet. It is used for testing. • 2. Private VIP, which is accessible only from the Alibaba Cloud internal network.	-
VPC	Virtual Private Cloud (VPC) is generally used on Alibaba Cloud.	-
Region	A region is a geographical location, such as East China. This concept is generally used for Alibaba Cloud.	-
Azone	A physical area with independent power grids and networks within one region, such as Hangzhou Zone A. This concept is generally used for Alibaba Cloud.	-
Logical SQL statement	A logical SQL statement is an SQL statement sent from an application to .	-
Physical SQL statement	A physical SQL statement is an SQL statement obtained after parses a logical SQL statement and sends it to ApsaraDB RDS for MySQL for execution.	Logical SQL statements and physical SQL statements may be the same or different. Logical and physical SQL statements may be in a one-to-one or one-to-many mapping.
QPS	The queries per second (QPS) is the average number of logical SQL statements executed by per second in a statistical period,	instead of the number of transactions. Most control statements, such as COMMIT and SET, are not counted in QPS.
RT	The response time (RT) is the average response time (in milliseconds) of logical SQL statements executed by in a statistical period. The RT of an SQL statement is calculated as follows: (Time when writes the last packet of the result set) - (Time when receives the SQL statement)	-
Physical QPS	The physical QPS is the average number of physical SQL statements that executes on ApsaraDB RDS for MySQL per second in a statistical period.	-

Term	Description	Remarks
Physical RT	The physical RT is the average response time (in milliseconds) of physical SQL statements executed by on ApsaraDB RDS for MySQL in a statistical period. The RT of a physical SQL statement is calculated as follows: (Time when receives the result set returned by ApsaraDB RDS for MySQL) - (Time when starts to obtain the connection to ApsaraDB RDS for MySQL)	This includes the time of establishing a connection to ApsaraDB RDS for MySQL or obtaining a connection from the connection pool, the network transmission time, and the time of executing the SQL statement by ApsaraDB RDS for MySQL.
Connections	The number of connections established between the application and ,	instead of the number of connections established between and ApsaraDB RDS for MySQL.
Inbound traffic	The network traffic generated when the application sends SQL statements to .	This traffic is irrelevant to the traffic used for interaction between and ApsaraDB RDS for MySQL.
Outbound traffic	The network traffic generated when sends the result set to the application.	This traffic is irrelevant to the traffic used for interaction between and ApsaraDB RDS for MySQL.
Number of active threads (ThreadRunning)	The number of threads running on a instance. This parameter can be used to indicate the load of the instance.	-
Global	The total monitoring data of all databases on a instance.	-
Memory usage	The Java Virtual Machine (JVM) memory usage of a server process.	-
Total memory usage	The memory usage of the machine where the server node is located.	This metric is available only when servers are deployed on ECS instances. Generally, this metric is used for Alibaba Cloud.

Term	Description	Remarks
CPU utilization	The CPU utilization of the machine where a server node is located.	This metric is available only when servers are deployed on ECS instances. Generally, this metric is used for Alibaba Cloud.
System load	The load of the machine where a server node is located.	This metric is available only when servers are deployed on ECS instances. Generally, this metric is used for Alibaba Cloud.
Service port	The port used by servers to provide MySQL-based services to external applications.	Generally, the port number is 3306. However, when multiple nodes (mostly physical machines) are deployed on one machine, the port number will change accordingly.
Management port	The port used by servers to provide management application program interfaces (APIs).	Generally, the port number is the service port number plus 100.
Start time	The time when servers start.	-
Running time	The continuous running time of the servers since the last startup time.	-
Total memory size	The maximum JVM memory size of a server node.	-
Memory usage	The JVM memory that is already used by the server nodes.	-
Number of nodes	Required. The number of machines. A instance is essentially a cluster, and the number of nodes refers to the number of machines in the cluster.	-
Instance type	Required. The type of the instance, including dedicated and shared instances. A dedicated instance works in the exclusive mode. A shared instance works in the multi-tenant mode, which is generally used in Alibaba Cloud.	-
Machine type	Required. The type of the machine where a PolarDB-X server node is deployed. Valid values are Auto-selected, PHY, and ECS. The inventory is divided into physical machine inventory and virtual machine inventory according to the type of machines where the PolarDB-X servers are deployed. The two types cannot be mixed because their deployment and O&M methods are different.	-
AliUid	Required. The UID of the instance. In Apsara Stack, this ID is provided by the account system in the deployment environment.	-

Term	Description	Remarks
Backend port	The backend port of the VIP. For a server node, this port is the service port of machine where the PolarDB-X server node is deployed.	-
Frontend port	The frontend port of the VIP for user access. Each VIP has a set of frontend ports and backend ports. The VIP forwards data from frontend ports to backend ports.	-
Private network/Internet	The network type of the VIP. Valid values: • Internet: the public VIP, which is accessible from the Internet. • Private network: the private VIP (including VPC VIP), which is accessible from private networks.	-
lbId	The ID of an SLB instance, which is the unique ID of VIP. A VIP is managed based on this ID.	-
Forwarding mode	The port forwarding mode of the VIP. The following modes are supported: • FNAT: This mode is recommended when the backend machine is a virtual machine or VPC needs to be supported. • NAT: This mode can be selected when the backend machine is a physical machine. Currently, this mode is only used on Alibaba Cloud. • Open FNAT: This mode is applicable only to Alibaba Cloud.	-
VPC ID	The ID of the destination VPC, that is, the VPC to be accessed.	-
VSwitch ID	The ID of the destination VSwitch, which determines the CIDR block where the VPC VIP of the instance is in.	-
APPName	The app name of the destination database. Each database has a corresponding app name for loading configurations.	-
UserName	The user name used to log on to the destination database.	-
DBName	The name of the destination database you want to log on to.	-
IP address whitelist	Only the IP addresses specified in the IP address whitelist can access the instance.	-
Read-only instance	ApsaraDB RDS for MySQL instances where physical databases reside are divided into the following two types based on whether data can be written into the instances: • Primary instance: Both read and write requests are allowed on such an instance. In Apsara Stack, ApsaraDB RDS for MySQL is supported. In Alibaba Cloud, ApsaraDB for RDS is supported. • Read-only instance: Only read requests are allowed on such an instance. In Apsara Stack, ApsaraDB RDS for MySQL is supported. In Alibaba Cloud, ApsaraDB for RDS is supported.	-

Term	Description	Remarks
Read SQL statement	A type of SQL statements used to read data, such as the SELECT statement. determines whether an SQL statement is a read-only SQL statement when it is not in a transaction. If the SQL statement is in a transaction, PolarDB-X treats it as a write SQL statement during read/write splitting.	-
Read/write splitting	If read-only ApsaraDB RDS for MySQL instances exist, you can configure in the console to allocate read SQL statements to the primary and read-only instances proportionally. automatically identifies the type of SQL statements and allocates them proportionally.	-
Smooth scale-out	On the basis of horizontal partitioning, the data distribution on ApsaraDB RDS for MySQL instances is dynamically adjusted for scale-out. Generally, scale-out is completed asynchronously without any modification to the business code.	-
Broadcast of small tables	You can synchronize the data in a single table in a database to all database shards in advance, to convert the cross-database JOIN query into a JOIN query that can be completed on physical databases.	-
Horizontal partitioning	Horizontal partitioning distributes the data rows originally stored in one table to multiple tables based on specified rules to achieve horizontal linear scaling.	-
Partition mode	This mode allows you to create multiple database shards on an ApsaraDB RDS for MySQL instance. These database shards make up a database. In this mode, all functions can be used.	-
Non-partition mode	In this mode, a database that has been created on an ApsaraDB RDS for MySQL instance is used as a database. In this mode, only read/write splitting is allowed, while other features such as database sharding and table sharding are not allowed.	-
Imported database	An existing database on the ApsaraDB RDS for MySQL instance selected for creating a database. This is a unique concept for the creation of a PolarDB-X database.	-
Read policy	The ratio of read SQL statements assigned by to the primary and read-only ApsaraDB RDS for MySQL instances.	-
Full table scan	If no shard field is specified in a SQL statement, runs the SQL statement on all table shards and summarizes the results. You can disable this function because of its high overheads.	-
Shard key	A column in a logical table. routes data and SQL statements to a physical table based on this column.	-
Data import	The operation of importing data from an existing ApsaraDB RDS for MySQL instance to a database.	-
Full data migration	The operation of migrating all existing records from a database to . An offset is recorded before full migration starts.	-
Offset	In a MySQL binary log file, each row represents a data change operation. The position of a line in the binary log file is called an offset.	-

Term	Description	Remarks
Incremental data migration	The operation of reading all MySQL binary log records from the recorded offset, converting them into SQL statements, and then running them in . Incremental migration continues before the switchover.	-
Switchover	A step of data import and smooth scale-out, which writes all the remaining incremental records from MySQL binary logs to .	-
Cleanup	The last step of smooth scale-out, which cleans redundant data and configurations generated during smooth scale-out.	-
Heterogeneous indexing	For table shards of a database, the WHERE condition of a SQL statement for query must contain the shard key whenever possible. In this way, routes the query request to a specific database shard, improving the query efficiency. If the WHERE condition of the SQL statement does not contain the shard key, performs a full table scan. provides heterogeneous indexing to solve this problem. The data in a database shard or table shard of a instance is fully or partially synchronized to another table based on different shard keys. The destination table to which the data is synchronized is called a heterogeneous index table.	-
PolarDB-X sequence	A sequence (a 64-digit number of the BIGINT data type in MySQL) aims to ensure that the data (for example, PRIMARY KEY and UNIQUE KEY) in the defined unique field is globally unique and in ordered increments.	-
hint	To facilitate usage, defines some hints to specify special actions.	-

14.AnalyticDB for PostgreSQL

14.1. User Guide

14.1.1. What is AnalyticDB for PostgreSQL?

AnalyticDB for PostgreSQL (formerly known as HybridDB for PostgreSQL) is a distributed cloud database service that uses multiple compute nodes to provide massively parallel processing (MPP) data warehousing services.

AnalyticDB for PostgreSQL is developed based on the open source Greenplum database project and enhanced by Alibaba Cloud. This service has the following features:

- Compatible with Greenplum and all tools that support it.
- Supports OSS, JSON, and HyperLogLog, a probability cardinality estimation algorithm.
- Supports SQL:2003-compliant syntax and OLAP aggregate functions to provide flexible hybrid analysis.
- Supports both row store and column store to enhance analytics performance.
- Leverages data compression technologies to reduce storage costs.
- Provides online expansion and performance monitoring services to enable DBAs, developers, and data analysts to focus on improving enterprise productivity and creating core business value instead of managing and maintaining large numbers of MPP clusters.

14.1.2. Quick start

14.1.2.1. Overview

This topic provides a quick start guide about how to perform management tasks for AnalyticDB for PostgreSQL instances such as creating an instance and logging on to a database.

- Log on to the AnalyticDB for PostgreSQL console

  This topic describes how to log on to the AnalyticDB for PostgreSQL console.

- Create an instance

  You can create an instance in the console and then manage the instance.

- Configure a whitelist

  To ensure a secure and stable database, you must add IP addresses or CIDR blocks that are allowed to access the database to a whitelist of the instance before you use the AnalyticDB for PostgreSQL instance.

- Create an initial account

  After you create an instance, you must create an initial account to log on to the database.

- Connect to a database

  You can use a client that supports PostgreSQL or Greenplum to connect to the database.

14.1.2.2. Log on to the AnalyticDB for PostgreSQL console

This topic describes how to log on to the AnalyticDB for PostgreSQL console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- We recommend that you use the Google Chrome browser.

1. In the address bar, enter the URL used to log on to the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that are used to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login** to go to the Apsara Uni-manager Management Console.

14.1.2.3. Create an instance

You can create an instance in the console and then manage the instance.

1. Log on to the AnalyticDB for PostgreSQL console.
2. In the upper-right corner of the page, click **Create Instance**.
3. On the **AnalyticDB for PostgreSQL** buy page, configure the following parameters.

Section	Parameter	Description
Region	Organization	The organization to which the instance belongs.
	Resource Set	The resource set to which the instance belongs.
	Region	The region of the instance. **Note** If you need to access the AnalyticDB for PostgreSQL instance from an ECS instance over VPC, you must deploy the instance in the same region and zone as those of the ECS instance.
	Zone	The zone of the instance.
Basic Settings	Engine	Currently, only the integrated computing and storage version is supported.
	Engine Version	The engine version of the instance.
	Node Type	The unit of computing resources. Different group types have different storage capacities and computing capabilities.
	Nodes	The number of compute nodes. An instance must contain at least two compute nodes. The performance of an instance scales linearly with the number of compute nodes.

Section	Parameter	Description
Network	Network Type	Valid values: ◦ *Classic Network*: Cloud services on a classic network are not isolated from each other. Unauthorized access to a cloud service is blocked only by the security group or whitelist policy of the service. ◦ *VPC*: A VPC helps you to build an isolated network environment in Alibaba Cloud. You can customize the route table, IP address range, and gateway in a VPC. We recommend that you select VPC for enhanced security. You can create a VPC in advance, or change the network type to VPC after instance creation.
	VPC	The VPC where the AnalyticDB for PostgreSQL instance is located. **Note** Virtual Private Cloud (VPC): You can use a VPC to build an isolated network environment in Alibaba Cloud. You can customize the route table, IP address range, and gateway in a VPC.
	VSwitch	The VSwitch where the AnalyticDB for PostgreSQL instance is located.
	IP Whitelist	The IP addresses that are allowed to access the instance.

4. After you have configured the preceding parameters, click **Submit**.

14.1.2.4. Configure a whitelist

To ensure a secure and stable database, you must add IP addresses or CIDR blocks that are allowed to access the database to a whitelist.

1. Log on to the AnalyticDB for PostgreSQL console.
2. Find the target instance and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Security Controls**. The **Security Controls** page appears.
4. On the **Whitelist Settings** tab, click **Modify** corresponding to the *default* whitelist. The **Modify Group** page appears.

   Note You can also click Clear corresponding to the *default* whitelist to delete the IP addresses of the default whitelist, and then click Add Group to create a new whitelist.

5. Delete 127.0.0.1 from the *default* whitelist and enter your IP addresses in the whitelist. The following table lists the parameters.

Parameter	Description
Whitelist Name	Specify the name of the whitelist. The whitelist name must be 2 to 32 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter and end with a letter or digit. The default whitelist cannot be modified or deleted.

Parameter	Description
IP Addresses	Enter the CIDR blocks or IP addresses that are allowed to access the database. Use commas (,) to separate multiple CIDR blocks or IP addresses. ○ A whitelist can contain IP addresses such as 10.10.10.1 and CIDR blocks such as 10.10.10.0/24. This CIDR block indicates that any IP addresses in the 10.10.10.X format have access to the database. ○ The percent sign (%) or 0.0.0.0/0 indicates that any IP addresses are allowed to access the database. **Notice** This configuration is not recommended because it reduces the security of the database. ○ Default whitelists of new instances contain the loopback address 127.0.0.1. This configuration allows no access from external IP addresses. ○ You can add up to 999 IP addresses or CIDR blocks to a whitelist group.

6. Click **OK** to create a whitelist.

What's next

- We recommend that you regularly maintain the whitelist to ensure secure access for AnalyticDB for PostgreSQL.
- You can click **Modify** or **Delete** to modify or delete custom whitelists.

14.1.2.5. Create an initial account

After you create an instance, you must create an initial account to log on to the database.

1. Log on to the AnalyticDB for PostgreSQL console.
2. Find the instance that you want to manage and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Account Management**. The **Account Management** page appears.
4. In the upper-right corner of the page, click **Create Account**. The **Create Account** page appears.
5. Enter the database account and password, and click **OK**.

Parameter	Description
Account	The name of the account must be 2 to 16 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a letter and end with a letter or digit.
New Password	The password must be 8 to 32 characters in length. It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters.
Password	Enter the password again.

14.1.2.6. Obtain the client tool

The interface protocol of AnalyticDB for PostgreSQL is compatible with Greenplum Community Edition and PostgreSQL 8.2. Because of this, you can use the Greenplum or PostgreSQL client to connect to AnalyticDB for PostgreSQL.

> **Note**
>
> Apsara Stack is an isolated environment. You must deploy software installation packages to the internal environment.

Graphical client tools

AnalyticDB for PostgreSQL users can directly use client tools that support Greenplum, such as SQL Workbench, Navicat Premium, Navicat for PostgreSQL, and pgAdmin III (1.6.3).

Command-line client psql (for RHEL 6, RHEL 7, CentOS 6, and CentOS 7)

For Red Hat Enterprise Linux (RHEL) and CentOS 6 or 7, you can download the tools from the following addresses and decompress the packages to use them:

- For RHEL 6 or CentOS 6, click hybriddb_client_package_el6.
- For RHEL version 7 or CentOS version 7, click hybriddb_client_package_el7.

Command-line client psql (for other Linux systems)

The compilation methods for client tools applicable to other Linux systems are as follows:

1. Obtain the source code by using one of the following methods:
   - Obtain the git directory. You must first install the git tool.

     ```
     git clone https://github.com/greenplum-db/gpdb.git
     cd gpdb
     git checkout 5d870156
     ```

   - Download the code.

     ```
     wget https://github.com/greenplum-db/gpdb/archive/5d87015609abd330c68a5402c1267fc86cbc9e1f.zip
     unzip 5d87015609abd330c68a5402c1267fc86cbc9e1f.zip
     cd gpdb-5d87015609abd330c68a5402c1267fc86cbc9e1f
     ```

2. Use gcc and other compilers.

   ```
   ./configure
   make -j32
   make install
   ```

3. Use psql and pg_dump. The paths of the two tools are as follows:

   psql: */usr/local/pgsql/bin/psql*

   pg_dump: */usr/local/pgsql/bin/pg_dump*

Command-line client psql (for Windows and other systems)

For client tools for Windows and other systems, go to the Pivotal website to download HybridDB Client

14.1.2.7. Connect to a database

The Greenplum Database and AnalyticDB for PostgreSQL are both developed based on PostgreSQL 8.2 and fully compatible with its messaging protocol. AnalyticDB for PostgreSQL users can use tools that support the PostgreSQL 8.2 message protocol, such as libpq, JDBC, ODBC, psycopg2, and pgAdmin III.

Context

AnalyticDB for PostgreSQL provides psql, a binary program of Red Hat. For more information about the download link, see Obtain the client tool. The Greenplum official website provides an easy-to-install installation package that includes JDBC, ODBC, and libpq. For more information, see Greenplum official documentation.

> **Note**
> - Apsara Stack is an isolated environment. To access Apsara Stack, you must prepare the necessary software installation packages in advance.
> - AnalyticDB for PostgreSQL instances can only be accessed by clients deployed on ECS instances within the same region and zone.

psql

psql is a common tool used together with Greenplum, and provides a variety of command functions. Its binary files are located in the *bin* directory of Greenplum. The procedure is as follows:

1. Connect to AnalyticDB for PostgreSQL by using one of the following methods:
   - Connection string

     ```
     psql "host=yourgpdbaddress.gpdb.rds.aliyuncs.com port=3432 dbname=postgres user=gpdbaccount password=gpdbpassword"
     ```

   - Specified parameters

     ```
     psql -h yourgpdbaddress.gp.aliyun-inc.com -p 3432 -d postgres -U gpdbaccount
     ```

     Parameters:

     - -h: specifies the host address.
     - -p: specifies the port number.
     - -d: specifies the database. The default database is postgres.
     - -U: specifies the user to connect to the database.

     In psql, you can run the `psql --help` command to view more options. You can run the `\?` command to view the commands supported in psql.
2. Enter the password to go to the psql shell interface.

   ```
   postgres=>
   ```

References

- For more information about the Greenplum psql usage, visit psql.
- AnalyticDB for PostgreSQL also supports psql statements of PostgreSQL. Pay attention to the differences between Greenplum psql and PostgreSQL psql. For more information, visit PostgreSQL 8.3.23 Documentation - psql.

pgAdmin III

pgAdmin III is a PostgreSQL graphical client and can be directly used to connect to AnalyticDB for PostgreSQL. For more information, click here. For more information about other graphical clients, see Obtain the client tool.

1. Download pgAdmin III 1.6.3 or earlier versions.

   You can download pgAdmin III 1.6.3 from the PostgreSQL website. pgAdmin III 1.6.3 supports various operating systems, such as Windows, macOS, and Linux.

> **Note** AnalyticDB for PostgreSQL is compatible with PostgreSQL 8.2. Therefore, you must use pgAdmin III 1.6.3 or earlier to connect to AnalyticDB for PostgreSQL. pgAdmin 4 and later versions are not supported.

2. Choose **File > Add Server**.
3. In the New Server Registration dialog box that appears, enter the configuration information.
4. Click **OK** to connect to AnalyticDB for PostgreSQL.

JDBC

JDBC uses the interface provided by PostgreSQL. The download methods are as follows:

Click PostgreSQL JDBC Driver to download the official JDBC of PostgreSQL, and then add it to the environment variables.

The sample code is as follows:

```
import java.sql.Connection; import java.sql.DriverManager; import java.sql.ResultSet; import java.sql.SQLException; import java.sql.Statement; public class gp_conn { public static void main(String[] args) { try { Class.forName("org.postgresql.Driver"); Connection db = DriverManager.getConnection("jdbc:postgresql://mygpdbpub.gpdb.rds.aliyuncs.com:3432/postgres","mygpdb","mygpdb"); Statement st = db.createStatement(); ResultSet rs = st.executeQuery("select * from gp_segment_configuration;"); while (rs.next()) { System.out.print(rs.getString(1)); System.out.print(" | "); System.out.print(rs.getString(2)); System.out.print(" | "); System.out.print(rs.getString(3)); System.out.print(" | "); System.out.print(rs.getString(4)); System.out.print(" | "); System.out.print(rs.getString(5)); System.out.print(" | "); System.out.print(rs.getString(6)); System.out.print(" | "); System.out.print(rs.getString(7)); System.out.print(" | "); System.out.print(rs.getString(8)); System.out.print(" | "); System.out.print(rs.getString(9)); System.out.print(" | "); System.out.print(rs.getString(10)); System.out.print(" | "); System.out.println(rs.getString(11)); } rs.close(); st.close(); } catch (ClassNotFoundException e) { e.printStackTrace(); } catch (SQLException e) { e.printStackTrace(); } } }
```

Python

Python uses psycopg2 to connect to Greenplum and PostgreSQL. The procedure is as follows:

1. Install psycopg2. There are three installation methods in CentOS:
   - Method 1: Run the `yum -y install python-psycopg2` command.
   - Method 2: Run the `pip install psycopg2` command.
   - Method 3: Run the source code:

     ```
     yum install -y postgresql-devel*
     wget http://initd.org/psycopg/tarballs/PSYCOPG-2-6/psycopg2-2.6.tar.gz
     tar xf psycopg2-2.6.tar.gz
     cd psycopg2-2.6
     python setup.py build
     sudo python setup.py install
     ```
2. Run the following commands to set PYTHONPATH and reference it:

```
import psycopg2
 sql = 'select * from gp_segment_configuration;'
 conn = psycopg2.connect(database='gpdb', user='mygpdb', password='mygpdb', host='mygpdbpub.gpdb.
rds.aliyuncs.com', port=3432)
 conn.autocommit = True
 cursor = conn.cursor()
 cursor.execute(sql)
 rows = cursor.fetchall()
 for row in rows:
     print row
 conn.commit()
 conn.close()
```

A similar output is displayed:

```
(1, -1, 'p', 'p', 's', 'u', 3022, '192.168.2.158', '192.168.2.158', None, None)(6, -1, 'm', 'm',
's', 'u', 3019, '192.168.2.47', '192.168.2.47', None, None)(2, 0, 'p', 'p', 's', 'u', 3025, '192.
168.2.148', '192.168.2.148', 3525, None)(4, 0, 'm', 'm', 's', 'u', 3024, '192.168.2.158', '192.16
8.2.158', 3524, None)(3, 1, 'p', 'p', 's', 'u', 3023, '192.168.2.158', '192.168.2.158', 3523, Non
e)(5, 1, 'm', 'm', 's', 'u', 3026, '192.168.2.148', '192.168.2.148', 3526, None)
```

libpq

libpq is the C language interface to AnalyticDB for PostgreSQL. You can use the libpq library to access and manage PostgreSQL databases in a C program. You can locate its static and dynamic libraries under the lib directory.

For the example programs, visit Example Programs.

For more information about libpq, visit PostgreSQL 9.4.17 Documentation - Chapter 31. libpq - C Library.

ODBC

PostgreSQL ODBC is an open-source version based on the GNU Lesser General Public License (LGPL) protocol. You can download it from the PostgreSQL website.

1. Install the driver.

   ```
   yum install -y unixODBC.x86_64
   yum install -y postgresql-odbc.x86_64
   ```

2. View the driver configuration.

```
cat /etc/odbcinst.ini
# Example driver definitions
# Driver from the postgresql-odbc package
# Setup from the unixODBC package
[PostgreSQL]
Description = ODBC for PostgreSQL
Driver = /usr/lib/psqlodbcw.so
Setup = /usr/lib/libodbcpsqlS.so
Driver64 = /usr/lib64/psqlodbcw.so
Setup64 = /usr/lib64/libodbcpsqlS.so
FileUsage = 1
# Driver from the mysql-connector-odbc package
# Setup from the unixODBC package
[MySQL]
Description = ODBC for MySQL
Driver = /usr/lib/libmyodbc5.so
Setup = /usr/lib/libodbcmyS.so
Driver64 = /usr/lib64/libmyodbc5.so
Setup64 = /usr/lib64/libodbcmyS.so
FileUsage = 1
```

3. Configure the DSN. Replace the `****` in the following code with the corresponding connection information.

```
[mygpdb]
Description = Test to gp
Driver = PostgreSQL
Database = ****
Servername = ****.gpdb.rds.aliyuncs.com
UserName = ****
Password = ****
Port = ****
ReadOnly = 0
```

4. Test connectivity.

```
echo "select count(*) from pg_class" | isql mygpdb
+---------------------------------------+
| Connected!                            |
|                                       |
| sql-statement                         |
| help [tablename]                      |
| quit                                  |
|                                       |
+---------------------------------------+
SQL> select count(*) from pg_class
+----------------------+
| count                |
+----------------------+
| 388                  |
+----------------------+
SQLRowCount returns 1
1 rows fetched
```

5. After ODBC is connected to the instance, connect the application to ODBC. For more information, see PostgreSQL ODBC Driver and psqlODBC HOWTO - C#.

14.1.3. Instances

14.1.3.1. Reset the password

If you forget the password of your database account, you can reset the password in the AnalyticDB for PostgreSQL console.

> **Note** We recommend that you change your password periodically to ensure data security.

1. Log on to the AnalyticDB for PostgreSQL console.
2. Find the target instance and click its ID. The **Basic Information** page appears.
3.
4. Click **Reset Password** in the corresponding Actions column of the account. The **Reset Account Password** page appears.
5. After you enter and confirm the new password, click **OK**.

> **Note** The password must be 8 to 32 characters in length. It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. We recommend that you do not use a previously used password.

14.1.3.2. View monitoring information

You can go to the monitoring information page in the console to view the operation status of an instance.

1. Log on to the AnalyticDB for PostgreSQL console.
2. Find the instance that you want to manage and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Monitoring and Alarms**. The **Monitoring and Alarms** page appears.

   Specify a duration of time n up to seven days in length to view the metrics for that last n period.

14.1.3.3. Switch the network type of an instance

The default network type of an instance is Virtual Private Cloud (VPC). After an instance is created, you can switch its network type between classic network and VPC as needed.

Context

AnalyticDB for PostgreSQL supports two network types: classic network and VPC. Both network types use BGP connections, and are independent of the public network of your service provider. These network types only differ in functions, and you can choose a network type based on your requirements. The two network types are applicable to different scenarios:

- Classic network: IP addresses are allocated by Alibaba Cloud. Classic networks are easy to configure and use. This network type is suitable for users who do not need to perform complex operations, or who only require short deployment cycles.

- VPC: a logically isolated private network. You can customize the network topology and IP addresses and connect through a leased line. This network type is suitable for advanced users.

> **Warning** Switching the network type will cause the database service to stop. Proceed with caution.

1. Log on to the AnalyticDB for PostgreSQL console.
2. Find the target instance and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Database Connection**. The **Database Connection** page appears.
4. In the upper-right corner of the page, click **Switch to Classic Network** or **Switch to VPC**.
5. If you click **Switch to VPC**, you must select the destination **VPC** and **VSwitch**. Click **OK**.

   > **Note** To switch the network type to VPC, a VPC and a VSwitch must exist or be created in the zone where the instance is located.

6. If you click **Switch to Classic Network**, click **OK** in the displayed message.

> **Note** After you switch the network type, it takes 3 to 30 minutes for the instance to enter the running state.

14.1.3.4. Restart an instance

To better meet your needs, AnalyticDB for PostgreSQL automatically updates the database kernel version. When you create an instance, the latest database kernel is used by default. After a new version is released, you can restart your instance to update the database kernel and use its extended features. This topic describes how to restart an instance.

> **Warning** Restarting an instance will cause the database service to stop. Proceed with caution.

1. Log on to the AnalyticDB for PostgreSQL console.
2. Find the instance that you want to manage and click its ID. The **Basic Information** page appears.
3. In the upper-right corner of the page, click **Restart Instance**.

> **Note** The restart process typically takes from 3 to 30 minutes. During the restart period, the instance cannot provide external services. We recommend that you take precautionary measures before restarting instances. After the instance has been restarted and enters the running state, you can access the database.

14.1.3.5. Import data

14.1.3.5.1. Import or export data from or to OSS in parallel

AnalyticDB for PostgreSQL can import or export data from or to OSS tables in parallel by using the OSS external table feature, gpossext. AnalyticDB for PostgreSQL also supports GZIP compression for OSS external tables to reduce file size and storage costs. gpossext can read from and write to TEXT and CSV files, even when they are compressed in GZIP packages.

- Create an OSS external table extension (oss_ext)

  To use an OSS external table, you must first create an OSS external table extension in AnalyticDB for PostgreSQL. You must create an extension for each database that you need to access.

  - Creation statement: `CREATE EXTENSION IF NOT EXISTS oss_ext;`

- Deletion statement: `DROP EXTENSION IF EXISTS oss_ext;`

- Import data in parallel
  i. Distribute data evenly among multiple OSS files for storage. We recommend that you set the number of OSS files to an integer that is the multiple of the number of compute nodes in AnalyticDB for PostgreSQL.
  ii. Create a READABLE external table in AnalyticDB for PostgreSQL.
  iii. Execute the following statement to import data in parallel:

```
INSERT INTO <destination table> SELECT * FROM <external table>
```

> **Note**
> - The data import performance depends on the OSS performance and resources of the AnalyticDB for PostgreSQL instance, such as CPU, I/O, memory, and network resources. To ensure the best import performance, we recommend that you use column store and compression when you create a table. For example, you can specify the following clause: `WITH (APPENDONLY=true, ORIENTATION=column, COMPRESSTYPE=zlib, COMPRESSLEVEL=5, BLOCKSIZE=1048576)`. For more information, see Greenplum Database official documentation on database table creation syntax.
> - We recommend that you configure OSS and AnalyticDB for PostgreSQL instances within the same region to implement the best import performance.

- Export data in parallel
  i. Create a WRITABLE external table in AnalyticDB for PostgreSQL.
  ii. Execute the following statement to export data to OSS in parallel:

```
INSERT INTO <external table> SELECT * FROM <source table>
```

- Create OSS external tables

> **Note** The syntax to create and use external tables is the same as that of Greenplum Database, except for the syntax of location-related parameters.

```
CREATE [READABLE] EXTERNAL TABLE tablename
( columnname datatype [, ...] | LIKE othertable )
LOCATION ('ossprotocol')
FORMAT 'TEXT'
            [( [HEADER]
               [DELIMITER [AS] 'delimiter' | 'OFF']
               [NULL [AS] 'null string']
               [ESCAPE [AS] 'escape' | 'OFF']
               [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
               [FILL MISSING FIELDS] )]
          | 'CSV'
            [( [HEADER]
               [QUOTE [AS] 'quote']
               [DELIMITER [AS] 'delimiter']
               [NULL [AS] 'null string']
               [FORCE NOT NULL column [, ...]]
               [ESCAPE [AS] 'escape']
               [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
               [FILL MISSING FIELDS] )]
[ ENCODING 'encoding' ]
[ [LOG ERRORS [INTO error_table]] SEGMENT REJECT LIMIT count
       [ROWS | PERCENT] ]
CREATE WRITABLE EXTERNAL TABLE table_name
( column_name data_type [, ...] | LIKE other_table )
LOCATION ('ossprotocol')
FORMAT 'TEXT'
               [( [DELIMITER [AS] 'delimiter']
               [NULL [AS] 'null string']
               [ESCAPE [AS] 'escape' | 'OFF'] )]
          | 'CSV'
               [([QUOTE [AS] 'quote']
               [DELIMITER [AS] 'delimiter']
               [NULL [AS] 'null string']
               [FORCE QUOTE column [, ...]] ]
               [ESCAPE [AS] 'escape'] )]
[ ENCODING 'encoding' ]
[ DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY ]
ossprotocol:

    id=userossid key=userosskey bucket=ossbucket compressiontype=[none|gzip] async=[true|false]
ossprotocol:
   oss://oss_endpoint dir=[folder/[folder/]...]/file_name
    id=userossid key=userosskey bucket=ossbucket compressiontype=[none|gzip] async=[true|false]
ossprotocol:
   oss://oss_endpoint filepath=[folder/[folder/]...]/file_name
    id=userossid key=userosskey bucket=ossbucket compressiontype=[none|gzip] async=[true|false]
```

Parameters

Common parameters

Parameter	Description

Parameter	Description
Protocol and endpoint	It is in the `protocol name://oss_endpoint` format. The protocol name is oss. oss_endpoint is the domain name used by users to access OSS in a region. **Note** You can access the database from a VPC host by using an internal endpoint containing "internal" in the name to avoid generating public traffic.
id	The AccessKey ID of the OSS account.
key	The AccessKey secret of the OSS account.
bucket	The bucket where the data file is located. You must use OSS to create the bucket before data import.

prefix	The prefix of the path name corresponding to the data file. Prefixes are directly matched and cannot be controlled by regular expressions. The prefix, filepath, and dir parameters are mutually exclusive and only one parameter can be specified at a time.
	• If you create a READABLE external table for data import, all OSS files that contain the specified prefix will be imported.
	  ◦ If you set prefix to test/filename, the following files will be imported:
	  ▪ test/filename
	  ▪ test/filenamexxx
	  ▪ test/filename/aa
	  ▪ test/filenameyyy/aa
	  ▪ test/filenameyyy/bb/aa
	  ◦ If you set prefix to test/filename/, only the following file out of the preceding files will be imported:
	  test/filename/aa
	• if you create a WRITABLE external table for data export, each exported file will have a unique name based on this parameter.
	
	Note One or more files can be exported for each compute node. The names of exported files are in the `prefix_tablename_uuid.x` format. uuid indicates a timestamp in microseconds as an int64 value. x indicates the node ID. You can use an external table for multiple export operations. Each export operation is assigned to a uuid value. The files exported during each operation share a uuid value.

Parameter	Description
dir	The virtual folder path in OSS. The prefix, filepath, and dir parameters are mutually exclusive and only one parameter can be specified at a time. • A folder path must end with a forward slash (/) such as `test/mydir/`. • If you use this parameter when creating an external table for data import, all files under the specified virtual directory (except for its subdirectories and contained files) will be imported. Unlike filepath, dir does not require you to specify the names of files in the directory. • If this parameter is used in creating an external table for data export, all data will be exported to multiple files within the specified directory. The names of exported files are in the `filename.x` format, where x is a digit. The values of x may not be consecutive.

filepath	The file name that contains a path in OSS. The prefix, filepath, and dir parameters are mutually exclusive and only one parameter can be specified at a time. You can only specify the filepath parameter when you create a READABLE external table for data import.
	• The file name includes the file path, but not the bucket name.
	• The filename specified for data import must be in the `filename` or `filename.x` format. The values of x must be consecutive digits starting from 1.
	For example, if filepath is set to filename and OSS contains the following files, the imported files include filename, filename.1, and filename.2, but filename.4 is not imported because filename.3 does not exist.
	`filename`
	`filename.1`
	`filename.2`
	`filename.4`

Import mode parameters

Parameter	Description
async	Specifies whether to load data asynchronously. • Asynchronous data import is enabled by default. You can set async to false or f to disable asynchronous data import. • Enables the worker thread to load data from OSS to accelerate the import performance. The default import mode is asynchronous mode. • Asynchronous data import consumes more hardware resources than normal data import.
compressiontype	The compression format of the imported file. Valid values: • none: specifies to import files without compressing them. This is the default value. • gzip: specifies compress imported files in the GZIP format. Only the GZIP format is supported.
compressionlevel	The compression level of the files written to OSS. Valid values: 1 to 9. Default value: 6.

Export mode parameters

Parameter	Description
oss_flush_block_size	The size of each data block written to OSS. Valid values: 1 MB to 128 MB. Default value: 32 MB.
oss_file_max_size	The maximum size of each file written to OSS. If the limit is exceeded, subsequent data is written to another file. Valid values: 8 MB to 4000 MB. Default value: 1024 MB.
num_parallel_worker	The number of parallel compression threads for data written to OSS. Valid values: 1 to 8. Default value: 3.

Additionally, you must pay attention to the following items for the export mode:

- WRITABLE is the keyword of the external table for data export. You must specify this keyword when creating an external table.
- Only the prefix and dir parameters are supported for data export. The filepath parameter is not supported.
- You can use the DISTRIBUTED BY clause to write data from compute nodes to OSS based on the specified distribution keys.

Other common parameters

The following error-tolerance parameters can be used for data import and export:

Error-tolerance parameters

Parameter	Description
oss_connect_timeout	The connection timeout period. Unit: seconds. Default value: 10.
oss_dns_cache_timeout	The DNS timeout period. Unit: seconds. Default value: 60.
oss_speed_limit	The minimum rate tolerated. Default value: 1024 bit/s (1 Kbit/s).
oss_speed_time	The maximum amount of time tolerated. Unit: seconds. Default value: 15.

If the default values are used for the preceding parameters, a timeout will occur when the transmission rate is lower than 1 Kbit/s for 15 consecutive seconds. For more information, see **Troubleshooting** in *OSS SDK reference*.

The other parameters are compatible with the original external table syntax of Greenplum Database. For more information about the syntax, see Greenplum Database official documentation on external table syntax. These parameters include:

- FORMAT: indicates the supported file format, such as TEXT and CSV.
- ENCODING: indicates the data encoding format of a file, such as UTF-8.
- LOG ERRORS: indicates that the clause can ignore imported erroneous data and write the data to error_table. You can also use the count parameter to specify the error reporting threshold.

Examples

```
# Create a READABLE external table of OSS.
create readable external table ossexample
        (date text, time text, open float, high float,
        low float, volume int)
        location('oss://oss-cn-hangzhou.aliyuncs.com
        prefix=osstest/example id=XXX
```

```
        key=XXX bucket=testbucket compressiontype=gzip')
        FORMAT 'csv' (QUOTE '''' DELIMITER E'\t')
        ENCODING 'utf8'
        LOG ERRORS INTO my_error_rows SEGMENT REJECT LIMIT 5;
create readable external table ossexample
        (date text, time text, open float, high float,
        low float, volume int)
        location('oss://oss-cn-hangzhou.aliyuncs.com
        dir=osstest/ id=XXX
        key=XXX bucket=testbucket')
        FORMAT 'csv'
        LOG ERRORS SEGMENT REJECT LIMIT 5;
create readable external table ossexample
        (date text, time text, open float, high float,
        low float, volume int)
        location('oss://oss-cn-hangzhou.aliyuncs.com
        filepath=osstest/example.csv id=XXX
        key=XXX bucket=testbucket')
        FORMAT 'csv'
        LOG ERRORS SEGMENT REJECT LIMIT 5;
# Create a WRITABLE external table of OSS.
create WRITABLE external table ossexample_exp
        (date text, time text, open float, high float,
        low float, volume int)
        location('oss://oss-cn-hangzhou.aliyuncs.com
        prefix=osstest/exp/outfromhdb id=XXX
        key=XXX bucket=testbucket') FORMAT 'csv'
        DISTRIBUTED BY (date);
create WRITABLE external table ossexample_exp
        (date text, time text, open float, high float,
        low float, volume int)
        location('oss://oss-cn-hangzhou.aliyuncs.com
        dir=osstest/exp/ id=XXX
        key=XXX bucket=testbucket') FORMAT 'csv'
        DISTRIBUTED BY (date);
# Create a heap table named example to which you want to import data.
create table example
        (date text, time text, open float,
         high float, low float, volume int)
         DISTRIBUTED BY (date);
# Import data to the example heap table from the ossexample table in parallel.
insert into example select * from ossexample;
# Export data from example to OSS in parallel
insert into ossexample_exp select * from example;
# As shown in the following execution plan, all compute nodes are involved in the task.
# All compute nodes read data from OSS in parallel. AnalyticDB for PostgreSQL performs a redistributi
on motion operation to compute the data by using a hash algorithm, and then distributes the data to i
ts compute nodes after computing. After a compute node receives data, it performs an insert operation
to add the data to AnalyticDB for PostgreSQL.
explain insert into example select * from ossexample;
                                        QUERY PLAN
-------------------------------------------------------------------------------------------------
 Insert (slice0; segments: 4)  (rows=250000 width=92)
   ->  Redistribute Motion 4:4  (slice1; segments: 4)  (cost=0.00..11000.00 rows=250000 width=92)
         Hash Key: ossexample.date
         ->  External Scan on ossexample  (cost=0.00..11000.00 rows=250000 width=92)
(4 rows)
# As shown in the following query plan, each compute node exports local data directly to OSS without
redistributing the data.
```

```
explain insert into ossexample_exp select * from example;
                          QUERY PLAN
------------------------------------------------------------------
 Insert (slice0; segments: 3)  (rows=1 width=92)
   ->  Seq Scan on example  (cost=0.00..0.00 rows=1 width=92)
(2 rows)
```

TEXT and CSV format description

The following parameters specify the formats of files read from and written to OSS. You can specify the parameters in the external DDL parameters.

- \n: a line delimiter or line break for TEXT and CSV files.
- DELIMITER: specifies the delimiter of columns.
  - If the DELIMITER parameter is specified, the QUOTE parameter must also be specified.
  - Recommended column delimiters include commas (,), vertical bars (|), \t, and other special characters.
- QUOTE: encloses user data that contains special characters by column.
  - Strings that contain special characters will be enclosed by QUOTE to differentiate user data from the control characters.
  - To optimize the efficiency, it is unnecessary to enclose data such as integers in QUOTE characters.
  - QUOTE cannot be the same string as specified in DELIMITER. The default value of QUOTE is double quotation marks (").
  - User data that contains QUOTE characters must also contain ESCAPE characters to differentiate user data from machine code.
- ESCAPE: specifies the escape character.
  - Place an escape character before a special character that needs to be escaped to indicate that it is not a special character.
  - If ESCAPE is not specified, the default value is the same as QUOTE.
  - You can also use other characters as ESCAPE characters such as backslashes (\), which is used by MySQL.

Default control characters for TEXT and CSV files

Default control characters for TEXT and CSV files

Control character	TEXT	CSV
DELIMITER	\t (tab)	, (comma)
QUOTE	" (double quotation mark)	" (double quotation mark)
ESCAPE	N/A	Same as QUOTE
NULL	\N (backslash-N)	Empty string without quotation marks

> **Note** All control characters must be single-byte characters.

SDK troubleshooting

The following Error log information table lists the error logs generated when an error occurs during the import or export process.

Error log information

Keyword	Description
code	The HTTP status code of the error request.
error_code	The error code returned by OSS.
error_msg	The error message returned by OSS.
req_id	The UUID used to identify the request. If you require assistance in solving a problem, you can submit a ticket containing the req_id of the failed request to OSS developers.

For more information, see . You can handle timeout-related errors by using parameters related to oss_ext.

14.1.3.5.2. Import data from MySQL

You can use the mysql2pgsql tool to migrate tables from MySQL to AnalyticDB for PostgreSQL, Greenplum Database, PostgreSQL, or PPAS.

Background information

mysql2pgsql connects a source MySQL database to a destination AnalyticDB for PostgreSQL database, queries data to be exported from the MySQL database, and then imports the data to the destination database by using the \COPY statement. The tool supports multi-thread import. Each worker thread imports a part of database tables.

To download the binary installation package of mysql2pgsql, click here.

To view instructions on source code compilation of mysql2pgsql, click here.

Procedure

1. Modify the my.cfg configuration file to configure the connection information of source and destination databases.
   i. Modify the connection information of the source MySQL database.

   > **Note** You must have the read permissions on all user tables.

   ```
   [src.mysql]
   host = "192.168.1.1"
   port = "3306"
   user = "test"
   password = "test"
   db = "test"
   encodingdir = "share"
   encoding = "utf8"
   ```

ii. Modify the connection information of the destination PostgreSQL, PPAS, or AnalyticDB for PostgreSQL database.

> **Note** You must have the write permissions on the destination table.

```
[desc.pgsql]
connect_string = "host=192.168.1.2 dbname=test port=3432  user=test password=pgsql"
```

2. Import data by using mysql2pgsql.

```
./mysql2pgsql -l <tables_list_file> -d -n -j <number of threads> -s <schema of target table>
```

Parameters

Parameter	Description

-l	Optional. Used to specify a text file that contains tables to be synchronized. If you do not specify this parameter, all the tables in the database that is specified in the configuration file will be synchronized. `<tables_list_file>` is the name of a file that contains a collection of tables to be synchronized and conditions for table queries. The content format is as follows:
	`table1 : select * from table_big where column1 < '2016-08-05'`
	`table2 :`
	`table3`
	`table4: select column1, column2 from tableX where column1 ! = 10`
	`table5: select * from table_big where column1 >= '2016-08-05'`

-d	Optional. Indicates the table creation DDL statement that creates the destination table but does not synchronize data.
-n	Optional. Must be used along with -d to specify that the table partition definition is not included in the DDL statement.
-j	Optional. Used to specify the number of threads used for data synchronization. If you do not specify this parameter, five concurrent threads will be used by default.
-s	Optional. Used to specify the schema of the destination table. Only one schema at a time can be specified by the command. If you do not specify the parameter, the data is imported into the table under the public schema.

Typical usage

Full database migration

1. Obtain the DDL statements of the corresponding destination table by running the following command:

   ```
   ./mysql2pgsql -d
   ```

2. Create a table in the destination database based on these DDL statements with the distribution key information added.
3. Run the following command to synchronize all tables:

   ```
   ./mysql2pgsql
   ```

   This command will migrate the data from all MySQL tables in the database that is specified in the configuration file to the destination database. By default, five concurrent threads are used to read and import data from involved tables.

Partial table migration

1. Create a new file tab_list.txt and enter the following content:

```
t1
t2 : select * from t2 where c1 > 138888
```

2. Run the following command to synchronize the specified t1 and t2 tables (note that for the t2 table, only data that meets the c1 > 138888 condition is migrated):

```
./mysql2pgsql -l tab_list.txt
```

14.1.3.5.3. Import data from PostgreSQL

You can use the pgsql2pgsql tool to migrate tables across AnalyticDB for PostgreSQL, Greenplum Database, PostgreSQL, and PPAS.

Context

pgsql2pgsql supports the following features:

- Full migration across PostgreSQL, PPAS, Greenplum Database, and AnalyticDB for PostgreSQL.
- Full migration and incremental migration from PostgreSQL or PPAS (version 9.4 or later) to AnalyticDB for PostgreSQL or ApsaraDB RDS for PPAS.

You can download the software packages from the dbsync project library.

- To download the binary installation package of pgsql2pgsql, click here.
- To view instructions on source code compilation of pgsql2pgsql, click here.

Procedure

1. Modify the my.cfg configuration file to configure the connection information of source and destination databases.
   i. Modify the connection information of the source PostgreSQL database.

   > **Note** In the connection information of the source PostgreSQL database, we recommend that you set the user to the owner of the source database.

   ```
   [src.pgsql]
   connect_string = "host=192.168.0.1 dbname=test port=3432  user=test password=pgsql"
   ```

   ii. Modify the connection information of the local temporary PostgreSQL database.

   ```
   [local.pgsql]
   connect_string = "host=192.168.0.2 dbname=test port=3432  user=test2 password=pgsql"
   ```

   iii. Modify the connection information of the destination PostgreSQL database.

   > **Note** You must have the write permissions on the destination table.

   ```
   [desc.pgsql]
   connect_string = "host=192.168.0.2 dbname=test port=3432  user=test3 password=pgsql"
   ```

> **Note**
>
> - If you need to synchronize incremental data, you must have the permissions to create replication slots in the source database.
> - PostgreSQL versions 9.4 and later support logic flow replication, meaning that source databases of the versions support incremental migration. The kernel supports logic flow replication only if you configure the following kernel parameters:
>
>   wal_level = logical
>
>   max_wal_senders = 6
>
>   max_replication_slots = 6

2. Use pgsql2pgsql to perform full database migration.

   ```
   ./pgsql2pgsql
   ```

   By default, the migration program migrates the table data of all users from the source PostgreSQL database to the destination PostgreSQL database.

3. View the status information.

   You can view the status information in a single migration process by connecting to the local temporary database. The information is stored in the db_sync_status table, including the start and end time of the full migration, the start time of the incremental migration, and the status of incremental synchronization.

14.1.3.5.4. Import data by using the \COPY statement

You can use the `\COPY` statement to import the data of local text files into AnalyticDB for PostgreSQL databases. The local text files must be formatted, such as files that use commas (,), semicolons (;), or special characters as delimiters.

Context

- Parallel writing of large amounts of data is not available because the `\COPY` statement writes data in serial using the coordinator node. If you need to import a large amount of data in parallel, you can use the OSS-based data import method.
- The `\COPY` statement is a psql instruction. If you use the database statement `COPY` instead of the `\COPY` statement, you must note that only stdin is supported. This COPY statement does not support file because the root user does not have the superuser permissions to perform operations on files.
- AnalyticDB for PostgreSQL also allows you to use JDBC to execute the COPY statement. The CopyIn method is encapsulated within JDBC. For more information, see Interface CopyIn.
- For more information about how to use the COPY statement, see COPY.

Procedure

1. Import data by using the following sample code:

```
\COPY table [(column [, ...])] FROM {'file' | STDIN}
     [ [WITH]
       [OIDS]
       [HEADER]
       [DELIMITER [ AS ] 'delimiter']
       [NULL [ AS ] 'null string']
       [ESCAPE [ AS ] 'escape' | 'OFF']
       [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
       [CSV [QUOTE [ AS ] 'quote']
            [FORCE NOT NULL column [, ...]]
       [FILL MISSING FIELDS]
       [[LOG ERRORS [INTO error_table] [KEEP]
        SEGMENT REJECT LIMIT count [ROWS | PERCENT] ]
\COPY {table [(column [, ...])] | (query)} TO {'file' | STDOUT}
      [ [WITH]
        [OIDS]
        [HEADER]
        [DELIMITER [ AS ] 'delimiter']
        [NULL [ AS ] 'null string']
        [ESCAPE [ AS ] 'escape' | 'OFF']
        [CSV [QUOTE [ AS ] 'quote']
             [FORCE QUOTE column [, ...]] ]
      [IGNORE EXTERNAL PARTITIONS ]
```

14.1.4. Databases

14.1.4.1. Overview

The operations based on the Greenplum Database in AnalyticDB for PostgreSQL are the same as those in the Greenplum Database, including schema, supported data types, and user permissions. Except for certain operations exclusive to the Greenplum Database (such as the partition keys and AO tables), you can refer to PostgreSQL for other operations.

References

- Pivotal Greenplum Official Documentation
- Greenplum 4.3 Best Practices

14.1.4.2. Create a database

After you log on to the AnalyticDB for PostgreSQL instance, you can execute SQL statements to create databases.

Similar to PostgreSQL, in AnalyticDB for PostgreSQL you can execute SQL statements to create databases. For example, after **psql** is connected to Greenplum, execute the following statements:

```
=> create database mygpdb;
CREATE DATABASE
=> \c mygpdb
psql (9.4.4, server 8.3devel)
You are now connected to database "mygpdb" as user "mygpdb".
```

14.1.4.3. Create a partition key

AnalyticDB for PostgreSQL is a distributed database and data is distributed across all the data nodes. You must create partition keys to distribute the data. The partition keys are vital to query performance. Partition keys are used to ensure **even data distribution**. Proper selection of keys can significantly improve query performance.

Specify a partition key

In AnalyticDB for PostgreSQL, tables can be distributed across all compute nodes in either hash or random mode. You must specify the partition key when creating a table. Imported data will be distributed to the specific compute node based on the hash value calculated by the partition key.

```
=> create table vtbl(id serial, key integer, value text, shape cuboid, location geometry, comment tex
t) distributed by (key);
CREATE TABLE
```

If you do not specify the partition key (that means a statement without the `distributed by (key)` field), AnalyticDB for PostgreSQL will randomly allocate the ID field by using the round-robin algorithm.

Rules for selecting the partition key

- Select evenly distributed columns or multiple columns to prevent data skew.
- Select fields commonly used for connection operations, especially for highly concurrent statements.
- Select the condition columns that feature high concurrency queries and high filterability.
- Do not use random distribution.

14.1.4.4. Construct data

In some test scenarios, you must construct data to fill the database.

1. Create a function that generates random strings.

```
CREATE OR REPLACE FUNCTION random_string(integer) RETURNS text AS $body$
SELECT array_to_string(array
                     (SELECT substring('0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrst
uvwxyz'
                                       FROM (ceil(random()*62))::int
                                       FOR 1)
                      FROM generate_series(1, $1)), '');
$body$
LANGUAGE SQL VOLATILE;
```

2. Create a partition key.

```
CREATE TABLE tbl(id serial, KEY integer, locate geometry, COMMENT text) distributed by (key);
```

3. Construct data.

```
INSERT INTO tbl(KEY, COMMENT, locate)
 SELECT
     KEY,
     COMMENT,
     ST_GeomFromText(locate) AS locate
 FROM
     (SELECT
         (a + 1) AS KEY,
         random_string(ceil(random() * 24)::integer) AS COMMENT,
         'POINT(' || ceil(random() * 36 + 99) || ' ' || ceil(random() * 24 + 50) || ')' AS locate

     FROM
         generate_series(0, 99999) AS a)
     AS t;
```

14.1.4.5. Query data

This topic describes the query statements and how to view the query plans.

Query statement sample

```
=> select * from tbl where key = 751;
| id  | key | value | shape        | locate                                          | comment        |
+-----+-----+-------+--------------+-------------------------------------------------+----------------+
| 751 | 751 | red   | 0101000000000000000C05B4000000000000004A40 | B9hPhjeNWPqV |
(1 row)
Time: 513.101 ms
```

View a query plan

```
=> explain select * from tbl where key = 751;
Gather Motion 1:1  (slice1; segments: 1)  (cost=0.00..1519.28 rows=1 width=53)
  ->  Seq Scan on tbl  (cost=0.00..1519.28 rows=1 width=53)
        Filter: key = 751
Settings:  effective_cache_size=8GB; gp_statistics_use_fkeys=on
Optimizer status: legacy query optimizer
```

14.1.4.6. Manage extensions

You can use extensions to expand database features. AnalyticDB for PostgreSQL enables you to manage extensions.

Extension types

AnalyticDB for PostgreSQL supports the following extensions:

- PostGIS: supports geographic information data.
- MADlib: supports the machine learning function library.
- fuzzystrmatch: supports the fuzzy matching of strings.
- orafunc: compatible with some Oracle functions.
- oss_ext: supports reading data from OSS.
- hll: collects statistics by using the HyperLogLog algorithm.
- pljava: supports compiling user-defined functions (UDF) in the PL/Java language.

- pgcrypto: supports cryptographic hash functions.
- intarray: supports integer array-related functions, operators, and indexes.

Create an extension

Execute the following statements to create an extension:

```
CREATE EXTENSION <extension name>;
CREATE SCHEMA <schema name>;
CREATE EXTENSION IF NOT EXISTS <extension name> WITH SCHEMA <schema name>;
```

> **Note**
>
> Before you create the MADlib extension, you must create the plpythonu extension first.
>
> ```
> CREATE EXTENSION plpythonu;
> CREATE EXTENSION madlib;
> ```

Delete an extension

Execute the following statements to delete an extension:

```
DROP EXTENSION <extension name>;
DROP EXTENSION IF EXISTS <extension name> CASCADE;
```

> **Note** If there are objects dependent on the extension, you must add the CASCADE keyword to delete all dependent objects.

14.1.4.7. Manage users and permissions

This topic describes how to manage users and permissions in AnalyticDB for PostgreSQL.

Manage users

The system prompts you to specify an initial username and password when you create an instance. This initial user is the root user. After the instance is created, you can use the root user account to connect to the database. The system also creates superusers such as aurora and replicator for internal management.

You can run the `\du+` command to view the information of all the users after you connect to the database by using the client tool of PostgreSQL or Greenplum. Example:

```
postgres=> \du+
                                   List of roles
  Role name   |            Attributes             | Member of |  Description
--------------+-----------------------------------+-----------+---------------
 root_user    |                                   |      | rds_superuser
 ...
```

AnalyticDB for PostgreSQL does not provide superuser permissions, but offers a similar role, RDS_SUPERUSER, which is consistent with the permission system of ApsaraDB RDS for PostgreSQL. The root user (such as root_user in the preceding example) has the permissions of the RDS_SUPERUSER role. You can only identify this permission attribute by viewing the user description.

The root user has the following permissions:

- Can create databases and users and perform actions such as LOGIN, excluding the SUPERUSER permissions.
- Can view and modify the data tables of other users and perform actions such as SELECT, UPDATE, DELETE, and changing owners.
- Can view the connection information of other users, cancel their SQL statements, and kill their connections.
- Can create and delete extensions.
- Can create other users with RDS_SUPERUSER permissions. Example:

```
CREATE ROLE root_user2 RDS_SUPERUSER LOGIN PASSWORD 'xyz' ;
```

Manage permissions

You can manage permissions at the database, schema, and table levels. For example, if you want to grant read permissions on a table to a user and revoke their write permissions, you can execute the following statements:

```
GRANT SELECT ON TABLE t1 TO normal_user1;
REVOKE UPDATE ON TABLE t1 FROM normal_user1;
REVOKE DELETE ON TABLE t1 FROM normal_user1;
```

14.1.4.8. Manage JSON data

JavaScript Object Notation (JSON) has become a basic data type in the Internet and IoT fields. For more information about JSON, visit JSON official website. PostgreSQL support for JSON has been well developed. Optimized by Alibaba Cloud, AnalyticDB for PostgreSQL supports the JSON type based on the PostgreSQL syntax.

Check whether the current version supports JSON

Execute the following statement to check whether the current version supports JSON:

```
=> SELECT '""'::json;
```

If the following output is displayed, it indicates the JSON type is supported and the instance is ready for use. If the operation fails, restart the instance.

```
 json
------
 ""
(1 row)
```

If the following output is displayed, it indicates the JSON type is not supported.

```
ERROR:  type "json" does not exist
LINE 1: SELECT '""'::json;
               ^
```

The preceding command converts data from the string type to the JSON type. PostgreSQL supports operations on JSON data based on this conversion.

JSON conversion in the database

Database operations include reading and writing. The written data is typically converted from the string type to the JSON type. The contents of a string must meet the JSON standard, such as strings, digits, arrays, and objects. Example:

String

```
=> SELECT '"hijson"'::json;
 json
-------
 "hijson"
(1 row)
```

`::` is used for explicit type conversion in PostgreSQL, Greenplum, and AnalyticDB for PostgreSQL. The database calls the input function in JSON type during the conversion. Therefore, the JSON format check is performed as follows:

```
=> SELECT '{hijson:1024}'::json;
ERROR:  invalid input syntax for type json
LINE 1: SELECT '{hijson:1024}'::json;
               ^
DETAIL:  Token "hijson" is invalid.
CONTEXT:  JSON data, line 1: {hijson...
=>
```

In the preceding example, `hijson` must be enclosed in double quotation marks (`"`) because JSON requires the KEY value to be a string. A syntax error is returned when `{hijson:1024}` is entered.

Apart from explicit type conversion, database records can also be converted to JSON.

Typically, JSON is not used for a string or a digit, but an object that contains one or more key-value pairs. AnalyticDB for PostgreSQL can support most JSON scenarios after data is converted from the string type to objects. Example:

```
=> select row_to_json(row('{"a":"a"}', 'b'));
           row_to_json
---------------------------------
 {"f1":"{\"a\":\"a\"}","f2":"b"}
(1 row)
=> select row_to_json(row('{"a":"a"}'::json, 'b'));
        row_to_json
---------------------------
 {"f1":{"a":"a"},"f2":"b"}
(1 row)
```

You can see the differences between the string and JSON here. The whole record is conveniently converted into the JSON type.

JSON data types

- Object

  The object is the most frequently used data type in JSON. Example:

  ```
  => select '{"key":"value"}'::json;
          json
    -----------------
     {"key":"value"}
    (1 row)
  ```

- Integer and floating point number

  JSON only supports three data types for numeric values: integer, floating point number, and constant expression. AnalyticDB for PostgreSQL supports all three types.

```
=> SELECT '1024'::json;
 json
------
 1024
(1 row)
=> SELECT '0.1'::json;
 json
------
 0.1
(1 row)
```

The following information is required in some special situations:

```
=> SELECT '1e100'::json;
 json
-------
 1e100
(1 row)
=> SELECT '{"f":1e100}'::json;
    json
-------------
 {"f":1e100}
(1 row)
```

Extra-long numbers are also supported. Example:

```
=> SELECT '9223372036854775808'::json;
        json
---------------------
 9223372036854775808
(1 row)
```

- Array

```
=> SELECT '[[1,2], [3,4,5]]'::json;
        json
------------------
 [[1,2], [3,4,5]]
(1 row)
```

Operators

Operators supported by JSON

```
=> select oprname,oprcode from pg_operator where oprleft = 3114;
 oprname |          oprcode
---------+---------------------------
 ->      | json_object_field
 ->>     | json_object_field_text
 ->      | json_array_element
 ->>     | json_array_element_text
 #>      | json_extract_path_op
 #>>     | json_extract_path_text_op
(6 rows)
```

Basic usage

```
=> SELECT '{"f":"1e100"}'::json -> 'f';
 ? column?
----------
 "1e100"
(1 row)
=> SELECT '{"f":"1e100"}'::json ->> 'f';
 ? column?
----------
 1e100
(1 row)
=> select '{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}'::json#>array['f4','f6'];
 ? column?
-----------
 "stringy"
(1 row)
=> select '{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}'::json#>'{f4,f6}';
 ? column?
-----------
 "stringy"
(1 row)
=> select '{"f2":["f3",1],"f4":{"f5":99,"f6":"stringy"}}'::json#>>'{f2,0}';
 ? column?
----------
 f3
(1 row)
```

JSON functions

Supported JSON functions

```
postgres=# \df *json*
                                                  List of functions
   Schema   |           Name            | Result data type |                     Argument data types
|  Type
------------+---------------------------+------------------+-----------------------------------------
------------------+--------
 pg_catalog | array_to_json             | json             | anyarray
| normal
 pg_catalog | array_to_json             | json             | anyarray, boolean
| normal
 pg_catalog | json_array_element        | json             | from_json json, element_index integer
| normal
 pg_catalog | json_array_element_text   | text             | from_json json, element_index integer

(24 rows)
```

Basic usage

```
=> SELECT array_to_json('{{1,5},{99,100}}'::int[]);
  array_to_json
-----------------
 [[1,5],[99,100]]
(1 row)
=> SELECT row_to_json(row(1,'foo'));
     row_to_json
---------------------
 {"f1":1,"f2":"foo"}
(1 row)
=> SELECT json_array_length('[1,2,3,{"f1":1,"f2":[5,6]},4]');
 json_array_length
-------------------
                 5
(1 row)
=> select * from json_each('{"f1":[1,2,3],"f2":{"f3":1},"f4":null,"f5":99,"f6":"stringy"}') q;
 key |   value
-----+-----------
 f1  | [1,2,3]
 f2  | {"f3":1}
 f4  | null
 f5  | 99
 f6  | "stringy"
(5 rows)
=> select json_each_text('{"f1":[1,2,3],"f2":{"f3":1},"f4":null,"f5":"null"}');
  json_each_text
-------------------
 (f1,"[1,2,3]")
 (f2,"{""f3"":1}")
 (f4,)
 (f5,null)
(4 rows)
=> select json_array_elements('[1,true,[1,[2,3]],null,{"f1":1,"f2":[7,8,9]},false]');
  json_array_elements
-----------------------
 1
 true
 [1,[2,3]]
 null
 {"f1":1,"f2":[7,8,9]}
 false
(6 rows)
create type jpop as (a text, b int, c timestamp);
=> select * from json_populate_record(null::jpop,'{"a":"blurfl","x":43.2}', false) q;
   a    | b | c
--------+---+---
 blurfl |   |
(1 row)
=>     select * from json_populate_recordset(null::jpop,'[{"a":"blurfl","x":43.2},{"b":3,"c":"2012-01
-20 10:42:53"}]',false) q;
   a    | b |            c
--------+---+--------------------------
 blurfl |   |
        | 3 | Fri Jan 20 10:42:53 2012
(2 rows)
```

Code examples

Create a table

```
create table tj(id serial, ary int[], obj json, num integer);
=> insert into tj(ary, obj, num) values('{1,5}'::int[], '{"obj":1}', 5);
INSERT 0 1
=> select row_to_json(q) from (select id, ary, obj, num from tj) as q;
               row_to_json
-------------------------------------------
 {"f1":1,"f2":[1,5],"f3":{"obj":1},"f4":5}
(1 row)
=> insert into tj(ary, obj, num) values('{2,5}'::int[], '{"obj":2}', 5);
INSERT 0 1
=> select row_to_json(q) from (select id, ary, obj, num from tj) as q;
               row_to_json
-------------------------------------------
 {"f1":1,"f2":[1,5],"f3":{"obj":1},"f4":5}
 {"f1":2,"f2":[2,5],"f3":{"obj":2},"f4":5}
(2 rows)
```

Join multiple tables

```
create table tj2(id serial, ary int[], obj json, num integer);
=> insert into tj2(ary, obj, num) values('{2,5}'::int[], '{"obj":2}', 5);
INSERT 0 1
=> select * from tj, tj2 where tj.obj->>'obj' = tj2.obj->>'obj';
 id |  ary  |    obj    | num | id |  ary  |    obj    | num
----+-------+-----------+-----+----+-------+-----------+-----
  2 | {2,5} | {"obj":2} |   5 |  1 | {2,5} | {"obj":2} |   5
(1 row)
=> select * from tj, tj2 where json_object_field_text(tj.obj, 'obj') = json_object_field_text(tj2.obj
, 'obj');
 id |  ary  |    obj    | num | id |  ary  |    obj    | num
----+-------+-----------+-----+----+-------+-----------+-----
  2 | {2,5} | {"obj":2} |   5 |  1 | {2,5} | {"obj":2} |   5
(1 row)
```

Use the JSON function index

```
CREATE TEMP TABLE test_json (
       json_type text,
       obj json
);
=> insert into test_json values('aa', '{"f2":{"f3":1},"f4":{"f5":99,"f6":"foo"}}');
INSERT 0 1
=> insert into test_json values('cc', '{"f7":{"f3":1},"f8":{"f5":99,"f6":"foo"}}');
INSERT 0 1
=> select obj->'f2' from test_json where json_type = 'aa';
 ? column?
----------
 {"f3":1}
(1 row)
=> create index i on test_json (json_extract_path_text(obj, '{f4}'));
CREATE INDEX
=> select * from test_json where json_extract_path_text(obj, '{f4}') = '{"f5":99,"f6":"foo"}';
 json_type |                 obj
-----------+---------------------------------------
 aa        | {"f2":{"f3":1},"f4":{"f5":99,"f6":"foo"}}
(1 row)
```

> **Note**
>
> JSON data cannot be used as the partition key and does not support JSON aggregate functions.

Example of using Python to access the database:

```
#! /bin/env python
import time
import json
import psycopg2
def gpquery(sql):
    conn = None
    try:
        conn = psycopg2.connect("dbname=sanity1x2")
        conn.autocommit = True
        cur = conn.cursor()
        cur.execute(sql)
        return cur.fetchall()
    except Exception as e:
        if conn:
            try:
                conn.close()
            except:
                pass
            time.sleep(10)
        print e
    return None
def main(_):
    sql = "select obj from tj;"
    #rows = Connection(host, port, user, pwd, dbname).query(sql)
    rows = gpquery(sql)
    for row in rows:
        print json.loads(row[0])
if __name__ == '__main__':
    main()
```

14.1.4.9. Use HyperLogLog

AnalyticDB for PostgreSQL is highly optimized by Alibaba Cloud, and not only has the features of Greenplum Database, but also supports HyperLogLog. It is suitable for industries such as Internet advertising and estimation analysis that require quick estimation of business metrics such as PV and UV.

Create a HyperLogLog extension

You can execute the following statement to create a HyperLogLog extension:

```
CREATE EXTENSION hll;
```

Basic types

- Execute the following statement to create a table containing the hll field:

  ```
  create table agg (id int primary key,userids hll);
  ```

- Execute the following statement to convert int to hll_hashval:

  ```
  select 1::hll_hashval;
  ```

Basic operators

- The hll type supports =, !=, <>, ||, and #.

```
select hll_add_agg(1::hll_hashval) = hll_add_agg(2::hll_hashval);
select hll_add_agg(1::hll_hashval) || hll_add_agg(2::hll_hashval);
select #hll_add_agg(1::hll_hashval);
```

- The hll_hashval type supports =, !=, and <>.

```
select 1::hll_hashval = 2::hll_hashval;
select 1::hll_hashval <> 2::hll_hashval;
```

Basic functions

- Hash functions such as Hll_hash_boolean, hll_hash_smallint, and hll_hash_bigint.

```
select hll_hash_boolean(true);
select hll_hash_integer(1);
```

- hll_add_agg: converts the int format to the hll format.

```
select hll_add_agg(1::hll_hashval);
```

- hll_union: aggregates the hll fields.

```
select hll_union(hll_add_agg(1::hll_hashval),hll_add_agg(2::hll_hashval));
```

- hll_set_defaults: sets the precision.

```
select hll_set_defaults(15,5,-1,1);
```

- hll_print: displays debug information.

```
select hll_print(hll_add_agg(1::hll_hashval));
```

Examples

```
create table access_date (acc_date date unique, userids hll);
insert into access_date select current_date, hll_add_agg(hll_hash_integer(user_id)) from generate_ser
ies(1,10000) t(user_id);
insert into access_date select current_date-1, hll_add_agg(hll_hash_integer(user_id)) from generate_s
eries(5000,20000) t(user_id);
insert into access_date select current_date-2, hll_add_agg(hll_hash_integer(user_id)) from generate_s
eries(9000,40000) t(user_id);
postgres=# select #userids from access_date where acc_date=current_date;
     ? column?
------------------
 9725.85273370708
(1 row)
postgres=# select #userids from access_date where acc_date=current_date-1;
     ? column?
------------------
 14968.6596883279
(1 row)
postgres=# select #userids from access_date where acc_date=current_date-2;
     ? column?
------------------
 29361.5209149911
(1 row)
```

14.1.4.10. Use the CREATE LIBRARY statement

AnalyticDB for PostgreSQL introduces the CREATE LIBRARY and DROP LIBRARY statements to allow you to import custom software packages.

Syntax

```
CREATE LIBRARY library_name LANGUAGE [JAVA] FROM oss_location OWNER ownername
CREATE LIBRARY library_name LANGUAGE [JAVA] VALUES file_content_hex OWNER ownername
DROP LIBRARY library_name
```

Parameters

Parameter	Description
library_name	The name of the library to be installed. If the library to be installed has the same name as an existing library, you must delete the existing library before installing the new one.
LANGUAGE [JAVA]	The programming language to be used. Only PL/Java is supported.
oss_location	The location of the package. You can specify the OSS bucket and object names. Only one object can be specified and the specified object cannot be a compressed file. The format is as follows: `oss://oss_endpoint filepath=[folder/[folder/]...]/file_name id=userossid key=userosskey bucket=ossbucket`
file_content_hex	The content of the file. The byte stream is in hexadecimal notation. For example, 73656c6563742031 indicates the hexadecimal byte stream of "select 1". You can use this syntax to import packages without using OSS.
ownername	Specifies the user.
DROP LIBRARY	Deletes a library.

Examples

- Example 1: Install a JAR package named analytics.jar.

```
create library example language java from 'oss://oss-cn-hangzhou.aliyuncs.com filepath=analytics.jar id=xxx key=yyy bucket=zzz';
```

- Example 2: Import the file content with the byte stream in hexadecimal notation.

```
create library pglib LANGUAGE java VALUES '73656c6563742031' OWNER "myuser";
```

- Example 3: Delete a library.

```
drop library example;
```

- Example 4: View installed libraries.

```
select name, lanname from pg_library;
```

14.1.4.11. Create and use the PL/Java UDF

AnalyticDB for PostgreSQL allows you to compile and upload JAR software packages written in PL/Java language, and use these JAR packages to create user-defined functions (UDFs). The PL/Java language supported by AnalyticDB for PostgreSQL is Community Edition PL/Java 1.5.0 and the JVM version is 1.8. This topic describes how to create a PL/Java UDF. For more information about PL/Java examples, see PL/Java code. For more information about the compiling method, see PL/Java documentation.

Procedure

1. In AnalyticDB for PostgreSQL, execute the following statement to create a PL/Java extension. You only need to execute the statement once for each database.

```
create extension pljava;
```

2. Compile the UDF based on your business needs. For example, you can use the following code to compile the Test.java file:

```
public class Test
 {
     public static String substring(String text, int beginIndex,
                int endIndex)
             {
                     try {
                         Process process = null;
                         process = Runtime.getRuntime().exec("ech Test running");
                     } catch (Exception e) {
                        return "" + e;
                     }
                     return text.substring(beginIndex, endIndex);
             }
 }
```

3. Compile the manifest.txt file:

```
 Manifest-Version: 1.0
 Main-Class: Test
 Specification-Title: "Test"
 Specification-Version: "1.0"
 Created-By: 1.7.0_99
 Build-Date: 01/20/2016 21:00 AM
```

4. Run the following commands to compile and package the program:

```
javac Test.java
 jar cfm analytics.jar manifest.txt Test.class
```

5. Upload the analytics.jar file generated in step 4 to OSS by using the following OSS console command.

```
osscmd put analytics.jar oss://zzz
```

6. In AnalyticDB for PostgreSQL, execute the CREATE LIBRARY statement to import the file to AnalyticDB for PostgreSQL:

```
create library example language java from 'oss://oss-cn-hangzhou.aliyuncs.com filepath=analytics.
jar id=xxx key=yyy bucket=zzz';
```

> **Note** You can only use the filepath variable in the CREATE LIBRARY statement to import files one at a time. Additionally, the CREATE LIBRARY statement also supports byte streams to import files without using OSS. For more information, see Use the CREATE LIBRARY statement.

7. In AnalyticDB for PostgreSQL, execute the following statements to create and use the UDF.

```
create table temp (a varchar) distributed randomly;
 insert into temp values ('my string');
 create or replace function java_substring(varchar, int, int) returns varchar as 'Test.substring'
language java;
 select java_substring(a, 1, 5) from temp;
```

14.1.5. Table

14.1.5.1. Create a table

You can create tables within your databases.

Syntax

The complete syntax for creating a table is as follows. Depending on your business needs, not all clauses will be required. Use the clauses that can fulfill your business needs.

```
CREATE [[GLOBAL | LOCAL] {TEMPORARY | TEMP}] TABLE table_name (
[ { column_namedata_type [ DEFAULT default_expr ]
   [column_constraint [ ... ]
[ ENCODING ( storage_directive [,...] ) ]
]
   | table_constraint
   | LIKE other_table [{INCLUDING | EXCLUDING}
                      {DEFAULTS | CONSTRAINTS}] ...}
   [, ... ] ]
   )
   [ INHERITS ( parent_table [, ... ] ) ]
   [ WITH ( storage_parameter=value [, ... ] )
   [ ON COMMIT {PRESERVE ROWS | DELETE ROWS | DROP} ]
   [ TABLESPACE tablespace ]
   [ DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY ]
   [ PARTITION BY partition_type (column)
       [ SUBPARTITION BY partition_type (column) ]
          [ SUBPARTITION TEMPLATE ( template_spec ) ]
       [...]
    ( partition_spec )
        | [ SUBPARTITION BY partition_type (column) ]
          [...]
    ( partition_spec
      [ ( subpartition_spec
           [(...)]
        ) ]
    )
```

The column_constraint clause can be defined as follows:

```
[CONSTRAINT constraint_name]
   NOT NULL | NULL
   | UNIQUE [USING INDEX TABLESPACE tablespace]
            [WITH ( FILLFACTOR = value )]
   | PRIMARY KEY [USING INDEX TABLESPACE tablespace]
                 [WITH ( FILLFACTOR = value )]
   | CHECK ( expression )
   | REFERENCES table_name [ ( column_name [, ... ] ) ]
            [ key_match_type ]
            [ key_action ]
```

The storage_directive clause of columns can be defined as follows:

```
COMPRESSTYPE={ZLIB | QUICKLZ | RLE_TYPE | NONE}
 [COMPRESSLEVEL={0-9} ]
 [BLOCKSIZE={8192-2097152} ]
```

The storage_parameter clause of tables can be defined as follows:

```
APPENDONLY={TRUE|FALSE}
BLOCKSIZE={8192-2097152}
ORIENTATION={COLUMN|ROW}
CHECKSUM={TRUE|FALSE}
COMPRESSTYPE={ZLIB|QUICKLZ|RLE_TYPE|NONE}
COMPRESSLEVEL={0-9}
FILLFACTOR={10-100}
OIDS[=TRUE|FALSE]
```

The table_constraint clause can be defined as follows:

```
[CONSTRAINT constraint_name]
UNIQUE ( column_name [, ... ] )
       [USING INDEX TABLESPACE tablespace]
       [WITH ( FILLFACTOR=value )]
| PRIMARY KEY ( column_name [, ... ] )
              [USING INDEX TABLESPACE tablespace]
              [WITH ( FILLFACTOR=value )]
| CHECK ( expression )
| FOREIGN KEY ( column_name [, ... ] )
         REFERENCES table_name [ ( column_name [, ... ] ) ]
         [ key_match_type ]
         [ key_action ]
         [ key_checking_mode ]
```

Valid values of key_match_type:

```
  MATCH FULL
| SIMPLE
```

Valid values of key_action:

```
  ON DELETE
| ON UPDATE
| NO ACTION
| RESTRICT
| CASCADE
| SET NULL
| SET DEFAULT
```

Valid values of key_checking_mode:

```
  DEFERRABLE
| NOT DEFERRABLE
| INITIALLY DEFERRED
| INITIALLY IMMEDIATE
```

Valid values of partition_type:

```
    LIST
  | RANGE
```

The partition_specification clause can be defined as follows:

```
partition_element [, ...]
```

The partition_element clause can be defined as follows:

```
   DEFAULT PARTITION name
  | [PARTITION name] VALUES (list_value [,...] )
  | [PARTITION name]
     START ([datatype] 'start_value') [INCLUSIVE | EXCLUSIVE]
     [ END ([datatype] 'end_value') [INCLUSIVE | EXCLUSIVE] ]
     [ EVERY ([datatype] [number | INTERVAL] 'interval_value') ]
  | [PARTITION name]
     END ([datatype] 'end_value') [INCLUSIVE | EXCLUSIVE]
     [ EVERY ([datatype] [number | INTERVAL] 'interval_value') ]
[ WITH ( partition_storage_parameter=value [, ... ] ) ]
[ TABLESPACE tablespace ]
```

The subpartition_spec or template_spec clause can be defined as follows:

```
subpartition_element [, ...]
```

The subpartition_element clause can be defined as follows:

```
   DEFAULT SUBPARTITION name
  | [SUBPARTITION name] VALUES (list_value [,...] )
  | [SUBPARTITION name]
     START ([datatype] 'start_value') [INCLUSIVE | EXCLUSIVE]
     [ END ([datatype] 'end_value') [INCLUSIVE | EXCLUSIVE] ]
     [ EVERY ([datatype] [number | INTERVAL] 'interval_value') ]
  | [SUBPARTITION name]
     END ([datatype] 'end_value') [INCLUSIVE | EXCLUSIVE]
     [ EVERY ([datatype] [number | INTERVAL] 'interval_value') ]
[ WITH ( partition_storage_parameter=value [, ... ] ) ]
[ TABLESPACE tablespace ]
```

The storage_parameter clause of partitions can be defined as follows:

```
   APPENDONLY={TRUE|FALSE}
   BLOCKSIZE={8192-2097152}
   ORIENTATION={COLUMN|ROW}
   CHECKSUM={TRUE|FALSE}
   COMPRESSTYPE={ZLIB|QUICKLZ|RLE_TYPE|NONE}
   COMPRESSLEVEL={1-9}
   FILLFACTOR={10-100}
   OIDS[=TRUE|FALSE]
```

Parameters

The Table creation parameters table describes the key parameters for creating a table.

Table creation parameters

Parameter	Description
TABLE_NAME	The name of the table to be created.
column_name	The name of a column to be created in the new table.
data_type	The data type of the column. For columns that contain textual data, set the data type to VARCHAR or TEXT. We do not recommend the CHAR type.
DEFAULT default_expr	Specifies a default value for the column. The system will assign this default value to all columns that do not have a value. The default values can be any variable-free expression. Subqueries or cross-references to other columns in the table are not allowed. The data type of the default expression must match the data type of the column. If a column does not have a default value, the default value is null.
ENCODING storage_directive	Specifies the type of compression and block size for the column data. This clause is valid only for append-optimized, column-oriented tables. Column compression settings are inherited from the table level to the partition level to the sub-partition level. The lowest-level settings have priority over inherited settings.
INHERITS	Specifies that all columns in the new table automatically inherit a parent table. You can use INHERITS to create a persistent relationship between the new child table and its parent table. Schema modifications to the parent table are applied to the child table as well. When the parent table is also scanned, the data of the child table is scanned as well.
LIKE other_table	Specifies a table from which the new table automatically copies all column names, data types, NOT NULL constraints, and distribution policies. Storage properties such as append-optimized or partition structure are not copied. Unlike INHERITS, the new table is completely decoupled from the original table after the new table is created.
CONSTRAINT constraint_name	Configures a column or table constraint. When a constraint is violated, the constraint name will be displayed in the error message. Constraint names can be used to communicate helpful information to client applications. Constraint names that contain spaces must be enclosed by double quotation marks ('').
WITH (storage_option=value)	Configures storage options for the table or its indexes.
ON COMMIT	The operation that the system performs on the temporary tables at the end of a transaction. Valid values: • **PRESERVE ROWS**: No special action is taken. The data will be retained after the transaction is complete. The data will only be released when the session is disconnected. • **DELETE ROWS**: All rows in the temporary table are deleted. • **DROP**: The temporary table is deleted.
TABLESPACE tablespace	Specifies the name of the tablespace in which the new table is to be created. If not specified, the default tablespace of the database is used.

Parameter	Description
DISTRIBUTED BY	Specifies the distribution policy for the database. • DISTRIBUTED BY (column, [...]): specifies the partition key. The system uses hash distribution based on the distribution key. To evenly distribute data, you must set the partition key to the primary key of the table or a unique column or a set of columns. • DISTRIBUTED RANDOMLY: distributes data randomly. Note We recommend that you do not use random distribution.
PARTITION BY	Configures the partition key to partition the table. Partitioning large tables improves data access efficiency. To partition a table is to create a top-level (parent) table and multiple lower-level (child) tables. A parent table is always empty when the partition table is created. Data is stored in the lowest-level child tables. In a multi-level partition table, data is only stored in the lowest-level sub-partitions. Valid values: RANGE, LIST, and a combination of the two.
SUBPARTITION BY	Configures a multi-level partitioned table.
SUBPARTITION TEMPLATE	You can specify a sub-partition template to create sub-partitions (lower-level child tables). This sub-partition template is applied to all parent partitions to ensure the same sub-partition structure.

Examples

Create a table and configure the partition key. The primary key is the default partition key in AnalyticDB for PostgreSQL.

```
CREATE TABLE films (
code        char(5) CONSTRAINT firstkey PRIMARY KEY,
title       varchar(40) NOT NULL,
did         integer NOT NULL,
date_prod   date,
kind        varchar(10),
len         interval hour to minute
);
CREATE TABLE distributors (
did    integer PRIMARY KEY DEFAULT nextval('serial'),
name   varchar(40) NOT NULL CHECK (name <> '')
);
```

Create a compressed table and configure the partition key.

```
CREATE TABLE sales (txn_id int, qty int, date date)
WITH (appendonly=true, compresslevel=5)
DISTRIBUTED BY (txn_id);
```

Use sub-partition templates of each level and the default partition to create a three-level partition table.

```
CREATE TABLE sales (id int, year int, month int, day int,
region text)
DISTRIBUTED BY (id)
PARTITION BY RANGE (year)
  SUBPARTITION BY RANGE (month)
    SUBPARTITION TEMPLATE (
       START (1) END (13) EVERY (1),
       DEFAULT SUBPARTITION other_months )
  SUBPARTITION BY LIST (region)
    SUBPARTITION TEMPLATE (
       SUBPARTITION usa VALUES ('usa'),
       SUBPARTITION europe VALUES ('europe'),
       SUBPARTITION asia VALUES ('asia'),
       DEFAULT SUBPARTITION other_regions)
( START (2008) END (2016) EVERY (1),
  DEFAULT PARTITION outlying_years);
```

14.1.5.2. Principles and scenarios of row store, column store, heap tables, and AO tables

AnalyticDB for PostgreSQL supports row store, column store, heap tables, and AO tables. This topic describes their principles and scenarios.

Row store and column store

Comparison

Dimension	Row store	Column store
Definition	Row store stores data in the form of rows. Each row is a tuple. To read a column, you must deform all of the columns that precede the target column. Because of this, the costs for accessing the first and the last columns are different.	Column store stores data as columns corresponding to a file or a batch of files. The cost of reading any column is the same. However, if you need to read multiple columns, you must access multiple files. The more columns you access, the higher the overheads are.
Compression ratio	Low.	High.
Cost of reading any column	Columns with larger column numbers cost more.	Same.
Vector computing and JIT architecture	Not suitable. Not suitable for batch computation.	Suitable. More efficient when accessing and obtaining statistics of a batch of data.

Dimension	Row store	Column store
Scenarios	If you need to perform a large number of update and delete operations due to OLTP requirements such as when querying table details where multiple columns are returned, you can use row store. You can use partition tables if you have diversified requirements. For example, if you need to partition the data based on time, you can use row store to query the details of recent data and use column store to obtain more statistics from historical data.	You can use column store if you need data statistics because of the OLAP requirements. If you need a higher compression ratio, you can use column store.

Heap tables

A heap table is heap storage. All changes to the heap table generate redo logs that can be used to restore data by time point. However, heap tables cannot implement logical incremental backup because any data block in the table may be changed and it is not convenient to record the position by using the heap storage.

Commit and redo logs are used to ensure reliability when transactions are finished. You can also implement redundancy by building secondary nodes through redo logs.

Append-optimized (AO) tables

AO tables are used to append data for storage. When you delete the updated data, you can use another bitmap file to mark the row to be deleted and use the bit and offset to determine whether a row is deleted.

When the transaction is finished, you must call the fsync function to record the offset of the data block that performs the last write operation. Even if the data block only contains one record, a new data block will be appended for the next transaction. The data block is synchronized to the secondary node for data redundancy.

AO tables are not suitable for small transactions because the fsync function is called at the end of each transaction, and this data block will not be reused even if there is space left.

AO tables are suitable for OLAP scenarios, batch data writing, high compression ratio, and logical backup that supports incremental backup. During backup, you only need to record the offset from the backup and the bitmap deletion mark for each full backup.

Usage scenarios of heap tables

- When multiple small transactions are handled, use a heap table.
- When you need to restore data by time point, use a heap table.

Usage scenarios of AO tables

- When you need to use column store, use an AO table.
- When data is written in batches, use an AO table.

14.1.5.3. Enable the column store and compression features

If you want to improve performance, speed up data import, or reduce costs for tables with infrequent updates and multiple fields, we recommend that you use column store and compression. This will increase the compression ratio threefold to ensure faster performance and import speed.

To enable the column store and compression features, you must specify the column store and compression options when creating a table. For example, you can add the following clause to the CREATE statement to enable the two features. For more information about the table creation syntax, see Create a table.

```
with (APPENDONLY=true, ORIENTATION=column, COMPRESSTYPE=zlib, COMPRESSLEVEL=5, BLOCKSIZE=1048576, OIDS=false)
```

Note AnalyticDB for PostgreSQL only supports zlib and RLE_TYPE compression algorithms. If you specify the quicklz algorithm, it is automatically converted to zlib.

14.1.5.4. Add a field to a column store table and set the default value

This topic describes how to add a field to a column store table and set the default value for the field, and how to use the ANALYZE statement to view the impact of updated data on the size of the column store table.

Context

In a column store table, each column is stored as a file, and two columns in the same row correspond to each other by using the offset. For example, if you add two fields of the INT8 type, you can quickly locate column B from column A by using the offset.

When you add the field, AO tables are not rewritten. If an AO table contains the records of deleted data, the added field must be filled with the deleted records before using the offset.

Procedure

1. Create three AO column store tables.

```
postgres=# create table tbl1 (id int, info text) with (appendonly=true, blocksize=8192, compresstype=none, orientation=column);
NOTICE:  Table doesn't have 'DISTRIBUTED BY' clause -- Using column named 'id' as the Greenplum Database data distribution key for this table.
HINT:  The 'DISTRIBUTED BY' clause determines the distribution of data. Make sure column(s) chosen are the optimal data distribution key to minimize skew.
CREATE TABLE
postgres=# create table tbl2 (id int, info text) with (appendonly=true, blocksize=8192, compresstype=none, orientation=column);
NOTICE:  Table doesn't have 'DISTRIBUTED BY' clause -- Using column named 'id' as the Greenplum Database data distribution key for this table.
HINT:  The 'DISTRIBUTED BY' clause determines the distribution of data. Make sure column(s) chosen are the optimal data distribution key to minimize skew.
CREATE TABLE
postgres=# create table tbl3 (id int, info text) with (appendonly=true, blocksize=8192, compresstype=none, orientation=column);
NOTICE:  Table doesn't have 'DISTRIBUTED BY' clause -- Using column named 'id' as the Greenplum Database data distribution key for this table.
HINT:  The 'DISTRIBUTED BY' clause determines the distribution of data. Make sure column(s) chosen are the optimal data distribution key to minimize skew.
CREATE TABLE
```

2. Insert 10 million entries to the first two tables and 20 million entries to the third one.

```
postgres=# insert into tbl1 select generate_series(1,10000000),'test';
INSERT 0 10000000
postgres=# insert into tbl2 select generate_series(1,10000000),'test';
INSERT 0 10000000
postgres=# insert into tbl3 select generate_series(1,20000000),'test';
INSERT 0 20000000
```

3. Analyze the tables and display their sizes.

```
postgres=# analyze tbl1;
ANALYZE
postgres=# analyze tbl2;
ANALYZE
postgres=# analyze tbl3;
ANALYZE
postgres=# select pg_size_pretty(pg_relation_size('tbl1'));
 pg_size_pretty
----------------
 88 MB
(1 row)
postgres=# select pg_size_pretty(pg_relation_size('tbl2'));
 pg_size_pretty
----------------
 88 MB
(1 row)
postgres=# select pg_size_pretty(pg_relation_size('tbl3'));
 pg_size_pretty
----------------
 173 MB
(1 row)
```

4. Update all the data in the first table. Display the table size after the update. The size is twice as large as the size before the update.

```
postgres=# update tbl1 set info='test';
UPDATE 10000000
postgres=# analyze tbl1;
ANALYZE
postgres=# select pg_size_pretty(pg_relation_size('tbl1'));
 pg_size_pretty
----------------
 173 MB
(1 row)
```

5. Add fields to the three tables and set the default values.

```
postgres=# alter table tbl1 add column c1 int8 default 1;
ALTER TABLE
postgres=# alter table tbl2 add column c1 int8 default 1;
ALTER TABLE
postgres=# alter table tbl3 add column c1 int8 default 1;
ALTER TABLE
```

6. Analyze the tables and view the table sizes.

```
postgres=# analyze tbl1;
ANALYZE
postgres=# analyze tbl2;
ANALYZE
postgres=# analyze tbl3;
ANALYZE
postgres=# select pg_size_pretty(pg_relation_size('tbl1'));
 pg_size_pretty
----------------
 325 MB
(1 row)
postgres=# select pg_size_pretty(pg_relation_size('tbl2'));
 pg_size_pretty
----------------
 163 MB
(1 row)
postgres=# select pg_size_pretty(pg_relation_size('tbl3'));
 pg_size_pretty
----------------
 325 MB
(1 row)
```

When you add fields to the AO tables, the number of entries in the existing files will prevail. Even if all the entries are deleted, you must initialize the original data in the newly added fields.

14.1.5.5. Configure the table partition

For fact tables or large-sized tables in the database, we recommend that you configure table partitions.

Configure the table partition

You can use the table partitioning feature to delete data by using the `ALTER TABLE DROP PARTITION` statement to delete all the data in a partition, and import data by using the `ALTER TABLE EXCHANGE PARTITION` statement to add a new data partition on a regular basis.

AnalyticDB for PostgreSQL supports range partitioning, list partitioning, and composite partitioning. Range partitioning only supports partitioning by fields of the numeric or datetime data types.

The following example shows a table that uses range partitioning.

```
CREATE TABLE LINEITEM (
L_ORDERKEY              BIGINT NOT NULL,
L_PARTKEY               BIGINT NOT NULL,
L_SUPPKEY               BIGINT NOT NULL,
L_LINENUMBER    INTEGER,
L_QUANTITY              FLOAT8,
L_EXTENDEDPRICE FLOAT8,
L_DISCOUNT              FLOAT8,
L_TAX                   FLOAT8,
L_RETURNFLAG    CHAR(1),
L_LINESTATUS    CHAR(1),
L_SHIPDATE              DATE,
L_COMMITDATE    DATE,
L_RECEIPTDATE   DATE,
L_SHIPINSTRUCT  CHAR(25),
L_SHIPMODE              CHAR(10),
L_COMMENT               VARCHAR(44)
)  WITH  (APPENDONLY=true, ORIENTATION=column, COMPRESSTYPE=zlib, COMPRESSLEVEL=5, BLOCKSIZE=1048576,
OIDS=false) DISTRIBUTED BY (l_orderkey)
PARTITION BY RANGE (L_SHIPDATE) (START (date '1992-01-01') INCLUSIVE END (date '2000-01-01') EXCLUSIV
E EVERY (INTERVAL '1 month' ));
```

Principles of table partitioning

The purpose of partitioning is to minimize the amount of data that needs to be scanned during a query, so partitions must be associated with the query conditions.

- Principle 1: Select the fields related to the query conditions to configure partitions and reduce the amount of data to be scanned.
- Principle 2: When multiple query conditions exist, configure sub-partitions to further reduce the amount of data to be scanned.

14.1.5.6. Configure the sort key

A sort key is an attribute of a table. Data on disks is stored in the order of the sort key.

Context

Sort keys have two major advantages:

- Speed up and optimize column-store operations. The min and max meta information the system collects seldom overlaps with each other, which features good filterability.
- Eliminate the need to perform ORDER BY and GROUP BY operations. The data directly read from the disk is ordered as required by the sorting conditions.

Create a table

```
Command:     CREATE TABLE
Description: define a new table
Syntax:
CREATE [[GLOBAL | LOCAL] {TEMPORARY | TEMP}] TABLE table_name (
[ { column_name data_type [ DEFAULT default_expr ]     [column_constraint [ ... ]
[ ENCODING ( storage_directive [,...] ) ]
]
   | table_constraint
   | LIKE other_table [{INCLUDING | EXCLUDING}
                      {DEFAULTS | CONSTRAINTS}] ...}
   [, ... ] ]
   [column_reference_storage_directive [, ] ]
   )
   [ INHERITS ( parent_table [, ... ] ) ]
   [ WITH ( storage_parameter=value [, ... ] )
   [ ON COMMIT {PRESERVE ROWS | DELETE ROWS | DROP} ]
   [ TABLESPACE tablespace ]
   [ DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY ]
   [ SORTKEY (column, [ ... ] )]
   [ PARTITION BY partition_type (column)
       [ SUBPARTITION BY partition_type (column) ]
          [ SUBPARTITION TEMPLATE ( template_spec ) ]
       [...]
    ( partition_spec )
        | [ SUBPARTITION BY partition_type (column) ]
          [...]
    ( partition_spec
      [ ( subpartition_spec
           [(...)]
         ) ]
)
```

Examples:

```
create table test(date text, time text, open float, high float, low float, volume int) with(APPENDONLY=true,ORIENTATION=column) sortkey (volume);
```

Sort the table

```
VACUUM SORT ONLY [tablename]
```

Modify the sort key

This statement only modifies the catalog and does not sort data. You must execute the `VACUUM SORT ONLY` statement to sort the table.

```
ALTER [[GLOBAL | LOCAL] {TEMPORARY | TEMP}] TABLE table_name SET SORTKEY (column, [ ... ] )
```

Examples:

```
alter table test set sortkey (high,low);
```

14.1.6. Best practices

14.1.6.1. Configure memory and load parameters

You must configure memory and load parameters to improve database stability.

Background information

AnalyticDB for PostgreSQL is an MPP database with high computational and resource requirements. It consumes all of the resources provided to it, allowing AnalyticDB for PostgreSQL to have higher processing speeds but making it very easy to reach its limits.

The worst-case scenario in the event of the CPU, network, or hard disk exceeding its limits is a hardware bottleneck. However, in the event that memory is completely consumed, the database may crash.

How to avoid OOM errors

Out of memory (OOM) indicates that the system is unable to provide sufficient memory requested by a process. The following prompt appears when OOM errors occur:

```
Out of memory (seg27 host.example.com pid=47093) VM Protect failed to allocate 4096 bytes, 0 MB avail
able
```

Causes

Possible causes of the OOM error include:

- The memory of the database node is insufficient.
- Kernel parameters related to the memory of the operating system are incorrectly configured.
- Data skew has occurred, causing a compute node to request a large amount of memory.
- Query skew has occurred. For example, if the grouping fields of some aggregate or window functions are not distribution keys, the data must be redistributed. After redistribution, data will be skewed in a certain computer node and result in the node requesting a large amount of memory.

Solutions

1. Modify the queries to request less memory.
2. Use the resource queue provided by AnalyticDB for PostgreSQL to limit the number of concurrent queries. Reduce the number of queries executed within the cluster at the same time to reduce the overall memory requested by the system.
3. Reduce the number of compute nodes deployed on a host. For example, deploy 8 compute nodes instead of 16 compute nodes on a host with 128 GB of memory. This allows each compute node to use twice the amount of memory compared with the latter.
4. Increase the memory of a host.
5. Set the gp_vmem_protect_limit parameter to limit the maximum VMEM that can be used by a single compute node. The memory size of a single host and the number of compute nodes deployed on the host determine the maximum memory size that a single compute node can use on average.
6. For SQL statements that have unpredictable memory usage, you can set the statement_mem parameter in the session to limit the memory usage of a single SQL statement, so as to prevent a single SQL statement from consuming all available memory.
7. Set the statement_mem parameter at the database level to apply to all the sessions in the database.
8. Use the resource queue to limit the maximum memory usage of the resource group. Add database users to the resource group to limit the overall memory used by these users.

Configure memory-related parameters

Properly configuring the operating system, database parameters, and resource queue can effectively reduce the probability of OOM.

When calculating the average memory usage of a single compute node on a single host, you must consider both the primary and secondary compute nodes. When the cluster encounters a host failure, the system will switch the service from primary compute nodes to the corresponding secondary compute nodes. During this time, the number of compute nodes on the host will be greater than usual. Therefore, you must consider the number of resources that will be occupied by the secondary compute nodes during failover.

The following tables describe how to configure parameters of the operating system kernel and database to avoid OOM.

The following Operating system kernel parameters table describes the parameter configuration of the operating system kernel.

Operating system kernel parameters

Parameter	Description
huge page	Do not configure the huge page parameter of the system. AnalyticDB for PostgreSQL does not support the latest version of PostgreSQL and therefore does not support the huge page feature. The huge page parameter locks a part of the allocated memory. Database nodes will not be able to use this part of the memory.
vm.overcommit_memory	If you use the swap space, set this parameter to 2. If you do not use the swap space, set this parameter to 0. Valid values: • 0: The requested memory space cannot exceed the difference between the total memory and the resident set size (RSS). An error is returned only when the memory has been exceeded. • 1: Most processes use the malloc function to apply for the memory, but do not use all the memory applied. When this parameter is set to 1, the memory requested by the malloc function will be allocated under any circumstances unless there is not sufficient memory. • 2: The swap space is also considered when the system calculates the memory space that can be applied for. You can apply for a large amount of memory even if the swap space is triggered.
overcommit_ratio	The larger the value, the more memory that process can apply for and the less that will be reserved for the operating system. For the formula used to calculate the memory parameters, see Examples to calculate the memory parameters. When this parameter is set to 2, the memory address that can be applied for cannot exceed swap + memory × overcommit_ratio.

The following Database parameters table describes the parameter configuration of the database.

Database parameters

Parameter	Description
gp_vmem_protect_limit	Specifies the maximum amount of memory that all processes can apply for on each node. If the value is too large, it may result in a system OOM error or even more serious problems. If the value is too small, SQL statements may not be executed even when the system has enough memory.

Parameter	Description
runaway_detector_activation_percent	Default value: 90. This value is specified as a percentage. When the memory used by any compute node exceeds runaway_detector_activation_percent × gp_vmem_protect_limit/100, the query is terminated to prevent OOM. The termination starts from the query that occupies the maximum memory until the memory reaches a value lower than runaway_detector_activation_percent × gp_vmem_protect_limit/100. You can use the gp_toolkit.session_level_memory_consumption view to observe the memory usage of each session and runaway information.
statement_mem	Specifies the maximum amount of memory that a single SQL statement can apply. When the maximum memory is exceeded, spill files are created. Default value: 125. Unit: MB. We recommend that you set this parameter according to the following formula: `(gp_vmem_protect_limit × 0.9)/max_expected_concurrent_queries` **Note** • You can specify the statement_mem parameter in a session. If the current concurrency is low and a session needs to run a query that requires a large amount of memory, you must specify this parameter in the session. • Statement_mem is suitable for limiting memory usage in low concurrency scenarios. If you use statement_mem to limit the memory for high concurrency scenarios, each query is allocated with a very small amount of memory. As a result, the performance of a small number of queries with high memory requirements in high concurrency scenarios is affected. We recommend that you use the resource queue to limit the maximum memory usage in high concurrency scenarios.
gp_workfile_limit_files_per_query	Specifies the maximum number of spill files that can be created by each query. When the memory requested by the query exceeds the statement_mem limit, spill files (also known as work files) are created, which is similar to the swap space of the operating system. When the number of spill files used exceeds the limit, the query will be terminated. Default value: 0, which indicates that an unlimited number of spill files can be created.
gp_workfile_compress_algorithm	Specifies the compression algorithm for spill files. Valid values: none and zlib. Specifies the compression algorithm. The values optimize storage space or I/O by sacrificing CPU. You can set this parameter when the disk is insufficient or the spill files meet a write bottleneck.

Examples to calculate the memory parameters

The environment is as follows:

- Host configuration:

```
Total RAM = 256 GB
SWAP = 64 GB
```

- Four hosts, each deployed with eight primary compute nodes and eight secondary compute nodes.

  When a host fails, the eight primary compute nodes are distributed to the remaining three hosts. A single host can be deployed with at most three extra primary compute nodes from the failed host. A single host can be deployed with at most 11 primary compute nodes.

1. Calculate the total memory allocated to AnalyticDB for PostgreSQL by the operating system.

   Reserve 7.5 GB and 5% of memory for the operating system and calculate the available memory for all applications, and divide the available memory by the empirical coefficient of 1.7.

```
gp_vmem = ((SWAP + RAM) - (7.5 GB + 0.05 × RAM))/1.7
        = ((64 + 256) - (7.5 + 0.05 × 256))/1.7
        = 176
```

2. Use the empirical coefficient of 0.026 to calculate overcommit_ratio.

```
vm.overcommit_ratio = (RAM - (0.026 × gp_vmem))/RAM
                    = (256 - (0.026 × 176))/256
                    =. 982
Set vm.overcommit_ratio to 98.
```

3. Calculate gp_vmem_protect_limit (the protection parameter of the maximum memory usage for each compute node), and divide gp_vmem by maximum_acting_primary_segments (the number of primary compute nodes to be run on each other host after one host fails).

```
gp_vmem_protect_limit calculation
gp_vmem_protect_limit = gp_vmem/maximum_acting_primary_segments
                      = 176/11
                      = 16 GB
                      = 16384 MB
```

Configure the resource queue

You can use resource queues to limit the number of concurrent queries and the total memory usage. When a query is running, it is added to the corresponding queue and the resources used are recorded in the queue. The resource limit of the queue is applied to all sessions in the queue.

The resource queue in AnalyticDB for PostgreSQL is similar to cgroup in Linux.

The syntax to create a resource queue is as follows:

```
Command:     CREATE RESOURCE QUEUE
Description: create a new resource queue for workload management
Syntax:
CREATE RESOURCE QUEUE name WITH (queue_attribute=value [, ... ])
where queue_attribute is:
   ACTIVE_STATEMENTS=integer
         [ MAX_COST=float [COST_OVERCOMMIT={TRUE|FALSE}] ]
         [ MIN_COST=float ]
         [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
         [ MEMORY_LIMIT='memory_units' ]
|  MAX_COST=float [ COST_OVERCOMMIT={TRUE|FALSE} ]
         [ ACTIVE_STATEMENTS=integer ]
         [ MIN_COST=float ]
         [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
         [ MEMORY_LIMIT='memory_units' ]
```

The Resource queue creation parameters table describes the parameters for creating the resource queue.

Resource queue creation parameters

Parameter	Description
ACTIVE_STATEMENTS	The number of SQL statements that are allowed to run (in the active state) concurrently. The value -1 indicates an unlimited number of SQL statements can run concurrently.

Parameter	Description

MEMORY_LIMIT 'memory_units kB, MB or GB'	Specifies the maximum memory usage allowed by all SQL statements in the resource queue. The value -1 indicates unlimited memory usage, but it is easy to trigger OOM errors because it is limited by the database or system parameters mentioned in the preceding sections.
	The memory usage of SQL statements is limited by resource queues and parameters.
	• When the gp_resqueue_memory_policy parameter is set to none, the limit is the same as that in the Greenplum databases earlier than version 4.1.
	• When the gp_resqueue_memory_policy parameter is set to auto and you have specified the statement_mem parameter for a session or at the database level, the allowed memory of a single query will exceed the MEMORY_LIMIT of the resource queue.
	Example:
	`=> SET statement_mem='2GB';`
	`=> SELECT * FROM my_big_table WHERE column='value' ORDER BY id;`
	`=> RESET statement_mem;`
	• The system parameter max_statement_mem can limit the maximum memory usage at the compute node level. The memory requested by a single query cannot exceed max_statement_mem.
	You can modify the statement_mem parameter at the session level, but do not modify the max_statement_mem parameter. We recommend that you specify max_statement_mem as follows:
	`(seghost_physical_memory) / (average_number_concurrent_queries)`
	• When the gp_resqueue_memory_policy parameter is set to eager_free, it indicates that the query is divided into several stages and that the database allocates the memory requested in the current stage. For example, if a query requests 1 GB of memory in total but only needs 100 MB during each stage, the database will allocate 100 MB of memory to the query. You can use eager_free to reduce the possibility of insufficient memory for the query.

MAX_COST float	The maximum cost of the queries that are allowed to execute concurrently by the resource group. The cost is the estimated total cost in the SQL execution plan. The value of the parameter can be specified as a floating-point number (such as 100.0) or an exponent (such as 1e+2). A value of -1 indicates the cost is unlimited.
COST_OVERCOMMIT boolean	Specifies whether the limit of max_cost can be exceeded when the system is idle. The value TRUE indicates the limit can be exceeded.
MIN_COST float	When the resources requested exceed the limit, the queries are queued. However, when the cost of a query is lower than the min_cost, the query can run without queuing.
PRIORITY= {MIN|LOW|MEDIUM|HIGH|MAX}	The priority of the current resource queue. When resources are insufficient, CPU resources are allocated to the resource queue with a higher priority. The SQL statements in the resource queue with a higher priority can obtain CPU resources first. We recommend that you allocate users that initiate queries with high real-time requirements to resource queues with higher priority. This parameter is similar to the CPU resource group in the Linux cgroup and the time slice policy of real-time and common tasks.

Example of modifying resource queue limits:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=-1.0, MIN_COST= -1.0);
```

Example of putting the user in the resource queue:

```
ALTER ROLE sammy RESOURCE QUEUE poweruser;
```

The following table describes the parameters of resource queues.

Resource queue parameters

Parameter	Description
gp_resqueue_memory_policy	Specifies the memory management policy of the resource queue.
gp_resqueue_priority	Specifies whether to enable query prioritization. Valid values: • On. • Off. If this parameter is disabled, existing priority settings are not evaluated.
gp_resqueue_priority_cpucores_per_segment	Specifies the number of CPU cores allocated to each compute node. For example, if an 8-core host is configured with two primary compute nodes, you can set the parameter to 4. If there are no other nodes on the primary node, set the parameter to 8. When the CPU is preempted, the SQL statements running in the resource group with higher priority are allocated with CPU resources first.
gp_resqueue_priority_sweeper_interval	Specifies the interval at which CPU utilization is recalculated for all active statements. The share value is calculated when the SQL statement is executed. You can calculate the share value based on the priority and gp_resqueue_priority_cpucores_per_segment. The smaller the value and the more frequent the calculation, the better the result brought by the priority settings and the larger the overhead.

Tips for configuring resource queues:

- We recommend that you create a resource queue for each user.

  The default resource queue of AnalyticDB for PostgreSQL is pg_default. If no queue is created, all users are assigned to pg_default. This operation is not recommended. We recommend that you create a resource queue for each user. Typically, a database user corresponds to a business. Different database users may correspond to different businesses or users, such as business users, analysts, developers, and DBAs.

- We do not recommend that you use superusers to execute queries.

  Queries initiated by superusers are only limited by the preceding parameters and not by the resource queue. We do not recommend that you use superusers to execute queries if you want to use resource queues to limit the use of resources.

- ACTIVE_STATEMENTS indicates the SQL statements that can be executed concurrently within the resource queue. When the cost of a query is lower than the min_cost, the query can run without queuing.
- You can specify the MEMORY_LIMIT parameter to set the allowed maximum memory usage of all the SQL statements in a resource queue. The statement_mem parameter has higher priority that can break through the limit of resource queues.

> **Note** The memory of all resource queues cannot exceed gp_vmem_protect_limit.

- You can distinguish businesses by configuring the priorities of resource queues.

  For example, assume that report forms have top priority, while common businesses and analysts have lower priorities. In this case, you can create three resource queues with the max, high, and medium priorities, respectively.

- If the number of resources requested at different times vary, you can use the crontab command to adjust the limits of resource queues periodically based on usage patterns.

  For example, the queue of analysts has top priority during the day, while the queue of forms has lower priority at night. AnalyticDB for PostgreSQL does not support resource limits by time period. Therefore, you can only deploy tasks externally by using the ALTER RESOURCE QUEUE statement.

- You can use the view provided by gp_toolkit to observe the resource usage of the resource queues.

```
gp_toolkit.gp_resq_activity
gp_toolkit.gp_resq_activity_by_queue
gp_toolkit.gp_resq_priority_backend
gp_toolkit.gp_resq_priority_statement
gp_toolkit.gp_resq_role
gp_toolkit.gp_resqueue_status
```

15.KVStore for Redis

15.1. User Guide

15.1.1. What is KVStore for Redis?

KVStore for Redis is a key-value storage database service that is compatible with open source Redis protocols. KVStore for Redis supports various data types, such as strings, lists, sets, sorted sets, and hash tables. The service also provides advanced features, such as transactions, message subscription, and message publishing.

You can easily deploy and manage KVStore for Redis databases in the KVStore for Redis console.

- You can create an instance to initialize a database.
- Before you use a KVStore for Redis instance, add IP addresses or CIDR blocks that are used to access the database to the instance whitelist.
- You can manage instances in the KVStore for Redis console.
- To secure data, you can periodically or immediately back up or restore databases in the KVStore for Redis console.
- You can log on to a database by using a client and then execute SQL statements to perform database operations.

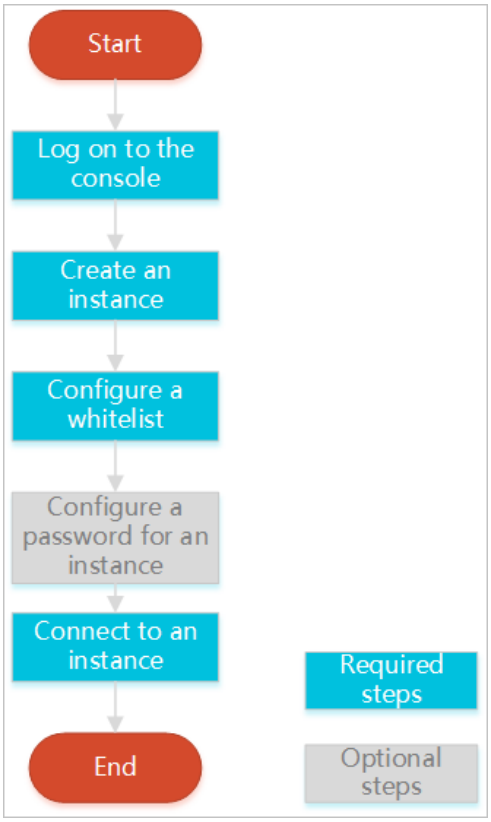
15.1.2. Quick Start

15.1.2.1. Get started with KVStore for Redis

This topic describes a series of operations from creating a KVStore for Redis instance to logging on to a database. This helps you understand the procedures to use KVStore for Redis instances.

The flowchart to use KVStore for Redis instances is as follows.

Flowchart for the KVStore for Redis instance



- Log on to the KVStore for Redis console

  This topic describes how to log on to the KVStore for Redis console.

- Create an instance

  KVStore for Redis supports two network types: classic network and VPC. You can create KVStore for Redis instances of different network types.

- Configure a whitelist

  Before using a KVStore for Redis instance, add IP addresses or CIDR blocks used to access the database to the instance whitelist to improve database security and stability.

- If you have not specified a password when creating the instance, set the password of the instance on the **Instance Information** page.

- Connect to the instance

  You can use a client that supports Redis protocols or use the Redis command-line interface (redis-cli) program to connect to the KVStore for Redis instance.

15.1.2.2. Log on to the KVStore for Redis console

This topic describes how to log on to the KVStore for Redis console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.

2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, choose **Products > KVStore for Redis**.

15.1.2.3. Create an instance

This topic describes how to create an instance in the KVStore for Redis console.

Prerequisites

To use the Virtual Private Cloud (VPC) service, you must create a VPC in the same region as KVStore for Redis.

> **Note** You must specify the network type when you create the instance, and cannot modify the network type later.

Procedure

1. Log on to the KVStore for Redis console.
2. Click **Create Instance** in the upper-right corner.
3. Set the following parameters.

   KVStore for Redis instance parameters

Category	Parameter	Description
Basic Settings	Organization	The organization to which the KVStore for Redis instance to be created belongs.
	Resource Set	The resource set to which the KVStore for Redis instance belongs. **Notice** After you select a resource set, the KVStore for Redis instance is available only to the members of the specified resource set.
Region	Region	Specifies the region where the KVStore for Redis instance is located.
	Zone	Specifies the zone where the KVStore for Redis instance is located.
	Engine Version	The following engine versions are supported: ○ Redis 2.8 ○ Redis 4.0

Category	Parameter	Description
Specifications	Architecture Type	The architecture type of the KVStore for Redis instance. KVStore for Redis provides cluster and standard architectures. The cluster architecture meets large-capacity or high-performance requirements. Native Redis databases run in a single-threading model. If your database does not require high performance, we recommend that you use a standard instance. To achieve higher performance, select a cluster instance.
	Node Type	The node type for the KVStore for Redis instance. KVStore for Redis supports the primary-secondary dual-node structure.
	Instance Class	The specification of the instance. The maximum number of connections and maximum internal bandwidth vary, depending on the instance specification.
Network	Network Type	The network type of the instance. On the Apsara Stack platform, a classic network and a VPC have the following differences: ○ Classic network: Cloud services in a classic network are not isolated. Unauthorized access to a cloud service is blocked only by a security group or a whitelist policy of the service. ○ VPC: A VPC provides an isolated network environment on Apsara Stack. You can customize the routing table, Classless Inter-Domain Routing (CIDR) blocks, and gateway of a VPC. You can also migrate applications to the cloud by using a leased line or virtual private network (VPN) without service interruption to integrate your on-premises data center and cloud resources in a VPC into a virtual data center. **Note** Before you select the VPC type, create a VPC. For more information, see the "Create a VPC" and "Create a VSwitch" topics of *VPC User Guide* .
Set Password	Instance Name	Enter the name of the KVStore for Redis instance. ○ The name must be 2 to 128 characters in length. ○ The name can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter.
	Set Password	You can select **Now** or **Later**.
	Password	Set a password used to connect to the instance. The password must follow these rules: ○ The password must be 8 to 30 characters in length. ○ The password must contain uppercase letters, lowercase letters, and digits. Special characters are not supported.
	Confirm Password	Enter the specified password again.

4. After you set the parameters, click **Submit**.

15.1.2.4. Configure a whitelist

Before using a KVStore for Redis instance, add IP addresses or CIDR blocks used to access the database to the instance whitelist to improve database security and stability.

Context

> **Note** A properly configured whitelist can guarantee the highest-level security protection for your KVStore for Redis instance. We recommend that you maintain the whitelist on a regular basis.

Procedure

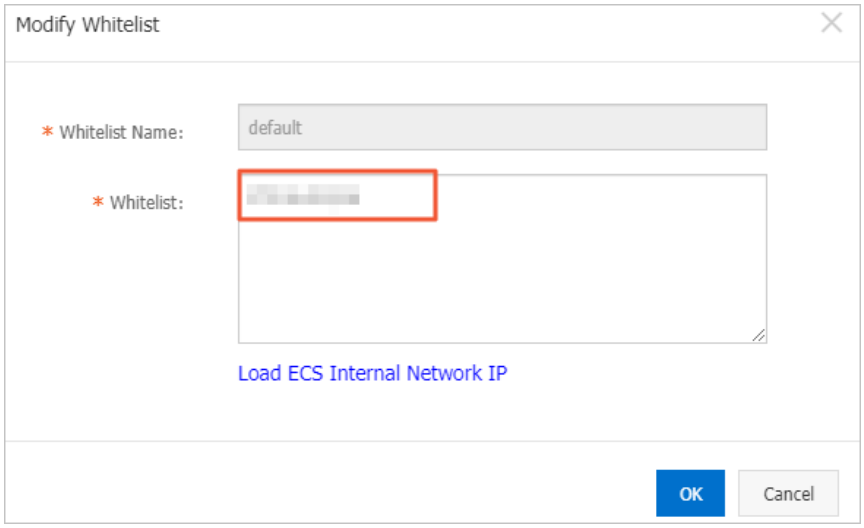
1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. On the **Instance Information** page, click **Whitelist Settings** in the left-side navigation pane.
4. On the **Whitelist Settings** page, proceed in either of the following ways:
   - To customize the whitelist group name, create a new whitelist group:
     a. Click **Add a Whitelist Group** in the upper-right corner.
     b. In the Add a Whitelist Group dialog box that appears, set **Group Name**.

     > **Note** A group name must be 2 to 32 characters in length and contain lowercase letters, digits, or underscores (_). The group name must start with a lowercase letter and end with a letter or digit. You cannot change this name after you create the whitelist group.

   - If you do not require a custom whitelist group, click **Modify** next to the target whitelist group.
5. In the **Add a Whitelist Group** or **Modify Whitelist of Group** dialog box that appears, proceed in either of the following ways:
   - Manually modify the **Whitelist of Group** field:

a. In the **Whitelist of Group** field, enter the IP addresses or CIDR blocks that you can use to connect to the KVStore for Redis instance.

Manually modify the whitelist group



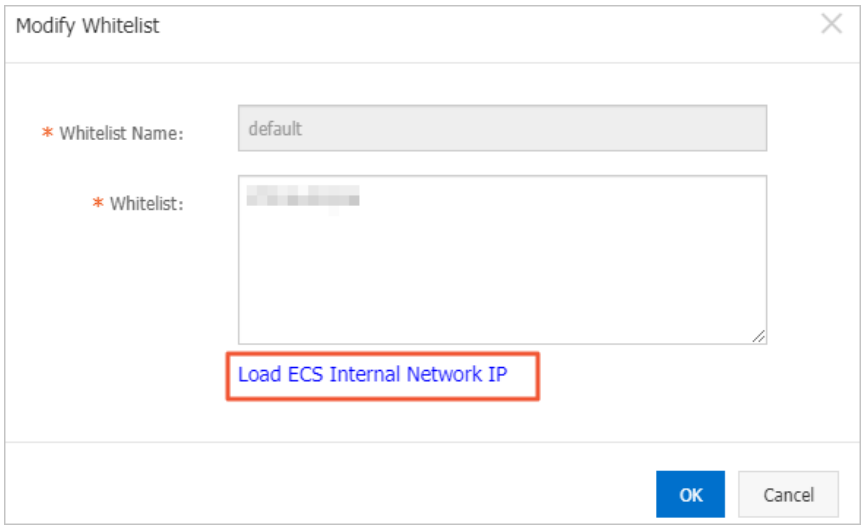
> **Note**
>
> - Set the whitelist to `0.0.0.0/0` to allow connections from all IP addresses.
> - Set the whitelist to `127.0.0.1` to block connections from all IP addresses.
> - Set the whitelist to a CIDR block to allow connections from the IP addresses within the CIDR block, such as `10.10.10.0/24`.
> - When you enter multiple IP addresses or CIDR blocks, separate them with commas (,) and leave no space before or after each comma.
> - You can add 1,000 or fewer IP addresses or CIDR blocks to each whitelist group.

b. Click **OK**.

- Load internal IP addresses of target ECS instances under the current Alibaba Cloud account:

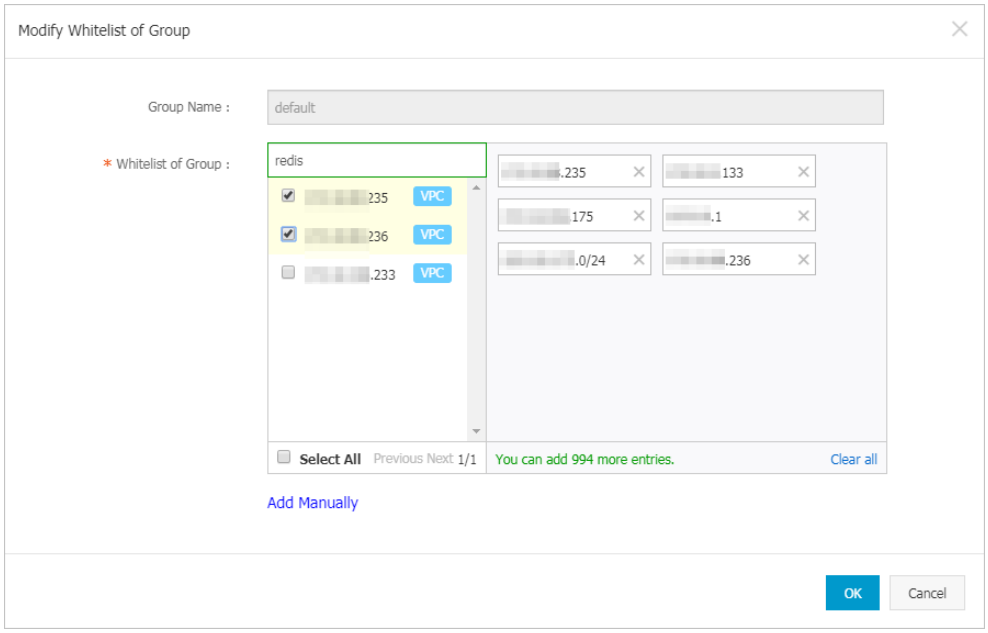
a. Click **Load ECS Internal IP Addresses**.

Load internal IP addresses of target ECS instances



b. Select internal IP addresses of target ECS instances.

Select internal IP addresses of target ECS instances



> **Note** You can perform a fuzzy search by ECS instance name, ID, or IP address on the search bar above the list of ECS internal IP addresses.

c. Click **OK**.

15.1.2.5. Connect to an instance

15.1.2.5.1. Use a Redis client

You can connect to an KVStore for Redis instance by using clients for different programming languages.

The database service of KVStore for Redis is compatible with that of native Redis. Therefore, you can connect to both database services in similar ways. All clients that are compatible with the Redis protocol support connections to KVStore for Redis. You can use any of these clients that are suitable for your applications.

For more information about Redis clients, visit https://redis.io/clients.

Prerequisites

- The internal IP address of the Elastic Compute Service (ECS) instance or the public IP address of the local host has been added to a whitelist of the KVStore for Redis instance. For more information, see Configure a whitelist.
- If you use a custom account to connect to the KVStore for Redis instance, the connection password must be in the format of `<user>:<password>`. For example, if the username of a custom account is `admin` and the password is `password`, the password used to connect to the KVStore for Redis instance must be in the format of `admin:password`.

Jedis clien

You can use a Jedis client to connect to KVStore for Redis in any of the following ways:

- Single Jedis connection. This method is not recommended because a client cannot automatically reconnect to KVStore for Redis after a connection times out.
- JedisPool-based connection. This method is recommended.

To use a Jedis client to connect to an KVStore for Redis instance, perform the following steps:

1. Download and install the Jedis client. For more information, see Jedis.
2. Example of single Jedis connection
   i. Open the Eclipse client, create a project, and then enter the following code:

```
import redis.clients.jedis.Jedis;
public class jedistest {
public static void main(String[] args) {
try {
     String host = "xx.kvstore.aliyuncs.com";//You can view the connection address of the tar
get instance in the console.
     int port = 6379;
     Jedis jedis = new Jedis(host, port);
     //Authentication information.
     jedis.auth("password");//password
     String key = "redis";
     String value = "aliyun-redis";
     //Select a database. Default value: 0.
     jedis.select(1);
     //Set a key.
     jedis.set(key, value);
     System.out.println("Set Key " + key + " Value: " + value);
     //Obtain the configured key and value.
     String getvalue = jedis.get(key);
     System.out.println("Get Key " + key + " ReturnValue: " + getvalue);
     jedis.quit();
     jedis.close();
}
catch (Exception e) {
 e.printStackTrace();
 }
}
}
```

   ii. Run the project. You have connected to KVStore for Redis if you see the following result in the Eclipse console.

```
Set Key redis Value aliyun-redis
Get Key redis ReturnValue aliyun-redis
```

   Then, you can use a Jedis client to manage your KVStore for Redis instance. You can also connect to your KVStore for Redis instance by using JedisPool.

3. Example of JedisPool-based connection
   i. Open the Eclipse client, create a project, and then configure the following pom file:

```
<dependency>
<groupId>redis.clients</groupId>
<artifactId>jedis</artifactId>
<version>2.7.2</version>
<type>jar</type>
<scope>compile</scope>
</dependency>
```

ii. Add the following application to the project:

```
import org.apache.commons.pool2.PooledObject;
import org.apache.commons.pool2.PooledObjectFactory;
import org.apache.commons.pool2.impl.DefaultPooledObject;
import org.apache.commons.pool2.impl.GenericObjectPoolConfig;
import redis.clients.jedis.HostAndPort;
import redis.clients.jedis.Jedis;
import redis.clients.jedis.JedisPool;
import redis.clients.jedis.JedisPoolConfig;
```

iii. If your Jedis client version is Jedis-2.7.2, enter the following code in the project:

```
JedisPoolConfig config = new JedisPoolConfig();
//Maximum number of idle connections. You can customize this parameter. Make sure that the sp
ecified maximum number of idle connections does not exceed the maximum number of connections
that the KVStore for Redis instance supports.
config.setMaxIdle(200);
//Maximum number of connections. You can customize this parameter. Make sure that the specifi
ed maximum number of connections does not exceed the maximum number of connections that the K
VStore for Redis instance supports.
config.setMaxTotal(300);
config.setTestOnBorrow(false);
config.setTestOnReturn(false);
String host = "*.aliyuncs.com";
String password = "Password";
JedisPool pool = new JedisPool(config, host, 6379, 3000, password);
Jedis jedis = null;
try {
jedis = pool.getResource();
/// ... do stuff here ... for example
jedis.set("foo", "bar");
String foobar = jedis.get("foo");
jedis.zadd("sose", 0, "car");
jedis.zadd("sose", 0, "bike");
Set<String> sose = jedis.zrange("sose", 0, -1);
} finally {
if (jedis ! = null) {
jedis.close();
}
}
/// ... when closing your application:
pool.destroy();
```

iv. If your Jedis client version is Jedis-2.6 or Jedis-2.5, enter the following code in the project:

```
JedisPoolConfig config = new JedisPoolConfig();
//Maximum number of idle connections. You can customize this parameter. Make sure that the sp
ecified maximum number of idle connections does not exceed the maximum number of connections
that the KVStore for Redis instance supports.
config.setMaxIdle(200);
//Maximum number of connections. You can customize this parameter. Make sure that the specifi
ed maximum number of connections does not exceed the maximum number of connections that the K
VStore for Redis instance supports.
config.setMaxTotal(300);
config.setTestOnBorrow(false);
config.setTestOnReturn(false);
String host = "*.aliyuncs.com";
String password = "Password";
JedisPool pool = new JedisPool(config, host, 6379, 3000, password);
Jedis jedis = null;
boolean broken = false;
try {
     jedis = pool.getResource();
     /// ... do stuff here ... for example
     jedis.set("foo", "bar");
     String foobar = jedis.get("foo");
     jedis.zadd("sose", 0, "car");
     jedis.zadd("sose", 0, "bike");
     Set<String> sose = jedis.zrange("sose", 0, -1);
}
catch(Exception e)
{
     broken = true;
} finally {
if (broken) {
     pool.returnBrokenResource(jedis);
} else if (jedis ! = null) {
     pool.returnResource(jedis);
 }
}
```

v. Run the project. You have connected to KVStore for Redis if you see the following result in the Eclipse console.

```
Set Key redis Value aliyun-redis
Get Key redis ReturnValue aliyun-redis
```

Then, you can use a Jedis client to manage your KVStore for Redis instance.

PhpRedis client

To use a PhpRedis client to connect to an KVStore for Redis instance, perform the following steps:

1. Download and install the PhpRedis client. For more information, see PhpRedis.
2. In an editor that supports PHP editing, enter the following code:

```
<? php
 /* Replace the following parameter values with the host name and port number of the target instance. */
 $host = "localhost";
 $port = 6379;
 /* Replace the following parameter values with the ID and password of the target instance. */
 $user = "test_username";
 $pwd = "test_password";
 $redis = new Redis();
 if ($redis->connect($host, $port) == false) {
         die($redis->getLastError());
   }
 if ($redis->auth($pwd) == false) {
         die($redis->getLastError());
  }
  /* You can perform database operations after authentication. For more information, visit https://github.com/phpRedis/phpredis. */.
 if ($redis->set("foo", "bar") == false) {
         die($redis->getLastError());
 }
 $value = $redis->get("foo");
 echo $value;
 ? >
```

3. Run the code. Then, you can use a PhpRedis client to connect to your KVStore for Redis instance. For more information, visit https://github.com/phpredis/phpredis.

Redis-py client

To use a redis-py client to connect to an KVStore for Redis instance, perform the following steps:

1. Download and install the redis-py client. For more information, see redis-py.
2. In an editor that supports Python editing, enter the following code. You can use a redis-py client to connect to the KVStore for Redis instance and perform database operations.

```
#! /usr/bin/env python
#-*- coding: utf-8 -*-
import redis
#Replace the following parameter values with the host name and port number of the target instance.
host = 'localhost'
port = 6379
#Replace the following parameter value with the password of the target instance.
pwd = 'test_password'
r = redis.StrictRedis(host=host, port=port, password=pwd)
#You can perform database operations after you establish a connection. For more information, visit https://github.com/andymccurdy/redis-py.
r.set('foo', 'bar');
print r.get('foo')
```

C or C++ client

To use a C or C++ client to connect to an KVStore for Redis instance, perform the following steps:

1. Download, compile, and install the C client by using the following code:

```
    git clone https://github.com/redis/hiredis.git
    cd hiredis
    make
    sudo make install
```

2. Enter the following code in the C or C++ editor:

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <hiredis.h>
int main(int argc, char **argv) {
unsigned int j;
redisContext *c;
redisReply *reply;
if (argc < 4) {
        printf("Usage: example xxx.kvstore.aliyuncs.com 6379 instance_id password\n");
        exit(0);
}
const char *hostname = argv[1];
const int port = atoi(argv[2]);
const char *instance_id = argv[3];
const char *password = argv[4];
struct timeval timeout = { 1, 500000 }; // 1.5 seconds
c = redisConnectWithTimeout(hostname, port, timeout);
if (c == NULL || c->err) {
if (c) {
        printf("Connection error: %s\n", c->errstr);
        redisFree(c);
} else {
        printf("Connection error: can't allocate redis context\n");
}
exit(1);
}
/* AUTH */
reply = redisCommand(c, "AUTH %s", password);
printf("AUTH: %s\n", reply->str);
freeReplyObject(reply);
/* PING server */
reply = redisCommand(c,"PING");
printf("PING: %s\n", reply->str);
freeReplyObject(reply);
/* Set a key */
reply = redisCommand(c,"SET %s %s", "foo", "hello world");
printf("SET: %s\n", reply->str);
freeReplyObject(reply);
/* Set a key using binary safe API */
reply = redisCommand(c,"SET %b %b", "bar", (size_t) 3, "hello", (size_t) 5);
printf("SET (binary API): %s\n", reply->str);
freeReplyObject(reply);
/* Try a GET and two INCR */
reply = redisCommand(c,"GET foo");
printf("GET foo: %s\n", reply->str);
freeReplyObject(reply);
reply = redisCommand(c,"INCR counter");
printf("INCR counter: %lld\n", reply->integer);
freeReplyObject(reply);
/* again ... */
reply = redisCommand(c,"INCR counter");
printf("INCR counter: %lld\n", reply->integer);
freeReplyObject(reply);
/* Create a list of numbers, from 0 to 9 */
reply = redisCommand(c,"DEL mylist");
freeReplyObject(reply);
for (j = 0; j < 10; j++) {
```

```
            char buf[64];
            snprintf(buf,64,"%d",j);
            reply = redisCommand(c,"LPUSH mylist element-%s", buf);
            freeReplyObject(reply);
        }
    /* Let's check what we have inside the list */
    reply = redisCommand(c,"LRANGE mylist 0 -1");
    if (reply->type == REDIS_REPLY_ARRAY) {
            for (j = 0; j < reply->elements; j++) {
            printf("%u) %s\n", j, reply->element[j]->str);
    }
    }
    freeReplyObject(reply);
    /* Disconnects and frees the context */
    redisFree(c);
    return 0;
    }
```

3. Compile the code.

```
gcc -o example -g example.c -I /usr/local/include/hiredis -lhiredis
```

4. Run a test.

```
 example xxx.kvstore.aliyuncs.com 6379 instance_id password
```

Now, the C or C++ client is connected to the KVStore for Redis instance.

.NET client

To use a .NET client to connect to an KVStore for Redis instance, perform the following steps:

1. Download and use the .NET client.

```
 git clone https://github.com/ServiceStack/ServiceStack.Redis
```

2. Create a .NET project on the .NET client.
3. Add the reference file stored in the library file directory ServiceStack.Redis/lib/tests to the client.
4. Enter the following code in the .NET project to connect to the KVStore for Redis instance. For more information about API operations, visit https://github.com/ServiceStack/ServiceStack.Redis.

```
using System;
 using System.Collections.Generic;
 using System.Linq;
 using System.Text;
 using System.Threading.Tasks;
 using ServiceStack.Redis;
 namespace ServiceStack.Redis.Tests
 {
        class Program
 {
 public static void RedisClientTest()
 {
        string host = "127.0.0.1";/*IP address of the host that you want to connect to*/
        string password = "password";/*Password*/
        RedisClient redisClient = new RedisClient(host, 6379, password);
        string key = "test-aliyun";
        string value = "test-aliyun-value";
        redisClient.Set(key, value);
        string listKey = "test-aliyun-list";
        System.Console.WriteLine("set key " + key + " value " + value);
```

```
        string getValue = System.Text.Encoding.Default.GetString(redisClient.Get(key));
        System.Console.WriteLine("get key " + getValue);
        System.Console.Read();
 }
 public static void RedisPoolClientTest()
 {
        string[] testReadWriteHosts = new[] {
        "redis://password@127.0.0.1:6379"/*redis://Password@IP address that you want to connect
to:Port*/
 };
 RedisConfig.VerifyMasterConnections = false;//You must set the parameter.
 PooledRedisClientManager redisPoolManager = new PooledRedisClientManager(10/*Number of connectio
ns in the pool*/, 10/*Connection pool timeout value*/, testReadWriteHosts);
 for (int i = 0; i < 100; i++){
        IRedisClient redisClient = redisPoolManager.GetClient();//Obtain the connection.
        RedisNativeClient redisNativeClient = (RedisNativeClient)redisClient;
        redisNativeClient.Client = null;//KVStore for Redis does not support the CLIENT SETNAME
command. Set Client to null.
 try
 {
        string key = "test-aliyun1111";
        string value = "test-aliyun-value1111";
        redisClient.Set(key, value);
        string listKey = "test-aliyun-list";
        redisClient.AddItemToList(listKey, value);
        System.Console.WriteLine("set key " + key + " value " + value);
        string getValue = redisClient.GetValue(key);
        System.Console.WriteLine("get key " + getValue);
        redisClient.Dispose();//
 }catch (Exception e)
 {
        System.Console.WriteLine(e.Message);
 }
 }
        System.Console.Read();
 }
 static void Main(string[] args)
 {
        //Single-connection mode.
        RedisClientTest();
        //Connection-pool mode.
        RedisPoolClientTest();
 }
 }
 }
```

node-redis client

To use a node-redis client to connect to an KVStore for Redis instance, perform the following steps:

1. Download and install a node-redis client.

```
npm install hiredis redis
```

2. Enter and run the following code on the node-redis client to connect to the KVStore for Redis instance.

```
var redis = require("redis"),
client = redis.createClient(<port>, <"host">, {detect_buffers: true});
client.auth("password", redis.print)
```

> **Note** In the code, the port field specifies the port of the KVStore for Redis instance. Default value: 6379. The host field specifies the endpoint of the KVStore for Redis instance. The following example shows the settings of the port and host fields:

```
client = redis.createClient(6379, "r-abcdefg.redis.rds.aliyuncs.com", {detect_buffers: true})
;
```

3. Use the KVStore for Redis instance.

```
  // Write data to the instance.
client.set("key", "OK");
// Query data on the instance. The instance returns data of the String type.
client.get("key", function (err, reply) {
console.log(reply.toString()); // print `OK`
});
// If a buffer is imported, a buffer is returned.
client.get(new Buffer("key"), function (err, reply) {
console.log(reply.toString()); // print `<Buffer 4f 4b>`
});
client.quit();
```

C# client StackExchange.Redis

To use the C# client StackExchange.Redis to connect to an KVStore for Redis instance, perform the following steps:

1. Download and install StackExchange. Redis.
2. Add a reference.

```
using StackExchange.Redis;
```

3. Initialize ConnectionMultiplexer.

   ConnectionMultiplexer is the core of StackExchange.Redis, and shared and reused in the entire application. You must use ConnectionMultiplexer as a singleton. ConnectionMultiplexer is initialized in the following way:

```
 // redis config
 private static ConfigurationOptions configurationOptions = ConfigurationOptions.Parse("127.0.0.1
:6379,password=xxx,connectTimeout=2000");
  //the lock for singleton
 private static readonly object Locker = new object();
  //singleton
 private static ConnectionMultiplexer redisConn;
 //singleton
 public static ConnectionMultiplexer getRedisConn()
 {
     if (redisConn == null)
     {
         lock (Locker)
         {
             if (redisConn == null || ! redisConn.IsConnected)
             {
                 redisConn = ConnectionMultiplexer.Connect(configurationOptions);
             }
         }
     }
     return redisConn;
 }
```

> **Note**
>
> ConfigurationOptions contains multiple options, such as keepAlive, connectRetry, and name. For more information, see StackExchange.Redis.ConfigurationOptions.

4. GetDatabase() returns a lightweight object. You can obtain this object from the object of ConnectionMultiplexer.

```
redisConn = getRedisConn();
var db = redisConn.GetDatabase();
```

5. The following examples show five types of data structures, which are strings, hashes, lists, sets, and sorted sets. The API operations used in these examples are different from their usage in the native Redis service.
   - string

```
//set get
string strKey = "hello";
string strValue = "world";
bool setResult = db.StringSet(strKey, strValue);
Console.WriteLine("set " + strKey + " " + strValue + ", result is " + setResult);
//incr
string counterKey = "counter";
long counterValue = db.StringIncrement(counterKey);
Console.WriteLine("incr " + counterKey + ", result is " + counterValue);
//expire
db.KeyExpire(strKey, new TimeSpan(0, 0, 5));
Thread.Sleep(5 * 1000);
Console.WriteLine("expire " + strKey + ", after 5 seconds, value is " + db.StringGet(strKey));
//mset mget
KeyValuePair<RedisKey, RedisValue> kv1 = new KeyValuePair<RedisKey, RedisValue>("key1", "value
1");
KeyValuePair<RedisKey, RedisValue> kv2 = new KeyValuePair<RedisKey, RedisValue>("key2", "value
2");
db.StringSet(new KeyValuePair<RedisKey, RedisValue>[] {kv1,kv2});
RedisValue[] values = db.StringGet(new RedisKey[] {kv1.Key, kv2.Key});
Console.WriteLine("mget " + kv1.Key.ToString() + " " + kv2.Key.ToString() + ", result is " + v
alues[0] + "&&" + values[1]);
```

   - hash

```
string hashKey = "myhash";
//hset
db.HashSet(hashKey,"f1","v1");
db.HashSet(hashKey,"f2", "v2");
HashEntry[] values = db.HashGetAll(hashKey);
//hgetall
Console.Write("hgetall " + hashKey + ", result is");
for (int i = 0; i < values.Length;i++)
{
  HashEntry hashEntry = values[i];
  Console.Write(" " + hashEntry.Name.ToString() + " " + hashEntry.Value.ToString());
}
Console.WriteLine();
```

   - list

```
//list key
string listKey = "myList";
//rpush
db.ListRightPush(listKey, "a");
db.ListRightPush(listKey, "b");
db.ListRightPush(listKey, "c");
//lrange
RedisValue[] values = db.ListRange(listKey, 0, -1);
Console.Write("lrange " + listKey + " 0 -1, result is ");
for (int i = 0; i < values.Length; i++)
{
 Console.Write(values[i] + " ");
}
Console.WriteLine();
```

- set

```
//set key
string setKey = "mySet";
//sadd
db.SetAdd(setKey, "a");
db.SetAdd(setKey, "b");
db.SetAdd(setKey, "c");
//sismember
bool isContains = db.SetContains(setKey, "a");
Console.WriteLine("set " + setKey + " contains a is " + isContains );
```

- sorted set

```
string sortedSetKey = "myZset";
//sadd
db.SortedSetAdd(sortedSetKey, "xiaoming", 85);
db.SortedSetAdd(sortedSetKey, "xiaohong", 100);
db.SortedSetAdd(sortedSetKey, "xiaofei", 62);
db.SortedSetAdd(sortedSetKey, "xiaotang", 73);
//zrevrangebyscore
RedisValue[] names = db.SortedSetRangeByRank(sortedSetKey, 0, 2, Order.Ascending);
Console.Write("zrevrangebyscore " + sortedSetKey + " 0 2, result is ");
for (int i = 0; i < names.Length; i++)
{
  Console.Write(names[i] + " ");
}
Console.WriteLine();
```

15.1.2.5.2. Use redis-cli

You can use the Redis command-line interface (redis-cli) tool to connect to a KVStore for Redis instance.

Notice Only connections over an internal network are supported by KVStore for Redis. Therefore, only the Elastic Compute Service (ECS) instances that run in the same Virtual Private Cloud (VPC) network as KVStore for Redis and that are installed with redis-cli can connect to KVStore for Redis for data management.

Install the redis-cli utility

Install a Linux-based Redis software distribution that includes the redis-cli utility. For more information about the detailed procedure, see Redis community.

Prerequisites

Connection over an internal network

- If the KVStore for Redis instance that you want to manage and the ECS instance that connects to the KVStore for Redis instance run in a classic network, both instances must be located in the same region.
- You have added the internal IP address of the ECS instance to an IP address whitelist of the KVStore for Redis instance.
- The operating system of the local host must be Linux.
- You have installed the Redis software distribution on the ECS instance.
-

Connection over the Internet

- You have applied for a public endpoint for the KVStore for Redis instance.
- You have added the public IP address of the local host to an IP address whitelist of the KVStore for Redis instance.
- The operating system of the local host must be Linux.
- You have installed the Redis software distribution on the local host.
-

Connect to a KVStore for Redis instance

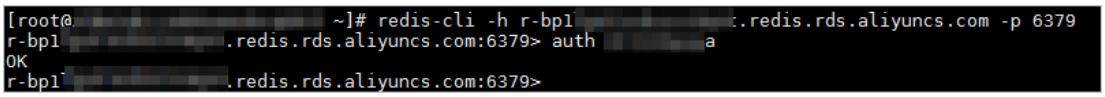
On the command line, run the following command to connect to a KVStore for Redis instance.

```
redis-cli -h <host> -p <port> -a <password>
```

Parameters

Parameter	Description
-h	The endpoint of the KVStore for Redis instance.
-p	The service port of the KVStore for Redis instance. The default port number is 6379 and cannot be changed.
-a	The password used to connect to the KVStore for Redis instance. You can skip this parameter to avoid revealing the password in plaintext and enhance security. After you run the preceding command, you can enter `auth <password>` to complete the authentication. The following figure shows an example.

Sample code



15.1.3. Instance management

15.1.3.1. Change the password

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.

4.

15.1.3.2. Configure a whitelist

Before using a KVStore for Redis instance, add IP addresses or CIDR blocks used to access the database to the instance whitelist to improve database security and stability.

Context

> **Note** A properly configured whitelist can guarantee the highest-level security protection for your KVStore for Redis instance. We recommend that you maintain the whitelist on a regular basis.

Procedure

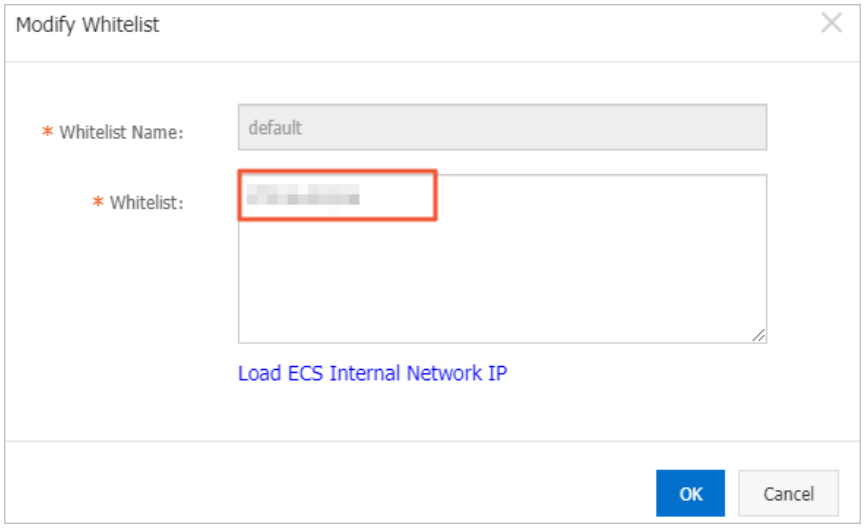
1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, find the target instance. Click the instance ID or click **Manage** in the **Actions** column.
3. On the **Instance Information** page, click **Whitelist Settings** in the left-side navigation pane.
4. On the **Whitelist Settings** page, proceed in either of the following ways:
   - To customize the whitelist group name, create a new whitelist group:
     a. Click **Add a Whitelist Group** in the upper-right corner.
     b. In the Add a Whitelist Group dialog box that appears, set **Group Name**.

     > **Note** A group name must be 2 to 32 characters in length and contain lowercase letters, digits, or underscores (_). The group name must start with a lowercase letter and end with a letter or digit. You cannot change this name after you create the whitelist group.

   - If you do not require a custom whitelist group, click **Modify** next to the target whitelist group.
5. In the **Add a Whitelist Group** or **Modify Whitelist of Group** dialog box that appears, proceed in either of the following ways:
   - Manually modify the **Whitelist of Group** field:

a. In the **Whitelist of Group** field, enter the IP addresses or CIDR blocks that you can use to connect to the KVStore for Redis instance.

Manually modify the whitelist group



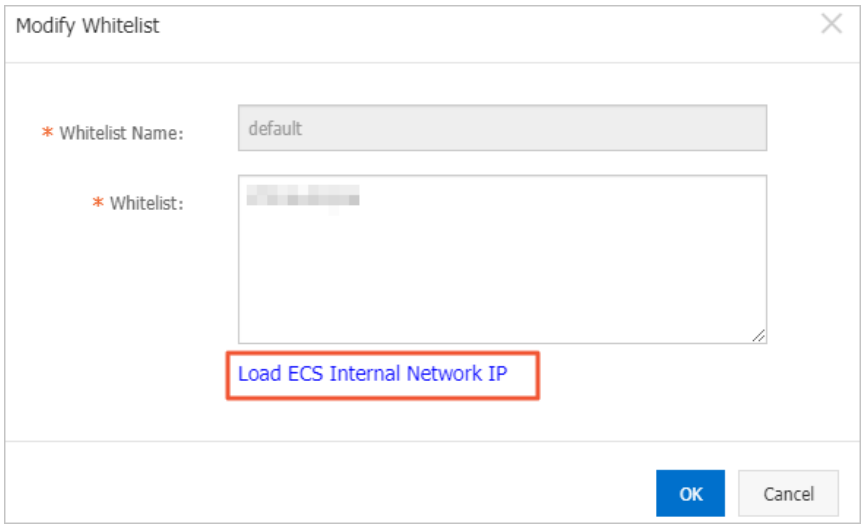
> **Note**
>
> - Set the whitelist to `0.0.0.0/0` to allow connections from all IP addresses.
> - Set the whitelist to `127.0.0.1` to block connections from all IP addresses.
> - Set the whitelist to a CIDR block to allow connections from the IP addresses within the CIDR block, such as `10.10.10.0/24`.
> - When you enter multiple IP addresses or CIDR blocks, separate them with commas (,) and leave no space before or after each comma.
> - You can add 1,000 or fewer IP addresses or CIDR blocks to each whitelist group.

b. Click **OK**.

- Load internal IP addresses of target ECS instances under the current Alibaba Cloud account:

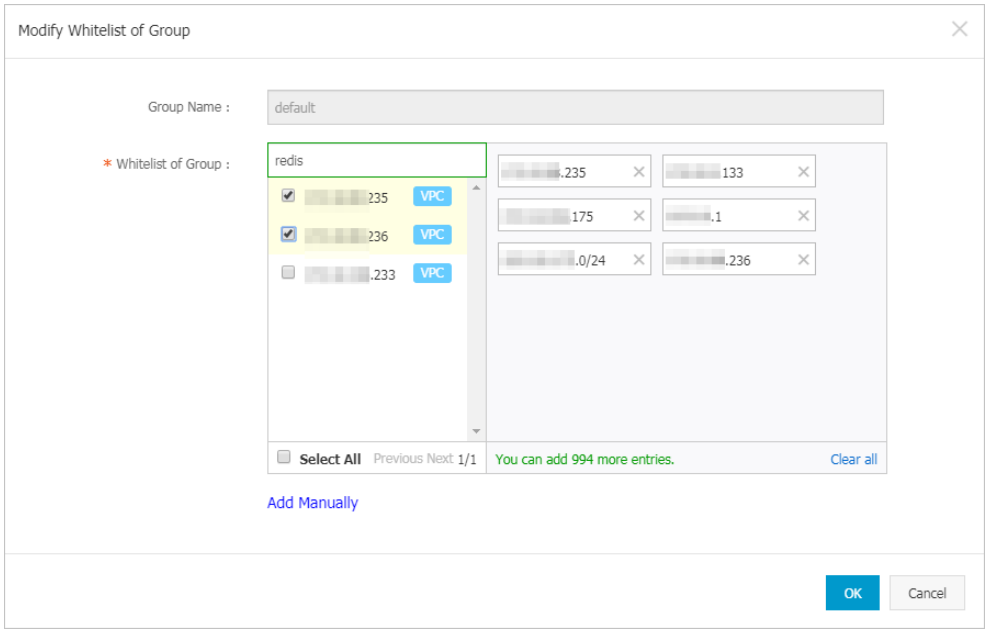
a. Click **Load ECS Internal IP Addresses**.

Load internal IP addresses of target ECS instances



b. Select internal IP addresses of target ECS instances.

Select internal IP addresses of target ECS instances



Note You can perform a fuzzy search by ECS instance name, ID, or IP address on the search bar above the list of ECS internal IP addresses.

c. Click **OK**.

15.1.3.3. Change configurations

Context

Procedure

1. Log on to the KVStore for Redis console.
2.
3. On the **Change Configurations** page, change the configurations and click **Submit**.

   The following example provides common configurations:

Configuration	Description
Architecture Type	The architecture type of the KVStore for Redis instance. KVStore for Redis provides cluster and standard architectures. The cluster architecture meets large-capacity or high-performance requirements. Native Redis databases run in a single-threading model. If your database does not require high performance, we recommend that you use a standard instance. To achieve higher performance, select a cluster instance.
Instance Class	The specification of the instance. The maximum number of connections and maximum internal bandwidth vary, depending on the instance specification.

15.1.3.4. Set a maintenance window

Context

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4. Select time periods and click **Save**.

> **Note** The time periods are in UTC+8.

15.1.3.5. Upgrade the minor version

Context

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.

15.1.3.6. Configure SSL encryption

Context

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.
5. In the **Configure SSL** dialog box that appears, turn on the **Enable** switch. The switch will turn from green to gray when it is enabled. Click **OK**.
   - If an error message is displayed to indicate that the instance is in an abnormal state, click OK in the message that appears.
   - If an error message is displayed to indicate that the feature is not supported in this version, upgrade the minor version of the instance. For more information, see Upgrade the minor version.
   - After the operation, you must wait for a short period of time before the system displays the operation result.
   - You can also click **Update Validity** and **Download CA Certificate** in the upper-right corner of the SSL Settings page to perform relevant operations.

15.1.3.7. Clear data

Context

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.

15.1.3.8. Release an instance

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.

15.1.3.9. Manage database accounts

KVStore for Redis allows you to create up to 20 database accounts for an instance. You can grant permissions to these accounts and manage your instance based on the actual needs to minimize misoperations.

Prerequisites

The engine version of the instance is Redis 4.0 or later.

> **Note** If the engine version of the instance is not Redis 4.0, only the default account is available. The default account is created when you create the instance. For more information about how to change the password of the default account, see Change the password.

Context

Create an account

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. On the Instances page, find the instance that you want to manage and click the instance ID. By default, the **Instance Information** page is displayed. In the left-side navigation pane, click **Account Management**.

   > **Note** If Account Management is not available for an instance of Redis 4.0 or later, you can try to upgrade the minor version. For more information, see Upgrade the minor version.

4.
5. In the **Create Account** dialog box that appears, set the following parameters and click **OK**.

   Set account parameters

Parameter	Description
Account	Your account must meet the following requirements: ○ The account name can contain lowercase letters, digits, underscores (_), and hyphens (-). ○ The name must start with a lowercase letter. ○ The name must be 1 to 16 characters in length.

Parameter	Description
Privilege	The permissions granted to the account. Valid values: Read-only, Read/Write, and Replicate. If you select Replicate, you are authorized to use the SYNC and PSYNC commands after you connect to an instance with this account. **Note** You can create accounts that have the replicate permission only for standard instances of Redis 4.0 or later.
Password Settings	The password of your account must meet the following requirements: ○ The password must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. ○ The password must be 8 to 32 characters in length. Special characters include: ! @#$%^&*()+-=_
Confirm Password	Enter the password again.
Description	The description of an account must meet the following requirements: ○ The description can contain letters, Chinese characters, digits, underscores (_), and hyphens (-). ○ The description must start with a letter or Chinese character, ○ and cannot start with *http://* or *https://*. ○ The description must be 2 to 256 characters in length. You can skip this parameter when you create an account.

Note After you create an account, the account is in the **Unavailable** status. After about one minute, its status changes to **Available**.

15.1.3.10. Use a Lua script

Support for Lua commands

Note If the Eval command cannot be executed, such as when the "`ERR command eval not support for normal user`" message is displayed, you can try to Upgrade the minor version. During the upgrade, the instance may be disconnected and become read-only for a few seconds. We recommend that you upgrade the version of an instance during off-peak hours.

15.1.3.11. Restart an instance

Procedure

1. Log on to the KVStore for Redis console.
2.
3. In the dialog box that appears, select a restart time and click **OK**.
   ○ Restart Immediately: restarts the instance immediately.

- Restart Within Maintenance Window: restarts the instance within the preset maintenance window.

15.1.3.12. Export the list of instances

Procedure

1. Log on to the KVStore for Redis console.
2.
3.

15.1.4. Connection management

15.1.4.1. View connection strings

Context

> Note
> - The virtual IP address of a KVStore for Redis instance may change when you maintain or modify the service. To ensure connection availability, we recommend that you use a connection string to access the KVStore for Redis instance.
> - For more information about how to apply for a public connection string, see Applies for a public connection string.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.

15.1.4.2. Apply for a public endpoint

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4. In the **Apply for External IP Address** dialog box that appears, enter an endpoint and port number, and click **OK**.

   > Note
   > - The custom endpoint prefix must be 8 to 64 characters in length and can contain lowercase letters and digits. It must start with a lowercase letter.
   > - The custom port ranges from 1024 to 65535. The default value is 6379.
   > - After you apply for a public endpoint, you must add the public IP address to an IP address whitelist of the instance to connect to the instance over the Internet. For more information, see Configure a whitelist.

5.

15.1.4.3. Modify the endpoint of an KVStore for Redis instance

Prerequisites

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4. In the **Modify Public Endpoint** dialog box, set the following parameters:

Parameter	Description
Connection type	Select **Internal Endpoint** or **Public Endpoint**.
Endpoint	Set the prefix of the endpoint. ○ The endpoint can contain lowercase letters and digits. ○ It must start with a lowercase letter. ○ The endpoint must be 8 to 64 characters in length.
Port	Specify a port number. Valid value: 1024 to 65535. **Note** It takes about 10 minutes for the modified port number of the public endpoint to take effect. You can refresh the page to view the latest port number information.

5. In the **Modify Public Endpoint** dialog box, modify **Connection Type**, **Endpoint**, and **Port**, and then click **OK**.

> **Note**
> ○ The custom endpoint prefix must be 8 to 64 characters in length and can contain lowercase letters and digits. It must start with a lowercase letter.
> ○ The custom port number ranges from 1024 to 65535. The default value is 6379.

15.1.5. Parameter configuration

Context

Configure parameters in the KVStore for Redis console

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.
5.

15.1.6. Backup and recovery

15.1.6.1. Back up data automatically

An increasing number of applications use KVStore for Redis for persistent storage. Because of this, KVStore for Redis supports routine backup mechanisms to restore data after misoperations occur. Alibaba Cloud provides secondary nodes to back up .rdb files as snapshots. Backup operations do not affect the performance of your instance. You can customize the backup operation in the console.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.
5.
6.

15.1.6.2. Back up data manually

You can initiate a manual backup task in the console at any time.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.
5.

15.1.6.3. Download backup files

To archive these backup files for a longer period, you can copy their URLs in the console and download the database backup files to a local directory.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.
5. In the **Download Backup File** dialog box that appears, click one of the following buttons to continue with the procedure:
   - **Download**: downloads the backup file to a local directory.
   - **Get URL for Internet**: copies the public URL for downloading the backup file, and downloads the backup file over the Internet.
   - **Get URL for Intranet**: copies the internal URL for downloading the backup file, and downloads the backup file over the internal network.
   - **Cancel**: cancels downloading the backup file.

15.1.6.4. Restore data

You can use backup files to restore data in the console.

Context

Notice

- Data restoration is highly risky. Check the data to be restored before performing this operation. Proceed with caution.
- This feature is not applicable to non-cluster KVStore for Redis instances.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.
5. In the **Restore Data** dialog box that appears, click **Continue**.

   You can apply backup files to a new instance by cloning an instance.

15.1.6.5. Clone an instance

You can apply backup files to a new instance by cloning an instance.

Context

Note This feature is applicable to non-cluster KVStore for Redis instances.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.
5.

15.1.7. Performance monitoring

15.1.7.1. View monitoring data

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.
5. Set a time range in which you want to query monitoring data and click **OK**.

   Note For more information about the monitoring metrics, see Understand metrics.

15.1.7.2. Customize metrics

Context

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.
5.

15.1.7.3. Modify monitoring frequency

Context

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3.
4.
5.

15.1.7.4. Understand metrics

KVStore for Redis supports more than 10 group of metrics for real-time monitoring. You can use these metrics to monitor the running status of your KVStore for Redis instances. This topic describes these metrics.

Basic monitoring metrics

Metric	Unit	Description	Statistical method
CpuUsage	%	The CPU usage.	Monitor the CPU usage when collecting monitoring data.
UsedMemory	Bytes	The amount of the used memory.	Monitor the amount of the used memory when collecting monitoring data.
TotalQps	Counts/s	The number of requests received by an instance per second.	Divide the number of requests in a monitoring cycle by the number of seconds in the monitoring cycle.
ConnCount	Counts	The number of connections.	Monitor the number of connections when collecting monitoring data.

Metric	Unit	Description	Statistical method
InFlow	Kbit/s	The amount of data received by an instance per second.	Divide the amount of data received in a monitoring cycle by the number of seconds in the monitoring cycle.
OutFlow	Kbit/s	The amount of data sent by an instance per second.	Divide the amount of data sent in a monitoring cycle by the number of seconds in the monitoring cycle.
FailedCount	Counts/s	The average number of abnormal requests per second.	Divide the total number of abnormal requests in a monitoring cycle by the number of seconds in the monitoring cycle.
AvgRt	μs	The average response time of all requests. **Note** For more information, see Response time metrics.	Divide the processing time of all requests in a monitoring cycle by the number of requests in the monitoring cycle.
MaxRt	μs	The maximum response time of requests. **Note** For more information, see Response time metrics.	Monitor the maximum amount of time consumed for processing a single request in a monitoring cycle.
Keys	Counts	The total number of keys.	Monitor the number of keys when collecting monitoring data.
Expires	Counts	The total number of keys for which an expiration time is set.	Monitor the total number of keys for which an expiration time is set when collecting monitoring data.
ExpiredKeys	Counts	The total number of expired keys.	Monitor the cumulative sum when collecting monitoring data. After the instance is restarted, the cumulative sum is calculated again.

Metric	Unit	Description	Statistical method
EvictedKeys	Counts	The total number of keys that are evicted because the memory is fully occupied.	Monitor the cumulative sum when collecting monitoring data. After the instance is restarted, the cumulative sum is calculated again.
request	Bytes	The total amount of request data received by KVStore for Redis nodes in a monitoring cycle.	See the description of this metric.
response	Bytes	The total amount of response data sent by KVStore for Redis nodes in a monitoring cycle.	See the description of this metric.
request_max	Bytes	The maximum amount of data that a single request has in a monitoring cycle.	See the description of this metric.
response_max	Bytes	The maximum amount of data that a single response has in a monitoring cycle.	See the description of this metric.
traffic_control_input	Counts	The number of times that downstream throttling is triggered.	Monitor the cumulative sum in a monitoring cycle.
traffic_control_output	Counts	The number of times that upstream throttling is triggered.	Monitor the cumulative sum in a monitoring cycle.
traffic_control_input_status	Counts	Indicates whether downstream throttling has been triggered in a monitoring cycle. A value of 0 indicates that throttling has not been triggered, and a value of 1 indicates that throttling has been triggered.	See the description of this metric.
traffic_control_output_status	Counts	Indicates whether upstream throttling has been triggered in a monitoring cycle. A value of 0 indicates that throttling has not been triggered, and a value of 1 indicates that throttling has been triggered.	See the description of this metric.

Metric	Unit	Description	Statistical method
hit_rate	%	The request hit ratio. This metric indicates the probability that data exists in a KVStore for Redis instance when the data is requested.	Calculate the percentage of the hit requests to the total number of requests in a monitoring cycle.
hit	Counts	The number of hit requests.	Monitor the number of hit requests in a monitoring cycle.
miss	Counts	The number of missed requests.	Monitor the number of missed requests in a monitoring cycle.
evicted_keys_per_sec	Counts/s	The number of keys that are evicted per second.	Divide the total number of keys evicted in a monitoring cycle by the number of seconds in the monitoring cycle.

Other monitoring metrics

Besides the basic monitoring metrics, the system uses other monitoring metrics to monitor specific types of data or specific features. These monitoring metrics are classified into:

- Metrics that reflect the number of times that commands are used. For example, the del, dump, and exists metrics for keys monitoring indicate the number of times the DEL, DUMP, and EXISTS commands are used.
- Response time metrics of commands. For example, the metrics that are ended with avg_rt for keys monitoring, such as del_avg_rt, dump_avg_rt, and exists_avg_rt indicate the average response time of the DEL, DUMP, and EXISTS commands in a monitoring cycle.

Response time metrics

All groups of monitoring metrics include response time metrics. Such metrics are ended with Rt or rt, for example, the AvgRt and MaxRt metrics in the basic monitoring metrics or the del_avg_rt and exists_avg_rt metrics in the keys monitoring.

The AvgRt and MaxRt metrics in the basic monitoring group are the most frequently-used response time metrics. These metrics have different meanings for proxy nodes and data nodes.

- For a cluster instance or a read/write splitting instance, the AvgRt metric of a proxy node reflects the average time consumed by the proxy node to process a command. A proxy node processes a command by following these steps:
  i. The proxy node receives a command and forwards the command to a data node.
  ii. The data node processes the command and responds to the proxy node.
  iii. The proxy node returns the command processing result.

  The AvgRt metric of the proxy node includes the amount time consumed by the data node to process a command, the waiting time, and the amount of time consumed for network communication between the proxy node and the data node.
- For data nodes of a cluster instance or a read/write splitting instance or for a standard instance, the AvgRt metric reflects the average time consumed by a data node to process a command. This metric records the period from the time when the data node receives the command to the time when the data node returns the processing result. This metric does not include the time consumed by the proxy node to process the command and the time consumed for network communication.

- The MaxRt metric indicates the maximum response time of requests. The statistical method of this metric is similar to that of the AvgRt metric for all KVStore for Redis instances.

16.ApsaraDB for MongoDB

16.1. User Guide

16.1.1. Usage notes

You must get familiar with the precautions and limits of ApsaraDB for MongoDB before you start.

To ensure the stability and security of ApsaraDB for MongoDB instances, take note of the limits, see Instance types in *ApsaraDB for MongoDB ApsaraDB for MongoDB limits*.

ApsaraDB for MongoDB limits

Item	Limit
Scale out nodes	You cannot scale out secondary nodes.
	• When a replica set instance is created, three nodes are added. • ApsaraDB for MongoDB provides a primary node, a secondary node, and a hidden node for each replica set instance. The hidden node is invisible to you. • You cannot scale out secondary nodes.
Restart an instance	You must restart an ApsaraDB for MongoDB instance in the ApsaraDB for MongoDB console or by calling the API operation.

16.1.2. Log on to the ApsaraDB for MongoDB console

This topic describes how to log on to the ApsaraDB for MongoDB console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

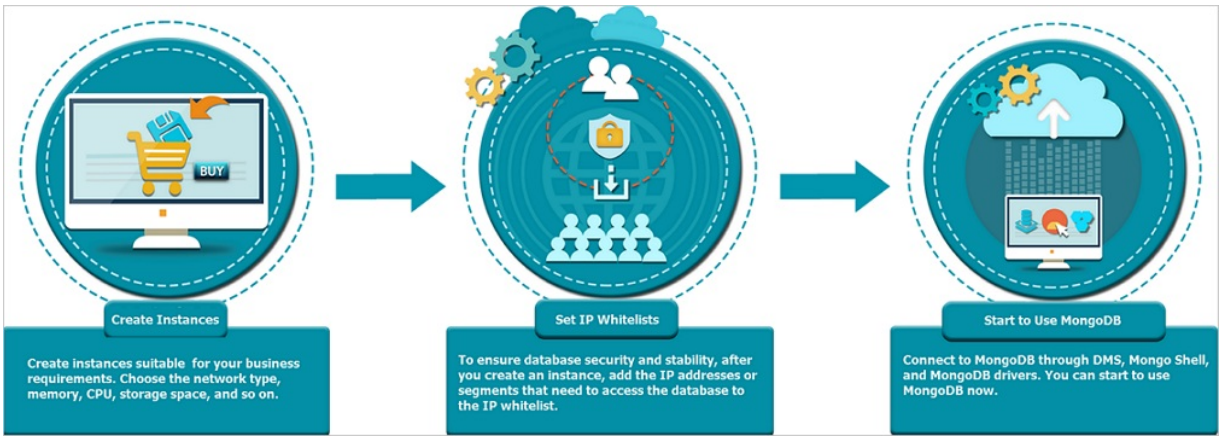
   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 10 to 32 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Log On**.
4. In the top navigation bar, choose **Products** > **Database Services** > **ApsaraDB for MongoDB**.

16.1.3. Quick start

16.1.3.1. Use ApsaraDB for MongoDB

This topic is a quick start guide to basic usage operations for ApsaraDB for MongoDB, such as creating an instance, configuring a whitelist, and connecting to an instance. Flowcharts are used to describe the basic procedures in ApsaraDB for MongoDB, and guide you to create an ApsaraDB for MongoDB instance.



- Create an ApsaraDB for MongoDB instance

  An instance is a virtual database server on which you can create and manage multiple databases.

- Configure a whitelist for an ApsaraDB for MongoDB instance

  After you create an ApsaraDB for MongoDB instance, you need to configure a whitelist for the instance to allow external devices to access the instance.

  A whitelist can enhance access security for ApsaraDB for MongoDB instances. We recommend that you update the whitelist on a regular basis. The normal services of the instance are not affected if you configure a whitelist.

- Connect to a replica set instance by using the mongo shell

  After you create an instance and configure a whitelist, you can use the mongo shell to connect to the instance.

16.1.3.2. Create an ApsaraDB for MongoDB instance

This topic describes how to create an instance in the ApsaraDB for MongoDB console.

Prerequisites

An account is obtained to log on to the ApsaraDB for MongoDB console.

Create a replica set instance

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, click **Create Instance** in the upper-left corner. On the **Create ApsaraDB for MongoDB Instance** page, configure the parameters.

   The following table describes the required parameters.

   Parameters for creating a replica set instance

Section	Parameter	Description
Basic Settings	**Organization**	Select an organization for the new instance.
	Resource Set	Select a resource set for the new instance.
Region	**Region**	Select a region for the new instance.
	Zone	Select a zone for the new instance
Specifications	**Database Engine**	Select a database engine for the new instance. In this case, you can select only **MongoDB**.
	Engine Version	Select a database engine version for the new instance. Valid values: ○ 3.0 ○ 3.4 ○ 4.0 ○ 4.2
	Node Type	ApsaraDB for MongoDB supports the following options: ○ Three-node Replica Set: uses dedicated memory and I/O resources but shares CPU and storage resources with other general-purpose instances on the same server. ○ Dedicated Instance: uses dedicated CPU, memory, storage, and I/O resources to ensure long-term performance. In this case, an instance is not affected by other instances on the same server. ○ Dedicated Host: exclusively uses all resources of a server. This is the top configuration of exclusive specifications.
	Node Specifications	Select a node specification for the new instance. For more information, see descriptions in the ApsaraDB for MongoDB console.
	Storage Capacity (GB)	The storage space of the instance, which contains the space for data, system files, log files, and transaction files. For more information, see *Instance types* in *ApsaraDB for MongoDB Product Introduction*.
Network	**Network Type**	ApsaraDB for MongoDB supports the following options: ○ **Classic Network**: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. ○ **VPC**: Virtual Private Cloud (VPC) is an isolated network environment built in Apsara Stack. You can customize route tables, CIDR blocks, and gateways in a VPC. We recommend that you select VPC for improved security. **Note** If you select the **VPC** network type, you must configure the **VPC** and **vSwitch** parameters.
	VPC	Select a VPC. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.

Section	Parameter	Description
	vSwitch	Select a vSwitch. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
Password Settings	**Instance Name**	Set the name of the new instance. The name must be 2 to 256 characters in length, The name must start with a letter, and can contain digits, letters, underscores (_), and hyphens (-).
	Password Setting	Determine when to set the password for logging on to databases in the new instance. You can select **Set Now** to set the logon password immediately, or select **Set after Purchase** to set the logon password after you create the instance. For more information, see Reset the password for an ApsaraDB for MongoDB instance.
	Logon Password	Set a password. The password must meet the following requirements: ○ It must be 8 to 32 characters in length. ○ It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. ○ The name can contain special characters. Special characters include ! # $ % ^ & * ( ) _ + =
	Confirm Password	Enter the password again. The password you enter here must be the same as that in New Password.

3. Click **Submit** to create the instance.

Create a sharded cluster instance

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.
3. Click **Create Instance** in the upper-left corner to go to the **Create MongoDB Instance** page. Configure the parameters.

   The following table describes the required parameters.

   Parameters for creating a sharded cluster instance

Section	Parameter	MNS logs
Basic Settings	**Organization**	Select an organization for the new instance.
	Resource Set	Select a resource set for the new instance.
	Region	Select a region for the new instance.

Section	Parameter	MNS logs
Region	Zone	Select a zone for the new instance
Specifications	Database Engine	Select a database engine for the new instance. In this case, you can select only **MongoDB**.
	Engine Version	Select a database engine version for the new instance. Valid values: ○ 3.4 ○ 4.0 ○ 4.2
Network	Network Type	ApsaraDB for MongoDB supports the following options: ○ **Classic Network**: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. ○ **VPC**: Virtual Private Cloud (VPC) is an isolated network environment built in Apsara Stack. You can customize route tables, CIDR blocks, and gateways in a VPC. We recommend that you select VPC for improved security. **Note** If you select the **VPC** network type, you must configure the **VPC** and **vSwitch** parameters.
	VPC	Select a VPC. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
	vSwitch	Select a vSwitch. If no vSwitch exists, you can click **Create vSwitch** to create a vSwitch. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
Mongos Specifications	Mongos Specifications	The specifications of the mongos node. For more information, see descriptions in the ApsaraDB for MongoDB console.
	Quantity	The number of the mongos nodes. You can select 2 to 32 mongos nodes.
Shard Specifications	Shard Specifications	The specifications of the shard node. For more information, see descriptions in the ApsaraDB for MongoDB console.
	Storage Capacity (GB)	The storage space of the instance, which contains the space for data, system files, log files, and transaction files. For more information, see *Instance types* in *ApsaraDB for MongoDB Product Introduction*.
	Quantity	The number of the shard nodes. You can select 2 to 32 shard nodes.
Config Server	Config Server Specifications	The specifications of Configserver nodes. It is fixed at **1 vCPU, 2 GiB memory** and cannot be customized.

Section	Parameter	MNS logs
Specifications	Storage Capacity (GB)	The storage space of the Configserver node. It is fixed at 20 GB and cannot be customized.
Password Settings	Instance Name	Set the name of the new instance. The name must be 2 to 256 characters in length, and can contain digits, letters, underscores (_), and hyphens (-). It must start with a letter.
	Password Setting	Determine when to set the password for logging on to databases in the new instance. You can select **Set Now** to set the logon password immediately, or select **Set after Purchase** to set the logon password after you create the instance. For more information, see Reset the password for an ApsaraDB for MongoDB instance.
	Logon Password	Set a password. The password must meet the following requirements: ○ It must be 8 to 32 characters in length. ○ It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. ○ The name can contain special characters. Special characters include ! # $ % ^ & * ( ) _ + =
	Confirm Password	Enter the password again. The password you enter here must be the same as that in New Password.

4. Click **Submit** to create the instance.

16.1.3.3. Configure a whitelist for an ApsaraDB for MongoDB instance

This topic describes how to configure a whitelist for an ApsaraDB for MongoDB instance. Before you use an ApsaraDB for MongoDB instance, you must add the IP addresses or Classless Inter-Domain Routing (CIDR) blocks that you use for database access to a whitelist of this instance. This improves database security and stability. Proper configuration of whitelists can enhance access security of ApsaraDB for MongoDB. We recommend that you maintain the whitelists on a regular basis.

Context

The system creates a default whitelist for each instance. This whitelist can be modified or cleared, but it cannot be deleted. After an ApsaraDB for MongoDB instance is created, the system automatically adds the IP address 127.0.0.1 to the **default** whitelist of this instance. The IP address 0.0.0.0/0 indicates that all IP addresses are allowed to access this instance. You must add the IP addresses or CIDR blocks that you allow to access this ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, choose **Data Security > Whitelist Settings**.

5. You can manually configure a whitelist or import ECS Internal IP addresses to the whitelist.

   Manually modify a whitelist

   i. Find the whitelist you want to modify and choose > **Manually Modify** in the **Actions** column.

   ii. Enter IP addresses or CIDR blocks.

   > Note
   > - Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or CIDR blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix in the CIDR block. An IP address prefix can contain 1 to 32 bits.
   > - If the IP whitelist is empty or only contains `0.0.0.0/0`, all devices are granted access. This is risky for your ApsaraDB for MongoDB instance. We recommend that you add only the IP addresses or CIDR blocks of your own web servers to the whitelist.

   iii. Click **OK**.

   Load IP addresses of ECS instances

   i. Find the whitelist, and choose > **Import ECS Intranet IP** in the **Actions** column.

   ii. From the displayed internal IP addresses of ECS instances that belong to the current account, select the IP addresses and click > to add them to the whitelist.

   iii. Click **OK**.

16.1.3.4. Overview of replica set instance connections

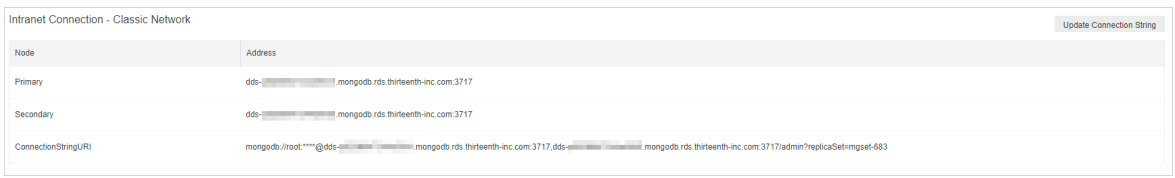
ApsaraDB for MongoDB supports both connection strings and connection string URIs. You can use a connection string to connect to either the primary or secondary node, and use a connection string URI to connect to both of them. For high availability, we recommend that you use connection string URIs to connect your application to both primary and secondary nodes. This topic provides an overview of replica set instance connections.

Prerequisites

A whitelist is configured for the instance. For more information, see Configure a whitelist for an ApsaraDB for MongoDB instance.

View connection strings

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, click the ID of an instance, or click in the **Actions** column corresponding to the instance and select **Manage**.
3. In the left-side navigation pane, click **Database Connection** to view connection strings.



Description of connection strings

Item	Description
Type	• Intranet Connection - Classic Network: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. • Intranet Connection - VPC: A VPC is an isolated network with higher security and performance than a classic network. By default, ApsaraDB for MongoDB provides endpoints on a VPC.
Role	• Primary: the primary node in the replica set instance. If you connect to this node, you can perform read and write operations on the databases of the replica set instance. • Secondary: the secondary node in the replica set instance. If you connect to this node, you can perform only read operations on the databases of the replica set instance. • Connection String URI: ApsaraDB for MongoDB allows you to use a connection string URI to connect to a replica set instance to achieve load balancing and high availability.
Connection string	The connection string of a primary or secondary node is in the following format: `<host>:<port>` • <host>: the endpoint used to connect to the instance. • <port>: the port used to connect to the instance.
Connection string URI	A connection string URI is in the following format: `mongodb://[username:password@]host1[:port1][,host2[:port2],...[,hostN[:portN]]][/[database][?options]]` • mongodb://: the prefix, indicating a connection string URI. • username:password@: the username and password used to log on to a database of the replica set instance. You must separate them with a colon (:). • hostX:portX: the endpoint and port of a node in the replica set instance. • /database: the database corresponding to the username and password if authentication is enabled. • ?options: additional connection options. **Note** If your application is in a production environment, we recommend that you use a connection string URI to connect to the instance. This way, when a node fails, the read and write operations of your application are not affected as a result of the failover.

Related information

- Connect to a replica set instance by using the mongo shell

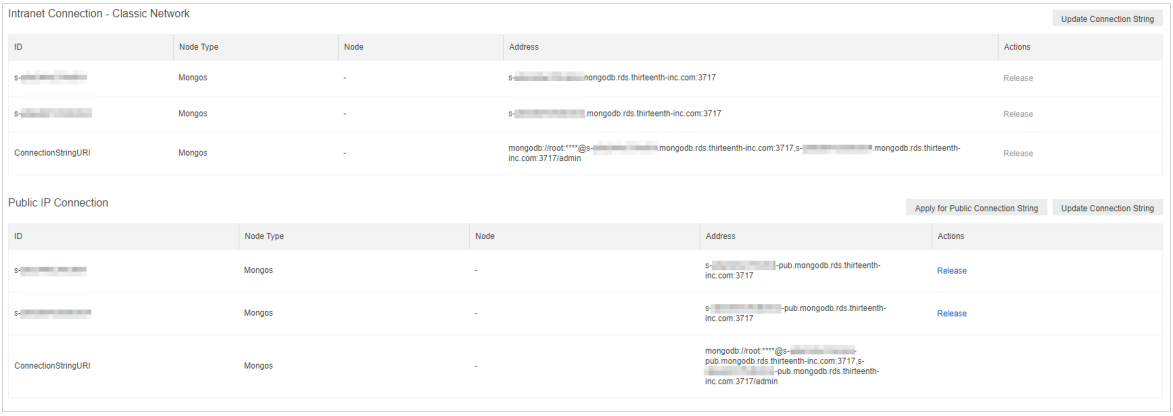
16.1.3.5. Overview of sharded cluster instance connections

ApsaraDB for MongoDB supports both connection strings and connection string URIs. You can use a connection string to connect to one mongos, and use a connection string URI to connect to more mongos. For high availability, we recommend that you use connection string URIs to connect your application to more mongos. This topic provides an overview of sharded cluster instance connections.

View connection strings

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.

3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, click **Database Connection** to view connection strings.



Description of connection strings

Item	Description
Type	• Intranet Connection - Classic Network: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. • Intranet Connection - VPC: A VPC is an isolated network with higher security and performance than a classic network. By default, ApsaraDB for MongoDB provides endpoints on a VPC. • Public IP Connection: Connecting to a sharded cluster instance over the Internet is risky. Therefore, ApsaraDB for MongoDB does not provide public endpoints. If you want to connect to an ApsaraDB for MongoDB instance from a device outside of Alibaba Cloud (such as a local device), you must apply for a public endpoint. For more information, see Apply for a public endpoint for an ApsaraDB for MongoDB instance.
Mongos ID	The connection string of a mongos is in the following format: `<host>:<port>` • <host>: the endpoint used to connect to the instance. • <port>: the port used to connect to the instance. **Note** During regular tests, you can use a connection string to directly connect to a mongos.

Item	Description
Connection string URI	A connection string URI is in the following format: `mongodb://[username:password@]host1[:port1][,host2[:port2],...[,hostN[:portN]]][/[database][?options]]` • mongodb://: the prefix, indicating a connection string URI. • username:password@: the username and password used to log on to a database of the sharded cluster instance. You must separate the username and password with a colon (:). • hostX:portX: the endpoint and port of a mongos in the sharded cluster instance. • /database: the database corresponding to the username and password if authentication is enabled. • ?options: additional connection options. **Note** If your application is in a production environment, we recommend that you use a connection string URI to connect to the instance. Then your client can automatically distribute your requests to multiple mongos to balance loads. When a mongos fails, your client automatically redirects requests to other mongos in the normal state.

Log on to a database of an ApsaraDB for MongoDB instance

1. Obtain the connection string and the following information:
   - The username used to log on to the database. The initial username is root.
   - The password of the database user. If you forget the password of the root user, you can reset it. For more information, see Set a password for a sharded cluster instance.
   - The name of the database corresponding to the username if authentication is enabled. If the database username is root, enter admin.
2. Log on to the database.
   - Use DMS to log on to a replica set instance of ApsaraDB for MongoDB
   - Connect to a replica set instance by using the mongo shell

16.1.3.6. Use the mongo shell to connect to an ApsaraDB for MongoDB instance

This topic describes how to use the mongo shell to connect to an ApsaraDB for MongoDB instance.The mongo shell is a database management tool provided by ApsaraDB for MongoDB. You can install it on your client or in an ECS instance.

Prerequisites

- The version of the mongo shell is the same as your ApsaraDB for MongoDB instance. This ensures successful authentication. For information about the installation procedure, visit MongoDB official documentation. Choose the version in the upper-left corner of the page based on your client version.
- The IP address of your client is added to a whitelist of the ApsaraDB for MongoDB instance. For more information, see Configure a whitelist for an ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.

3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, click **Database Connection** to view connection strings.

   > **Note**
   > - Replica set instances: Obtain the endpoint or connection string URI information of a node.
   > - Sharded cluster instances: Obtain the endpoint or connection string URI information of the mongos mode.
   >
   > For more information about connection strings, see Overview of replica set instance connections or Overview of sharded cluster instance connections.

5. Connect to the ApsaraDB for MongoDB instance from your client or ECS instance where the mongo shell is installed.

   Replica set instances:

   - Connection string of a node

     During regular tests, you can directly connect to a primary or secondary node. Take note that after the primary node fails, the system automatically switches to the secondary node, and the roles of connected nodes change. This affects the read and write operations of your application.

     Command format:

     ```
     mongo --host <host> -u <username> -p --authenticationDatabase <database>
     ```

     > **Note**
     > - <host>: the connection string of the primary or secondary node.
     > - <username>: the username you use to log on to a database of the instance. The initial username is **root**.
     > - <database>: the name of database corresponding to the username if authentication is enabled. If the database username is root, enter admin.

     Example:

     ```
     mongo --host dds-bp**********.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase admin
     ```

     When `Enter password:` is displayed, enter the password of the database user and press Enter. If you forget the password of the root user, you can reset it. For more information, see Reset the password for an ApsaraDB for MongoDB instance.

     > **Note** The password characters are not displayed when you enter the password.

   - HA connection (recommended): You can use a connection string URI to connect to both the primary and secondary nodes of a replica set instance. This ensures that your application is always connected to the primary node and the read and write operations of your application are not affected even if the roles of the primary and secondary nodes are switched.

     Command format:

     ```
     mongo "<ConnectionStringURI>"
     ```

> **Note**
> - Double quotation marks ("") must be used.
> - <ConnectionStringURI>: the connection string URI of the instance.
>
> You must replace `****` in the connection string URI with the database password. For more information about how to set a database password, see Reset the password for an ApsaraDB for MongoDB instance.

Example:

```
mongo "mongodb://root:****@dds-**********.mongodb.rds.intra.env17e.shuguang.com:3717,dds-*****
*****.mongodb.rds.intra.env17e.shuguang.com:3717/admin? replicaSet=mgset-*****"
```

Sharded cluster instances:

- Connection string of the mongos node

  Command format:

  ```
  mongo --host <mongos_host> -u <username> -p --authenticationDatabase <database>
  ```

  > **Note**
  > - <mongos_host>: the connection string of a mongos node in the sharded cluster instance.
  > - <username>: the username you use to log on to a database of the instance. The initial username is **root**.
  > - <database>: the name of database corresponding to the username if authentication is enabled. If the database username is root, enter admin.

  Example:

  ```
  mongo --host s-bp**********.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase
  admin
  ```

- HA connection (recommended): You can use a connection string URI to connect to a database. If one mongos node fails, another mongos node takes over business to ensure the high availability of the connection.

  Command format:

  ```
  mongo "<ConnectionStringURI>"
  ```

  > **Note**
  > - Double quotation marks ("") must be used.
  > - <ConnectionStringURI>: the connection string URI of the instance.
  >
  > You must replace `****` in the connection string URI with the database password. For more information about how to set a database password, see Reset the password for an ApsaraDB for MongoDB instance.

  Example:

  ```
  mongo "mongodb://root:****@s-**********.mongodb.rds.intra.env17e.shuguang.com:3717,s-*********
  *.mongodb.rds.intra.env17e.shuguang.com:3717/admin"
  ```

16.1.4. Instances

16.1.4.1. Create an ApsaraDB for MongoDB instance

This topic describes how to create an instance in the ApsaraDB for MongoDB console.

Prerequisites

An account is obtained to log on to the ApsaraDB for MongoDB console.

Create a replica set instance

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, click **Create Instance** in the upper-left corner. On the **Create ApsaraDB for MongoDB Instance** page, configure the parameters.

   The following table describes the required parameters.

   Parameters for creating a replica set instance

Section	Parameter	Description
Basic Settings	Organization	Select an organization for the new instance.
	Resource Set	Select a resource set for the new instance.
Region	Region	Select a region for the new instance.
	Zone	Select a zone for the new instance
Specifications	Database Engine	Select a database engine for the new instance. In this case, you can select only **MongoDB**.
	Engine Version	Select a database engine version for the new instance. Valid values: ○ 3.0 ○ 3.4 ○ 4.0 ○ 4.2
	Node Type	ApsaraDB for MongoDB supports the following options: ○ Three-node Replica Set: uses dedicated memory and I/O resources but shares CPU and storage resources with other general-purpose instances on the same server. ○ Dedicated Instance: uses dedicated CPU, memory, storage, and I/O resources to ensure long-term performance. In this case, an instance is not affected by other instances on the same server. ○ Dedicated Host: exclusively uses all resources of a server. This is the top configuration of exclusive specifications.
	Node Specifications	Select a node specification for the new instance. For more information, see descriptions in the ApsaraDB for MongoDB console.

Section	Parameter	Description
	Storage Capacity (GB)	The storage space of the instance, which contains the space for data, system files, log files, and transaction files. For more information, see *Instance types* in *ApsaraDB for MongoDB Product Introduction*.
Network	**Network Type**	ApsaraDB for MongoDB supports the following options: ○ **Classic Network**: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. ○ **VPC**: Virtual Private Cloud (VPC) is an isolated network environment built in Apsara Stack. You can customize route tables, CIDR blocks, and gateways in a VPC. We recommend that you select VPC for improved security. **Note** If you select the **VPC** network type, you must configure the **VPC** and **vSwitch** parameters.
	VPC	Select a VPC. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
	vSwitch	Select a vSwitch. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
Password Settings	**Instance Name**	Set the name of the new instance. The name must be 2 to 256 characters in length, The name must start with a letter, and can contain digits, letters, underscores (_), and hyphens (-).
	Password Setting	Determine when to set the password for logging on to databases in the new instance. You can select **Set Now** to set the logon password immediately, or select **Set after Purchase** to set the logon password after you create the instance. For more information, see Reset the password for an ApsaraDB for MongoDB instance.
	Logon Password	Set a password. The password must meet the following requirements: ○ It must be 8 to 32 characters in length. ○ It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. ○ The name can contain special characters. Special characters include ! # $ % ^ & * ( ) _ + =
	Confirm Password	Enter the password again. The password you enter here must be the same as that in New Password.

3. Click **Submit** to create the instance.

Create a sharded cluster instance

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.

3. Click **Create Instance** in the upper-left corner to go to the **Create MongoDB Instance** page. Configure the parameters.

   The following table describes the required parameters.

   Parameters for creating a sharded cluster instance

Section	Parameter	MNS logs
Basic Settings	**Organization**	Select an organization for the new instance.
	Resource Set	Select a resource set for the new instance.
Region	**Region**	Select a region for the new instance.
	Zone	Select a zone for the new instance
Specifications	**Database Engine**	Select a database engine for the new instance. In this case, you can select only **MongoDB**.
	Engine Version	Select a database engine version for the new instance. Valid values: ○ 3.4 ○ 4.0 ○ 4.2
Network	**Network Type**	ApsaraDB for MongoDB supports the following options: ○ **Classic Network**: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. ○ **VPC**: Virtual Private Cloud (VPC) is an isolated network environment built in Apsara Stack. You can customize route tables, CIDR blocks, and gateways in a VPC. We recommend that you select VPC for improved security. **Note** If you select the **VPC** network type, you must configure the **VPC** and **vSwitch** parameters.
	VPC	Select a VPC. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
	vSwitch	Select a vSwitch. If no vSwitch exists, you can click **Create vSwitch** to create a vSwitch. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
Mongos Specifications	**Mongos Specifications**	The specifications of the mongos node. For more information, see descriptions in the ApsaraDB for MongoDB console.
	Quantity	The number of the mongos nodes. You can select 2 to 32 mongos nodes.

Section	Parameter	MNS logs
Shard Specifications	Shard Specifications	The specifications of the shard node. For more information, see descriptions in the ApsaraDB for MongoDB console.
	Storage Capacity (GB)	The storage space of the instance, which contains the space for data, system files, log files, and transaction files. For more information, see *Instance types* in *ApsaraDB for MongoDB Product Introduction*.
	Quantity	The number of the shard nodes. You can select 2 to 32 shard nodes.
Config Server Specifications	Config Server Specifications	The specifications of Configserver nodes. It is fixed at **1 vCPU, 2 GiB memory** and cannot be customized.
	Storage Capacity (GB)	The storage space of the Configserver node. It is fixed at 20 GB and cannot be customized.
Password Settings	Instance Name	Set the name of the new instance. The name must be 2 to 256 characters in length, and can contain digits, letters, underscores (_), and hyphens (-). It must start with a letter.
	Password Setting	Determine when to set the password for logging on to databases in the new instance. You can select **Set Now** to set the logon password immediately, or select **Set after Purchase** to set the logon password after you create the instance. For more information, see Reset the password for an ApsaraDB for MongoDB instance.
	Logon Password	Set a password. The password must meet the following requirements: ○ It must be 8 to 32 characters in length. ○ It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. ○ The name can contain special characters. Special characters include ! # $ % ^ & * ( ) _ + =
	Confirm Password	Enter the password again. The password you enter here must be the same as that in New Password.

4. Click **Submit** to create the instance.

16.1.4.2. View the details of an ApsaraDB for MongoDB instance

This topic describes how to view the details of an ApsaraDB for MongoDB instance, such as the basic information, internal network connection information, status, and configurations. This topic describes how to view the details of an ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Go to the instance details page. Either of the following methods can be used:

- Find the instance and click its ID to go to the **Basic Information** page, where you can view the details of the instance.
- In the Operations column corresponding to the instance, choose > **Manage** to go to the **Basic Information** page, where you can view the details of the instance.

16.1.4.3. Restart an ApsaraDB for MongoDB instance

You can manually restart an instance when the number of connections exceeds the threshold or any performance issue occurs on the instance. This topic describes how to restart an ApsaraDB for MongoDB instance.

Prerequisites

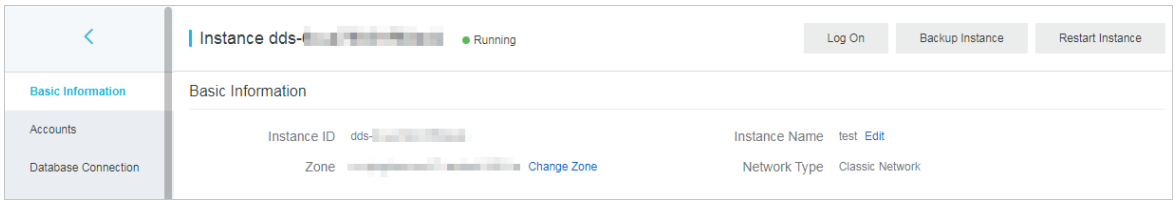
The instance is in the **Running** state.

Context

Note When an ApsaraDB for MongoDB instance is restarted, all its connections are terminated. Plan your operations in advance before you restart an ApsaraDB for MongoDB instance. Proceed with caution.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click in the **Actions** column corresponding to the instance and select **Manage**.
4. In the upper-right corner of the page, click **Restart Instance**.



Note You can also choose > **Restart** in the **Actions** column corresponding to the instance.

5. In the **Restart Instance** message, click **OK**.

16.1.4.4. Change the specifications of an ApsaraDB for MongoDB instance

This topic describes how to change the specifications of an ApsaraDB for MongoDB instance. You can upgrade or downgrade an ApsaraDB for MongoDB instance to meet your business needs.

Prerequisites

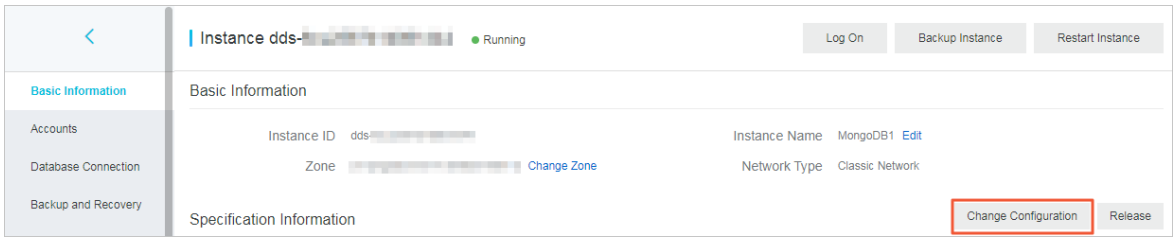
The instance must be an ApsaraDB for MongoDB replica set instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see

Log on to the ApsaraDB for MongoDB console.

2. On the **Replica Set Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
3. Click **Change Configuration** in the upper right corner of the Specification Information section to go to the **Modify Instance** page.



> **Note** To go to the **Modify Instance** page, you can also choose ⋮ > **Change Configuration** in the **Actions** column corresponding to the instance on the **Replica Set Instances** page.

4. On the **Modify Instance** page, change the instance specifications.

   You can change values of the following parameters:

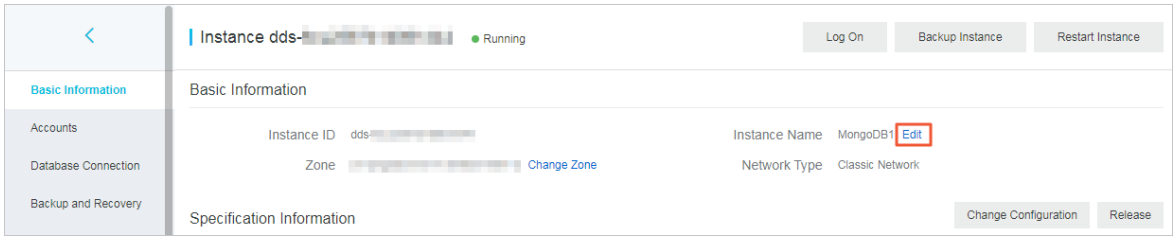
   - **Node Type**
   - **Node Specifications**
   - **Storage Capacity**
5. Click **Submit**.

16.1.4.5. Change the name of an ApsaraDB for MongoDB instance

This topic describes how to change the name of an ApsaraDB for MongoDB instance for better management.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. Click **Edit** next to **Instance Name**.



> **Note**
> - The instance name must start with an English letter. It cannot start with http:// or https://.
> - The instance name can contain letters, underscores (_), hyphens (-), and digits.
> - The instance name must be 2 to 128 characters in length.

5. Click **OK**.

16.1.4.6. Reset the password for an ApsaraDB for MongoDB instance

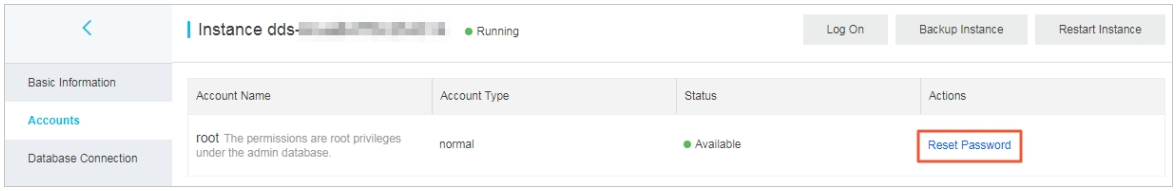
This topic describes how to reset your password in the ApsaraDB for MongoDB console.

Context

> **Notice** We recommend that you change your password on a regular basis to ensure data security.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, click **Accounts**.
5. Click **Reset Password** in the Actions column and configure the parameters in the Reset Password panel.



Parameters for resetting a password describes the parameters.

Parameters for resetting a password

Parameter	Description
New Password	Specify the new password of the account based on the following rules: ○ The password must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. Special characters include !#$%^&*()_+= ○ The password must be 8 to 32 characters in length.
Confirm New Password	Enter the password again. The password you enter here must be the same as that in New Password.

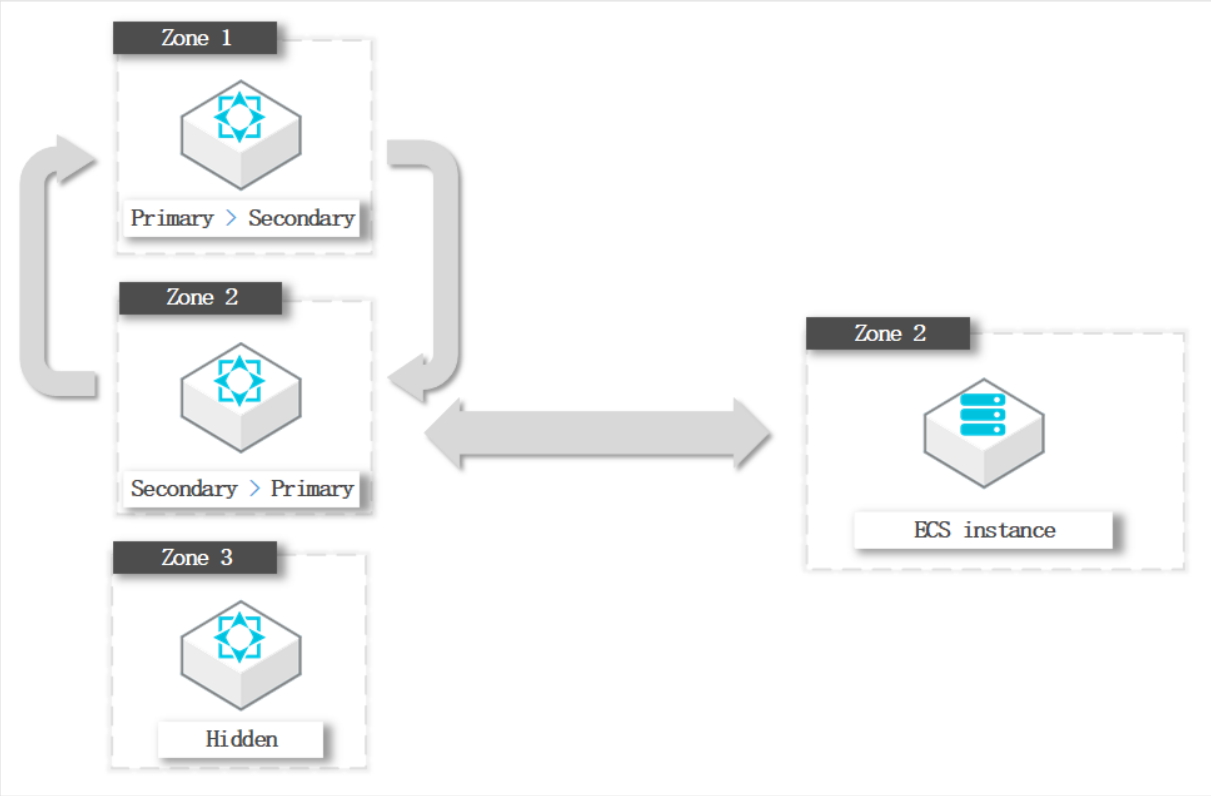
6. Click **OK**.

16.1.4.7. Switch node roles

You can switch the node roles of an ApsaraDB for MongoDB instance in the ApsaraDB for MongoDB console based on your business deployment.

Typical scenario

When an ECS instance and an ApsaraDB for MongoDB instance are in the same zone and connected over the internal network, the latency is minimal. If they are connected across different zones, the latency increases and the performance of ApsaraDB for MongoDB instances and your business will be affected.



In this example, the ECS instance to which the application belongs is in Zone 2. If the primary node of the ApsaraDB for MongoDB instance is in Zone 1, the ECS instance needs to connect to the primary node across zones.

To optimize the business deployment architecture, you can switch the roles of the primary and secondary nodes. In this example, you can change the role of the node in Zone 2 to primary and the role of the node in Zone 1 to secondary. Note that only the node roles are changed. ECS and ApsaraDB for MongoDB instances can be connected in the same zone without changing the actual zones and role IDs.

Precautions

- Switching node roles will cause a transient disconnection of up to 30 seconds. Perform this operation during off-peak hours or ensure that your application has a reconnection mechanism.
- Switching node roles only changes the roles of nodes, but not the zones and role IDs of nodes.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in

the **Actions** column corresponding to the instance and select **Manage**.

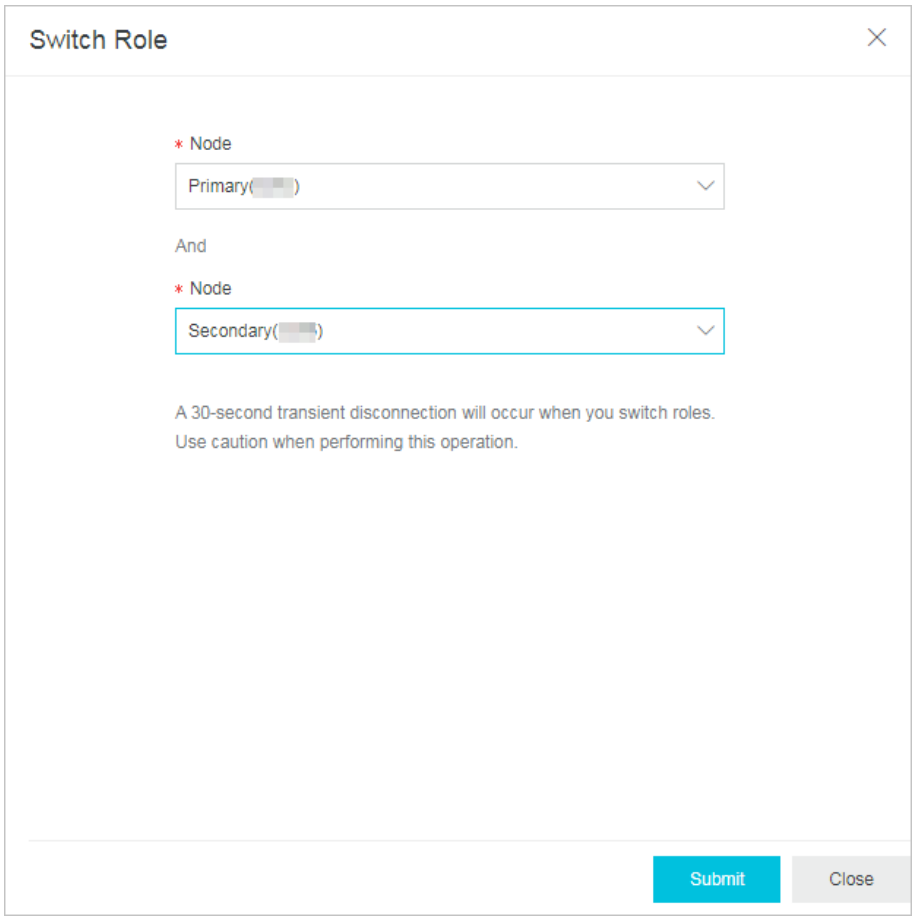
4. In the left-side navigation pane, click **Service Availability**.
5. Subsequent steps on the **Service Availability** page vary depending on instance types.
   - Replica set instance
     a. Click **Switch Role** in the upper-right corner of the page.
     b. In the **Switch Role** dialog box that appears, select the nodes.

     c. Click **OK**.
   - Sharded cluster instance

> **Note** For sharded cluster instances, you can only manage the zone distribution of shard and Configserver nodes.

     a. In the upper-right corner of the **Zone Distribution for Shards** or **Zone Distribution for Configservers** section, click **Switch Role**.

b. In the **Switch Role** dialog box that appears, select the nodes.



- Click **OK**.

16.1.4.8. Release an ApsaraDB for MongoDB instance

This topic describes how to manually release an ApsaraDB for MongoDB instance to meet your business needs.
This topic describes how to manually release an ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the lower-right corner of the **Basic Information** section, click **Release**.

   > **Note** You can also go to the Replica Set Instances page, find the instance, click the ⋮ icon in the **Actions** column, and then choose **Release**.

5. In the **Release Instance** message, click **OK**.

> **Warning** After you release an ApsaraDB for MongoDB instance, data in the instance can no longer be recovered. Proceed with caution.

16.1.4.9. Primary/secondary failover

16.1.4.9.1. Trigger a primary/secondary failover for a replica set instance

An ApsaraDB for MongoDB replica set instance consists of three nodes by default. ApsaraDB for MongoDB provides connection strings for you to connect to the primary node and a secondary node. The other secondary node is hidden as a backup to ensure high availability. If a node is faulty, the high availability system of ApsaraDB for MongoDB automatically triggers a primary/secondary failover to ensue the availability of the instance. You also can manually trigger a primary/secondary failover for an ApsaraDB for MongoDB instance in scenarios such as routine disaster recovery drills.

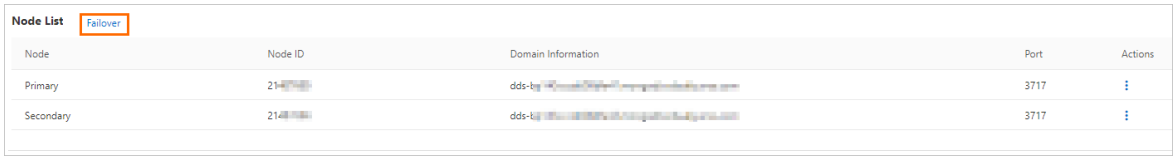
Context

After you log on to the ApsaraDB for MongoDB console or call the SwitchDBInstanceHA operation to trigger a primary/secondary failover for a replica set instance, ApsaraDB for MongoDB interchanges the roles of the primary and secondary nodes.

> **Note**
> - You can trigger a primary/secondary failover only for replica set and sharded cluster instances, but not for standalone instances due to their single-node architecture.
> - Each time you trigger a primary/secondary failover for an instance, the instance may have a transient connection error of about 30 seconds. Ensure that your applications can automatically re-establish a connection.
> - You can trigger a primary/secondary failover only for instances in the running state.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
3. In the **Node List** section, click **Failover**, as shown in the following figure.



4. In the dialog box that appears, click **OK**.
5. The instance status changes to **HA Switching**.The failover is successful when the instance status changes back to **Running**.

   The failover operation is complete in about one minute. Then the instance returns to normal.

> **Note** If you have connected to the connection string of the primary node for an instance, you are connecting to a secondary node after a failover and you have no write permissions on the instance. In this case, you must connect to the connection string of the new primary node and obtain read and write permissions. For more information, see Overview of replica set instance connections.

16.1.4.9.2. Trigger a primary/secondary failover for a sharded cluster instance

Each shard or Configserver of a sharded cluster instance consists of three nodes by default. If a node is faulty, the high availability system of ApsaraDB for MongoDB automatically triggers a primary/secondary failover to ensure the availability of the shard. You can also manually trigger a primary/secondary failover for an ApsaraDB for MongoDB instance in scenarios such as routine disaster recovery drills.

Precautions

ApsaraDB for MongoDB provides connection strings for you to connect to the primary and secondary nodes. The hidden node is invisible to you and only used to ensure high availability. After you log on to the ApsaraDB for MongoDB console or call the SwitchDBInstanceHA operation to trigger a primary/secondary failover for a shard of a sharded cluster instance, ApsaraDB for MongoDB switches the roles of the primary and secondary nodes.

> **Note**
> - You can trigger a primary/secondary failover only for the shard or Configserve node in the running state.
> - Each time you trigger a primary/secondary failover for an instance, the instance may have a transient connection error of about 30 seconds. We recommend that you perform this operation during off-peak hours and ensure that your applications can automatically re-establish a connection.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the **Shard List** or **ConfigServer List** section, find the node and choose ⋮ > **Failover** in the Actions column.

   > **Note** You can trigger a primary/secondary failover separately for each shard node. The failover operation takes effect only for the current shard node and does not affect other shard nodes of the same sharded cluster instance.

5. In the **Failover** message, click **OK**.

   > **Note** The failover operation is complete in about one minute.

16.1.4.10. Monitoring

This topic describes the performance metrics provided by ApsaraDB for MongoDB to check the status of ApsaraDB for MongoDB instances. You can view these performance metrics in the ApsaraDB for MongoDB console.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click  in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, click **Monitoring Info**.

   You can select a time range to query historical performance metrics. The following table describes metric details.

   Performance metrics

Performance metric	Description	Monitoring frequency
CPU Utilization Percentage	cpu_usage: the CPU utilization of the instance	Every 300 seconds
Memory Usage Percentage	mem_usage: the memory usage of the instance	Every 300 seconds
IOPS Usage	The input/output operations per second (IOPS) of the instance. The following items are included: ◦ data_iops: the IOPS of the data disk. ◦ log_iops: the IOPS of the log disk.	Every 300 seconds
IOPS Usage Percentage	iops_usage: the ratio of the IOPS used by the instance to the maximum IOPS allowed	Every 300 seconds
Disk Usage	The total disk space used by the instance. The following items are included: ◦ ins_size: the total space used. ◦ data_size: the space used on the data disk. ◦ log_size: the space used on the log disk.	Every 300 seconds
Disk Usage Percentage	disk_usage: the ratio of the total disk space used by the instance to the maximum disk space that can be used	Every 300 seconds

Performance metric	Description	Monitoring frequency
Operation QPS	The queries per second (QPS) of the instance. The following items are included: ◦ The number of insert operations. ◦ The number of query operations. ◦ The number of delete operations. ◦ The number of update operations. ◦ The number of getmore operations. ◦ The number of command operations.	Every 300 seconds
Connections	current_conn: the number of current connections to the instance	Every 300 seconds
Cursors	The number of cursors used by the instance. The following items are included: ◦ total_open: the number of cursors that are opened. ◦ timed_out: the number of cursors that timed out.	Every 300 seconds
Network Traffic	The network traffic of the instance. The following items are included: ◦ bytes_in: the inbound network traffic. ◦ bytes_out: the outbound network traffic. ◦ num_requests: the number of requests that are processed.	Every 300 seconds
Global Lock Waiting Queues	The length of the queues that are waiting for global locks for the instance. The following items are included: ◦ gl_cq_total: the length of the queue that is waiting for both global read and write locks. ◦ gl_cq_readers: the length of the queue that is waiting for global read locks. ◦ gl_cq_writers: the length of the queue that is waiting for global write locks.	Every 300 seconds

Performance metric	Description	Monitoring frequency
WiredTiger	The cache metrics of the WiredTiger engine used by the instance. The following items are included: ○ bytes_read_into_cache: the amount of data that is read into the cache. ○ bytes_written_from_cache: the amount of data that is written from the cache to the disk. ○ maximum_bytes_configured: the size of the maximum available disk space that is configured.	Every 300 seconds
Primary/Secondary Replication Latency	repl_lag: the latency in data synchronization between the primary and secondary nodes of the instance	Every 300 seconds

16.1.5. Backup and restoration

16.1.5.1. Configure automatic backup for an ApsaraDB for MongoDB instance

This topic describes how to configure automatic backup for an ApsaraDB for MongoDB instance. ApsaraDB for MongoDB automatically backs up data based on the backup policy you specify.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, click **Backup and Recovery**.
5. In the upper-left corner of the page, click **Backup Settings**. Configure the parameters in the Backup Settings panel.

   The following table describes the parameters.

   Backup policy parameters

Parameter	Description
Retention Days	The number of days for which you want to retain backup files. It can only be seven days.
Backup Time	The hour at which you want to perform the backup task.
Day of Week	The backup cycle. You can select one or more days in a week.

6. Click **OK**.

16.1.5.2. Manually back up an ApsaraDB for MongoDB instance

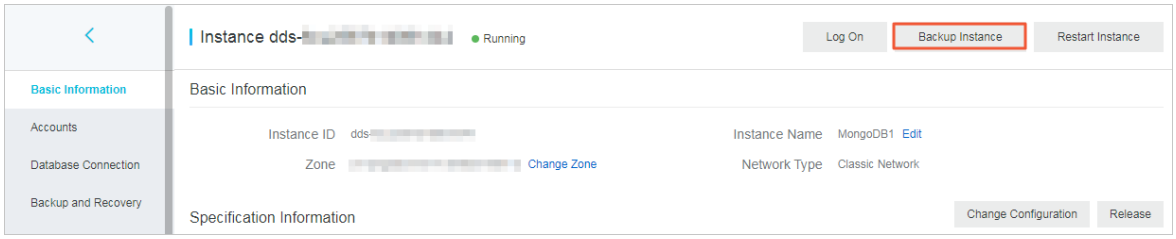
This topic describes how to manually back up an ApsaraDB for MongoDB instance.

Backup methods

- Physical backup: This method backs up physical database files of an ApsaraDB for MongoDB instance. Compared with logical backup, physical backup provides faster data backup and recovery.
- Logical backup: The mongodump tool is used to store operation records of databases to a logical backup file. Then, data can be restore data by using the mongorestore tool.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the upper-right corner of the page, click **Backup Instance**.



5. In the dialog box that appears, set **Backup Method** and click **OK**.

16.1.5.3. Restore data to the current ApsaraDB for MongoDB instance

This topic describes how to restore data to the current ApsaraDB for MongoDB instance. This helps minimize the data loss caused by incorrect operations.

Prerequisites

The instance is a replica set instance with three nodes.

Background information

- The time required to restore data to your current instance varies depending on factors such as the data volume, task queue status, and network conditions. When the status of the instance changes to **Running**, the restoration is complete.
- If you restore data to your current instance, all existing data is overwritten and cannot be restored.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column

corresponding to the instance and select **Manage**.

3. In the left-side navigation pane, click **Backup and Recovery**.
4. On the **Backup and Recovery** page that appears, find the backup set and choose > **Data Recovery** in the Actions column.

   > **Note** If you have upgraded the database version, you cannot use the backup files of the earlier database version to restore data.

5. In the **Roll Back Instance** message, click **OK**.

   > **Note** The instance status becomes **Restoring from Backup** after you click **OK**. You can click **Refresh** in the upper-right corner of the **Backup and Recovery** page to update the instance status. The restoration is complete when the instance status changes to **Running**.

16.1.6. Database connection

16.1.6.1. Modify a public or internal endpoint of an ApsaraDB for MongoDB instance

This topic describes how to modify the public and internal endpoints of an ApsaraDB for MongoDB instance in the ApsaraDB for MongoDB console.

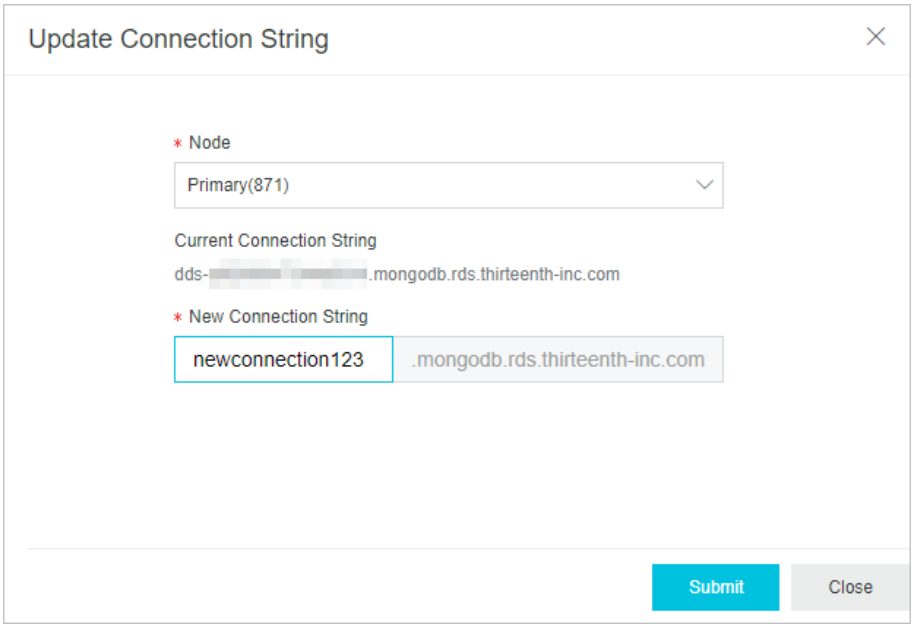
Limits

Architecture	Limit
Replica set instance	You can modify the public and internal endpoints of both primary and secondary nodes.
Sharded cluster instance	You can only modify the public and internal endpoints of a mongos.

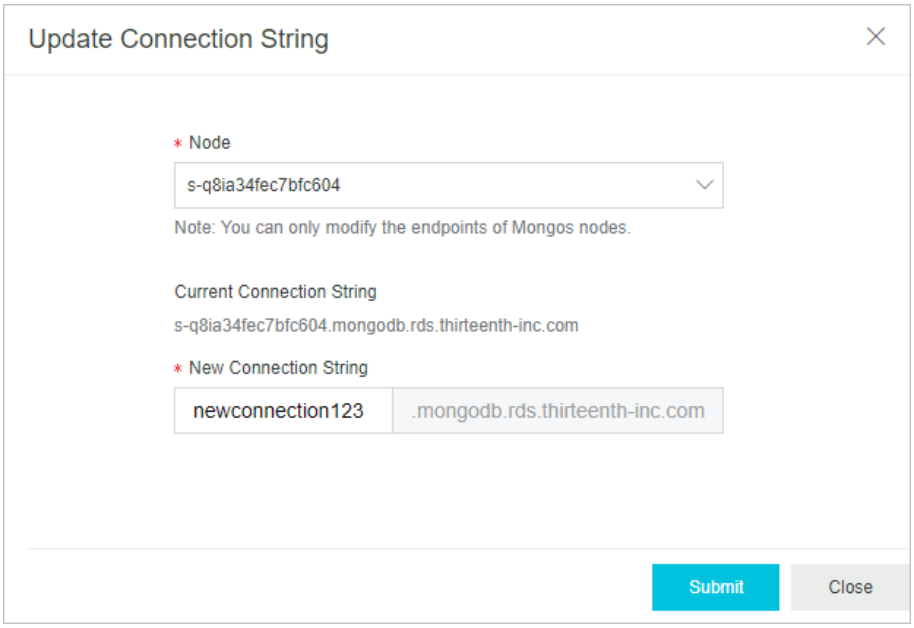
Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, click **Database Connection**.
5. In the **Intranet Connection** or **Public IP Connection** section, click **Update Connection String**.
6. In the dialog box that appears, enter a new endpoint.

   Replica set instance



Sharded cluster instance



> **Note**
> - You can only modify the prefix of the endpoint.
> - It must start with a lowercase letter and end with a letter or a digit. The password must be 8 to 64 characters in length and can contain lowercase letters, digits, and hyphens (-).

7. Click **Submit**.

What's next

After you modify the public or internal endpoint, you must connect a client or an application to your ApsaraDB for MongoDB instance by using the new endpoint.

16.1.6.2. Use the mongo shell to connect to an ApsaraDB for MongoDB instance

This topic describes how to use the mongo shell to connect to an ApsaraDB for MongoDB instance.The mongo shell is a database management tool provided by ApsaraDB for MongoDB. You can install it on your client or in an ECS instance.

Prerequisites

- The version of the mongo shell is the same as your ApsaraDB for MongoDB instance. This ensures successful authentication. For information about the installation procedure, visit MongoDB official documentation. Choose the version in the upper-left corner of the page based on your client version.
- The IP address of your client is added to a whitelist of the ApsaraDB for MongoDB instance. For more information, see Configure a whitelist for an ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, click **Database Connection** to view connection strings.

   > **Note**
   > - Replica set instances: Obtain the endpoint or connection string URI information of a node.
   > - Sharded cluster instances: Obtain the endpoint or connection string URI information of the mongos mode.
   >
   > For more information about connection strings, see Overview of replica set instance connections or Overview of sharded cluster instance connections.

5. Connect to the ApsaraDB for MongoDB instance from your client or ECS instance where the mongo shell is installed.

   Replica set instances:

   - Connection string of a node

     During regular tests, you can directly connect to a primary or secondary node. Take note that after the primary node fails, the system automatically switches to the secondary node, and the roles of connected nodes change. This affects the read and write operations of your application.

     Command format:

     ```
     mongo --host <host> -u <username> -p --authenticationDatabase <database>
     ```

> **Note**
> - <host>: the connection string of the primary or secondary node.
> - <username>: the username you use to log on to a database of the instance. The initial username is **root**.
> - <database>: the name of database corresponding to the username if authentication is enabled. If the database username is root, enter admin.

Example:

```
mongo --host dds-bp**********.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase admin
```

When `Enter password:` is displayed, enter the password of the database user and press Enter. If you forget the password of the root user, you can reset it. For more information, see Reset the password for an ApsaraDB for MongoDB instance.

> **Note** The password characters are not displayed when you enter the password.

- HA connection (recommended): You can use a connection string URI to connect to both the primary and secondary nodes of a replica set instance. This ensures that your application is always connected to the primary node and the read and write operations of your application are not affected even if the roles of the primary and secondary nodes are switched.

  Command format:

  ```
  mongo "<ConnectionStringURI>"
  ```

  > **Note**
  > - Double quotation marks ("") must be used.
  > - <ConnectionStringURI>: the connection string URI of the instance.
  >
  >   You must replace `****` in the connection string URI with the database password. For more information about how to set a database password, see Reset the password for an ApsaraDB for MongoDB instance.

  Example:

  ```
  mongo "mongodb://root:****@dds-**********.mongodb.rds.intra.env17e.shuguang.com:3717,dds-**********.mongodb.rds.intra.env17e.shuguang.com:3717/admin? replicaSet=mgset-*****"
  ```

Sharded cluster instances:

- Connection string of the mongos node

  Command format:

  ```
  mongo --host <mongos_host> -u <username> -p --authenticationDatabase <database>
  ```

> **Note**
> - <mongos_host>: the connection string of a mongos node in the sharded cluster instance.
> - <username>: the username you use to log on to a database of the instance. The initial username is **root**.
> - <database>: the name of database corresponding to the username if authentication is enabled. If the database username is root, enter admin.

Example:

```
mongo --host s-bp**********.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase admin
```

- HA connection (recommended): You can use a connection string URI to connect to a database. If one mongos node fails, another mongos node takes over business to ensure the high availability of the connection.

  Command format:

  ```
  mongo "<ConnectionStringURI>"
  ```

  > **Note**
  > - Double quotation marks ("") must be used.
  > - <ConnectionStringURI>: the connection string URI of the instance.
  >
  >   You must replace `****` in the connection string URI with the database password. For more information about how to set a database password, see Reset the password for an ApsaraDB for MongoDB instance.

  Example:

  ```
  mongo "mongodb://root:****@s-**********.mongodb.rds.intra.env17e.shuguang.com:3717,s-*********.mongodb.rds.intra.env17e.shuguang.com:3717/admin"
  ```

16.1.6.3. Use DMS to log on to an ApsaraDB for MongoDB instance

You can use DMS to connect to an ApsaraDB for MongoDB instance.

Prerequisites

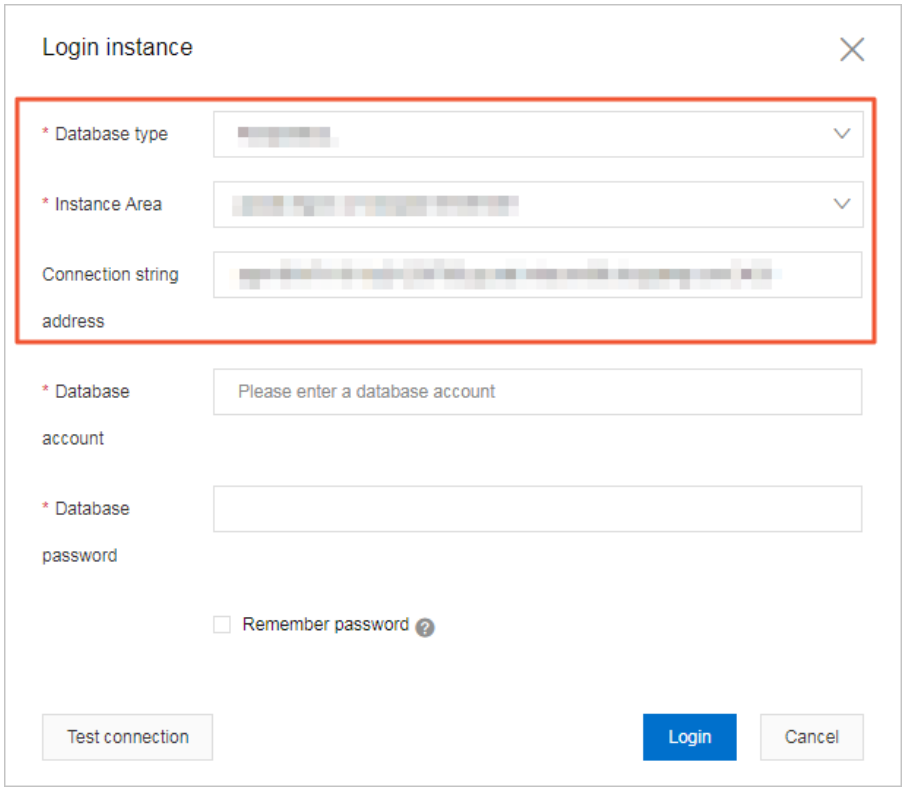
The IP address whitelist is configured. For more information about how to configure the IP address whitelist, see Configure a whitelist for an ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. Click **Log On** in the upper-right corner of the page.

> **Note** For a sharded cluster instance, you must also select the Mongos node.

5. In the **Login instance** dialog box of the **DMS** console, check values of **Database type**, **Instance Area**, and **Connection string address**. If the information is correct, enter **Database account** and **Database password**, as shown in the following figure.



Parameter	Description
Database type	The engine of the database. By default, the engine of the database to be connected is displayed.
Instance Area	The region where the instance is deployed. By default, the region of the current instance is displayed.
Connection string address	The endpoint of the instance. By default, the endpoint of the current instance is displayed.
Database account	The account of the database to be connected.
Database password	The password of the account used to connect to the database.

6. Click **Login**.

> **Note** If you want your web browser to remember the password, select **Remember password** before you click **Login**.

16.1.6.4. Apply for a public endpoint for an ApsaraDB for MongoDB instance

This topic describes how to apply for a public endpoint for an ApsaraDB for MongoDB instance when you want to connect to this instance over the Internet.

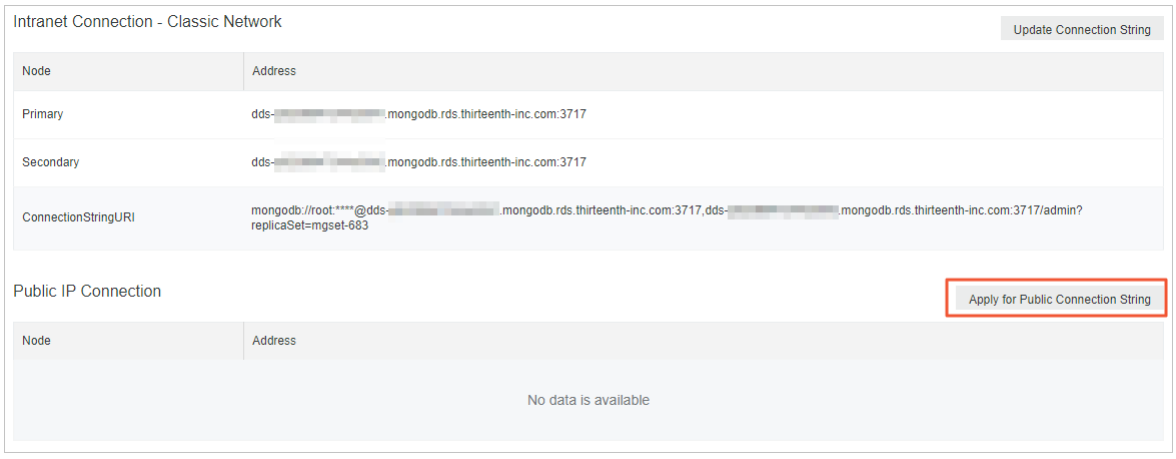
Context

The following table describes the VPC and classic network endpoints supported by ApsaraDB for MongoDB.

Type	Description
VPC endpoint	• A VPC is an isolated network with higher security and performance than a classic network. • By default, ApsaraDB for MongoDB provides endpoints on a VPC.
Classic network endpoint	Cloud services on a classic network are not isolated. Unauthorized access can only be blocked by using security groups or whitelists.
Public endpoint	• It is risky to connect to an ApsaraDB for MongoDB instance over the Internet. Therefore, ApsaraDB for MongoDB does not provide public endpoints. • If you want to connect to a replica set instance from a device outside Alibaba Cloud (for example, a local client), you must apply for a public endpoint.

Apply for a public endpoint for a replica set instance

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
3. In the left-side navigation pane, click **Database Connection**.
4. In the **Public IP Connection** section, click **Apply for Public Connection String**.



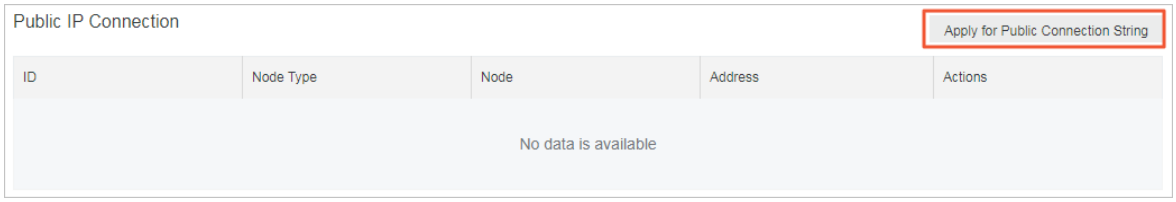
5. In the **Apply for Public Connection String** message that appears, click **OK**.

> **Note** If you want to connect to an ApsaraDB for MongoDB (Serverless) instance by using a public endpoint, you must add the public IP address of your client to a whitelist of this instance. For more information, see Configure a whitelist for an ApsaraDB for MongoDB instance.

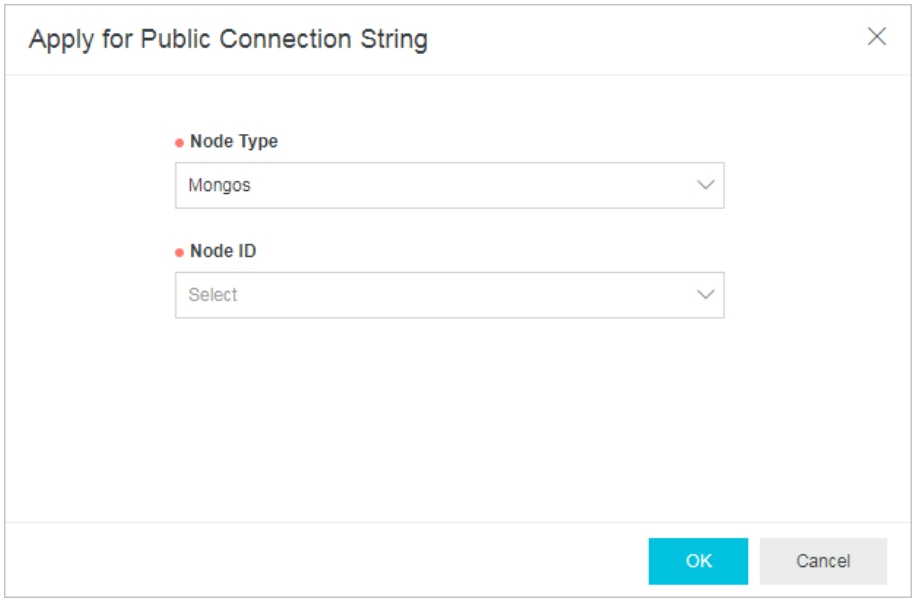
After the application is complete, the replica set instance generates new endpoints for both the primary and secondary nodes and the corresponding connection string URI. For more information, see Overview of replica set instance connections.

Apply for a public endpoint for a sharded cluster instance

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, click **Database Connection**.
5. In the **Public IP Connection** section, click **Apply for Public Connection String**.



6. In the dialog box that appears, specify **Node Type** and **Node ID**, and click **OK**.



Parameter	Value	Description
Mongos	The mongos node. You can only apply for public endpoints for mongos nodes. Your applications are connected to mongos nodes in most cases.	
Node ID	The ID of the component for which you want to apply for a public endpoint.	None

Note To apply for a public endpoint for other mongos, repeat this step. You can only apply for a new public endpoint after the current one is created.

References

- To ensure data security, we recommend that you release a public endpoint if you no longer need it. For more information, see Release a public connection string.
- Before you connect to a replica set instance over the Internet, we recommend that you enable SSL encryption. For more information, see Use the mongo shell to connect to an ApsaraDB for MongoDB database in SSL encryption mode.

16.1.6.5. Release a public connection string

To ensure data security, you can release a public connection string that is no longer needed in the console.

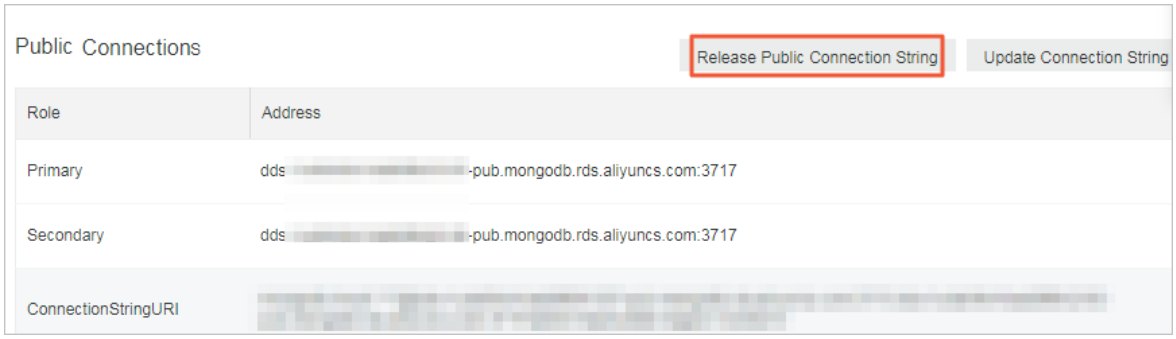
Precautions

- You can release one or more public connection strings of the mongos nodes for a sharded cluster instance.
- After the public connection string is released for an instance or node, you cannot connect to the instance or node through the original public connection string.
- After the public connection string is released, we recommend that you delete the corresponding public IP address from the whitelist to ensure data security. For more information, see Configure a whitelist.

Release a public endpoint for a replica set instance

> **Note** After the public connection string of a replica set instance is released, the public connection strings of the primary and secondary nodes are released.

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
3. On the page that appears, click **Database Connection** in the left-side navigation pane.
4. In the **Public IP Connection** section, click **Release Public Connection String**.



5. In the message that appears, click **OK**.

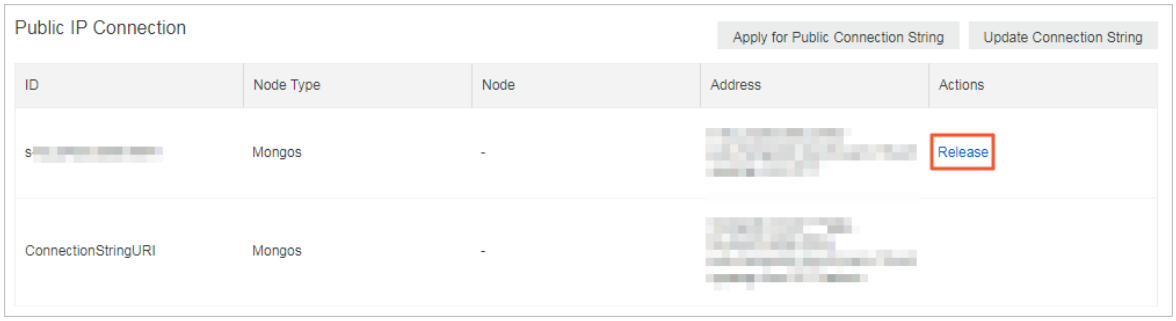
Release a public endpoint for a sharded cluster instance

You can release one or more public connection strings of the mongos, shard, and Configserver nodes for a sharded cluster instance.

> **Note** After the public connection string of a shard or Configserver node is released, the public connection strings of the primary and secondary nodes are released.

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.

2. In the left-side navigation pane, click **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, click **Database Connection**.
5. In the **Public IP Connection** section, find the mongos, shard, or Configserver node for which you want to release the public connection string.
6. In the **Actions** column corresponding to the instance, click **Release**.



> **Note** You can repeat this step to release the public connection strings of other nodes. To release the public connection string of the next node, you must wait until the public connection string of the current node is released or the status of the current node becomes **Running**.

7. In the message that appears, click **OK**.

16.1.6.6. Overview of replica set instance connections

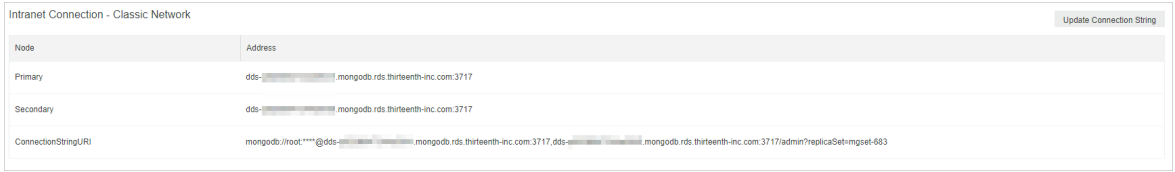
ApsaraDB for MongoDB supports both connection strings and connection string URIs. You can use a connection string to connect to either the primary or secondary node, and use a connection string URI to connect to both of them. For high availability, we recommend that you use connection string URIs to connect your application to both primary and secondary nodes. This topic provides an overview of replica set instance connections.

Prerequisites

A whitelist is configured for the instance. For more information, see Configure a whitelist for an ApsaraDB for MongoDB instance.

View connection strings

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
3. In the left-side navigation pane, click **Database Connection** to view connection strings.



Description of connection strings

Item	Description
Type	• Intranet Connection - Classic Network: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. • Intranet Connection - VPC: A VPC is an isolated network with higher security and performance than a classic network. By default, ApsaraDB for MongoDB provides endpoints on a VPC.
Role	• Primary: the primary node in the replica set instance. If you connect to this node, you can perform read and write operations on the databases of the replica set instance. • Secondary: the secondary node in the replica set instance. If you connect to this node, you can perform only read operations on the databases of the replica set instance. • Connection String URI: ApsaraDB for MongoDB allows you to use a connection string URI to connect to a replica set instance to achieve load balancing and high availability.
Connection string	The connection string of a primary or secondary node is in the following format: `<host>:<port>` • <host>: the endpoint used to connect to the instance. • <port>: the port used to connect to the instance.
Connection string URI	A connection string URI is in the following format: `mongodb://[username:password@]host1[:port1][,host2[:port2],...[,hostN[:portN]]][/[database][?options]]` • mongodb://: the prefix, indicating a connection string URI. • username:password@: the username and password used to log on to a database of the replica set instance. You must separate them with a colon (:). • hostX:portX: the endpoint and port of a node in the replica set instance. • /database: the database corresponding to the username and password if authentication is enabled. • ?options: additional connection options. **Note** If your application is in a production environment, we recommend that you use a connection string URI to connect to the instance. This way, when a node fails, the read and write operations of your application are not affected as a result of the failover.

Related information

- Connect to a replica set instance by using the mongo shell

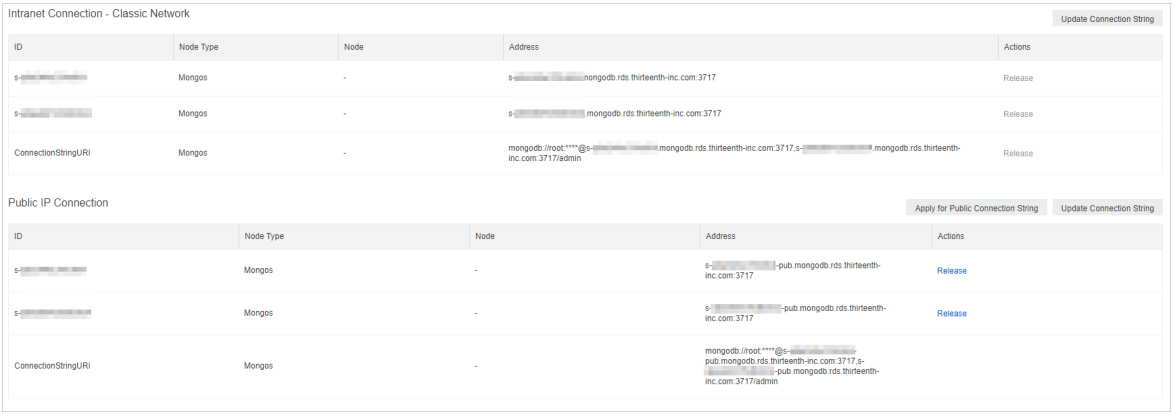
16.1.6.7. Overview of sharded cluster instance connections

ApsaraDB for MongoDB supports both connection strings and connection string URIs. You can use a connection string to connect to one mongos, and use a connection string URI to connect to more mongos. For high availability, we recommend that you use connection string URIs to connect your application to more mongos. This topic provides an overview of sharded cluster instance connections.

View connection strings

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.

3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, click **Database Connection** to view connection strings.



Description of connection strings

Item	Description
Type	• Intranet Connection - Classic Network: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. • Intranet Connection - VPC: A VPC is an isolated network with higher security and performance than a classic network. By default, ApsaraDB for MongoDB provides endpoints on a VPC. • Public IP Connection: Connecting to a sharded cluster instance over the Internet is risky. Therefore, ApsaraDB for MongoDB does not provide public endpoints. If you want to connect to an ApsaraDB for MongoDB instance from a device outside of Alibaba Cloud (such as a local device), you must apply for a public endpoint. For more information, see Apply for a public endpoint for an ApsaraDB for MongoDB instance.
Mongos ID	The connection string of a mongos is in the following format: `<host>:<port>` • <host>: the endpoint used to connect to the instance. • <port>: the port used to connect to the instance. **Note** During regular tests, you can use a connection string to directly connect to a mongos.

Item	Description
Connection string URI	A connection string URI is in the following format: `mongodb://[username:password@]host1[:port1][,host2[:port2],...[,hostN[:portN]]][/[database][?options]]` • mongodb://: the prefix, indicating a connection string URI. • username:password@: the username and password used to log on to a database of the sharded cluster instance. You must separate the username and password with a colon (:). • hostX:portX: the endpoint and port of a mongos in the sharded cluster instance. • /database: the database corresponding to the username and password if authentication is enabled. • ?options: additional connection options. **Note** If your application is in a production environment, we recommend that you use a connection string URI to connect to the instance. Then your client can automatically distribute your requests to multiple mongos to balance loads. When a mongos fails, your client automatically redirects requests to other mongos in the normal state.

Log on to a database of an ApsaraDB for MongoDB instance

1. Obtain the connection string and the following information:
   - The username used to log on to the database. The initial username is root.
   - The password of the database user. If you forget the password of the root user, you can reset it. For more information, see Set a password for a sharded cluster instance.
   - The name of the database corresponding to the username if authentication is enabled. If the database username is root, enter admin.
2. Log on to the database.
   - Use DMS to log on to a replica set instance of ApsaraDB for MongoDB
   - Connect to a replica set instance by using the mongo shell

16.1.7. Data security

16.1.7.1. Configure a whitelist for an ApsaraDB for MongoDB instance

This topic describes how to configure a whitelist for an ApsaraDB for MongoDB instance. Before you use an ApsaraDB for MongoDB instance, you must add the IP addresses or Classless Inter-Domain Routing (CIDR) blocks that you use for database access to a whitelist of this instance. This improves database security and stability. Proper configuration of whitelists can enhance access security of ApsaraDB for MongoDB. We recommend that you maintain the whitelists on a regular basis.

Context

The system creates a default whitelist for each instance. This whitelist can be modified or cleared, but it cannot be deleted. After an ApsaraDB for MongoDB instance is created, the system automatically adds the IP address 127.0.0.1 to the **default** whitelist of this instance. The IP address 0.0.0.0/0 indicates that all IP addresses are allowed to access this instance. You must add the IP addresses or CIDR blocks that you allow to access this ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, choose **Data Security > Whitelist Settings**.
5. You can manually configure a whitelist or import ECS Internal IP addresses to the whitelist.

   Manually modify a whitelist

   i. Find the whitelist you want to modify and choose **> Manually Modify** in the **Actions** column.

   ii. Enter IP addresses or CIDR blocks.

   > Note
   > - Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or CIDR blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix in the CIDR block. An IP address prefix can contain 1 to 32 bits.
   > - If the IP whitelist is empty or only contains `0.0.0.0/0`, all devices are granted access. This is risky for your ApsaraDB for MongoDB instance. We recommend that you add only the IP addresses or CIDR blocks of your own web servers to the whitelist.

   iii. Click **OK**.

   Load IP addresses of ECS instances

   i. Find the whitelist, and choose **> Import ECS Intranet IP** in the **Actions** column.

   ii. From the displayed internal IP addresses of ECS instances that belong to the current account, select the IP addresses and click > to add them to the whitelist.

   iii. Click **OK**.

16.1.7.2. Add or delete a whitelist

This topic describes how to add or delete whitelists that consist of the IP addresses allowed to access the databases.

Context

If your business involves multiple applications and you need to add a whitelist for each of them, you can sort the IP addresses into different whitelists.

Create a whitelist

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click in the **Actions** column corresponding to the instance and select **Manage**.

4. In the left-side navigation pane, choose **Data Security > Whitelist Setting**.
5. Click **Add a Whitelist Group** in the upper-left corner of the page.
6. In the panel that appears, configure **Group Name** and **IP White List** and click **OK**.

> **Note**
> - **Group Name**: The name must be 2 to 32 characters in length, and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter and end with a lowercase letter or digit.
> - **IP White List**
>   - Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or CIDR blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix in the CIDR block. An IP address prefix can contain 1 to 32 bits.
>   - If the whitelist is empty or only contains 0.0.0.0/0, all devices are granted access. This is risky for your ApsaraDB for MongoDB instance. We recommend that you add only the IP addresses or CIDR blocks of your own web servers to the whitelist.

Delete a whitelist

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, choose **Data Security > Whitelist Setting**.
5. Find the whitelist, and choose ⋮ > **Delete Whitelist Group** in the **Actions** column.

> **Note** You cannot delete the **default** whitelist.

6. In the Delete Whitelist Group message, click **OK**.

16.1.7.3. Audit logs

This topic describes audit logs provided in the ApsaraDB for MongoDB console. You can query the statement execution logs, operations logs, and error logs of an ApsaraDB for MongoDB instance to locate and analyze faults.

Context

The audit log feature records all operations that a client performs on a connected database. This feature provides references for you to perform fault analysis, behavior analysis, and security auditing because you can obtain the operation execution details from the audit logs. Audit logs are essential in the regulatory operations of Finance Cloud and other core business scenarios.

> **Note** Audit logs are stored for seven days, after which they are deleted.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see

Log on to the ApsaraDB for MongoDB console.

2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, choose **Data Security > Audit Logs**.
5. Click **Enable Audit Log** in the upper-left corner. In the Enable Audit message, click **OK**.

Result

On the **Audit Log** page, specify the time range, database name, database user, and keyword to query audit logs. You can also perform the following operations:

- **Export File**: exports an audit log file.
- **File List**: displays a list of audit logs.
- **Disable Audit Log**: stops the collection of information on database operations and deletes the saved audit logs.

16.1.7.4. Configure SSL encryption for an ApsaraDB for MongoDB instance

This topic describes how to enhance link security by enabling Secure Sockets Layer (SSL) encryption and installing SSL CA certificates on your application services. The SSL encryption feature encrypts network connections at the transport layer to improve data security and ensure data integrity during communication.

Prerequisites

- The instance is a replica set instance.
- The MongoDB version of the instance is 3.4, 4.0, or 4.2.

Notes

When you enable or disable SSL encryption or update SSL CA certificates for an instance, the instance is restarted. Plan your operations in advance and make sure that your application is configured to reconnect to the instance after it is disconnected.

> **Note** When an instance is restarted, all its nodes are restarted in turn and each node has a transient connection error of about 30 seconds. If the instance contains more than 10,000 collections, the transient connection error last longer.

Precautions

- You can download SSL CA certificate files only from the ApsaraDB for MongoDB console.
- After you enable SSL encryption for an instance, the CPU utilization of the instance is significantly increased. We recommend that you enable SSL encryption only when necessary. For example, you can enable SSL encryption when you connect to an ApsaraDB for MongoDB instance over the Internet.

  > **Note** Internal network connections are more secure than Internet connections and do not need SSL encryption.

- After you enable SSL encryption for an instance, both SSL and non-SSL connections are supported.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, choose **Data Security > SSL**.
5. Perform one of the following operations.

> **Note** When you enable or disable SSL encryption or update SSL CA certificates for an instance, the instance is restarted. Plan your operations in advance and make sure that your applications can automatically re-establish a connection.

Operation	Prerequisite	Procedure
Enable SSL encryption	The SSL encryption status is **Disabled**.	Turn on **SSL Status**. In the message that appears, click **OK**.
Update an SSL CA certificate	The SSL encryption status is **Enabled**.	Click **Update Certificate**. In the message that appears, click **OK**.
Download an SSL CA certificate file	The SSL encryption status is **Enabled**.	Click **Download Certificate** to download an SSL CA certificate file to your computer.
Disable SSL encryption	The SSL encryption status is **Enabled**.	Turn off **SSL Status**. In the message that appears, click **OK**.

16.1.7.5. Configure TDE for an ApsaraDB for MongoDB instance

This topic describes how to configure Transparent Data Encryption (TDE) for an ApsaraDB for MongoDB instance. Before data files are written to disks, TDE encrypts the data files. When data files are loaded from disks to the memory, TDE decrypts the data files. TDE does not increase the sizes of data files. When you use TDE, you do not need to modify your application that uses the ApsaraDB for MongoDB instance. To enhance data security, you can enable the TDE feature for an instance in the ApsaraDB for MongoDB console.

Prerequisites

The MongoDB version of the instance is 4.0 or 4.2.

> **Note** Before you enable TDE, you can create a MongoDB 4.0 or 4.2 instance to test the compatibility between your application and the database version. You can release the instance after the test is complete.

Notes

- When you enable TDE, your instance is restarted, and your application is disconnected from the instance. We recommend that you enable TDE during off-peak hours and make sure that your application can reconnect to the instance after it is disconnected.
- TDE increases the CPU utilization of your instance.

Precautions

- You cannot disable TDE after it is enabled.

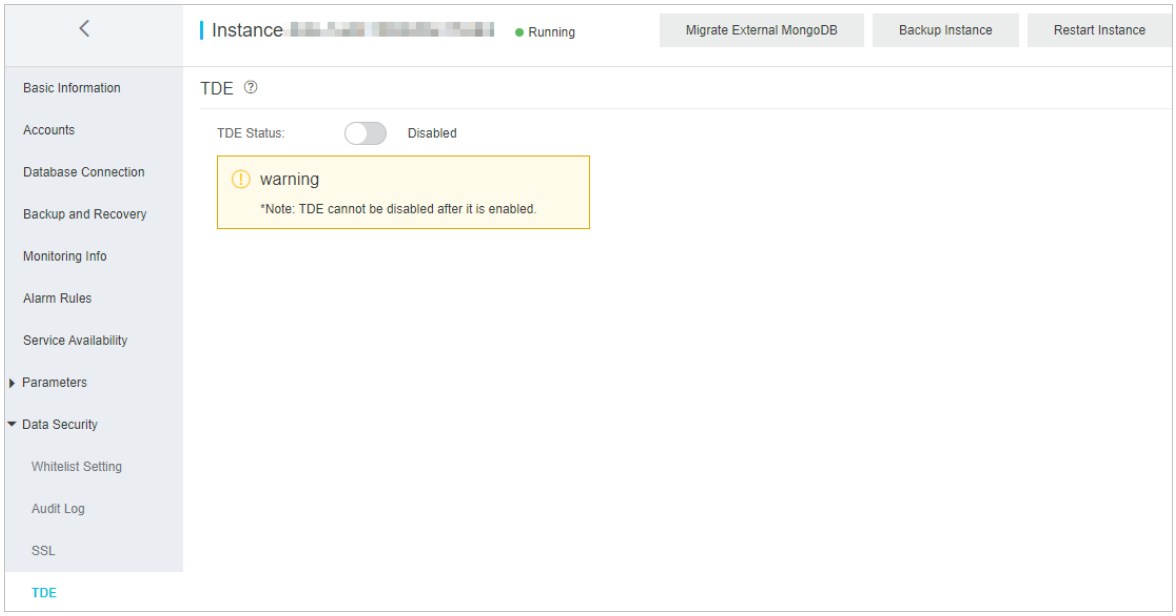
- You can enable TDE for an instance and disable encryption for a collection.

  > **Note** In special business scenarios, you can choose not to encrypt a collection when you create it. For more information, see Disable encryption for a specified collection.

- After you enable TDE, only new collections are encrypted. Existing collections are not encrypted.
- Key Management Service (KMS) generates and manages the keys used by TDE. ApsaraDB for MongoDB does not provide keys or certificates required for encryption.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, choose **Data Security > TDE**.
5. Turn on **TDE Status** to enable TDE.



6. In the **Restart Instance** dialog box, click **OK**.
   The instance status changes to **Modifying TDE**. After the status changes to **Running**, TDE is enabled.

Disable encryption for a specified collection

After you enable TDE, all new collections are encrypted. When you create a collection, you can perform the following steps to disable encryption for the collection:

1. Connect to a replica set instance by using the mongo shell. For more information, see Connect to a replica set instance by using the mongo shell.
2. Run the following command to create a collection and disable the encryption feature:

```
db.createCollection("<collection_name>",{ storageEngine: { wiredTiger: { configString: "encryption=(name=none)" } } })
```

> **Note** <collection_name>: the name of the collection.

Example:

```
db.createCollection("customer",{ storageEngine: { wiredTiger: { configString: "encryption=(name=none)" } } })
```

16.1.7.6. Use the mongo shell to connect to an ApsaraDB for MongoDB database in SSL encryption mode

This topic describes how to use the mongo shell to connect to an ApsaraDB for MongoDB database in Secure Sockets Layer (SSL) encryption mode. SSL encryption can encrypt network connections at the transport layer to improve data security and ensure data integrity.

Prerequisites

- The instance is a replica set instance, and the database version of the instance is 3.4, 4.0, or 4.2.
- The mongo shell of the required version is installed on the local server or ECS instance from which you want to connect to the database. For more information about the installation procedure, visit MongoDB official documentation.
- SSL encryption is enabled for the instance. For more information, see Configure SSL encryption.
- The IP address of the local server or the ECS instance is added to a whitelist of the ApsaraDB for MongoDB instance. For more information, see Configure a whitelist for an ApsaraDB for MongoDB instance.

Precautions

After you enable SSL encryption for an instance, the CPU utilization of the instance is significantly increased. We recommend that you enable SSL encryption only when necessary.

Procedure

A local server with a Linux operating system is used in the following example.

1. Download an SSL CA certificate package. For more information, see Configure SSL encryption.
2. Decompress the package and upload the certificate files to the local server or the ECS instance where the mongo shell is installed.

   > **Note** In this example, the *.pem* file is uploaded to the */root/sslcafile/* directory of the local server.

3. On the local server or the ECS instance, run the following command to connect to a database of the ApsaraDB for MongoDB instance:

   ```
   mongo --host <host> -u <username> -p --authenticationDatabase <database> --ssl --sslCAFile <sslCAFile_path> --sslAllowInvalidHostnames
   ```

> **Note**
>
> - <host>: the connection string of the primary or secondary node for a replica set instance or of mongos node for a sharded cluster instance. For more information, see Overview of replica set instance connections or Overview of sharded cluster instance connections. If you want to connect to a database of the ApsaraDB for MongoDB instance over an internal network, make sure that the ApsaraDB for MongoDB instance has the same network type as the ECS instance. If the network type is VPC, make sure that the two instances are in the same VPC.
> - <username>: the username you use to log on to a database of the ApsaraDB for MongoDB instance. The default username is root.
> - <database>: the name of database corresponding to the username if authentication is enabled. If the database username is root, enter admin.
> - <sslCAFile_path>: the path of the SSL CA certificate files.

Example:

```
mongo --host dds-bpxxxxxxxx-pub.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase
admin --ssl --sslCAFile /root/sslcafile/ApsaraDB-CA-Chain.pem  --sslAllowInvalidHostnames
```

4. When `Enter password:` is displayed, enter the password of the database user and press Enter.

> **Note**
>
> - The password characters are not displayed when you enter the password.
> - If you forget the password of the root user, you can reset it. For more information, see Reset the password for an ApsaraDB for MongoDB instance.

16.1.8. CloudDBA

16.1.8.1. Authorize DAS to manage ApsaraDB for MongoDB instances

Database Autonomy Service (DAS) supports fast scaling, switchover, and centralized management of multiple environments. DAS is integrated into ApsaraDB for MongoDB to facilitate operations and maintenance (O&M). This topic describes how to authorize DAS to manage your ApsaraDB for MongoDB instances when you use the real-time performance, session, and capacity analysis features of CloudDBA for the first time.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, choose **CloudDBA > Realtime performance**.
5. Specify **Database Account** and **Password**, and click **Authorize**.

Result

The page is refreshed. Then, you can use the real-time performance, session, and capacity analysis features. You

will not be prompted for authorization again.

16.1.8.2. Performance trends

This topic describes how to view performance trends in specific ranges, compare performance trends, and customize charts to view performance trends on your ApsaraDB for MongoDB instances.

Go to the Performance page

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, choose **CloudDBA > Performance Trends**.

> **Note** For more information about performance trends, see relevant topics in Database Autonomy Service (DAS) User Guide.

16.1.8.3. Real-time performance

This topic describes how to view real-time monitoring statistics of your ApsaraDB for MongoDB instances, such as read/write latency, queries per second (QPS), operations, connections, and network traffic.

Prerequisites

Database Autonomy Service (DAS) is authorized to manage ApsaraDB for MongoDB instances. For more information, see Authorize DAS to manage ApsaraDB for MongoDB instances.

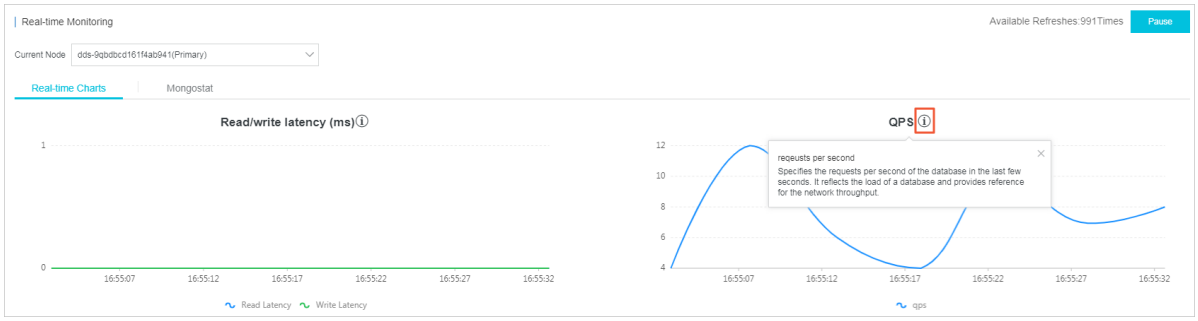
Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, choose **CloudDBA > Realtime performance**.

Real-time Monitoring

On the Real-time Monitoring page, you can select the Real-time Charts or Mongostat tab to view monitoring statistics. When you refresh or go to the **Real-time Monitoring** page, the information on the Real-time Charts and Mongostat tabs is refreshed, and the number of available refreshes is reset in the upper-right corner.

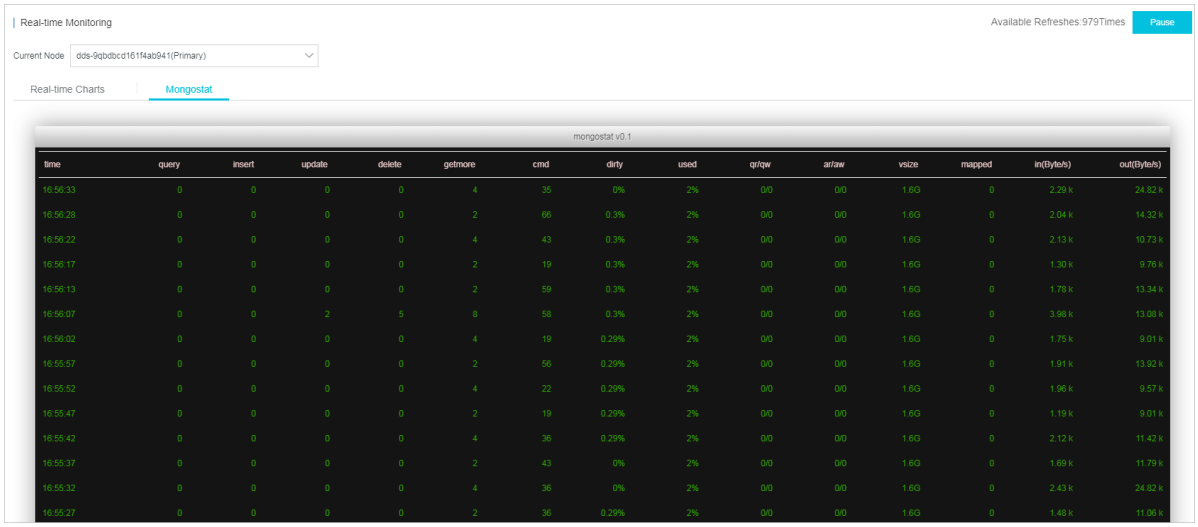
- Real-time Charts



The **Real-time Charts** tab is displayed on the Real-time Monitoring page. Line charts on the tab are refreshed every five seconds.

> **Note** For more information about individual metrics, click the icon above each chart.

- mongostat



Click the **Mongostat** tab. On the tab, you can view Mongostat command outputs. A new line of monitoring data is added every five seconds. The tab can contain up to 999 lines of information.

> **Note** For more information about Mongostat command outputs, visit MongoDB official documentation.

16.1.8.4. Instance sessions

This topic describes how to view real-time monitoring statistics of your ApsaraDB for MongoDB instances, such as read/write latency, queries per second (QPS), operations, connections, and network traffic.

Prerequisites

Database Autonomy Service (DAS) is authorized to manage your ApsaraDB for MongoDB instances. For more information, see Authorize DAS to manage ApsaraDB for MongoDB instances.

View instance sessions

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.

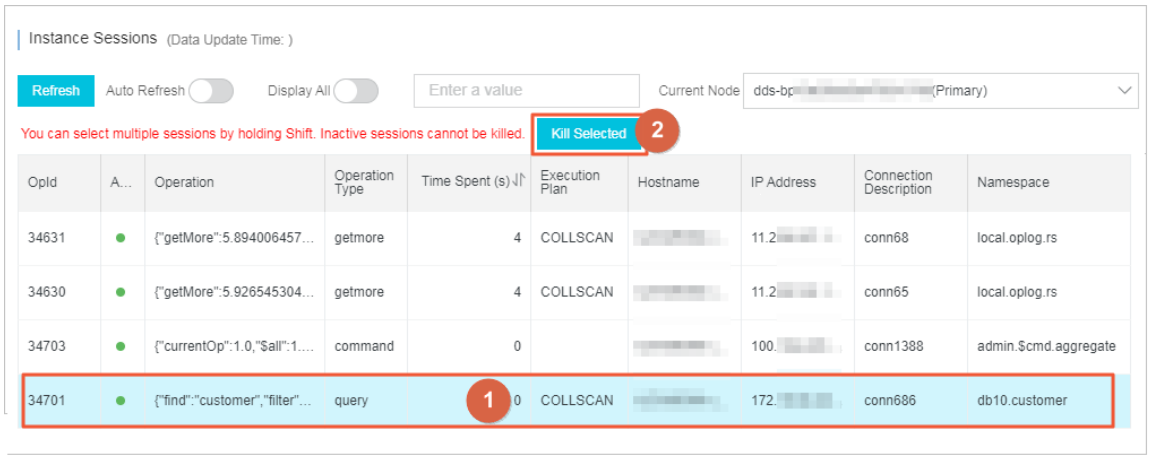
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, choose **CloudDBA > Session**.

> **Note**
> - If you turn on **Auto Refresh**, the system updates session data on the page every 30 seconds.
> - By default, the system displays only active sessions. You can turn on **Display All** to view both active and inactive sessions.
> - In the **Session Statistics** section, you can view information about sessions in the **Overview**, **Statistics by Client**, and **Statistics by Namespace** charts.

Terminate instance sessions

> **Warning** To avoid unexpected results, we recommend that you do not terminate system-level sessions.

1. In the **Instance Sessions** section, select the sessions you want to terminate and click **Kill Selected**.



2. In the message that appears, click **OK**.

16.1.8.5. Capacity analysis

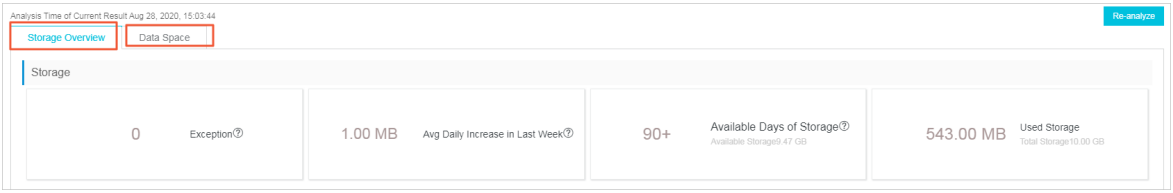
This topic describes how to view information about the capacity analysis feature, including **storage**, **exceptions**, **storage trend**, **tablespaces**, and **data space**. The information helps you detect and resolve exceptions in the database storage to ensure database stability.

Prerequisites

Database Autonomy Service (DAS) is authorized to manage ApsaraDB for MongoDB instances. For more information, see Authorize DAS to manage ApsaraDB for MongoDB instances.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, choose **CloudDBA > Capacity analysis**.
5. In the upper-right corner, click **Re-analyze**. Then, wait until the analysis is complete.
6. On the **Storage Overview** or **Data Space** tab, view the analysis results.



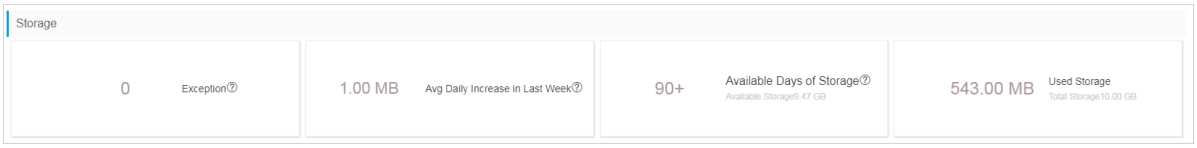
For more information about Storage Overview, see Storage Overview.

For more information about Data Space, see Data Space.

Storage Overview

On the Storage Overview tab, you can view information in the **Storage**, **Exceptions**, **Storage Trend**, and **Tablespaces** sections.

- **Storage Overview**

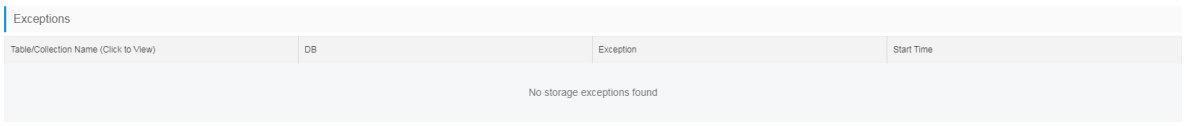


Item	Description
Exceptions	The number of detected storage exceptions. ApsaraDB for MongoDB can detect the following types of exceptions: ○ Over 90% of the storage capacity is used. ○ The total physical storage will be unavailable in seven days. ○ The number of indexes in a collection exceeds 10.
Avg Daily Increase in Last Week	The average daily increase of storage usage over the last seven days. Formula: (Storage usage at the time of collection - Storage usage seven days ago)/7. **Note** ○ The increase speed is the average value during the seven days before the collection time. ○ This parameter is only used as a reference for scenarios in which the traffic remains stable. Abrupt storage changes caused by batch imports, deletion of historical data, instance migration, or instance re-creation affect the accuracy of the data.

Item	Description
Available Days of Storage	The estimated number of days during which storage space is available. Formula: Size of available storage space/Average daily increase over the last week. **Note** ○ 90+ indicates that the disk storage is sufficient for more than 90 days of usage. ○ This parameter is used only as a reference for scenarios in which the traffic remains stable. Abrupt storage changes caused by batch imports, deletion of historical data, instance migration, or instance re-creation affect the accuracy of the data.
Used Storage	The size of used storage space in contrast to the total size of storage space.

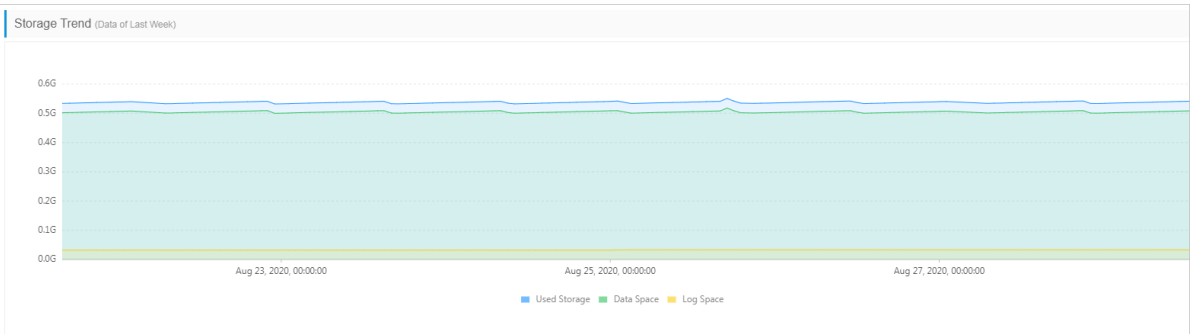
- **Exceptions**

  Information about detected storage exceptions. You can resolve the exceptions based on information in this section.



- **Storage Trend**

  Changes of storage usage over the last week, such as changes of **used storage**, **data space**, and **log space**.



- **Tablespaces**

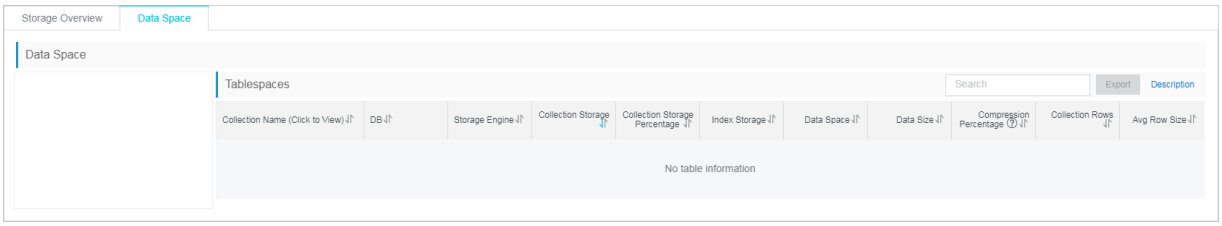
  Information of all tables, such as the database name, storage engine, and collection storage.

Note You can click a collection name to view its indexes.

Data Space

The Data Space tab shows the total storage capacity and tablespace information of each database.

> **Note**
> - You can click a data space to view its tablespace information.
> - You can click a collection name to view its indexes.



16.1.8.6. Slow query logs

This topic describes how to view slow query logs of ApsaraDB for MongoDB instances. You can locate, analyze, diagnose, and track slow query logs to create indexes, which improves the utilization of resources in the instances.

Procedure

1. Log on to the ApsaraDB for MongoDB console. For more information about how to log on to the console, see Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. On the **Replica Set Instances** or **Sharded Cluster Instances** page, click the ID of an instance, or click ⋮ in the **Actions** column corresponding to the instance and select **Manage**.
4. In the left-side navigation pane, choose **CloudDBA > Slow query log**.

   > **Note** By default, slow query logs generated in the past 15 minutes are displayed in the trend chart. You can specify the time range and click **Search** to view slow query logs in specific periods of time. The maximum time range is one day.

5. View details of slow query logs by using one of the following methods:

   Method 1:

   i. Click the **Slow Log Details** tab in the lower part of the page.

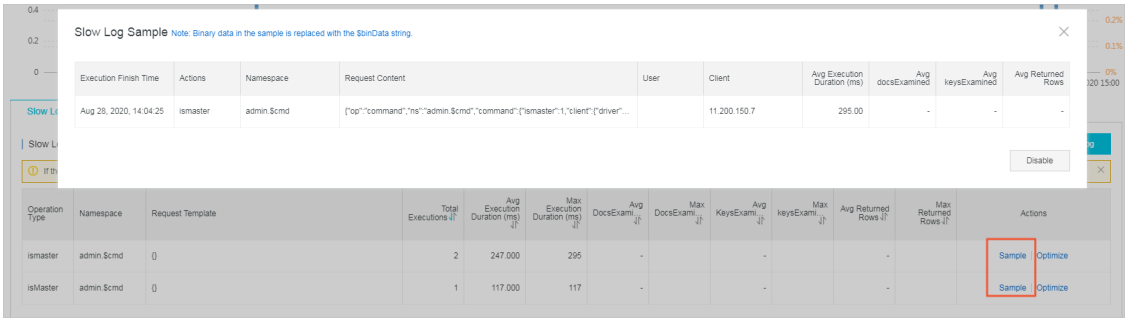
   ii. On the **Slow Log Details** tab, select the database that you want to query.

   > **Note** If the request content of the target database is hidden, you can move the pointer over the corresponding **request content** and view the complete content.

   Method 2:

   i. In the slow log trend chart, click the time of a specific slow query log and view its details on the **Slow Log Statistical** tab.

ii. On the **Slow Log Statistical** tab, click **Sample** in the **Actions** column.
In the **Slow Log Sample** dialog box, you can view details of the slow query log.



Note If the request content of the target database is hidden, you can move the pointer over the corresponding **request content** and view the complete content.

Export slow query logs

You can click **Export Slow Log** on the **Slow Log Statistical** tab to save the slow query log information to your computer.

17.ApsaraDB for OceanBase

17.1. 文档标题缺失，请补全后重新导出

17.1.1. What is ApsaraDB for OceanBase?

ApsaraDB for OceanBase is a financial-grade, distributed relational database service that features high performance, high availability, and high scalability. It supports active geo-redundancy and geo-disaster recovery to ensure high availability. It also supports high scalability to meet the increasing business requirements.

These features of ApsaraDB for OceanBase help you handle the challenges that are brought by rapid business growth. ApsaraDB for OceanBase also provides scalable and low latency database services in high throughput scenarios. This ensures improved user experience. For example, during the Double 11 in 2017, ApsaraDB for OceanBase handled all the transactions and payment requests. The maximum number of transactions that were made on Alipay reached 256,000 per second. The maximum number of processed requests per second reached 42 million. ApsaraDB for OceanBase accelerates the development of Internet finance.

The distributed engine of ApsaraDB for OceanBase uses the Paxos protocol and maintains multiple replicas. For the Paxos protocol, transactions can be committed only after they are approved by a majority of the acceptors. The Paxos protocol and multiple-replica design allow ApsaraDB for OceanBase to offer high availability and disaster recovery capabilities. ApsaraDB for OceanBase can help you achieve zero downtime. ApsaraDB for OceanBase supports high-availability architectures, such as active geo-redundancy and geo-disaster recovery. You can deploy the ApsaraDB for OceanBase service across data centers, regions, or continents. ApsaraDB for OceanBase provides financial-grade availability features and ensures strong consistency of transactions.

ApsaraDB for OceanBase is similar to an in-memory database and adopts a read/write splitting architecture. To ensure high efficiency for the storage engine, ApsaraDB for OceanBase stores baseline data in solid-state drives (SSDs) and stores incremental data in memory. This ensures that ApsaraDB for OceanBase offers high performance services. ApsaraDB for OceanBase is a cloud-based database service that supports multi-tenant data isolation. Each cluster of ApsaraDB for OceanBase can provide services for multiple tenants. The tenants are isolated so that they are not affected by each other.

ApsaraDB for OceanBase is compatible with most of the MySQL 5.6 features. This allows you to migrate MySQL-based services to ApsaraDB for OceanBase based on zero or small code modifications. This improves the efficiency of developing applications and migrating services. In ApsaraDB for OceanBase, you can create partitioned tables and use subpartitions. This serves as an alternative to MySQL sharding solutions. The ApsaraDB for OceanBase console provides an easy way for you to manage complex databases. For example, you can use the console to upgrade or downgrade instances, view performance data, and view optimization suggestions.

17.1.2. Quick start

17.1.2.1. Log on to the ApsaraDB for OceanBase O&M console

This topic describes how to use the Apsara Uni-manager Operations Console to log on to the ApsaraDB for OceanBase O&M console. The Google Chrome browser is used in an example in this topic.

Prerequisites

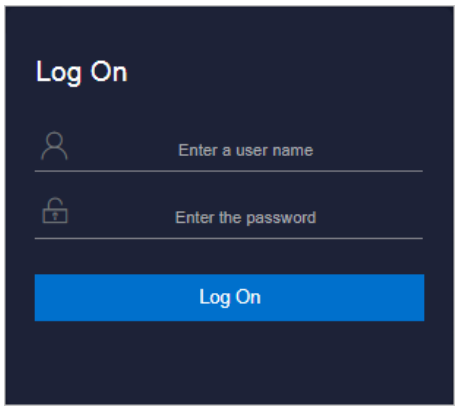
- The endpoint of the Apsara Uni-manager Operations Console and the username and password used to log on to the console are obtained from the deployment personnel or an administrator.

  The endpoint of the Apsara Uni-manager Operations Console is in the following format: *region-id*.ops.console.*intranet-domain-id*.

- A browser is available. We recommend that you use Google Chrome.

Procedure

1. In the address bar, enter the URL *region-id*.aso.*intranet-domain-id*.com and press the Enter key.



> **Note** You can select a language from the drop-down list in the upper-right corner of the page.

2. Enter your username and password.

> **Note** Obtain the username and password for logging on to the ASO console from the deployment personnel or an administrator.

When you log on to the ASO console for the first time, you must change the password of your username as prompted.

To enhance security, a password must meet the following requirements:

- It must contain uppercase and lowercase letters.
- It must contain digits.
- It must contain special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).
- It must be 10 to 20 characters in length.

3. Click **Log On** to go to the **ASO** console.
4. In the left-side navigation pane, click **Product Management**. Then, choose **Products > Database Services** and click **OceanBase Cloud Platform**. You are directed to the ApsaraDB for OceanBase O&M console.

17.1.2.2. Log on to the ApsaraDB for OceanBase console

This topic describes how to use the Apsara Uni-manager Management Console to log on to the ApsaraDB for OceanBase console. The Google Chrome browser is used in an example in this topic.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Context

If you use the Apsara Uni-manager Management Console to log on to the ApsaraDB for OceanBase console, you are granted with only the permissions to view monitoring data and manage instances. If you need to perform operations and maintenance (O&M) tasks on clusters, follow the instructions described in Log on to the Apsara Stack Operations console for ApsaraDB for OceanBase and perform O&M tasks based on your business needs.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 10 to 32 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

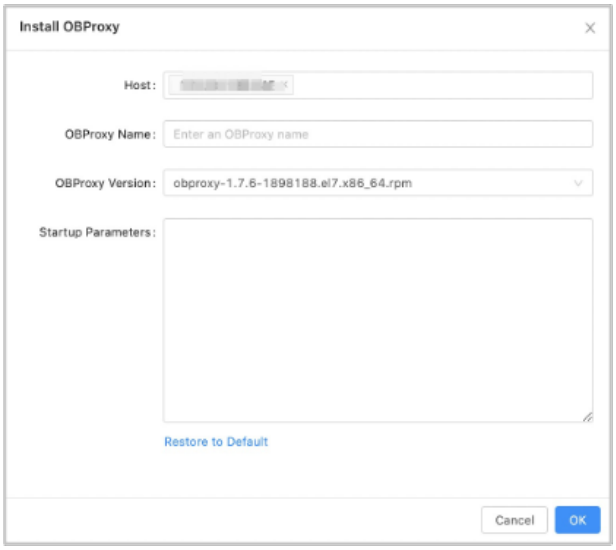
3. Click **Log On**.
4. In the top navigation bar, click **Products** and choose **Database Services > ApsaraDB for OceanBase**.
5. Select an organization from the **Organization** drop-down list and select a region from the **Region** drop-down list. Then, click **OceanBase Cloud Platform**. You are directed to the ApsaraDB for OceanBase console.

17.1.2.3. Install OBProxy

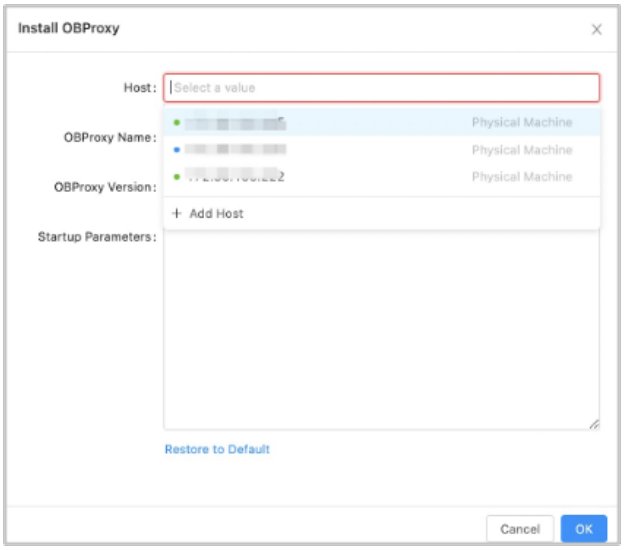
In the upper-right corner of the page, click Return to Old Version to go to the OBProxy page and install OBProxy.

Procedure

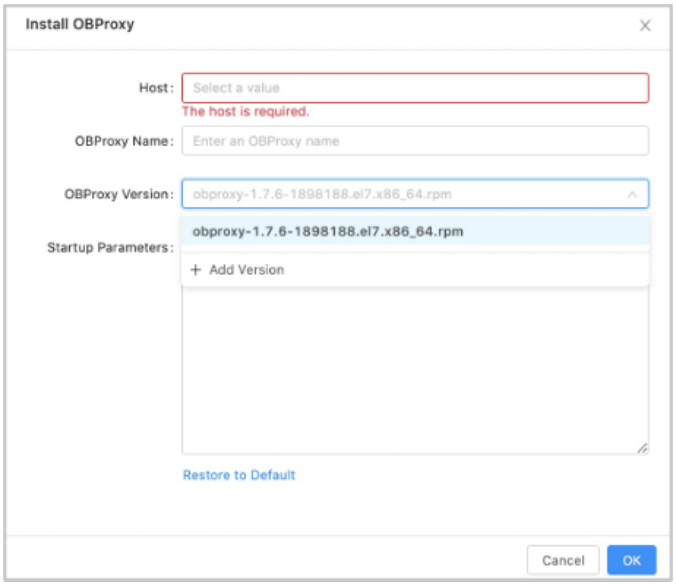
1. In the navigation pane, choose **Maintenance** to go to the **OBProxy** page.
2. Click **Install OBProxy**.
3. In the dialog box that appears, specify the following parameters:



- **Host**: Select a host from the drop-down list, or click **Add Host** to add a new host.



- OBProxy Version: Select an OBProxy version from the drop-down list, or click **Add Version** and click **Upload** in the dialog box that appears, to upload the corresponding OBProxy file.



4. Click **OK**. This will generate an OBProxy operations task. You can choose **System Management > Tasks** to check the installation progress.

17.1.2.4. Create a cluster

This topic describes how to create a cluster as needed.

Prerequisites

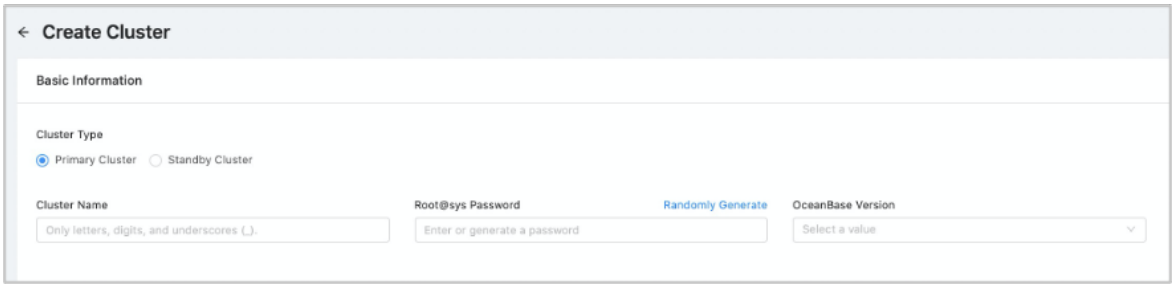
The permissions to create a cluster are granted to the current user.

Procedure

1. After you log on to OCP, find the entry to create a cluster based on your actual business scenario.
   - If you do not have a cluster to manage, the system prompts you to create a cluster on the **Cluster Overview** page. In the dialog box that appears, click **Create Cluster**.

- If you have a cluster to manage, click **Create Cluster** in the upper-right corner of the **Cluster Overview** page.

2. On the **Create Cluster** page, configure the basic cluster information.



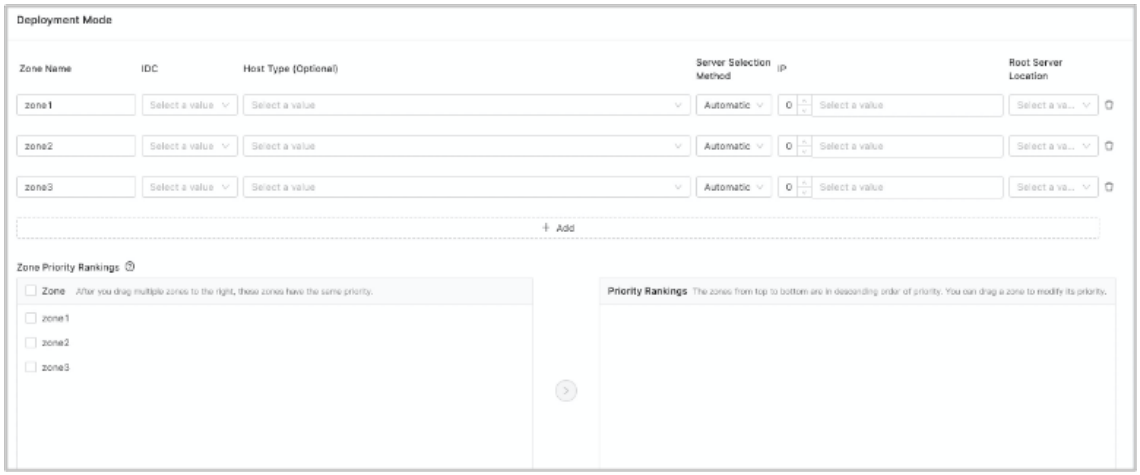
The following table describes the parameters related to the basic cluster information.

Parameter	Description
Cluster Type	You can select **Primary Cluster** or **Standby Cluster**. Before you select **Standby Cluster**, make sure that a primary cluster is created.
Cluster Name	The name of the cluster that you want to manage. The cluster name must be 2 to 48 characters in length, and can contain letters, digits, and underscores (_). It must start with a letter.
Root@sys Password	You can set a custom password or use a password that is generated by the system in a random way. The password must meet the following complexity requirements: • The password must be 8 to 32 characters in length. • The password must contain at least two digits, two uppercase letters, two lowercase letters, and two special characters. The following special characters are supported: . _+@#$%)
OceanBase Version	You can select an existing version from the drop-down list, or click **Add Version** at the bottom of the drop-down list to upload a version.

3. Configure the deployment mode for the cluster.

By default, you can add three zones. To add four or more zones in the cluster, click **Add** at the lower part of the field.

To deploy the cluster to one or two zones, click the Delete icon next to the zone that you want to delete.



The following table describes the parameters for a zone.

Parameter	Description
Zone Name	In most cases, a default name is generated. You can customize the name as needed. The zone name must be 2 to xx characters in length, and can contain letters, digits, and underscores (_). It must start with a letter.
IDC	The data center to which the zone belongs. Ensure that the zones you specify for the cluster belong to the same data center.
Host Type	This parameter is optional. If you select a host type, the hosts are filtered based on the host type.
Server Selection Method	You can select **Automatic** or **Manual**.
IP	You can select multiple IP addresses. If you select **Automatic** from the **Server Selection Method** drop-down list, you only need to specify the number of IP addresses. OCP selects the specific number of available servers in an automatic way. If you select **Manual** from the **Server Selection Method** drop-down list, you must manually select multiple IP addresses from the drop-down list.
Root Server Location	You can select an IP address for the root server.

Parameter	Description
Priority Rankings	The priority rankings of the zones. This parameter specifies the priority of each zone to be selected as the primary zone on the system tenant. The list on the left displays all the zones in the current cluster. You can select one or more zones from the left-side list and add them to the right-side list. By default, a zone that you select first has a higher priority than a zone that you select later. If you select multiple zones at a time, they have the same priority. After you move zones to the right-side list, you can drag a zone to change its priority in the right-side list. The zones from top to bottom are in descending order of priority.

4. After you configure the preceding parameters, click **Submit**.
5. In the **Confirm Information** dialog box, confirm the information and click **OK**.

17.1.2.5. Create a tenant

A tenant is a container for various database objects and resources such as CPU, memory, and I/O. You can create tenants in a cluster based on your business requirements.

You can use one of the following two methods to create a tenant:

- Create a tenant on the Tenant Overview page.
- Create a tenant on the Tenant Management page of a specified cluster.

This topic describes how to create a tenant on the Tenant Management page of a specified cluster.

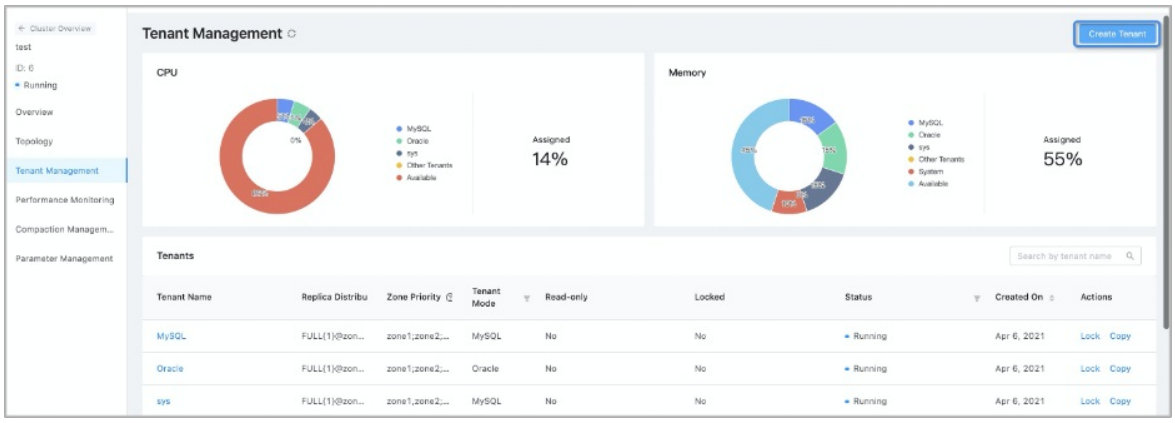
Prerequisites

- The cluster where you create a tenant must be a primary cluster and must be in running state.
- The current user you log on to is the system administrator, OCP tenant administrator role, or other roles that have permissions to manage the cluster.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster where you want to create a tenant.
3. In the left-side navigation pane of the page that appears, click **Tenant Management**.

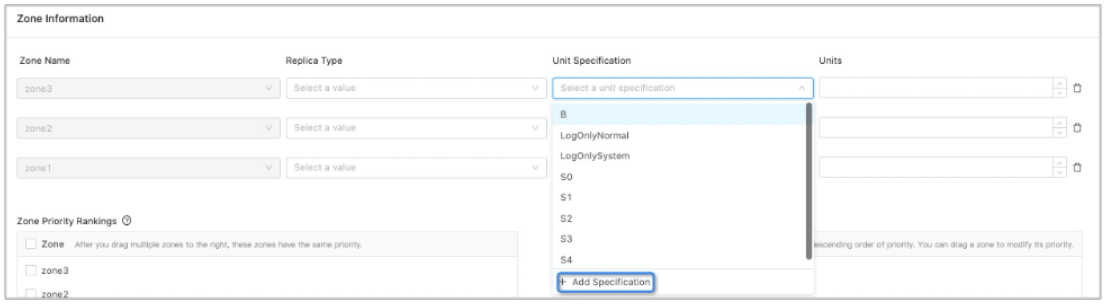
4. In the upper-right corner, click **Create Tenant**.



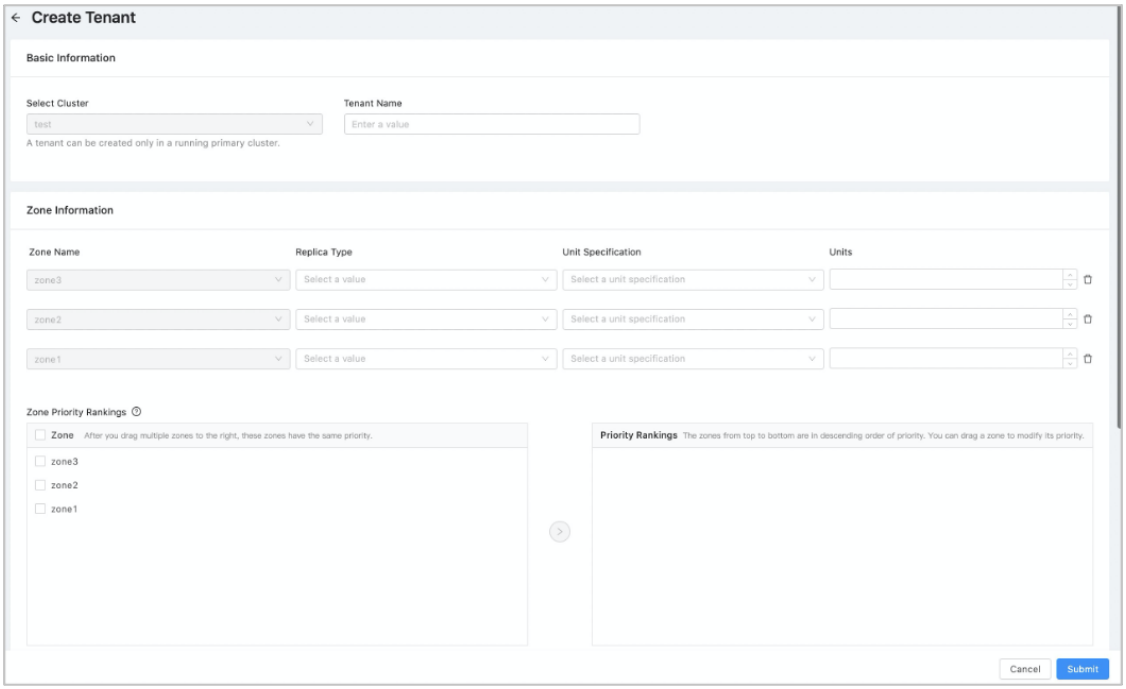
5. Configure **Basic Information**.
   i. The default cluster is the current cluster.
   ii. Enter a **Tenant Name**. The tenant name must be 2 to 64 characters in length and can contain letters, digits, and underscores (_).
6. Configure **Zone Information**.
   i. Specify the Replica Type, Unit Specification, and Units for zone 1, zone 2, and zone 3.

      After you select a cluster, the page shows a list of zones that can be configured based on the zone information of the selected cluster. For zones that do not store data replicas, you can delete the zone by clicking the delete icon on the rightmost side.

      - You can select Full-featured Replica, Read-only Replica, and Log Replica from the Replica Type drop-down list.
      - OCP provides a set of built-in Unit specifications. You can also click Add Specification at the bottom of the Unit Specification drop-down list to add custom specifications.
      - Specify the number of units in the zone. Note that the number of units cannot exceed the number of servers in the zone.



ii. Configure the **Zone Priority Rankings**. If you drag multiple zones to the right, these zones have the same priority.



7. Configure the **Basic Settings**.

i. Settings

- If the tenant mode is MySQL, its administrator account is "root".
- If the tenant mode is Oracle, its administrator account is "SYS". The password must be 8 to 32 characters in length and contain at least two digits, two uppercase letters, two lowercase letters, and two special characters. Special characters include: _+@#$%.

ii. Select a **Tenant Mode**.

- You can select Oracle or MySQL.
- The Oracle tenant mode is supported only when the OceanBase version of the selected cluster is 2.1 or later.

iii. Configure the **Character Set and Encoding**.

- If you select the MySQL tenant mode, the following character sets are available: utf8mb4, binary, gbk, and gb18030. Default value: utf8mb4.
- If you select the Oracle tenant mode, the following character sets are available: utf8mb4, gbk, and gb18030. Default value: utf8mb4.

iv. Optional. Configure **Remarks**.

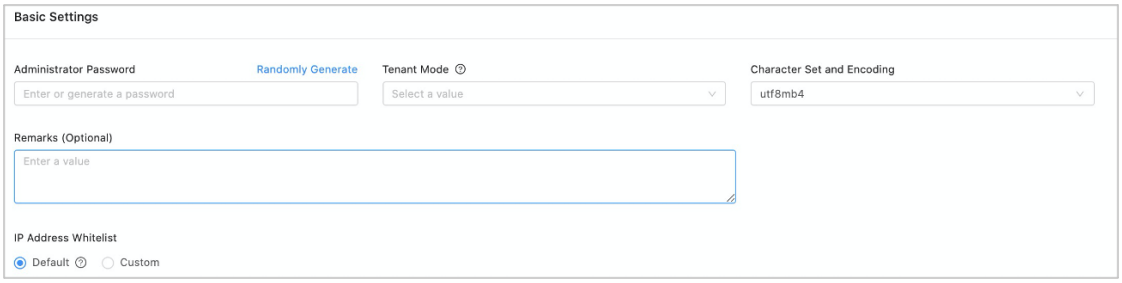
v. Configure the **IP Address Whitelist**.

- You can specify the clients that the tenant can log on to. If you do not specify, the default configuration is "%". It indicates that the tenant can log to all clients. When you customize the whitelist, note that the whitelist must include the IP addresses of the OCP server and the OBProxy on which the OCP server depends. Otherwise, OCP cannot manage this tenant.
- Default: Accesses from all IP addresses is supported.
- Custom: Configure an IP address whitelist. Only accesses from the IP addresses in the whitelist are supported.

- Description of whitelist format:

- IP addresses. For example, 10.10.10.10,10.10.10.11.
- Subnet mask. For example, 10.10.10.0/24.
- Fuzzy match. For example, 10.10.10. % or 10.10.10. _
- A mix of multiple formats. For example, 10.10.10.10,10.10.10.11,10.10.10. %,10.10.10. _,10.10.10.0/24

> **Note**
> The percent sign (%) indicates that all clients can connect to the tenant.



8. Click **Submit**.

17.1.3. OceanBase Cloud Platform

17.1.3.1. Clusters management

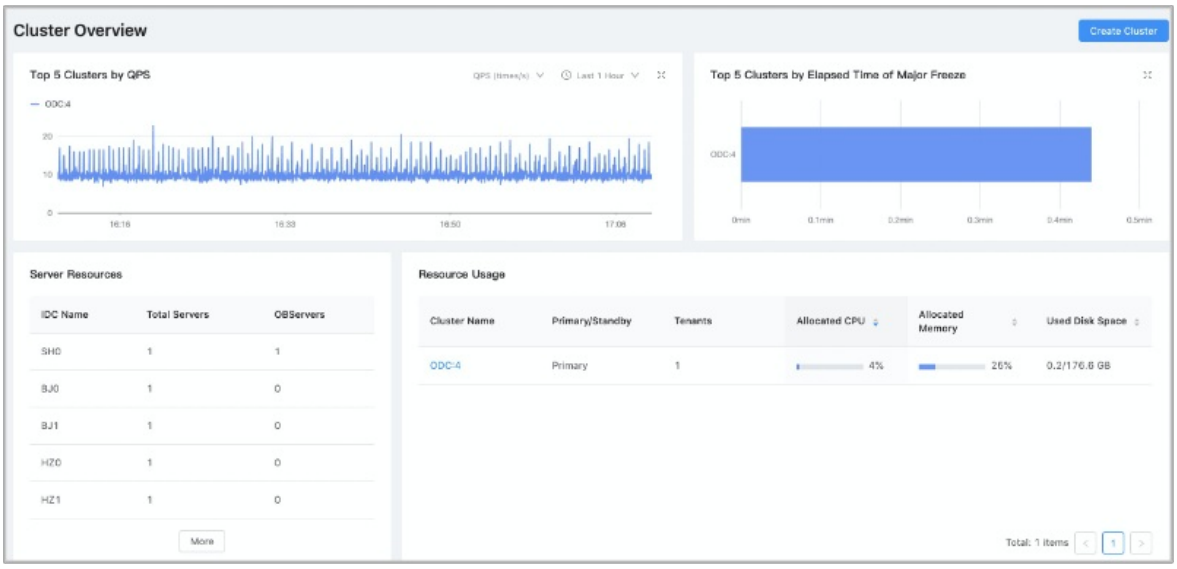
17.1.3.1.1. Overview

OCP provides full lifecycle management for ApsaraDB for OceanBase clusters. For example, you can create, monitor, configure, upgrade, or delete clusters on OCP. You can also perform O&M operations on clusters.

17.1.3.1.2. Cluster overview

This topic describes the information you can view on the Cluster Overview page.

After you log on to OCP, the **Cluster Overview** page appears. To view the overview data of a cluster, the current logon user must have the permissions to manage the cluster or the read-only permissions on the cluster.



The **Cluster Overview** page displays the information of the cluster for the current logon user. The information includes **Top 5 Clusters by QPS**, **Top 5 Clusters by Elapsed Time of Major Freeze**, **ServerResources**, **Resource Usage**, and **Clusters**.

Top 5 clusters by QPS

The **Top 5 Clusters by QPS** section shows the top five clusters in terms of the average value of a performance metric within a specific time period.

You can select the performance metric you want to view and the corresponding time range based on your business needs.

You can select the following performance metrics:

- QPS (times/s)
- Query response time (us)
- Number of active sessions
- CPU usage (%)

You can select the following time ranges:

- Last 1 hour
- Last 24 hours
- Last 7 days

Top 5 clusters by elapsed time of major freeze

The **Top 5 Clusters by Elapsed Time of Major Freeze** section shows the top five clusters in terms of the average elapsed time of major freezes in the last three days in a column chart. Major freeze operation allows you to merge dynamic data with static data, but it is time-consuming. If the amount of incremental data generated by minor freezes exceeds a specified threshold, a major freeze operation is triggered.

If no clusters are merged within the last three days, this section is empty.

Server resources

The **Server Resource** section displays the total number of servers and the number of OBServer deployed in each data center. This section can provide a reference for cluster scaling.

Resource usage

The **Resource Usage** section displays the name and type of every cluster, and the number of tenants in a cluster. The section also displays the unit and unit numbers of allocated resources in a cluster, including the percentage of allocated CPU and memory, used disk space, and total disk space.

Clusters

The **Clusters** section displays the name, ID, OceanBase version, deployment mode, state, creation time, and alert information of each cluster. The deployment mode indicates the region where each zone is deployed and the number of OBServers

By default, only the information of primary clusters is displayed. Click the icon on the left side to view the information of standby clusters.

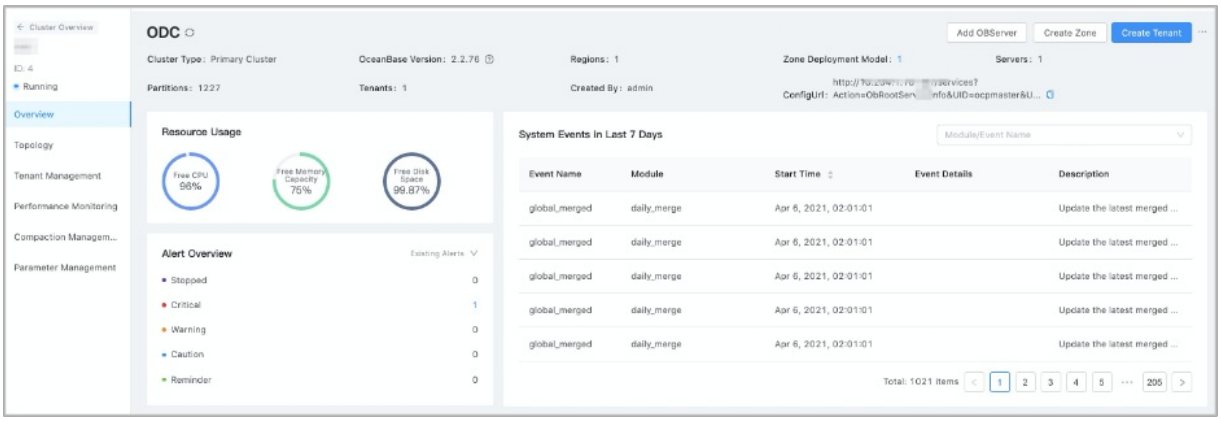
You can click the name of a cluster to go to the cluster details page.

17.1.3.1.3. Manage a single cluster

17.1.3.1.3.1. Cluster overview

You can select a cluster on the cluster overview page to view the overall information of the cluster. You can view the summary information, resource usage, alert overview information, system events of the last seven days, and the zone and OBServer lists.

In the **Clusters** section of the **Cluster Overview** page, find the cluster you want to view and click its cluster name. The **Overview** page for the cluster appears.



The cluster overview information

The Overview page displays the following information of the cluster: cluster type, OceanBase version, the creator, configUrl and the number of regions, zones, servers, partitions, and tenants.

Resource usage

The Resource Usage section displays the percentage of the following available system resources: free CPU, free memory capacity, and free disk space.

Alert overview

The Alert Overview section displays the information of all alerts related to the current cluster. The alert information is classified and displayed by alert severity.

Currently, the alerts are classified into the following five types: stopped, critical, warning, caution, and reminder.

By default, various existing alerts are displayed. You can view the alerts generated in the last 24 hours, the last 7 days, or the last 30 days based on business requirements.

System events in the last 7 days

This section displays the event details related to the RootService of the current cluster, and all events are sorted by the start time of the event.

The displayed information of each system event includes the event name, module, start time, event details, and event description.

The system displays event details and description for common events and does not display event details and description for uncommon events.

Zones

The Zones section displays the following basic information of each zone in the current cluster: Zone Name, Region, IDC, Root Server, and Status. It also provides a zone-level operation and maintenance (O&M) portal that allows you to add OBServers, and restart, stop, and delete the OBServer process of all nodes in a zone.

OBServers

The OBServers section displays the basic information of each OBServer in the current cluster, including the IP address, the port, the data center, the host type. This section also displays the zone where an OBServer resides and the available resources such as CPU, memory, and disk space.

In addition, OCP provides portals for common O&M operations on each OBServer in the current cluster to facilitates basic O&M operations. These portals allow you to restart, start, stop, replace, and delete OBServers.

17.1.3.1.3.2. Manage clusters

Create a standby cluster

If you have a primary cluster, you can create a standby cluster for the primary cluster.

Prerequisites

Make sure the current logon user is granted the permissions for managing clusters

Procedure

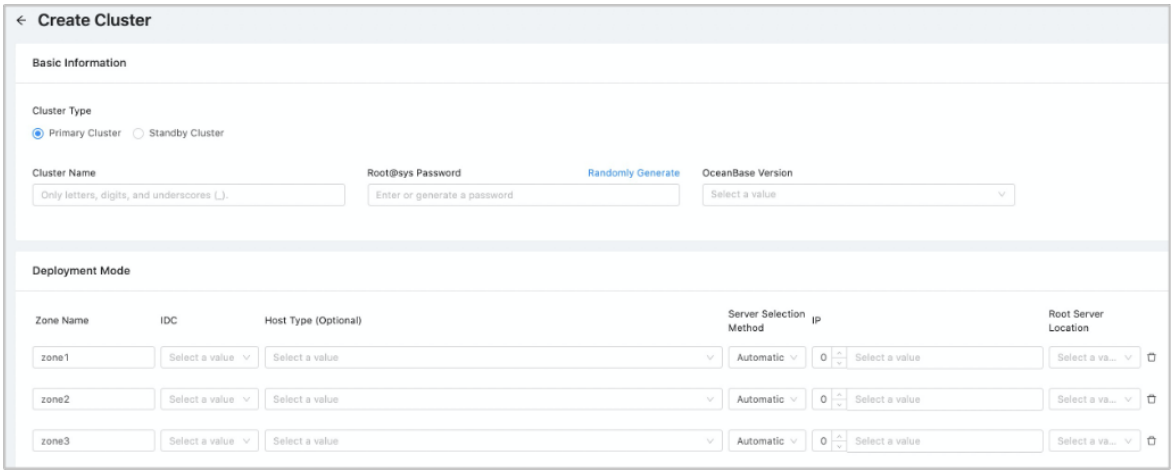
1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. You can use one of the following two methods to go to the page for creating a standby cluster.
   - In the upper-right corner of the **Cluster Overview** page, click **Create Cluster**. On the **Create Cluster** page, set **Cluster Type** as

     Standby Cluster, and select a primary cluster from the **Primary Cluster** drop-down list.
   - In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster to which you want to add a standby cluster.

     In the upper-right corner of the **Overview** page, choose **Create Standby Cluster**.
3. On the **Create Cluster** page, set the deployment mode of the standby cluster.

   By default, you can add three zones. If you want to create more than three zones for the cluster, click **Add** at the lower part of the field.

   If you want to deploy less than three zones, click the delete icon next to the zone that you want to delete.



The following table describes the parameters you must configure for a zone.

Parameter	Description
Zone Name	In most cases, a default name is generated. You can customize the zone name based on your business requirements.

Parameter	Description
IDC	The data center to which the zone belongs. The zones you create must be deployed in the same data center.
Host Type	Optional. The IP addresses are filtered based on the host type you select.
Server Selection Method	You can select **Automatic** or **Manual**.
IP	You can select multiple IP addresses. If you select **Automatic** from the **Server Selection Method** drop-down list, you only need to specify the number of IP addresses. OCP automatically selects the specific number of available physical servers. If you select **Manual** from the **Server Selection Method** drop-down list, you must manually select several IP addresses from the IP drop-down list.
Root Server Location	You can select an IP address as the server where the root server is located.

v. Click **Submit**.

vi. In the **Confirm Information** message, check the information and click **OK**.

Upgrade the version of a cluster

When a new cluster version is available, you can upgrade the version for the cluster that you manage.

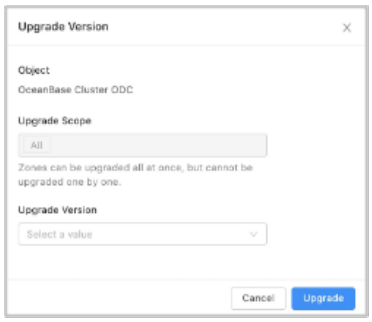
Prerequisites

You have the permissions to manage the cluster.

Procedure

1. Log on to OceanBase Cloud Platform (OCP). By default, the **Cluster Overview** page appears after you log on to OPC.
2. In the **Clusters** section of the **Cluster Overview** page, select the cluster that you want to manage, and then click the cluster name.
3. Click the icon in the upper-right corner of the **Overview** page and select **Upgrade Version**.

4. In the **Upgrade Version** dialog box, select the version to be upgraded.



If the version to be upgraded is not uploaded to OCP, you can click **Add Version** in the lower part of the **Upgrade Version** list to upload the related package.

5. Click **Upgrade**.
6. In the **Confirm Upgrade Path** dialog box, click **OK**.

Change a password

You can change the password of the root user under the cluster system tenant based on your needs.

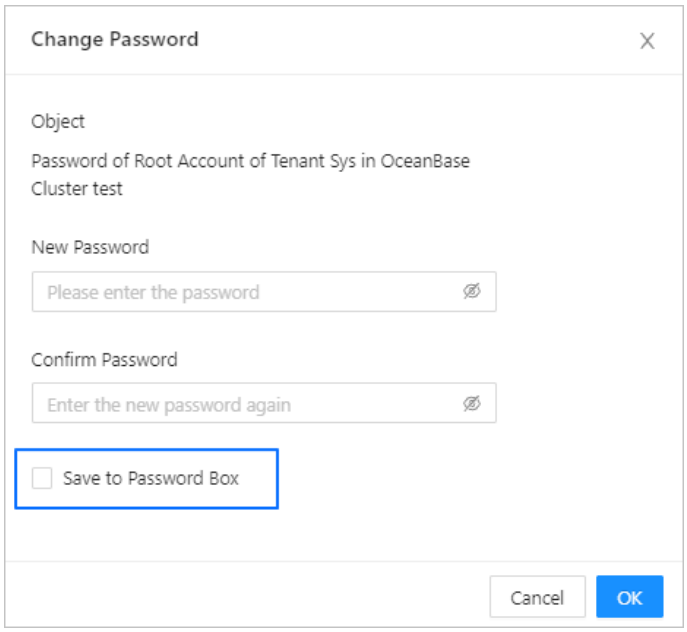
Prerequisites

You have the permissions to manage the cluster.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster** page, click the name of the cluster that you want to manage.
3. In the upper-right corner of the **Overview** page, click the More icon and select **Change Password**.
4. In the **Change Password** dialog box, enter and confirm the new password.

> **Note**
>
> By default, the **Save to Password Box** check box is selected. In this case, when you log on to OCP next time, you can use the new password to log on to the cluster.



5. Click **OK**.

Restart clusters

You can restart the OBServer processes of all nodes in a cluster or restart the OBServer processes in specific zones based on your business needs.

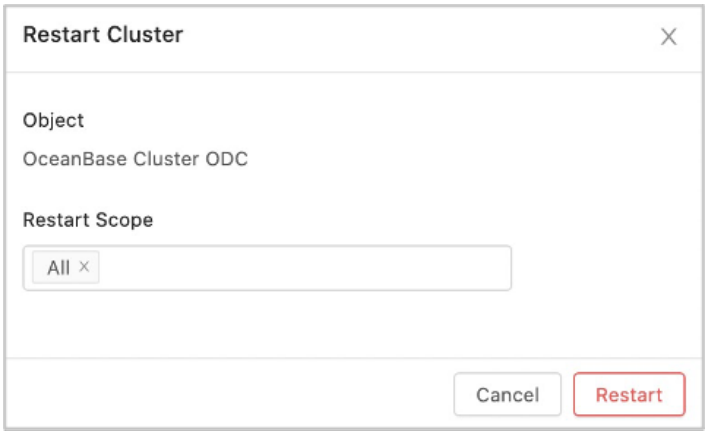
Prerequisites

Make sure the current logon user is granted the permissions for managing clusters

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the upper-right corner of the **Overview** page, click the More icon and select **Restart Cluster**.
4. In the **Restart Scope** field, you can select **All**, a specific zone, or several zones. Then, click **Restart**.

If you select **All**, the system restarts the OBServer processes of all nodes in the cluster. If you select some zones, the system restarts the OBServer processes of these zones.



Stop a cluster

You can stop a cluster based on your business needs. Stopping a cluster stops the OBServer processes running on all nodes in the cluster.

Prerequisites

Make sure the current logon user is granted the permissions for managing clusters.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to stop.
3. In the upper-right corner of the **Overview** page, click the icon and select **Stop Cluster**.

   > **Notice**
   >
   > Stopping a cluster stops the OBServer processes on all nodes in the cluster. Proceed with caution.

4. In the message, click **Stop**.

Delete a cluster

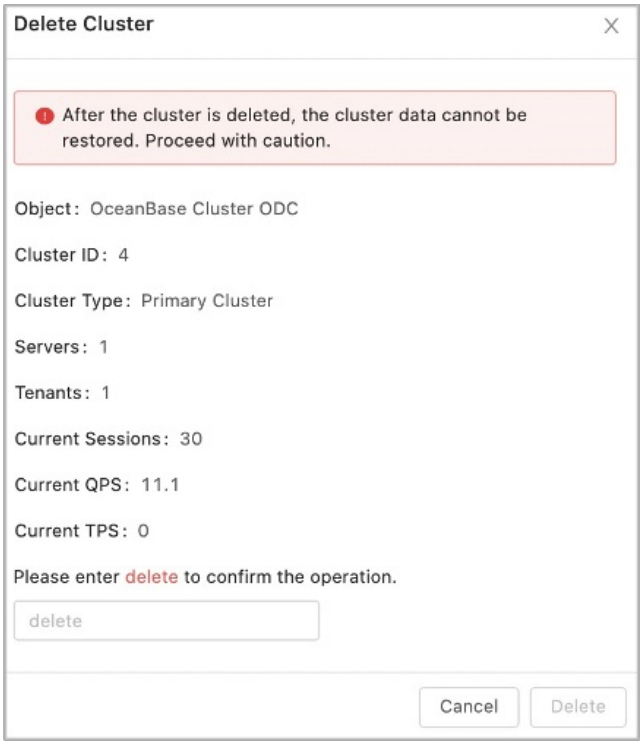
You can delete ApsaraDB for OceanBase clusters based on your needs.

Prerequisites

Permissions to manage the cluster are granted to the current user.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to delete.
3. In the upper-right corner of the **Overview** page, click the iconand select **Delete Cluster**.
4. In the **Delete Cluster** dialog box, enter delete and click **Delete**.



17.1.3.1.3.3. Manage zones

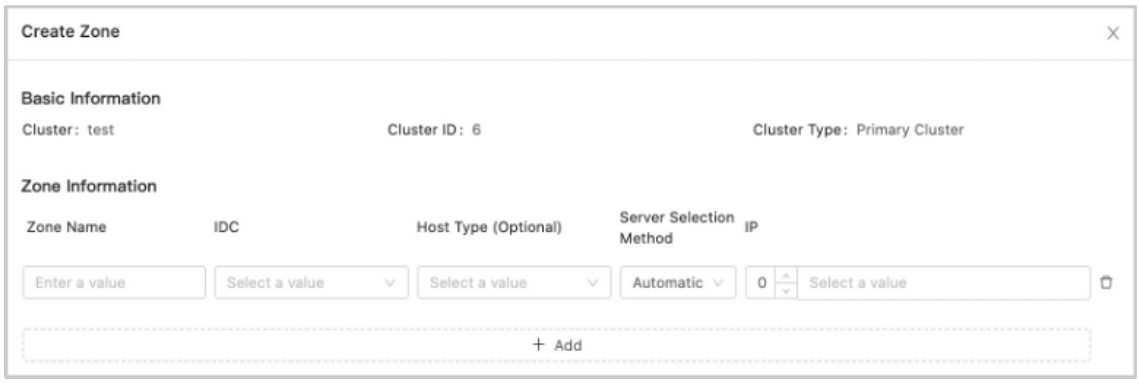
Create a zone

You can create a zone in a cluster that you manage.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the upper-right corner of the **Overview** page, click **Create Zone**.
4. In the panel that appears, specify the zone information.

By default, you can add one zone. To add more than one zone, you can click **Add** in the lower part.



The following table lists the zone information you must specify.

Parameter	Description
Zone Name	Customize the name of the zone.
IDC	The data center to which the zone belongs.
Host Type	(Optional) The IP addresses are filtered based on the host type you select.
Server Selection Method	You can select **Automatic** or **Manual**.
IP	You can select multiple IP addresses. If you select **Automatic** from the **Server Selection Method** drop-down list, you only need to specify the number of IP addresses. OCP automatically selects the specific number of available physical machines. If you select **Manual** from the **Server Selection Method** drop-down list, you must manually select several IP addresses from the IP drop-down list.

5. After you configure the preceding parameters, click **OK**.

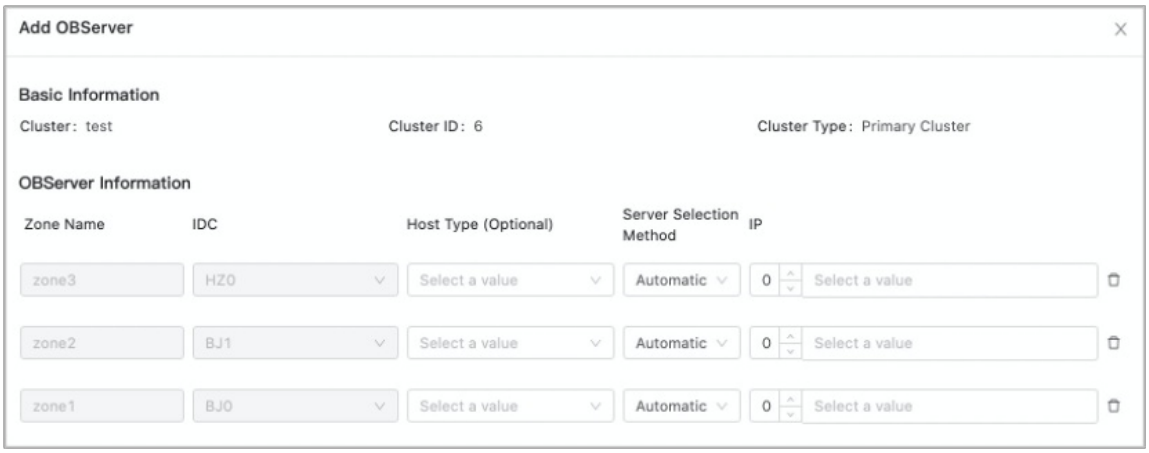
Add an OBServer node

You can add an OBServer node to a cluster that you manage.

Procedure

- Add an OBServer node to a cluster
  i. Log on to OCP. By default, the **Cluster Overview** page appears.
  ii. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
  iii. In the upper-right corner of the **Overview** page, click **Add OBServer**.

iv. In the **OBServerInformation** section, set the host type, server selection mode, and IP address of the OBServer to be added for each zone.



v. Click **OK**.

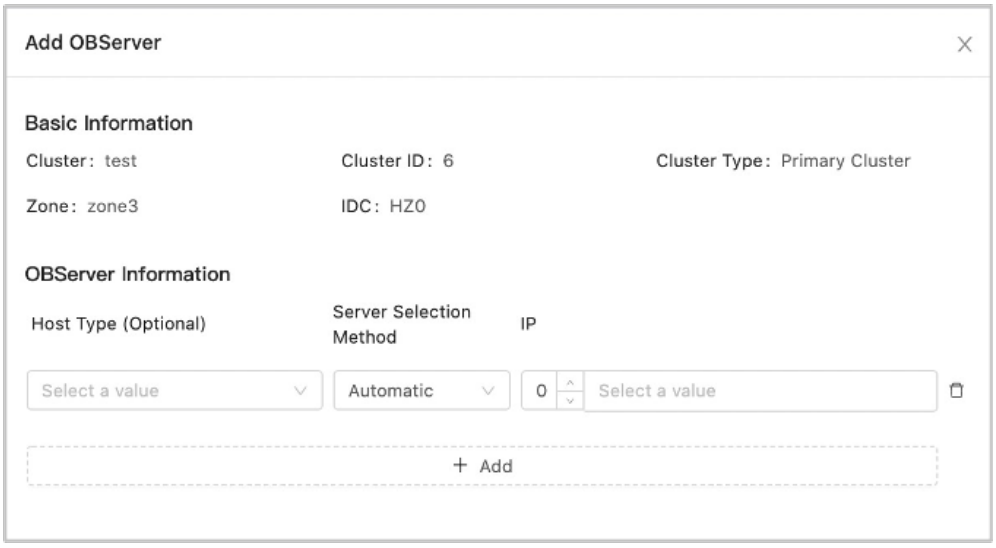
- Add an OBServer node to a specified zone

i. Log on to OCP. By default, the **Cluster Overview** page appears.

ii. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.

iii. In the **Zones** section of the **Overview** page, find the zone to which you want to add an OBServer node, and click **Add OBServer** in the **Actions** column.

iv. By default, one OBServer node is added. To add more OBServer nodes, click the **Add** button in the lower part.



v. Click **OK**.

Restart a zone

You can restart a zone in a cluster. After you restart a zone, the OBServer processes on all nodes in the zone are restarted.

Procedure

1. Log on to OceanBase Cloud Platform (OCP). By default, the **Cluster Overview** page appears.

2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the **Zones** section of the **Overview** page, find the zone that you want to restart, and click **Restart** in the **Actions** column.

   > **Notice**
   >
   > After you restart a zone, the OBServer processes on all nodes in the zone are restarted. Proceed with caution.

4. In the message that appears, click **Restart**.

Stop a zone

You can stop a zone in a cluster. After you stop a zone, the OBServer processes on all nodes in the zone are stopped.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the **Zones** section of the **Overview** page, click the icon for the zone that you want to stop in the **Actions** column and select **Stop**.
4. In the message that appears, click **Stop**.

Delete a zone

You can delete a zone from a cluster. After you delete a zone, all nodes in the zone and node data are deleted.

Procedure

1. Log on to OceanBase Cloud Platform (OCP). By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the **Zones** section of the **Overview** page, find the zone that you want to delete, click the icon in the **Actions** column, and then click **Delete**.
4. In the message that appears, click **Delete**.

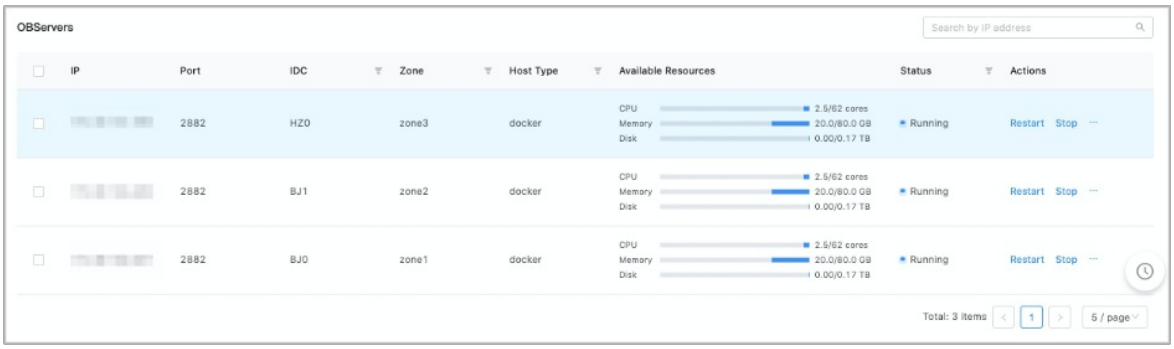
17.1.3.1.3.4. Manage an OBServer process

Restart an OBServer

When an OBServer is faulty, you can restart the OBServer.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to stop.
3. In the **OBServers** section of the **Overview** page, find the OBServer node that you want to stop and click Restart in the **Actions** column.



4. In the **Restart** message, click **Restart**.

Start an OBServer process

If an OBServer process on a node stops, you can start the OBServer process.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the **OBServers** section of the **Overview** page, find the OBServer process that you want to start, and click **Start** in the **Actions** column.
4. In the **Start** message, click **Start**.

Stop an OBServer process

You can stop an OBServer process on a node based on your needs.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the **OBServers** section of the **Overview** page, find the OBServer node that you want to stop and click **Stop** in the **Actions** column.
4. In the **Stop** message, click **Stop**.

Replace an OBServer

You can replace an OBServer on a node based on your needs. After the replacement operation is performed, the system removes the OBServer on the current node from the cluster. Then, the OBServer software is installed on the new node and added to the cluster.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to replace.

3. In the **OBServers** section of the **Overview** page, find the OBServer node that you want to replace. Then, click the icon in the **Actions** column and click **Replace**.

4. In the **ReplaceOBServer** dialog box, select the OBServer node that you want to replace, and click **Replace**.

Delete an OBServer process

You can delete an OBServer process from a node based on your needs.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the **OBServers** section of the **Overview** page, find the OBServer node that you want to delete, click the icon in the **Actions** column, and then click **Delete**.

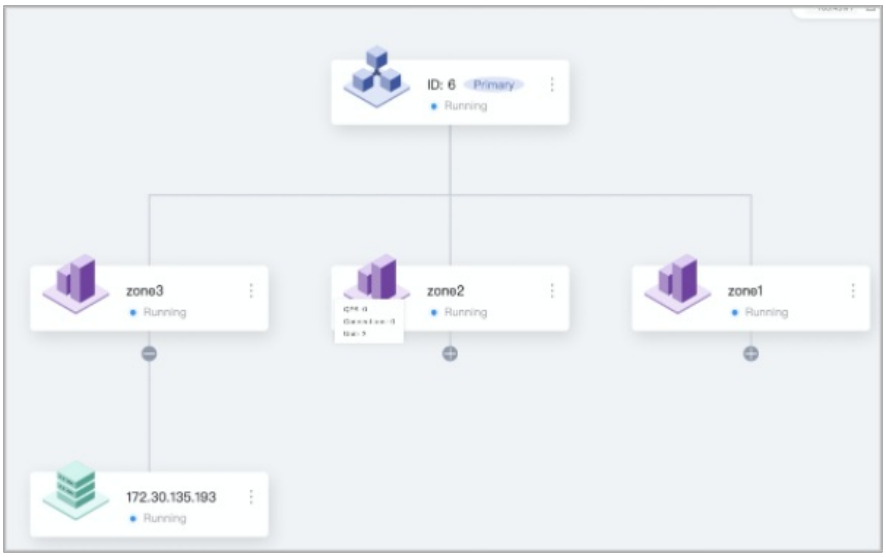
> **Notice**
>
> After you delete an OBServer node, all data on the node is deleted and cannot be restored. Proceed with caution.

4. In the **DeleteOBServer** message, select the OBServer node that you want to delete, and click **Delete**.

17.1.3.1.3.5. View a cluster topology

OCP enables the cluster topology feature. You can view the logical relationships between the zones and OBServer nodes of the cluster and tenant.

In the Clusters section of the Cluster Overview page, click the name of the cluster that you want to manage. In the left-side navigation pane of the page that appears, click Topology. The cluster topology appears.



On the page that appears, you can click the buttons in the upper-right corner to adjust the topology size or refresh the topology.

The topology displays information at three layers: cluster, zone, and server.

Cluster

The cluster layer displays the cluster ID, cluster type, and current status of the cluster. The cluster type can be primary or secondary.

If the cluster is a secondary cluster, you can also view the synchronization latency between the primary and secondary clusters.

The topology also provides an entry to manage the cluster.

For a primary cluster, you can create secondary clusters, add zones or OBServers, upgrade the cluster version, change the password, or restart, stop, or delete the cluster. For a secondary cluster, you can switch it to the primary role or view the cluster.

Zone

The zone layer displays the name and current status of a zone.

You can move the pointer over the zone icon to view the running status of the current zone, such as the queries per second (QPS), number of connections, and number of units.

The topology also provides an entry to manage the zone. In this case, you can add an OBServer and restart, stop, or delete zones.

Server

The server layer displays the IP address and current status of a server.

You can move the pointer over the server icon to view the running status of the current server, such as the QPS, number of connections, and SQL port.

The topology also provides an entry to manage the server. In this case, you can restart, start, stop, replace, or delete servers.

17.1.3.1.3.6. Manage a tenant

View the resource distribution of tenants

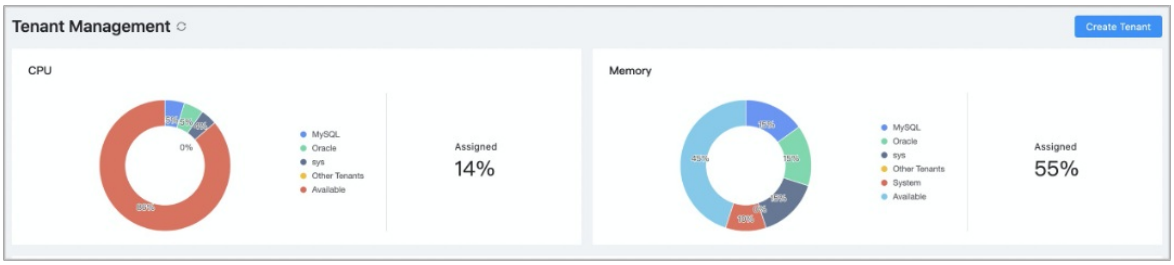
You can view the resource distribution of all tenants in a cluster that you manage.

Prerequisites

All permissions on the specified cluster and permissions to manage the cluster tenants are granted.

Procedure

1. Log on to OceanBase Cloud Platform (OCP). By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the left-side navigation pane of the page that appears, click **Tenant Management**.



4. On the **Tenant Management** page, view information about the resource distribution.

   You can view the percentage of CPU and memory resources used by each tenant and the remaining CPU and memory resources of the system.

   You can move the pointer over a slice in a pie chart to view the resources used by a specified tenant.

Create a tenant

You can create a tenant in the cluster that you manage.

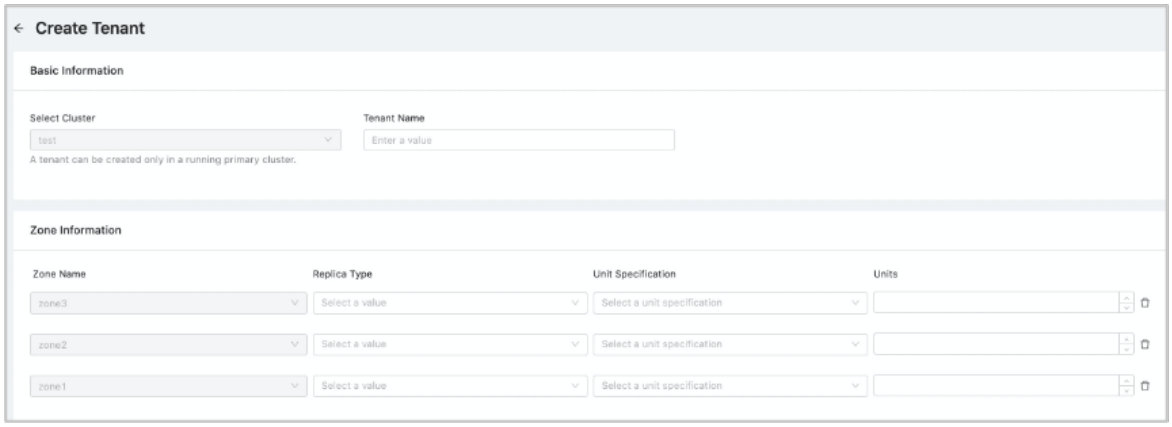
Prerequisites

All permissions on the specified cluster and permissions to manage the cluster tenants are granted.

Procedure

1. Log on to OceanBase Cloud Platform (OCP). By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. On the page that appears, use one of the following two methods to go to the **Create Tenant** page.
   - In the upper-right corner of the **Overview** page, click **Create Tenant**.

- In the left-side navigation pane, click **Tenant Management**. In the upper-right corner of the page that appears, click **Create Tenant**.



4. Enter a name for the new tenant.

   A tenant name must meet the following requirements:

   - The name can contain uppercase and lowercase letters, digits, and underscores (_).
   - The name must be 2 to 64 characters in length.

5. Configure zones for the new cluster tenant.

   By default, the system displays the available zones of the cluster. If you do not want to distribute data replicas to some zones, you can click the Delete icon on the right to delete the zones. The following table describes the parameters for configuring zones.

Parameter	Description
Replica Type	Valid values: ○ Full-featured Replica ○ Read-only Replica ○ Log Replica
Unit Specification	OCP provides a set of unit specifications. For information about how to select a specification, see **OCP resource unit specifications** in the appendix. You can also click **Add Specification** in the lower part of the drop-down list to add a custom specification.
Units	The number of units in the zone. **Note: The number of units cannot exceed the number of OBServers in the zone.**

Parameter	Description
Zone Priority Rankings	The priority of the zone. The setting affects the priority of the primary zones of the system tenant. The list on the left displays all the zones in the current cluster. You can select one or more zones from the left-side list and add them to the right-side list. By default, a zone that you select first has a higher priority than a zone that you select later. If you select multiple zones at a time, they have the same priority. After you move the zones to the right-side list, you can adjust the priority by dragging them. The zone that ranks at the top of the list box has a higher priority than the zones below.

6. Configure basic settings for the new tenant. The following table describes the basic parameters and description.

Parameter	Description
Administrator Password	The password of the tenant administrator. In MySQL mode, the root user is the administrator. In Oracle mode, the SYS user is the administrator. The password must meet the following requirements: ◦ The password can contain 8 to 32 characters in length. ◦ The password must contain at least two digits, two uppercase letters, two lowercase letters, and two special characters. ◦ The password can contain the following special characters: . _+@#$%
Tenant Mode	The MySQL and Oracle tenant modes are supported. The Oracle tenant mode is supported only when the version of the selected ApsaraDB for OceanBase cluster is 2.1 or later.
Character Set and Encoding	In MySQL mode, the following character sets are supported: utf8mb4, binary, gbk, and gb18030. By default, utf8mb4 is used. In Oracle mode, the following character sets are supported: utf8mb4, gbk, and gb18030. By default, utf8mb4 is used.
Remarks	The remarks. This parameter is optional.

Parameter	Description
IP Address Whitelist	You can specify a list of clients that the tenant can connect to. If you leave this parameter empty, the default value is **%**. This indicates that the tenant can connect to all clients. When you configure a custom whitelist, take note that the IP addresses of the OCP server and OBProxy must be added to the whitelist. Otherwise, you cannot manage the tenant on OCP. The whitelist can be in one of the following formats: ○ IP address: 10.10.10.10 and 10.10.10.11 ○ Subnet mask: 10.10.10.0/24 ○ IP address for fuzzy match: 10.10.10.% or 10.10.10._ ○ Combined formats: 10.10.10.10, 10.10.10.11, 10.10.10.%, 10.10.10._, and 10.10.10.0/24

7. Click **Submit**.

View tenants

You can view basic information about all cluster tenants.

Prerequisites

All permissions on the specified cluster and permissions to manage the cluster tenants are granted.

Procedure

1. Log on to OceanBase Cloud Platform (OCP). By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the left-side navigation pane of the page that appears, click **Tenant Management**.
4. In the **Tenants** section of the **Tenant Management** page, you can view basic information about all tenants, including the tenant name, replica type, zone priority, tenant mode, and tenant status.

View tenant monitoring data

You can view the performance of the top five tenants that have the highest workloads in a cluster.

Prerequisites

All permissions on the specified cluster and permissions to manage the cluster tenants are granted.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.

2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the left-side navigation pane of the page that appears, click **Tenant Management**.
4. In the **Top 5 Tenants** section of the **Tenant Management** page, view the performance of the top five tenants that have the highest workloads in the current cluster. The performance monitoring metrics include the TPS, QPS, SQL response time, transaction response time, active sessions, event wait_number, event wait_time, capacity_table quantity, and capacity_partition quantity.
   - You can also view monitoring data of the last hour, last day, or last week based on your needs.

   - The following table describes the performance monitoring metrics.

Metric	Description	Data source
QPS	The average number of SQL statements that are processed per second.	v$sysstat
TPS	The average number of transactions that are processed per second.	v$sysstat
SQL Response Time	The SQL response time. The unit is microsecond.	v$sysstat
Response Time of Transactions	The average amount time for processing each transaction on the server. The unit is microsecond.	v$sysstat
Active Sessions	The number of active sessions.	__all_virtual_processlist

Event Wait_Count	The average number of wait events per second.	v$system_event
Event Wait_Time	The average amount of time spent on waiting for an event.	v$system_event
Capacity_Number of Tables	The number of tables.	gv$table
Capacity_Number of Partitions	The number of partitions.	v$partition

Manage a tenant

You can lock or replicate a tenant.

Prerequisites

You are granted all the permissions for a specified cluster and the permissions for managing tenants in the cluster.

Procedure

- Lock a tenant
  i. Log on to OCP. By default, the **Cluster Overview** page appears.
  ii. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to lock.
  iii. In the left-side navigation pane of the page that appears, click **Tenant Management**.
  iv. In **Tenants** section of the **Tenant Management** page, find the tenant that you want to lock and click **Lock** in the **Actions** column.

  > **Notice**
  > After you lock a tenant, new users cannot connect to the tenant. Proceed with caution.

  v. In the message that appears, click **Lock**.

- Replicate a tenant
  i. Log on to OCP. By default, the **Cluster Overview** page appears.
  ii. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to replicate.
  iii. In the left-side navigation pane of the page that appears, click **Tenant Management**.
  iv. In the **Tenants** section of the **Tenant Management** page, find the tenant you want to replicate and click **Copy** in the **Actions** column.

v. For information about how to specify basic information and zone information on the **Replicate Tenant** page, see Create a tenant.

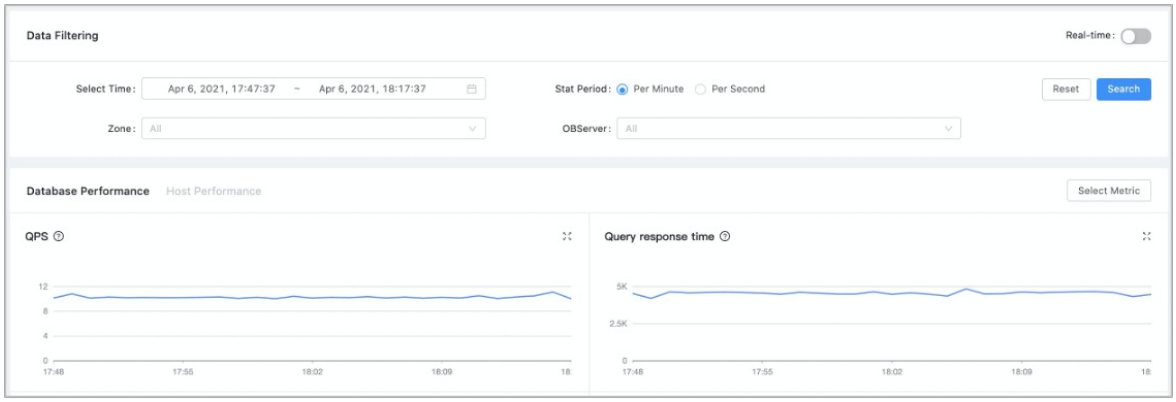
vi. Click **Submit**. After you submit the request, the system creates a new tenant based on the current tenant. However, the data of the current tenant is not replicated.

17.1.3.1.3.7. Performance monitoring

You can view monitoring data of a cluster from different dimensions.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to view.
3. In the left-side navigation pane of the page that appears, click **Performance Monitoring**.
4. In the **Data Filtering** section, specify filter conditions and click **Search**.



The following table describes some of the filter conditions.

Filter condition	Description
Select Time	Select a time range. The monitoring data collected during the specified time range is returned.
Stat Period	Statistical period refers to the statistical period of point data. It allows you to collect data **per minute** or **per second**. That is, you can collect a point per minute or per second. OCP also collects data in another statistical period based on the selected time range. The calculation rules is to collect returned data as close to 1440 points as possible. If the selected time range is too long, the statistical period may longer than 1 minute.
Zone	Select the zone that you want to view.
OBServer	Select the OBServer that you want to view.

5. Switch between the tabs to view the performance metrics of a database or a host in the cluster.

To view other performance metrics, click **Select Metric** on the right of the section. In the Select Metric panel, select the metrics that you want to view. A maximum of 10 metrics can be selected at a time.

For information about database performance and host performance metrics, see Appendix 6. Metrics.

17.1.3.1.3.8. Manage major freezes

Details of major freeze

Major freeze operation allows you to merge dynamic data with static data, but it is time-consuming. If the amount of incremental data generated by minor freezes exceeds a specified threshold, a major freeze operation is triggered. You can view the details about major freeze of clusters.

Procedure

1. Log on to the OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the left-side navigation pane of the page that appears, click **Compaction Management**.
4. On the **Details of Major Freeze** tab, you can view the details of major freeze.

The Details of Major Freeze tab shows the details of the last major freeze in the cluster. If the cluster is in merging state, the major freeze version is displayed. If the state is idle, the information of the last major freeze is displayed.

> **Note**
>
> If the cluster is in merging state, the **Start Time** and **End Time** shows the estimated completion time. The estimated completion time is estimated based on the average value of the last three major freezes and may deviate greatly from the actual time.

In most cases, the estimation is relatively accurate in a stable environment. In a new environment, the accuracy of estimation is low due to a lack of data.

You can also view **Total Partition Replicas** and **Replicas of Partitions After Major Freeze** to learn the progress of a major freeze at the partition level and estimate the completion time.

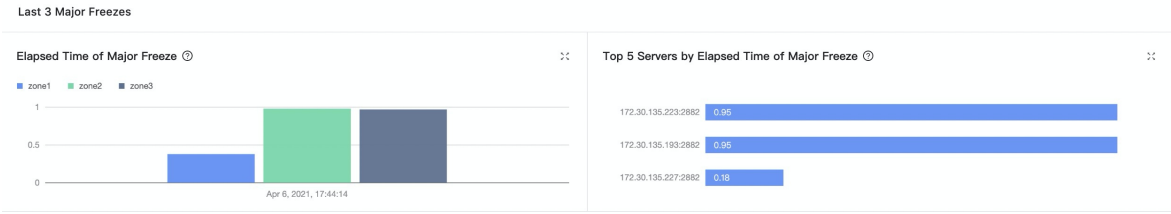
> **Notice**
>
> The completion time estimated directly based on the replicas of partitions after major freeze is inaccurate. The sizes of different partitions vary greatly. The major freeze time of different partitions also varies greatly.

Major freeze statistics

You can view the Major freeze statistics of a cluster.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to view.
3. In the left-side navigation pane of the page that appears, click **Compaction Management**.
4. In the **Last 3 Major Freezes** section of the **Details of Major Freeze** tab, you can view the statistics of major freeze.



Major freeze statistics provide the following four statistical graphs for the last three major freezes:

- Elapsed Time of Major Freeze
- Top 5 Servers by Elapsed Time of Major Freeze
- Top 5 Tenants by Average Minor Freezes
- Top 5 Tenants by Peak Memory Usage Before Major Freeze

The major freeze time and performance data helps you learn the health of the OceanBase cluster because major freeze affects the overall performance of the cluster.

In most cases, we want the daily major freeze is triggered at the time point that we specify.

If the number of times of minor freeze and memory usage exceed a specific threshold, the major freeze is triggered in a cluster. You can determine whether the resources allocated to a tenant are sufficient by viewing the metrics of the tenant. You can upgrade the resource specifications of a tenant to prevent major freeze in a cluster triggered by insufficient resources.

Perform a major freeze

You can trigger an immediate major freeze for an idle cluster. If an error occurs during the major freeze, after you analyze and troubleshoot the error, you can click Continue Major Freeze to remove the error tag and continue the major freeze.

Procedure

1. Log on to OceanBase Cloud Platform (OCP). By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the left-side navigation pane of the page that appears, click **Compaction Management**.

4. In the **Last Major Freeze** section of the **Details of Major Freeze** tab, find **Basic Information**.

5. If **Status** is **Idle**, click **Initiate Major Freeze**.
6. If an error occurs during the cluster major freeze, click Continue Major Freeze to remove the error tag and continue the major freeze.

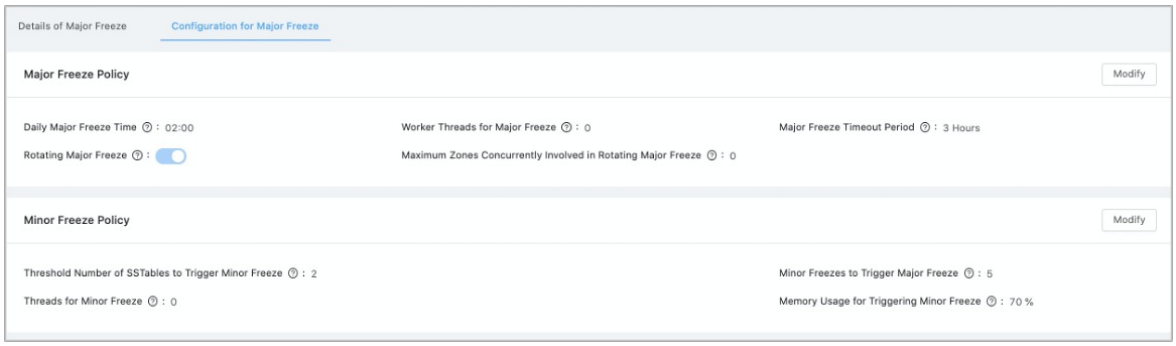
> **Notice**
>
> We recommend that you contact technical personnel for troubleshooting when a major freeze error occurs. If you remove the error tag and continue the major freeze without troubleshooting, the impacts of the issue may be expanded.

Modify major freeze configurations

You can configure major freeze and minor freeze policies based on your needs to perform daily major freeze operations.

Procedure

1. Log on to OceanBase Cloud Platform (OCP). By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the left-side navigation pane of the page that appears, click **Compaction Management**.
4. Click the **Configuration for Major Freeze** tab.



5. Configure the major freeze policy.
   i. In the **Major Freeze Policy** section, click **Modify**.
   ii. Move the pointer over the icon of each configuration item to view system prompts and configure the major freeze policy.
   iii. Click **Save**.

6. Configure the minor freeze policy.
   i. In the **Minor Freeze Policy** section, click **Modify**.
   ii. Move the pointer over the icon of each configuration item to view system prompts and configure the minor freeze policy.
   iii. Click **Save**. Click **Save**.

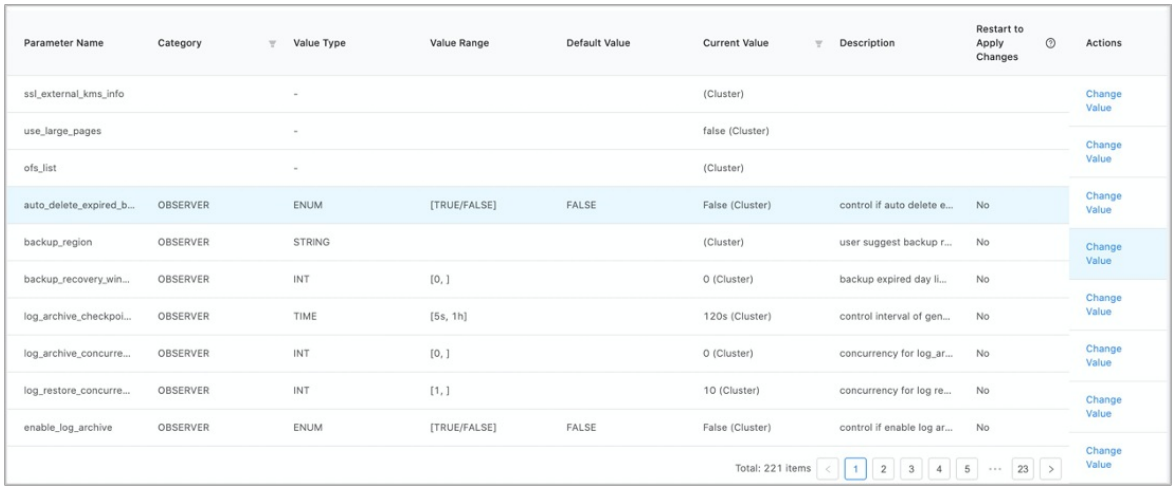
17.1.3.1.3.9. Manage parameters

View parameters

You can view parameters on OceanBase Cloud Platform (OCP). For example, you can view the name, category, value type, value range, default value, current value, and description of each parameter. You can also view whether the parameter takes effect after a restart.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the left-side navigation pane of the page that appears, click **Parameter Management**.
4. On the **Parameters** tab, you can view all parameters in the current cluster. For example, you can view the parameter name, value type, value range, default value, current value, and parameter description. You can also view whether the parameter takes effect after a restart.



Parameter Name	Category	Value Type	Value Range	Default Value	Current Value	Description	Restart to Apply Changes	Actions
ssl_external_kms_info		-			(Cluster)			Change Value
use_large_pages		-			false (Cluster)			Change Value
ofs_list		-			(Cluster)			Change Value
auto_delete_expired_b...	OBSERVER	ENUM	[TRUE/FALSE]	FALSE	False (Cluster)	control if auto delete e...	No	Change Value
backup_region	OBSERVER	STRING			(Cluster)	user suggest backup r...	No	Change Value
backup_recovery_win...	OBSERVER	INT	[0,]		0 (Cluster)	backup expired day li...	No	Change Value
log_archive_checkpoi...	OBSERVER	TIME	[5s, 1h]		120s (Cluster)	control interval of gen...	No	Change Value
log_archive_concurre...	OBSERVER	INT	[0,]		0 (Cluster)	concurrency for log_ar...	No	Change Value
log_restore_concurre...	OBSERVER	INT	[1,]		10 (Cluster)	concurrency for log re...	No	Change Value
enable_log_archive	OBSERVER	ENUM	[TRUE/FALSE]	FALSE	False (Cluster)	control if enable log ar...	No	Change Value

Total: 221 items < 1 2 3 4 5 ··· 23 >

> **Note**
> - **0 (Cluster)** of the **Current Value** parameter indicates all OBServers in the cluster have the same value of this parameter. For example, **backup_region**.
> - If the parameter has different values in the zone or OBServer, a combination of values appears, such as **12;10 Custom**.

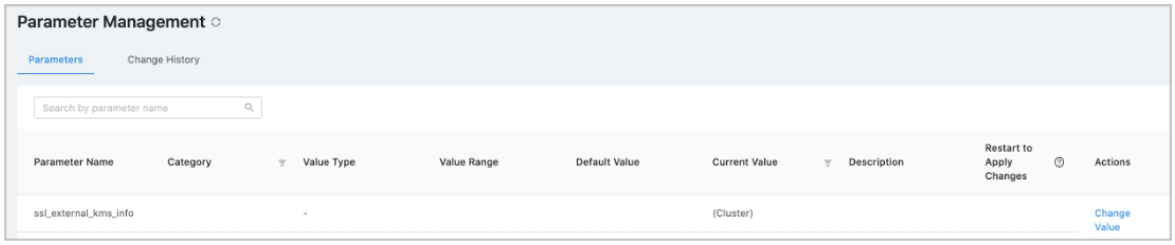
Modify parameter values

You can modify cluster parameter values and the effective scope based on your needs.

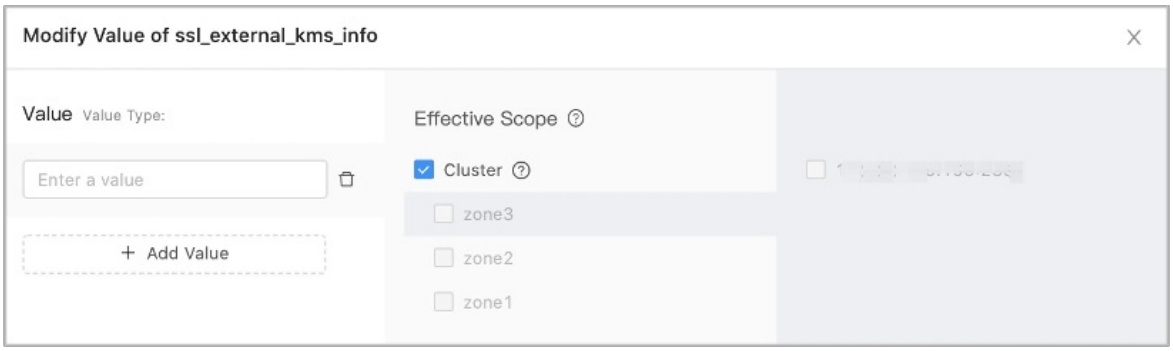
Procedure

1. Log on to OceanBase Cloud Platform (OCP). By default, the **Cluster Overview** page appears.

2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster that you want to manage.
3. In the left-side navigation pane of the page that appears, click **Parameter Management**.
4. Optional. In the upper-left corner of the **Parameters** tab, enter a keyword to search for parameters that meet specified conditions.



5. Find the parameter for which you want to modify the value, and click **Change Value** in the **Actions** column.
6. In the dialog box that appears, modify the parameter value and effective scope, and click **OK**.



You can specify a parameter to take effect in the cluster, zone, or OBServer based on your needs. To configure global settings, select **Cluster** in Effective Scope.

The default effective scope is **Cluster**. If you want to change the effective scope to a zone or an OBServer, you can clear the **Cluster** check box in **Effective Scope**. Then, the system displays a list of zones in the cluster. In this case, if you select a zone, the parameter takes effect in the zone. If you select a zone and then select an OBServer in this zone, the parameter takes effect in the OBServer.

You can also configure a parameter to take effect at different levels. For example, you can set **backup_concurrency** to **10** in **Zone 1**, **12** in **Zone 2**, and 20 in **Server 1**. You can click **Add Value** in the **Value** column to form 3 rows of values. You can specify an effective scope for each value.

> **Note**
>
> After you click **Add Value** and add multiple rows of values, the parameter of the cluster is modified one by one starting from the first row. Every time a modification is completed, a record is generated on the **Change History** tab.

Parameter types

ApsaraDB for OceanBase supports multiple parameter types, including BOOL, CAPACITY, DOUBLE, INT, MOMENT, STRING, STRING_LIST, and TIME.

The following table describes the main parameter types and default units.

Parameter	Description
BOOL	The Boolean type. Valid values: true and false.

Parameter	Description
CAPACITY	The capacity. The unit can be byte, kilobyte, megabyte, gigabyte, terabyte, or petabyte. The unit is not case-sensitive. By default, the unit is megabyte.
DOUBLE	The double-precision floating-point type. A 64-bit value of this type is accurate to 15 digits after the decimal point and has 16 significant digits at most.
INT	The 64-bit integer type. The value can be a positive integer, negative integer, or zero.
MOMENT	The time point. The value is in the hh:mm format, for example, 02:00. You can also set this parameter to disable. This indicates that the time is not specified. MOMENT is used only in the major_freeze_duty_time parameter.
STRING	The string type. You can enter a string based on the parameter description of ApsaraDB for OceanBase.
STRING_LIST	A list of strings. Strings are separated with semicolons (;).
TIME	The time type. The unit can be microsecond, millisecond, second, minute, hour, or day. By default, the unit is second. The unit is not case-sensitive.

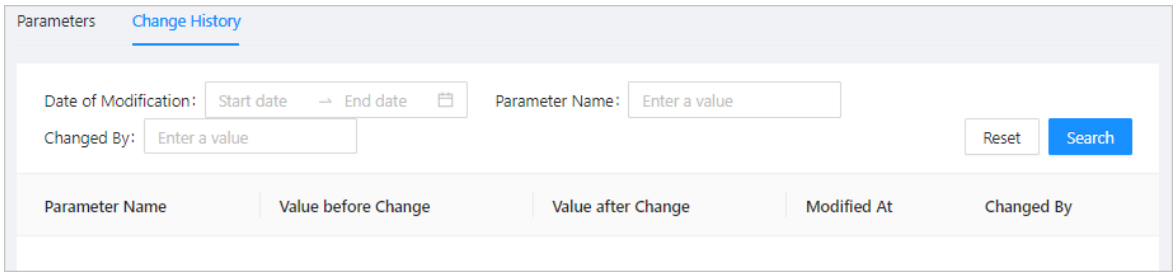
View the history of parameter changes

You can modify parameters in OCP. The Change History tab allows you to view the history of all parameter changes. You can view Parameter Name, Value Before Change, Value After Change, Modified At, and Changed By.

Procedure

1. Log on to OCP. By default, the **Cluster** Overview page appears.
2. In the **Clusters** section of the **Cluster** Overview page, click the name of the cluster that you want to manage.
3. In the left-side navigation pane of the page that appears, click **Parameter Management**.
4. Click the **Change History** tab.
5. You can filter data by specifying **Date of Modification**, **Parameter Name**, or **Changed By**.

   In the **Parameter Name** field, you can enter a keyword to search for parameters that meet specific conditions. However, in the **Changed By** field, you must enter an exact username.



6. In the search result, view the history of parameter changes.

17.1.3.2. Tenant management

17.1.3.2.1. Overview

A tenant is a logical concept. ApsaraDB for OceanBase allocates resources by tenant. You can also manage database objects and resources based on tenants. Tenants play an important role in system O&M, such as the O&M of ApsaraDB for OceanBase clusters. After you log on to OCP, click Tenants in the left-side navigation pane to go to the Tenant Overview page. By default, the Tenant Overview page displays a list of tenants that you have permissions to view and the top five tenants.

17.1.3.2.2. Create a tenant

A tenant is a container for various database objects and resources such as CPU, memory, and I/O. You can create tenants in a cluster based on your business requirements.

You can use one of the following two methods to create a tenant:

- Create a tenant on the Tenant Overview page.
- Create a tenant on the Tenant Management page of a specified cluster.

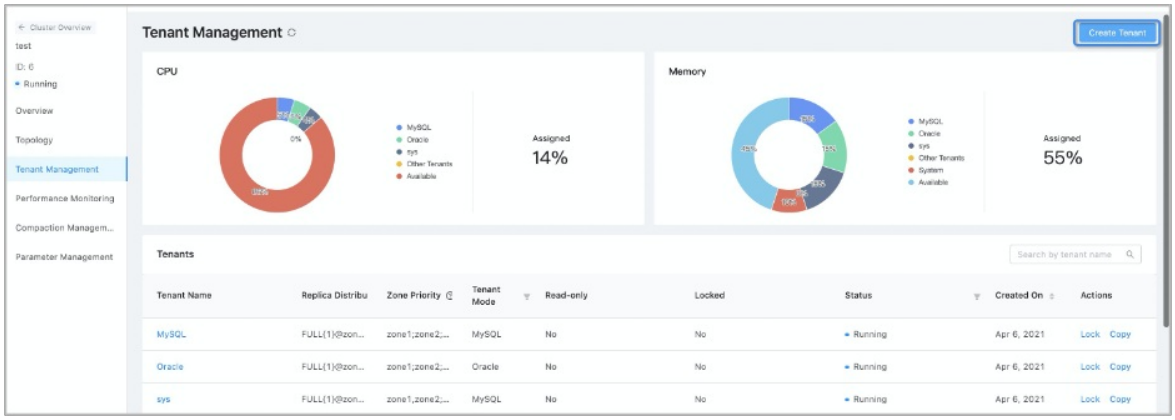
This topic describes how to create a tenant on the Tenant Management page of a specified cluster.

Prerequisites

- The cluster where you create a tenant must be a primary cluster and must be in running state.
- The current user you log on to is the system administrator, OCP tenant administrator role, or other roles that have permissions to manage the cluster.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the **Clusters** section of the **Cluster Overview** page, click the name of the cluster where you want to create a tenant.
3. In the left-side navigation pane of the page that appears, click **Tenant Management**.
4. In the upper-right corner, click **Create Tenant**.

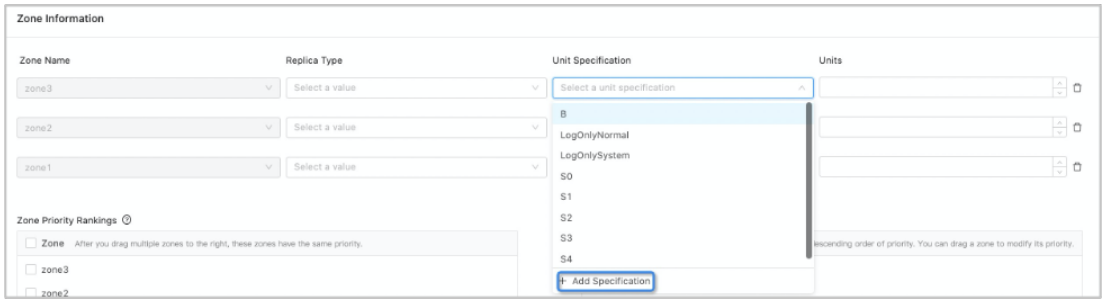


5. Configure **Basic Information**.
   i. The default cluster is the current cluster.
   ii. Enter a **Tenant Name**. The tenant name must be 2 to 64 characters in length and can contain letters, digits, and underscores (_).
6. Configure **Zone Information**.

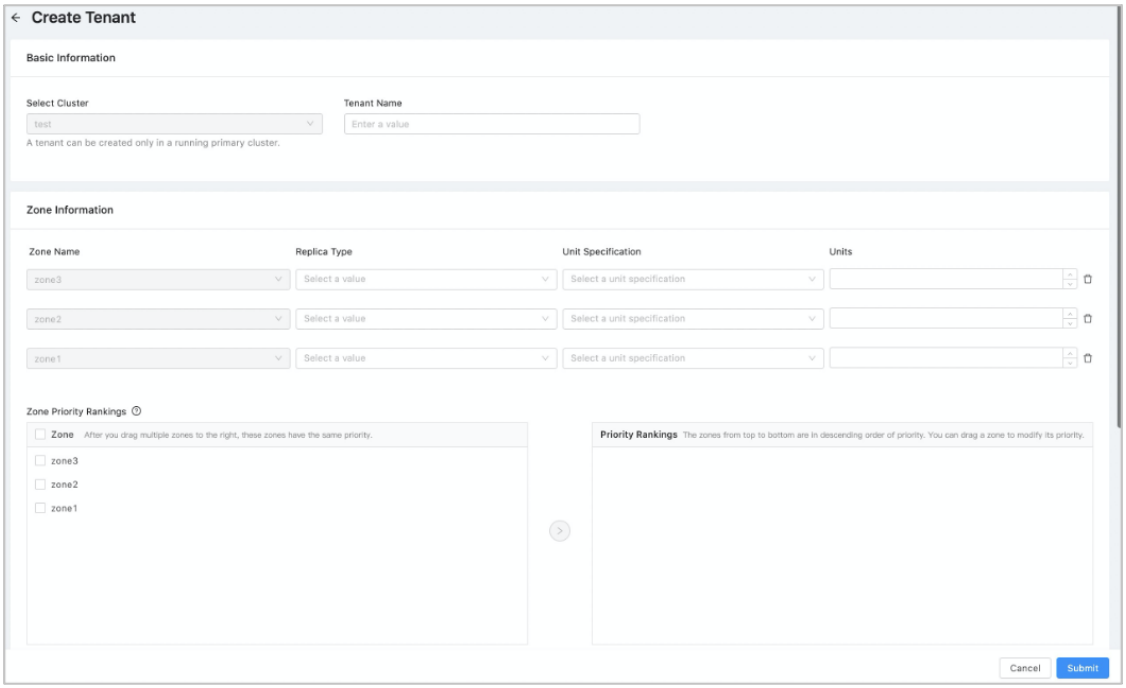
i. Specify the Replica Type, Unit Specification, and Units for zone 1, zone 2, and zone 3.

After you select a cluster, the page shows a list of zones that can be configured based on the zone information of the selected cluster. For zones that do not store data replicas, you can delete the zone by clicking the delete icon on the rightmost side.

- You can select Full-featured Replica, Read-only Replica, and Log Replica from the Replica Type drop-down list.
- OCP provides a set of built-in Unit specifications. You can also click Add Specification at the bottom of the Unit Specification drop-down list to add custom specifications.
- Specify the number of units in the zone. Note that the number of units cannot exceed the number of servers in the zone.



ii. Configure the **Zone Priority Rankings**. If you drag multiple zones to the right, these zones have the same priority.



7. Configure the **Basic Settings**.

i. Settings

- If the tenant mode is MySQL, its administrator account is "root".
- If the tenant mode is Oracle, its administrator account is "SYS". The password must be 8 to 32 characters in length and contain at least two digits, two uppercase letters, two lowercase letters, and two special characters. Special characters include: _+@#$%.

ii. Select a **Tenant Mode**.

- You can select Oracle or MySQL.

- The Oracle tenant mode is supported only when the OceanBase version of the selected cluster is 2.1 or later.

iii. Configure the **Character Set and Encoding**.

- If you select the MySQL tenant mode, the following character sets are available: utf8mb4, binary, gbk, and gb18030. Default value: utf8mb4.
- If you select the Oracle tenant mode, the following character sets are available: utf8mb4, gbk, and gb18030. Default value: utf8mb4.

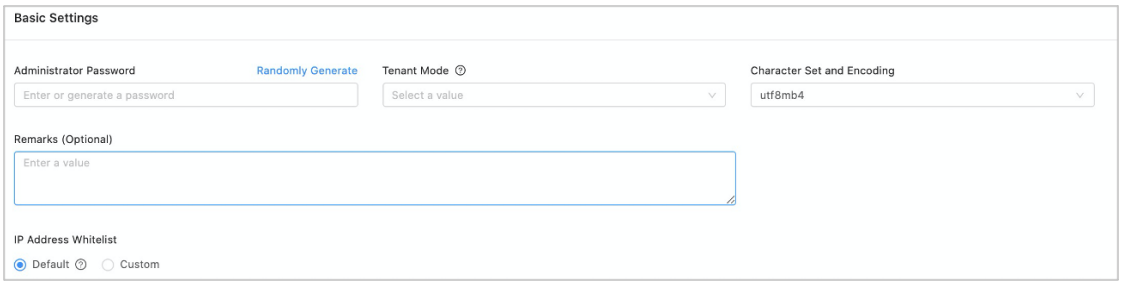
iv. Optional. Configure **Remarks**.

v. Configure the **IP Address Whitelist**.

- You can specify the clients that the tenant can log on to. If you do not specify, the default configuration is "%". It indicates that the tenant can log to all clients. When you customize the whitelist, note that the whitelist must include the IP addresses of the OCP server and the OBProxy on which the OCP server depends. Otherwise, OCP cannot manage this tenant.
- Default: Accesses from all IP addresses is supported.
- Custom: Configure an IP address whitelist. Only accesses from the IP addresses in the whitelist are supported.

- Description of whitelist format:
  - IP addresses. For example, 10.10.10.10,10.10.10.11.
  - Subnet mask. For example, 10.10.10.0/24.
  - Fuzzy match. For example, 10.10.10. % or 10.10.10. _
  - A mix of multiple formats. For example, 10.10.10.10,10.10.10.11,10.10.10. %,10.10.10. _,10.10.10.0/24

> **Note**
> The percent sign (%) indicates that all clients can connect to the tenant.



8. Click **Submit**.

17.1.3.2.3. View tenants

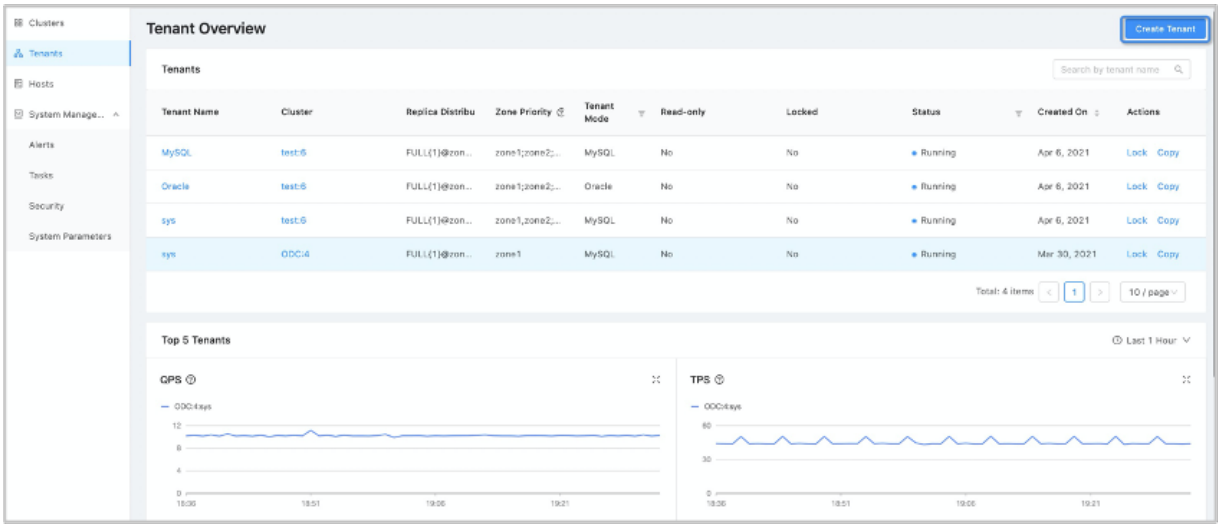
Assume that you have been granted the read-only or all permissions on specified tenants. On the Tenants page, you can view the details and monitoring data of the specified tenants.

Tenants

The Tenants section displays Tenant Name, Cluster, Replica Distribution, Zone Priority, Tenant Mode, Read-only, Locked, Status, and Created On. In the Tenants section, you can lock or replicate a specified tenant, or enter a keyword to search for tenants whose names meet specified conditions. Paged query is also supported.

Replica Distribution specifies the replica type of the tenant in each zone. Zone Priority specifies the priority of the zones that are to be selected as the primary zone. The replica leader is located in the primary zone.

Assume that you have permissions to manage tenants. In this case, you can create, delete, or modify tenants, or have read-only permissions on tenants. The permissions vary based on users. Some users can manage more tenants than other users. Therefore, the number of tenants displayed in the Tenants section varies based on users. Assume that User A has the read-only permission on a specified tenant, but User B has permissions to modify and delete the tenant. In this case, the Actions column displays different user permissions.



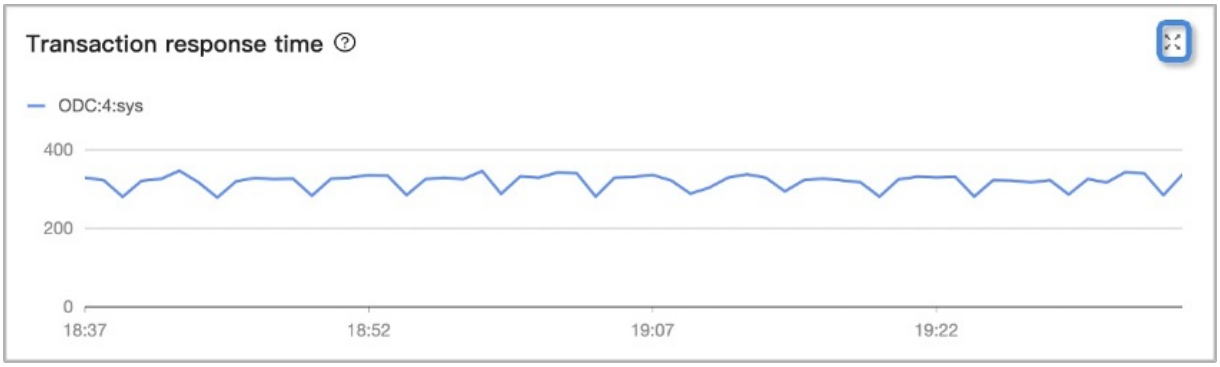
Top 5 Tenants

The **Top 5 Tenants** section displays the performance of the top five tenants in all clusters during a recent period of time. The tenants are ranked by the global core monitoring metrics. The following list describes the core monitoring metrics:

- QPS: The average number of SQL statements processed per second. Data source: v$sysstat.
- TPS: The average number of transactions processed per second. Data source: v$sysstat.
- SQL Response Time: The SQL response time. The unit is microsecond. Data source: v$sysstat.
- Transaction Response Time: The average time for the server to process a transaction. The unit is microsecond. Data source: v$sysstat.
- Active sessions: The number of active sessions. Data source: __all_virtual_processlist.
- Event wait_number: The average number of wait events per second. Data source: v$system_event.
- Event wait_time: The average amount of time spent on waiting for an event. The unit is microsecond. Data source: v$system_event.
- Capacity_table quantity: The number of tables. Data source: gv$table.
- Capacity_partition quantity: The number of partitions. Data source: v$partition.

By default, the Top 5 Tenants section displays the monitoring data of the top five tenants in the last hour. You can also select Last 24 Hours or Last 7 Days from the drop-down list.

When you move the pointer over a specific point in time in the window of a metric, the details of the monitoring data appear, as shown in the following figure. You can view the current time, tenant name, and metric value of the tenant.



To zoom in on the window of a monitoring metric, click the zoom-in icon in the upper-right corner of the window. A resized window appears on the current page. In this case, you can move the pointer over a specific point in time to view the metric value. To return to the Tenant Overview page, click the close button to close the window.

17.1.3.2.4. Manage tenants

17.1.3.2.4.1. Manage tenant replicas

You can create replicas in all cluster zones under a tenant. You can create one replica in each zone.

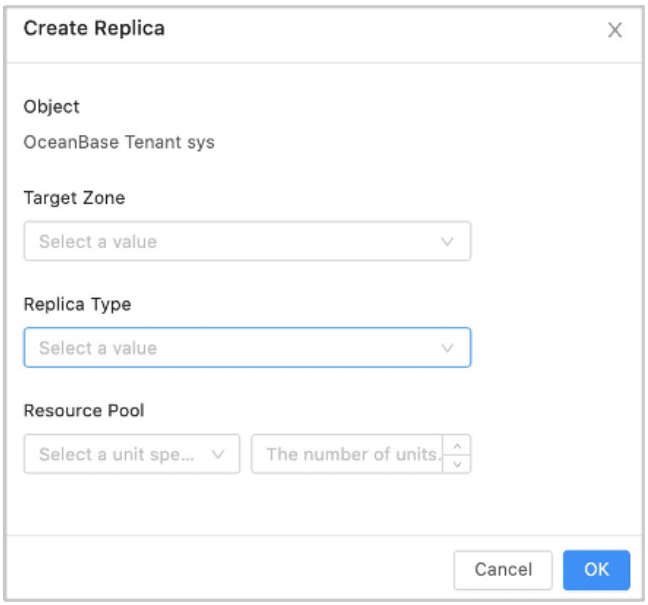
Procedure

- Create a replica
  i. Log on to OCP. In the left-side navigation pane, click **Tenants**.
  ii. In the **Tenants** section, find the tenant that you want to manage, and click the tenant name.
  iii. In the upper-right corner of the page, click **Create Replica**.

> **Note**
> If replicas are created in all cluster zones under a tenant, you cannot create replicas for the zones.

  iv. Specify **Target Zone**, and add a replica to the zone. You cannot select a zone that has an existing replica.

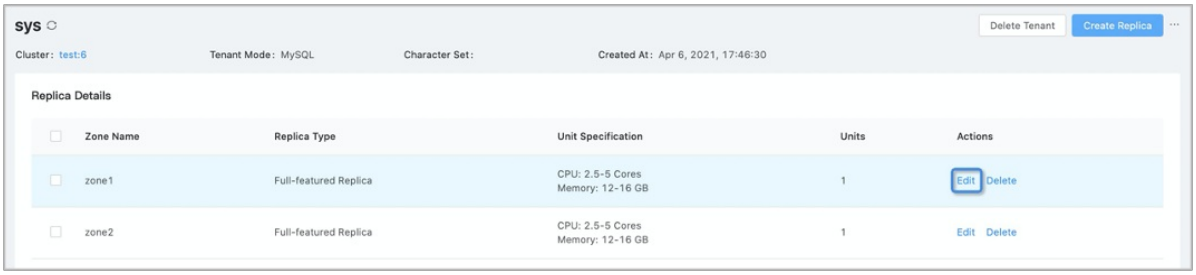
v. Specify **Replica Type** and **Resource Pool**. For more information, see Create a tenant.



vi. Click **OK**.

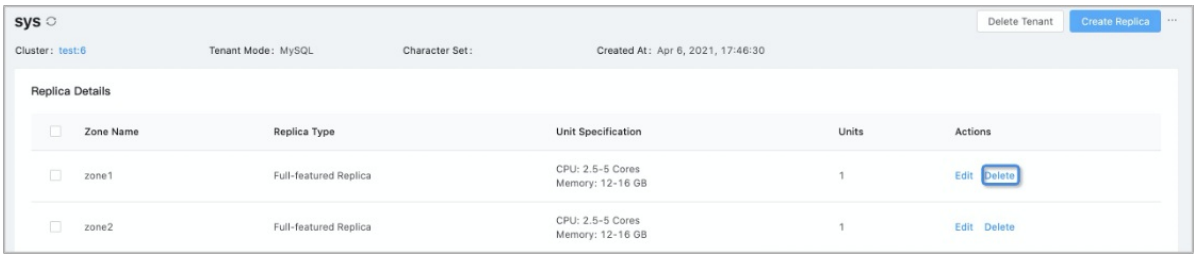
- Edit a replica

  On the tenant overview page, you can view all replicas under the current tenant and the replica details. The Replica Details section displays the distribution of replicas in the zones under the tenant. For example, you can view Zone Name, Replica Type, Unit Specification, and Units. To modify a replica, find the replica that you want to edit, and click **Edit** in the **Actions** column. This allows you to re-configure the replica under the tenant.



- Delete replicas

  You can delete replicas that you no longer need as an administrator. Find the replica that you want to delete, and click Delete in the Actions column. In the message that appears, click Delete to delete the replica from the zone.



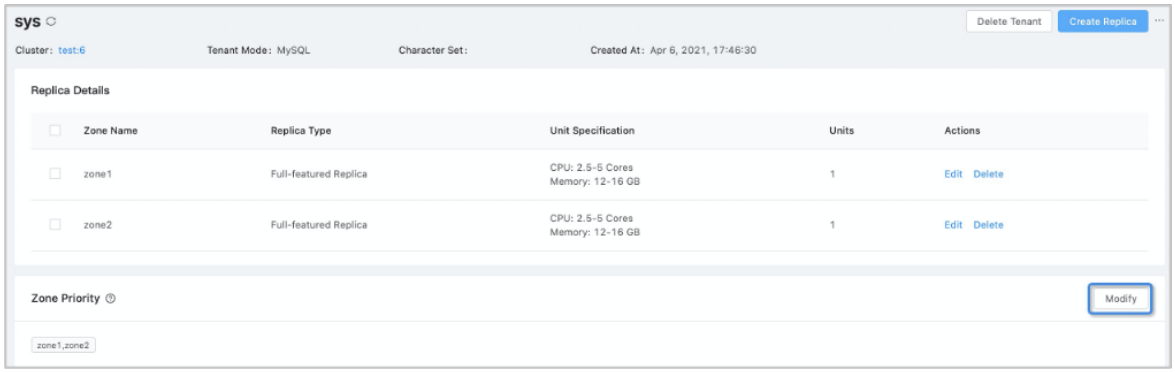
> **Note**
>
> Assume that the system tenant of an ApsaraDB for OceanBase cluster has five replicas in the zones.If two zones are stopped due to exceptions, you cannot delete the replicas. However, you can delete the replicas from the failed zones at a time.

17.1.3.2.4.2. Modify the zone priority

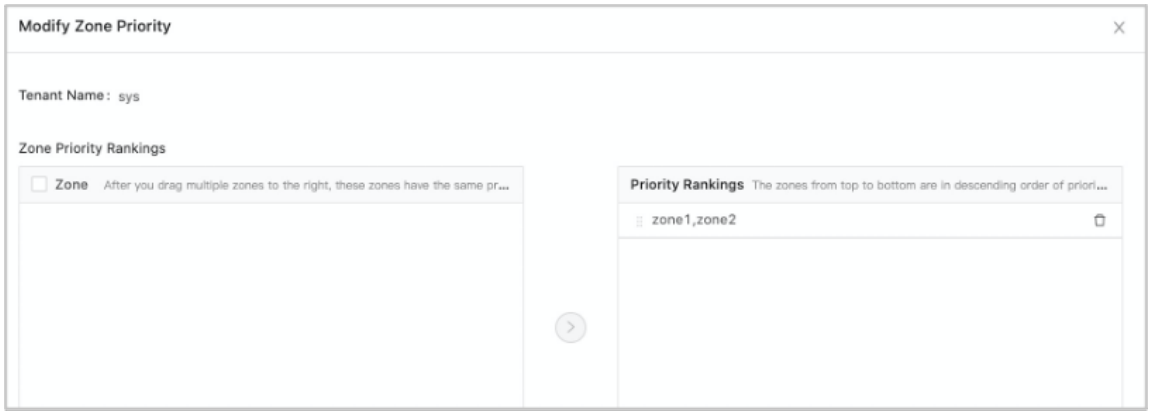
The zone priority specifies the priority of the zones that are to be selected as the primary zone. The replica leader is located in the primary zone. The zone priority is set when you create a tenant. After a tenant is created, you can also modify the zone priority based on your needs.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, click **Tenants**.
3. In the **Tenants** section, find the tenant that you want to manage, and click the tenant name.
4. In the **Zone Priority** section, click **Modify** in the upper-right corner.



5. Reset **Zone Priority Rankings**.
   - You can select multiple zones at a time. After you drag multiple zones to the right at a time, these zones have the same priority.
   - The zones from top to bottom are in descending order of priority. You can drag a zone to modify its priority.



6. Click **OK**.

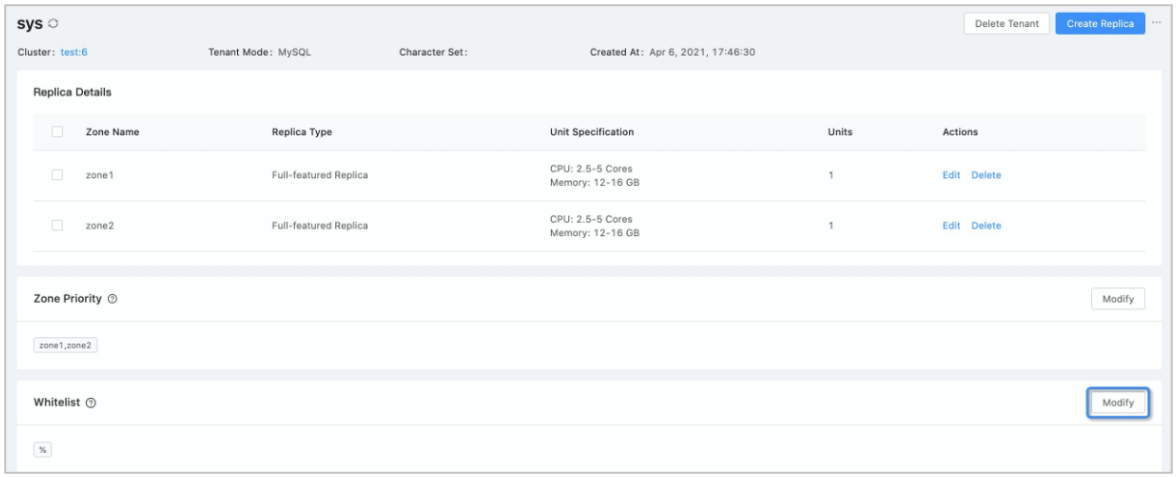
17.1.3.2.4.3. Modify the tenant whitelist

The tenant whitelist is a list of IP addresses that can connect to the tenant. Assume that you do not configure a tenant whitelist when you create a tenant or you want to modify the tenant whitelist. In this case, you can modify the whitelist on the tenant overview page.

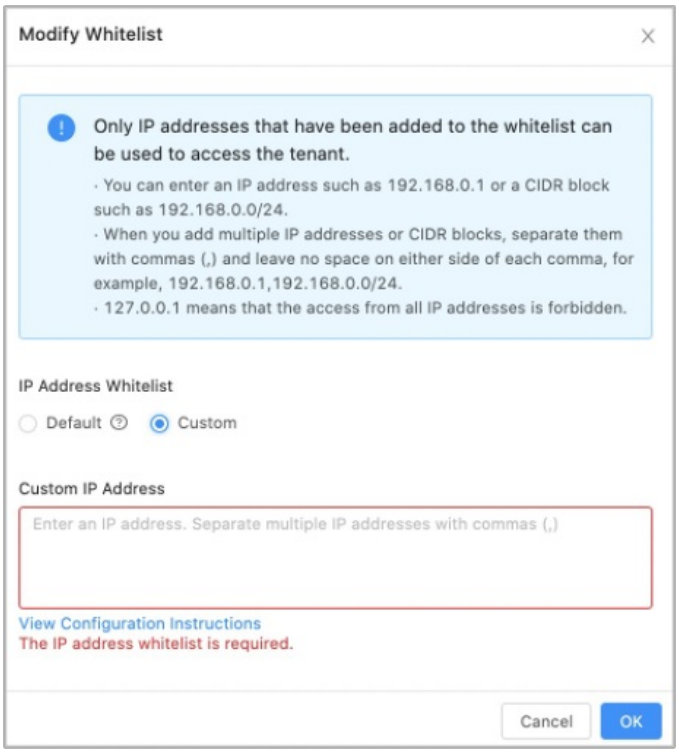
Procedure

1. Log on to OCP.

2. In the left-side navigation pane, click **Tenants**.
3. In the **Tenants** section, find the tenant that you want to manage, and click the tenant name.
4. In the **Whitelist** section, click **Modify** in the upper-right corner.



5. Configure a whitelist.
   - **Default**: All IP addresses can connect to the tenant.
   - **Whitelist**: Only IP addresses in the whitelist can connect to the tenant.Re-configure the whitelist based on the instructions on the page. The whitelist can contain up to 128 characters.



6. Click **OK**.

17.1.3.2.4.4. Change a password

In MySQL mode, the administrator account is the root user. In Oracle mode, the administrator account is the system user. On the Overview page of the specified tenant, you can reset the administrator password for the tenant as a system administrator or tenant administrator.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, click **Tenants**.
3. In the **Tenants** section, find the tenant that you want to manage, and click the tenant name.
4. In the upper-right corner of the page, click the More icon and select **Change Password**.
5. In the Change Password dialog box, enter and confirm the new password.
6. Determine whether to select the **Set the default connection information and save it to the password box** check box.

   We recommend that you select the check box. In this case, when you log on to OCP under the tenant next time, you can use the new password to log on to the cluster.
7. Click **OK**.

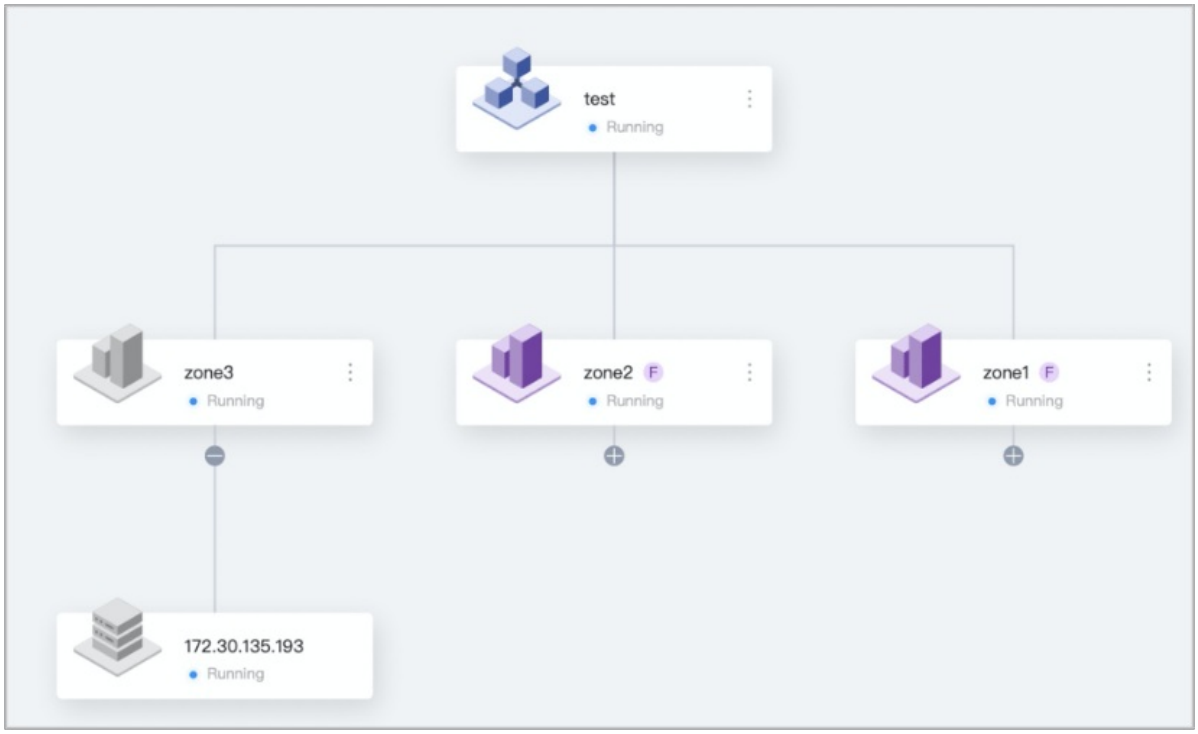
17.1.3.2.4.5. View a tenant topology

After you log on to OCP, click Tenants in the left-side navigation pane to go to the Tenant Overview page. In the left-side navigation pane, click Topology to view the topology of the current tenant.

The topology displays the distribution of replicas in the cluster under the tenant. In the upper-right corner of the page, you can resize or refresh the topology.

The topology displays information at three layers:

- The cluster layer
- The zone layer
- The server layer

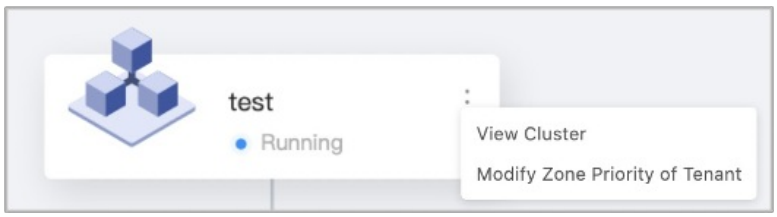


Cluster

The cluster layer displays the name of the cluster under the tenant and the current status of the cluster.

To perform more operations, click the More icon in the upper-right corner.

- To view the cluster topology, click **View Cluster**.
- To modify the zone priority, click **Modify Zone Priority of Tenant**.

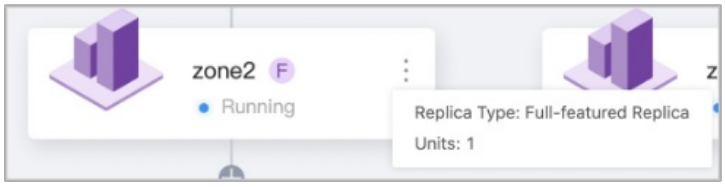


Zone

The zone layer displays the name and current status of the zone.

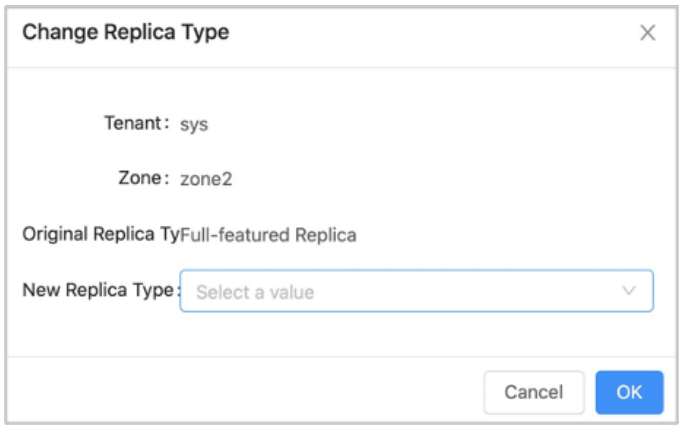
If a zone under the tenant has a replica, the zone is displayed in purple. You can view the abbreviation of the replica type next to the tenant name. If no replica is created in a zone, the zone is displayed in gray.

- If you move the pointer over the zone icon, you can view the replica type and number of units in the zone.

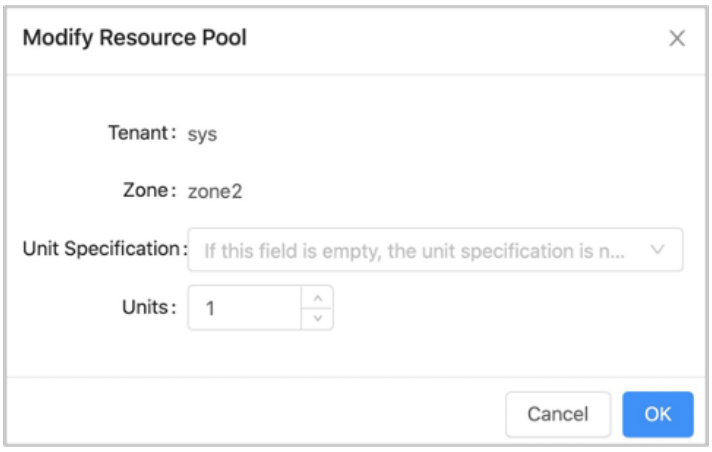


- To perform more operations, click the More icon in the upper-right corner.

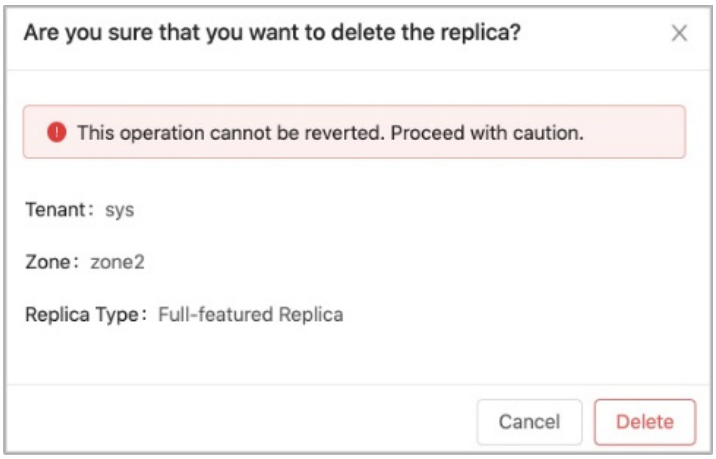
  - To modify the replica type, click **Change Replica Type**. The following dialog box appears.



- To modify the resource pool of a zone under the tenant, click **Modify Resource Pool**. The following dialog box appears.



- To delete a replica, click **Delete Replica**. In the message that appears, click **Delete**.



Server

The server layer displays the IP address, port number, and current status of a server.

If a server under the tenant has a unit, the server icon is green. Otherwise, the server icon is gray.

To perform more operations, click the More icon in the upper-right corner of the server icon.

You can delete a unit. In the message that appears, click **Delete** to delete the specified unit.

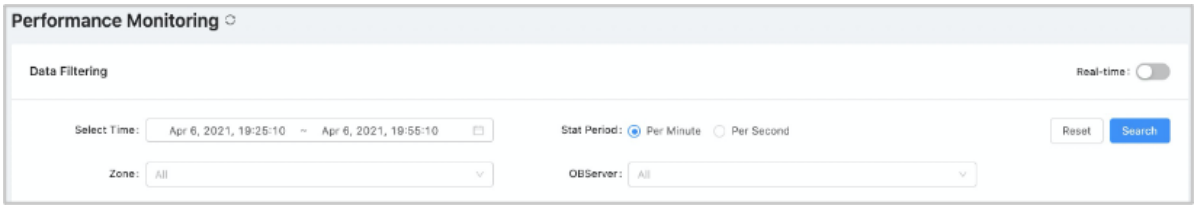
17.1.3.2.4.6. View the performance monitoring data

The Performance Monitoring page displays the performance monitoring data. This topic describes how to filter performance data and view tenant monitoring metrics.

Filter data

You can filter tenant performance data from multiple dimensions based on your needs.

- **Select Time**: You can specify a time range. Data generated during this range will be returned.
- **Stat Period**:
  - The statistical period of each data point. You can select Per Minute or Per Second. Per Minute indicates that a data point is created per minute, and Per Second indicates that a data point is created per second. OCP also calculates a statistical period based on the specified time range.
  - The calculation rule is to return about 1440 data points. If you specify a wide time range, the statistical period may be longer than 1 minute.
- **Zone**: View the performance monitoring data in a specified zone.
- **OBServer**: View the performance monitoring data in a specified OBServer.

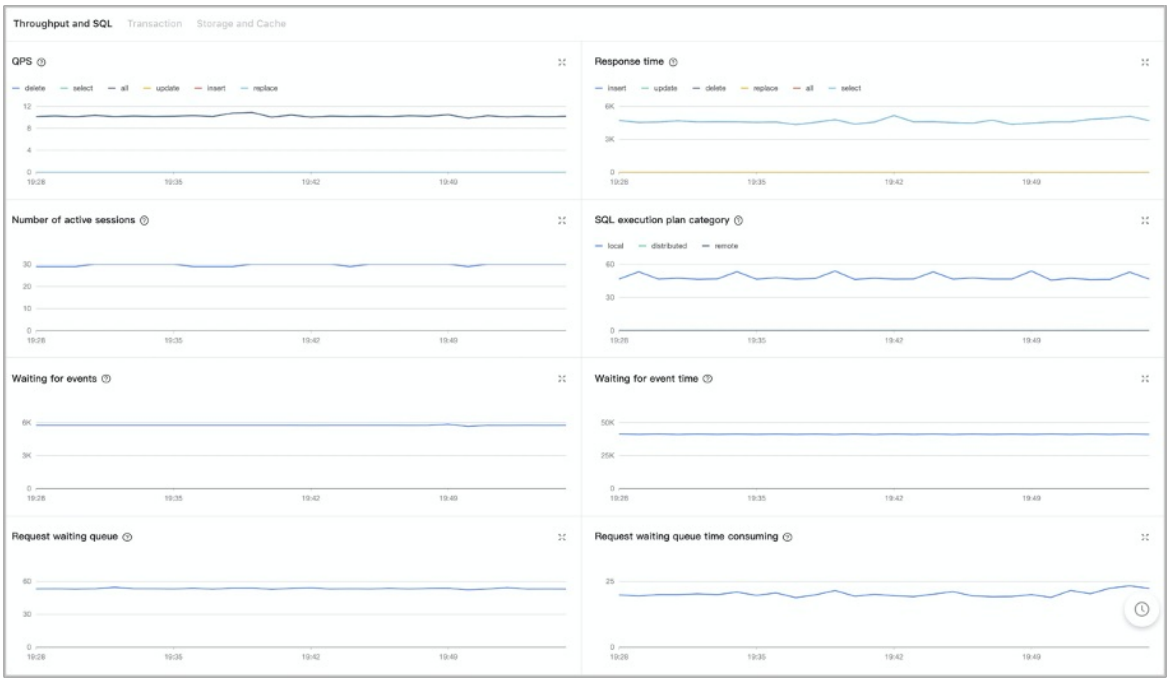


OCP allows you to view tenant performance monitoring data in real time. In the upper-right corner of the page, turn on the **Real-time** switch to view monitoring data in real time. OCP refreshes data on a regular basis based on the specified refresh frequency. By default, OCP displays data that is collected per second in the last two minutes. Refresh Frequency can be 10 Seconds or 1 Second.

Tenant monitoring metrics

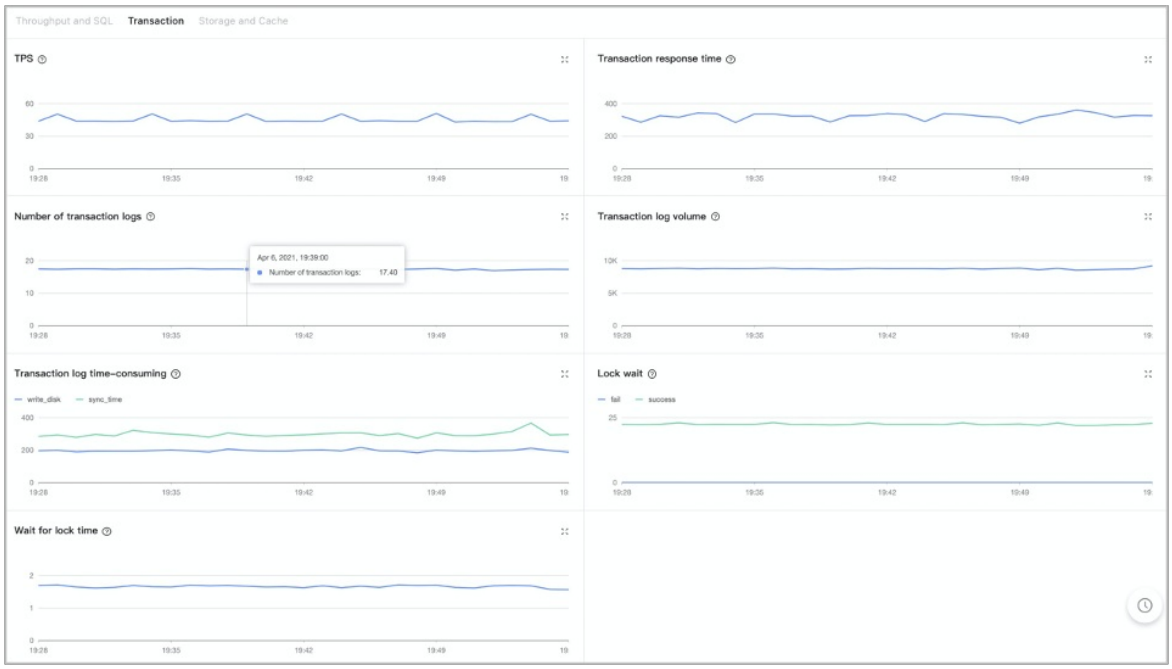
- The Throughput and SQL tab displays the following monitoring metrics:
  - QPS: the average number of SQL statements that are processed per second.
  - Response Time: the response time. The unit is microsecond.
  - Active Sessions: the number of active sessions.
  - Category of SQL Execution Plans: the category of SQL execution plans.
  - Wait Events: the number of wait events per second.
  - Time That Is Consumed by Wait Events: the average time consumed by wait events. The unit is microsecond.
  - Wait Queue of Requests: the number of SQL requests that enter the wait queue per second.

- Time That Is Consumed by the Wait Queue of Requests: the wait time of SQL requests in the wait queue. The unit is microsecond.

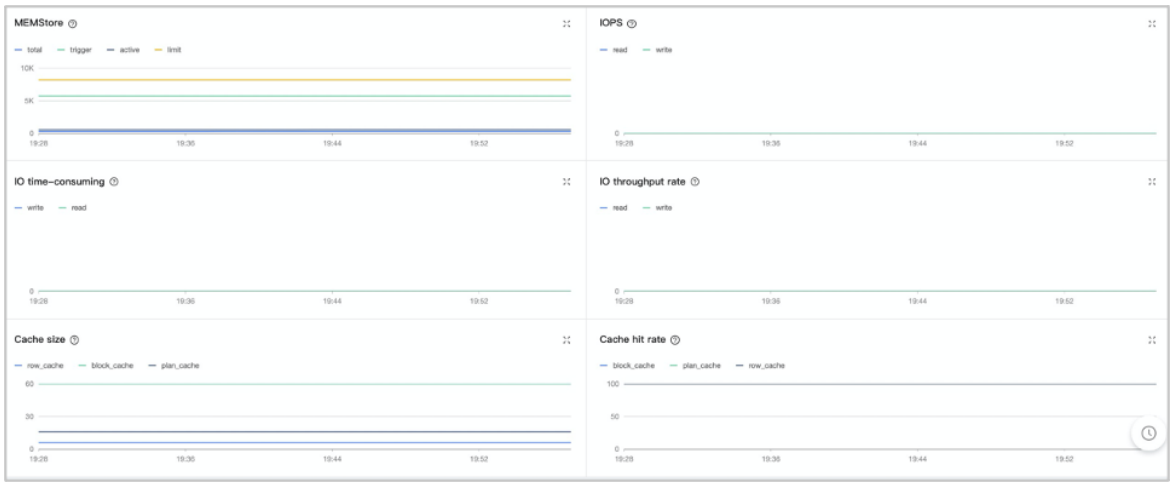


- The Transaction tab displays the following monitoring metrics:
  - TPS: the average number of transactions processed per second.
  - Response Time of Transactions: the average time for processing each transaction on a server. The unit is microsecond.
  - Number of Transaction Logs: the number of transaction logs that are committed per second.
  - Volume of Transaction Logs: the size of transaction logs that are committed per second. The unit is byte.
  - Time Consumption of Transaction Logs: the average time for processing transaction logs on a server. The unit is microsecond.
  - Lock Wait: the number of lock waits for a transaction per second.

- Time That Is Consumed by Waiting for Locks: the average time for lock waits. The unit is microsecond.



- The Storage and Cache tab displays the following monitoring metrics:
  - MEMStore: the size of memory that stores data written into ApsaraDB for OceanBase. The unit is MB.
  - IOPS: the average I/O operations per second.
  - I/O Time: the average time for each I/O operation. The unit is microsecond.
  - I/O Throughput Rate: the average amount of data that is processed by each I/O operation per second. The unit is byte.
  - Cache Size: the cache size. The unit is MB.
  - Cache Hit Rate: the cache hit ratio.



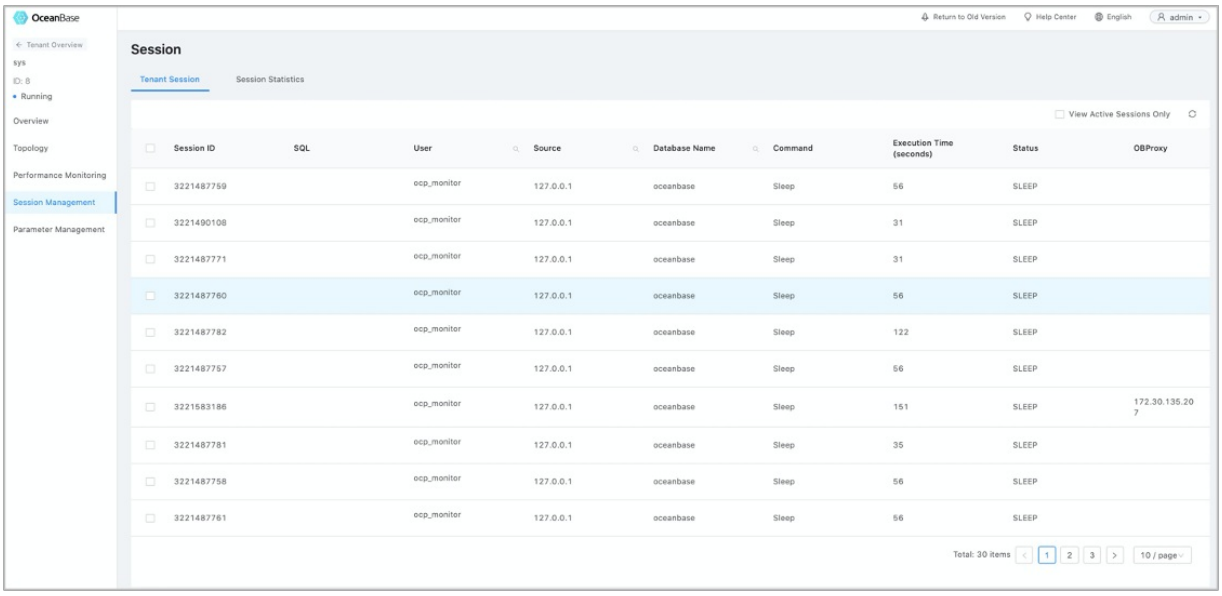
17.1.3.2.4.7. Manage sessions

View tenant sessions

After you log on to OCP, click Tenants in the left-side navigation pane. By default, the Tenant Overview page appears. In the left-side navigation pane, click Session Management. By default, all sessions under the current tenant appear. You can click the refresh button in the upper-right corner to refresh the page.

View sessions

The **Tenant Session** tab displays all current sessions under the tenant. You can view Session ID, SQL, User, Source, Database Name, Command, Execution Time (seconds), Status, and OBProxy.

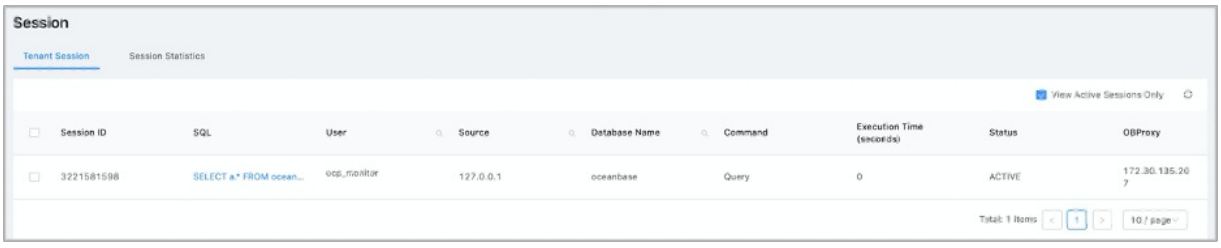


Retrieve sessions

You can retrieve sessions in the User, Source, or Database Name column. To open the search box, click the search icon to the right of each column name.

View active sessions

Assume that you have selected the **View Active Sessions Only** check box in the upper-right corner of the Tenant Session tab. In this case, the sessions are filtered by status. Only sessions in the **ACTIVE** state appear.

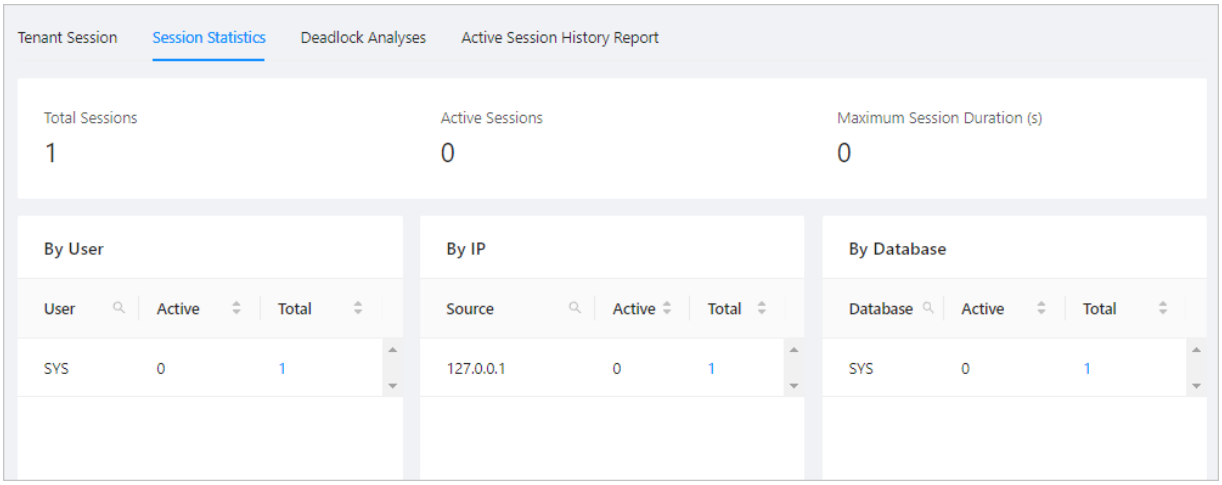


View session statistics

On the left side of the tenants overview page, click Session Management. By default, all sessions of the current tenant is displayed. Click Session Statistics to go to the Session Statistics tab. The statistics of all sessions of the current tenant are displayed on the page.

The statistics include the overall information of sessions, such as the **Total Sessions, Active Sessions, and Maximum Active Session Duration**. You can calculate the **Active Sessions** and **Total Sessions** of a user **By User**, **By IP**, or **By Database**.

> **Note**
>
> The by IP feature is available only in OceanBase 2.2.30 or later.



17.1.3.2.4.8. Parameter management

View the parameters

You can view the name, category, value type, value range, default value, current value, and description of each parameter of the current tenant. You can also view whether the parameter takes effect after the OBServer is restarted. The search box above the list supports fuzzy search by parameter name.

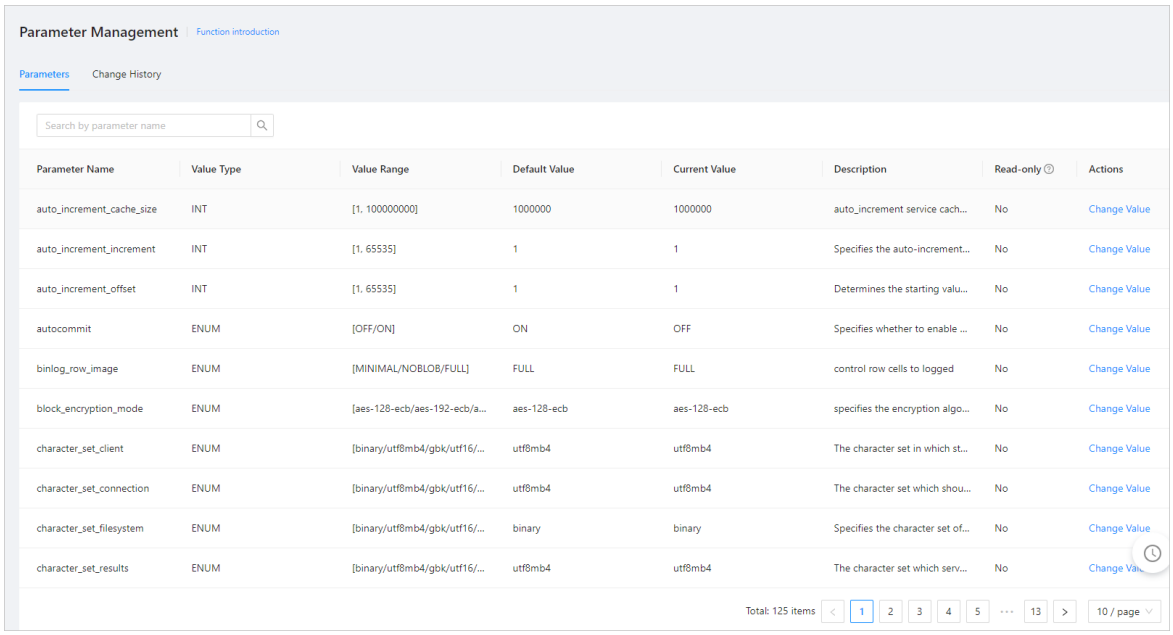
Prerequisites

The password of the root user of the tenant stored in the password box is correct and the tenant whitelist is configured correctly.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, click **Tenants**. In the Tenants, click the name of the tenant that you want to view.
3. In the left-side navigation pane of the page that appears, click **Parameter Management**.
4. On the **Parameters** tab, you can view the information of all parameters in the cluster.
   - The information displayed includes the parameter name, value type, value range, default value, current value, description, and whether the parameters are read-only.

- The **Default Value** indicates the default value of the new tenant. Read-only indicates whether the parameter can be modified. If the parameter is editable, the Change Value button is displayed in the **Actions** column.

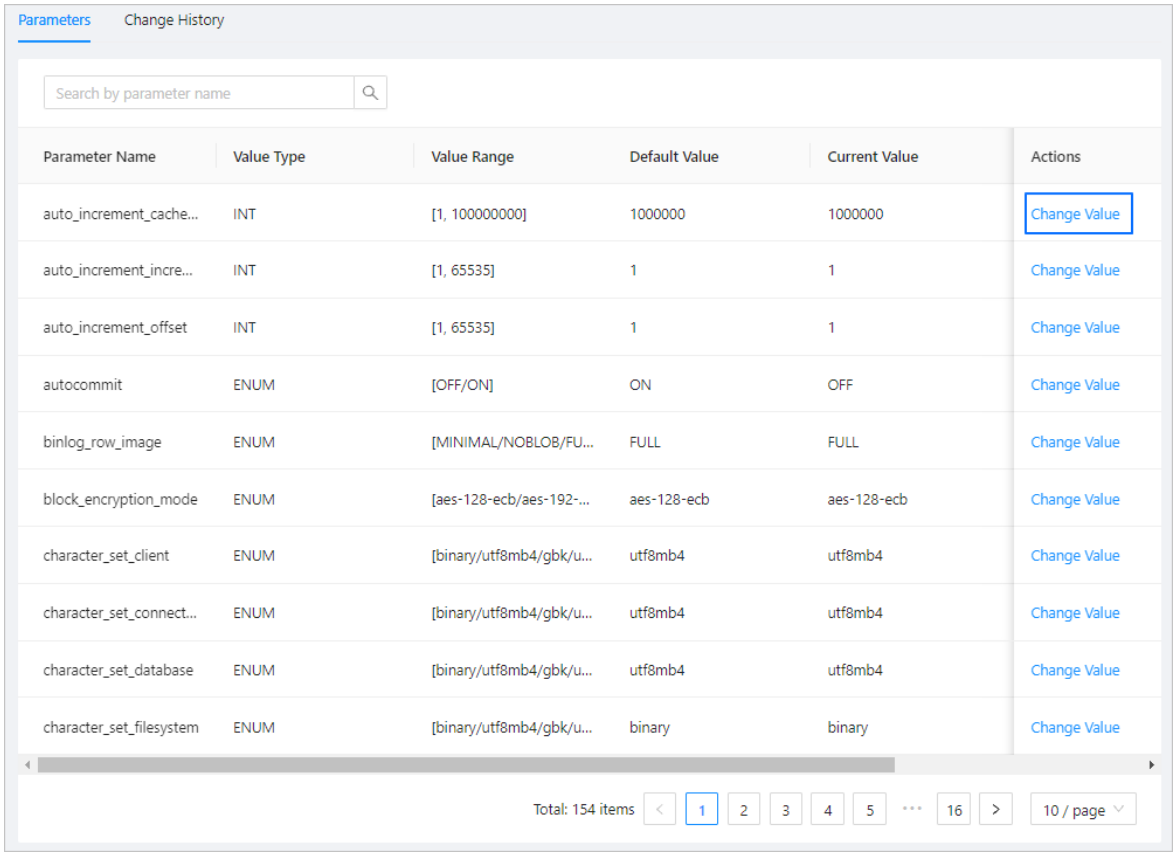


Modify a parameter

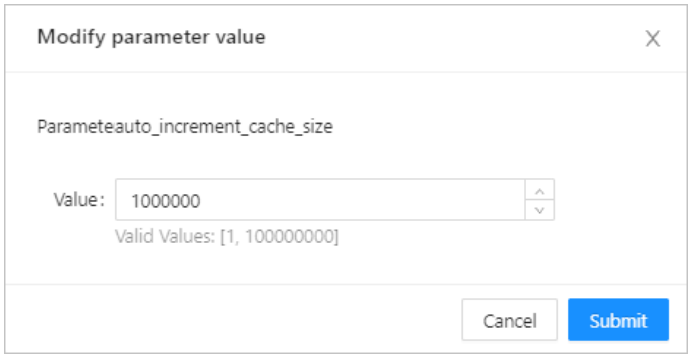
You can modify the tenant parameter values as needed. All changes to the parameter values take effect in real time.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the left-side navigation pane, click **Tenants**.
3. In the **Tenants** section of the **Tenant Overview** page, click the name of the tenant that you want to manage.
4. In the left-side navigation pane of the page that appears, click **Parameter Management**.
5. Optional. In the upper-right corner of the **Parameters** page, enter a keyword in the search box to search for parameters whose names meet specified conditions.
6. Find the parameter you want to modify and click the Modify icon.



7. In the dialog box that appears, modify the parameter value.



8. Click **OK**.

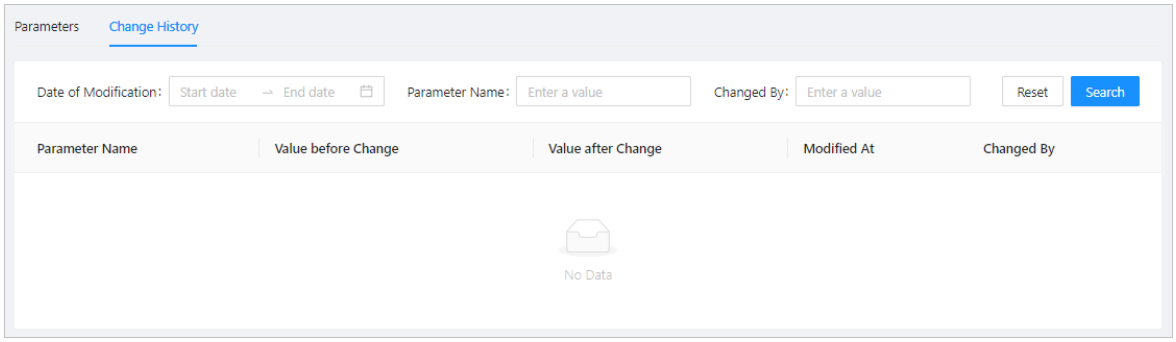
View the parameter modification history

On the Change History tab, you can view the modification records of the parameters of a tenant. The information includes the parameter name, value before and after change of each parameter, the time when a parameter is modified, and the operation user.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the left-side navigation pane, click **Tenants**.
3. In the **Tenants** section of the **Tenant Overview** page, click name of the tenant that you want to view.
4. In the left-side navigation pane of the page that appears, click **Parameter Management**.
5. Click the **Change History** tab.
6. You can filter parameters by specifying **Date of Modification**, **Parameter Name**, or **Changed By**.

The **Parameter Name** field supports fuzzy match. However, the **Changed By** field supports only exact match.



7. In the search results, view the history of parameter changes.

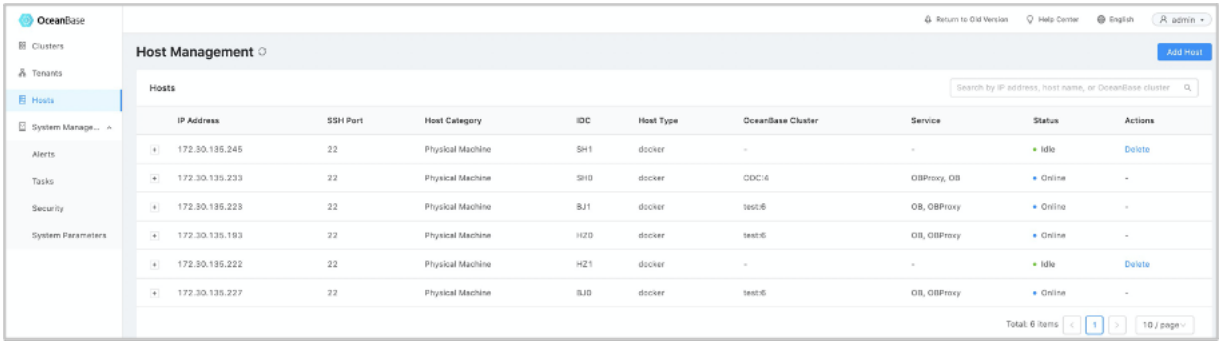
17.1.3.3. Host management

17.1.3.3.1. View host information

Host overview

If you are granted the system administrator or the HOST_MANAGER role, you can click **Hosts** in the left-side navigation pane to go to the Host Management page. The **Hosts** section displays the information about all hosts at the current point in time. You can view IP Address, SSH Port, Host Category, IDC, Host Type, OceanBase Cluster, Service, and Status, as shown in the following figure. You can perform paged queries. You can also search based on host IP addresses, host names, and names of ApsaraDB for OceanBase clusters.

You can expand the collapsed section to view Host ID, Host Name, Operating System, Mapping Port (Host:Container), and Description.



Host status

The host status is an important identifier for monitoring hosts and services running on hosts. OCP supports the following host statuses:

- **Newly Submitted**: The OCP-Agent is to be installed and started on the host.
- **Available**: The host is available for other services.
- **Online**: One or more services are running on the host.
- **Offline**: The host fails to be connected or monitored.
- **Deleting**: The configurations and services on the host are being deleted by OCP.

Host type

The current version supports two types of hosts: physical hosts and container hosts.

- You can deploy multiple services on a physical host. However, to avoid conflicts between services of the same type, you can deploy only one service for each type.
- You can deploy only one service on a container host. Based on the deployment requirements for ApsaraDB for OceanBase clusters, we recommend that you do not deploy ApsaraDB for OceanBase clusters on container hosts.

Port mapping of container ports

OCP servers must initiate remote operations and monitoring to the host irregularly. Container hosts must use the following "port mapping" method based on Docker: Access the IP address and port of the host from the OCP server and map them to the internal port of the Docker container.

By default, four port mappings are needed when you add a container host. The four mappings are created between the ports of processes running in the container and the host ports in the following format:

```
 <Host port>:<Docker port>,<Host port>:<Docker port>. The processes include ocp-agent and node exporter
```

.

The following table describes the mappings.

Service	Container port number	Whether same to the host port	Remarks
OCP-Agent	62888	No	None
OBProxy monitoring	From 62881	No	First available port starting from 62881

17.1.3.3.2. Delete hosts

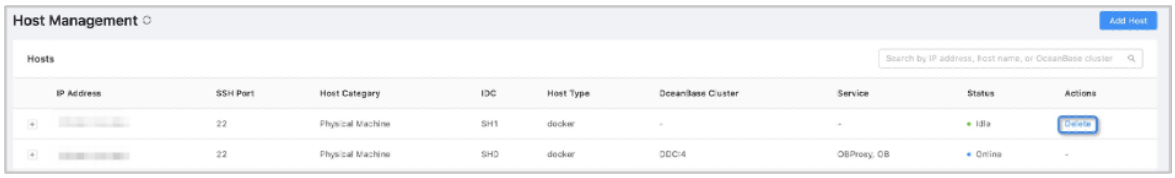
If the Hosts page displays hosts in different states, the shortcut operations Delete and Force Delete are displayed in the Actions column of some hosts in specific states. This indicates that the hosts in the online state can be deleted. The hosts in the newly submitted and offline states can be forcibly deleted.

> Notice
>
> - If you forcibly delete a host, the background tasks related to the host may be interrupted. The services and agent programs running on the host may not be successfully released. Therefore, we recommend that you restore the host to the "online" state before deleting it.
> - We also recommend that you manually check the services and processes running on the host and perform necessary cleanup, such as forcibly stopping processes, removing installation packages, and removing files.

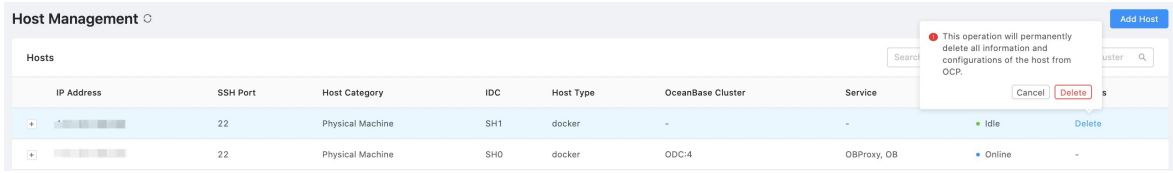
Procedure

1. Log on to OCP.
2. In the left-side navigation pane, click **Hosts**.
3. Find the host that you want to delete forcibly in **Hosts**.

4. In the Actions column, click **Force Delete**.



5. In the message that appears, click **Force Delete**.



17.1.3.4. Alert management

17.1.3.4.1. Overview

This topic describes how OCP enables the alert feature to generate alerts and send notifications when an exception is detected in an ApsaraDB for OceanBase cluster or application.

Core features

- Generate alerts based on alert rules.
- Aggregate alert events to avoid generating a large number of notifications.
- Configure the format and content of alert notifications based on templates.
- Configure alert notification channels. You can configure the HTTP and script channels.

Quick start

Alerts and alert notifications are key features for OCP to monitor service statuses. The users of different roles must perform different operations to use the features.

After OCP is deployed, you must initialize the Alerts module as an administrator. For example, you can add alert items and configure alert channels. You must also manage the existing alert items and channels based on business requirements. OCP allows you to subscribe to alert notifications, and view alert events and notifications for different modules. You can also block alerts.

We recommend that you configure the Alerts module on OCP based on the following process:

1. Perform the following steps as an administrator:
   i. Configure alert notification channels.
   ii. Create alert items.
2. Perform the following steps as a common user:
   i. Subscribe to alerts.
   ii. View alert events.
   iii. Optional. Block alerts.

17.1.3.4.2. Alert related concepts

This topic describes the concepts of alert target, alert scope, alert item, alert, alert item group, alert level, template, alert aggregation group, and alert clearance.

Alert target

An alert target is a target that is monitored by the alert task and uniquely identifies an alert. It can be an OceanBase cluster, a server, or a service.

Based on the alert item, an alert target can be a tag value or a combination of tag values, such as `obregion=obocp:svr_ip=*. *. *. *` identifies a server in the OceanBase Cloud Platform (OCP) cluster.

Alert scope

The alert scope defines the scope of an alert and is consistent with the metric scope. For example, when the CPU utilization exceeds the threshold, it can be a problem for the entire cluster, the tenant, or a single server.

Valid values of the alert scope:

- Cluster
- Tenant
- Application Cluster
- Service
- Server
- Process (reserved)

Alert item

An alert item is the metadata of an alert. It consists of many elements such as the alert type, name, trigger rule, overview, and details.

Alert items can be divided into two types based on how they are generated:

- **Expression-triggered alert items**: Alert items that are created on the console and generated by the alert rule engine based on the monitoring metrics.
- **Custom-triggered alert items**: Alert items that are automatically triggered by other components.

For expression-triggered alert items, the alert rule expressions are configured in the alert items. For custom-triggered alert items, the alert rule expressions are empty.

Alert

An alert is a notification generated by the system when an alert item occurs on a notification target.

For example, when the alarm_b alert item occurs on Server A (an alert target), the alert signal is sent every minute. However, it is counted as one alert on OCP, and only one record is displayed on the Alert Events page.

Alert item group

You can set multiple groups for each alert item for easy configuration of alert subscriptions.

Alert level

Each alert item has an alert level.

Level	Meaning	Color	Description

Level	Meaning	Color	Description
1	Stopped	Purple	The system is completely unavailable and needs immediate recovery. For example, `OBService cannot be started.`
2	Critical	Red	The system availability decreases and the necessary measures must be taken to prevent the system from becoming completely unavailable. For example, `the server memory usage exceeds the threshold of 90% and this condition has lasted for 3 minutes.`
3	Warning	Orange	The system is still available but it is about to become unavailable. You must take measures to prevent the reduction of availability. For example, `the proportion of connections of an OceanBase tenant exceeds the threshold of 80%.`
4	Caution	Blue	Based on the trend, you can tell that the important performance metrics of the system are declining. You can locate potential problems through troubleshooting to prevent the trigger of alerts. This alert level is reserved but no alert matches this level at present.

Level	Meaning	Color	Description
5	Reminder	Green	Technically, a reminder is not an alert. It usually indicates that an administrator has performed an important action. For example, `the administrator deleted a cluster.`

Templates

Templates are used to generate dynamic content using variables during the runtime. They can be used for:

- Generating alerts (configuring the alert overview and details templates for alert items)
- Notifications (configuring the message and message aggregation templates for channels)
- Channel parameters (for example, configuring the Header and Body content templates in the HTTP channel)

Sample template:

- alarm_summary:

  ```
  The CPU utilization of ${alarm_targe} exceeds the threshold.
  ```

- alarm_description:

  ```
  The CPU utilization of ${alarm_targe} exceeds the threshold of ${alarm_threshold} for ${alarm_duration}
  ```

  .

For more information about the supported template variables, see Appendix 4. OCP alert template variables.

Alert aggregation

To avoid alert storms caused by too many alerts, you can aggregate the alert channels.

Aggregation rules:

- Aggregate OceanBase log alerts by alert type, log error code, and OceanBase cluster.
- Aggregate other OceanBase alerts by alert type and OceanBase cluster.
- Aggregate application alerts by alert type and alert target.

Alert clearance

An alert is cleared when a fault is recovered. After that, the monitoring module identifies that the fault is resolved and notifies the alert service, or the alert service clears the alert automatically after the clearance timeout expires.

The logic of clearing alerts after a timeout period:

- Each alert item has a check cycle and ignorance cycle.
- During the new check cycle, the monitoring module calls the alert API to set the alert item as cleared if it finds that the alert item meets the clearance criteria.
- When the ignorance cycle expires, the alert item is considered cleared if the alert item is no longer reported.

17.1.3.4.3. Configure alert items

17.1.3.4.3.1. Create an alert item

This topic describes how to create an alert item.

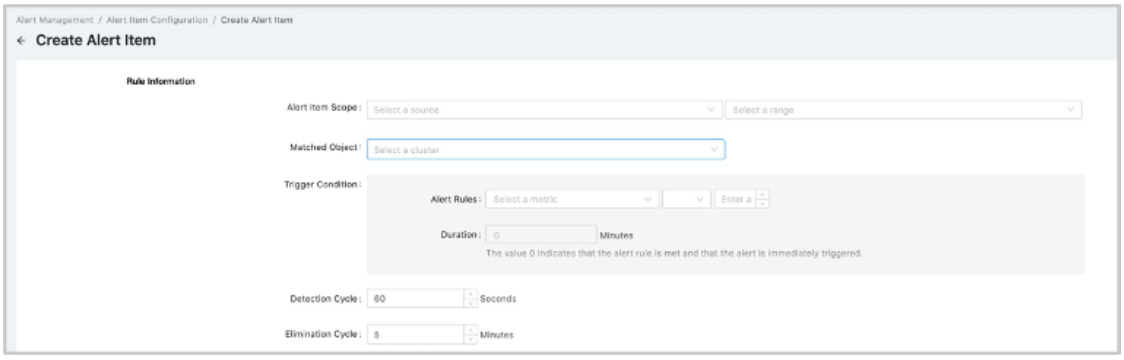
Prerequisites

The current logon user are granted the ADMIN or ALARM_MANAGER role.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management** > **Alerts**.
3. On the Alert Item Configuration tab, click **Create Alert Item** in the upper-right corner.
4. Configure the Rule Information for the alert item.
   i. Configure the Alert Item Scope.
   ii. Configure the Matched Object to determine the objects to which the alert rule applies.
   iii. Configure the Trigger Condition.
   - You can select different metrics from the Alert Rules drop-down list based on the scope of alert item.
   - 0 in the Duration field indicates that the alert is immediately triggered. You can set the duration to prevent false positives caused by indicator glitches.

   iv. Configure the detection cycle and elimination cycle.



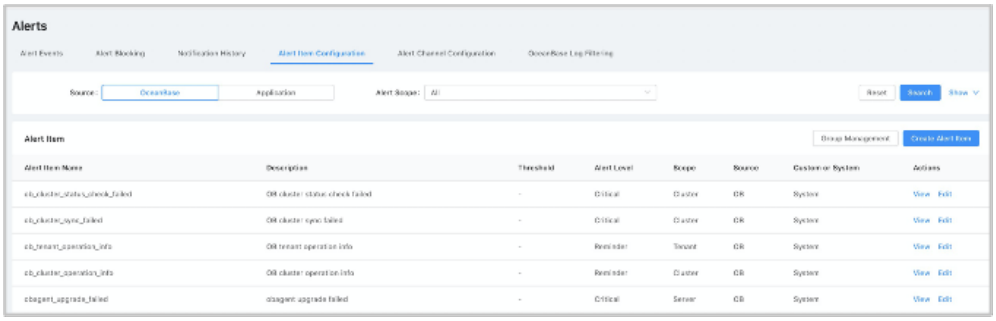
5. Configure the basic information of the alert item.
   i. Configure the Alert Item Name and Chinese name.
   ii. Configure the Alert Level.
   iii. Specify the Alert Overview Template as prompted.
   iv. Specify the Alert Details Template as prompted.
   - The alert overview template is referenced in the template field of a channel and corresponds to alarm_summary.

- The alert details template is referenced in the template field of a channel and corresponds to alarm_description.

6. Click **OK**.

17.1.3.4.3.2. View alert items

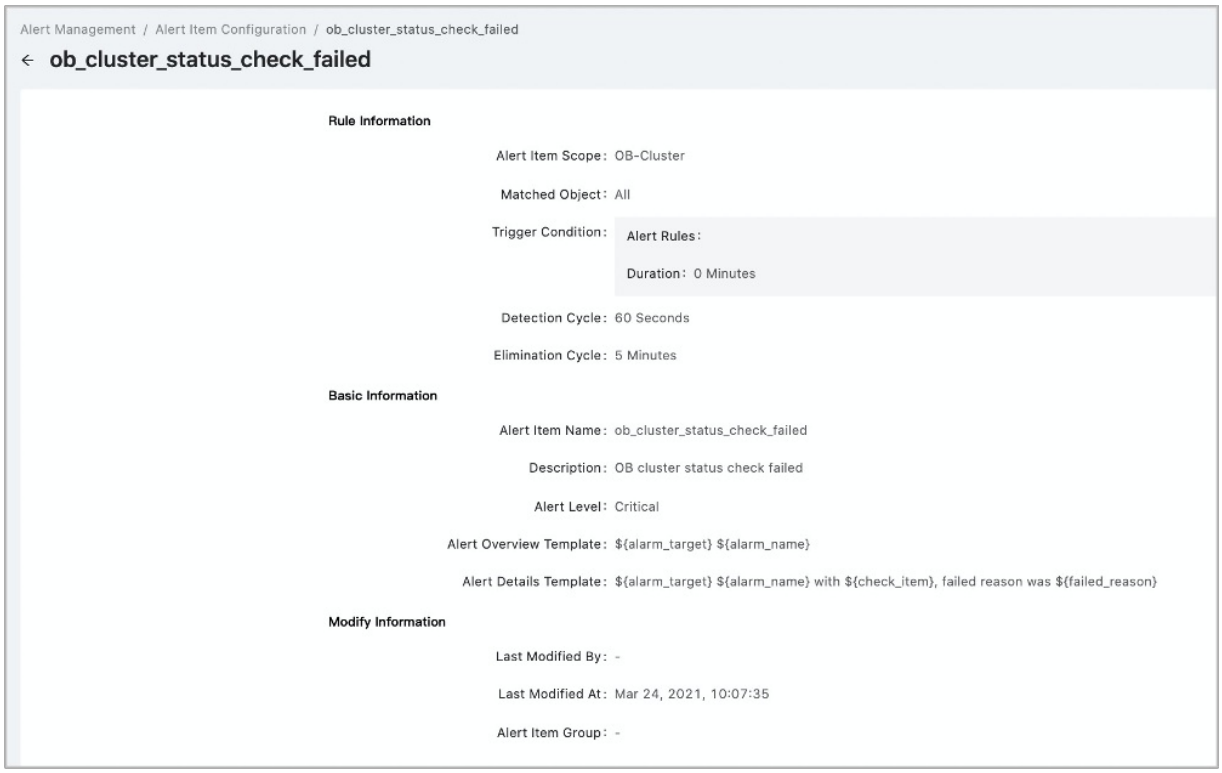
In the left-side navigation pane, choose System Management > Alerts. On the Alert Item Configuration tab, you can view all the existing alert items.



An alert item is displayed in each row of the alert item list. You can view, edit, or delete an alert item in the rightmost **Actions** column.

> **Note**
>
> System alert items cannot be deleted. The edit operation only allows you to modify only a limited number of configuration items, such as the threshold, duration, and alert level.

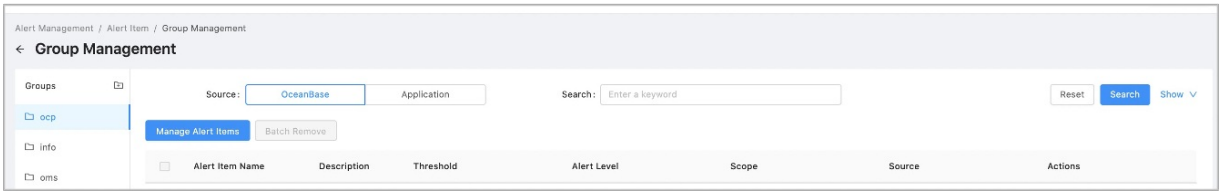
Click **View** to view the detailed configuration information of an alert item.



17.1.3.4.3.3. Group alert items

OCP allows you to classify alert items and assign them into different groups. In this case, you can subscribe to alert notifications in a simple way.

In the left-side navigation pane, choose **System Management > Alerts**. On the **Alert Item Configuration** tab, click **Group Management** to view the groups of all alert items. You can click a group name to view the alert items in the group.



Manage a group

- Retrieve alert items: OCP allows you to use multiple methods to retrieve alert items. For example, you can search for alert items by **source, keyword, application, alert level**, and **alert scope**.
- Group alert items: In the Groups section, click the group name to view the alert items in the group. On the page that appears, click **Manage Alert Items**, and add the alert items in the left-side section to the right-side section.
- Remove alert items from a group: In the Groups section, click the group name to view the alert items in the group. On the page that appears, select the alert items that you want to remove from the group, and click **Batch Remove**.

> **Note**
>
> This operation only removes the alert items from the group, and the alert items are not deleted.

- Create a custom group: In the Groups section, click the Create icon next to Groups, and enter the name of the new group.
- Change a group name: Find the group name that you want to change, click the More icon on the right, and click **Rename**.
- Delete a group: Find the group name that you want to delete, click the More icon on the right, and click **Delete**.

Default groups

The system provides four default groups. You can edit these groups, but cannot delete them.

Group name	Description
dba	The alert items that the database administrator must pay attention to.
dev	The alert items that the developers must pay attention to.
oms	The alert items that the administrator of OceanBase Migration Service (OMS) must pay attention to.
backup	The alert items that the administrator of backup and recovery must pay attention to.
info	The reminders, such as a reminder of O&M operation results.
ocp	The alert items for OCP basic modules, such as host alerts.

17.1.3.4.3.4. Edit an alert item

System administrators and OCP alert administrators can modify an alert item based on business requirements.

Prerequisites

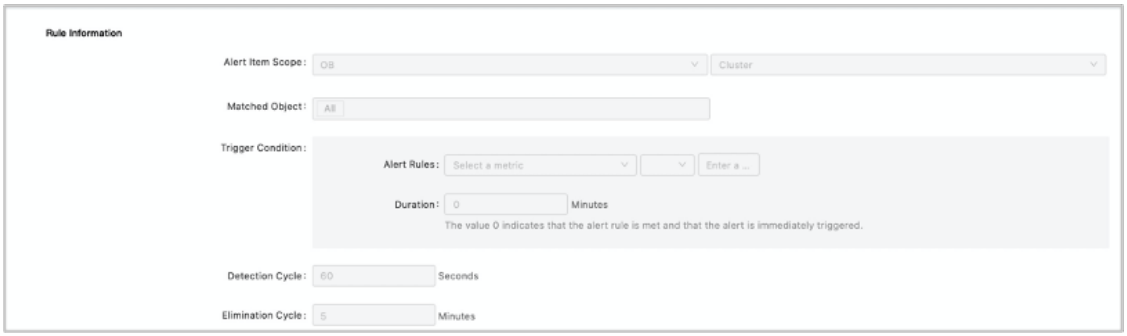
The current logon user is granted the system administrator and OCP alert management roles.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Alerts**.
3. On the **Alert Item Configuration** tab, find the alert item that you want to edit.
4. Reset the Rule Information of the alert item.
   i. Configure the **Alert Item Scope**.
   ii. Configure the **Matching Objects** to determine the objects to which the alert item applies.
   iii. Specify the **Trigger Condition**.
   - You can select different metrics from the Alert Rules drop-down list based on the scope of the alert item.

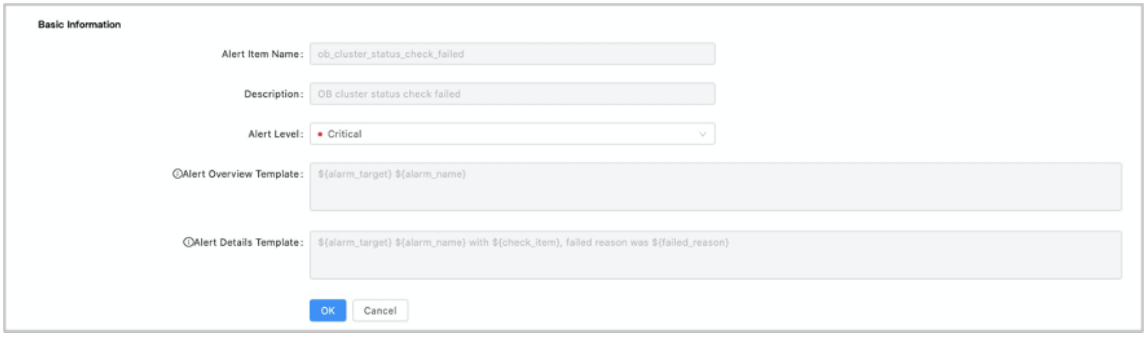
- The value **0** in the Duration field indicates that the alert is immediately triggered. You can specify the duration to avoid false positives due to indicator glitches.

iv. Configure **Detection Cycle** and **Elimination Cycle**.



5. Configure the **Basic Information** of the alert item.
   i. Configure the **Alert Item Name** and Chinese **name**.
   ii. Configure **Alert Level**.
   iii. Specify the **Alert Overview Template** as prompted
   iv. Specify the **Alert Details Template** as prompted.

- The alert overview template is referenced in the template field of a channel and corresponds to alarm_summary.
- The alert details template is referenced in the template field of a channel and corresponds to alarm_description.



6. Click **OK**.

17.1.3.4.3.5. Delete an alert item

You can delete an alert item as a system administrator or an OCP alert administrator based on your needs. Alert items that are predefined by the system cannot be deleted.

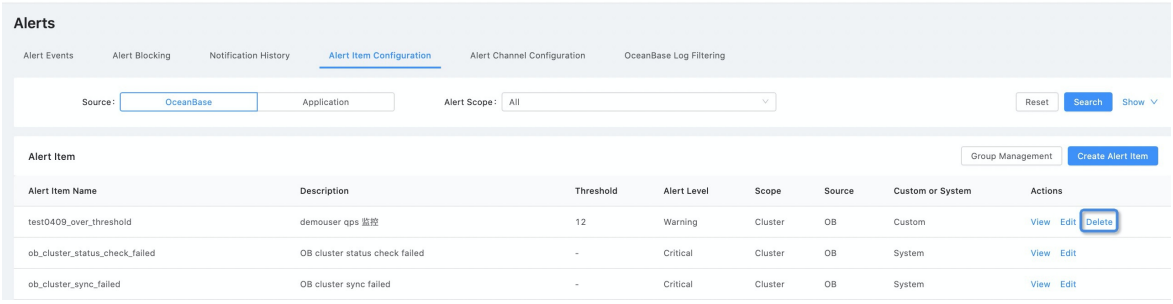
Prerequisites

- The current user you log on to is the ADMIN or ALARM_MANAGER role.
- The alert item that you delete is a custom alert item instead of an alert item that is predefined by the system.

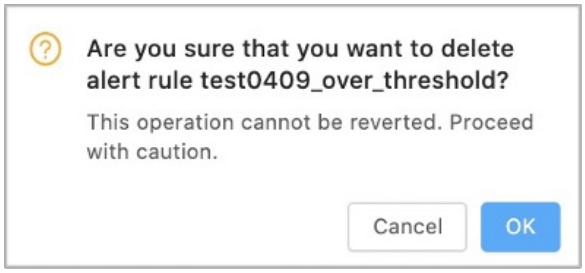
Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Alerts**.
3. On the **Alert Item Configuration** tab, find the alert item that you want to delete.

4. In the Actions column, click **Delete**.



5. In the message that appears, click **OK**.



17.1.3.4.4. Alert channel configuration

17.1.3.4.4.1. Notification channels

Alerting is an independent feature. Before you configure notification channels and subscribe to alerts, you can view alerts only on the Alert Events page of OCP. To receive alert notifications, configure notification channels and subscribe to alerts.

Notification channels are the channels through which alert notifications are sent. You can configure the following types of channels:

- HTTP
- Custom scripts

> **Note**
>
> You can configure the time parameters of the alert aggregation in the channel. After you update the notification channel, its aggregation is restarted. In this case, if a valid alert item exists, you will receive an alert notification in a short while.

17.1.3.4.4.2. Create an alert channel

This topic describes how to create an alert channel.

Alerting is a standalone feature. If you do not configure alert channels or subscriptions, you can view alerts only on the **Alert Events** page of the OceanBase Cloud Platform (OCP) console. To receive alert notifications, you must configure an alert channel and subscribe to an alert.

The alert channel allows OCP to send notifications and supports the following channel types:

- HTTP
- Custom script

> **Note**
>
> You can configure the time variables for alert aggregation when you configure a channel. After an alert channel is updated, the channel restarts alert aggregation. If a valid alert item exists, you may receive alert notifications faster.

Prerequisite

You have configured the basic information of the recipients.

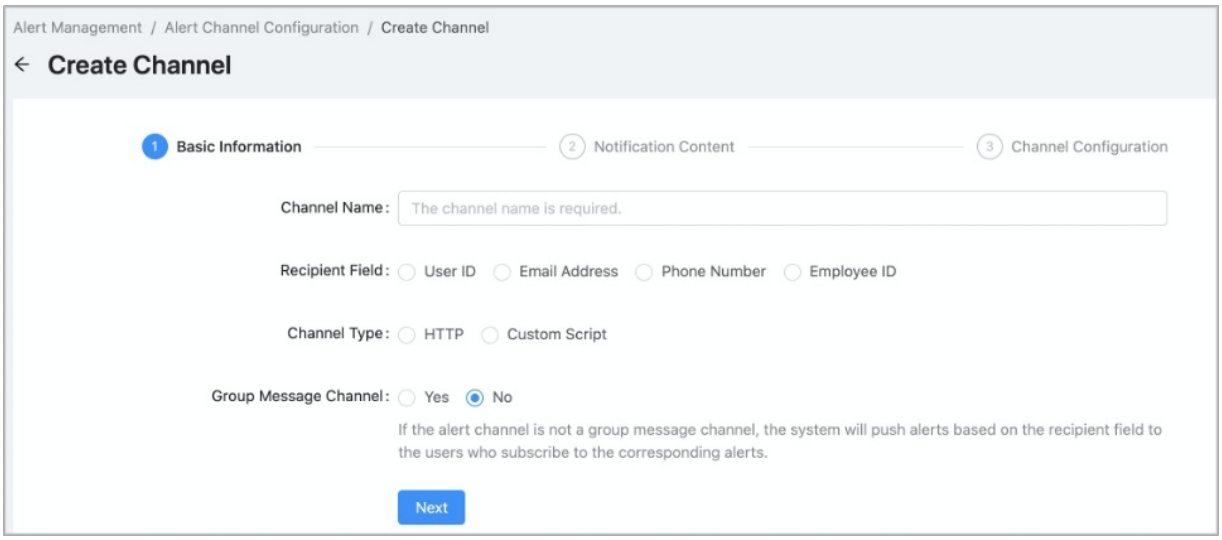
Procedure

1. Log on to the OCP console.
2. In the left-side navigation pane, choose **System Management > Alerts**.
3. On the **Alert Channel Configuration** page, click **Create Channel**.
4. i. Set the Basic Information of the channel.
   a. Enter the **channel name**.
   b. Select the **recipient field**.
   - The recipient field can be set as **User ID, Email Address, Phone Number** or **Employee ID**.
   - The recipient field is associated with the basic information of the OCP user.

   a. Set the notification type.
   - **HTTP**
   - **Custom script**

   a. Specify whether this channel is a **group message channel**.
   - If you select Yes, the system pushes notifications even when no one subscribes to the alerts.
   - If you select No, the system pushes messages to users who have subscribed to the corresponding alerts based on the Recipient Field.

   a. Click **Next**.

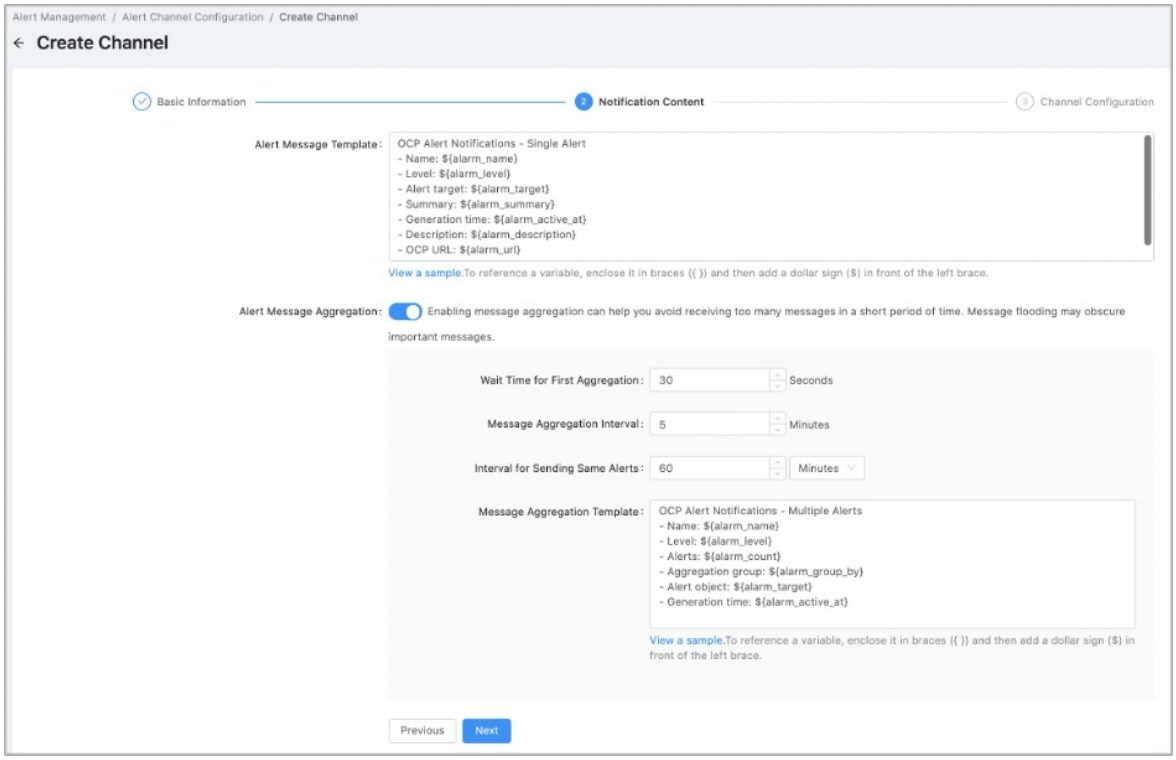


5. Edit the **notification content**.

i. Edit the **alert message template**.
   - Variables are supported in the alert message template.
   - You can customize the alert message template as prompted.

ii. Specify whether to **Enable Alert Message Aggregation**.
   - Alert message aggregation can help you avoid missing important messages when you receive too many messages in a short time. You can check the aggregation rule as prompted
   - If you enable message aggregation, you must also configure the parameters such as the aggregation message template.

iii. Click **Next**.



6. Configure the channel. Configure the parameters for the channel type that you selected. Take the HTTP channel as an example.

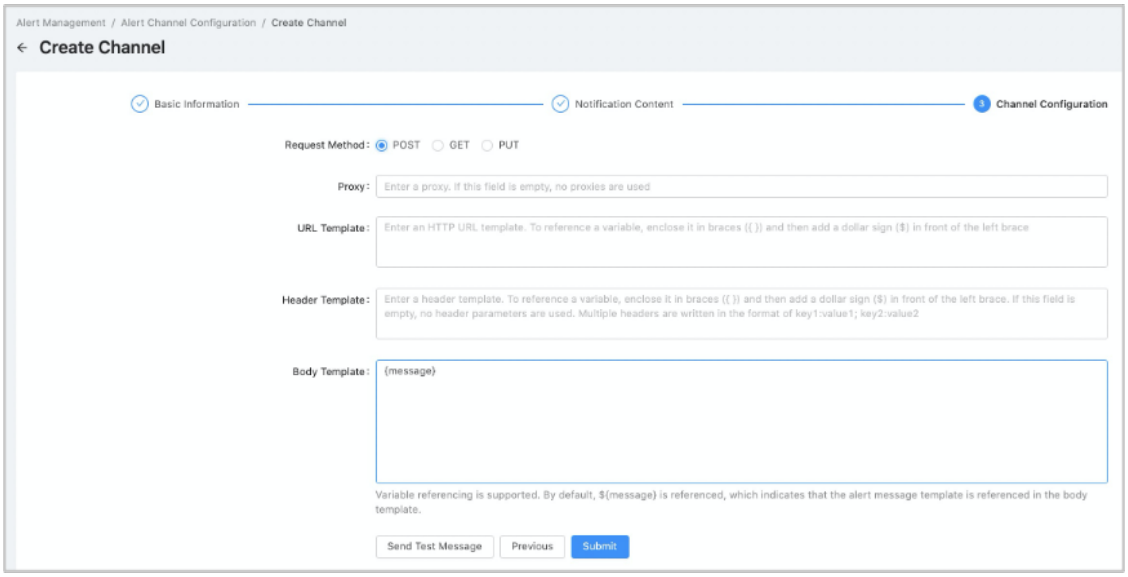
   i. Select the **request method**. The following request methods are supported: POST, GET, and PUT.

   ii. Specify the **proxy**. If you do not specify this field, no proxy is used.

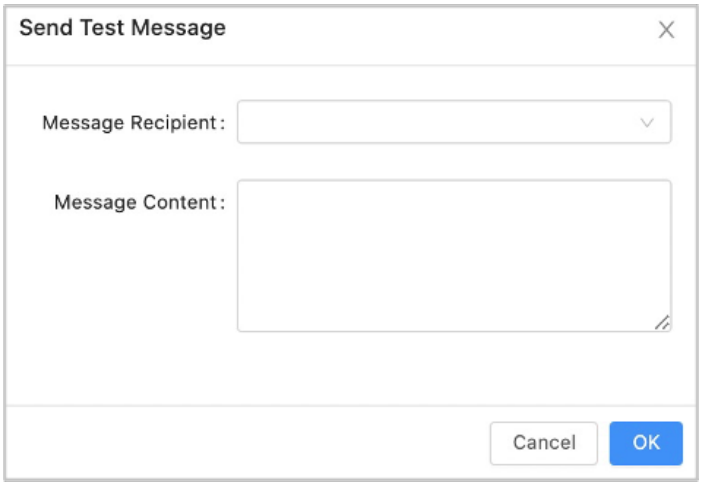
   iii. Edit the **URL template**. You can enter $ and {} to reference variables.

   iv. Edit the **header template**. You can enter $ and {} to reference variables. If you do not specify this field, no header parameter is used.

v. You can reference variables when you edit the **body template**. By default, ${message} is referenced, indicating that the alert message template is referenced in the body template.



vi. Click **Send Test Message**. If the message is sent, click **Submit**.

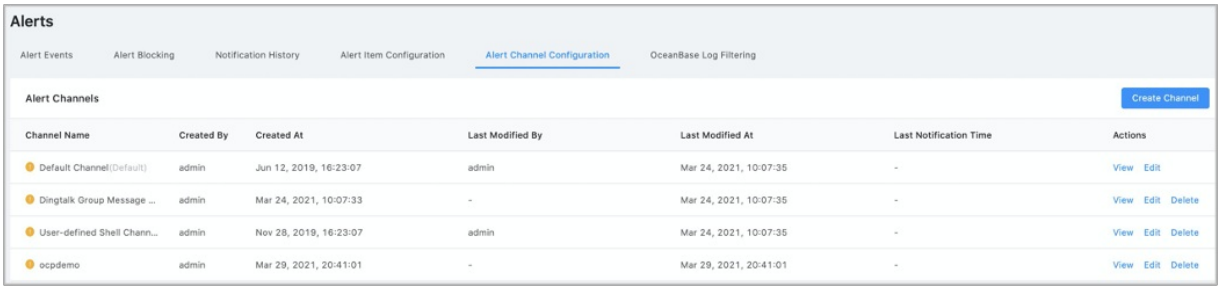


17.1.3.4.4.3. View alert notification channels

This topic describes how to view alert notification channels.

Alert notification channels

In the Alert Channels section, you can view all channels. You can edit or delete a channel as an administrator.

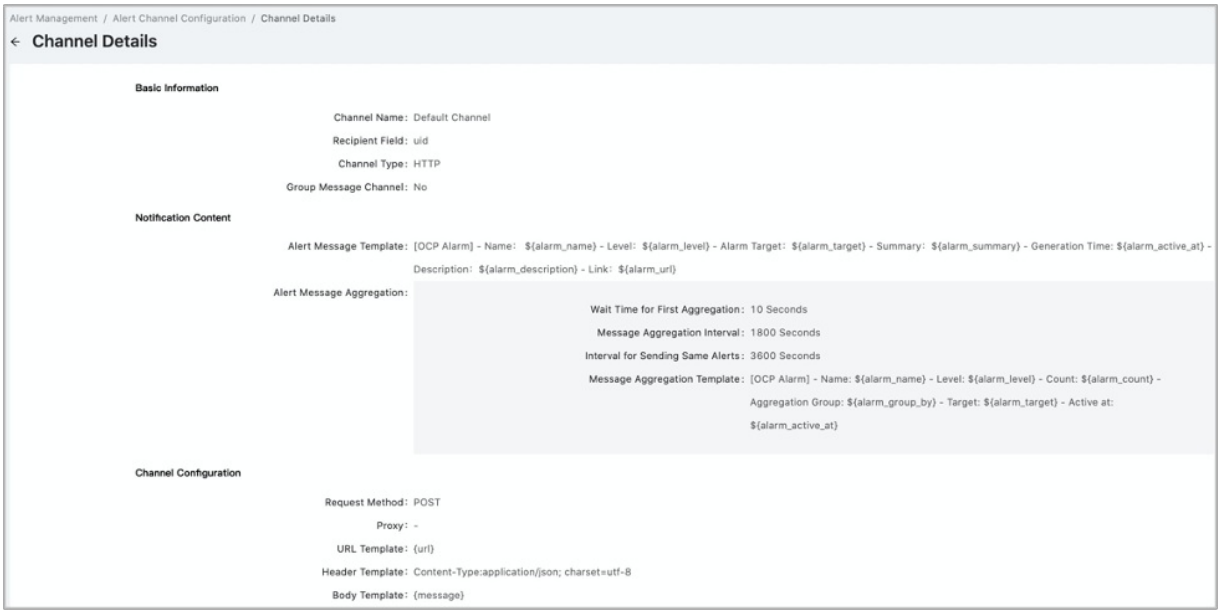


Default channel

OCP presets a default channel for O&M alert notifications. You can subscribe to the notifications. Take note of the following considerations:

- You cannot delete the default channel.
- Before you use the default channel, make sure the channel is configured.

View the configuration of the default channel:



17.1.3.4.4.4. Edit an alert notification channel

After an alert notification channel is created, you can modify the basic information, content, and configuration of the notification channel as an administrator based on business needs.

Prerequisites

An alert notification channel is created.

Procedure

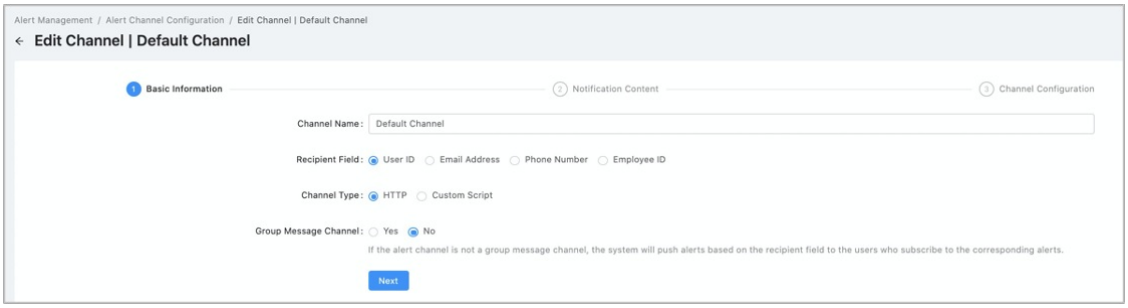
1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Alerts**.
3. On the **Alert Channel Configuration** page, find the channel that you want to modify.
4. Click **Edit** in the **Actions** column.
5. Reset **Basic Information** for the channel.
   i. Specify **Channel Name**.
   ii. Specify **Recipient Field**.
   - You can set Recipient Field to **User ID, Email Address, Phone Number**, or **Employee ID**.
   - Recipient Field is associated with the basic information of the OCP user.

   iii. Specify Channel Type.
   - **HTTP**
   - **Custom Script**

   iv. Specify **Group Message Channel**.

- If you set Group Message Channel to Yes, the system sends notifications to all group users regardless of whether a user subscribes to the notifications.
- If you set Group Message Channel to No, the system sends notifications based on Recipient Field. This field specifies the users who have subscribed to the notifications.

v. Click **Next**.



5. Reset **Notification Content**.

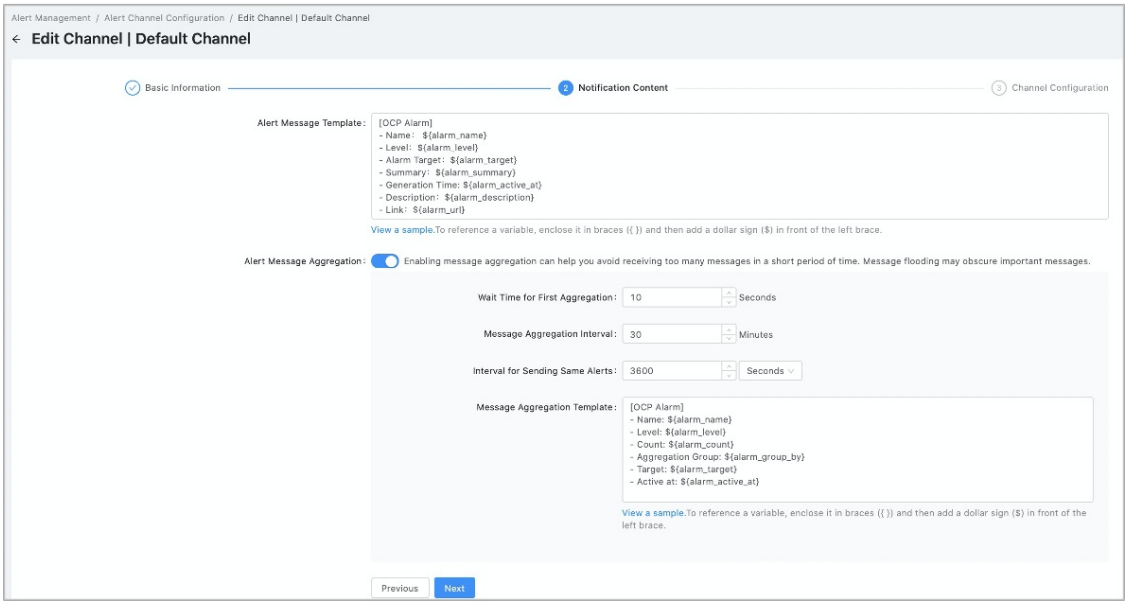
i. Specify **Alert Message Template**.

- Alert notification templates that have variables are supported.
- You can configure custom alert messages based on the instructions on the page.

ii. Specify whether to enable **Alert Message Aggregation**.

- Alert message aggregation helps you avoid receiving a large number of messages in a short period of time. Message flooding may obscure important messages. You can view the aggregation rules based on the instructions on the page.
- To enable message aggregation, configure the parameters, such as Message Aggregation Template.

iii. Click **Next**.



6. Reset **Channel Configuration**.

Configure the parameters based on the selected channel type.

If you set **Channel Type** to **HTTP**, configure the parameters based on the following description.

i. Specify **Request Method**. Valid values: POST, GET, and PUT.

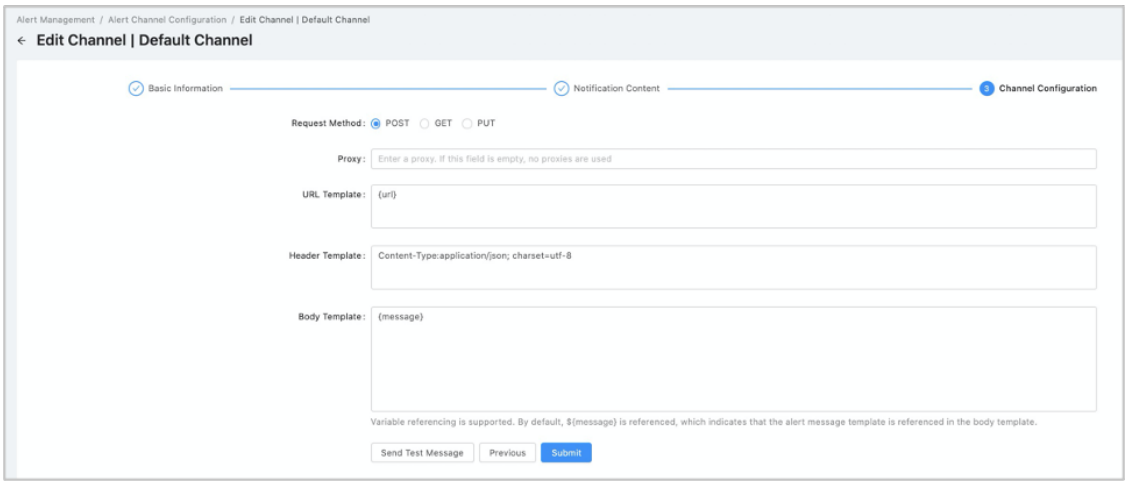
ii. Specify **Proxy**. Leave this parameter empty if no proxy is used.

iii. Specify **URL Template**. To reference a variable, enclose it by using braces ({}) and a dollar sign ($).

iv. Specify **Header Template**. To reference a variable, enclose it by using braces ({}) and a dollar sign ($). If this field is empty, no header parameters are used.

v. Specify **Body Template**. You can reference variables. By default, the **${message}** variable is referenced. This indicates that the alert message template is referenced in the body template.

vi. Click **Send Test Message**. In the dialog box that appears, select the recipient, enter the message content, and then click **OK**. If the message is sent, click **Submit**.



If you set **Channel Type** to **Custom Script**, configure the parameters based on the following description.

i. Select a configuration method for the script-based channel. If you select **Configuration Script Content**, enter the script content again. The script content must meet the following requirements:

- Only Bash or Python scripts are supported.
- The first line of the script must contain shebang that specifies the program to run the script.

For more information about sample custom scripts, see **Configure alert notification channels** > **Configuration examples** in this document.

If you set **Configuration Method** to **Configure Script Name**, rename the script file based on the instructions.

- The script file name can contain only letters, digits, underscores (_), and periods (.).
- Attackers may exploit the Script Name field to introduce shell injection. For security risks, the script name cannot contain spaces or tab characters.

b. Click **Send Test Message**. In the dialog box that appears, select the recipient, enter the message content, and then click **OK**.

c. If the message is sent, click **Submit**.

When a message is sent through a script-based channel, OCP calls the script you configure and passes all the variables related to the notification to the script through environment variables. For information about variables in message notifications, see Appendix 4 OCP alert template variables.

17.1.3.4.4.5. Delete an alert channel

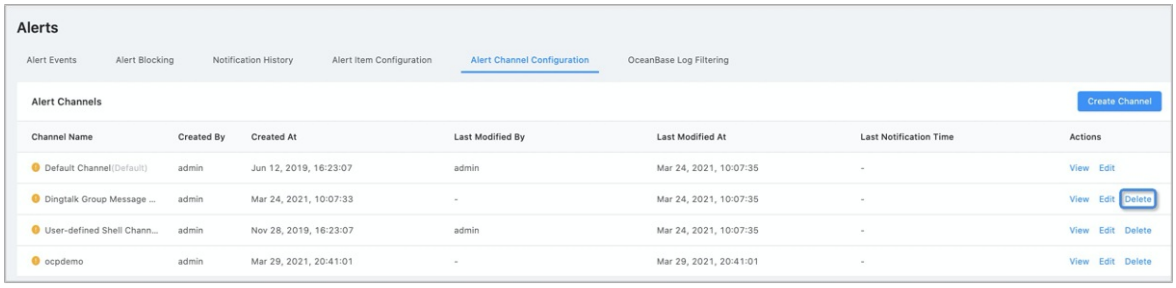
The administrator can delete custom alert channels based on business requirements.

Prerequisites

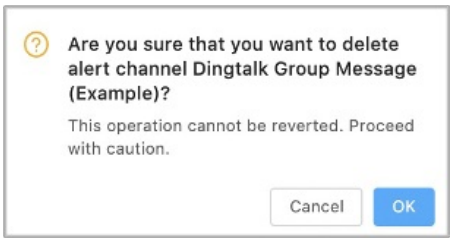
- The channel that you want to delete is not the default channel.
- The current user you log on to is the system administrator or OCP alert administrator.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Alerts**.
3. On the **Alert Channel Configuration** tab, find the channel that you want to delete.
4. In the **Actions** column, click **Delete**.



5. In the message that appears, click **OK**.



17.1.3.4.4.6. Configuration examples

This topic describes some examples on how to configure an alert channel.

DingTalk group messages

Group messages can be sent through the webhook URL of a DingTalk chatbot. For more information about DingTalk chatbot, see Official documentation of DingTalk chatbot.

Procedure

1. Configure the DingTalk chatbot. To configure a chatbot for a DingTalk group, you must record the Webhook URL. To use DingTalk chatbot, you must configure the security settings. OCP supports only the following two types of security settings for the HTTP alert channels: **Custom Keywords** and **IP Addresses**. The following figure shows the page of DingTalk chatbot security settings.

   - Set the **Custom Keywords**. Enter one or more keywords in the custom keywords field that match the message template configured for the OCP alert channel. If the first line of the default template contains "OCP alert notifications", you can set the custom keywords as "OCP alerts".
   - Configure the **IP Addresses**. Note that the IP address you configure must be the public IP address of the OCP server. You can run the following command to view the public IP address of the server: curl -w "\n\n" -s http://whatismijnip.nl. If the server does not have a fixed public IP address, contact your network administrator to obtain the public IP CIDR block of the server.
2. Create an alert channel in the alert channel configuration page. Set the channel type as **HTTP** and select **Mobile Number** for the recipient field. Select **Yes** for the group message channel field.
3. Configure the notification content.
   - Message template

```
OCP Alert Notification - Single Alert
- Name: ${alarm_name}
- Level: ${alarm_level}
- Alert target: ${alarm_target}
- Summary: ${alarm_summary}
- Generation time: ${alarm_active_at}
- Description: ${alarm_description}
- OCP URL: ${alarm_url}
```

- Message aggregation template

```
OCP Alert Notification - Multiple Alerts
- Name: ${alarm_name}
- Level: ${alarm_level}
- Alerts: ${alarm_count}
- Aggregation group: ${alarm_group_by}
- Alert target: ${alarm_target}
- Generation time: ${alarm_active_at}
```

4. Alert channel configuration
   - Request Method: POST.
   - Header Template: `Content-Type:application/json; charset=utf-8`

     > **Note**
     > The URL template is the Webhook URL recorded in step 1.

   - Header Template: `Content-Type: application/json; charset=utf-8`
   - Body template:

```
{
  "msgtype": "text",
  "text": {
    "content": ${message_json}
  },
  "at": {
    "atMobiles": ${recipients_json_array},
    "isAtAll": false
  }
}
```

> **Note**
> The format of the Body Template is JSON. To reference the variables at the end of the `_json` and the `json_array`, do not enclose them in `"`. This is because the values of these variables are processed by JSON's serialization. Enclosing these variables in `"` results in JSON format error. For comparison, when you reference a variable not in JSON format, you must enclose it in `"`. For example, `"{message}"`.

DingTalk group messages in Markdown format

DingTalk messages in Markdown format is available. In the following examples, messages in rich text format (RTF) are configured by using the formatting capability of Markdown. The configuration method is the same as that for text format messages. However, several templates are configured in different ways. For example, the font color of the message in RTF is configured by referencing

```
${alarm_level_color}
```

For more information about the font colors of alert messages in different levels.

For more information about the message types that DingTalk supports, see DingTalk development documentation.

- Message template

```
<font color=${alarm_level_color} > OCP Alert Notification - Single Alert</font>
- Name: ${alarm_name}
- Level: ${alarm_level}
- Alert target: ${alarm_target}
- Summary: ${alarm_summary}
- Generation time: ${alarm_active_at}
- Description: ${alarm_description}
- [View on OCP](${alarm_url})
```

- Message aggregation template

```
<font color=${alarm_level_color} > OCP Alert Notification - Multiple Alerts
- Name: ${alarm_name}
- Level: ${alarm_level}
- Alerts: ${alarm_count}
- Aggregation group: ${alarm_group_by}
- Alert target: ${alarm_target}
- Generation time: ${alarm_active_at}
```

- Body template

```
{
    "msgtype": "markdown",
    "markdown": {
        "title": "test of DingTalk alert messages in Markdown format in OCP",
        "text": ${message_json}
    }
}
```

Custom script channel

Custom script channels are designed for special alert recipients. In most cases, the custom script channels are used in scenarios where alerts cannot be configured in HTTP format or alert have special requirements in format. You can customize some special logic in a script. For example, you can convert the alert time and add the default parameters of the third-party alert gateway through custom script channels.

1. Configure the basic information. Select **Custom Script** for channel type. Select options in other fields based on your needs.
2. Configure the notification content.
   - Message template

```
[OCP alert notification]
- Name: ${alarm_name}
- Level: ${alarm_level}
- Alert target: ${alarm_target}
- Summary: ${alarm_summary}
- Generation time: ${alarm_active_at}
- Description: ${alarm_description}
- OCP URL: ${alarm_url}
```

- Message aggregation template

```
[OCP alert notification]
- Name: ${alarm_name}
- Level: ${alarm_level}
- Alerts: ${alarm_count}
- Aggregation group: ${alarm_group_by}
- Alert target: ${alarm_target}
- Generation time: ${alarm_active_at}
```

3. Configure alert channels.

- Script Name: Select when you configure the channel **Set the Configuration Method** as **Configure Script Name**.

By default, the system provides a sample custom script: alarm_send_script_demo.sh. You can modify the sample custom script or add a custom script. When you modify or add a script file, make sure that the script file is stored in the /home/admin directory of each OCP.

Currently, only Bash or Python scripts are supported.

- **Shell script sample**

Send DingTalk group messages:

```
#! /bin/sh

echo "Below is a list of alarm paras"

# below variables can be referenced by prefix "$", for example, $alarm_name or ${alarm_name}
echo "alarm_name:$alarm_name"
echo "app_type:$app_type"
echo "alarm_threshold:$alarm_threshold"
echo "alarm_time=$alarm_time"
echo "alarm_last_interval:$alarm_last_interval"
echo "alarm_time:$alarm_time"
echo "alarm_level:$alarm_level"
echo "alarm_type:$alarm_type"
echo "alarm_summary:$alarm_summary"
echo "alarm_url:$alarm_url"
echo "app:$app"
echo "alarm_duration:$alarm_duration"
echo "alarm_status:$alarm_status"
echo "alarm_scope:$alarm_scope"
echo "alarm_active_at:$alarm_active_at"
echo "alarm_target:$alarm_target"
echo "alarm_description:$alarm_description"
echo "message:$message"
echo "receiver:$receiver"
echo "alarm_id:$alarm_id"

# this function defines to how to assembly request by yourself according to your requirements
# this demo shows you how to send alarm to ding ding
function send(){
    # this token is ding ding group token, please apply and assign it to variable token
    token=''
    # URL="https://oapi.dingtalk.com/robot/send?access_token=$token"
    URL=''
    curl -X POST ${URL} -H 'Content-Type: application/json' -d '{"msgtype":"text","text":{"content":"
'"${message}"'"}}'
}

# invoke function to
send
```

- **Python script sample**

Output alert information to a text file:

```
#! python
# -*- coding: utf-8 -*-
import os

# Obtain the values of the environment variables
message = os.environ['message']
print "hello {}".format(message)
with open("./sample.txt", "a") as file_object:
    file_object.write("{}".format(message))
```

When you write a script, note the following items:

- The return code exitCode of a script is used to determine whether the execution is successful.

`exitCode==0`

Indicates that the script execution succeeds. A non-zero value indicates that the execution fails.

- If a script fails to be executed, the error information can be sent to stderr. OCP records the error message for subsequent troubleshooting.
- Scripts should be executed as soon as possible. We recommend that execution time be controlled within 1 second. OCP sets the time-out period for a single script calling. The default time-out period is 10 seconds. If the output is not returned within 10 seconds, OCP forces the script process to stop.
- When you write scripts, do not use multi-process programming. This can prevent the message accumulation when OCP fails to stop a script process.

- Script Content: Select when you configure the channel **Set the Configuration Method** as **Configure Script Content**.

You can customize the channel of the script. You can specify both the name and the content of a script. You can directly enter a Bash or Python script in the **Script Content** field.

4. Send test messages.

When you debug a script, you can send test messages. By default, the test messages include the variable ${message} in the script. Make sure that the variable is in the body of the test message that you send. The logic to determine whether a custom script is successfully sent depends on the specific situation. If the system considers that the script execution succeeds, the script is successfully sent. However, in the developer mode of the browser, users can debug a script based on the response content of the _test request corresponding to the test message that you sent.

17.1.3.4.5. Alert subscription settings

By default, alerts can be viewed only on the Alerts page. Users can subscribe to alerts only after the administrator has configured an alert channel.

You can receive alert notifications only when the following two conditions are met:

1. The administrator has configured an alert channel.
2. You have subscribed to an alert.

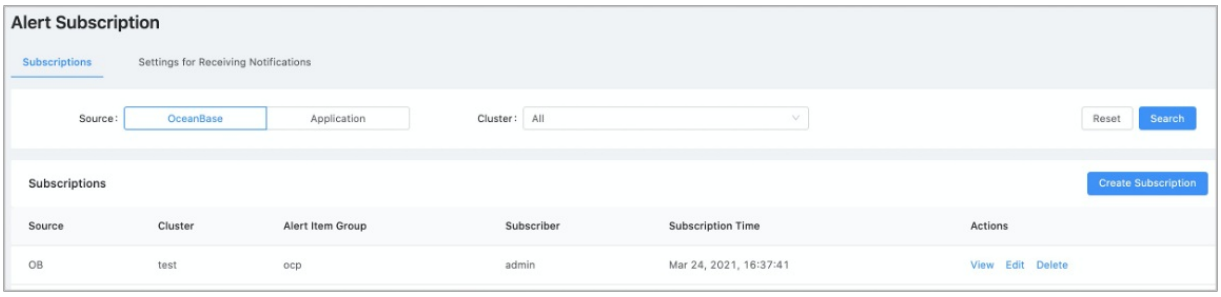
To send alert notifications from OCP, perform the following steps:

1. Configure an alert channel. The administrator configures the alert channel.
2. Create a new subscription. You can configure the subscriptions.
3. Configure the settings for receiving notifications. You can configure whether to receive notifications and the reception limits.

View alert subscriptions

Log on to the OCP console. Expand the hidden list in the User Center in the upper-right corner, and click **Alert Subscription**. On the Subscriptions tab, you can filter alerts by **Source** and **Cluster**.

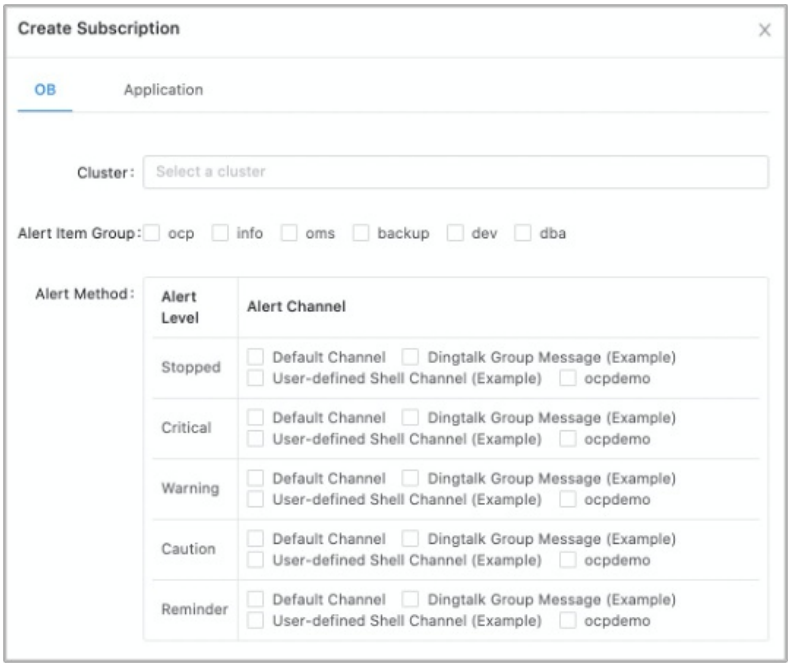
By default, the page displays the **Source, Cluster, Alert Item Group, Subscriber** and **Subscription Time**.



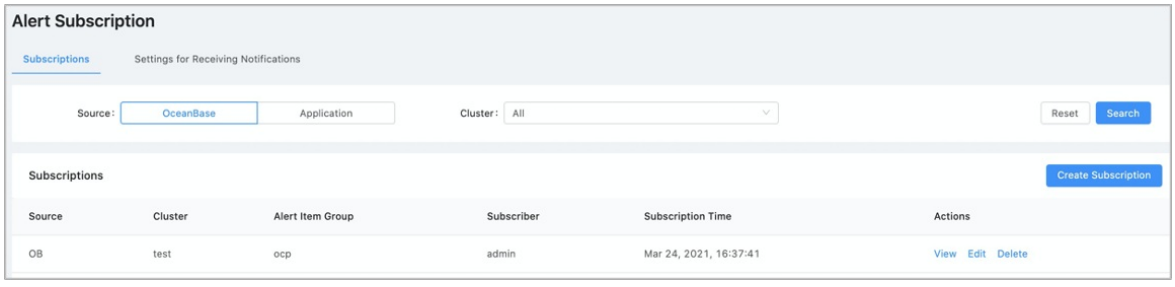
Create an alert

> **Note**
>
> You can only select a cluster that you have the read permission when you configure an alert subscription. If your read permission for a cluster is revoked after you configure an alert subscription, you cannot receive alert messages from this cluster even though the alert subscription configuration still exists.

1. Log on to the OCP console.
2. Expand the hidden list in the User Center in the upper-right corner, click **Alert Subscription**.
3. Click **Create Subscription**.
4. Click the **OceanBase** or **Application** tab and specify the OceanBase cluster or application as needed.
5. Select the **alert item groups** that you want to subscribe to.
6. Select the **alert method**. Set the alert channel for alerts of each alert level. You can configure multiple channels for each level at the same time and you must configure channels for at least one alert level.



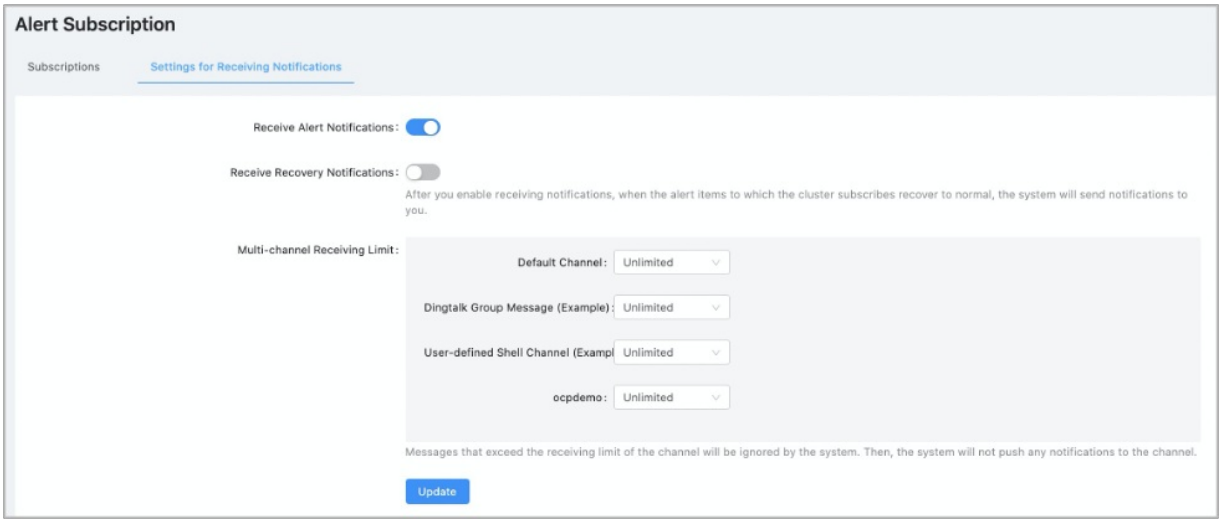
7. Click **OK**. After you complete the alert subscription settings, you can view the details and edit or delete subscriptions on the **Subscriptions** page.



Settings for receiving notifications

You can configure the settings for receiving notifications.

You will also receive fault recovery notifications for alerts that you have subscribed to. Fault recovery notifications cannot be aggregated. To avoid receiving too many such notifications, we recommend that you disable fault recovery notifications. The following table lists the setting items for receiving notifications. You can customize the settings as needed.



17.1.3.4.6. View alert events

This topic describes how to view the details of an alert event.

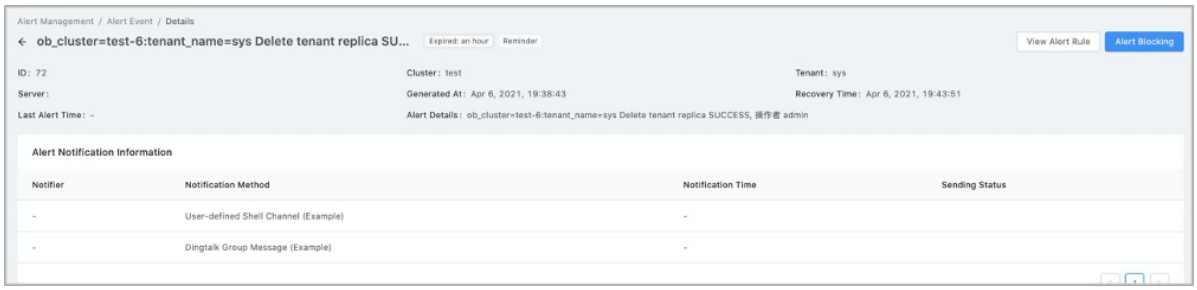
Alert event list

You can view and query all events in the alert event list. The alert event list supports multiple search conditions. You can enter a keyword to match the alert overview, alert details, and values of all tags. For example, If you set Source to OceanBase, you can enter a keyword to match the values of tags. The tags include cluster group, cluster, tenant, and host IP address.

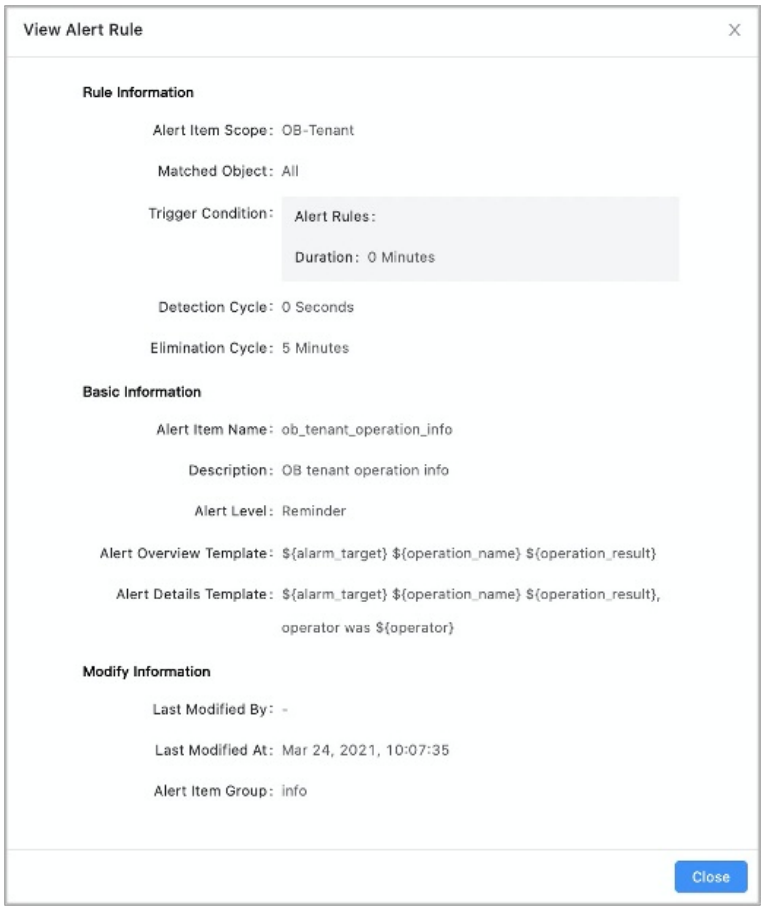
Alert event details

In the alert event list, click an alert to go to the details page of the alert event. Then, you can perform the following operations:

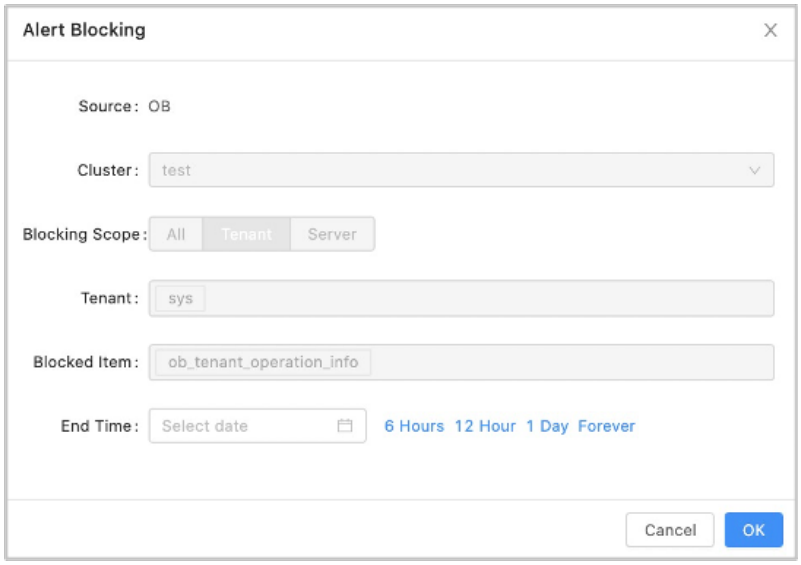
- View the details of the alert event.



- Click **View Alert Rule** in the upper-right corner to view the alert rule.



- Click **Alert Blocking** in the upper-right corner to block the alert.



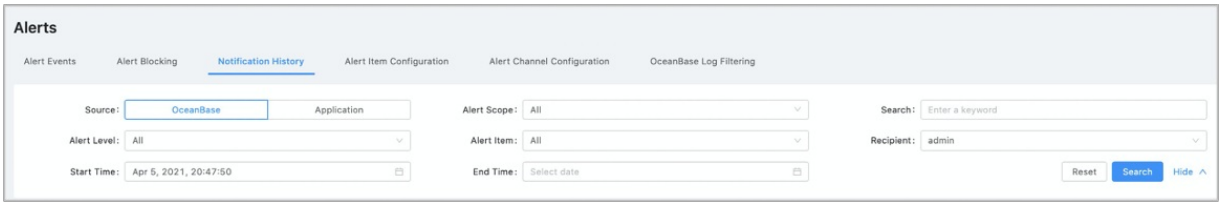
- View the notification records of the alert.

17.1.3.4.7. View the alert notification

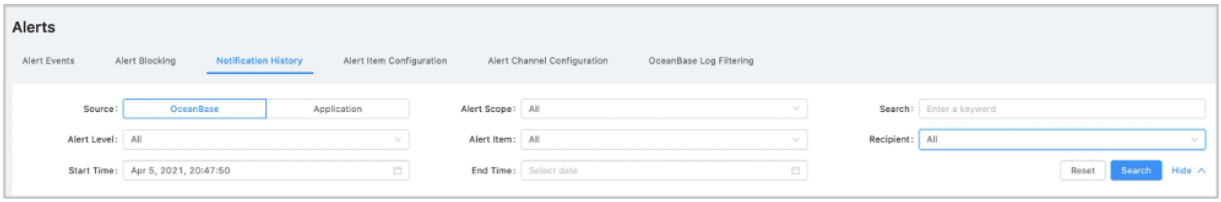
The Notification History tab displays the notification delivery records and the state of each notification. You can only view notification records in the last 90 days. Notifications older than 90 days are automatically archived.

You can view the message content, message form, notification channel, source, cluster, alert time, and recipient of a specified message.

By default, the current user is specified for the **Recipient** field as a filter condition.



> **Note**
>
> To view the alerts sent through a group message channel, select **All** from the **Recipient** drop-down list as a filter condition.

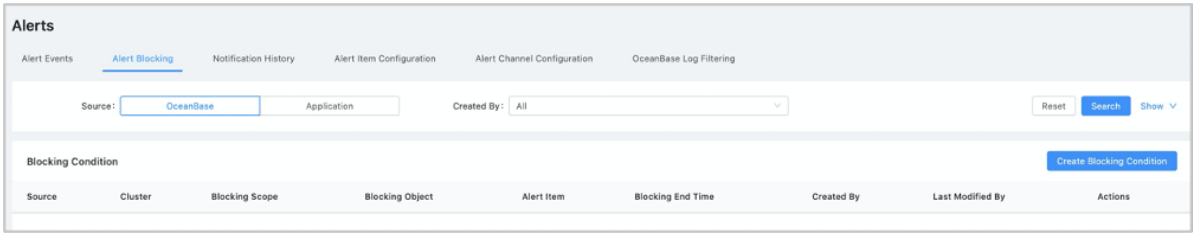


17.1.3.4.8. Block alert notifications

This topic describes how to block alert notifications.

The Alert Blocking tab displays all configurations for blocking alert notifications. By default, the configurations created by the current user appear.

- After you configure settings to block alert notifications, wait up to 30 seconds for the settings to take effect.
- The configurations for blocking alert notifications have a validity period. The system automatically archives the configurations that have exceeded the validity period more than seven days.
- When you perform an O&M task for an ApsaraDB for OceanBase cluster, the system automatically blocks alert notifications for the O&M task.



Procedure

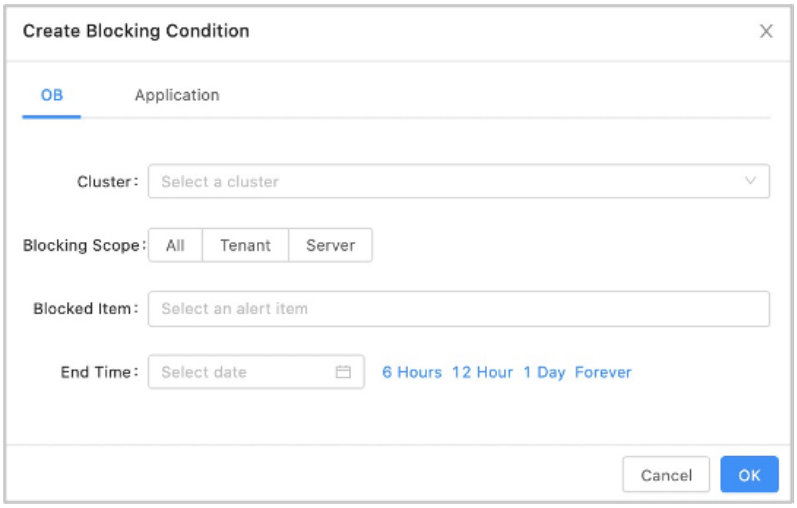
You can configure settings to block alert notifications in a few clicks on the Alert Events and Notification pages. You need to specify a validity period for the settings. You can perform the following steps to block alert notifications on the **Alert Blocking** page.

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Alerts**.
3. On the Alert Blocking tab, click **Create Blocking Condition**.
4. Click the **OB** tab or **Application** tab based on your needs. The following examples are based on the **OB** tab.
    i. Select an ApsaraDB for OceanBase cluster. You must select one cluster.

ii. Specify **Blocking Scope**.

iii. Specify **Blocked Item**.

iv. Specify **End Time**.



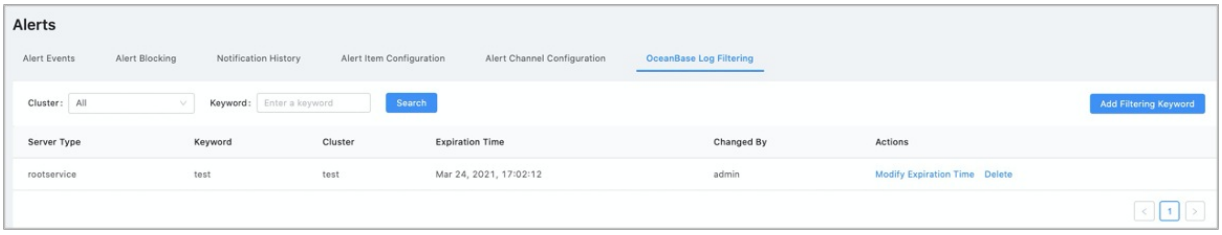
5. Click OK.

17.1.3.4.9. OceanBase log filtering

OceanBase log alert is not triggered based on the alert rule. The implementation principle is that the OBServers monitor logs. If a log of ERROR level is found, the alert is triggered. If false positives occur, you can set log filtering rules on the OceanBase Log Filtering tab.

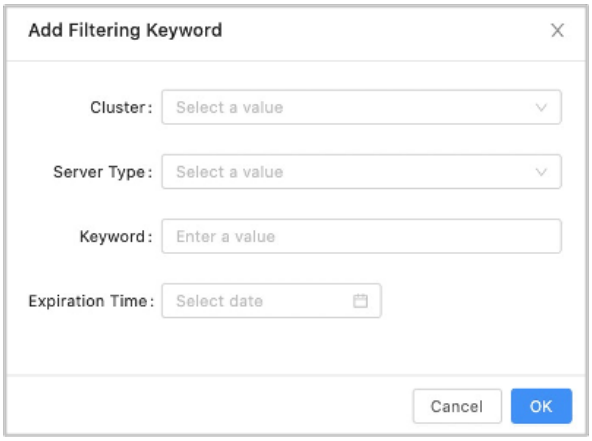
View keyword filtering rules

The **OceanBase Log Filtering** tab displays the configured log filtering rules.



Add filtering keyword

In the upper-right corner, click Add Filter Keyword, and specify the cluster, server type, keyword, and filter time. Keywords support the syntax of regular expression functions. Logs that match the keywords do not trigger alerts.



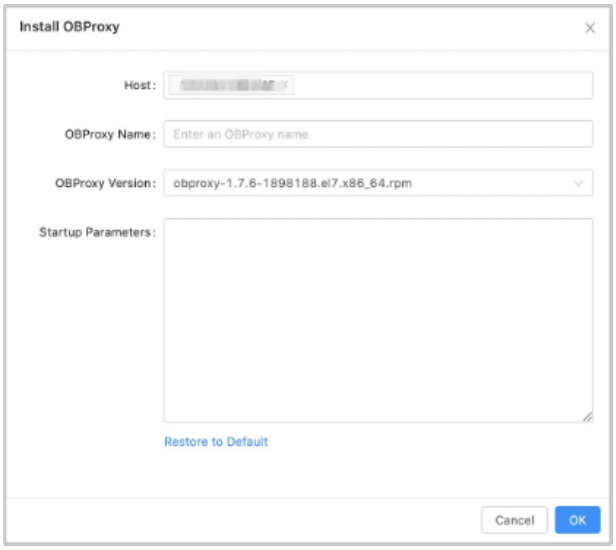
17.1.3.5. OBProxy O&M

17.1.3.5.1. Install OBProxy

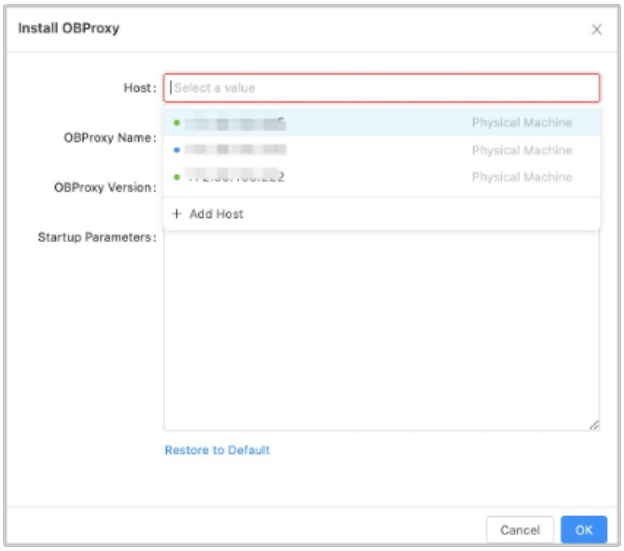
In the upper-right corner of the page, click Return to Old Version to go to the OBProxy page and install OBProxy.

Procedure

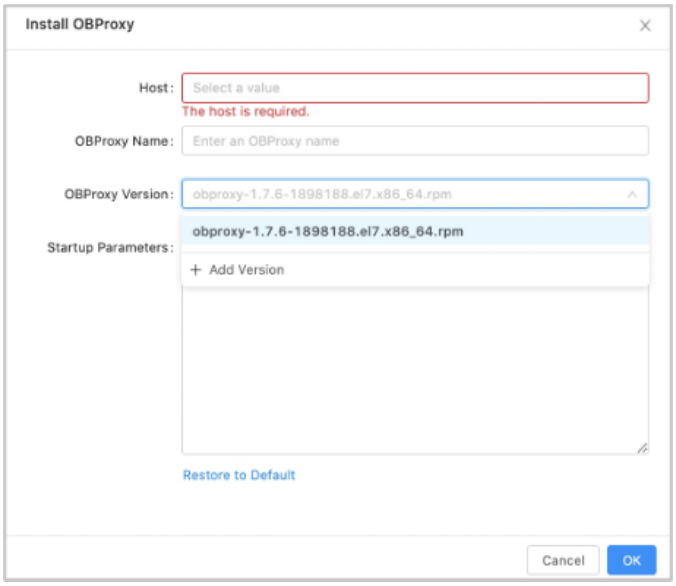
1. In the navigation pane, choose **Maintenance** to go to the **OBProxy** page.
2. Click **Install OBProxy**.
3. In the dialog box that appears, specify the following parameters:



- **Host**: Select a host from the drop-down list, or click **Add Host** to add a new host.



- OBProxy Version: Select an OBProxy version from the drop-down list, or click **Add Version** and click **Upload** in the dialog box that appears, to upload the corresponding OBProxy file.



4. Click **OK**. This will generate an OBProxy operations task. You can choose **System Management > Tasks** to check the installation progress.

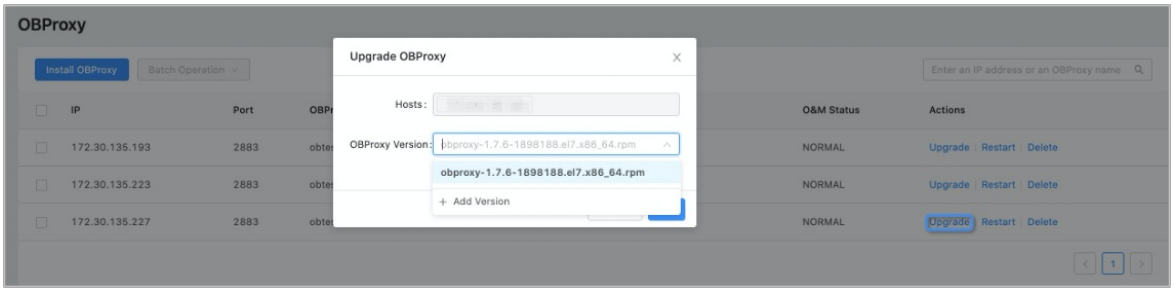
17.1.3.5.2. Upgrade OBProxy

In the upper-right corner of the page, click Return to Old Version to go to the OBProxy page and upgrade OBProxy.

Procedure

1. In the navigation pane, choose **Maintenance** to go to the OBProxy page.
2. Click **Upgrade** on the right of the IP address of the corresponding host.

3. In the dialog box that appears, select the target version, or click **Add Version** to add an OBProxy version.



4. Click **OK**. You can choose **System management> Tasks** to check the upgrade progress.

17.1.3.5.3. Restart an OBProxy

In the upper-right corner of the interface, click Back to Old Version to restart a running OBProxy.

Procedure

1. In the left-side navigation pane, click **O&M**. The OBProxy page appears.
2. Select the OBProxy that you want to restart and click **Restart** next to it.

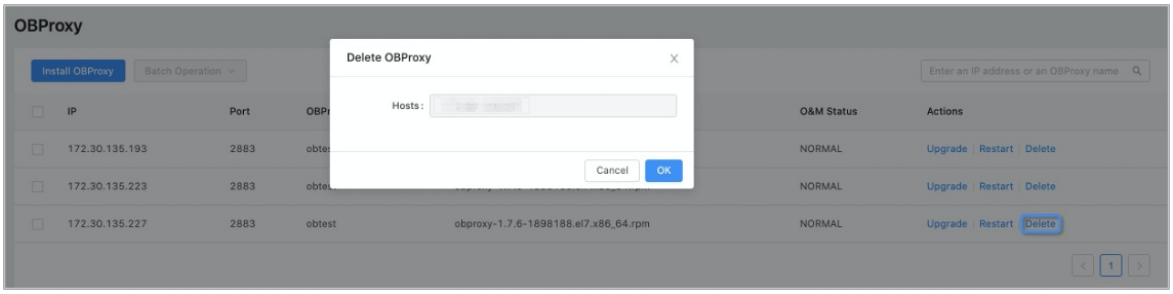
3. Click **OK**. You can view the progress by choosing **System Management > Tasks**.

17.1.3.5.4. Delete OBProxy

In the upper-right corner of the page, click Return to Old Version to go to the OBProxy page and delete redundant OBProxy.

Procedure

1. In the navigation pane, choose **Maintenance** to go to the OBProxy page.
2. Click **Delete** on the right of the corresponding instance.



3. Click **OK**. To view the deletion progress, choose **System Management > Tasks**.

17.1.3.5.5. Startup parameters

This topic describes the startup parameters.

When you install the OBProxy, you must specify startup parameters in the dialog box that appears. The startup parameters fall into the following two types:

- Startup parameters that take effect immediately after the update.
- Startup parameters that do not take effect until the OBProxy is restarted.

Parameters that take effect immediately after the update

name	info	default	range	need reboot
`mysqlclient_query_timeout`	The query timeout period for the MySQL client in the OBProxy to connect to the OBServer.	120s	[1s]	false
`mysqlclient_net_wait_timeout`	The query timeout period that the proxy sets when it uses the MySQL client to connect to the OBServer, `read_timeout`, and `write_time_out`. The value -1 indicates that the operation never times out.	10s	[-1,]	false
`mysqlclient_connection_refresh_interval`	The interval for refreshing the MySQL connection pool in the OBProxy. The actual configured time is 50 times the value	200ms	[200ms,]	false
`mysqlclient_connection_pool_warn_time`	The amount of time required for generating an alert in the connection pool. If a connection is occupied for a long period of time, an alert log is generated.	1s	[0s,]	false

name	info	default	range	need reboot
mysqlclient_conn_limit_per_observer	The maximum number of SQL connections that can be processed by each connection pool.	10	[1,]	false
proxy_info_check_interval	The interval of proxy detection of configuration updates	20s	[1s,1h]	false
schema_refresh_interval	The interval for refreshing the schema.	20s	[1s,1h]	false
server_state_refresh_interval	The interval for refreshing the OBServer status.	20s	(0s,1h]	false
config_server_refresh_interval	The interval for refreshing the config server.	20s	[60s,1d]	false
stat_sync_interval	The interval of the tasks to synchronize global statistics. The value of 0 indicates that the task is suspended	60s	[0s,1d]	false
stat_dump_interval	The interval for dumping global task data.	6000s	[0s, 1d]	false
stat_table_sync_interval	The interval of the tasks to update the global items of an internal table	60s	[0s,1d]	false
fetch_proxy_bin_random_time	The maximum amount of random time that is waited to fetch a new binary file during a hot upgrade of the OBProxy.	300s	[1s,1h]	false

name	info	default	range	need reboot
`hot_upgrade_rollback_timeout`	The default amount of time that is waited to perform a rollback after a hot upgrade of the OBProxy.	24h	[1s,30d]	false
`hot_upgrade_failure_retries`	The number of retries after a hot upgrade failure.	5	[1,20]	false
`fetch_proxy_bin_timeout`	The timeout period for fetching a binary file during a hot upgrade.	120s	[1s,1200s]	false
`hot_upgrade_graceful_exit_timeout`	The timeout period for the OBProxy to cancel the hot upgrade.	120s	[0s, 30d]	false
`log_cleanup_interval`	The interval for cleaning up logs.	3600s	[5s,30d]	false
`log_dir_size_threshold`	The maximum size of the OBProxy logs. If this parameter value is exceeded, log cleanup is enabled.	64GB	[256MB,1T]	false
`conn_id_fetch_count`	The number of connection IDs you can obtain at a time.	10240	[10,100000]	false
`long_async_task_timeout`	The timeout period for asynchronous tasks that run on the OBServer	60s	[1s,1h]	false

name	info	default	range	need reboot
short_async_task_timeout	The timeout period for asynchronous tasks that may require short-term access to an OBServer	5s	[1s,1h]	false
client_max_connections	The maximum number of clients that can connect to the OBProxy.	8192	[0,65535]	false
observer_query_timeout_delta	The time period that is added to the ob_query_timeout value due to the network latency. ob_query_timeout indicates the timeout period for querying the OBServer.	20s	[1s,30s]	false
connect_observer_max_retries	The maximum number of retries when the OBProxy fails to connect to the OBServer.	3	[2,5]	false
net_config_poll_timeout	The timeout period for network connections.	10ms	[0,]	false
default_inactivity_timeout	The default timeout period for TCP connections.	180000s	[1s,30d]	false
sock_send_buffer_size_out	The size of the send socket buffer.	0	[0,8MB]	false
sock_recv_buffer_size_out	The size of the receive socket buffer.	0	[0,8MB]	false

name	info	default	range	need reboot
sock_option_flag_out	Specifies the socket flag parameter	0	[0,1]	false
sock_packet_mark_out	Specifies the socket mark parameter	0	[0,1]	false
sock_packet_tos_out	Specifies the socket tos parameter	0	[0,1]	false
server_tcp_init_cwnd	The initial size of the TCP congestion window when you create a connection xxx.	0	[0,64]	false
proxy_mem_limited	The maximum memory size that can be used for the OBProxy. If this parameter value is exceeded, the OBProxy automatically suspends.	800MB	[100MB,4GB]	false
enable_flow_control	Specifies whether to enable throttling in the tunnel.	false	• true • false	false
flow_high_water_mark	The upper limit of the traffic in the tunnel.	0	[0,16MB]	false
flow_low_water_mark	The lower limit of the traffic in the tunnel.	0	[0,16MB]	false

name	info	default	range	need reboot
flow_consumer_reenable_threshold	The maximum number of times that data is forwarded in the tunnel.	0	[0,131072]	false
flow_event_queue_threshold	The maximum number of tasks xxx	0	[0,20]	false
tunnel_request_size_threshold	The maximum request size that the OBProxy can receive. If this parameter value is exceeded, the OBProxy forwards client requests without parsing through the tunnel.	84KB	[4KB, 16MB]	false
default_buffer_size	The default block size for requests and responses.	8KB	[1KB, 64KB]	false
default_buffer_water_mark	The default water mark for the buffer.	32KB	[4B, 64KB]	false
enable_trans_detail_stats	Specifies whether collect transaction status information.	true	• true • false	true
enable_mysqlsm_info		true		false
enable_report_session_stats	Specifies whether to report session statistics to internal tables.	true	• true • false	false
slow_transaction_time_threshold	The maximum amount of time for executing a transaction. If this parameter value is exceeded, a warning log is printed.	5s	[0s,30d]	false

name	info	default	range	need reboot
`slow_proxy_process_time_threshold`	The maximum amount of time for the OBProxy to pre-process requests. If this parameter value is exceeded, a warning log is printed.	2ms	[0s,30d]	false
`query_digest_time_threshold`	The maximum amount of time for processing a request. If this parameter value is exceeded, a warning log is printed to obproxy_digest.log.	100ms	[0s,30d]	false
`slow_query_time_threshold`	The maximum amount of time for processing a slow query. If this parameter value is exceeded, a warning log is printed to obproxy_slow.log.	500ms	[0s,30d]	false
`congestion_failure_threshold`	The maximum number of server failures in a congestion_fail_window cycle. If this parameter value is exceeded, the OBProxy adds the server to the blacklist.	5	[0,]	false
`min_keep_congestion_interval`	The minimum amount of time that is waited to remove a server from the blacklist.	20s	[1s,1d]	false

name	info	default	range	need reboot
`congestion_fail_window`	The time period during which server failures are calculated. This parameter is used in conjunction with congestion_failure_threshold.	120s	[1s,1h]	false
`congestion_retry_interval`	The interval of retries for a live but unavailable server that is added to the blacklist	20s	[1s,1h]	false
`enable_congestion`	Specifies whether to enable the blacklist.	true	• true • false	false

Parameters that do not take effect until the OBProxy is restarted

name	info	default	range	need reboot
`stack_size`	The size of the thread stack. Specify this parameter when you create a thread.	1MB	[1MB,10MB]	true
`work_thread_num`	The number of worker threads. Specify this parameter when you initialize worker threads.	8	[1,128]	true
`task_thread_num`	The number of task threads. It is used when you initialize task threads	2	[1,4]	true
`dedup_queue_thread_num`	The number of threads to run fetch tasks	2	[1,4]	true

dedup_queue_bucket_num	`dedup_queue` The parameter `bucket_num` of	256	[256,1024]	true
dedup_queue_task_queue_size	`dedup_queue` The parameter `task_queue_size` of	1024	[512,1024]	true
kv_cache_bucket_num	It is used when you initialize kvcache	1024	[512,2048]	true
net_accept_threads	The number of threads to run the accept requests	2	[0,8]	true
frequent_accept	The parameter to initialize the net accept requests	true	• true • false	true

17.1.3.6. Backup and recovery

17.1.3.6.1. Overview

The backup and recovery feature of OceanBase Cloud Platform (OCP) supports full backup and incremental backup for ApsaraDB for OceanBase clusters and tenants. The log backup, full recovery, and incomplete recovery features are supported.

The following procedure shows how to back up and recover data in OCP:

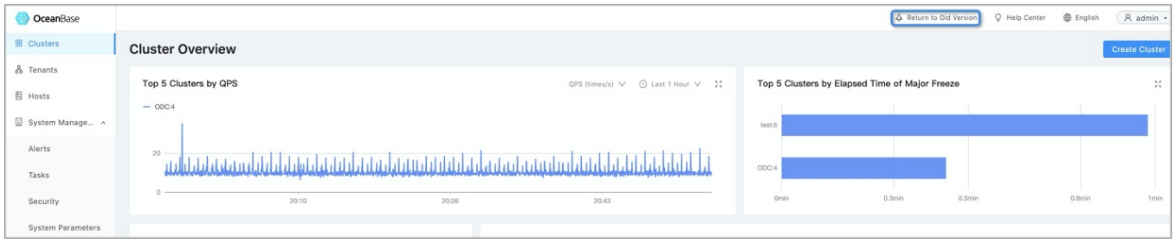
1. Create backup and recovery configuration files.
2. Upload and install backup and recovery agents.
3. Create a backup scheduling task for a cluster.
4. View the result of the backup task that is initiated by the scheduling task.
5. Initiate a recovery task.
6. Connect to the recovered tenant and view the recovered data.

17.1.3.6.2. Go to the Backup and Recovery page

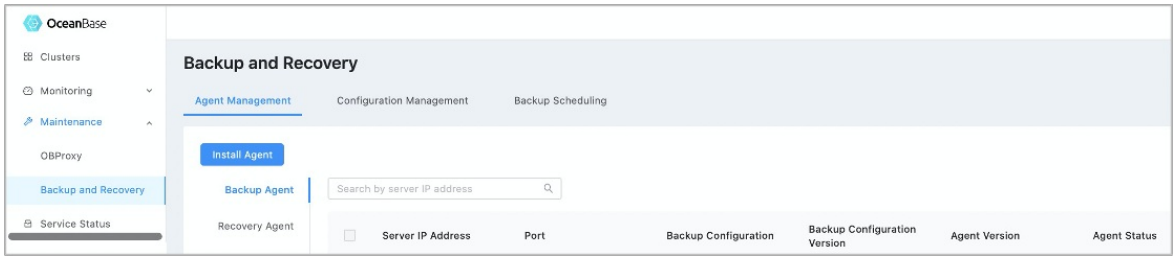
The Backup and Recovery page is displayed in the old version of OceanBase Cloud Platform (OCP). To use the backup and recovery features, you must switch the OCP version to the old version. On the Backup and Recovery page, you can perform O&M operations, use the backup scheduling feature, and view tasks.

Procedure

1. Log on to OCP.
2. In the upper-right corner of the page, click **Return to Old Version**.



3. In the left-side navigation pane, choose **Maintenance > Backup and Recovery**.



17.1.3.6.3. Preparations

Before you back up and recover data, you must prepare metadatabases and storage media.

Create a metadatabase for backup and recovery

When you install OCP based on Docker images, four versions of metadatabases are created by default within a metadatabase tenant. The versions are backup1472, backup147x, backup21, and backup2230. You can select to use these four versions based on your ApsaraDB for OceanBase version.

Prepare a storage medium

You can select Object Storage Service (OSS) or Network File System (NFS) as the storage medium for backup and recovery. NFS is applicable to independent external scenarios, and OSS is applicable to Apsara Stack scenarios.

OSS configuration

You must obtain the following settings to set the required parameters when you perform related operations on the Configuration Management tab:

- OSS account
- Bucket
- Endpoint
- AccessKey pair: An AccessKey pair is composed of an AccessKey ID and an AccessKey secret. The AccessKey pair is used to perform access identity verification.

NFS configuration

The backup agent, recovery agent, OceanBase Cloud Platform (OCP), and the ApsaraDB for OceanBase cluster to be restored must have access to the specified NFS directory for backup and recovery. Therefore, the NFS directory must be mounted to these hosts. The mounted on-premises directory must be the same as the directory in the backup configuration file.

- NFS server configuration

In this example, the directory name is obbackup.

```
yum install -y nfs-utils portmap
service nfs start
echo '/obbackup *(rw,all_squash,anonuid=500,anongid=500)' >/etc/exports
chmod 777 /obbackup
service nfs restart
exportfs
```

- NFS client configuration

The backup agent, recovery agent, OCP, and the ApsaraDB for OceanBase cluster to be restored must be mounted as a NFS client. Otherwise, data cannot be recovered.

```
showmount -e 11.166.84.52 #The IP address is an example IP address.
mkdir /obbackup
chmod 777 /obbackup
mount -o soft 11.166.84.52:/docker /obbackup
```

17.1.3.6.4. Manage backup and recovery configuration files

17.1.3.6.4.1. Add a backup configuration file

This topic describes how to add a backup configuration file.

Prerequisites

- A metadatabase for backup and recovery is created.
- A storage medium is prepared.

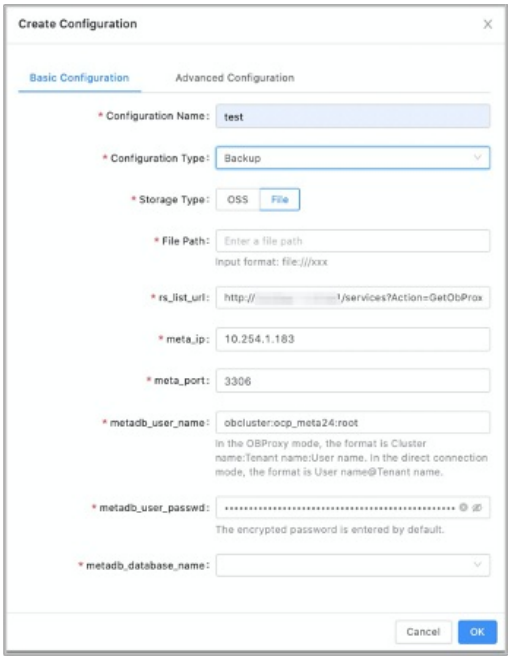
Procedure

1. Log on to OceanBase Cloud Platform (OCP).
2. Switch to the old version of OCP and open the Backup and Recovery page.
3. On the **Configuration Management** tab, click **Create Configuration** in the upper-left corner.
4. Set the required parameters on the **Basic Configuration** tab.
   i. Set the **Configuration Name** parameter.
   ii. Set **Configuration Type** to **Backup**.
   iii. Set the **Storage Type** parameter.

By default, the database information of the OCP metadatabase is automatically filled in. The OCP database includes a backup and recovery metadatabase. Modify the settings based on the actual metadatabase.

- If you set Storage type to **OSS**, you must set the File Path, access_key_id, secret_access_key, rs_list_url, meta_ip, meta_port, metadb_user_name, metadb_user_passwd, and metadb_database_name parameters. Some parameters are automatically set, confirm whether the settings are correct.
- If you set Storage type to **File**, you only need to enter the related information of the mounted NFS file.

Parameter	Description
File path	The OSS file path or the file path where the NFS file is mounted.
host	The endpoint.
access_key_id	The AccessKey ID of the OSS account.
secret_access_key	The AccessKey secret of the OSS account.
rs_list_url	The RS List URL provided by current OCP is filled by default.
meta_ip	The IP address of the backup and recovery metadatabase.
meta_port	The port number of the backup and recovery metadatabase.
metadb_user_name	The username of the backup and recovery metadatabase.
metadb_user_passwd	The password of the backup and recovery metadatabase.
metadb_database_name	Select an appropriate metadatabase as prompted.



5. (Optional) On the **Advanced Configuration** tab, set the required parameters of **Advanced Configuration**. The parameters of Advanced Configuration are automatically set. You do not need to modify the related settings.
6. Click **OK**.

17.1.3.6.4.2. Add a recovery configuration file

This topic describes how to add a recovery configuration file.

Prerequisites

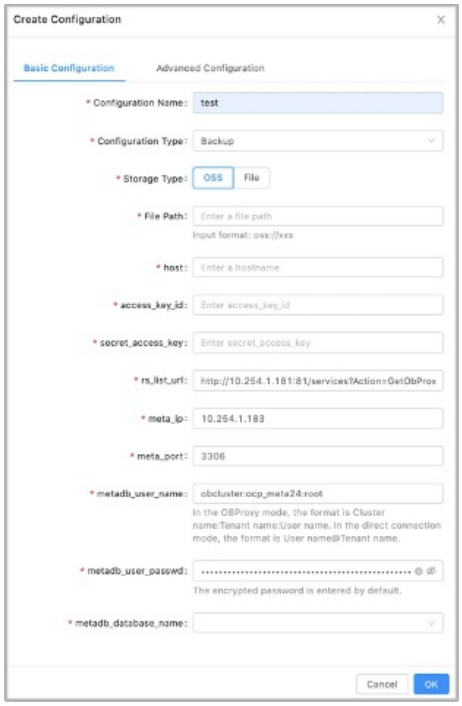
- A metadatabase for backup and recovery is created.
- A storage medium is prepared.

Procedure

1. Log on to OceanBase Cloud Platform (OCP).
2. Switch to the old version of OCP and open the Backup and Recovery page.
3. On the **Configuration Management** tab, click **Create Configuration** in the upper-left corner.
4. Set the required parameters on the **Basic Configuration** tab.
   i. Set the **Configuration Name** parameter.
   ii. Set **Configuration Type** to **Recovery**.
   iii. Set the required parameters.

By default, the database information of the OCP metadatabase is automatically filled in. The OCP database includes a backup and recovery metadatabase. Modify the settings based on the actual metadatabase.

Parameter	Description
ocpMetaDb.clusterName	The name of the cluster where the backup and recovery metadatabase resides. The cluster must be managed by OCP.
ocpMetaDb.tenantName	The tenant to which the backup and recovery metadatabase belongs.
ocpMetaDb.userName	The username of the backup and recovery metadatabase.
ocpMetaDb.dbName	Select an appropriate metadatabase as prompted.
ocpMetaDb.encryptedPassword	The password of the backup and recovery metadatabase.
ocpMetaDb.configUrl	The configUrl of the cluster where the backup and recovery metadatabase resides. This parameter is automatically set and you do not need to modify the related settings.



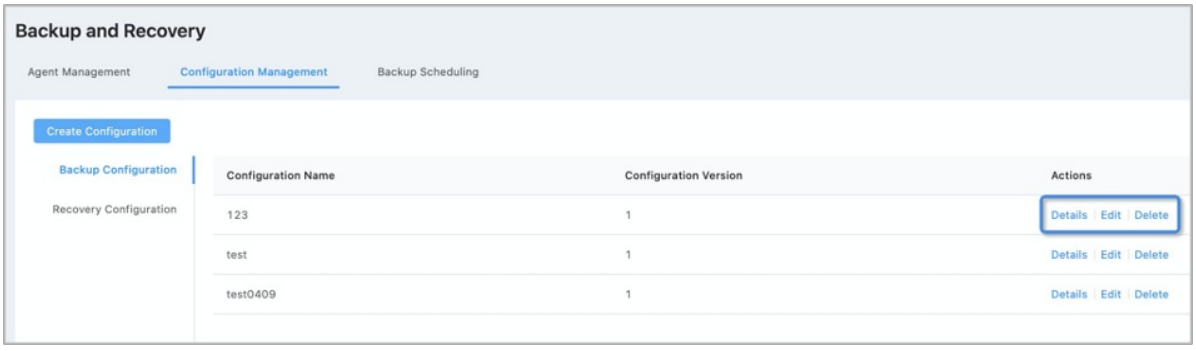
5. (Optional) On the **Advanced Configuration** tab, set the required parameters of **Advanced Configuration**. The parameters of Advanced Configuration are automatically set. You do not need to modify the related settings.
6. Click **OK**.

17.1.3.6.4.3. Manage a configuration file

The related parameters in backup and recovery configuration files must be correctly set. Otherwise, the related backup and recovery agents cannot work as required. This results in failed backup and recovery.

You can manage your configuration files on the Configuration Management tab based on your business requirements. You can perform the following operations on a configuration file:

- **View the details of the configuration file.**
- **Modify the configurations.**
- **Delete a backup or recovery configuration file.**



17.1.3.6.5. Install backup and recovery agents

17.1.3.6.5.1. Install backup and recovery agents

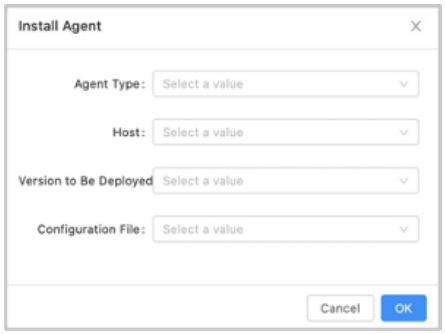
This topic describes how to install backup and recovery agents.

Prerequisites

A host is required to install a backup or recovery agent. Make sure that an idle host is available. If no available hosts are available, you can add a host on the **Host Management** page of the new version of OceanBase Cloud Platform (OCP) based on the related documentation of **Host Management**.

Procedure

1. Log on to OCP.
2. Switch to the old version of OCP and open the Backup and Recovery page.
3. On the **Agent Management** tab, click **Install Agent**.
4. Set the **Agent Type** parameter and specify a host.
5. Set the **Version to Be Deployed** parameter. If no versions are available, you can click Add Version to upload a new installation package.
6. The related backup or recovery configuration file is automatically filtered based on the specified deployment version. If no configuration files are available, add a backup configuration file first.
7. Click OK.



8. After you click OK, a dialog box appears on the page. You can click the link to view the progress.

The progress page is displayed in the new version of OCP. After you view the progress, you need to switch back to the old version. Then, you can perform related O&M operations on the agent.

The process of installing a recovery agent is the same as that of the backup agent. Both backup and recovery agents can be installed on the same host. However, a version is based on the version number of the agent installed first. Different versions cannot be separately specified.

17.1.3.6.5.2. Manage backup and recovery agents

Installed backup and recovery agents are displayed on the Agent Management tab of the Backup and Recovery page. You can perform some common O&M operations on these installed agents.

You can perform the following operations:

- View the task history of an agent. In the **Task History** column, click **View** to view the historical O&M status of the agent.
- Restart an agent.
- Delete an agent.
- Upgrade an agent.
- Update the configurations of an agent.

  If you want to update the configuration file of an agent, you can modify the configurations on the **Configuration Management** tab, and then update the configurations. The system automatically pushes the latest configurations to the agent side.

17.1.3.6.6. Run backup tasks

17.1.3.6.6.1. Cluster backup scheduling

After you have created backup and restoration configuration profiles and installed the backup component, you can back up data at any time.

Create a cluster backup scheduling task

Prerequisites

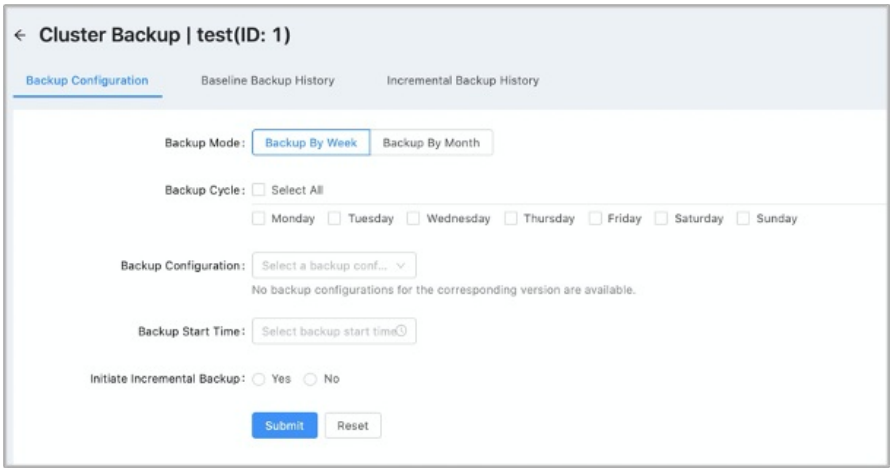
- You have created the backup configuration profile of the corresponding version.
- You have installed the backup component.

Procedure

1. Log on to the OceanBase Cloud Platform (OCP) console.
2. In the upper-right corner, click **Return to Old Version**.
3. In the left-side navigation pane, choose **Clusters**.
4. In the **Actions** column of the specific cluster, click **Cluster Backup**.
5. Specify related configuration parameters.
   i. Set the backup mode and backup period.
   - The backup mode includes weekly backup and monthly backup.
   - The backup period varies with the backup mode. You can select the weekday or the day of a month for backup.

   ii. Select the backup configuration profile.
   - The drop-down list only displays profiles that match the specified version.
   - If no matching backup configuration profile is available for the current version, you must create one first.

   iii. Set the backup start time.
   iv. Specify whether to enable incremental backup, where incremental backup is to back up logs.



6. Click **Submit**.

Manage cluster backup scheduling

After you have created a cluster backup scheduling task, the system automatically initiates the backup task at the specified time and period. You can also modify the task based on business needs. The system supports the following management operations at present:

- Pause a backup scheduling task.

In the Actions column of the specific backup task, choose Actions > Pause to temporarily suspend the task.

- Restart a backup scheduling task.

In the Actions column of the specific backup task, choose Actions > Restart to restart the task. The system will initiate the task at the specified time and period.

View backup history

On the **Backup Scheduling** tab of the **Backup and Recovery** page, you can view the basic information of all the scheduling tasks, including the cluster name, tenant name, backup mode, backup period, status of the current scheduling task, status of the baseline backup task, incremental backup task, and initiator.

You can click the name of a cluster to view its backup scheduling history, baseline backup history, incremental backup history, and restoration history. On the Backup Scheduling History tab, you can filter backup scheduling tasks by state.

- Backup Scheduling History: This tab shows the following information: the task name, ID, cluster, initiator, status, progress, start time, and end time.
- **Baseline Backup History**: This tab shows the following information: the task ID, backup type, task type, task quantity, cluster, tenant, start time, end time, data version, backup URL, backup status, and backup size. You can select a backup task to initiate a data restoration.
- **Incremental Backup History**: This tab shows the following information: the cluster name, tenant whitelist, majorVersion, backup URL, agentServerIp, checkpoint, delay (in seconds), status, stop flag, and error.

17.1.3.6.6.2. Tenant backup scheduling

You cannot back up a tenant and the related cluster at the same time.

Only one tenant backup schedule can be created in a cluster.

- If no backup schedules are available, you can create a cluster backup schedule or a tenant backup schedule.
- If a cluster backup schedule is created, all tenants in the cluster follow the scheduling configuration of the cluster by default. You cannot configure a tenant scheduling task.
- If a tenant backup schedule is created, you cannot create a backup schedule for the related cluster. Before you configure a cluster backup schedule, you must cancel the backup scheduling task of the related tenant and suspend the related incremental backup task.

Prerequisites

No running backup scheduling tasks or incremental backup tasks in the cluster to which the specified tenant belongs.

Procedure

1. Log on to OceanBase Cloud Platform (OCP).
2. In the upper-right corner of the page, click **Return to Old Version**.
3. In the left-side navigation pane, click **Tenants**.
4. Click **Cluster Backup** in the **Actions** column of the specified cluster.

5. Set the required parameters.
   i. Set the **Backup Mode** and **Backup Cycle** parameters.
   - The valid values of the **Backup Mode** parameter are **Backup By Week** and **Backup By Month**.
   - The backup cycle can be set to the specified day or day of the week for backup based on the specified backup mode.

   ii. Set the **Backup Configuration** parameter.
   - Only the backup configuration files of the related version are displayed in the drop-down list.
   - If no backup configuration files are available, create a backup configuration file before you configure a cluster backup schedule.

   iii. Set the **Back Start Time** parameter.

   iv. Set the **Initiate Incremental Backup** parameter. Incremental backup is log backup.
6. Click **Submit**.

Manage a tenant backup schedule

After you create a tenant backup schedule, the system automatically initiates backup tasks based on the preset cycle and time. You can modify the backup scheduling tasks based on your business requirements. The following operations are supported to manage your schedules:

- Suspend a backup scheduling task. Click **Suspend** in the Actions column of a specified backup scheduling task to suspend the task.
- Click **Rerun** in the Actions column of a specified backup scheduling task to rerun the task. Then, the system automatically initiates backup tasks based on the preset cycle and time.

17.1.3.6.6.3. Back up now

You can initiate an instant backup task for a cluster or tenant that has a backup schedule. If a backup schedule is available, you can manually perform a baseline backup task.

> **Note**
>
> A major freeze version of ApsaraDB for OceanBase can only have one baseline backup task. If multiple backup tasks are initiated based on the same version, errors are reported for subsequent backup tasks. However, the backup tasks of this version are available.

Prerequisites

A backup scheduling task is configured for a cluster or a tenant.

Procedure

1. Log on to OceanBase Cloud Platform (OCP).
2. In the upper-right corner of the page, click **Return to Old Version**.
3. In the left-side navigation pane, click **Tenants** or **Clusters**.
4. Click **Back Up Now** in the **Actions** column of the tenant or cluster.

5. In the dialog box that appears, click **OK**.

17.1.3.6.7. Recover backup data

After the system performs a backup operation, it can initiate a recovery task based on the backup. The minimum granularity of recovery tasks is tenant-level data. Multiple tenants can be recovered in batches.

Prerequisites

A baseline backup task is performed on the cluster or tenant to be recovered.

Procedure

1. Log on to OceanBase Cloud Platform (OCP).
2. Go to the Backup and Recovery page.
3. On the **Backup Scheduling** tab, click the name of the specified cluster.
4. On the **Baseline Backup History** tab, find the baseline backup to be restored.
5. In the **Actions** column, click **Initiate Recovery**. The click position and the recovery version have no relations. The system automatically calculates and chooses a baseline version for recovery based on recovery time.
6. Specify **Cluster for Recovery** and **Restore to Point in Time**. The cluster to be recovered can be a source cluster or another cluster.
7. Enter the user password.
8. Select the tenant to be restored and confirm the settings of **Target Tenant Name, Restore Locality, Restore Pool List, and Restore Primary Zone**. The system automatically fills the related fields based on the backup information. You must confirm whether the filled content is correct.
   - If you recover data to the source cluster, you must change the tenant name to a new name.
   - Restore Pool List indicates the related resource configurations of the tenant. The resource pool name cannot exist in the destination cluster.
9. Click **OK**. After the recovery request is successfully initiated, a success message appears.

View the status of a recovery task

In the **Recovery History** column, you can view the status of the recovery task. You must refresh the page to view the updated information.

The recovery process consists of the following two phases. Only when both phases are successful, the tenant recovery is successful.

- Baseline recovery
- Incremental recovery

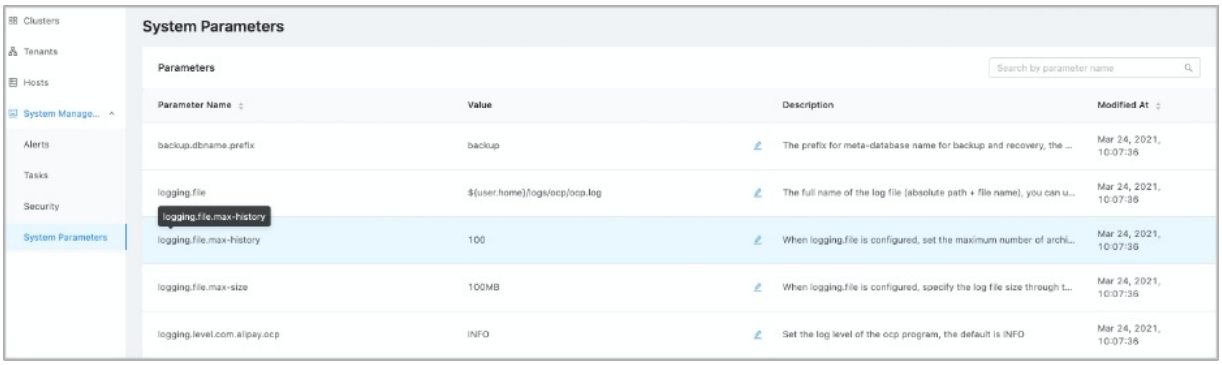
Use a recovery tenant

The connection password of the recovery tenant is empty. When the message is prompted, enter to confirm.

17.1.3.6.8. Monitoring and alert configurations

Backup and recovery settings are configured as system parameters in OceanBase Cloud Platform (OCP).

On the System Management>System Parameters page of the new version of OCP, enter backup in the search box to query and view the parameters of backup and recovery.



Monitoring configurations

In the current OCP version, you can manage and configure the following parameters of backup and recovery:

- Status monitoring of agents.
- Monitoring of failed baseline backup tasks.
- Monitoring of incremental backup task latency. For more information, see `ocp.backup.alarm.inc-backup-delay-threshold`.
- Monitoring of failed backup scheduling tasks.
- Monitoring of expired backup file cleaning. For more information, see `ocp.backup.alarm.backup-data-retention-days`.
- Monitoring for the log cleaning of backup agents. For more information, see `ocp.backup.alarm.backup-liboblog-expire-days`.

> **Note**
>
> The current version does not support the monitoring for the capacity of backup files.

Alert configurations

The following table describes the parameters of alerts.

Parameter	Default value	Description
ocp.backup.alarm.base-backup-last-finished-threshold	12960	The baseline has not been successfully backed up for 9 days, the initial threshold is 9 days (12960 minutes), the unit is minutes
ocp.backup.alarm.base-backup-timeout	10	Baseline backup scheduling timeout period (minutes)
ocp.backup.alarm.inc-backup-delay-threshold	3600	Incremental backup delay alarm threshold (seconds)

Parameter	Default value	Description
ocp.backup.alarm.last-data-backup-max-interval-minutes	1440	Check whether the baseline backup task failed in a certain time range recently, the default is 1 day, the unit is minute; that is, the maximum allowable interval between the last successful data backup and the current time

For more information about alert configurations, see related documentation to subscribe and configure.

17.1.3.7. Manage users and permissions

17.1.3.7.1. Overview of access control

In the OCP platform, users are those who use the OCP platform and operate functional systems. A role is a set of permissions and functions as a carrier of the permissions. Each user must assume one or more roles and have the permissions of these roles before the user performs the corresponding operations in the OCP platform. The permissions of a user are the union of the permissions of all the roles that the user assumes.

The initial account admin in the OCP platform is a user that has the system administrator role. The admin account has management permissions on all the clusters and functional modules in the OCP platform. A system administrator can create another user and assign one or more roles to the user to allow the user to assume corresponding functions in the business architecture. For example, the system administrator can create a user that has the user management permission USER_MANAGER so that the user can create other users on the behalf of the administrator.

17.1.3.7.2. Manage users

17.1.3.7.2.1. Create a user

For security purposes, such as information security and traditional security, we recommend that you grant the minimum permissions that are required by a user when you create the user. The minimum permission set of OCP is the PROFILE role. A user who has this role can perform operations, such as accessing the personal center and modifying personal information and the password box.

OCP initially presets common roles. These common roles are called default roles. The default roles include roles, such as the system administrator role ADMIN that has all management permissions and the TENANT_MANAGER role that has all the management permissions on ApsaraDB for OceanBase tenants. The default roles basically cover general requirements for managing user permissions. If you need to provide finer-grained permissions on clusters and tenants through a user, you can create a custom role and specify the specific cluster ID and tenant ID when you create the user.

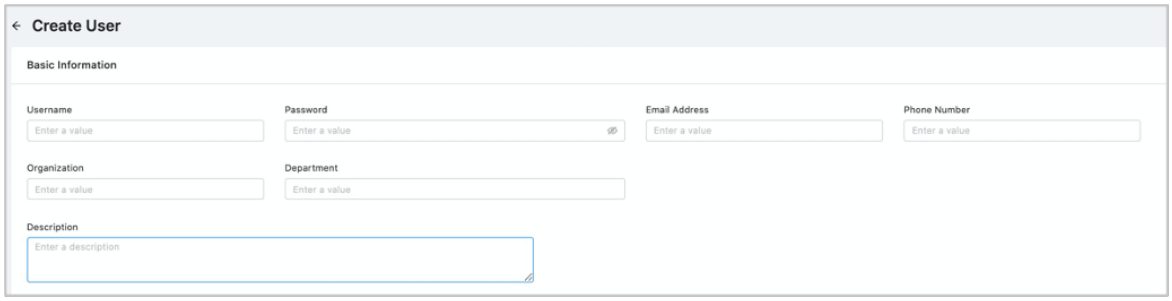
Prerequisites

The current logon user has the system administrator role ADMIN or the user management role USER_MANAGER and the corresponding permissions.

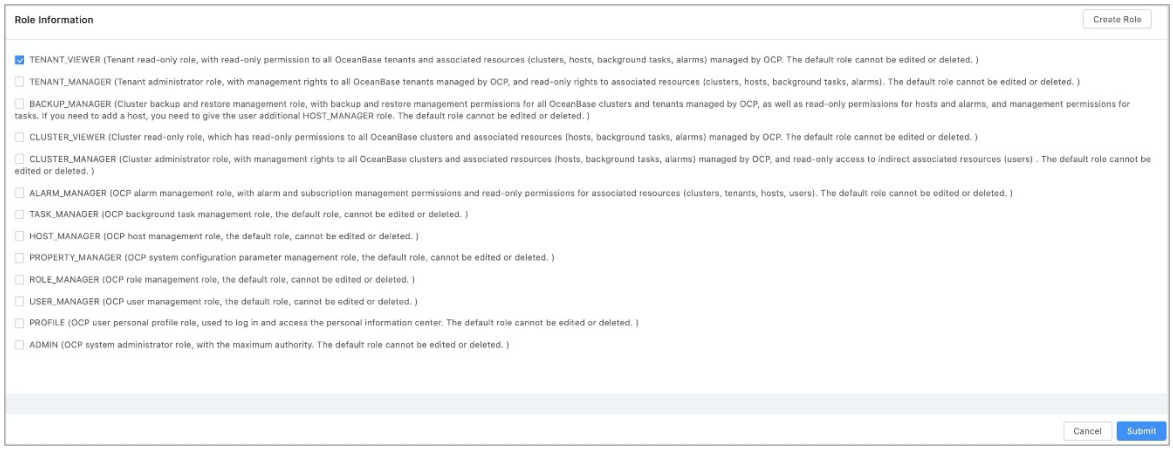
Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Security**.
3. In the upper-right corner of the page, click **Create User**.

4. Specify basic information for the new user.
   - Specify **Username, Password, Email Address, Phone Number, Organization, and Department** for the new user, and enter role descriptions.
   - Among the preceding parameters, Username, Password, and Email Address cannot be left blank.
   - The username must start with a lowercase letter, and can contain lowercase letters, digits, underscores (_), hyphens (-), and periods (.).The username must be 4 to 48 characters in length. The username cannot be modified after it is created.
   - The password must be 8 to 32 characters in length, and must contain at least two digits, two uppercase letters, two lowercase letters, and two special characters (_+@#$%).



5. Specify role information for the new user.
   - One or more roles must be specified for the user.
   - If an appropriate role does not exist in OCP, you can click **Create Role** in the upper-right corner of the section to create a role, and assign the role to the new user.



6. In the lower-right corner of the page, click **Submit**.

17.1.3.7.2.2. View a user list

System administrators or user administrators can view all the user information in the current OCP, including the email address, phone number, department, organization, and description of the user and the roles that are owned by the user.

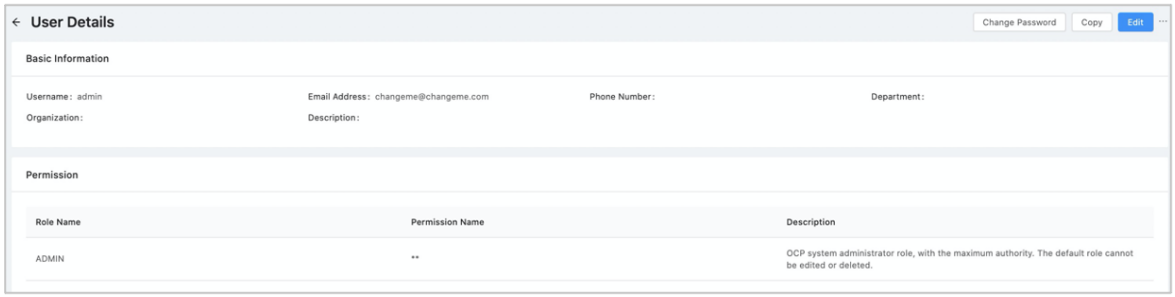
Prerequisites

The current logon user has the system administrator role ADMIN or the user management role USER_MANAGER and the corresponding permissions.

Procedure

1. Log on to OCP.

2. In the left-side navigation pane, choose **System Management > Security**.
3. In the search box, enter a username or a keyword of the username to search for the specified user.
4. In the search results, click the username to go to the **User Details** page. On the **User Details** page, you can view the email address, phone number, department, organization, and description of the user and the roles that are owned by the user.



17.1.3.7.2.3. View user details

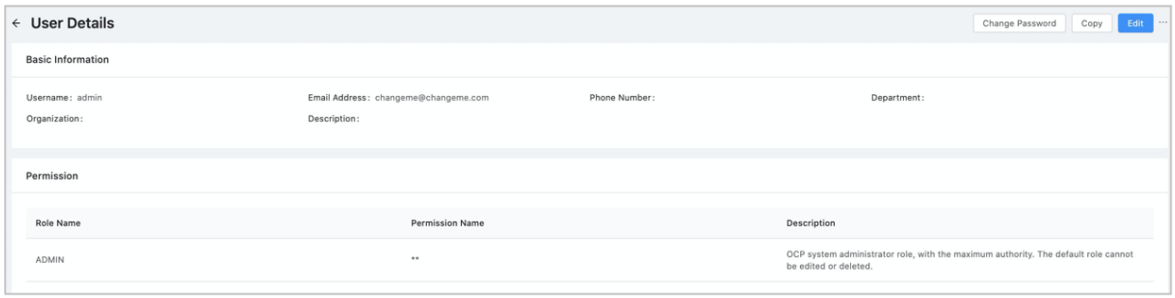
System administrators or user administrators can view all the user information in the current OCP, including the email address, phone number, department, organization, and description of the user and the roles that are owned by the user.

Prerequisites

The current logon user has the system administrator role ADMIN or the user management role USER_MANAGER and the corresponding permissions.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Security**.
3. In the search box, enter a username or a keyword of the username to search for the specified user.
4. In the search results, click the username to go to the **User Details** page. On the **User Details** page, you can view the email address, phone number, department, organization, and description of the user and the roles that are owned by the user.



17.1.3.7.2.4. Copy a user

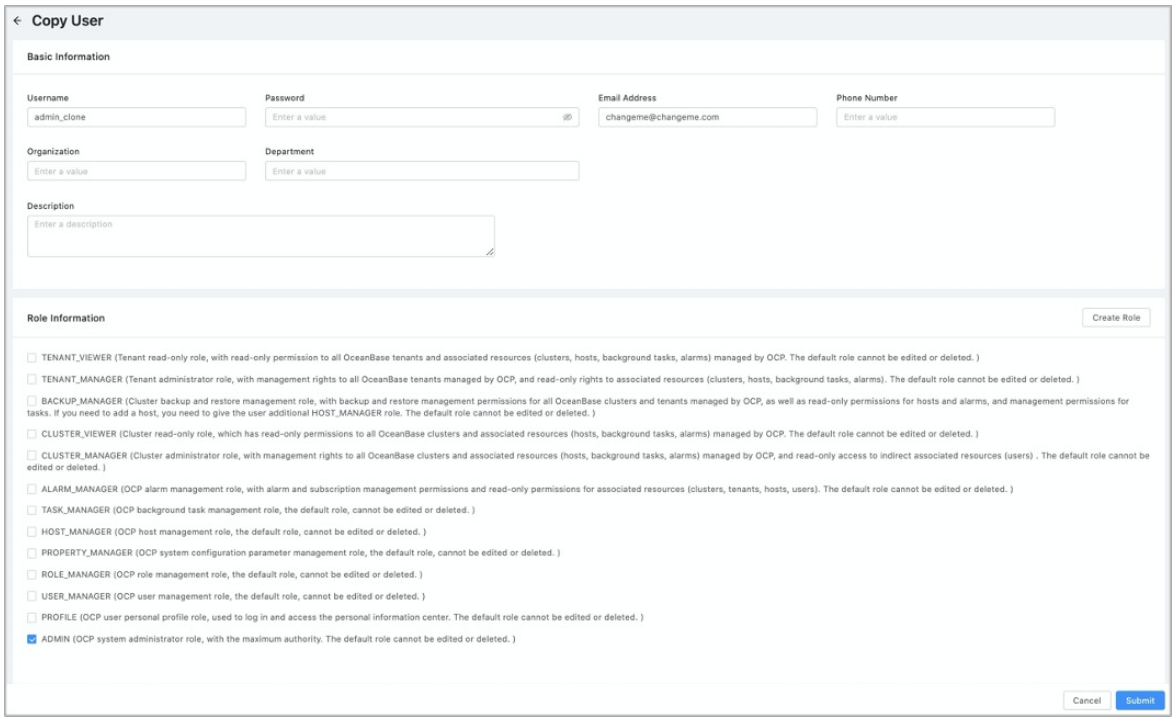
If you need to create a user whose basic information is the same as that of an existing user, you can copy the existing user to create the user. The user copying method eliminates the need of repeatedly entering same basic information, and applies to scenarios where you need to create users in batches.

Prerequisites

The current logon user has the system administrator role ADMIN or the user management role USER_MANAGER and the corresponding permissions.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Security**.
3. Find the user to be copied, and click **Copy** in the corresponding **Actions** column.
4. Specify basic information and role information for the new user. The basic information and role of the new user are the same as those of the user to be copied except for the username and the password. You can edit information based on the information of the user to be copied.



5. In the lower-right corner of the page, click **Submit**.

17.1.3.7.2.5. Edit a user

After users are created, you can modify the basic information and permission information about the users, such as passwords, email addresses, and phone numbers. After you modify the role of a user, the modifications take effect the next time the user logs on.

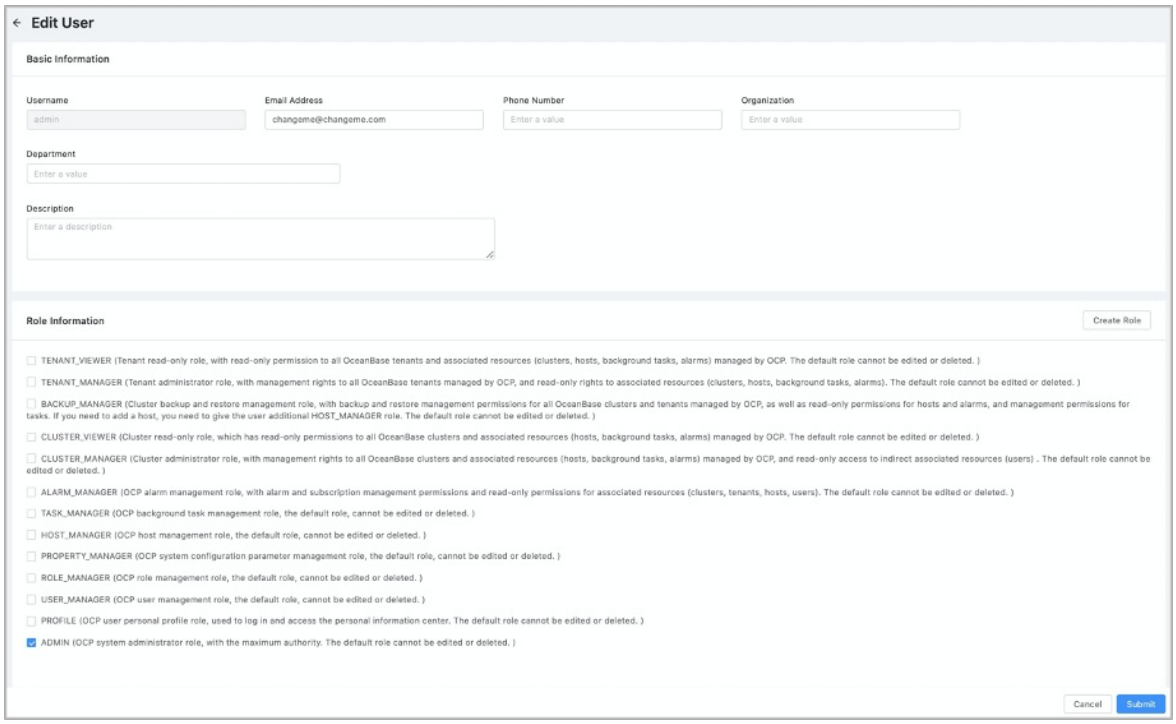
Prerequisites

The current logon user has the system administrator role ADMIN or the user management role USER_MANAGER and the corresponding permissions.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Security**.
3. Find the specified user, and click **Edit** in the corresponding **Actions** column.

4. Enter basic information about the user again. You can also reassign a role to the user.



5. In the lower-right corner of the page, click **Submit**.

17.1.3.7.2.6. Delete a user

User information involves in recording and tracking the historical operations of users. Therefore, after a user is deleted in OCP, the account information, such as the username and the email address, is retained. If you create a user that has the same username or email address as the deleted user, the system prompts you that a user that has the same username or email address already exists. You can select another username and email address as prompted and try again.

Prerequisites

The current logon user has the system administrator role ADMIN or the user management role USER_MANAGER and the corresponding permissions.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Security**.
3. Find the specified user, expand the hidden list in the corresponding **Actions** column, and click **Delete**.

4. In the dialog box that appears, click **Delete**.

17.1.3.7.3. Manage roles

17.1.3.7.3.1. Overview

A role in OCP is a set of permissions. Roles only take effect after they are assigned to users. OCP roles consist of default roles and custom roles.

OCP roles consist of default roles and custom roles.

- Default roles are preset roles that are built in the system. The default roles basically cover general requirements for managing user permissions. For example, the system administrator role ADMIN has all management permissions, and the TENANT_MANAGER role has all the management permissions on ApsaraDB for OceanBase tenants.
- Custom roles are the roles that are created by users in OCP. The custom roles have finer-grained management permissions on clusters and tenants than the initial default roles. For example, the specified users can view only the specified clusters and the specified tenants in the specified clusters. However, you can grant custom roles only the relevant management permissions on clusters, tenants, and backup and recovery and the system permissions to create clusters.

Default roles

Default role cannot be edited or deleted. The following table describes the default roles that are provided by OCP and the permissions of these roles.

Role name	Description	Permission list
TENANT_VIEWER	The tenant read-only role. This role has read-only permissions on all the ApsaraDB for OceanBase tenants that are managed by OCP and the associated resources (clusters, hosts, background tasks, and alerts).	CLUSTER:*:TENANT:*:READ, CLUSTER:*:READ, HOST:*:READ, TASK:*:READ, ALARM:*:READ
TENANT_MANAGER	The tenant administrator role. This role has management permissions on all the ApsaraDB for OceanBase tenants that are managed by OCP and read-only permissions on the associated resources (clusters, hosts, background tasks, and alerts).	CLUSTER:*:TENANT:*:*, CLUSTER:*:READ, HOST:*:READ, TASK:*:READ, ALARM:*:READ

Role name	Description	Permission list
BACKUP_MANAGER	The management role of cluster backup and recovery. This role has management permissions on the backup and recovery of all the ApsaraDB for OceanBase clusters and tenants that are managed by OCP. This role also has read-only permissions on hosts and alerts, and management permissions on tasks. If you need to add a host, you must grant an additional HOST_MANAGER role to the user.	CLUSTER:*:BACKUP:*:*, CLUSTER:*:READ, CLUSTER:*:TENANT:*:READ, HOST:*:READ, ALARM:*:READ, TASK:*:*
CLUSTER_VIEWER	The cluster read-only role. This role has read-only permissions on all the ApsaraDB for OceanBase clusters that are managed by OCP and the associated resources (hosts, background tasks, and alerts).	CLUSTER:*:READ, HOST:*:READ, TASK:*:READ, ALARM:*:READ
CLUSTER_MANAGER	The cluster administrator role. This role has management permissions on all the ApsaraDB for OceanBase clusters that are managed by OCP and the associated resources (hosts, background tasks, and alerts). This role also has read-only permissions on the indirectly associated resources (users).	CLUSTER:*:*, HOST:*:*, TASK:*:*, ALARM:*:*, USER:*:READ
ALARM_MANAGER	The alert management role in OCP. This role has management permissions on alerts and subscriptions and read-only permissions on the associated resources (clusters, tenants, hosts, and users).	ALARM:*:*, CLUSTER:*:READ, HOST:*:READ, USER:*:READ
TASK_MANAGER	The management role of background tasks in OCP.	TASK:*:*
HOST_MANAGER	The host management role in OCP. This role has all the management permissions on hosts.	HOST:*:*

Role name	Description	Permission list
PROPERTY_MANAGER	The management role of system configuration parameters in OCP.	PROPERTY:*:*
ROLE_MANAGER	The management role of roles in OCP. This role has all the role-related management permissions.	ROLE:*:*
USER_MANAGER	The user management role in OCP. This role has all the user-related management permissions.	USER:*:*
PROFILE	The user personal information role in OCP. This role is used to log on to and access the personal center.	PROFILE:*:*
ADMIN	The system administrator role in OCP. This role has the maximum permission of OCP.	**

Custom roles

You can grant custom roles only the relevant management permissions on clusters, tenants, and backup and recovery and the system permissions to create clusters. You can use custom roles and default roles in combination to provide a variety of authorization policies.

You can grant the following permissions to custom roles.

Permission type	Permission content
Cluster permissions	The permissions of the specified cluster: **Create Tenant**, **Read-only**, **Update**, **Delete**, or **All Permissions**.
Tenant permissions	The permissions of the **specified ApsaraDB for OceanBase tenant** in the **specified ApsaraDB for OceanBase cluster**: **Read-only**, **Update**, **Delete**, or **All Permissions**.
Backup and recovery permissions	The following permissions of the specified cluster: • **Create**: Install components and initiate backup and recovery. • **Read-only**: View backup and configuration status. • **Update**: Update configurations and maintain components. • **Delete**: Delete configurations.

Permission type	Permission content
System permissions	Permissions to **create ApsaraDB for OceanBase clusters**.

17.1.3.7.3.2. Create a role

If the preset default roles in OCP cannot meet your requirements, system administrators or role administrators can create custom roles and grant more fine-grained management permissions to the custom roles. You can use custom roles and default roles in combination to provide a variety of authorization policies.

> **Note**
>
> You can grant custom roles only the relevant management permissions on clusters, tenants, and backup and recovery and the system permissions to create clusters.

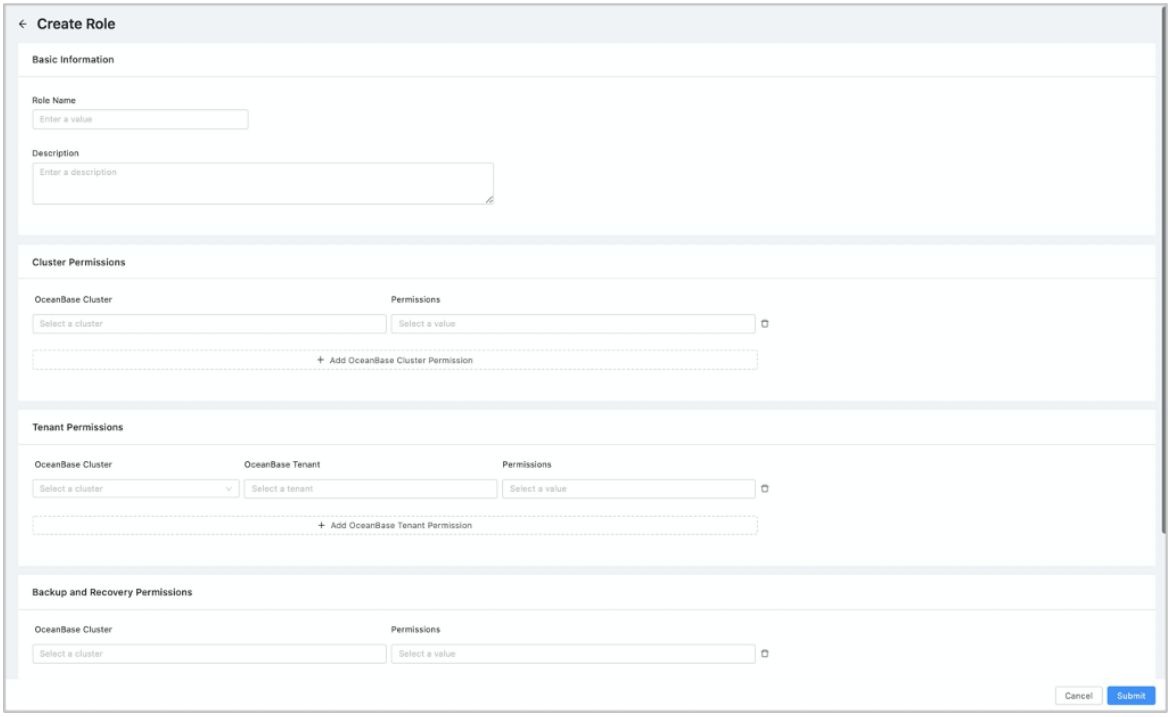
Prerequisites

The current logon user has the system administrator role ADMIN or the role management role ROLE_MANAGER and the corresponding permissions.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Security**.
3. In the upper-right corner of the **Role Management** tab, click **Create Role**.
4. Specify the **Role Name** and **Description** parameters.
5. Grant the role the relevant management permissions on clusters, tenants, and backup and recovery and the system permissions to create clusters based on service requirements.
   - No intersection exists between read-only permissions and management permissions, such as creation and editing permissions. If you need to grant management permissions to a role, you must also grant read-only permissions to the role.

- If tenant-relevant read-only or management permissions are required, you must also grant the role the read-only or management permissions on the cluster that corresponds to the tenant.



6. In the lower-right corner of the page, click **Submit**.

17.1.3.7.3.3. View role information

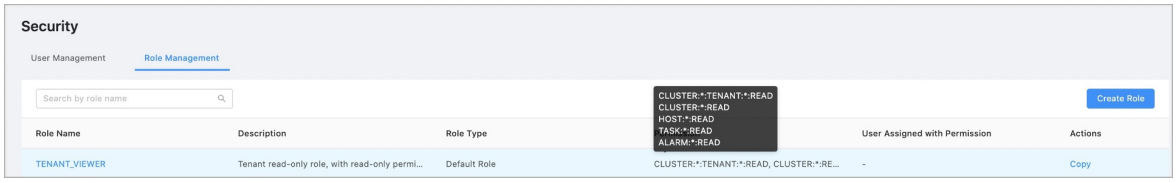
System administrators and role administrators can view information about specific roles or all the roles in the current OCP, including the role name, the description, and the permission content.

Prerequisites

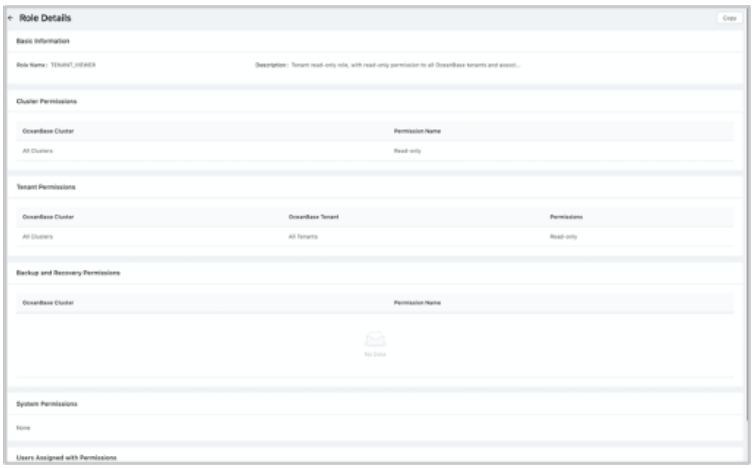
The current logon user has the system administrator role ADMIN or the role management role ROLE_MANAGER and the corresponding permissions.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Security**.
3. In the search box on the **Role Management** tab, enter the specified role name or a keyword, and click the search icon. In the list, you can view the following information about the specified role: **Description**, **Role Type**, **Permission** content, and **User Assigned with Permission**.



4. Click the role name in the search results. On the Role Details page, all the information about this role is displayed.



17.1.3.7.3.4. Copy a role

If you need to add other fine-grained permissions based on the existing role, you can create a role by copying a role.

Even if you create a role by copying a default role, the new role is still a custom role. You can grant the new role only the relevant management permissions on clusters, tenants, and backup and recovery and the system permissions to create clusters. The new role does not have the relevant system management features of the default role.

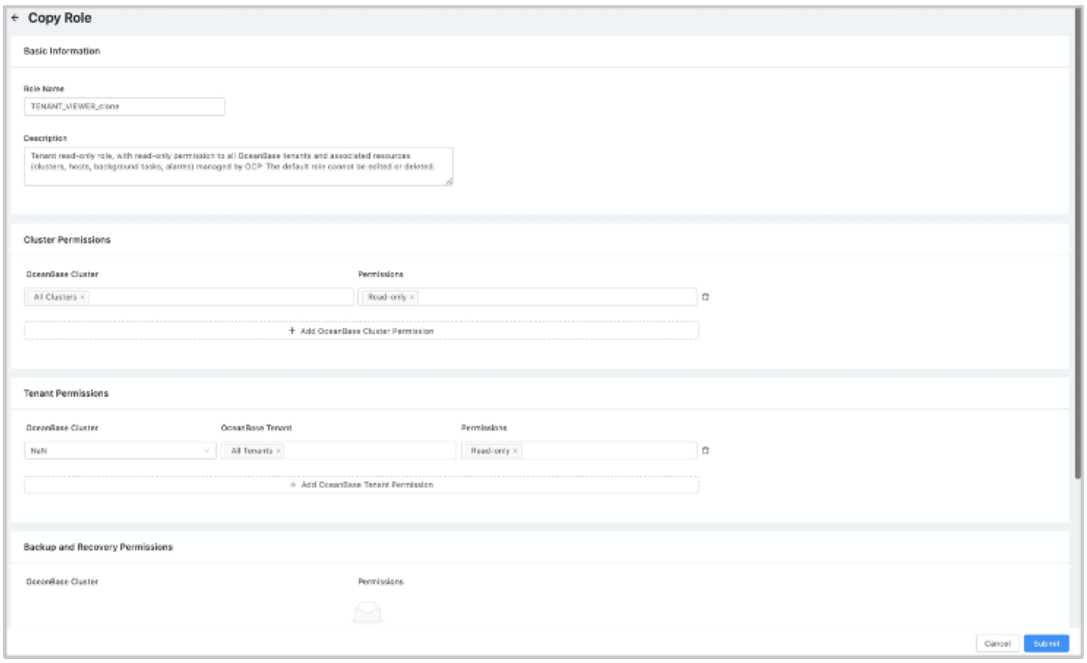
Prerequisites

The current logon user has the system administrator role ADMIN or the role management role ROLE_MANAGER and the corresponding permissions.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Security**.
3. On the **Role Management** tab, find the role to be copied, and click **Copy** in the corresponding **Actions** column.

4. Edit basic information and permission information about the new role.



5. In the lower-right corner of the page, click **Submit**.

17.1.3.7.3.5. Edit a role

After system administrators or role administrators create custom roles, they can modify the information and permissions of the custom roles anytime.

> **Note**
>
> - After you modify a role that has been assigned to a user, the modifications take effect the next time the user logs on.
> - Default roles cannot be modified.

Prerequisites

The current logon user has the system administrator role ADMIN or the role management role ROLE_MANAGER and the corresponding permissions.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Security**.
3. On the **Role Management** tab, find the specified role, and click **Edit** in the corresponding **Actions** column.
4. Modify the descriptions or permissions of the role based on your business requirements.
5. In the lower-right corner of the page, click **Submit**.

17.1.3.7.3.6. Delete a role

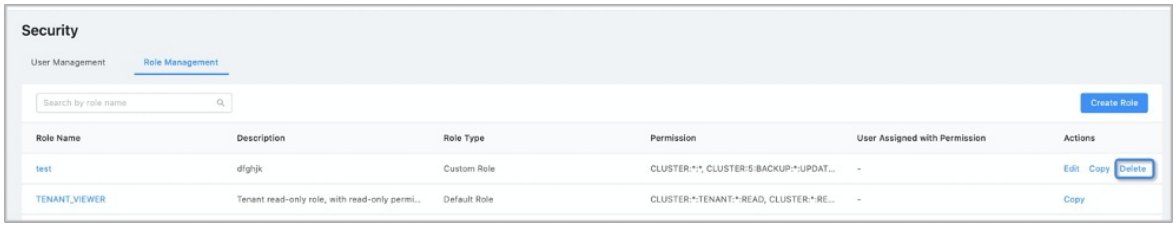
System administrators and role administrators can delete custom roles anytime based on business requirements. Default roles cannot be deleted.

Prerequisites

The current logon user has the system administrator role ADMIN or the role management role ROLE_MANAGER and the corresponding permissions.

Procedure

1. Log on to OCP.
2. In the left-side navigation pane, choose **System Management > Security**.
3. On the **Role Management** tab, find the specified role, and click **Delete** in the corresponding **Actions** column.



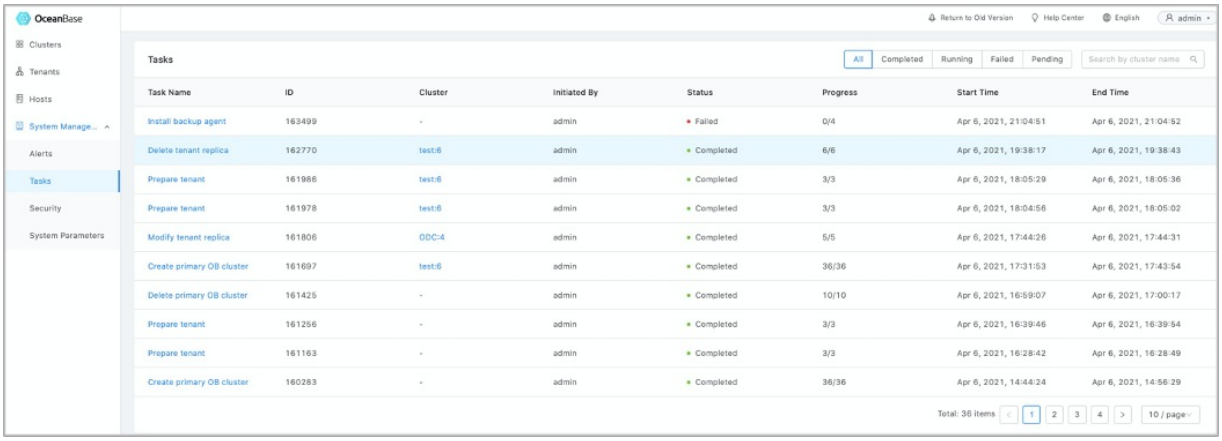
4. In the dialog box that appears, click **Delete**.

17.1.3.8. Manage tasks

17.1.3.8.1. View a task list

This topic describes the information that you can view in a task list.

By default, the **Tasks** page displays all the tasks in the clusters that the current logon user has permissions to view. The list displays the following task information: **Task Name**, **ID**, **Cluster**, **Initiated By**, **Status**, **Progress**, **Start Time**, and **End Time**. Among the information, **Cluster** is displayed in the format of Cluster name:Cluster ID. On the **Tasks** page, you can filter tasks by task status. The task statuses are **Completed**, **Running**, **Failed**, and **Pending**. By default, tasks in all statuses are displayed. You can also search for all the relevant tasks of a specified cluster by cluster name.



17.1.3.8.2. View task details

In the left-side navigation pane, choose System Management > Tasks. On the Tasks page, you can click the specified task name to view the task details.

On the task details page, a topology displays the upstream and downstream relationships of each step and the status of each step. You can move the topology by dragging and dropping the pointer in a blank area, and zoom out or zoom in the topology by scrolling the mouse wheel. You can also adjust the size of the canvas by using the zoom control in the upper-right corner. The topology is zoomed out or zoomed in by centering on the mouse pointer. For a long task flow, you can first zoom out the topology to quickly locate the desired step, and then zoom in the topology. This helps you quickly locate the step.

Retry or abort failed tasks

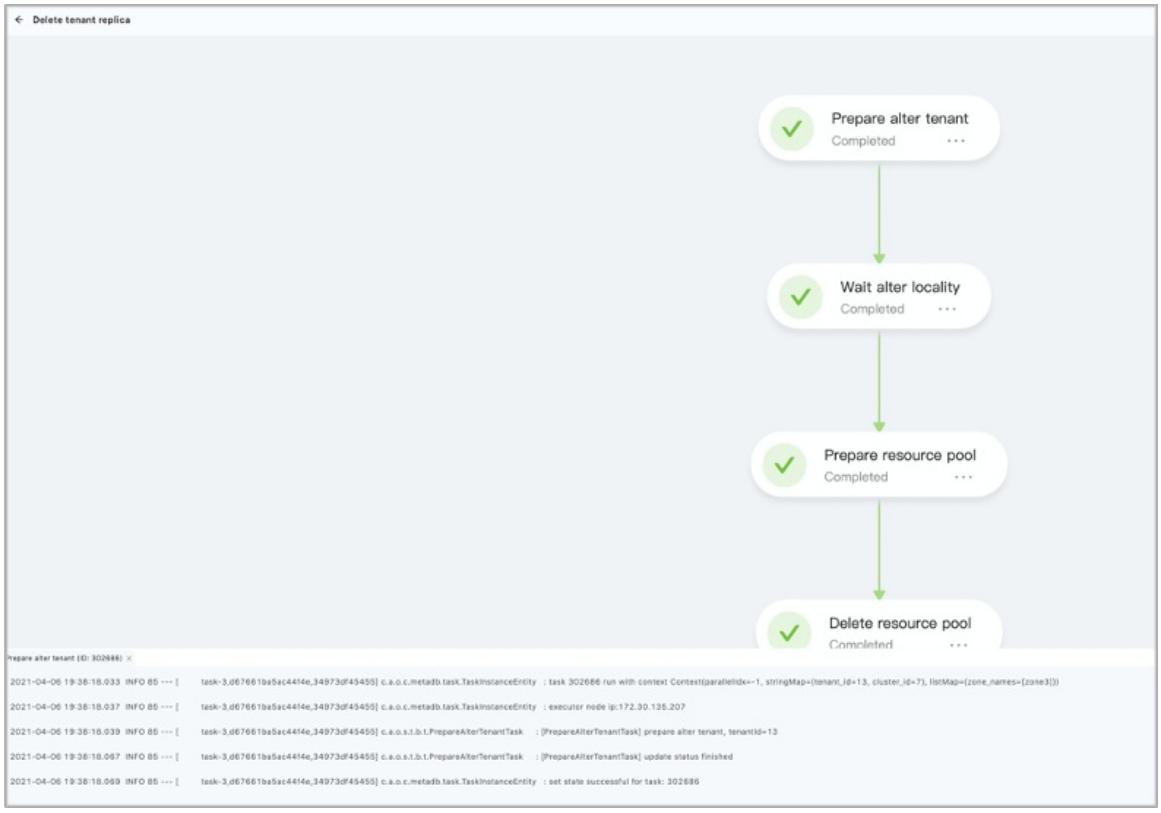
For failed tasks, OCP provides the Retry or Abort Task operation in the upper-right corner of a task topology.

- Abort Task: Perform a rollback operation for each step from the failed node to the root node of the task. This is primarily used to reclaim the resources and modify the status of the task.
- Retry: Perform the rollback and retry steps in sequence, starting from the failed node. If the operations are successful, continue to run the downstream nodes.

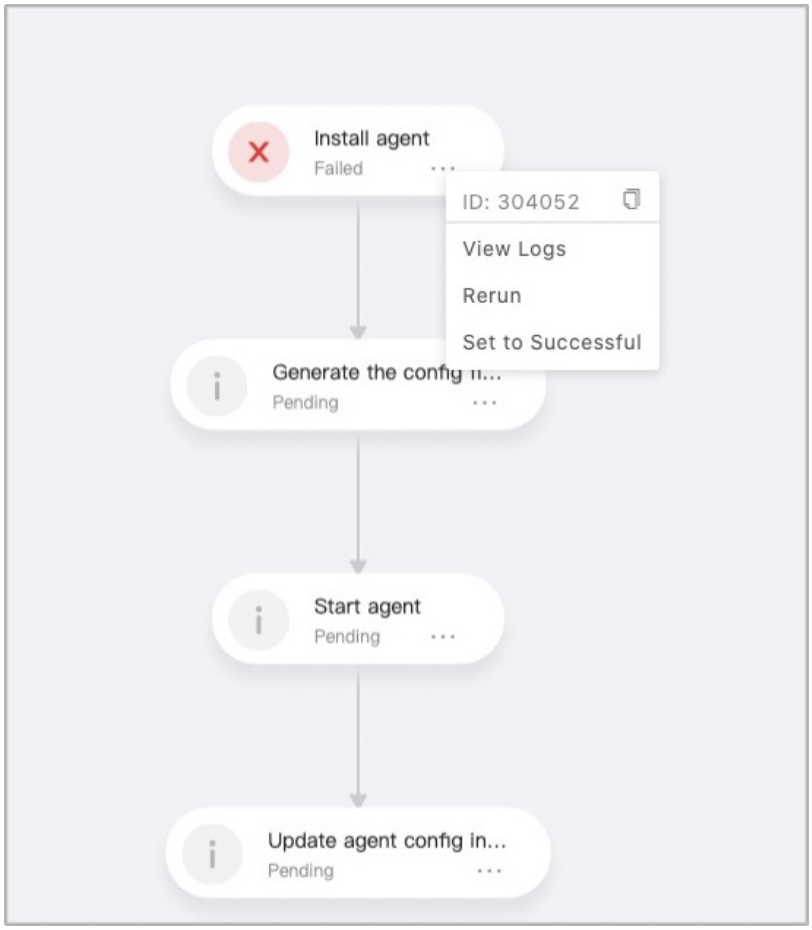
View the details of steps

You can perform different operations based on the node status for the specified step of a task. For example, you can view the step ID and logs. You can expand the hidden menu on the right of a specific step to view the operations that are supported by the current node.

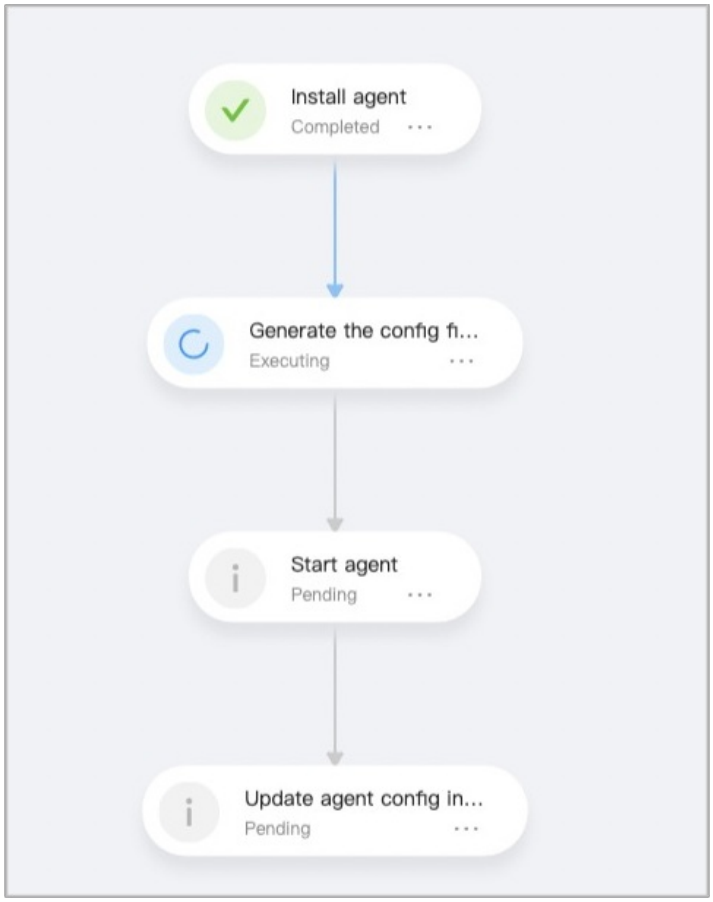
- For nodes whose status is successful, you can query logs. After you unfold the menu, the log information appears in the window at the bottom of the screen. You can enlarge the window by dragging the window.



- For nodes whose status is failed, you can perform the Rerun and Set to Successful operations in addition to viewing log information. Rerun indicates that you run the current node again. This means that you perform the rollback operation first and then rerun the current node. If the operations are successful, continue to run downstream nodes. Set to Successful indicates that you can set the status of the current node to successful and continue to run downstream nodes.



- For running nodes, you can view logs or stop running the nodes. After a node stops running, the status of the node becomes failed.



- For nodes that are pending for running, you cannot perform an operation.

17.1.3.9. Manage system parameters

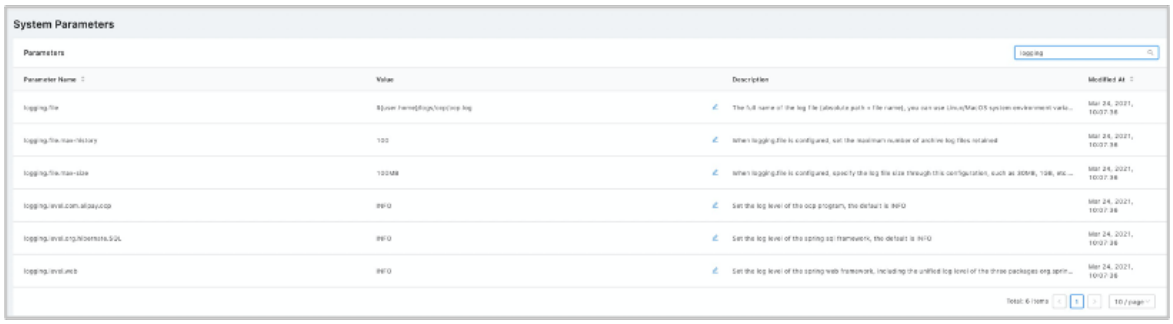
17.1.3.9.1. View system parameters

In OCP, system parameters are generally used to configure features, such as account logon and backup and recovery.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the left-side navigation pane, choose **System Management > System Parameters**. The System Parameters page displays a list of all the parameters for which OCP allows you to change values.
3. In the search box in the upper-right corner of the page, enter the name of the system parameter you need to view or a parameter keyword. Then, click the search icon to search for the specified system parameter.
   - The page displays the following parameter information: **Parameter Name**, **Value**, **Description**, and **Modified At**.
   - The parameter list also supports paging queries.

- The parameter description includes details, such as the parameter usage, valid values, and whether to restart to make the parameter take effect.

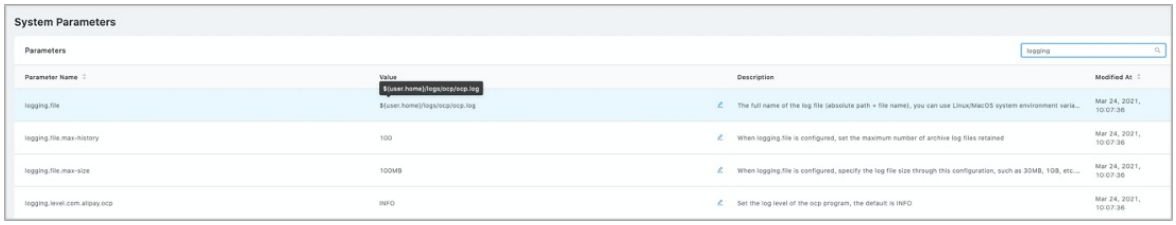


17.1.3.9.2. Modify system parameters

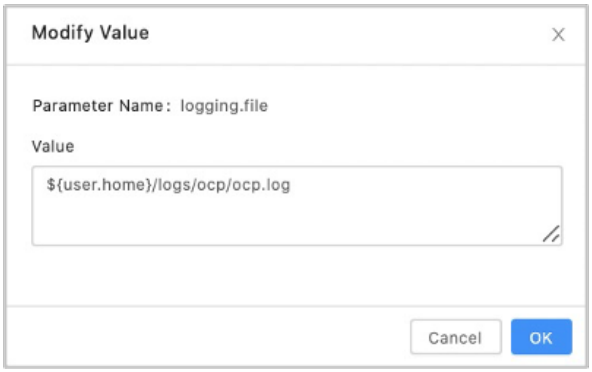
System parameters in OCP are generally used to configure features, such as account logon and backup and recovery. You can modify the relevant settings by changing the values of the system parameters.

Procedure

1. Log on to OCP. By default, the **Cluster Overview** page appears.
2. In the left-side navigation pane, choose **System Management > System Parameters**. The System Parameters page displays a list of all the parameters for which OCP allows you to change values.
3. In the search box in the upper-right corner of the page, enter the name of the system parameter you need to view or a parameter keyword. Then, click the search icon to search for the specified system parameter.
4. Click the Edit icon that corresponds to the specified parameter.



5. Enter a new parameter value.



6. Click **OK** to submit modifications.
   - The modifications take effect in about 10 minutes after the parameter is modified.
   - Some parameters require a restart to take effect. For more detailed descriptions about specific parameters, see Appendix 1. OCP configuration parameters.

17.1.3.10. Personal center

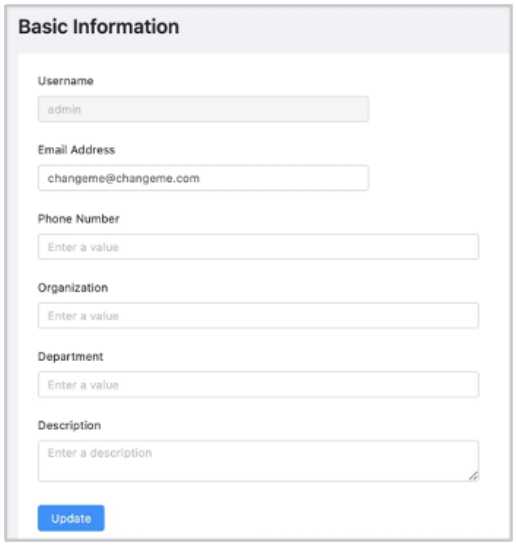
17.1.3.10.1. Specify personal information

After you log on to OCP, the current logon username appears in the upper-right corner of the system. You can click the current logon username to go to the personal center. In the personal center, you can specify your personal information, such as the contact information, the organization, and the department.

Procedure

1. In the upper-right corner of the OCP system interface, click the current logon username and select **Personal Settings**.

2. On the **Basic Information** page, specify your email address, phone number, organization, department, and personal description.



3. After you complete the settings, click **Update**.

17.1.3.10.2. Change the logon password

After you initially log on to OCP, you must change the password at the earliest opportunity to prevent an account leakage.

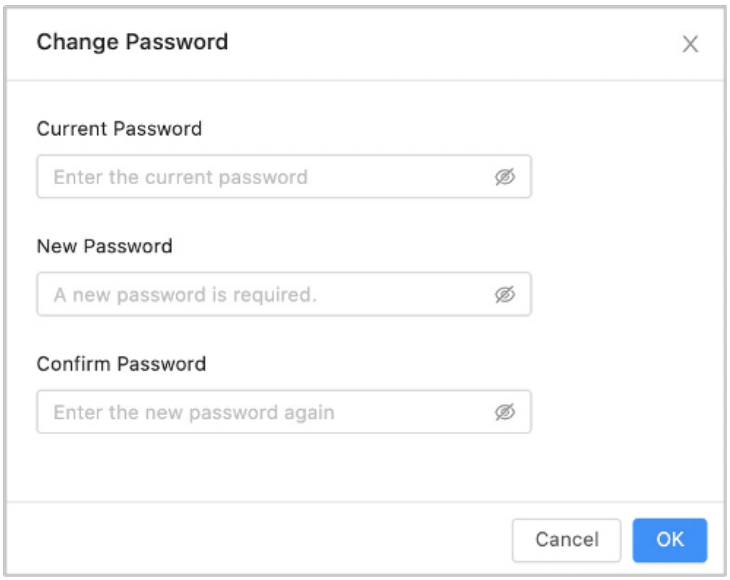
Background

We recommend that you regularly change your password to ensure account security.

Procedure

1. In the upper-right corner of the OCP system interface, click the current logon username and select **Change Password**.

2. In the **Change Password** dialog box, enter the old password and a new password and confirm the new password.



When you change the password, the new password must meet the requirements on the combination of uppercase letters, lowercase letters, and digits, and the length requirements.

- Must be 8 to 32 characters in length.
- Must contain at least two digits, two uppercase letters, two lowercase letters, and two special characters. Special characters are: _+@#$%

3. Click **OK**.

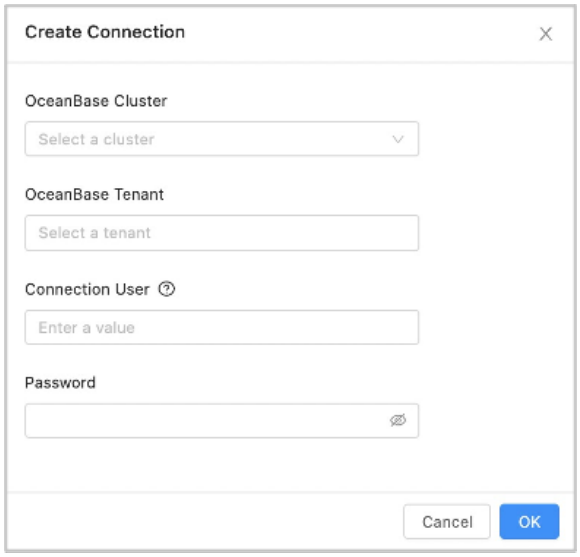
17.1.3.10.3. Password box

Personal password boxes are used to manage the connection information of the current logon user, such as the username and password for logging on to ApsaraDB for OceanBase, in a centralized manner. When you perform management operations on an ApsaraDB for OceanBase cluster or tenant in OCP, OCP must authenticate the connection information that corresponds to the password box of the current user.

Procedure

1. In the upper-right corner of the OCP system interface, click the current logon username and select **Password Box**. The **Password Box** page appears. For security purposes, the password on the page appears as ***.
2. Perform the following operations:

- To create a connection, click **Create Connection**. In the **Create Connection** dialog box, configure the relevant connection information and click **OK**.



- To delete connection information, select the connection information to be deleted, and then click **Delete** in the corresponding **Actions** column.
- Update connection information

> **Note**
>
> - To update the connection information of a cluster, you must delete the connection information first and add it again.
> - If you directly add connection information without deleting the original connection information, the new connection information does not overwrite the existing connection information. The system prompts that the duplicate record already exists.

17.1.3.11. Appendix

17.1.3.11.1. Appendix 1. OCP configuration parameters

This topic describes all the system parameters in OCP for the reference of OCP administrators. By default, the parameters automatically take effect in about 10 minutes after they are modified. Some parameters can take effect only after the OCP Server is started. For more information, see the special notes "Restart to take effect" included in the parameter description column.

Parameter	Default value	Parameter description

Parameter	Default value	Parameter description
ocp.active.standby.cluster.enabled	TRUE	Specifies whether to support the hot standby database feature of ApsaraDB for OceanBase. By default, this feature is enabled. By default, this feature is disabled when the old version of OCP is upgraded to version 2.4.x. If you need to enable this feature, you must make sure that the version of the OBProxy is not earlier than 1.7.2.
ocp.config-url.site.url		The Uniform Resource Locator (URL) for external access to the OCP config url service. By default, this parameter is empty. This indicates that the value that is the same as the value of ocp.site.url is used. If the config url service is separately deployed, you must specify a value that is different from the value of ocp.site.url.
ocp.env	private	The OCP environment. This configuration item is compatible with versions that are earlier than 2.3.x.
ocp.site.url	http://localhost:8080	The URL for external access to the OCP website. The URL must start with http instead of https and includes the Virtual IP Address (VIP), domain, and port. The URL cannot include a slash (/) at the end, such as http://localhost:8080.
ocp.system.default.language	zh-CN	The default language of the system (non-frontend language settings). If you do not specify this parameter, zh-CN is used. Restart to take effect.
ocp.system.default.timezone		The default time zone of the system. If you do not specify this parameter, the system default time zone is used. Restart to take effect.
ocp.version	2.4.2	The version number of OCP.
server.port	8080	Set the port number for the application server to start. Default value: 8080. Restart to take effect.

Parameter	Default value	Parameter description
springdoc.api-docs.enabled	FALSE	The OpenAPI 3 document API: specifies whether to enable the API. Default value: FALSE.

Security and logon module

Parameter	Default value	Parameter description
server.servlet.session.timeout	30m	The time-out period for logon sessions. Default value: 30m. The value of this parameter is at least 60s. If no suffix unit is added, the default unit is second.
ocp.iam.auth	local	The logon option of the web page. Valid values: local (OCP account in local MetaDB) and buc (employee account of Alibaba Group). Default value: local. Restart to take effect.
ocp.iam.auth.basic.enabled	TRUE	Specifies whether to enable the Basic Auth logon mode. Generally, this logon mode is used for clients, such as applications and SDKs. Default value: true. You can enable this configuration and ocp.iam.auth at the same time. Restart to take effect.
ocp.iam.auth.whitelist	/api/v2/time,.*Action=(ObRootServiceInfo|ObRootServiceRegister|ObIDCRegionInfo|GetObProxyConfig|AllocateClusterIdByNameAndIdx|DeleteObRootServiceInfoByClusterName).*	The whitelist of OCP logon-free APIs. The value is a comma-separated URL string that can be matched by regular expressions. Default value: /api/v2/time. Restart to take effect.
ocp.iam.csrf.enabled	TRUE	Specifies whether to enable cross-site request forgery (CSRF) security protection. In general, we recommend that you enable this feature for logons based on web pages. Default value: true. Restart to take effect.

Parameter	Default value	Parameter description
ocp.iam.csrf.url.excluded	/api/v2/iam/login.*,.*Action=(ObRootServiceInfo|ObRootServiceRegister|ObIDCRegionInfo|GetObProxyConfig|AllocateClusterIdByNameAndIdx|DeleteObRootServiceInfoByClusterName).*	You can specify a URL list to skip CSRF protection. Regular expression matching is supported. Default value: /api/v2/iam/login.*. This option only takes effect if CSRF security protection is enabled. The URL is a complete string that contains path and query param.
ocp.iam.login.lockout-minutes	30	Specifies the time when the logon from the client IP address is temporarily blocked if the logon failures limit is exceeded. Unit: min. The default value is 30 min.
ocp.iam.login.max-attempts	5	The number of consecutive username or password errors that are allowed during logon. If the limit is exceeded, the logon from the client IP address is temporarily blocked. The default value is five times.

OCP meta database connection (MetaDB)

Parameter	Default value	Parameter description
spring.datasource.druid.initialSize	10	The number of physical connections that are established during initialization. Restart to take effect.
spring.datasource.druid.keepAlive	TRUE	For connections within the number specified by minIdle in the connection pool, if the idle time exceeds minEvictableIdleTimeMillis (the default value is 1,800 seconds), the keepAlive operation is performed. Restart to take effect.
spring.datasource.druid.maxActive	100	The maximum number of connection pools. Restart to take effect.
spring.datasource.druid.maxWait	2000	The maximum waiting time when a connection is obtained. Unit: ms. Restart to take effect.

Parameter	Default value	Parameter description
spring.datasource.druid.minIdle	2	The minimum number of connection pools. Restart to take effect.
spring.datasource.druid.name	metadb-connect-pool	**MetaDB** druid connection pool name. Restart to take effect.
spring.datasource.druid.testWhileIdle	TRUE	Recommended configuration: **true** This does not affect performance and ensures security. It is checked when you apply for a connection. Restart to take effect.
spring.datasource.druid.validationQuery	SELECT 1 FROM DUAL	The SQL statement that is used to check whether the connection is valid. Restart to take effect.

OCP monitoring database connection (MonitorDB)

Parameter	Default value	Parameter description
ocp.monitordb.database	chacha_dev	The name of the database for storing monitoring data.
ocp.monitordb.driverClassName	com.alipay.oceanbase.obproxy.mysql.jdbc.Driver	The Java Database Connectivity (JDBC) driver. Restart to take effect.
ocp.monitordb.druid.initialSize	10	The number of physical connections that are established during initialization. Restart to take effect.
ocp.monitordb.druid.keepAlive	TRUE	For connections within the number specified by minIdle in the connection pool, if the idle time exceeds minEvictableIdleTimeMillis (the default value is 1,800 seconds), the keepAlive operation is performed. Restart to take effect.

Parameter	Default value	Parameter description
ocp.monitordb.druid.maxActive	100	The maximum number of connection pools. Restart to take effect.
ocp.monitordb.druid.maxWait	2000	The maximum waiting time when a connection is obtained. Unit: ms. Restart to take effect.
ocp.monitordb.druid.minIdle	2	The minimum number of connection pools. Restart to take effect.
ocp.monitordb.druid.name	monitordb-connect-pool	druid connection pool name. Restart to take effect.
ocp.monitordb.druid.testWhileIdle	TRUE	We recommend that you set the value to true. This does not affect performance and ensures security. It is checked when you apply for a connection. Restart to take effect.
ocp.monitordb.druid.validationQuery	SELECT 1 FROM DUAL	The SQL statement that is used to check whether the connection is valid. Restart to take effect.
ocp.monitordb.host	10.101.194.179	The hostname of the database for storing monitoring data.
ocp.monitordb.password	root	The password of the database for storing monitoring data.
ocp.monitordb.port	2888	The port of the database for storing monitoring data.
ocp.monitordb.username	root@ocp_meta#obocp	The username of the database for storing monitoring data.

Alert module

Parameter	Default value	Parameter description
ocp.alarm.send.batch-max	20	The maximum number of new notifications that are retrieved at a time.

Parameter	Default value	Parameter description
ocp.alarm.send.once-retry-times	3	The maximum number of retries when alarms are sent each time.
ocp.alarm.send.once-timeout-ms	10000	The time-out period for sending alarms each time.
ocp.alarm.send.period.ms	2000	The interval (ms) for sending notifications. The default value is 2,000 ms. Restart to take effect.
ocp.alarm.send.retry-timeout-minutes	60	The retry time-out period (min). If the period is exceeded, the system does not retry to send notifications. The default value is 60 min.
ocp.alarm.send.total-failed-retry-times	3	The maximum number of retries when notifications fail to be sent.
ocp.alarm.send.total-timeout-seconds	60	The time-out period for a single machine to send one notification.
ocp.backup.agent.relation.file.full-path.name	#{systemProperties['user.home'].concat('/ocp-server/etc/backup_agent_ob_relations_config.yaml')}	The file that describes the version of the backup and recovery component, the dependent metadatabase, and the mapping relationships between the version of the backup and recovery component and the version of ApsaraDB for OceanBase.

Backup and recovery module

Parameter	Default value	Parameter description
ocp.backup.alarm.backup-data-retention-days	7	The days that backup data is retained.
ocp.backup.alarm.backup-liboblog-expire-days	7	The latest days that the backup libblog is retained
ocp.backup.alarm.base-backup-last-finished-threshold	12960	The baseline fails to be backed up in the last nine days. The threshold is initially set to nine days (12,960 min). Unit: min

Parameter	Default value	Parameter description
ocp.backup.alarm.base-backup-timeout	10	The time-out period (min) for baseline backup scheduling.
ocp.backup.alarm.inc-backup-delay-threshold	3600	The alert threshold of the latency of incremental backup (in seconds).
ocp.backup.alarm.last-data-backup-max-interval-minutes	1440	Checks whether the baseline backup task fails in a recent time. The default value is one day. Unit: min.
backup.dbname.prefix	backup	The custom prefix of the metadatabase name of backup and recovery. The default prefix is backup. If the prefix is changed, only the names of new databases are affected during OCP initialization or upgrades, and the names of the existing databases are not changed.

Parameter	Default value	Parameter description
ocp.agent.rpc.port	62888	The service port of OCP-Agent. It is used by a remote procedure call (RPC).
ocp.ob-agent.version	t-oceanbase-ob-agent-2.4.0-1884988.alios7.x86_64.rpm	The OB-Agent version.
ocp.ocp-agent.version	t-oceanbase-ocp-agent-2.4.0-1884049.alios7.x86_64.rpm	The OCP-Agent version.

OCP-Agent and OB-Agent

Parameter	Default value	Parameter description
ocp.agent.rpc.port	62888	The service port of OCP-Agent. It is used by the RPC.
ocp.ob-agent.version	t-oceanbase-ob-agent-2.4.0-1884988.alios7.x86_64.rpm	The OB-Agent version.
ocp.ocp-agent.version	t-oceanbase-ocp-agent-2.4.0-1884049.alios7.x86_64.rpm	The OCP-Agent version.

OBProxy connections

Parameter	Default value	Parameter description
ocp.system.obproxy.address	localhost	The OBProxy address that is used to connect to the ApsaraDB for OceanBase cluster.
ocp.system.obproxy.metadb.cluster-name	obdv1	The cluster where OBProxy metadata resides. If MetaDB is not used when OBProxy is deployed, you can ignore this configuration.
ocp.system.obproxy.metadb.database	obproxy	The OBProxy metadatabase. If MetaDB is not used when OBProxy is deployed, you can ignore this configuration.
ocp.system.obproxy.metadb.user	root@obproxy	The user of the OBProxy metadatabase. If MetaDB is not used when OBProxy is deployed, you can ignore this configuration.
ocp.system.obproxy.port	2883	The OBProxy port that is used to connect to the ApsaraDB for OceanBase cluster.

Background tasks and scheduling

Parameter	Default value	Parameter description
ocp.task.executor.core-pool-size	16	The number of core threads in the task execution thread pool. Default value: 16. Restart to take effect.
ocp.task.executor.keep-alive-seconds	120	The time when idle threads in the task execution thread pool keep alive. Unit: s. The default value is 120s. Restart to take effect.
ocp.task.executor.max-pool-size	64	The maximum number of threads in the task execution thread pool. Default value: 64. Restart to take effect.

Parameter	Default value	Parameter description
ocp.task.executor.queue-capacity	1000	The size of the task execution thread queue. Default value: 1000. Restart to take effect.

Management of remote ApsaraDB for OceanBase connections

Parameter	Default value	Parameter description
obsdk.connectors.cache.cleanup.period.second	300	The interval for obsdk to clean up the connector cache. Unit: s. Valid values: 30 to 1800. Default value: 300.
obsdk.connectors.cache.max.idle.second	3600	The expiration time of the obsdk idle connector. Unit: s. Valid values: 300 to 18000. Default value: 3600.
obsdk.connectors.cache.size	50	The cache size of the obsdk connector. Valid values: 5 to 100. Default value: 50.
obsdk.connectors.print.sql	TRUE	Indicates whether to enable the SQL print in obsdk. By default, it is enabled.
obsdk.connectors.slow.query.threshold.millis	1000	The threshold of slow query logs in obsdk. Unit: ms. The default value is 1000 ms.
obsdk.ob.connection.mode	proxy	The connection mode of ApsaraDB for OceanBase. Valid values: proxy and direct. Default value: proxy.

Log module

Parameter	Default value	Parameter description
logging.file	${user.home}/logs/ocp/ocp.log	The full name (absolute path plus the file name) of the log file. You can use Linux or macOS system environment variables, such as ${HOME}, or the Java system variable ${user.home}. Default value: ${user.home}/logs/ocp/ocp.log.

Parameter	Default value	Parameter description
logging.file.max-history	100	After logging.file is configured, you can specify the maximum number of archived log files that are retained.
logging.file.max-size	100MB	After logging.file is configured, you can use this parameter to specify the log file size, such as 30 MB and 1 GB. Default value: 100MB.
logging.level.com.alipay.ocp	INFO	The log level of the OCP program. Default value: INFO.
logging.level.org.hibernate.SQL	INFO	The log level of the Spring SQL framework. Default value: INFO.
logging.level.web	INFO	The log level of the Spring Web framework. Default value: INFO.

Software package management

Parameter	Default value	Parameter description
ocp.file.default-block-split-size	1048576	The default file block size in the OCP file module. Unit: byte. The default value is 1 MB.
ocp.file.local.built-in.dir	#{systemProperties['user.home'].concat('/ocp-server/lib')}	The local path of the built-in files in the OCP file module.
ocp.file.local.dir	#{systemProperties['user.home'].concat('/data/files')}	The local path of the files in the OCP file module.
ocp.file.max-concurrent-count	16	The maximum number of files that are concurrently processed by a single node in the OCP file module. Default value: 16.
ocp.file.try-lock-timeout-milliseconds	10000	The lock time-out of a single node in the OCP file module, in milliseconds. Default value: 10000.

17.1.3.11.2. Appendix 2. Table of OCP resource unit specifications

This topic describes the built-in resource unit specifications in OCP. The minimum specification that is supported by ApsaraDB for OceanBase V2.0 or later is S1.

Specification name	Minimum number of CPUs	Maximum number of CPUs	Minimum memory	Maximum memory	Group
B	0.25	0.25	1 GB	1 GB	basic
LogOnlyNormal	1	1	2 GB	2 GB	logonly
LogOnlySystem	5	5	35 GB	35 GB	logonly
S0	0.5	0.5	2 GB	2 GB	standard
S1	1.5	1.5	6 GB	6 GB	standard
S2	3	3	12 GB	12 GB	standard
S3	6	6	20 GB	20 GB	standard
S4	12	12	40 GB	40 GB	standard

17.1.3.11.3. Appendix 3. Table of OCP error messages

This topic describes OCP error messages in a table.

Error code	Error message
1001	The passed parameter is empty or invalid: {0}. Check and try again.
1002	The record of the specified {0} type is not found. Parameter: {1}. Check and try again.
1003	
1004	Request processing timed out. Try again.

Error code	Error message
1005	A conflict occurs when the request is processed. Try again.
1006	The resource that has the same name already exists (type: {0}, parameter: {1}). Change to another name and try again.
1007	Unsupported unit: {0}
1010	The passed start and end time is invalid. Change the time and try again.
1011	Unsupported sorting field {0}.
1012	No configuration item found: {0}
1113	Failed to obtain the next value for the sequence.
1200	An exception occurs when RPC calls I/Os. server: {0} port: {1}
1201	Failed to call and execute RPC. server: {0} port: {1} command: {2} code: {3} result: {4}
1500	Failed to operate ApsaraDB for OceanBase. Error message: {0}
1998	
1999	An unknown error occurred. Cause: {0}, error message: {1}. Contact the administrator.
3000	The current user has not logged on or an error occurred during logon. Log on and try again.
3001	The current logon account has been disabled. Contact the administrator.
3002	The current logon account has expired. Contact the administrator.

Error code	Error message
3003	The current logon account has been locked. Contact the administrator.
3004	Invalid username or password. Try again. You have {0} remaining opportunities.
3005	The password has expired. Contact the administrator to reset the password.
3006	Invalid username or password. Try again. You have {0} remaining opportunities.
3007	Logon with the current account has been temporarily disabled. Contact the administrator.
3008	Invalid username {0}. The username must start with a lowercase letter and can contain lowercase letters, digits, underscores (_), and periods (.).The username must be 4 to 48 characters in length.
3009	Invalid password. The password must be 8 to 32 characters in length, and must contain at least two digits, two uppercase letters, two lowercase letters, and two special characters (_+@#$%)
3010	This operation requires the password of user {2} of tenant {1} in cluster {0}. Add the password to the password box first.
3011	The logon password of the account does not match the password provided. Check and try again.
3012	Invalid password ID format.
3013	The password whose ID is {0} does not exist in the password box.
3100	You have no permission to perform the corresponding operations. Contact the administrator.
3101	The expression of the permission cannot be empty. Check the permission settings and try again.

Error code	Error message
3102	The given expression {0} of the permission is invalid. Check the permission settings and try again.
3103	The system default role {0} cannot be deleted.
3104	The system default account {0} cannot be deleted.
3105	{0} is the username that is reserved by the system. Select another username and try again. Avoid including words, such as admin, sys, dba, and proxy.
4000	
4001	Task {0} does not exist.
4002	DAG {0} does not exist.
4003	A loop structure exists.
4004	Task context error.
4005	Failed to run the {0} command on host {1}.
4006	Failed to save file {0} on host {1}.
4007	Task {0} is in the {1} state. You cannot perform this operation.
5000	
6000	
7000	The specified resource {0}:{1} contains one or more child resources. Clear the child resources and try again.
7001	Host <{0}:{1}> already exists. Modify and try again.

Error code	Error message
7002	Failed to establish the SSH connection to the destination host {0}@{1}:{2} in the test. Cause: {3}. Modify the connection information and try again.
7004	The current host {0} is offline or in use. Release the host, recover the status of the host to {1}, and try again.
7005	Host <{0}:{1}> does not exist.
7006	This operation is not supported in the current host status {0}.
7007	The Internet data center (IDC) where host {0} resides does not match the IDC of the desired OBServer.
7008	The IDC where host {0} resides does not match the IDC of the desired zone.
7009	The region where host {0} resides does not match the region of the desired OBServer.
7010	Multiple {1} services of the same type cannot be deployed on host {0}. Select another host and try again.
7011	Multiple {1} services cannot be deployed on the host {0} of the container type. Select another host and try again.
7012	The agent service has been deployed on the current host {0}. Uninstall the agent and try again.
7013	The host whose IP address is <{0}> does not exist.
7014	The host whose IP address is <{0}> is not unique.
7500	File {0}:{1} does not exist.
7501	File block {0}:{1} is not found.
7502	The file that is named {1} and of the {0} type already exists.

Error code	Error message
7503	An error occurred while verifying the file suffix. The suffix is {0} but the expected suffix is {1}.
7504	An error occurred while verifying the real type of the file. The type is {0} but the expected type is {1}.
7505	Waiting for other requests to complete operating files timed out. Try again.
8000	Failed to access your personal center. Try again later.
8001	You are not allowed to delete the content of the password boxes of other users. Parameter: {0}
8002	The same connection information already exists. Delete the original record and create a connection again. Parameter: {0}
8500	The parameter {0} is empty or invalid:{1}. The root path of the website must start with http or https and contain the domain name and the port number. Check and try again.
10000	
11000	
11001	The specified cluster id={0} does not exist.
11002	The specified cluster name={0} does not exist.
11003	The specified cluster id={0}. The current type does not support this operation.
11004	The specified cluster id={0}. The current version does not support this operation. The minimum version that supports this operation is {1}.
11005	The information about the passed root server is invalid.

Error code	Error message
11007	This operation is not supported in the current status of cluster {0}.
11008	This operation is supported only when cluster {0} is in the {1} state.
11009	Invalid rootserver JSON {0}.
11010	No root server is found in the cluster whose ID is {0}.
11011	Invalid password. Make sure that the old password you enter is correct.
11012	The passed password parameter cannot be empty.
11013	The passed rpm package name cannot be empty.
11014	The cluster to be created already exists.
11015	The current cluster has a secondary cluster. This operation is not allowed.
11016	The secondary cluster does not support upgrade operations.
11017	No primary cluster is found in cluster {0}.
11018	Multiple primary cluster are found in cluster {0}
11019	The server list of cluster {0} is empty.
11020	The last O&M task of the cluster has not been completed.
11021	A cluster has been deployed on the passed machine.
11022	The hot secondary database feature of the cluster is not enabled.

Error code	Error message
11023	The specified cluster {0} does not meet the switching conditions.
11024	The addition operation is not completed in the specified secondary cluster {0}.
11030	The number of the passed machines does not match that of the OBServers to be imported to the cluster.
11031	The IP address of the passed machine does not match that of the OBServer to be imported to the cluster.
11032	Import the primary cluster first, and then import the secondary cluster.
11033	The cluster to be imported already exists.
11034	Region information about zone {0} is missing in the cluster to be imported.
11035	IDC information about zone {0} is missing in the cluster to be imported.
11050	The specified parameter {0} is not found.
11051	Format error for the value {1} of parameter {0}.
11052	When you specify a scope in which cluster parameters take effect, you can specify only a cluster, a zone, or a server. The current value {0} is invalid. Try again.
11100	Failed to connect to cluster {0}. Check whether the password of user {1} under the sys tenant of the cluster in the password box is correct. Check whether the whitelist of the sys tenant is correctly configured and whether the network is connected.
11201	The merged version number does not exist for the version {1} of the cluster whose ID is {0}.
11202	The merge query timed out. Try again.

Error code	Error message
11203	The name {0} of the metric for merging statistics is not supported.
11204	Failed to update the merge parameters because conflicting requests may exist. Check whether the update is successful a few seconds later.
11205	The merge operation cannot be initiated from a non-primary cluster. The cluster whose ID is {0} is a standby cluster.
11500	
11501	Failed to start ob agent on host {0}.
12000	
12001	The format of the entered zone name is invalid. The name must start with a letter, and can contain uppercase and lowercase letters, digits, and underscores (_). The name must be 2 to 64 characters in length.
12002	No zone {1} is found in the cluster whose ID is {0}.
12003	Zone {1} already exists in the cluster whose ID is {0}.
12004	This operation is not supported in the current status of the specified zone {0}.
12005	Failed to stop zone {0}.
12006	The specified zone {0} has a unit and cannot be deleted.
12007	The last O&M task in the zone has not been completed.
12008	The passed zone name already exists.
13000	
13001	The specified OBServer is not found. ID: {0}.

Error code	Error message
13002	The specified OBServer is not found. IP: {0}, port: {1}.
13003	This operation is not supported in the current status of the specified OBServer {0}.
13004	The observer {0} has not exited.
13005	Failed to start observer {0}.
13006	The IP address of the destination observer is invalid.
13007	The RPC port of the destination observer is invalid.
13008	The SQL port of the destination observer is invalid.
13009	The remaining number of servers cannot be less than the number of units of tenant {0} in zone {1}.
13010	The obagent {0} has not exited.
13011	The observer cannot be deleted. Cause: {0}.
13012	The last O&M task on the observer has not been completed.
13013	The specified OBServer is not found. IP: {0}.
13014	The specified observer is not unique. IP: {0}.
15000	
15001	The specified specification ID {0} does not exist.
15002	The specified specification name {0} does not exist.
15003	The format of the entered specification name is invalid. The name must start with a letter, and can contain uppercase and lowercase letters, digits, and underscores (_). The name must be 2 to 32 characters in length.

Error code	Error message
15004	The entered specification name {0} already exists.
15005	The entered CPU value is invalid. The minimum value is 0.5.
15006	The entered memory value is invalid. The minimum value is 1,073,741,824. Unit: byte.
15007	The entered disk value is invalid. The minimum value is 10,737,418,240. Unit: byte.
15008	The entered IOPS value is invalid. The minimum value is 128.
15009	
15010	The entered unit specification type is invalid. Valid values: SYSTEM and CUSTOM.
15020	The format of the entered tenant name is invalid. The name must start with a letter, and can contain uppercase and lowercase letters, digits, and underscores (_). The name must be 2 to 64 characters in length.
15021	Tenant {1} in cluster {0} already exists.
15022	Tenant {1} is not found in cluster {0}.
15023	The specified tenant ID {0} does not exist.
15024	The specified tenant ID {0} has been deleted.
15025	This operation is not supported in the current status of the specified tenant {0}.
15026	The specified tenant {0} is not allowed to be deleted.
15027	The operation is not allowed for the specified tenant {0}.
15028	Failed to set the password for the specified tenant whose ID is {0}.

Error code	Error message
15030	The entered tenant mode is invalid. Valid values: MYSQL and ORACLE.
15031	The entered length of the primary zone is invalid. The value must be less than 128.
15032	The entered primary zone is invalid.
15033	The entered whitelist length is invalid. The value must be less than 65,535.
15034	The entered password length is invalid. The value must be less than 32.
15035	The entered description length is invalid. The value must be less than 1,024.
15036	The minimum version that supports the Oracle mode is {0}. The current version is {1}.
15037	The passed zone is invalid
15040	The passed zone {0} is invalid.
15041	No zone {0} is found.
15042	No resource pool is available in the specified zone {0}.
15043	The specified unit {0} is not found.
15044	The specified unit {0} is the only resource unit in the zone to which the unit belongs and cannot be deleted.
15045	The passed number of units is invalid.
15046	The passed number of units cannot exceed the number of active servers in the zone.
15050	No server is available under tenant {0}.

Error code	Error message
15060	The specified tenant parameter {0} is not found.
15061	The specified tenant parameter {0} is of the read-only type.
15062	Failed to obtain the old value of the specified tenant parameter {0}.
15080	The passed replica type is invalid.
15082	The locality modification progress for tenant {0} is not found.
15083	Locality has not been modified for tenant {0}.
15084	The resource pool has not been scaled down for tenant {0}.
15100	Failed to connect to tenant {0}. Check whether the password of user root under the tenant in the password box is correct and whether the whitelist of the tenant is correctly configured.
20000	Backup and recovery is not supported in the {0} version of ApsaraDB for OceanBase.
20001	The configuration file {0} exists. However, no backup component applies to the cluster {2} of version {1}.
20002	The installation directory {1} whose IP address is {0} already exists. Check it manually.
20003	Backup scheduling needs to be configured first for cluster {0}.
20004	Parameter error.
20005	The backup configuration that apply to the cluster {1} of version {0} is not configured in the component. Configure it.

Error code	Error message
20006	None of the components {0} that apply to this cluster are online. Check it.
20007	The baseline backup task of the cluster or the tenant already exists.
20008	Immediate backup of the cluster failed.
20009	Failed to initiate data restoration.
20010	The URI in the backup configuration {0} is empty.
20011	The endpoint in the backup configuration {0} is empty.
20012	The accessKeyId in the backup configuration {0} is empty.
20013	The secretAccessKey in the backup configuration {0} is empty.
20014	The backup version number of tenant {0} is not found in the backup file.
20015	Failed to resolve the tenant information in the backup file.
20016	Failed to add the configuration file.
20017	Failed to delete the configuration because the configuration is being used by component {0}.
20018	The configuration name {0} already exists.
20020	The {0} component failed.
20021	The host already has a running O&M task (TaskId:{0}). Wait until the task is completed before you initiate a new O&M operation.
20030	The data backup is not started.
20031	The log backup is not started.

Error code	Error message
20032	The same cluster or tenants in the same cluster can have only one scheduling configuration. Cluster {0} and tenant {1} already exist. Delete the existing configuration before you add a configuration.
20040	Failed to create ResourceUnit {0} in the process of recovering the tenant. {1}
20041	The {0} format in the entered pool list is invalid. Check it.
20042	The pool in the entered pool list already exists. Change the pool name.
20043	The submitted new tenant {0} is being recovered. Check it.
20050	A switchover between primary and secondary databases may occur in cluster {0}. The secondary database {1} cannot be backed up. Back up the current primary database {1} to a new backup directory.
21000	
22000	

17.1.3.11.4. Appendix 4. OCP alert template variables

Alert template variables are used to configure alert rules and alert channels.

Category	Name	Description
Alert rule	app_type	Application type
Alert rule	alarm_type	Alert type
Alert rule	alarm_target	Alert object
Alert rule	alarm_scope	Scope
Alert rule	alarm_level	Alert severity

Category	Name	Description
Alert rule	alarm_evaluation_interval	Alert evaluation interval (second)
Alert rule	alarm_duration	Lasting duration (second)
Alert rule	alarm_status	Alert status
Alert rule	alarm_active_at	Time when the alert is triggered
Alert rule	alarm_resolved_at	Time when the alert is eliminated
Alert rule	alarm_last_interval	Lasting duration (second)
Alert rule	alarm_name	Alert name
Alert rule	value	Indicator value
Alert rule	alarm_threshold	Alert threshold
Alert rule	alarm_updated_at	Time when the alert is updated
Alert rule	service	Service name
Alert rule	ob_cluster_group	ApsaraDB for OceanBase cluster group
Alert rule	ob_cluster	ApsaraDB for OceanBase cluster
Alert rule	ob_cluster_id	ID of the ApsaraDB for OceanBase cluster
Alert rule	ob_tenant	ApsaraDB for OceanBase tenant
Alert rule	host_ip	IP address of the host
Alert rule	app_cluster	Application cluster
Notification message	app_type	Application type

Category	Name	Description
Notification message	alarm_type	Alert type
Notification message	alarm_target	Alert object
Notification message	alarm_scope	Scope
Notification message	alarm_level	Alert severity
Notification message	alarm_evaluation_interval	Alert evaluation interval (second)
Notification message	alarm_duration	Lasting duration (second)
Notification message	alarm_status	Alert status
Notification message	alarm_active_at	Time when the alert is triggered
Notification message	alarm_resolved_at	Time when the alert is eliminated
Notification message	alarm_last_interval	Lasting duration (second)
Notification message	alarm_name	Alert name
Notification message	value	Indicator value
Notification message	alarm_threshold	Alert threshold
Notification message	alarm_updated_at	Time when the alert is updated
Notification message	alarm_summary	Alert overview
Notification message	alarm_description	Alert details
Notification message	alarm_level_color	Color that corresponds to the alert severity
Notification message	alarm_id	Alert ID

Category	Name	Description
Notification message	alarm_url	URL of alert access on the OCP site
Notification message	service	Service name
Notification message	ob_cluster_group	ApsaraDB for OceanBase cluster group
Notification message	ob_cluster	ApsaraDB for OceanBase cluster
Notification message	ob_cluster_id	ID of the ApsaraDB for OceanBase cluster
Notification message	ob_tenant	ApsaraDB for OceanBase tenant
Notification message	host_ip	IP address of the host
Notification message	app_cluster	Application cluster
Aggregate message	app_type	Application type
Aggregate message	alarm_type	Alert type
Aggregate message	alarm_target	Alert object
Aggregate message	alarm_scope	Scope
Aggregate message	alarm_level	Alert severity
Aggregate message	alarm_evaluation_interval	Alert evaluation interval (second)
Aggregate message	alarm_duration	Lasting duration (second)
Aggregate message	alarm_status	Alert status
Aggregate message	alarm_active_at	Time when the alert is triggered
Aggregate message	alarm_resolved_at	Time when the alert is eliminated

Category	Name	Description
Aggregate message	alarm_last_interval	Lasting duration (second)
Aggregate message	alarm_name	Alert name
Aggregate message	value	Indicator value
Aggregate message	alarm_threshold	Alert threshold
Aggregate message	alarm_updated_at	Time when the alert is updated
Aggregate message	alarm_summary	Alert overview
Aggregate message	alarm_description	Alert details
Aggregate message	alarm_level_color	Color that corresponds to the alert severity
Aggregate message	alarm_id	Alert ID
Aggregate message	service	Service name
Aggregate message	ob_cluster_group	ApsaraDB for OceanBase cluster group
Aggregate message	ob_cluster	ApsaraDB for OceanBase cluster
Aggregate message	ob_tenant	ApsaraDB for OceanBase tenant
Aggregate message	host_ip	IP address of the host
Aggregate message	app_cluster	Application cluster
Aggregate message	alarm_group_by	Alert aggregation and grouping
Aggregate message	alarm_count	Number of Alerts
Channel configuration	app_type	Application type

Category	Name	Description
Channel configuration	alarm_type	Alert type
Channel configuration	alarm_target	Alert object
Channel configuration	alarm_scope	Scope
Channel configuration	alarm_level	Alert severity
Channel configuration	alarm_name	Alert name
Channel configuration	alarm_summary	Alert overview
Channel configuration	alarm_description	Alert details
Channel configuration	service	Service name
Channel configuration	ob_cluster_group	ApsaraDB for OceanBase cluster group
Channel configuration	ob_cluster	ApsaraDB for OceanBase cluster
Channel configuration	ob_tenant	ApsaraDB for OceanBase tenant
Channel configuration	host_ip	IP address of the host
Channel configuration	app_cluster	Application cluster
Channel configuration	message	Message (generated by the message template or the aggregate message template)
Channel configuration	message_json	JSON string of the message (the JSON format of the value of the message)
Channel configuration	recipients_uids	List of recipient user IDs that are separated with commas (,)
Channel configuration	at_recipients	The value of the @ recipient list

Category	Name	Description
Channel configuration	recipients_json_array	JSON array of the recipient list. It is used to @ recipients in DingTalk group messages

17.1.3.11.5. Appendix 5. List of background tasks

This topic describes the internal resident background tasks in OCP. These background tasks are generic terms for a category of tasks that are regularly triggered and executed by the OCP Server. The background tasks are primarily used for the purposes, such as maintaining OCP, checking the status of the managed objects, and cleansing data.

For information about the scheduling and running history of background tasks, see the details of the dag_instance and task_instance tables in the OCP MetaDB. You can perform a join query by using dag_instance.id = task_instance.dag_id). The dag_instance table records the execution details of the entire background tasks, whereas the task_instance table records the execution details of each subtask under the current background task.

You can search for the execution logs of background tasks by specific keyword in the OCP log file that is specified by the logging.file configuration parameter. The default OCP log file is ${user.home}/logs/ocp/ocp.log.

The following list of resident background tasks includes information, such as the task name, task description, remarks, and status troubleshooting. The information can be used as a reference for OCP system administrators and a troubleshooting guide.

Task name	Task description	Scheduling expression	Troubleshooting - database	Troubleshooting - OCP log
Archive alarm history data	Archive expired alert masking configurations and notifications.	0 0 3 * * *	ocp2_alarm_filter (alert masking configuration) ocp2_alarm_notification (alert notification) ocp2_alarm_filter_history (masking configuration history) ocp2_alarm_notification_history (notification history)	"Archive expired alarm history data: result=archive [filter|notification] success, affectRows=xxx"

Task name	Task description	Scheduling expression	Troubleshooting - database	Troubleshooting - OCP log
Sync all cluster info	Regularly synchronize ApsaraDB for OceanBase cluster information that is managed by OCP and update the information to the ob_cluster table. The information can be updated only when operateStatus of the ob_cluster table is NORMAL and clusterStatus is RUNNING.	0 * * * * *	ob_cluster (cluster information that is managed by OCP)	"cluster sync success, cluster=[id=xx,name=xx,..]" -- Success "cluster sync failed, cluster=xxx, exceptionType=xxx, message=xxx" -- Exception -- Synchronize process logs. " syncForCluster start, clusterId=xx init clusterSyncContext, context=xx create clusterOperator, clusterId=xx get current from ob cluster, clusterId=xx updateZones done, clusterId=xx syncForCluster done, clusterId=xx "
Refresh config properties	Refresh the configuration information of OCP.	0 */10 * * * *	config_properties (configuration of OCP system parameters)	"Refresh config properties on [host:port] at [date & time] "

Task name	Task description	Scheduling expression	Troubleshooting - database	Troubleshooting - OCP log
Maintain partition for monitordb	Process the partitions of the monitor tenant. New partitions are created for the partition table based on specific policies and expired partitions are deleted every day.	0 0 1 * * *	Monitor DB database: ob_cluster_system_event (collected Root Service events of ApsaraDB for OceanBase) ob_metric_data_1 (monitoring data collected per second) ob_metric_data_60 (monitoring data collected every 60 seconds)	-- Succeeded in maintaining the partition. "partition maintain start partition maintain success" -- Failed to maintain the partition. "partition maintain failed [exception msg]"
Sync system event	Synchronize system events. Regularly synchronize Root Service events from the ApsaraDB for OceanBase cluster to ob_cluster_system_event of monitordb.	0 */10 * * * *	Monitor DB database: ob_cluster_system_event (collected Root Service events of ApsaraDB for OceanBase) Internal table of ApsaraDB for OceanBase: oceanbase.__all_rootservice_event_history	-- Synchronization success "Batch saved [Number of records] events to database for cluster [cluster id] Sync-ed [Number of records] system events for cluster [cluster id], startTime [Start time], endTime [End time], limit [limit], offset [offset] Finished sync system events: cluster [cluster id], startTime [Start time], endTime [End time] " -- Synchronization failure "An exception occurred when saving events [exception log]"

Task name	Task description	Scheduling expression	Troubleshooting - database	Troubleshooting - OCP log
Check all cluster status	Regularly check the alive status of the ApsaraDB for OceanBase cluster in the ob_cluster table (check by establishing a database connection in a test). If the check fails, error logs are generated and an alert is sent.	0 * * * * *	ob_cluster (cluster information that is managed by OCP)	-- The cluster can be connected. "check cluster status okay, clusterId=[cluster id], obVersion=[ob version]" -- The cluster cannot be connected. "check cluster status unavailable, clusterId=[cluster id], failedReason=[exception msg]" -- Alert type and keyword "ob_cluster_status_check_failed" + "cluster connect check"

Task name	Task description	Scheduling expression	Troubleshooting - database	Troubleshooting - OCP log
Check host status	Check whether pos_proxy on the host can execute the remote command (whoami). If the execution fails, an alert is sent, and the host status (OFFLINE) is modified. If the execution is successful, the status is modified to the normal status (AVAILABLE or ONLINE). Check the number of node_exporters on the host. If the number is inexact, exception messages are generated and an alert is sent.	0 * * * * *	compute_host.status compute_host_agent.last_available_time ocp_exporter_address	"Host agent check result: current OS user is root" -- Agent check success "Check exporter status: host [id] desired exporter count: [number], actual exporter count: [number]" -- Exporter check success "Host agent check failed: host [host id] reason [exception msg]" -- Agent check failure "Alarm: host_unavailable for host ip [ip address]" -- Exporter check failure "Alarm: no_enough_exporter for host [id]" -- Exporter check failure "host_unavailable" -- Alert type of the agent failure "no_enough_exporter" -- Alert type of the exporter failure

Task name	Task description	Scheduling expression	Troubleshooting - database	Troubleshooting - OCP log
Submit scheduled dag	Implement a feature similar to crontab on the host. The feature is used to submit user-defined scheduled tasks. The user-defined scheduling expression is checked and compared with the current actual situation. If the condition is met, the user-defined task is submitted. Otherwise, the corresponding record status in the dag_schedule table is updated to ABNORMAL.	0 * * * * *	dag_schedule (details about task scheduling) dag_instance (running details of background tasks)	-- No user-defined task exists. "no cron job available in dag_schedule" -- An error occurred while submitting the user-defined task. "failed to get template for class [java class name], got exception: [exception msg]"

Task name	Task description	Scheduling expression	Troubleshooting - database	Troubleshooting - OCP log
Clean ocp task log files	Clean task logs on the OCP host.	0 0 1 * * *		The Python script that is used by OCP to clean logs: 'user.home' -> '/ocp-server/python-task/src/task/ob_task_clean_log.py' The directory of task logs to be cleaned: 'user.home' -> '/logs/task/' The log file of the Python process that cleans logs: 'user.home' -> '/logs/task/task.2.xxx.log' The logs of OCP cleaning task exceptions: "failed to clean task log files: [exception msg]"
Collect all cluster compaction info	Collect compaction information about all clusters.	0 * * * * *	ob_cluster_compaction (compaction records of ApsaraDB for OceanBase clusters) ob_zone_compaction (compaction records of ApsaraDB for OceanBase zones) ob_server_compaction (compaction records of ApsaraDB for OceanBase servers) ob_tenant_compaction_stats (compaction records of ApsaraDB for OceanBase tenants)	-- Collection success "Update cluster [cluster id] compaction status: from [xx] to [xx]" "Compaction post collect done, clusterId= [cluster id], version= [version]" -- Collection failure "Skip collect for not RUNNING cluster, clusterId=[cluster id], status=[xx]" "Skip collect for version 1, the first compaction will be version 2" "Validate compaction version failed: [reason]"

Task name	Task description	Scheduling expression	Troubleshooting - database	Troubleshooting - OCP log
Sync tenant information	Synchronize tenant information.	30 0/2 * * * ?	ob_tenant (tenant information table of ApsaraDB for OceanBase)	-- Synchronization success "[SyncAllTenantInfoTask] begin to sync tenant." "[SyncAllTenantInfoTask] sync tenants of specified cluster, clusterId=[cluster id]" "[SyncAllTenantInfoTask] sync tenant finished." -- Synchronization failure "Zero tenants found for cluster [cluster id]"
Detect alarms on schedule	Alarm detector related to backup and recovery.	0 */1 * * * *	dag_schedule (details about task scheduling) dag_instance (running details of background tasks)	-- Execution success generate tasks, templateName=Detect alarms, nodeCount=1, taskCount=1 set state running for task: [task id] set state successful for task: [task id] -- Execution failure Generate exception call stacks. Keyword: BackupAlarmService

Task name	Task description	Scheduling expression	Troubleshooting - database	Troubleshooting - OCP log
Clean expired data and log files on schedule	The scheduled cleaner related to backup and recovery cleans expired data and logs.	0 0 0 * * *	dag_schedule (details about task scheduling) dag_instance (running details of background tasks)	-- Execution success generate tasks, templateName=Clean expired data and log files, nodeCount=1, taskCount=1 set state running for task: [task id] set state successful for task: [task id] -- Execution failure Generate exception call stacks. Keyword :BackupCleanService
Check system obproxy	Check the health status of the OBProxy of the system that is used by OCP.	0 * * * * *	OCP system parameters: ocp.system.obproxy.address ocp.system.obproxy.port	-- The OBProxy status of the system is as expected. Generate the log "system obproxy is running". -- The OBProxy status of the system is abnormal. Generate the log "system obproxy is down". At the same time, an alert is pushed. -- Failed to use the check method. Generate the exception call stack: “check connection of system obproxy failed. exception: xxx"

Scheduling expression

The CRON expression in the following format is used for scheduling. The expression consists of the following six fields:

```
second, minute, hour, day of month, month, day(s) of week
```

Fields and values of the CRON expression

Field name	Valid value	Supported special characters
second	0-59	,-*/
minute	0-59	,-*/
hour	0-23	,-*/
day of month	1-31	,-*/?
month	1-12 or JAN-DEC	,-*/
day of week	1-7 or MON-SUN	,-*/?

Examples of the expression:

Expression	Description
*0 0 * * * * *	0 seconds, 0 minutes: Run once every hour and start at 0 seconds, 0 minutes.
*/10 * * * * *	Run once every 10 seconds.
*0 0 8-10 * * * *	Run once at 8:00, 9:00, and 10:00 every day and start at 0 seconds, 0 minutes.
*0 0/30 8-10 * * * *	Run at 8:00, 8:30, 9:00, 9:30,10:00, and 10:30 every day.
*0 0 9-17 * * MON-FRI*	Run from 9:00 to 17:00 from Monday to Friday.
*0 0 9-17 * * 1-5*	Run from 9:00 to 17:00 from Monday to Friday. A digit is used to represent the day of the week. The digit 1 represents Monday and the digit 7 represents Sunday. This is slightly different from the expression of crontab.
0 0 0 25 12 ?	00:00:00 on December 25 every year

17.1.3.11.6. Appendix 6. Metrics

This topic describes metrics.

Metric group	Metric name	Metric description	Calculation expression
CPU usage	cpu_percent	The CPU usage	100 * (1 - sum(rate(node_cpu_seconds_total{mode="idle", @LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(node_cpu_seconds_total{@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS))
I/O throughput rate	read	The amount of data read each time	avg(rate(node_disk_read_bytes_total{@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / 1048576
I/O throughput rate	write	The amount of data written each time	avg(rate(node_disk_written_bytes_total{@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / 1048576
I/O time consumption	read	The average time that is consumed by reading data per second	1000000 * avg(rate(node_disk_read_time_seconds_total{@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
I/O time consumption	write	The average time that is consumed by writing data per second	1000000 * avg(rate(node_disk_write_time_seconds_total{@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
IOPS	read	The number of reads per second	avg(rate(node_disk_reads_completed_total{@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)

Metric group	Metric name	Metric description	Calculation expression
IOPS	write	The number of writes per second	avg(rate(node_disk_writes_completed_total{@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Linux system load	load1	The average system load in the last 1 minute	avg(node_load1{@LABELS}) by (@GBLABELS)
Linux system load	load15	The average system load in the last 15 minutes	avg(node_load15{@LABELS}) by (@GBLABELS)
Linux system load	load5	The average system load in the last 5 minutes	avg(node_load5{@LABELS}) by (@GBLABELS)
MEMStore	active	The size of the active MemStore	sum(sysstat_value{metric_group="sysstat",stat_id="130000",@LABELS}) by (@GBLABELS) / 1048576
MEMStore	limit	The limit of the MemStore	sum(sysstat_value{metric_group="sysstat",stat_id="130004",@LABELS}) by (@GBLABELS) / 1048576
MEMStore	total	The total size of the MemStore	sum(sysstat_value{metric_group="sysstat",stat_id="130001",@LABELS}) by (@GBLABELS) / 1048576
MEMStore	trigger	The threshold that triggers the major freeze operation	sum(sysstat_value{metric_group="sysstat",stat_id="130002",@LABELS}) by (@GBLABELS) / 1048576

Metric group	Metric name	Metric description	Calculation expression
QPS	all	The number of SQL statements that are processed per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="40002",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40004",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40006",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40008",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40000",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
QPS	delete	The number of DELETE statements that are processed per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="40008",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
QPS	insert	The number of INSERT statements that are processed per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="40002",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)

Metric group	Metric name	Metric description	Calculation expression
QPS	replace	The number of REPLACE statements that are processed per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="40004",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
QPS	select	The number of SELECT statements that are processed per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="40000",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
QPS	update	The number of UPDATE statements that are processed per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="40006",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)

Metric group	Metric name	Metric description	Calculation expression
SQL response time	all	The average processing time of each SQL statement on the server	(sum(rate(sysstat_value{metric_group="sysstat",stat_id="40003",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40005",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40007",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40009",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40001",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)) /(sum(rate(sysstat_value{ metric_group="sysstat",stat_id="40002",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40004",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40006",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40008",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40000",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS))

Metric group	Metric name	Metric description	Calculation expression
Category of SQL execution plans	distributed	The number of distributed execution plans that are processed per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="40012",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Category of SQL execution plans	local	The number of local SQL execution plans that are processed per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="40010",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Category of SQL execution plans	remote	The number of remote execution plans that are processed per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="40011",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
TPS	trans_count	The number of transactions that are processed per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="30005",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Event wait_Time	wait_time	The average time that is consumed by wait events	sum(rate(time_wait{metric_group="waitevent",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(total_waits{metric_group="waitevent",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)

Metric group	Metric name	Metric description	Calculation expression
Event wait_Count	wait_count	The number of wait events per second	sum(rate(total_waits{metric_group="waitevent",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Response time of transactions	trans_time	The average processing time of each transaction on the server	sum(rate(sysstat_value{metric_group="sysstat",stat_id="30006",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(sysstat_value{metric_group="sysstat",stat_id="30005",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Number of transaction logs	log_count	The number of logs of transactions that are committed per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="30002",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Time consumption of transaction logs	sync_time	The average time that is consumed by synchronizing transaction logs among networks each time	sum(rate(sysstat_value{metric_group="sysstat",stat_id="30000",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(sysstat_value{metric_group="sysstat",stat_id="30001",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)

Metric group	Metric name	Metric description	Calculation expression
Time consumption of transaction logs	write_disk	The average time that is consumed by writing transaction logs to disks each time	sum(rate(sysstat_value{metric_group="sysstat",stat_id="80041",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(sysstat_value{metric_group="sysstat",stat_id="80040",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Volume of transaction logs	log_size	The size of logs of transactions that are committed per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="80057",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Memory	buffers	The size of the buffer cache of the kernel	avg(node_memory_Buffers_bytes{@LABELS}) by (@GBLABELS) / 1073741824
Memory	free	The size of available physical memory	avg(node_memory_MemFree_bytes{@LABELS}) by (@GBLABELS) / 1073741824
Memory	used	The size of used physical memory	(avg(node_memory_MemTotal_bytes{@LABELS}) by (@GBLABELS) - avg(node_memory_MemFree_bytes{@LABELS}) by (@GBLABELS) - avg(node_memory_Cached_bytes{@LABELS}) by (@GBLABELS) - avg(node_memory_Buffers_bytes{@LABELS}) by (@GBLABELS)) / 1073741824

Metric group	Metric name	Metric description	Calculation expression
Response time	all	The average processing time of each SQL statement on the server	(sum(rate(sysstat_value{metric_group="sysstat",stat_id="40003",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40005",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40007",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40009",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40001",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)) /(sum(rate(sysstat_value{metric_group="sysstat",stat_id="40002",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40004",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40006",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40008",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40000",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS))

Metric group	Metric name	Metric description	Calculation expression
Response time	delete	The average processing time of each DELETE statement on the server	sum(rate(sysstat_value{metric_group="sysstat",stat_id="40009",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(sysstat_value{metric_group="sysstat",stat_id="40008",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)

Response time	select	The average processing time of each SELECT statement on the server	sum(rate(sysstat_value{metric_group="sysstat",stat_id="40001",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(sysstat_value{metric_group="sysstat",stat_id="40000",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)

Metric group	Metric name	Metric description	Calculation expression
Response time	update	The average processing time of each UPDATE statement on the server	sum(rate(sysstat_value{metric_group="sysstat",stat_id="40007",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(sysstat_value{metric_group="sysstat",stat_id="40006",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Capacity_Number of partitions	partition_count	The number of partitions	sum(partition_count{metric_group="all_meta_table",@LABELS}) by (@GBLABELS)
Capacity_Number of tables	table_count	The number of tables	max(table_count{metric_group="all_table",@LABELS}) by (@GBLABELS)

Metric group	Metric name	Metric description	Calculation expression
Query response time	all	The average processing time of each SQL statement on the server	(sum(rate(sysstat_value{metric_group="sysstat",stat_id="40003",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40005",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40007",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40009",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40001",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)) /(sum(rate(sysstat_value{metric_group="sysstat",stat_id="40002",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40004",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40006",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40008",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="40000",@LABELS} [@INTERVAL]) by (@GBLABELS)) by (@GBLABELS))

Metric group	Metric name	Metric description	Calculation expression
Number of active sessions	active_session	The number of active sessions	sum(active_sessions{metric_group="all_virtual_processlist",@LABELS}) by (@GBLABELS)
Wait events	wait_count	The number of wait events per second	sum(rate(total_waits{metric_group="waitevent",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Time that is consumed by wait events	wait_time	The average time that is consumed by wait events	sum(rate(time_wait{metric_group="waitevent",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(total_waits{metric_group="waitevent",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)

Metric group	Metric name	Metric description	Calculation expression
Time that is consumed by waiting for locks	wait_time	The average wait time for write locks	sum(rate(sysstat_value{metric_group="sysstat",stat_id="60023",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / (sum(rate(sysstat_value{metric_group="sysstat",stat_id="60021",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) + sum(rate(sysstat_value{metric_group="sysstat",stat_id="60022",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS))
Cache hit ratio	block_cache	The block cache hit ratio	100 * 1 / (1 + sum(rate(sysstat_value{metric_group="sysstat",stat_id="50009",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(sysstat_value{metric_group="sysstat",stat_id="50008",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS))
Cache hit ratio	plan_cache	The cache hit ratio of execution plans	100 * sum(rate(hit_count{metric_group="plan_cache_stat",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(access_count{metric_group="plan_cache_stat",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)

Metric group	Metric name	Metric description	Calculation expression
Cache hit ratio	row_cache	The row cache hit ratio	100 * 1 / (1 + sum(rate(sysstat_value{metric_group="sysstat",stat_id="50001",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(sysstat_value{metric_group="sysstat",stat_id="50000",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS))
Cache size	block_cache	The block cache size	sum(cache_size{metric_group="all_virtual_kvcache_info",cache_name="user_block_cache",@LABELS}) by (@GBLABELS) / 1048576
Cache size	plan_cache	The cache size of execution plans	sum(mem_used{metric_group="plan_cache_stat",@LABELS}) by (@GBLABELS) / 1048576
Cache size	row_cache	The row cache size	sum(cache_size{metric_group="all_virtual_kvcache_info",cache_name="user_row_cache",@LABELS}) by (@GBLABELS) / 1048576
Network throughput rate	receive	The amount of data that is received per second	avg(rate(node_network_receive_bytes_total{@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / 1048576

Metric group	Metric name	Metric description	Calculation expression
Network throughput rate	send	The amount of data that is sent per second	avg(rate(node_network_transmit_bytes_total{@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / 1048576
Wait queue of requests	queue_count	The average number of times that SQL statements enter in the wait queue per second	sum(rate(sysstat_value{metric_group="sysstat",stat_id="20001",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Time that is consumed by the wait queue of requests	queue_time	The wait time of SQL statements in the wait queue	sum(rate(sysstat_value{metric_group="sysstat",stat_id="20002",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS) / sum(rate(sysstat_value{metric_group="sysstat",stat_id="20001",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Lock wait	fail	The number of failed write lock waits	sum(rate(sysstat_value{metric_group="sysstat",stat_id="60022",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)
Lock wait	success	The number of successful write lock waits	sum(rate(sysstat_value{metric_group="sysstat",stat_id="60021",@LABELS}[@INTERVAL]) by (@GBLABELS)) by (@GBLABELS)

17.1.4. SQL Reference (MySQL Mode)

17.1.4.1. Elements

17.1.4.1.1. Data types

ApsaraDB for OceanBase supports the following data types:

- Numeric types
- Date and time types
- String types
- Large object types

Numeric types

Numeric types can be divided into three categories:

- Integer types: `BOOL` or `BOOLEAN`, `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT` or `INTEGER`, and `BIGINT`.
- Fixed-point types: `DECIMAL` and `NUMERIC`.
- Floating-point types: `FLOAT` and `DOUBLE`.
- Bit-value type: `BIT`.

You can use the `UNSIGNED` keyword to declare all data types as unsigned data types. This operation changes the value ranges of the data types.

When you define a numeric data type, you can specify the precision and scale parameters. The meanings of the precision and scale parameters may vary based on the data type. For more information, see the description of each data type.

Integer types

An integer data type stores exact values of a fixed length. The value range depends on the data type length and whether the values are signed. The precision only indicates the minimum display width. For more information, see ZEROFILL keyword. The following table provides the details.

Type	Length (bytes)	Range (signed)	Range (unsigned)
`BOOL` / `BOOLEAN` / `TINYINT`	1	[-2 ^ 7 , 2 ^ 7 - 1]	[0, 2 ^ 8 - 1]
`SMALLINT`	2	[-2 ^ 15, 2 ^ 15 - 1]	[0, 2 ^ 16 - 1]
`MEDIUMINT`	3	[-2 ^ 23, 2 ^ 23 - 1]	[0, 2 ^ 24 - 1]
`INT` / `INTEGER`	4	[-2 ^ 31, 2 ^ 31 - 1]	[0, 2 ^ 32 - 1]

Type	Length (bytes)	Range (signed)	Range (unsigned)
`BIGINT`	8	[-2 ^ 63, 2 ^ 63 - 1]	[0, 2 ^ 64 - 1]

`BOOL` is equivalent to `BOOLEAN`, and the two types are equivalent to `TINYINT(1)`.

`INT` is equivalent to `INTEGER`.

Fixed-point types

A fixed-point type stores exact values of variable lengths. The value range and precision depend on the precision and scale parameters and whether the values are signed. The precision parameter specifies the maximum total number of valid digits in a decimal number. The scale parameter specifies the maximum number of digits after the decimal point in a decimal number. The maximum number of digits in the integer part is equal to the absolute difference between precision and scale. The maximum value of precision is 65. The maximum value of scale is 30. The default precision is 10. The default scale is 0. Examples

- `DECIMAL(5,2)` has three valid digits for the integer part and two valid digits for the fractional part. Therefore, the value range is [-999.99,999.99].
- If the value is `UNSIGNED`, the range is [0,999.99].

`DECIMAL` is equivalent to `NUMERIC`.

Floating-point types

A floating-point data type stores approximate numbers of a fixed length. The value range and precision depend on the type length, precision, scale, and whether the values are signed. The precision parameter specifies the maximum total number of valid digits in a decimal number. The scale parameter specifies the maximum number of valid digits after the decimal point in a decimal number. The maximum number of digits in the integer part is equal to the absolute difference between precision and scale. The maximum precision is 53. The maximum scale is 30.

The precision of a floating-point type is only a theoretical value based on the IEEE standard. The actual precision may vary due to hardware or operating system limits.

The following table lists the default settings when the precision and scale parameters are not specified.

Type	Length (bytes)	Range (signed)	Range (unsigned)	Precision
`FLOAT`	4	[-2 ^ 128, 2 ^ 128]	[0, 2 ^ 128]	7 digits
`DOUBLE`	8	[-2 ^ 1024, 2 ^ 1024]	[0, 2 ^ 1024]	15 digits

If the precision and scale parameters are specified, the value range is determined in the same way as the value range of a fixed-point type is determined.

ZEROFILL keyword

When you define a numeric type, you can use the ZEROFILL keyword to specify the minimum display width, and implicitly define the type as UNSIGNED. If the actual display width of the value is less than the minimum display width, the value is zero-padded to the minimum display width. The fractional part is padded with zeroes on the right to the width specified by the scale parameter. The integer part is padded with zeroes on the left to the width specified by the precision parameter. Examples

- `INT(5) ZEROFILL` : `123` is displayed as `00123` .
- `DECIMAL(10,5) ZEROFILL` : `123.456` is displayed as `00123.45600` .

Bit-value type

The BIT data type is used to store bit values. The BIT(M) data type can store M-bit values. M ranges from 1 to 64.

To specify bit values, use the b'value' notation. Set **value** to a binary number that consists of the digits 0 and 1. For example, b'111' indicates 7, and b'10000000' indicates 128.

When you insert a value into a BIT(M) column, if the length of the inserted value is less than **M**, the value is padded with zeros on the left. For example, the result of inserting b'101' into a BIT(6) column is equivalent to that of inserting b'000101'.

Date and time types

The following table provides the details.

Type	Syntax	Lower bound	Upper bound	Description
`DATETIME`	YYYY-MM-DD HH:MM:SS[.fraction]	0000-01-01 00:00:00.000000	9999-12-31 23:59:59.999999	The date and time. The time zone information is ignored.
`TIMESTAMP`	YYYY-MM-DD HH:MM:SS[.fraction]	0000-01-01 00:00:00.000000	9999-12-31 23:59:59.999999	The date and time. The time zone information is considered.
`DATE`	YYYY-MM-DD	0000-01-01	9999-12-31	The date.
`TIME`	HH:MM:SS[.fraction]	-838:59:59.000000	838:59:59.000000	The time.
`YEAR`	YYYY	1901	2155	The year.

The value ranges and precisions of `DATETIME` , `TIMESTAMP` , and `TIME` depend on the scale parameter. The scale parameter represents the maximum number of valid digits in the fractional part. The maximum value is 6, and the default value is 0.

String types

The following table describes common string types.

Type	Length	Maximum length in characters	Character set
VARCHAR	Variable length	262144 / 256K	UTF8MB4
VARBINARY	Variable length	1048576 / 1M	BINARY
CHAR	Fixed length	256	UTF8MB4
BINARY	Fixed length	256	BINARY
enum	Variable length	You can define a maximum of 65,535 elements and each element has a maximum length of 255 characters.	UTF8MB4
set	Variable length	You can define a maximum of 64 elements and each element has a maximum length of 255 characters.	UTF8MB4

Large object types

The following table provides information about large object types.

Type	Length	Maximum length in bytes	Character set
TINYTEXT	Variable length	256	UTF8MB4
TINYBLOB	Variable length	256	BINARY
TEXT	Variable length	65536 / 64K	UTF8MB4
BLOB	Variable length	65536 / 64K	BINARY

Type	Length	Maximum length in bytes	Character set
`MEDIUMTEXT`	Variable length	16777216 / 16M	`UTF8MB4`
`MEDIUMBLOB`	Variable length	16777216 / 16M	`BINARY`
`LONGTEXT`	Variable length	50331648 / 48M	`UTF8MB4`
`LONGBLOB`	Variable length	50331648 / 48M	`BINARY`

17.1.4.1.2. Expressions

Expressions are generalized notions. Each expression contains several input parameters and returns an output result. An input parameter may be a constant or a single row of data, or multiple rows of data. Expressions can be combined. The input of one expression can be the output of another expression.

Expressions can be divided into the following categories based on the source and form:

- Column reference
- Constant
- Operator
- Function

Examples

```
SELECT ABS(a + 1)
  FROM t1
 WHERE a > 0;
```

- a is a column reference.
- 0 and 1 are constants.
- `&gt;` and `+` are operators that take 0, 1, and the a expression as input.
- `ABS` is a function that takes the `+` expression as input.

17.1.4.1.3. Type conversion

ApsaraDB for OceanBase supports explicit type conversion and implicit type conversion.

You can perform explicit type conversion by using the `CAST` function.

Implicit type conversion occurs in the following scenario: An operation requires a parameter of a specified type, but the actual parameter value does not match the specified type. In this case, ApsaraDB for OceanBase converts the actual parameter value to the specified type before subsequent operations are performed.

17.1.4.1.4. Character sets

ApsaraDB for OceanBase supports the following character sets:

- `UTF8MB4`: variable-length encoding. The maximum length is 4 bytes.
- `BINARY`: fixed-length encoding. The fixed length is 1 byte.

`UTF8` (or `UTF8MB3`) is a subset of `UTF8MB4`. UTF8 is a variable-length encoding scheme that uses a maximum of 3 bytes to encode a character. To support seamless migration, ApsaraDB for OceanBase considers `UTF8` as the synonym of `UTF8MB4` in terms of the syntax.

17.1.4.1.5. Collations

ApsaraDB for OceanBase supports the following collations:

- `UTF8MB4_GENERAL_CI`
- `UTF8MB4_BIN`
- `BINARY`

17.1.4.1.6. Data comparison rules

ApsaraDB for OceanBase allows two or more types of data to be compared. The following list describes the possible comparison results:

- A non-zero value or TRUE
- 0 or False
- NULL

If the data types involved in a comparison are different, ApsaraDB for OceanBase automatically determines a data type for the comparison based on specific rules. Before comparison, the data is converted to this data type.

If the comparison type is text, you must also determine a collation for comparison.

17.1.4.1.7. Literals

Text literals

A text literal is a string that is enclosed by single quotation marks (`'`) or double quotation marks (`"`). If you enable the `ANSI_QUOTES` mode, you can use only single quotation marks (`'`) to enclose strings.

Numeric literals

Decimal numeric literals are divided into floating-point values and exact values that consist of integer and fixed-point values. Values can include a decimal point (`.`) as a decimal separator. Values that are prefixed with a minus sign (`-`) represent negative values.

Hexadecimal numeric literals only support integer values that are prefixed with `0X`, and allow letters from `A` to `F`. All letters are case-insensitive.

Datetime

Datetime literals can be in the text or numeric format.

- In the text format, you can use full separators, for example, `'2015-07-21 12:34:56.789'`. You can also use no separators, for example, `'20150721'`.
- The numeric format allows you to use only a decimal point (`.`) to separate the seconds and microseconds, for example, `20150721123456.789`.
- A decimal point (`.`) must be used between seconds and microseconds. If you require other separators, we recommend that you use only common separators such as hyphens (`-`), forward slashes (`/`), and colons (`:`).

Escape characters

An escape character is a backslash (`\`) that invokes an alternative interpretation on the following characters in a character sequence. Escape characters are case-sensitive. For example, `\b` represents the backspace and `\B` represents the `B` character.

The following table lists all escape characters.

Escape character	Description
`\b`	A backspace.
`\f`	A form feed.
`\n`	A line feed.
`\r`	A carriage return.
`\t`	A tab character.
`\\`	A backslash (\).
`\'`	A single quotation mark (').
`\"`	A double quotation mark (").

Escape character	Description
`\_`	An underscore (_).
`\%`	A percent sign (%).
`\0`	NULL
`\Z`	ASCII 26 (Ctrl+Z).

17.1.4.1.8. Comments

SQL statements

In general SQL statements, ApsaraDB for OceanBase supports the following three styles for comments:

- From a number sign (`#`) to the end of the line
- From a symbol (`--`) to the end of the line
- From a `/*` symbol to a `*/` symbol

Database objects

In a data definition language (DDL) statement, you can use the `COMMENT` clause to specify comments for a database object. Example:

```
create table t(pk INT PRIMARY KEY COMMENT 'Primary key');
```

17.1.4.2. Operators

17.1.4.2.1. Arithmetic operators

The following table lists all arithmetic operators.

Operator	Operand	Description
`+`	Unary or binary	As a unary operator, it indicates a positive number. As a binary operator, it indicates an addition.

Operator	Operand	Description
`-`	Unary or binary	As a unary operator, it indicates a negative number. As a binary operator, it indicates a subtraction.
`*`	Binary	The multiplication operator.
`/`	Binary	The division operator.
`DIV`	Binary	Divides an integer and returns the quotient.
`MOD` or `%`	Binary	Divides an integer and returns the remainder.

Integer division complies with the following rules:

- The quotient is rounded towards zero regardless of whether the quotient is positive or negative.
- The remainder has the same sign as the dividend.

Examples

```
OceanBase (root@oceanbase)> SELECT (-7) DIV (3.6), (-7) MOD (3.6);
+----------------+----------------+
| (-7) DIV (3.6) | (-7) MOD (3.6) |
+----------------+----------------+
|             -1 |           -3.4 |
+----------------+----------------+
1 row in set (0.01 sec)

OceanBase (root@oceanbase)> SELECT (-7) DIV (-3.4), (-7) % (-3.4);
+-----------------+---------------+
| (-7) DIV (-3.4) | (-7) % (-3.4) |
+-----------------+---------------+
|               2 |          -0.2 |
+-----------------+---------------+
1 row in set (0.02 sec)
```

17.1.4.2.2. Bitwise operators

`BIGINT UNSIGNED` is used for bitwise operations. The sign bits are ignored in the operations.

The following table lists all bitwise operators.

Operator	Operand	Description
&	Binary	Bitwise AND.
|	Binary	Bitwise OR.
~	Unary	Bitwise NOT.
^	Binary	Bitwise XOR.
<<	Binary	Logical left shift.
>>	Binary	Logical right shift.

17.1.4.2.3. Comparison operators

The following table lists all comparison operators.

Operator	Operand	Description	Effect of NULL on the operators
=	Binary	The equal operator.	The result is NULL.
<> / !=	Binary	The not equal operator.	The result is NULL.
>	Binary	The greater than operator.	The result is NULL.
>=	Binary	The greater than or equal operator.	The result is NULL.
<	Binary	The less than operator.	The result is NULL.
<=	Binary	The less than or equal operator.	The result is NULL.

Operator	Operand	Description	Effect of NULL on the operators
`[NOT] IN`	Binary	Specifies whether the value is in the set.	For more information, see the descriptions.
`[NOT] BETWEEN AND`	Ternary	Specifies whether the value is within the range.	For more information, see the descriptions.
`IS [NOT] TRUE`	Unary	Specifies whether the value is equal to TRUE.	The result is TRUE or FALSE.
`IS [NOT] FALSE`	Unary	Specifies whether the value is equal to FALSE.	The result is TRUE or FALSE.
`IS [NOT] NULL`	Unary	Specifies whether the value is equal to NULL.	The result is TRUE or FALSE.
`<=>`	Binary	The NULL-safe equal operator.	The result is TRUE or FALSE.

The following list describes the special treatment of the NULL value by some operators.

- `value [NOT] IN ()`:
  - If the value is NULL, the result is NULL.
  - If the value is not NULL and the set contains NULL, the result is TRUE when a non-NULL value in the set is equal to the value. Otherwise, the result is NULL.
- `value [NOT] BETWEEN lower AND upper`:
  - If the value is NULL or both the lower and upper values are NULL, the result is NULL.
  - Assume that the value is not NULL and the lower or upper value is NULL. In this case, the result that can be determined based on the value and the lower or upper value is returned.

Examples

```
OceanBase (root@oceanbase)> SELECT 1 IN (1, NULL), 1 IN (2, NULL);
+----------------+----------------+
| 1 IN (1, NULL) | 1 IN (2, NULL) |
+----------------+----------------+
|              1 |           NULL |
+----------------+----------------+
1 row in set (0.01 sec)

OceanBase (root@oceanbase)> SELECT 1 BETWEEN 0 AND NULL, 1 BETWEEN 2 AND NULL;
+----------------------+----------------------+
| 1 BETWEEN 0 AND NULL | 1 BETWEEN 2 AND NULL |
+----------------------+----------------------+
|                 NULL |                    0 |
+----------------------+----------------------+
1 row in set (0.01 sec)
```

17.1.4.2.4. Logical operators

The following table lists all logical operators.

Operator	Operand	Description
`AND` / `&amp;&amp;`	Binary	Logical AND
`OR` / `||`	Binary	Logical OR
`NOT` / `!`	Unary	Logical NOT

17.1.4.2.5. Date and time operators

The following table lists all date and time operators.

Operator	Operand	Description
`+`	Binary	The same as the `DATE_ADD` function.
`-`	Binary	The same as the `DATE_SUB` function.

Examples

```
OceanBase (root@oceanbase)> SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND;
+-----------------------------------------+
| '2008-12-31 23:59:59' + INTERVAL 1 SECOND |
+-----------------------------------------+
| 2009-01-01 00:00:00                     |
+-----------------------------------------+
1 row in set (0.01 sec)
```

17.1.4.2.6. Concatenation operators

The following table lists all concatenation operators.

Operator	Operand	Description
`||`	Binary	Concatenates two strings.

Based on the preceding description, the `||` operator can also be used as a logical OR operator. The semantic meaning of the operator is controlled by the SQL mode.

- If the SQL mode is `PIPES_AS_CONCAT`, `||` is an operator that concatenates strings.
- If the SQL mode is not `PIPES_AS_CONCAT`, `||` is a logical OR operator.

17.1.4.2.7. Hierarchical query operators

The following table lists all hierarchical query operators.

Operator	Operand	Description
`PRIOR`	Unary	Indicates that the column is from the parent row.
`CONNECT_BY_ROOT`	Unary	Indicates the root ancestor.

17.1.4.2.8. Collation operators

The following table lists all collation operators.

Operator	Operand	Description
`COLLATE`	Unary (suffix)	The collation.

Examples

```
SELECT last_name
  FROM employees
 ORDER BY last_name COLLATE UTF8MB4_GENERAL_CI;
```

17.1.4.3. Functions

17.1.4.3.1. Functions

Date and time functions

Date and time functions are used to display information about dates and times.

CURDATE

Declaration

```
CURDATE()
```

Description

This function returns the current date without the exact time.

Example

```
OceanBase (root@test)> SELECT CURDATE();
+------------+
| CURDATE()  |
+------------+
| 2018-05-05 |
+------------+
1 row in set (0.00 sec)
```

CURRENT_DATE

Declaration

```
CURRENT_DATE()
CURRENT_DATE
```

Description

This function performs the same operation as `CURDATE()`.

CURRENT_TIME

Declaration

```
CURRENT_TIME([scale])
```

Description

This function returns the current time without the exact date.

`scale` specifies the precision of the fractional seconds. Valid values: 0 to 6. Default value: 0.

Example

```
OceanBase (root@test)> SELECT CURRENT_TIME(6);
+-----------------+
| CURRENT_TIME(6) |
+-----------------+
| 11:11:45.215311 |
+-----------------+
1 row in set (0.01 sec)
```

CURRENT_TIMESTAMP

Declaration

```
CURRENT_TIMESTAMP([scale])
```

Description

This function returns the current date and time based on the specified time zone.

`scale` specifies the precision of the fractional seconds. Valid values: 0 to 6. Default value: 0.

Example

```
OceanBase (root@test)> SELECT CURRENT_TIMESTAMP(6);
+----------------------------+
| CURRENT_TIMESTAMP(6)       |
+----------------------------+

```

CURTIME

Declaration

```
CURTIME()
```

Description

This function performs the same operation as `CURRENT_TIME()`.

DATE_ADD

Declaration

```
DATE_ADD(date, INTERVAL expr unit)
```

Description

This function performs arithmetic calculations on date and time values.

- `date` represents the date and time base. You must specify the date, whereas the time is optional.
- `expr` represents the time interval, which can be negative.
- `unit` represents the unit of the time interval.

The following table lists all units for time intervals.

Unit	Type	Description	Syntax
`MICROSECOND`	Independent	Microseconds	`MICROSECONDS`
`SECOND`	Independent	Seconds	`SECONDS`
`MINUTE`	Independent	Minutes	`MINUTES`
`HOUR`	Independent	Hours	`HOURS`
`DAY`	Independent	Days	`DAYS`
`WEEK`	Independent	Weeks	`WEEKS`
`MONTH`	Independent	Months	`MONTHS`
`QUARTER`	Independent	Quarters	`QUARTERS`
`YEAR`	Independent	Years	`YEARS`
`SECOND_MICROSECOND`	Combination	From seconds to microseconds	`'SECONDS.MICROSECONDS'`
`MINUTE_MICROSECOND`	Combination	From minutes to microseconds	`'MINUTES:SECONDS.MICROSECONDS'`
`MINUTE_SECOND`	Combination	From minutes to seconds	`'MINUTES:SECONDS'`
`HOUR_MICROSECOND`	Combination	From hours to microseconds	`'HOURS:MINUTES:SECONDS.MICROSECONDS'`
`HOUR_SECOND`	Combination	From hours to seconds	`'HOURS:MINUTES:SECONDS'`

Unit	Type	Description	Syntax
`HOUR_MINUTE`	Combination	From hours to minutes	`'HOURS:MINUTES'`
`DAY_SECOND`	Combination	From days to seconds	`'DAYS HOURS:MINUTES:SECONDS'`
`DAY_MINUTE`	Combination	From days to minutes	`'DDAYSD HOURS:MINUTES'`
`DAY_HOUR`	Combination	From days to hours	`'DAYS HOURS'`
`YEAR_MONTH`	Combination	From years to months	`'YEARS-MONTHS'`

Example

```
OceanBase (root@test)> SELECT
    -> DATE_ADD(NOW(), INTERVAL 5 DAY),
    -> DATE_ADD('2014-01-10', INTERVAL 5 MICROSECOND),
    -> DATE_ADD('2014-01-10', INTERVAL 5 SECOND),
    -> DATE_ADD('2014-01-10', INTERVAL 5 MINUTE),
    -> DATE_ADD('2014-01-10', INTERVAL 5 HOUR),
    -> DATE_ADD('2014-01-10', INTERVAL 5 DAY),
    -> DATE_ADD('2014-01-10', INTERVAL 5 WEEK),
    -> DATE_ADD('2014-01-10', INTERVAL 5 MONTH),
    -> DATE_ADD('2014-01-10', INTERVAL 5 QUARTER),
    -> DATE_ADD('2014-01-10', INTERVAL 5 YEAR),
    -> DATE_ADD('2014-01-10', INTERVAL '5.000005' SECOND_MICROSECOND),
    -> DATE_ADD('2014-01-10', INTERVAL '05:05.000005' MINUTE_MICROSECOND),
    -> DATE_ADD('2014-01-10', INTERVAL '05:05' MINUTE_SECOND),
    -> DATE_ADD('2014-01-10', INTERVAL '05:05:05.000005' HOUR_MICROSECOND),
    -> DATE_ADD('2014-01-10', INTERVAL '05:05:05' HOUR_SECOND),
    -> DATE_ADD('2014-01-10', INTERVAL '05:05' HOUR_MINUTE),
    -> DATE_ADD('2014-01-10', INTERVAL '01 05:05:05.000005' DAY_MICROSECOND),
    -> DATE_ADD('2014-01-10', INTERVAL '01 05:05:05' DAY_SECOND),
    -> DATE_ADD('2014-01-10', INTERVAL '01 05:05' DAY_MINUTE),
    -> DATE_ADD('2014-01-10', INTERVAL '01 05' DAY_HOUR),
    -> DATE_ADD('2014-01-10', INTERVAL '1-01' YEAR_MONTH)
    -> \G

                  DATE_ADD('2014-01-10', INTERVAL '1-01' YEAR_MONTH): 2015-02-10
1 row in set (0.01 sec)
```

DATE_FORMAT

Declaration

```
DATE_FORMAT(date, format)
```

Description

This function returns the date and time in the specified format.

- `date` specifies the date and time.

- `format` specifies the output format.

The following table lists all output formats.

Format character	Description	Syntax
`%a`	The abbreviation of the day in a week.	`Sun..Sat`
`%b`	The abbreviation of the month.	`Jan..Dec`
`%c`	The numeric form of the month.	`1..12`
`%D`	The abbreviation of the day in a month.	`1st..31st`
`%d`	The numeric form of the day in a month.	`01..31`
`%e`	The numeric form of the day in a month.	`1.. 31`
`%f`	Microseconds.	`000000..999999`
`%H`	Hours.	`00..23`
`%h`	Hours.	`01..12`
`%I`	Hours.	`01..12`
`%i`	Minutes.	`00..59`
`%j`	The sequence number of the day in a year.	`001..366`
`%k`	Hours.	`0..23`

Format character	Description	Syntax
`%l`	Hours.	`0..12`
`%M`	The month name.	`January..December`
`%m`	The numeric form of the month.	`01..12`
`%p`	Morning or afternoon.	`AM/PM`
`%r`	Time in the 12-hour clock.	`hh:mm:ss AM/PM`
`%S`	Seconds.	`00..59`
`%s`	Seconds.	`00..59`
`%T`	Time in the 24-hour clock.	`hh:mm:ss`
`%U`	The sequence number of the week in a year when Sunday is the first day of each week.	`00..53`
`%u`	The sequence number of the week in a year when Monday is the first day of each week.	`00..53`
`%V`	The sequence number of the week in a year when Sunday is the first day of each week. This option is used in conjunction with `%X`.	`01..53`
`%v`	The sequence number of the week in a year when Monday is the first day of each week. This option is used in conjunction with `%x`.	`01..53`

Format character	Description	Syntax
`%W`	The name of the day in a week.	`Sunday..Saturday`
`%w`	The sequence number of the day in a week.	`0=Sunday..6=Saturday`
`%X`	The year of the week when Sunday is the first day of each week. This option is used in conjunction with `%V` .	
`%x`	The year of the week when Monday is the first day of each week. This option is used in conjunction with `%v` .	
`%Y`	The four-digit year.	
`%y`	The two-digit year.	
`%%`	The literal character `%` .	

Example

```
OceanBase (root@test)> SELECT
    -> DATE_FORMAT('2014-01-01', '%Y-%M-%d'),
    -> DATE_FORMAT('2014-01-01', '%X-%V'),
    -> DATE_FORMAT('2014-01-01', '%U')
    -> \G
*************************** 1. row ***************************
DATE_FORMAT('2014-01-01', '%Y-%M-%d'): 2014-January-01
   DATE_FORMAT('2014-01-01', '%X-%V'): 2013-52
      DATE_FORMAT('2014-01-01', '%U'): 00
1 row in set (0.01 sec)
```

DATE_SUB

Declaration

```
DATE_SUB(date, INTERVAL expr unit)
```

Description

This function performs arithmetic calculations on date and time values.

For more information, see `DATE_ADD()`.

DATEDIFF

Declaration

```
DATEDIFF(date1, date2)
```

Description

This function returns the number of days between `date1` and `date2`.

Only the date part of the parameter is used in the calculation, and the time part is ignored.

Example

```
OceanBase (root@test)> SELECT DATEDIFF('2015-06-19','1994-12-17');
+-------------------------------------+
| DATEDIFF('2015-06-19','1994-12-17') |
+-------------------------------------+
|                                7489 |
+-------------------------------------+
1 row in set (0.01 sec)
```

EXTRACT

Declaration

```
EXTRACT(unit FROM date)
```

Description

This function returns the specified portion of the `date` value as an integer value. If multiple portions are specified, all values are concatenated in order.

For information about the `unit` values, see `DATE_ADD()`. If the `unit` value is `WEEK`, see the description of `%U` in `DATE_FORMAT()`.

Example

```
SELECT EXTRACT(WEEK FROM '2013-01-01'),
EXTRACT(WEEK FROM '2013-01-06'),
EXTRACT(YEAR_MONTH FROM '2012-03-09'),
EXTRACT(DAY FROM NOW())\G;
* 1. row *
EXTRACT(WEEK FROM '2013-01-01'): 0
EXTRACT(WEEK FROM '2013-01-06'): 1
EXTRACT(YEAR_MONTH FROM '2012-03-09'): 201203
EXTRACT(DAY FROM NOW()): 18
1 row in set (0.00 sec)
```

FROM_DAYS

Declaration

```
FROM_DAYS(N)
```

Description

This function returns the `DATE` value based on the number of days `N`. N specifies the number of days that have elapsed since `0000-01-01`.

Example

```
OceanBase (root@test)> SELECT FROM_DAYS(736271), FROM_DAYS(700000);
+-------------------+-------------------+
| FROM_DAYS(736271) | FROM_DAYS(700000) |
+-------------------+-------------------+
| 2015-11-04        | 1916-07-15        |
+-------------------+-------------------+
1 row in set (0.00 sec)
```

FROM_UNIXTIME

Declaration

```
FROM_UNIXTIME(unix_timestamp)
FROM_UNIXTIME(unix_timestamp, format)
```

Description

- If you do not specify the `format` parameter, the function returns a `DATETIME` value that ignores the time zone.
- If you specify the `format` parameter, the function returns a date and time string in the specified format.

`unix_timestamp` specifies the UNIX timestamp. The value is the time that has elapsed since `1970-01-01 00:00:00.000000` in microseconds.

`format` supports the formats that are listed in the **description** of the `DATE_FORMAT()` function.

Example

```
OceanBase (root@test)> SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(), '%Y %D %M %h:%i:%s %x');
+-----------------------------------------------------------+
| FROM_UNIXTIME(UNIX_TIMESTAMP(), '%Y %D %M %h:%i:%s %x') |
+-----------------------------------------------------------+
| 2018 5th May 08:41:26 2018                                |
+-----------------------------------------------------------+
1 row in set (0.01 sec)
```

MONTH

Declaration

```
MONTH(date)
```

Description

This function returns the month of the `date`.

Example

```
OceanBase (root@test)> SELECT MONTH('2008-02-03');
+---------------------+
| MONTH('2008-02-03') |
+---------------------+
|                   2 |
+---------------------+
1 row in set (0.01 sec)
```

NOW

Declaration

```
NOW([scale])
```

Description

This function performs the same operation as `CURRENT_TIMESTAMP()`.

PERIOD_DIFF

Declaration

```
PERIOD_DIFF(p1, p2)
```

Description

This function returns the interval between two dates in months. The date can contain only the year and month information, and the format must be `YYYYMM` or `YYMM`.

Example

```
OceanBase (root@test)> SELECT PERIOD_DIFF(200802, 200703);
+----------------------------+
| PERIOD_DIFF(200802,200703) |
+----------------------------+
|                         11 |
+----------------------------+
1 row in set (0.01 sec)
```

STR_TO_DATE

Declaration

```
STR_TO_DATE(str, format)
```

Description

This function converts a `str` value to a `DATETIME`, `DATE`, or `TIME` value based on the specified `format`. The data type of the returned value depends on the date and time information included in the specified `format`.

`format` supports the formats that are listed in the **description** of the `DATE_FORMAT()` function.

Example

```
OceanBase (root@test)> SELECT STR_TO_DATE('2014-Jan-1st 5:5:5 pm', '%Y-%b-%D %r');
+-----------------------------------------------------+
| STR_TO_DATE('2014-Jan-1st 5:5:5 pm', '%Y-%b-%D %r') |
+-----------------------------------------------------+
| 2014-01-01 05:05:05                                 |
+-----------------------------------------------------+
1 row in set (0.01 sec)
```

TIME

Declaration

```
TIME(datetime
```

Description

This function converts a `datetime` value to a `TIME` value.

Example

```
OceanBase (root@test)> SELECT TIME('2003-12-31 01:02:03');
+-----------------------------+
| TIME('2003-12-31 01:02:03') |
+-----------------------------+
| 01:02:03.000000             |
+-----------------------------+
1 row in set (0.01 sec)
```

TIME_TO_USEC

Declaration

```
TIME_TO_USEC(date)
```

Description

This function converts a `date` value to the number of microseconds that have elapsed since `1970-01-01 00:00:00.000000` based on the time zone.

A `date` value can contain the date or both the date and the time.

Example

```
OceanBase (root@test)> SELECT TIME_TO_USEC('2014-03-25'), TIME_TO_USEC(NOW());
+----------------------------+---------------------+
| TIME_TO_USEC('2014-03-25') | TIME_TO_USEC(NOW()) |
+----------------------------+---------------------+
|           1395676800000000 |    1525528100000000 |
+----------------------------+---------------------+
1 row in set (0.01 sec)
```

TIMEDIFF

Declaration

```
TIMEDIFF(date1, date2)
```

Description

This function returns a `TIME` value that represents the time interval between two date and time values.

Example

```
OceanBase (root@test)> SELECT
    -> TIMEDIFF('2015-06-06 12:12:12', '2014-06-05 11:11:11'),
    -> TIMEDIFF('2015-06-06 12:12:12', '2015-06-05 11:11:11')
    -> \G
*************************** 1. row ***************************
TIMEDIFF('2015-06-06 12:12:12', '2014-06-05 11:11:11'): 838:59:59
TIMEDIFF('2015-06-06 12:12:12', '2015-06-05 11:11:11'): 25:01:01
1 row in set (0.00 sec)
```

TIMESTAMPDIFF

Declaration

```
TIMESTAMPDIFF(unit, date1, date2)
```

Description

This function returns the interval between two date and time values in the specified `unit`. `unit` can only be one of the independent units provided in the description of the `DATE_ADD()` function.

Example

```
OceanBase (root@test)> SELECT
    -> TIMESTAMPDIFF(SECOND, NOW(), '2011-01-01 11:11:11'),
    -> TIMESTAMPDIFF(DAY, '2011-01-01 11:11:11', NOW())
    -> \G
*************************** 1. row ***************************
TIMESTAMPDIFF(SECOND, NOW(), '2011-01-01 11:11:11'): -231677498
   TIMESTAMPDIFF(DAY, '2011-01-01 11:11:11', NOW()): 2681
1 row in set (0.00 sec)
```

TIMESTAMPADD

Declaration

```
TIMESTAMPADD(unit, interval_expr, date)
```

Description

This function performs arithmetic calculations on date and time values.

This function performs the same operation as `DATE_ADD()`. However, the `unit` value must be an independent unit.

Example

```
OceanBase (root@test)> SELECT
    -> TIMESTAMPADD(DAY, -5, '2010-01-01 00:00:00'),
    -> DATE_ADD('2010-01-01 00:00:00', INTERVAL -5 DAY)
    -> \G
*************************** 1. row ***************************
    TIMESTAMPADD(DAY, -5, '2010-01-01 00:00:00'): 2009-12-27 00:00:00
DATE_ADD('2010-01-01 00:00:00', INTERVAL -5 DAY): 2009-12-27 00:00:00
1 row in set (0.01 sec)
```

TO_DAYS

Declaration

```
TO_DAYS(date)
```

Description

This function returns the number of days based on the specified `date` value. The number of days indicates the number of days that have elapsed since `0000-01-01`.

Example

```
OceanBase (root@test)> SELECT TO_DAYS('2015-11-04'), TO_DAYS('20151104');
+-----------------------+---------------------+
| TO_DAYS('2015-11-04') | TO_DAYS('20151104') |
+-----------------------+---------------------+
|                736271 |              736271 |
+-----------------------+---------------------+
1 row in set (0.01 sec)
```

USEC_TO_TIME

Declaration

```
USEC_TO_TIME(usec)
```

Description

This function converts a `usec` value to a `TIMESTAMP` value.

`usec` is the number of microseconds that have elapsed since `1970-01-01 00:00:00.000000` based on the time zone.

Example

```
OceanBase (root@test)> SELECT USEC_TO_TIME(1);
+----------------------------+
| USEC_TO_TIME(1)            |
+----------------------------+
| 1970-01-01 08:00:00.000001 |
+----------------------------+
1 row in set (0.00 sec)
```

UNIX_TIMESTAMP

Declaration

```
UNIX_TIMESTAMP()
UNIX_TIMESTAMP(date)
```

Description

- If you do not specify the `date` parameter, the function returns the number of seconds that have elapsed since 1970-01-01 00:00:00 based on the time zone.
- If you specify the `date` parameter, the function returns the number of seconds between the specified time and 1970-01-01 00:00:00 based on the time zone.

Example

```
OceanBase (root@test)> SELECT UNIX_TIMESTAMP(), TIME_TO_USEC(NOW());
+------------------+---------------------+
| UNIX_TIMESTAMP() | TIME_TO_USEC(NOW()) |
+------------------+---------------------+
|       1525570561 |    1525570561000000 |
+------------------+---------------------+
1 row in set (0.01 sec)

OceanBase (root@test)> SELECT UNIX_TIMESTAMP('1997-10-04 22:23:00');
+---------------------------------------+
| UNIX_TIMESTAMP('1997-10-04 22:23:00') |
+---------------------------------------+
|                             875974980 |
+---------------------------------------+
1 row in set (0.01 sec)
```

UTC_TIMESTAMP

Declaration

```
UTC_TIMESTAMP()
```

Description

This function returns the current UTC time.

Example

```
OceanBase (root@test)> SELECT UTC_TIMESTAMP();
+---------------------+
| UTC_TIMESTAMP()     |
+---------------------+
| 2018-05-06 01:38:32 |
+---------------------+
1 row in set (0.01 sec)
```

YEAR

Declaration

```
YEAR(date)
```

Description

This function returns the year of the `date` value.

Example

```
OceanBase (root@test)> SELECT YEAR('1987-01-01');
+--------------------+
| YEAR('1987-01-01') |
+--------------------+
|               1987 |
+--------------------+
1 row in set (0.00 sec)
```

String functions

CONCAT

Declaration

```
CONCAT(str1, .., strN)
```

Description

This function concatenates multiple strings into one string. If an argument is `NULL`, the function returns `NULL`.

Example

```
OceanBase (root@test)> SELECT
    -> CONCAT('test','OceanBase', '1.0'),
    -> CONCAT('test','OceanBase', NULL)
    -> \G
*************************** 1. row ***************************
CONCAT('test','OceanBase', '1.0'): testOceanBase1.0
 CONCAT('test','OceanBase', NULL): NULL
1 row in set (0.01 sec)
```

CONCAT_WS

Declaration

```
CONCAT_WS(separator, str1, .., strN)
```

Description

This function concatenates multiple strings into one string, and separates adjacent strings with a `separator`. If an argument is `NULL`, the function ignores the `NULL` value.

Example

```
OceanBase (root@test)> SELECT
    -> CONCAT_WS('_', 'First', 'Second'),
    -> CONCAT_WS('_', 'First', NULL, 'Second')
    -> \G
*************************** 1. row ***************************
      CONCAT_WS('_', 'First', 'Second'): First_Second
CONCAT_WS('_', 'First', NULL, 'Second'): First_Second
1 row in set (0.00 sec)
```

SUBSTR

Declaration

```
SUBSTR(str, pos)
SUBSTR(str, pos, len)
SUBSTR(str FROM pos)
SUBSTR(str FROM pos FOR len)
```

Description

This function returns a substring of length `len` by starting at position `pos` of string `str`. If an argument is `NULL`, the function returns `NULL`.

- If you do not specify `len`, the returned substring starts from `pos` to the end of `str`.
- If `pos` is negative, the start position is determined by counting backward from the end of `str`.
- If `len` is less than or equal to 0, or `pos` is an invalid start position, an empty string is returned.

Example

```
OceanBase (root@test)> SELECT
    -> SUBSTR('abcdefg', 3),
    -> SUBSTR('abcdefg', 3, 2),
    -> SUBSTR('abcdefg', -3),
    -> SUBSTR('abcdefg', 3, -2),
    -> SUBSTR('abcdefg' from -4 for 2)
    -> \G
*************************** 1. row ***************************
           SUBSTR('abcdefg', 3): cdefg
        SUBSTR('abcdefg', 3, 2): cd
          SUBSTR('abcdefg', -3): efg
       SUBSTR('abcdefg', 3, -2):
SUBSTR('abcdefg' from -4 for 2): de
1 row in set (0.01 sec)
```

SUBSTRING

Declaration

```
SUBSTRING(str, pos)
SUBSTRING(str, pos, len)
SUBSTRING(str FROM pos)
SUBSTRING(str FROM pos FOR len)
```

Description

This function performs the same operation as `SUBSTR`.

TRIM

Declaration

```
TRIM([[{BOTH | LEADING | TRAILING}] [remstr] FROM] str)
```

Description

This function removes prefixes, suffixes, or both from a string. By default, the value is `BOTH`. If an argument is `NULL`, the function returns `NULL`.

Example

```
OceanBase (root@test)> SELECT
    -> TRIM(' bar '),
    -> TRIM(LEADING 'x' FROM 'xxxbarxxx'),
    -> TRIM(BOTH 'x' FROM 'xxxbarxxx'),
    -> TRIM(TRAILING 'x' FROM 'xxxbarxxx')
    -> \G
*************************** 1. row ***************************
                    TRIM(' bar '): bar
 TRIM(LEADING 'x' FROM 'xxxbarxxx'): barxxx
    TRIM(BOTH 'x' FROM 'xxxbarxxx'): bar
TRIM(TRAILING 'x' FROM 'xxxbarxxx'): xxxbar
1 row in set (0.01 sec)
```

LTRIM

Declaration

```
LTRIM(str)
```

Description

This function removes the spaces to the left of the string.

RTRIM

Declaration

```
RTRIM(str)
```

Description

This function removes the spaces to the right of the string.

ASCII

Declaration

```
ASCII(str)
```

Description

This function returns the ASCII code of the leftmost character of a string.

ORD

Declaration

```
ORD(str)
```

Description

This function returns the character code of the leftmost character of a string. If the leftmost character is a multibyte character, the function uses the following rules to calculate the code:

```
(1st byte code)
+ (2nd byte code * 256)
+ (3rd byte code * 256^2) ...
```

Example

```
OceanBase (root@test)> SELECT ORD('China');
+---------------+
| ORD('China') |
+---------------+
|      14989485 |
+---------------+
1 row in set (0.01 sec)
```

LENGTH

Declaration

```
LENGTH(str)
```

Description

This function returns the length of `str` in bytes.

Example

```
OceanBase (root@test)> SELECT LENGTH('China'), LENGTH('hello');
+------------------+-----------------+
| LENGTH('China') | LENGTH('hello') |
+------------------+-----------------+
|                6 |               5 |
+------------------+-----------------+
1 row in set (0.01 sec)
```

CHAR_LENGTH

Declaration

```
CHAR_LENGTH(str)
```

Description

This function returns the number of characters in a string.

Example

```
OceanBase (root@test)> SELECT CHAR_LENGTH('China'), CHAR_LENGTH('hello');
+-----------------------+----------------------+
| CHAR_LENGTH('China') | CHAR_LENGTH('hello') |
+-----------------------+----------------------+
|                     2 |                    5 |
+-----------------------+----------------------+
1 row in set (0.00 sec)
```

UPPER

Declaration

```
UPPER(str)
```

Description

This function converts lowercase letters in a string to uppercase letters.

Example

```
OceanBase (root@test)> SELECT UPPER('Hello, OceanBase!') ;
+------------------------------+
| UPPER('Hello, OceanBase!') |
+------------------------------+
| HELLO, OCEANBASE!          |
+------------------------------+
1 row in set (0.01 sec)
```

LOWER

Declaration

```
LOWER(str)
```

Description

This function converts uppercase letters in a string to lowercase letters.

Example

```
OceanBase (root@test)> SELECT LOWER('Hello, OceanBase!') ;
+------------------------------+
| LOWER('Hello, OceanBase!') |
+------------------------------+
| hello, oceanbase!          |
+------------------------------+
1 row in set (0.01 sec)
```

HEX

Declaration

```
HEX(str)
```

Description

This function converts a number or a string into a hexadecimal string.

Example

```
OceanBase (root@test)> SELECT HEX(255), HEX('abc');
+----------+------------+
| HEX(255) | HEX('abc') |
+----------+------------+
| FF       | 616263     |
+----------+------------+
1 row in set (0.00 sec)
```

UNHEX

Declaration

```
UNHEX(str)
```

Description

This function converts a hexadecimal string to a normal string.

Example

```
OceanBase (root@test)> SELECT UNHEX('4f6365616e42617365');
+-----------------------------+
| UNHEX('4f6365616e42617365') |
+-----------------------------+
| OceanBase                   |
+-----------------------------+
1 row in set (0.00 sec)
```

MD5

Declaration

```
MD5(str)
```

Description

This function returns the MD5 value of a string.

Example

```
OceanBase (root@test)> SELECT MD5(1);
+----------------------------------+
| MD5(1)                           |
+----------------------------------+
| c4ca4238a0b923820dcc509a6f75849b |
+----------------------------------+
1 row in set (0.00 sec)
```

INT2IP

Declaration

```
INT2IP(int_value)
```

Description

This function converts an integer to an IP address.

Example

```
OceanBase (root@test)> SELECT
    -> INT2IP(16777216),
    -> HEX(16777216),
    -> INT2IP(1)
    -> \G
*************************** 1. row ***************************
INT2IP(16777216): 1.0.0.0
   HEX(16777216): 1000000
       INT2IP(1): 0.0.0.1
1 row in set (0.01 sec)
```

IP2INT

Declaration

```
IP2INT('ip_addr')
```

Description

This function converts an IP address to an integer.

Example

```
OceanBase (root@test)> SELECT
    -> IP2INT('0.0.0.1'),
    -> HEX(IP2INT('0.0.0.1')),
    -> HEX(IP2INT('1.0.0.0'))
    -> \G
*************************** 1. row ***************************
     IP2INT('0.0.0.1'): 1
HEX(IP2INT('0.0.0.1')): 1
HEX(IP2INT('1.0.0.0')): 1000000
1 row in set (0.01 sec)
```

LIKE

Declaration

```
str1 [NOT] LIKE str2 [ESCAPE str3]
```

Description

This function compares strings based on wildcards. If an argument is `NULL`, the function returns `NULL`.

You can use the following wildcards:

- `%`: matches a string. No limits apply to the string length.
- `_`: matches a single character.

ESCAPE is used to define an escape character. If str3 is included in str2, the characters after str3 are processed as common characters during the match.

Example

```
OceanBase (root@test)> SELECT 'ab%' LIKE 'abc%' ESCAPE 'c';
+------------------------------+
| 'ab%' LIKE 'abc%' ESCAPE 'c' |
+------------------------------+
|                            1 |
+------------------------------+
1 row in set (0.01 sec)
```

REGEXP

Declaration

```
str [NOT] REGEXP | RLIKE pat
```

Description

This function performs pattern matching based on regular expressions. If an argument is `NULL`, the function returns `NULL`.

Example

```
OceanBase (root@test)> SELECT
    -> 1234 REGEXP 1,
    -> 'hello' RLIKE 'h%'
    -> \G
*************************** 1. row ***************************
     1234 REGEXP 1: 1
'hello' RLIKE 'h%': 0
1 row in set (0.01 sec)
```

REPEAT

Declaration

```
REPEAT(str, count)
```

Description

This function returns a string by repeating `str` for `count` times. If the `count` value is less than or equal to 0, an empty string is returned. If an argument is `NULL`, the function returns `NULL`.

Example

```
OceanBase (root@test)> SELECT
    -> REPEAT('1', -1),
    -> REPEAT(null, null),
    -> REPEAT('Abc', 4)
    -> \G
*************************** 1. row ***************************
   REPEAT('1', -1):
REPEAT(null, null): NULL
  REPEAT('Abc', 4): AbcAbcAbcAbc
1 row in set (0.01 sec)
```

SPACE

Declaration

```
SPACE(N)
```

Description

This function returns a string that contains `N` spaces.

SUBSTRING_INDEX

Declaration

```
SUBSTRING_INDEX(str, delim, count)
```

Description

This function returns the substring from string str before count occurrences of the delimiter delim. If the count value is positive, the function returns everything to the left of the final delimiter (counting from the left). If the count value is negative, the function returns everything to the right of the final delimiter (counting from the right). If an argument is NULL, the function returns NULL. If the str or delim value is an empty string, the function returns an empty string. If the count value is 0, the function returns an empty string.

str, delim, and count support implicit conversion between numbers and strings.

Example

```
Oceanbase>select substring_index('abcdabc', 'abc', 0), substring_index('abcdabc', 'abc', 1), substrin
g_index('abcdabc', 'abc', 2), substring_index('abcdabc', 'abc', 3), substring_index('abcdabc', 'abc',
-1), substring_index('abcdabc', 'abc', -2), substring_index('abcdabc', 'abc', -3)\G;
    * 1. row *
     substring_index('abcdabc', 'abc', 0):
     substring_index('abcdabc', 'abc', 1):
     substring_index('abcdabc', 'abc', 2): abcd
     substring_index('abcdabc', 'abc', 3): abcdabc
    substring_index('abcdabc', 'abc', -1):
    substring_index('abcdabc', 'abc', -2): dabc
    substring_index('abcdabc', 'abc', -3): abcdabc
    1 row in set (0.00 sec)
```

LOCATE

Declaration

```
LOCATE(substr,str) , LOCATE(substr,str,pos)
```

Description

The first syntax returns the position of the first occurrence of the substring substr in the string str. The second syntax returns the position of the first occurrence of the substring substr in the string str, which starts at the position pos. If substr is not included in str, the function returns 0.

Example

```
Oceanbase>SELECT LOCATE('bar', 'foobarbar');
        -> 4
Oceanbase>SELECT LOCATE('xbar', 'foobar');
        -> 0
Oceanbase>SELECT LOCATE('bar', 'foobarbar',5);
        -> 7
```

POSITION

Declaration

```
POSITION(substr IN str)
```

Description

This function performs the same operation as LOCATE.

INSTR

Declaration

```
INSTR(str,substr)
```

Description

This function returns the position of the first occurrence of the substring in str. This is the same as the two-parameter form of LOCATE(), except that the order of the parameters is reversed.

Example

```
Oceanbase>SELECT INSTR('foobarbar', 'bar');
        -> 4
Oceanbase>SELECT INSTR('xbar', 'foobar');
        -> 0
```

REPLACE

Declaration

```
REPLACE(str, from_str, to_str)
```

Description

This function returns the str string after all occurrences of from_str are replaced by to_str.

Example

```
Oceanbase>SELECT REPLACE('abc.efg.gpg.nowdew.abc.dabc.e', 'abc.', 'www');
+-----------------------------------------------------------+
| REPLACE('abc.efg.gpg.nowdew.abc.dabc.e', 'abc.', 'www') |
+-----------------------------------------------------------+
| wwwefg.gpg.nowdew.wwwdwwwe                                |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

FIELD

Declaration

```
FIELD(str,str1,str2,str3,...)
```

Description

This function returns the index position of the str string in the list of strings str1, str2, str3,... The sequence numbers for index positions start from 1. If str is not found, the function returns 0.

If all arguments in the FIELD() function are strings, the function compares the arguments based on the strings. If all arguments are numbers, the function compares the arguments based on the numbers. Otherwise, the function compares the arguments as values of the double data type.

If the str value is NULL, the function returns 0. This is because NULL cannot be compared with the other values. FIELD() is a supplement to ELT().

Example

```
Oceanbase>select field('abc','abc1','abc2','abc','abc4','abc'), field(NULL, 'null1', NULL);
+-----------------------------------------------+-----------------------------+
| field('abc','abc1','abc2','abc','abc4','abc') | field(NULL, 'null1', NULL) |
+-----------------------------------------------+-----------------------------+
|                                             3 |                           0 |
+-----------------------------------------------+-----------------------------+
1 row in set (0.00 sec)
```

ELT

Declaration

```
ELT(N, str1, str2, str3,...)
```

Description

This function returns the Nth element of a list of strings. For example, if you set N to 1, the function returns the string str1. If you set N to 2, the function returns the string str2. If N is less than 1 or greater than the number of the parameters, the function returns NULL. ELT() is a supplement to FIELD().

Example

```
Oceanbase>select elt(3, 'abc1', 'abc2', 'abc', 'abc4', 'abc'), elt(0, 'null1', NULL);
+-----------------------------------------------+-----------------------+
| elt(3, 'abc1', 'abc2', 'abc', 'abc4', 'abc') | elt(0, 'null1', NULL) |
+-----------------------------------------------+-----------------------+
| abc                                           | NULL                  |
+-----------------------------------------------+-----------------------+
1 row in set (0.00 sec)
```

INSERT

Declaration

```
INSERT (str1,pos,len,str2)
```

Description

This function replaces a specified substring of a string with a new substring. The str1 parameter specifies the source string and the str2 parameter specifies the new substring. The pos parameter specifies the start position of the original substring and the len parameter specifies the length of the original substring. If the pos value is greater than the length of the source string, the function returns the source string. If the len value is greater than the length of the str1 or str2 string, the function replaces the original substring that starts at the pos position. If an argument is NULL, the function returns NULL. This function supports multibyte characters.

- *The values of str1 and str2 must be strings. The values of pos and len must be integers. If an argument is NULL, the function returns NULL.*
- *The text characters in str1 and str2 are identified as byte streams.*
- *If the pos value is negative or greater than the length of the string str1, the function returns the string str1.*
- If the len value is less than 0 or greater than the length of the str value, the function returns a string that consists of the string str2 and a substring of the string str1. The substring starts from the first character of the string str1 value and ends at the position that is specified by the pos parameter.

Example

```
Oceanbase>select insert('Quadratic',-2,100,'What'), insert('Quadratic',7,3,'What'),
    -> insert('Quadratic',-1,3,'What'), insert('Quadratic',10,3,'What'), insert('Quadratic',5,-1,''),
    -> insert('Quadratic',7,-1,'What')\G;
* 1. row *
insert('Quadratic',-2,100,'What'): Quadratic
   insert('Quadratic',7,3,'What'): QuadraWhat
  insert('Quadratic',-1,3,'What'): Quadratic
  insert('Quadratic',10,3,'What'): Quadratic
      insert('Quadratic',5,-1,''): Quad
  insert('Quadratic',7,-1,'What'): QuadraWhat
1 row in set (0.01 sec)
```

LPAD

Declaration

```
LPAD(str, len, padstr)
```

Description

This function adds the padstr padding string to the left of the str string until the final string reaches the len value. If the str value is longer than the len value, str is truncated.

Example

```
OceanBase > SELECT LPAD('hi',4,'??') ;
+-------------------+
| LPAD('hi',4,'??') |
+-------------------+
| ?? hi             |
+-------------------+
1 row in set (0.01 sec)

OceanBase > SELECT LPAD('hi',1,'??') ;
+-------------------+
| LPAD('hi',1,'??') |
+-------------------+
| h                 |
+-------------------+
1 row in set (0.00 sec)
```

RPAD

Declaration

```
RPAD(str, len, padstr)
```

Description

This function adds the padstr padding string to the right of the str string until the final string reaches the len value. If the str value is longer than the len value, str is truncated.

Example

```
OceanBase (root@test)> SELECT RPAD('hi',4,'??') ;
+-------------------+
| RPAD('hi',4,'??') |
+-------------------+
| hi??              |
+-------------------+
1 row in set (0.00 sec)

OceanBase (root@test)> SELECT RPAD('hi',1,'??') ;
+-------------------+
| RPAD('hi',1,'??') |
+-------------------+
| h                 |
+-------------------+
1 row in set (0.00 sec)
```

UUID

Declaration

```
uuid()
```

Description

This function generates a globally unique identifier (ID).

Example

```
OceanBase (root@test)> select uuid();
+--------------------------------------+
| uuid()                               |
+--------------------------------------+
| f756a1f6-4de6-11e8-90af-90b11c53e421 |
+--------------------------------------+
1 row in set (0.00 sec)
```

BIN

Declaration

```
bin(N)
```

Description

This function returns the binary form of the number N.

Example

```
OceanBase > SELECT BIN(12);
+----------+
| BIN(12) |
+----------+
| 1100    |
+----------+
1 row in set (0.00 sec)
```

QUOTE

Declaration

```
quote(str)
```

Description

This function quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. This function returns a string that is enclosed by single quotation marks ('), and each single quotation marks ('), backslash (\), ASCII NUL, and Ctrl+Z is preceded with a backslash (\). If the argument is NULL, the function returns a word NULL that is not enclosed by single quotation marks (').

Example

```
OceanBase > SELECT QUOTE('Don\'t!') ;
+------------------+
| QUOTE('Don\'t!') |
+------------------+
| 'Don\'t!'        |
+------------------+
1 row in set (0.00 sec)

OceanBase > SELECT QUOTE(NULL);
+-------------+
| QUOTE(NULL) |
+-------------+
| NULL        |
+-------------+
1 row in set (0.00 sec)
```

REGEXP_SUBSTR

Declaration

```
regexp_substr(str,pattern,[position[,occurrence[,match_param[,subexpr]]]])
```

Description

This function searches for a substring that matches the regular expression pattern in the str string. If the substring does not exist, the function returns NULL. This function supports multibyte characters. Except for match_param, if an argument is NULL, the function returns NULL.

- str is the string to be searched. Multibyte characters are supported.
- pattern is the regular expression, and the regular expression rules are compatible with MySQL.
- position is an optional parameter that specifies where to begin the search. The position parameter must be a positive integer. An error is reported if the value is less than or equal to 0. If the input value is NULL, the function returns NULL. By default, the value is 1, which means that the search starts from the first character.
- occurrence is an optional parameter. This parameter specifies the number of times the string matches the regular expression. The occurrence parameter must be an integer that is greater than 0. An error is reported if the value is less than or equal to 0. If the input value is NULL, the function returns NULL. The default value is 1, which means that the function searches for the first occurrence of the pattern.
- match_param is an optional parameter that specifies the string type. This parameter supports only two characters: i and c. i specifies case-insensitive matching. c specifies case-sensitive matching. If you specify other characters, an error occurs. The default value is determined by the character set of str. The default value is used if match_param is NULL.
- subexpr is an optional parameter. This parameter specifies which group of the regular expression is used to match the string. subexpr must be an integer greater than or equal to 0. An error is reported if the value is smaller than 0. The default value is 0, which means that the function returns a substring that satisfies the entire pattern.

Example

```
oceanbase> select regexp_substr('I have 2 apples and 100 bucks!', '[[:blank:]][[:alnum:]]*', 1, 1) fr
om dual;
+-----------------------------------------------------------------------------------+
| regexp_substr('I have 2 apples and 100 bucks!', '[[:blank:]][[:alnum:]]*', 1, 1) |
+-----------------------------------------------------------------------------------+
|  have                                                                             |
+-----------------------------------------------------------------------------------+
1 row in set (0.00 sec)

oceanbase> select regexp_substr('foothebar', 'foo(.*)(bar)', 1, 1, 'c', 1) from dual;
+-----------------------------------------------------------+
| regexp_substr('foothebar', 'foo(.*)(bar)', 1, 1, 'c', 1) |
+-----------------------------------------------------------+
| the                                                       |
+-----------------------------------------------------------+
1 row in set (0.01 sec)
```

Type conversion functions

CAST

Declaration

```
CAST(expr AS type)
```

Description

This function explicitly converts an expression of one data type to another data type.

This function converts the value of expr to a new data type.

Parameters:

- expr specifies a valid SQL expression.
- AS separates two parameters. The parameter before AS specifies the data to be processed. The parameter after AS specifies the destination data type.
- type specifies a valid data type supported by ApsaraDB for OceanBase. Valid values:
  - DATE
  - DATETIME
  - DECIMAL
  - SIGNED [INTEGER]
  - TIME
  - UNSIGNED [INTEGER]

The CAST function for type conversion is applicable if one of the following conditions is met:

- The data types of the two expressions are the same.
- The data types of the two expressions can be converted in an implicit way.
- The data types must be explicitly converted.

If you attempt to perform an invalid conversion, ApsaraDB for OceanBase returns an error message.

If the length of a data type is not specified, the system uses the maximum length that is supported for the data type in ApsaraDB for OceanBase. For example, the maximum length for the VARCHAR data type is 262,143 bytes. The maximum length for a numeric data type is 65 bits for floating-point numbers.

You can use the CAST function to convert signed and unsigned 64-bit values. If you use a numeric operator such as a plus sign (+) and one of the operands is an unsigned integer, the function returns an unsigned value. To override a numeric operator, use the SIGNED or UNSIGNED cast operator to cast a value to a signed or unsigned 64-bit integer.

If an operand is a floating-point value, the result is a floating-point value.

Example

```
Oceanbase>SELECT CAST(123 AS BOOL);
+-------------------+
| CAST(123 AS bool) |
+-------------------+
|                 1 |
+-------------------+
1 row in set (0.00 sec)

Oceanbase>select cast(1-2 as unsigned), cast(cast(1-2 as unsigned) as signed);
+-----------------------+---------------------------------------+
| cast(1-2 as unsigned) | cast(cast(1-2 as unsigned) as signed) |
+-----------------------+---------------------------------------+
|  18446744073709551615 |                                    -1 |
+-----------------------+---------------------------------------+
1 row in set (0.00 sec)

Oceanbase>SELECT CAST(1 AS UNSIGNED) - 2.0;
+----------------------------+
| CAST(1 AS UNSIGNED) - 2.0 |
+----------------------------+
|                      -1.0 |
+----------------------------+
1 row in set (0.00 sec)

Oceanbase>select cast(0 as date);
+-----------------+

```

Mathematical functions

ROUND

Declaration

```
ROUND(X), ROUND(X,D)
```

Description

This function returns a number that is rounded to the specified length or precision.

This function rounds the X value to the nearest integer. If you specify two parameters for the function, the function rounds X to D decimal places. The Dth digit is obtained by rounding. To keep D digits of the X value to the left of the decimal point, set D to a negative value.

The data type of the returned value is the same as that of the first argument. You can assume that the value is an integer, a double-precision floating-point number, or a decimal value. This means that the returned result for an integer argument is also an integer. No fractional part is included in the returned result.

- For exact-valued numbers, ROUND() uses the rules of rounding up or rounding to the nearest number. A value that has a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. In other words, the value is rounded away from zero on the number axis. A value that has a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate numbers, ROUND() follows the bankers rounding rule. If a value has a fractional part, the function rounds the value to the nearest even integer.

Example

```
Oceanbase>select round(2.15,2);
+---------------+
| round(2.15,2) |
+---------------+
|          2.15 |
+---------------+
1 row in set (0.00 sec)

Oceanbase>select round(2555e-2,1);
+------------------+
| round(2555e-2,1) |
+------------------+
|             25.6 |
+------------------+
1 row in set (0.01 sec)

Oceanbase>select round(25e-1), round(25.3e-1),round(35e-1);
+--------------+----------------+--------------+
| round(25e-1) | round(25.3e-1) | round(35e-1) |
+--------------+----------------+--------------+
|            3 |              3 |            4 |
+--------------+----------------+--------------+
1 row in set (0.00 sec)
```

CEIL

Declaration

```
CEIL(expr)
```

Description

This function returns the smallest integer value that is no less than the specified expression.

This function supports comparison operations. The comparison result is a BOOLEAN value. The BOOLEAN value is converted to a numeric value: 1 for TRUE or 0 for FALSE.

If the value of expr is NULL, the function returns NULL.

If you specify a string of numbers, the function automatically converts the string to a numeric value.

The returned value is converted to a BIGINT number.

Example

```
Oceanbase>select ceil(1.2), ceil(-1.2), ceil(1+1.5), ceil(1=1),ceil(1<1),ceil(null);
+-----------+------------+-------------+-----------+-----------+------------+
| ceil(1.2) | ceil(-1.2) | ceil(1+1.5) | ceil(1=1) | ceil(1<1) | ceil(null) |
+-----------+------------+-------------+-----------+-----------+------------+
|         2 |         -1 |           3 |         1 |         0 |       NULL |
+-----------+------------+-------------+-----------+-----------+------------+
1 row in set (0.00 sec)

Oceanbase>select ceil(name);
ERROR 1166 (42703): Unkown column name 'name'

Oceanbase>select ceil('2');
+------------+
| ceil('2') |
+------------+
|         2 |
+------------+
1 row in set (0.00 sec)
```

FLOOR

Declaration

```
FLOOR(expr)
```

Description

This function is similar to CEIL(expr) and returns the largest integer value that is less than or equal to the specified expression.

The function supports comparison operations. The comparison result is a BOOLEAN value. The BOOLEAN value is converted to a numeric value: 1 for TRUE or 0 for FALSE.

If the value of expr is NULL, the function returns NULL.

If you specify a string of numbers, the function automatically converts the string to a numeric value.

The returned value is converted to a BIGINT number.

Example

```
Oceanbase>select floor(1.2), floor(-1.2), floor(1+1.5), floor(1=1),floor(1<1),floor(null);
+------------+-------------+--------------+------------+------------+-------------+
| floor(1.2) | floor(-1.2) | floor(1+1.5) | floor(1=1) | floor(1<1) | floor(null) |
+------------+-------------+--------------+------------+------------+-------------+
|          1 |          -2 |            2 |          1 |          0 |        NULL |
+------------+-------------+--------------+------------+------------+-------------+
1 row in set (0.00 sec)

Oceanbase>select floor(name);
ERROR 1166 (42703): Unkown column name 'name'

Oceanbase>select floor('2');
+-------------+
| floor('2') |
+-------------+
|          2 |
+-------------+
1 row in set (0.00 sec)
```

ABS

Declaration

```
ABS(expr)
```

Description

This function returns the absolute value for a specified numeric expression. The data type of the returned value is the same as that of the expression value.

The function supports comparison operations. The comparison result is a BOOLEAN value. The BOOLEAN value is converted to a numeric value: 1 for TRUE or 0 for FALSE.

If the value of expr is NULL, the function returns NULL.

If you specify a string of numbers, the function automatically converts the string to a numeric value.

The returned value is converted to a BIGINT number.

Example

```
Oceanbase>select abs(5), abs(-5.777), abs(0), abs(1/2), abs(1-5);
+--------+-------------+--------+----------+----------+
| abs(5) | abs(-5.777) | abs(0) | abs(1/2) | abs(1-5) |
+--------+-------------+--------+----------+----------+
|      5 |       5.777 |      0 |   0.5000 |        4 |
+--------+-------------+--------+----------+----------+
1 row in set (0.00 sec)
```

NEG

Declaration

```
NEG(expr)
```

Description

This function is a negation function that subtracts a specified operand from zero and returns the final result.

The function supports comparison operations. The comparison result is a BOOLEAN value. The BOOLEAN value is converted to a numeric value: 1 for TRUE or 0 for FALSE.

Example

```
Oceanbase>select neg(1), neg(1+1), neg(2*3), neg(1=1), neg(5<1);
+--------+----------+----------+----------+----------+
| neg(1) | neg(1+1) | neg(2*3) | neg(1=1) | neg(5<1) |
+--------+----------+----------+----------+----------+
|     -1 |       -2 |       -6 |       -1 |        0 |
+--------+----------+----------+----------+----------+
1 row in set (0.01 sec)
```

SIGN

Declaration

```
SIGN(X)
```

Description

This function returns the sign of a specified number. The function returns -1, 0, or 1 based on whether the specified X value is negative, zero, or positive.

The function supports comparison operations. The comparison result is a BOOLEAN value. The BOOLEAN value is converted to a numeric value: 1 for TRUE or 0 for FALSE.

If the value of X is NULL, the function returns NULL.

The function supports floating-point numbers and hexadecimal numbers.

Example

```
Oceanbase>SELECT SIGN(-32), SIGN(0), SIGN(234);
+-----------+---------+-----------+
| SIGN(-32) | SIGN(0) | SIGN(234) |
+-----------+---------+-----------+
|        -1 |       0 |         1 |
+-----------+---------+-----------+
1 row in set (0.01 sec)

Oceanbase>select sign(null),sign(false),sign(0x01);
+------------+-------------+------------+
| sign(null) | sign(false) | sign(0x01) |
+------------+-------------+------------+
|       NULL |           0 |          1 |
+------------+-------------+------------+
1 row in set (0.00 sec)
```

CONV

Declaration

```
CONV(N, from_base, to_base)
```

Description

This function converts a number from one base to another base. The function converts a number from the from_base base to the to_base base. The returned result is a string. The value of the N input parameter can be an integer or a string. The minimum base is 2 and the maximum base is 36. If the to_base value is a negative number, N is processed as a signed number. Otherwise, N is processed as an unsigned number. If the from_base value is a negative number, the value is processed as an integer and the value sign is ignored. The N parameter must be an integer or a string. The from_base and to_base parameters must be decimal integers within the valid value range: the union of [-36,-2] and [2,36].

Invalid input values result in errors. In the following scenarios, the input values are invalid:

- *The value of the from_base or to_base parameter is an invalid decimal integer value.*
- *The value of the from_base or to_base parameter does not fall within the valid value range: the union of [-36,-2] and [2,36].*
- N is an invalid numeric value. For example, N falls out of the following character range: 0 to 9, a to z, or A to Z.
- N falls out of the valid range of the from_base values. For example, the from_base value is 2, whereas N is 3.
- N falls out of the valid range of 64-bit integers. The valid range is [-9223372036854775807,9223372036854775807].

Example

```
Oceanbase>select conv(9223372036854775807,10,2);
+----------------------------------------------------------------+
| conv(9223372036854775807,10,2)                                 |
+----------------------------------------------------------------+
| 1111111111111111111111111111111111111111111111111111111111111111 |
+----------------------------------------------------------------+
1 row in set (0.00 sec)

Oceanbase>select conv('-acc',21,-7);
+--------------------+
| conv('-acc',21,-7) |
+--------------------+
| -16425             |
+--------------------+
1 row in set (0.00 sec)
```

MOD

Declaration

```
MOD(N,M)
```

Description

This function returns the remainder after a number is divided by another number. MOD(N,M), N % M, and N MOD M perform the same operations.

You can use the MOD() function to perform calculations on numbers that have fractional parts. This function returns the exact remainder after a number is divided by another number.

If one of the N and M values is NULL, the function returns NULL. If M is 0, the function returns NULL.

Example

```
Oceanbase>select mod(29,19), 29 mod 19, 29 % 19;
+------------+-----------+----------+
| mod(29,19) | 29 mod 19 | 29 % 19 |
+------------+-----------+----------+
|         10 |        10 |      10 |
+------------+-----------+----------+
1 row in set (0.00 sec)
```

POW

Declaration

```
POW(X,Y)
```

Description

This function raises X to the power of Y.

If one of the X and Y values is NULL, the function returns NULL.

Example

```
Oceanbase>select pow(4,2), pow(4,-2), pow(1,null);
+----------+-----------+-------------+
| pow(4,2) | pow(4,-2) | pow(1,null) |
+----------+-----------+-------------+
|       16 |    0.0625 |        NULL |
+----------+-----------+-------------+
1 row in set (0.00 sec)
```

POWER

Declaration

```
POWER(X,Y)
```

Description

POWER(X,Y) and POW(X,Y) are identical functions.

RAND

Declaration

```
rand([N])
```

Description

The RAND([N]) function accepts zero or one parameter (N) and returns a random floating-point number that falls within the range of [0,1.0). N is called a random seed. If you want to obtain a random integer in the range of [I,j), you can use the FLOOR(I + RAND() * (j - i)) expression.

If you do not specify N, a random seed is generated during initialization. The RAND() function generates a random number based on this random seed. Therefore, the RAND() function generates a different random number each time the function is invoked.

If you specify N, N is used as the random seed to generate random numbers. The function generates random numbers based on whether N is a constant:

- If N is a constant, N is used as the random seed during initialization. Then, the RAND(N) function generates a random number based on the initialized value. If the values of N are the same, the generated random number sequences are the same.
- If N is a variable, such as a column name, N is used as the random seed to generate a random number each time the function is invoked. If the values of N are the same, the generated random numbers are the same.

In addition to SELECT statements, the RAND([N]) function can also be used in conjunction with the WHERE, ORDER BY, and GROUP BY clauses. Regardless of whether these clauses are used, the RAND([N]) function runs based on the preceding rules. For example, if you want to sort a table in a random way, execute the following SQL statement: select from t1 order by rand(). If you want to sample 100 rows of a table in a random way, execute the following SQL statement: select from t1 order by rand() limit 100.

Example

```
mysql> select a, b, rand() from t3;
+------+------+----------------------+
| a    | b    | rand()               |
+------+------+----------------------+
|    1 |    1 |   0.641815407799385 |
|    2 |    2 | 0.16825051248841966 |
|    3 |    3 |  0.9158063697775886 |
+------+------+----------------------+
3 rows in set (0.00 sec)

mysql> select a, b, rand() from t3;
+------+------+----------------------+
| a    | b    | rand()               |
+------+------+----------------------+
|    1 |    1 | 0.07428034215632857 |
|    2 |    2 |  0.6239826321825224 |
|    3 |    3 |   0.897072165177271 |
+------+------+----------------------+
3 rows in set (0.00 sec)

mysql> select a, b, rand(3) from t3;
+------+------+----------------------+
| a    | b    | rand(3)              |
+------+------+----------------------+
|    1 |    1 |  0.9057697559760601 |
|    2 |    2 | 0.37307905813034536 |
|    3 |    3 | 0.14808605345719125 |
+------+------+----------------------+
3 rows in set (0.00 sec)

mysql> select a, b, rand(3) from t3;
+------+------+----------------------+
| a    | b    | rand(3)              |
+------+------+----------------------+
|    1 |    1 |  0.9057697559760601 |
|    2 |    2 | 0.37307905813034536 |
|    3 |    3 | 0.14808605345719125 |
+------+------+----------------------+
3 rows in set (0.00 sec)

mysql> select a, b, rand(a), rand(b) from t3;
+------+------+----------------------+----------------------+
| a    | b    | rand(a)              | rand(b)              |
+------+------+----------------------+----------------------+
|    1 |    1 | 0.40540353712197724 | 0.40540353712197724 |
|    2 |    2 |  0.6555866465490187 |  0.6555866465490187 |

+------+------+----------------------+----------------------+
3 rows in set (0.00 sec)
```

Comparison functions

GREATEST

Declaration

```
GREATEST(value1, ...)
```

Description

This function returns the maximum value among the specified input values. This function performs the opposite operation of the LEAST() function.

You must specify a minimum of two arguments. The function generates an error if only one argument is specified. If one of the arguments is NULL, the function returns NULL.

If the specified arguments contain numeric values and strings, the system converts the strings to numeric values in an implicit way. If the conversion fails, the system reports an error.

Example

```
Oceanbase>select greatest(2,1), greatest('2',1,0), greatest('a','b','c'), greatest('a', NULL, 'c'), g
reatest('2014-05-15','2014-06-01')\G
    * 1. row *
                         greatest(2,1): 2
                     greatest('2',1,0): 2
                greatest('a','b','c'): c
             greatest('a', NULL, 'c'): NULL
    greatest('2014-05-15','2014-06-01'): 2014-06-01
    1 row in set (0.01 sec)
    Oceanbase>select greatest(2);
    ERROR 1582 (42000): Incorrect parameter count in the call to native function 'greatest'
```

LEAST

Declaration

```
LEAST(value1, ...)
```

Description

This function returns the minimum value among the specified arguments. This function performs the opposite operation of the GREATEST() function.

You must specify a minimum of two arguments. If one of the arguments is NULL, the function returns NULL.

If the specified arguments contain numeric values and strings, the system converts the strings to numeric values in an implicit way. If the conversion fails, the system reports an error.

Example

```
Oceanbase>select least(2, null), least('2',4,9), least('a','b','c'), least('a',NULL,'c'), least('2014
-05-15','2014-06-01')\G;
* 1. row *
                      least(2, null): NULL
                      least('2',4,9): 2
                  least('a','b','c'): a
                 least('a',NULL,'c'): NULL
least('2014-05-15','2014-06-01'): 2014-05-15
1 row in set (0.01 sec)
Oceanbase>select least(2);
ERROR 1582 (42000): Incorrect parameter count in the call to native function 'least'
```

ISNULL

Declaration

```
ISNULL(expr)
```

Description

This function checks whether a specified value of an expression is NULL. If the expr value is NULL, the ISNULL() function returns 1. Otherwise, the function returns 0.

The ISNULL() function can be used as an alternative to the equal sign (=) comparison. If the equal sign (=) operator is used to check whether an expression value is NULL, the returned result is invalid in most cases. The ISNULL() function provides some features that are the same as the IS NULL operator.

Example

```
Oceanbase>SELECT ISNULL(null), ISNULL('test'), ISNULL(123.456), ISNULL('10:00');
+--------------+----------------+-----------------+-----------------+
| ISNULL(null) | ISNULL('test') | ISNULL(123.456) | ISNULL('10:00') |
+--------------+----------------+-----------------+-----------------+
|            1 |              0 |               0 |               0 |
+--------------+----------------+-----------------+-----------------+
1 row in set (0.01 sec)

Oceanbase>SELECT ISNULL(null+1);
+-----------------+
| ISNULL(null+1) |
+-----------------+
|              1 |
+-----------------+
1 row in set (0.00 sec)
```

Process control functions

CASE

Declaration

```
CASE value WHEN [compare-value] THEN result [WHEN [compare-value] THEN result ...] [ELSE result] END
OR
CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...] [ELSE result] END
```

Description

For the first case, the function returns the value that is equal to compare-value. For the second case, the function returns the first value whose preceding condition is true. If no matched results are available, the function returns the result of the ELSE part. If the ELSE part is unavailable, the function returns NULL.

Example

```
Oceanbase>select CASE 'b' when 'a' then 1 when 'b' then 2 END;
+-----------------------------------------------+
| CASE 'b' when 'a' then 1 when 'b' then 2 END |
+-----------------------------------------------+
|                                             2 |
+-----------------------------------------------+
1 row in set (0.01 sec)

Oceanbase>select CASE concat('a','b') when concat('ab','') then 'a' when 'b' then 'b' end;
+-----------------------------------------------------------------------------+
| CASE concat('a','b') when concat('ab','') then 'a' when 'b' then 'b' end |
+-----------------------------------------------------------------------------+
| a                                                                           |
+-----------------------------------------------------------------------------+
1 row in set (0.01 sec)

Oceanbase>select case when 1>0 then 'true' else 'false' end;
+--------------------------------------------+
| case when 1>0 then 'true' else 'false' end |
+--------------------------------------------+
| true                                       |
+--------------------------------------------+
1 row in set (0.00 sec)
```

IF

Declaration

```
IF(expr1,expr2,expr3)
```

Description

This function returns the expr2 value if the expr1 value is TRUE. The expr1 value is TRUE if expr1 is a non-NULL value that is not equal to 0. Otherwise, the function returns the expr3 value.

The IF() function returns numeric values or strings based on the data types of arguments.

If one of the expr2 and expr3 values is NULL, the data type of the IF() function result is the same as that of the non-NULL expression value.

Example

```
Oceanbase>select if(5>6, 'T','F'), if (5>6, 1, 0), if(null, 'True', 'False'), if(0, 'True', 'False')\
G
* 1. row *
         if(5>6, 'T','F'): F
           if (5>6, 1, 0): 0
if(null, 'True', 'False'): False
   if(0, 'True', 'False'): False
1 row in set (0.01 sec)
```

IFNULL

Declaration

```
IFNULL(expr1, expr2)
```

Description

This function returns expr1 if expr1 is not NULL. Otherwise, the function returns expr2. The IFNULL() function returns numeric values or strings based on the data types of arguments.

The following table describes the rules used by the IF() function to return data of the default type.

Expression	Returned value
expr1 or expr2 returns a string.	String
expr2 or expr3 returns a floating-point number.	Float-pointing number
expr2 or expr3 returns an integer.	Integer

If the expr2 and expr3 values are strings and one of the strings is case-sensitive, the returned value is case-sensitive.

Example

```
Oceanbase>SELECT IFNULL('abc', null), IFNULL(NULL+1, NULL+2), IFNULL(1/0, 0/1);
+---------------------+-----------------------+------------------+
| IFNULL('abc', null) | IFNULL(NULL+1, NULL+2) | IFNULL(1/0, 0/1) |
+---------------------+-----------------------+------------------+
| abc                 |                  NULL |           0.0000 |
+---------------------+-----------------------+------------------+
1 row in set (0.01 sec)
```

NULLIF

Declaration

```
NULLIF(expr1, expr2)
```

Description

If the expr1 value is equal to the expr2 value, the function returns NULL. Otherwise, the function returns the expr1 value. This function performs the same operation as the CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END statement.

This function evaluates the expr1 value twice if the expr1 and expr2 values are not equal.

Example

```
Oceanbase>SELECT NULLIF('ABC', 123), NULLIF('123',123), NULLIF(NULL, 'abc');
+--------------------+--------------------+---------------------+
| NULLIF('ABC', 123) | NULLIF('123',123) | NULLIF(NULL, 'abc') |
+--------------------+--------------------+---------------------+
| ABC                | NULL               | NULL                |
+--------------------+--------------------+---------------------+
1 row in set, 1 warning (0.01 sec)
```

ORA_DECODE

Declaration

```
 ora_decode (condition, value 1, return value 1, value 2, return value 2, ... value n, return value n, default value)
```

Description

The ORA_DECODE() function is equivalent to the DECODE() function provided by Oracle. ApsaraDB for OceanBase 1.0 is compatible with MySQL, and also supports some Oracle functions. The names of the supported Oracle functions are prefixed with ORA_ in ApsaraDB for OceanBase 1.0.

The following section describes the meaning of this function:

```
IF condition = value 1
THEN RETURN (return value 1)
ELSIF condition = value 2
THEN RETURN (return value 2)
......
ELSIF condition = value n
THEN RETURN (return value n)
ELSE RETURN (default value)
END IF
```

17.1.4.3.2. Aggregate functions

Aggregate functions perform calculations on a set of values and return a single value. Aggregate functions ignore NULL values. In most cases, aggregate functions are used in conjunction with GROUP BY clauses in SELECT statements.

All aggregate functions are deterministic. Each time you call aggregate functions by using the same set of input values, the aggregate functions return the same value.

In ApsaraDB for OceanBase, you can specify only one expression value for each aggregate function. For example, COUNT(c1, c2) is not supported, and only COUNT(c1) is supported.

AVG

Declaration

```
AVG(([DISTINCT] expr)
```

Description

This function returns the average value of a specified data set. The function ignores the NULL values in the specified data set. The DISTINCT keyword is used to return the average value of the distinct expr values. If no matched rows are found, the AVG() function returns NULL.

Example

```
Oceanbase>select * from oceanbasetest;
+----+------+------+
| id | ip   | ip2  |
+----+------+------+
|  1 |    4 | NULL |
|  3 |    3 | NULL |
|  4 |    3 | NULL |
+----+------+------+
3 rows in set (0.01 sec)

Oceanbase>select avg(ip2), avg(ip), avg(distinct(ip)) from oceanbasetest;
+----------+---------+-------------------+
| avg(ip2) | avg(ip) | avg(distinct(ip)) |
+----------+---------+-------------------+
|     NULL |  3.3333 |            3.5000 |
+----------+---------+-------------------+
1 row in set (0.00 sec)

Oceanbase>select avg(distinct(ip)),avg(ip),avg(ip2) from oceanbasetest;
+-------------------+---------+----------+
| avg(distinct(ip)) | avg(ip) | avg(ip2) |
+-------------------+---------+----------+
|            3.5000 |  3.3333 |     NULL |
+-------------------+---------+----------+
1 row in set (0.00 sec)
```

COUNT

Declaration

```
COUNT([DISTINCT] expr)
```

Description

This function returns the number of non-NULL values in the rows retrieved by the SELECT statement. If no matched rows are found, COUNT() returns 0. The DISTINCT keyword is used to return the number of the distinct expr values.

COUNT(*) returns the number of retrieved rows, regardless of whether they contain NULL values.

Example

```
Oceanbase>select * from oceanbasetest;
+----+------+------+
| id | ip   | ip2  |
+----+------+------+
|  1 |    4 | NULL |
|  3 |    3 | NULL |
|  4 |    3 | NULL |
+----+------+------+
3 rows in set (0.00 sec)

Oceanbase>select count(ip2), count(ip), count(distinct(ip)), count(*) from oceanbasetest;
+------------+-----------+--------------------+----------+
| count(ip2) | count(ip) | count(distinct(ip)) | count(*) |
+------------+-----------+--------------------+----------+
|          0 |         3 |                  2 |        3 |
+------------+-----------+--------------------+----------+
1 row in set (0.00 sec)
```

MAX

Declaration

```
MAX([DISTINCT] expr)
```

Description

This function returns the maximum value of a specified data set.

You can specify strings in the MAX() function. In this case, the maximum string is returned. The DISTINCT keyword can be used to return the maximum value of the distinct expr values. MAX() returns the same maximum value regardless of whether you omit the DISTINCT keyword.

Assume that table a has three rows. For the id column, the values are 1, 2, and 3. For the num column, the values are 10, 20, and 30.

Example

```
Oceanbase>SELECT MAX(num) FROM a;
+-----------------+
| MAX(num)        |
+-----------------+
|              30 |
+-----------------+
1 row in set (0.00 sec)
```

MIN

Declaration

```
MIN([DISTINCT] expr)
```

Description

This function returns the minimum value of a specified data set.

You can specify strings in the MIN() function. In this case, the minimum string is returned. The DISTINCT keyword can be used to return the minimum value of the distinct expr values. MIN() returns the same minimum value regardless of whether you omit the DISTINCT keyword.

Assume that table a has three rows. For the id column, the values are 1, 2, and 3. For the num column, the values are 10, 20, and 30.

Example

```
Oceanbase>SELECT MIN(num) FROM a;
+-----------------+
| MIN(num)        |
+-----------------+
|              10 |
+-----------------+
1 row in set (0.00 sec)
```

SUM

Declaration

```
SUM([DISTINCT] expr)
```

Description

This function returns the sum value of the expr values. If no rows are found in expr, the SUM() function returns NULL. You can use the DISTINCT keyword to return the sum value of the distinct expr values.

If no matched rows are found, the SUM() function returns NULL.

Example

```
Oceanbase>select * from oceanbasetest;
+------+------+------+
| id   | ip   | ip2  |
+------+------+------+
|    1 |    4 | NULL |
|    3 |    3 | NULL |
|    4 |    3 | NULL |
+------+------+------+
3 rows in set (0.00 sec)

Oceanbase>select sum(ip2),sum(ip),sum(distinct(ip)) from oceanbasetest;
+----------+---------+-------------------+
| sum(ip2) | sum(ip) | sum(distinct(ip)) |
+----------+---------+-------------------+
|     NULL |      10 |                 7 |
+----------+---------+-------------------+
1 row in set (0.00 sec)
```

GROUP_CONCAT

Declaration

```
GROUP_CONCAT([DISTINCT] expr)
```

Description

This function concatenates non-NULL strings from a specified group into a single string.

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
    [ORDER BY {unsigned_integer | col_name | expr}
     ASC | DESC]
    [SEPARATOR str_val])
```

Example

```
Oceanbase> select * from book; //The table named book (book number, book title, publisher)
+--------+--------------------------------+-----------------------------+
| bookid | bookname                       | publishname                 |
+--------+--------------------------------+-----------------------------+
|      1 | git help                       | alibaba group publisher     |
|      2 | MySQL Optimization                  | Zhejiang University Press          |
|      3 | Java Programming Guide                   | Machinery Industry Press              |
|      3 | Java Programming Guide                      | Machinery Industry Press   |
|     4 | Large-Scale Distributed Storage System           | Machinery Industry Press              |
+--------+--------------------------------+-----------------------------+
5 rows in set (0.00 sec)

//Retrieve book titles.
Oceanbase>select group_concat(bookname) from book group by bookname;
+-----------------------------------+
| group_concat(bookname)            |
+-----------------------------------+
| git help                          |

|
| Large-Scale Distributed Storage System           | Machinery Industry Press
|
+--------------------------------+-------------------------------------------------------------------------
--+
4 rows in set (0.00 sec)
```

17.1.4.3.3. Analytic functions

Overview

Analytic functions, also called **window functions** in some database services, are similar to aggregate functions. The similarity lies in that the calculations are performed based on a set of rows. The difference is that an aggregate function returns only one row for each set of rows, but an analytic function returns one or more rows for each set of rows. Each of the rows returned by the analytic function is the result of window-based logic computing. Analytic functions can optimize queries that contain self joins in a significant way.

Features

ApsaraDB for OceanBase supports the following analytic functions:

- SUM
- MIN
- MAX
- COUNT
- AVG
- GROUP_CONCAT, a function that is specific to ApsaraDB for OceanBase
- ROW_NUMBER
- RANK
- DENSE_RANK
- PERCENT_RANK
- CUME_DIST
- FIRST_VALUE
- LAST_VALUE
- NTH_VALUE
- NTILE
- LEAD
- LAG
- RATIO_TO_REPORT
- STDDEV
- VARIANCE
- STDDEV_SAMP
- STDDEV_POP
- LISTAGG

ApsaraDB for OceanBase does not support the following window functions that are supported by Oracle:

- CORR
- COVAR_POP
- COVAR_SAMP
- MEDIAN
- PERCENTILE_CONT
- PERCENTILE_DISC

- VAR_POP
- VAR_SAMP
- REGR_(Linear Regression) Functions

Syntax of analytic functions

A window is also called a frame. ApsaraDB for OceanBase supports the ROWS and RANGE options for the FRAME clauses. The ROWS option defines frames based on the offsets that are the differences in physical row numbers from the current row number. The RANGE option defines frames based on the offsets that are the differences in logical row values from the current row value.

Syntax of analytic_function: analytic_function([arguments]) **OVER** (analytic_clause)

Syntax of analytic_clause: [query_partition_clause] [order_by_clause [windowing_clause]]

Syntax of query_partition_clause: **PARTITION BY** { expr[, expr]... | (expr[, expr]...) }

Syntax of order_by_clause: **ORDER** [**SIBLINGS**] **BY**{ expr | position | c_alias } [**ASC** | **DESC**] [**NULLS FIRST** | **NULLS LAST**] [, { expr | position | c_alias } [**ASC** | **DESC**][**NULLS FIRST** | **NULLS LAST**]]...

Syntax of windowing_clause

Syntax of windowing_clause:

{ **ROWS** | **RANGE** } { **BETWEEN** { **UNBOUNDED PRECEDING** | **CURRENT ROW** | value_expr { **PRECEDING** | **FOLLOWING** } } **AND**{ **UNBOUNDED FOLLOWING** | **CURRENT ROW** | value_expr { **PRECEDING** | **FOLLOWING** } } | { **UNBOUNDED PRECEDING** | **CURRENT ROW**| value_expr **PRECEDING**}}

The syntax of windowing_clause is compatible with that of Oracle.

Description

The following content describes the syntax and features of analytic functions, and also compares analytic functions used in ApsaraDB for OceanBase and Oracle.

sum/min/max/count/avg

Syntax of the AVG function: **AVG**([**DISTINCT** | **ALL**] expr) [**OVER**(analytic_clause)]

Syntax of the SUM function: **SUM**([**DISTINCT** | **ALL**] expr) [**OVER** (analytic_clause)]

Syntax of the MIN function: **MIN**([**DISTINCT** | **ALL**] expr) [**OVER** (analytic_clause)]

Syntax of the MAX function: **MAX**([**DISTINCT** | **ALL**] expr) [**OVER** (analytic_clause)]

Syntax of the COUNT function: **COUNT** ({ * | [**DISTINCT** | **ALL**] expr }) [**OVER** (analytic_clause)]

The preceding analytic functions have corresponding aggregate functions. The SUM function returns the sum of the expr values. The MIN function returns the minimum expr value. The MAX function returns the maximum expr value. The COUNT function returns the number of rows queried for a window. The AVG function returns the average expr value.

The COUNT function does not return null. If you specify expr, the function returns the number of non-null expr values. If you use an asterisk (*), the COUNT(*) function returns the number of all the rows.

```
create table exployees(last_name char(10), salary decimal, job_id char(32));
insert into exployees values('jim', 2000, 'cleaner');
insert into exployees values('mike', 12000, 'engineering');
insert into exployees values('lily', 13000, 'engineering');
insert into exployees values('tom', 11000, 'engineering');
OceanBase(TEST@TEST)>select last_name, sum(salary) over(partition by job_id) totol_s, min(salary) ove
r(partition by job_id) min_s, max(salary) over(partition by job_id) max_s, count(*) over(partition by
job_id) count_s from exployees;
+------------+---------+-------+-------+---------+
| LAST_NAME  | TOTOL_S | MIN_S | MAX_S | COUNT_S |
+------------+---------+-------+-------+---------+
| jim        |    2000 |  2000 |  2000 |       1 |
| mike       |   36000 | 11000 | 13000 |       3 |
| lily       |   36000 | 11000 | 13000 |       3 |
| tom        |   36000 | 11000 | 13000 |       3 |
+------------+---------+-------+-------+---------+
```

The syntax of the preceding five functions in ApsaraDB for OceanBase is not fully compatible with that in Oracle.

If you use the DISTINCT keyword in the SUM, COUNT, or AVG function, you can specify only query_partition_clause in analytic_clause. order_by_clause and windowing_clause are not allowed. **ApsaraDB for OceanBase does not support this option. If you use DISTINCT in ApsaraDB for OceanBase, you can also specify order_by_clause and windowing_clause.**

ApsaraDB for OceanBase does not support NULLS FIRST or NULLS LAST in order_by_clause.

For more information about the support for analytic_clause, see the "Syntax of windowing_clause" section.

nth_value/first_value/last_value

Syntax of the NTH_VALUE function: **NTH_VALUE** (measure_expr, n) [**FROM** { **FIRST** | **LAST** }][{ **RESPECT** | **IGNORE** } **NULLS**] **OVER** (analytic_clause)

The NTH_VALUE function, as its name suggests, returns the Nth value in the window defined by analytic_clause. [**FROM** { **FIRST** | **LAST** }] specifies whether to begin the calculation from the first or last row of the window. By default, FROM FIRST is used. [{RESPECT | IGNORE}] NULLS specifies whether to ignore null during the calculation. The N value must be a positive integer. If the N value is null, the function returns an error. If the N value is greater than the number of all the rows in the window, the function returns null.

Syntax of the FIRST_VALUE or LAST_VALUE function: **FIRST_VALUE** or LAST_VALUE { (expr) [{**RESPECT** | **IGNORE**} NULLS] | (expr [{**RESPECT** | **IGNORE**} NULLS])} **OVER** (analytic_clause)

The FIRST_VALUE function, as its name suggests, returns the first value in a set of values. The LAST_VALUE function returns the last value in a set of values.

```
create table exployees(last_name char(10), salary decimal, job_id char(32));
insert into exployees values('jim', 2000, 'cleaner');
insert into exployees values('mike', 12000, 'engineering');
insert into exployees values('lily', 13000, 'engineering');
insert into exployees values('tom', 11000, 'engineering');
OceanBase(TEST@TEST)>select last_name, first_value(salary) over(partition by job_id) totol_s, last_va
lue(salary) over(partition by job_id) min_s, max(salary) over(partition by job_id) max_s from exploye
es;
+------------+---------+-------+-------+
| LAST_NAME  | TOTOL_S | MIN_S | MAX_S |
+------------+---------+-------+-------+
| jim        |    2000 |  2000 |  2000 |
| mike       |   12000 | 11000 | 13000 |
| lily       |   12000 | 11000 | 13000 |
| tom        |   12000 | 11000 | 13000 |
+------------+---------+-------+-------+
```

The syntax of the preceding three functions is compatible with that of Oracle. No corresponding aggregate functions are available for the three functions.

lead/lag

The LAG or LEAD function allows you to query the value of the same field from a row that appears before or after the current row at the N offset. Self joins can also perform these operations. However, the LAG and LEAD analytic functions enable more efficient queries than self joins. The following syntax is used:

lag/lead { (value_expr [, offset [, default]]) [{ **RESPECT** | **IGNORE** } **NULLS**] | (value_expr [{ **RESPECT** | **IGNORE** } **NULLS**] [, offset [, default]])} **OVER** ([query_partition_clause] order_by_clause)

value_expr specifies the field whose values are to be compared, and offset specifies the offset from the current row that is defined by value_expr. The default value of the default parameter is null. This indicates that if you do not specify the default parameter for the LAG or LEAD function, a null value is returned. Assume that you specify parameters for the LAG function and the current row is the fourth row in the table. If you set the offset parameter to 6, the serial number of the row that you want to query is -2. This goes beyond the scope of the table. In this case, the function returns the default value.

[{ **RESPECT** | **IGNORE** } **NULLS**] specifies whether to ignore null during the calculation. The default value is **RESPECT**. This indicates that the null value is not ignored.

Take note of this point: The LEAD or LAG function must be followed by order_by_clause because this clause specifies the order in which the values in a column are sorted. The function can calculate the positions of the current row and the previous or subsequent rows only after the values are sorted. query_partition_clause is optional. If you do not specify this clause, the operation of the function applies to the global data.

```
create table exployees(last_name char(10), salary decimal, job_id char(32));
insert into exployees values('jim', 2000, 'cleaner');
insert into exployees values('mike', 12000, 'engineering');
insert into exployees values('lily', 13000, 'engineering');
insert into exployees values('tom', 11000, 'engineering');
OceanBase(TEST@TEST)>select last_name, lead(salary) over(order by salary) lead, lag(salary) over(orde
r by salary) lag from exployees;
+------------+-------+-------+
| LAST_NAME  | LEAD  | LAG   |
+------------+-------+-------+
| jim        | 11000 |  NULL |
| tom        | 12000 |  2000 |
| mike       | 13000 | 11000 |
| lily       |  NULL | 12000 |
+------------+-------+-------+
```

The LAG and LEAD functions in ApsaraDB for OceanBase are compatible with those in Oracle. Take note of the following point: In Oracle and ApsaraDB for OceanBase, you can specify whether to ignore null in the results returned by the LEAD or LAG function. No corresponding aggregate function is available for the LEAD or LAG function.

stddev/variance/stddev_samp/stddev_pop

Syntax of the VARIANCE function: **VARIANCE**([**DISTINCT** | **ALL**] expr) [**OVER** (analytic_clause)]. The VARIANCE function returns the variance of the expr value. You can set expr to a value of a numeric data type or non-numeric data type that can be converted to a numeric data type. The function returns the variance of the same data type as the argument.

Syntax of the STDDEV function: **STDDEV**([**DISTINCT** | **ALL**] expr) [**OVER** (analytic_clause)]. The STDDEV function returns the standard deviation of the expr value. The STDDEV and VARIANCE functions have the same syntax and parameter types.

Syntax of the STDDEV_SAMP function: **STDDEV_SAMP**(expr) [**OVER** (analytic_clause)]

Syntax of the STDDEV_POP function: **STDDEV_POP**(expr) [**OVER** (analytic_clause)]

```
create table exployees(last_name char(10), salary decimal, job_id char(32));
insert into exployees values('jim', 2000, 'cleaner');
insert into exployees values('mike', 12000, 'engineering');
insert into exployees values('lily', 13000, 'engineering');
insert into exployees values('tom', 11000, 'engineering');
OceanBase(TEST@TEST)>select last_name, stddev(salary) over(order by salary) std, variance(salary) ove
r(order by salary) var, stddev_pop(salary) over() std_pop, stddev_samp(salary) over() from exployees;
+------------+----------------------------------------+-----------------------------------------+-
----------------------------------------+-----------------------------------------+
| LAST_NAME  | STD                                    | VAR                                     |
STD_POP                                | STDDEV_SAMP(SALARY)OVER()               |
+------------+----------------------------------------+-----------------------------------------+-
----------------------------------------+-----------------------------------------+
| jim        |                                      0 |                                       0 |
4387.48219369606103020319415370815478043 8 | 5066.228051190221210556248068679881679227 |
| tom        | 6363.961030678927719607599258943641353564 |                                40500000 |
4387.48219369606103020319415370815478043 8 | 5066.228051190221210556248068679881679227 |
| mike       | 5507.570547286102020605808770872073470916 | 30333333.333333333333333333333333333333 |
4387.48219369606103020319415370815478043 8 | 5066.228051190221210556248068679881679227 |
| lily       | 5066.228051190221210556248068679881679227 | 25666666.666666666666666666666666666667 |
4387.48219369606103020319415370815478043 8 | 5066.228051190221210556248068679881679227 |
+------------+----------------------------------------+-----------------------------------------+-
----------------------------------------+-----------------------------------------+
```

The syntax of the preceding four functions in ApsaraDB for OceanBase is not fully compatible with that in Oracle.

If you use the DISTINCT keyword in the VARIANCE or STDDEV function, you can specify only query_partition_clause in analytic_clause. order_by_clause and windowing_clause are not allowed. **ApsaraDB for OceanBase does not support this option. If you use DISTINCT in ApsaraDB for OceanBase, you can also specify order_by_clause and windowing_clause.** For the STDDEV_POP and STDDEV_SAMP functions, you cannot use the DISTINCT or ALL keyword. **ApsaraDB for OceanBase does not support this option.**

ApsaraDB for OceanBase does not support NULLS FIRST or NULLS LAST in order_by_clause.

For more information about the support for analytic_clause, see the "Syntax of windowing_clause" section.

ntile

Syntax of the NTILE function: **NTILE**(expr) **OVER** ([query_partition_clause] order_by_clause). The NTILE function divides sorted partition rows into a specified number of groups, and the size of each group is the same if possible. The function assigns each row to a group by giving each row a group number. If the expr value is null, the function returns null.

```
create table exployees(last_name char(10), salary decimal, job_id char(32));
insert into exployees values('jim', 2000, 'cleaner');
insert into exployees values('mike', 12000, 'engineering');
insert into exployees values('lily', 13000, 'engineering');
insert into exployees values('tom', 11000, 'engineering');
OceanBase(TEST@TEST)>select last_name, ntile(10) over(partition by job_id order by salary) ntl from e
xployees;
+------------+------+
| LAST_NAME  | NTL  |
+------------+------+
| jim        |    1 |
| tom        |    1 |
| mike       |    2 |
| lily       |    3 |
+------------+------+
```

The syntax of the NTILE function in ApsaraDB for OceanBase is compatible with that in Oracle. Take note of this point: You must specify order_by_clause for the NTILE analytic function. No corresponding aggregate function is available for the NTILE function.

row_number

Syntax of the ROW_NUMBER function: **ROW_NUMBER( ) OVER** ([query_partition_clause] order_by_clause). query_partition_clause is optional. The ROW_NUMBER function can run as expected only after the values are sorted. This function assigns a unique serial number to each row after the rows are sorted by applying the ORDER BY clause on expr values.

```
create table exployees(last_name char(10), salary decimal, job_id char(32));
insert into exployees values('jim', 2000, 'cleaner');
insert into exployees values('mike', 12000, 'engineering');
insert into exployees values('lily', 13000, 'engineering');
insert into exployees values('tom', 11000, 'engineering');
OceanBase(TEST@TEST)>select last_name, row_number() over(partition by job_id order by salary) ntl fro
m exployees;
+------------+------+
| LAST_NAME  | NTL  |
+------------+------+
| jim        |    1 |
| tom        |    1 |
| mike       |    2 |
| lily       |    3 |
+------------+------+
```

The syntax of the ROW_NUMBER function in ApsaraDB for OceanBase is compatible with that in Oracle. Take note of this point: You must specify order_by_clause for the ROW_NUMBER analytic function. No corresponding aggregate function is available for the ROW_NUMBER function.

rank/dense_rank/percent_rank

Syntax of the RANK function: **RANK( ) OVER** ([query_partition_clause] order_by_clause). The RANK function is an analytic function and ranks all the rows for a given column that is specified by order_by_clause. In the following example, all the employees are ranked by salary:

Syntax of the DENSE_RANK function: **DENSE_RANK( ) OVER**([query_partition_clause] order_by_clause). The DENSE_RANK function acts like the RANK function except that DENSE_RANK assigns consecutive ranks.

Syntax of the PERCENT_RANK function: **PERCENT_RANK( ) OVER** ([query_partition_clause] order_by_clause). The PERCENT_RANK function acts like the RANK function except that PERCENT_RANK calculates the rank of a given row as a percentage.

```
create table exployees(last_name char(10), salary decimal, job_id char(32));
insert into exployees values('jim', 2000, 'cleaner');
insert into exployees values('mike', 12000, 'engineering');
insert into exployees values('lily', 13000, 'engineering');
insert into exployees values('tom', 11000, 'engineering');
OceanBase(TEST@TEST)>select last_name, rank() over(partition by job_id order by salary) rank, dense_r
ank() over(partition by job_id order by salary) dense_rank, percent_rank() over(partition by job_id o
rder by salary) percent_rank from exployees;
+------------+------+------------+--------------+
| LAST_NAME  | RANK | DENSE_RANK | PERCENT_RANK |
+------------+------+------------+--------------+
| jim        |    1 |          1 |            0 |
| tom        |    1 |          1 |            0 |
| mike       |    2 |          2 |           .5 |
| lily       |    3 |          3 |            1 |
+------------+------+------------+--------------+
```

In the preceding three functions, the syntax of the RANK function in ApsaraDB for OceanBase is compatible with that in Oracle. Take note of this point: You must specify order_by_clause for the RANK function. Take note of this point: The syntax of the RANK aggregate function differs from that of the RANK analytic function. For more information, see the syntax of the RANK function in the "Aggregate functions" section. The syntax of the DENSE_RANK function in ApsaraDB for OceanBase is compatible with that in Oracle. Take note of this point: You must specify order_by_clause for the DENSE_RANK function. Take note of this point: The syntax of the DENSE_RANK aggregate function differs from that of the DENSE_RANK analytic function. For more information, see the syntax of the DENSE_RANK function in the "Aggregate functions" section. The syntax of the PERCENT_RANK function in ApsaraDB for OceanBase is compatible with that in Oracle. Take note of this point: You must specify order_by_clause for the PERCENT_RANK function. Take note of this point: The syntax of the PERCENT_RANK aggregate function differs from that of the PERCENT_RANK analytic function. For more information, see the syntax of the PERCENT_RANK function in the "Aggregate functions" section.

cume_dist

Syntax of the CUME_DIST function: **CUME_DIST** () **OVER** ([query_partition_clause] order_by_clause). The CUME_DIST function calculates the cumulative distribution of a value. CUME_DIST returns a value that is greater than 0 and less than or equal to 1. Assume that the values in a specified column are sorted in ascending order. The CUME_DIST analytic function calculates the percentage of each value that is less than or equal to the current value for the specified column. The following example groups the employees by job_id and ranks the salary percentile of each employee in a specified window.

```
create table exployees(last_name char(10), salary decimal, job_id char(32));
insert into exployees values('jim', 2000, 'cleaner');
insert into exployees values('mike', 12000, 'engineering');
insert into exployees values('lily', 13000, 'engineering');
insert into exployees values('tom', 11000, 'engineering');
OceanBase(TEST@TEST)>select last_name, cume_dist() over(partition by job_id order by salary) rank fro
m exployees;
+------------+-----------------------------------------+
| LAST_NAME  | RANK                                    |
+------------+-----------------------------------------+
| jim        |                                       1 |
| tom        | .33333333333333333333333333333333333333 |
| mike       | .66666666666666666666666666666666666667 |
| lily       |                                       1 |
+------------+-----------------------------------------+
```

The syntax of the CUME_DIST function in ApsaraDB for OceanBase is compatible with that in Oracle. Take note of this point: The syntax of the CUME_DIST function includes query_partition_clause and order_by_clause. Take note of this point: The syntax of the CUME_DIST aggregate function differs from that of the CUME_DIST analytic function. For more information, see the syntax of the CUME_DIST function in the "Aggregate functions" section.

ratio_to_report

Syntax of the RATIO_TO_REPORT function: **RATIO_TO_REPORT** (expr) **OVER** ([query_partition_clause]). The RATIO_TO_REPORT function calculates the expr value and the ratio of the value to the sum of a set of values. If the expr value is null, the RATIO_TO_REPORT function returns null.

The sum of a set of values is determined by query_partition_clause. If you omit this clause, RATIO_TO_REPORT calculates the ratio of a value to the sum of all the expr values. You cannot use RATIO_TO_REPORT or other analytic functions in expr. However, you can use built-in functions in expr. This is similar to the expr values in aggregate functions. The following example is used to describe how to use RATIO_TO_REPORT to calculate the ratio of each employee's salary to the total salary of all the employees in the company:

```
create table exployees(last_name char(10), salary decimal, job_id char(32));
insert into exployees values('jim', 2000, 'cleaner');
insert into exployees values('mike', 12000, 'engineering');
insert into exployees values('lily', 13000, 'engineering');
insert into exployees values('tom', 11000, 'engineering');
OceanBase(TEST@TEST)>select last_name, salary, ratio_to_report(salary) over() as salary_ratio from ex
ployees where job_id = 'engineering';
+------------+--------+-----------------------------------------+
| LAST_NAME  | SALARY | SALARY_RATIO                            |
+------------+--------+-----------------------------------------+
| mike       |  12000 | .33333333333333333333333333333333333333 |
| lily       |  13000 | .36111111111111111111111111111111111111 |
| tom        |  11000 | .30555555555555555555555555555555555556 |
+------------+--------+-----------------------------------------+
```

The syntax of the RATIO_TO_REPORT function in ApsaraDB for OceanBase is compatible with that in Oracle. Take note of this point: You cannot specify order_by_clause for the RATIO_TO_REPORT analytic function.

Execution plans

The WINDOW FUNCTION operator is used to implement analytic functions in ApsaraDB for OceanBase. WINDOW FUNCTION works based on the partitioned and sorted output of the lower-level operator. Therefore, the system assigns a SORT operator if the SORT operator is required.

Example

```
mysql> explain select row_number() over (partition by table_id order by partition_id) from __all_root
_table;
+-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-----------------------------------+
| Query Plan
|
+-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-------------------------------------------------------------------------------------------------------
-----------------------------------+
| ==================================================
|ID|OPERATOR       |NAME            |EST. ROWS|COST|
--------------------------------------------------
|0 |WINDOW FUNCTION|                |1000     |2240|
|1 | SORT          |                |1000     |2049|
|2 |  TABLE SCAN   |__all_root_table|1000     |499 |
==================================================

Outputs & filters:
-------------------------------------
  0 - output([T_WIN_FUN_ROW_NUMBER()]), filter(nil),
      win_expr(T_WIN_FUN_ROW_NUMBER()), partition_by([__all_root_table.table_id]), order_by([__all_ro
ot_table.partition_id, ASC]), window_type(RANGE), upper(UNBOUNDED PRECEDING), lower(UNBOUNDED FOLLOWI
NG)
  1 - output([__all_root_table.table_id], [__all_root_table.partition_id]), filter(nil), sort_keys([_
_all_root_table.table_id, ASC], [__all_root_table.partition_id, ASC])
  2 - output([__all_root_table.table_id], [__all_root_table.partition_id]), filter(nil),
      access([__all_root_table.table_id], [__all_root_table.partition_id]), partitions(p0)
```

Remove a SORT operator

If the optimizer recognizes that the output of the lower-level operator is sorted, the optimizer does not assign a SORT operator. In this case, (tenant_id, table_id) is the prefix of the primary key in the __all_root_table table.

```
explain select row_number() over (partition by tenant_id, table_id order by partition_id) from __all_
root_table;
+-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
--+
| Query Plan
|
+-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------------
--+
| ==================================================
|ID|OPERATOR       |NAME            |EST. ROWS|COST|
--------------------------------------------------
|0 |WINDOW FUNCTION|                |1000     |690 |
|1 | TABLE SCAN    |__all_root_table|1000     |499 |
==================================================

Outputs & filters:
-------------------------------------
  0 - output([T_WIN_FUN_ROW_NUMBER()]), filter(nil),
      win_expr(T_WIN_FUN_ROW_NUMBER()), partition_by([__all_root_table.tenant_id], [__all_root_table.
table_id]), order_by([__all_root_table.partition_id, ASC]), window_type(RANGE), upper(UNBOUNDED PRECE
DING), lower(UNBOUNDED FOLLOWING)
  1 - output([__all_root_table.tenant_id], [__all_root_table.table_id], [__all_root_table.partition_i
d]), filter(nil),
      access([__all_root_table.tenant_id], [__all_root_table.table_id], [__all_root_table.partition_i
d]), partitions(p0)
 |
```

Combine calculations

When multiple analytic functions use the same sorted subset for calculation, all the functions use the same operator instead of multiple independent operators. This reduces memory overhead and range checks in an effective way.

In the following example, the calculation of the two analytic functions ROW_NUMBER() and RANK() can use the same sorted output. Therefore, only one SORT operator is assigned.

```
mysql> explain select row_number() over (partition by table_id order by partition_id), rank() over (p
artition by table_id, partition_id order by svr_ip) from __all_root_table;
| ====================================================
|ID|OPERATOR       |NAME            |EST. ROWS|COST|
----------------------------------------------------
|0 |WINDOW FUNCTION|                |1000     |3017|
|1 | SORT          |                |1000     |2826|
|2 |  TABLE SCAN   |__all_root_table|1000     |499 |
====================================================

Outputs & filters:
-------------------------------------
  0 - output([T_WIN_FUN_ROW_NUMBER()], [T_WIN_FUN_RANK()]), filter(nil),
      win_expr(T_WIN_FUN_RANK()), partition_by([__all_root_table.table_id], [__all_root_table.partiti
on_id]), order_by([__all_root_table.svr_ip, ASC]), window_type(RANGE), uppe                   r(UNBOU
NDED PRECEDING), lower(UNBOUNDED FOLLOWING)
      win_expr(T_WIN_FUN_ROW_NUMBER()), partition_by([__all_root_table.table_id]), order_by([__all_ro
ot_table.partition_id, ASC]), window_type(RANGE), upper(UNBOUNDED PRECEDING                   ), lowe
r(UNBOUNDED FOLLOWING)
  1 - output([__all_root_table.table_id], [__all_root_table.partition_id], [__all_root_table.svr_ip])
, filter(nil), sort_keys([__all_root_table.table_id, ASC], [__all_root_tabl                   e.parti
tion_id, ASC], [__all_root_table.svr_ip, ASC])
  2 - output([__all_root_table.table_id], [__all_root_table.partition_id], [__all_root_table.svr_ip])
, filter(nil),
      access([__all_root_table.table_id], [__all_root_table.partition_id], [__all_root_table.svr_ip])
, partitions(p0)
```

Store data on disks

Analytic functions also support storing intermediate data on disks during execution. This implements the same logic as the SORT operator.

17.1.4.3.4. Information functions

FOUND_ROWS

Declaration

```
found_rows()
```

Description

You may use a LIMIT clause in a SELECT statement to limit the number of rows that are returned from the database server to the client. In some cases, you need to retrieve the actual number of rows that the statement returns if the statement does not have the LIMIT clause. If you do not want to execute the statement again, you can use SQL_CALC_FOUND_ROWS in the SELECT statement. In this case, you can invoke the FOUND_ROW() function to retrieve the actual number of rows that are returned by the SELECT statement that does not have the LIMIT clause.

Example

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name
    -> WHERE id > 100 LIMIT 10;
mysql> SELECT FOUND_ROWS();
```

The second SELECT statement returns a number that indicates how many rows are returned by the first SELECT statement if the first statement does not have the LIMIT clause. If the preceding SELECT statements do not use the SQL_CALC_FOUND_ROWS option, the results of FOUND_ROWS() may differ based on whether the LIMIT clause is used.

For the SELECT SQL_CALC_FOUND_ROWS statement in the preceding example, the returned value of the FOUND_ROWS() function is valid only for a short period. The returned value becomes invalid when the statement that follows the SELECT SQL_CALC_FOUND_ROWS statement is executed. If you need to use the returned number of rows later, you must save the number.

Example

```
mysql> SELECT SQL_CALC_FOUND_ROWS * FROM ... ;
mysql> SET @rows = FOUND_ROWS();
```

If you use SQL_CALC_FOUND_ROWS in a query, the system calculates the number of rows in the full result set. This process requires less time than the process of running another query that does not use the LIMIT clause. This is because the result set in the former process does not need to be sent to the client.

Assume that you want to limit the number of rows that a query returns and do not want to run another query to retrieve the number of rows in the full result set. In this case, you can use SQL_CALC_FOUND_ROWS and FOUND_ROWS(). **For example**, you can use a web script for a paged display. The displayed information contains the links to pages for the other parts of the query results. You can use the FOUND_ROWS() function to determine the number of additional pages that are required to show the remaining results.

The implementation of SQL_CALC_FOUND_ROWS and FOUND_ROWS() in UNION queries is more complex than that in simple SELECT statements. This is because a UNION query may contain one or more LIMIT clauses. For example, you may use the LIMIT clauses in the SELECT statements of a UNION query, or use the clauses to limit the UNION results.

If SQL_CALC_FOUND_ROWS is used in a UNION query, the expected return result is the row count that is not limited by the global LIMIT clause. If you need to use SQL_CALC_FOUND_ROWS in a UNION query, ensure that the following requirements are met:

- The SQL_CALC_FOUND_ROWS keyword must appear in the first SELECT statement of the UNION query.
- The value of FOUND_ROWS() is exact only if UNION ALL is used. If UNION without ALL is used, duplicate removal occurs and the value of FOUND_ROWS() is only approximate.
- If the UNION query does not contain the LIMIT clauses, SQL_CALC_FOUND_ROWS is ignored. In this case, the query returns the number of rows in the temporary table that is created to process the UNION query.

LAST_INSERT_ID()

Declaration

```
last_insert_id()
```

Description

This function returns the auto-increment field value that is latest inserted in the current session. If you insert multiple rows into the table in the latest operation, the LAST_INSERT_ID() function returns the auto-increment field value of the first row.

Example

```
mysql>select LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                5 |
+------------------+
1 row in set (0.00 sec)
```

17.1.4.3.5. Other functions

COALESCE

Declaration

```
COALESCE(expr, expr, expr,...)
```

Description

This function evaluates expression values in sequence until the function finds a non-NULL value. Then, the function returns the non-NULL value. If the values of all the expressions are NULL, the function returns a NULL value.

All expressions must be in the same data type. If the data types of expressions are different, the system converts the data types into the same type in an implicit way.

Example

```
Oceanbase>SELECT COALESCE(NULL,NULL,3,4,5), COALESCE(NULL,NULL,NULL);
+---------------------------+--------------------------+
| COALESCE(NULL,NULL,3,4,5) | COALESCE(NULL,NULL,NULL) |
+---------------------------+--------------------------+
|                         3 |                     NULL |
+---------------------------+--------------------------+
1 row in set (0.00 sec)
```

NVL

Declaration

```
NVL(str1,replace_with)
```

Description

This function returns the replace_with value if the str1 value is NULL.

If you set str1 to NULL, the function returns a value that you set for the replace_with parameter. This helps you retrieve complete outputs. In most cases, the str1 value is a column name. No limits are placed on the values of replace_with. For example, you can specify hard-coded values, references to other columns, or expressions for the replace_with parameter.

Example

```
Oceanbase>SELECT NVL(NULL, 0), NVL(NULL, 'a');
+--------------+----------------+
| NVL(NULL, 0) | NVL(NULL, 'a') |
+--------------+----------------+
|            0 | a              |
+--------------+----------------+
1 row in set (0.00 sec)
```

SLEEP

Declaration

```
SLEEP(duration)
```

Description

This function suspends an SQL query for a specified duration that is measured in seconds. The function returns 0 after the suspension ends.

If only the SLEEP function is run in a query that is not interrupted, the function returns 0.

If only the SLEEP function is run in a query that is interrupted, the function returns 1 and does not return an error code.

If the SLEEP function is part of a query and the query is interrupted during the suspension, the function returns error code 1317.

Example

```
mysql> SELECT SLEEP(1000);
+------------------+
| SLEEP(1000) |
+------------------+
|          0 |
+------------------+

mysql> SELECT SLEEP(1000);
+------------------+
| SLEEP(1000) |
+------------------+
|          1 |
+------------------+

mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
ERROR 1317 (70100): Query execution was interrupted
```

Full-text search functions

Declaration

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
search_modifier:
{
    IN NATURAL LANGUAGE MODE
    | IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION
    | IN BOOLEAN MODE
    | WITH QUERY EXPANSION
}
```

Description

ApsaraDB for OceanBase V1.0 supports full-text search functions. You can use such functions to query full-text indexes. Before you use full-text search functions, ensure the following requirements are met.

- Full-text indexes are created on the columns that are specified in the MATCH(col1,col2,...) function. ApsaraDB for OceanBase supports only FULLTEXT CTXCAT indexes.
- The MATCH(col1,col2,...) function must include the columns that are specified for the FULLTEXT CTXCAT indexes. For example, you can create the FULLTEXT INDEX(c1,c2,c3) CTXCAT(c2,c3) index. In this scenario, the retrieved data can be matched only if the function is MATCH(c2,c3).
- You can specify the search mode for the full-text search function by using the search_modifier parameter. ApsaraDB for OceanBase supports only two modes: NATURAL LANGUAGE MODE and BOOLEAN MODE. The default mode is NATURAL LANGUAGE MODE.

By default or when you use IN NATURAL LANGUAGE MODE, the MATCH...AGAINST statement uses NATURAL LANGUAGE MODE for full-text searches. In NATURAL LANGUAGE MODE, the AGAINST clause accepts a search string and searches in the index by comparing character sets. For each row in the table, the MATCH function returns the correlation between the string and the row data. The correlation represents the similarity between the string and the text in the data table. By default, string columns created in ApsaraDB for OceanBase are case-insensitive. Therefore, keywords for full-text searches are case-insensitive. If you need to run case-sensitive full-text searches, you can specify case-sensitive data types for the columns on which full-text indexes are created. For example, you can specify the data type of the columns as UTF8MB4_BIN. If the MATCH...AGAINST function is used in the WHERE clause, MATCH is used to filter data that is irrelevant to the keywords in the function. ApsaraDB for OceanBase supports only MATCH...AGAINST=0 and MATCH...AGAINST>0. MATCH...AGAINST=0 indicates that no data matches the keywords and MATCH...AGAINST>0 indicates that at least one keyword is matched. The AGAINST parameter can accept multiple keywords. The keywords are separated with spaces, which indicates the logical OR relationship. If one of the keywords matches the text, this is considered as a match.

ApsaraDB for OceanBase can run full-text searches in BOOLEAN mode by using the IN BOOLEAN MODE keyword. In this mode, some special operators in front of the keywords have special semantic meanings. Examples

```
SELECT * FROM t1 WHERE MATCH (a, b) AGAINST ('Chrysanthemum Jasmine' IN BOOLEAN MODE);
+----+------------+------------+
| id | a            | b            |
+----+------------+------------+
| 1 | Alipay        | Chrysanthemum tea        |
| 2 | Taobao          | Jasmine        |
+----+------------+------------+

SELECT * FROM t1 WHERE MATCH (a, b)
    AGAINST ('+Chrysanthemum -Jasmine' IN BOOLEAN MODE);
+----+------------+------------+
| id | a            | b            |
+----+------------+------------+
| 1 | Alipay        | Chrysanthemum tea        |
+----+------------+------------+
```

The BOOLEAN full-text search in ApsaraDB for OceanBase supports the following operators: Plus signs (+) represent logical AND relationships. The search result must also include the keywords that are preceded by a plus sign (+). Hyphens (-) represent logical NOT relationships. The search result cannot include the keywords that are preceded by a hyphen (-).

```
If no operator is specified, the logical OR relationship is applied to the specified keywords. This i
ndicates that the search result includes at least one of the specified keywords that are not preceded
by an operator.
```

In BOOLEAN mode, take note of this point: All operators must be placed in front of the keywords, and operators behind the keywords are ignored. For example, the plus sign (+) in "+Chrysanthemum" has a semantic meaning, but is ignored in "Chrysanthemum+". Operators and keywords must be connected in a close way and cannot be separated by other characters. Otherwise, the operators are ignored. For example, the plus sign (+) in "+ Chrysanthemum" is ignored.

17.1.4.4. Queries and subqueries

17.1.4.4.1. Overview

An SQL query refers to the method used to obtain data from a database. An SQL query can be used in conjunction with conditional clauses such as WHERE and ordering clauses such as ORDER BY to obtain query results. A subquery is a query that is nested within an external query. The external query is also called the parent query or the outer query. The result of a subquery is passed back as input to the parent query or outer query. The parent query uses this value in the computation to determine the final output. SQL allows multiple levels of nested queries. This means one subquery can also have other subqueries nested. At the same time, subqueries can appear in various clauses in SQL statements, such as SELECT, FROM, and WHERE statements.

Subqueries

In databases, subqueries can be divided into dependent subqueries and independent subqueries. A dependent subquery is a subquery whose execution depends on the variables of an external query. In most case, such subqueries are calculated multiple times. An independent subquery is a subquery whose execution does not depend on the variables of an external query. Such subqueries are calculated only once. The following figure shows an independent subquery and a dependent subquery.

```
OceanBase (root@test)> create table t1(a int primary key, b int, c int);
Query OK, 0 rows affected (0.70 sec)
OceanBase (root@test)> create table t2(a int primary key, b int, c int);
Query OK, 0 rows affected (0.92 sec)
-- An independent subquery
OceanBase (root@test)> select * from t1 where t1.a in (select t2.a from t2);
Empty set (0.22 sec)
-- A dependent subquery. The outer query variable t1.b is used in the subquery.
OceanBase (root@test)> select * from t1 where t1.a in (select t2.a from t2 where t2.b = t1.b);
Empty set (0.05 sec)
```

Subquery unnesting

Subquery unnesting is a strategy to optimize databases. This strategy merges the subquery into the body of the outer query by converting some subqueries into equivalent multi-table JOIN operations. One of the benefits of this strategy is that the optimizer can select appropriate access paths, join methods, and join orders so that the query hierarchy is reduced as much as possible. The following figure shows an example of subquery unnesting, where the subquery is rewritten into a JOIN statement.

```
OceanBase (root@test)> create table t1(a int primary key, b int, c int);
Query OK, 0 rows affected (0.70 sec)
OceanBase (root@test)> create table t2(a int primary key, b int, c int);
Query OK, 0 rows affected (0.92 sec)
--- Dependent subqueries are unnested and rewritten into JOIN statements.
OceanBase (root@test)> explain select * from t1 where t1.a in (select t2.b from t2 where t2.c = t1.c)
;
| ======================================
|ID|OPERATOR      |NAME|EST. ROWS|COST|
--------------------------------------
|0 |HASH SEMI JOIN|    |1        |2924|
|1 | TABLE SCAN   |t1  |1000     |455 |
|2 | TABLE SCAN   |t2  |1000     |455 |
======================================

Outputs & filters:
-------------------------------------
  0 - output([t1.a], [t1.b], [t1.c]), filter(nil),
      equal_conds([t1.a = t2.b], [t2.c = t1.c]), other_conds(nil)
  1 - output([t1.c], [t1.a], [t1.b]), filter(nil),
      access([t1.c], [t1.a], [t1.b]), partitions(p0)
  2 - output([t2.c], [t2.b]), filter(nil),
      access([t2.c], [t2.b]), partitions(p0)
```

17.1.4.4.2. JOIN operations

The JOIN statement is used to combine two or more tables based on the JOIN conditions. The sets that are created by executing JOIN statements can be saved or used as tables. The JOIN statement is used to combine the properties of two tables based on the values in the tables. The JOIN types in a database include inner join, outer join, semi join, and anti join. Semi join and anti join are obtained by rewriting subqueries. SQL itself does not support the anti join or semi join expression.

JOIN conditions

JOIN conditions can be divided into equi join and non-equi join. Examples of equi join and non-equi join: t1.a = t2.b and t1.a < t2.b. Compared with non-equi join, one of the benefits of equi join is that it allows you to use efficient JOIN algorithms such as hash join and merge-sort join.

Self-join

Self join indicates that a table is joined with itself. The following figure shows an example of a self join.

```
OceanBase (root@test)> create table t1(a int primary key, b int, c int);
Query OK, 0 rows affected (0.70 sec)
--- Example of a self join
OceanBase (root@test)> select * from t1 as ta, t1 as tb where ta.b = tb.b
```

Inner join

Inner join is one of the most basic JOIN operations in a database. Inner join creates a new table that combines the columns of two tables (such as Table A and Table B) based on the JOIN conditions. A query compares each row in Table A with each row in Table B and finds combinations that satisfy the JOIN conditions. If a row in Table A and a row in Table B satisfy the JOIN conditions, the two rows are merged into one row in the new table. The result set of the JOIN operation is the outcome of first obtaining the Cartesian product of two tables and then returning all rows that match the JOIN conditions. A Cartesian product is also known as a cross join, which returns a result table where each row from Table A is combined with each row from Table B.

Outer join

Outer join does not require each record of the two joined tables to find a matching record in the other table. If all the records in a table, including non-matching records, are retained in the joined tables, this table is called a preserved table. Outer join can be divided into left outer join, right outer join, and full outer join based on whether to retain rows from the left, right, or both tables. If a row in the left table is not found in the right table, left outer join automatically returns NULL in the right table. If a row in the right table is not found in the left table, right outer join automatically returns NULL in the left table. If rows in the left and right tables do not match, full outer join automatically returns NULL in the tables.

Semi join

When Table A and Table B are left semi-joined, the operation only returns all rows in Table A that can be found in Table B. Right semi join only returns all rows in Table B that can be found in Table A. Semi join can only be obtained by subquery unnesting, as shown in the following figure.

```
OceanBase (root@test)> create table t1(a int primary key, b int, c int);
Query OK, 0 rows affected (0.70 sec)
OceanBase (root@test)> create table t2(a int primary key, b int, c int);
Query OK, 0 rows affected (0.92 sec)
--- A dependent subquery is unnested and rewritten as a semi join.
OceanBase (root@test)> explain select * from t1 where t1.a in (select t2.b from t2 where t2.c = t1.c)
;
| ======================================
|ID|OPERATOR      |NAME|EST. ROWS|COST|
--------------------------------------
|0 |HASH SEMI JOIN|    |1        |2924|
|1 | TABLE SCAN   |t1  |1000     |455 |
|2 | TABLE SCAN   |t2  |1000     |455 |
======================================

Outputs & filters:
-------------------------------------
  0 - output([t1.a], [t1.b], [t1.c]), filter(nil),
      equal_conds([t1.a = t2.b], [t2.c = t1.c]), other_conds(nil)
  1 - output([t1.c], [t1.a], [t1.b]), filter(nil),
      access([t1.c], [t1.a], [t1.b]), partitions(p0)
  2 - output([t2.c], [t2.b]), filter(nil),
      access([t2.c], [t2.b]), partitions(p0)
```

Anti join

When Table A and Table B are left anti-joined, the operation only returns all rows in Table A that cannot be found in Table B. Right anti join only returns all rows in Table B that cannot be found in Table A. Similar to semi join, anti join can be obtained only by subquery unnesting, as shown in the following figure.

```
OceanBase (root@test)> create table t1(a int primary key, b int, c int);
Query OK, 0 rows affected (0.70 sec)
OceanBase (root@test)> create table t2(a int primary key, b int, c int);
Query OK, 0 rows affected (0.92 sec)
--- A dependent subquery is rewritten as an anti join.
OceanBase (root@test)> explain select * from t1 where t1.a not in (select t2.b from t2 where t2.c = t
1.c);
| ======================================
|ID|OPERATOR      |NAME|EST. ROWS|COST|
--------------------------------------
|0 |HASH ANTI JOIN|    |995      |3262|
|1 | TABLE SCAN   |t1  |1000     |455 |
|2 | TABLE SCAN   |t2  |1000     |455 |
======================================

Outputs & filters:
-------------------------------------
  0 - output([t1.a], [t1.b], [t1.c]), filter(nil),
      equal_conds([t2.c = t1.c]), other_conds([t1.a = t2.b OR (T_OP_IS, t2.b, NULL, 0)])
  1 - output([t1.c], [t1.a], [t1.b]), filter(nil),
      access([t1.c], [t1.a], [t1.b]), partitions(p0)
  2 - output([t2.c], [t2.b]), filter(nil),
      access([t2.c], [t2.b]), partitions(p0)
```

17.1.4.4.3. Sets

The set operations on a database can combine the results of multiple queries into a result set. The following list describes the set operations:

- UNION
- INTERSECT
- In ApsaraDB for OceanBase, EXCEPT and MINUS are supported and have the same semantics. The queries of a set operation must result in the same number of columns and compatible data types. For UNION, the available UNION attributes are ALL and DISTINCT or UNIQUE. ALL indicates that duplicated rows are allowed in the set. DISTINCT or UNIQUE indicates that duplicated rows are not allowed in the set. For other set operations, you can use the DISTINCT keyword only, and cannot use the ALL keyword. By default, DISTINCT is used for all set operations. ApsaraDB for OceanBase supports the ORDER BY and LIMIT clauses for set operations. Other clauses are not allowed, as shown in the following figure.

```
OceanBase (root@test)> create table t1(a int primary key, b int, c int);
Query OK, 0 rows affected (0.16 sec)
OceanBase (root@test)> create table t2(a int primary key, b int, c int);
Query OK, 0 rows affected (0.10 sec)
--The ORDER BY and LIMIT clauses are supported in the UNION statement.
OceanBase (root@test)> (select * from t1 union all select * from t2) order by a limit 10;
Empty set (0.02 sec)
--Other clauses such as GROUP BY are not supported in the UNION statement, except the ORDER BY and LI
MIT clauses.
OceanBase (root@test)> OceanBase (root@test)> (select * from t1 union all select * from t2) group by
a limit 10;
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to your O
ceanBase version for the right syntax to use near 'OceanBase (root@test)> (select * from t1 union all
select * from t2) group by a ' at line 1
```

Example of the UNION statement

This example returns all the unique rows in t1 and t2.

```
OceanBase (root@test)> create table t1(a int, b int, c int);
Query OK, 0 rows affected (0.12 sec)
OceanBase (root@test)> create table t2(a int, b int, c int);
Query OK, 0 rows affected (0.11 sec)
OceanBase (root@test)> insert into t1 values (1,1,1),(2,2,2),(3,3,3);
Query OK, 3 rows affected (0.07 sec)
Records: 3  Duplicates: 0  Warnings: 0
OceanBase (root@test)> insert into t2 values (2,2,2),(3,3,3),(4,4,4);
Query OK, 3 rows affected (0.02 sec)
Records: 3  Duplicates: 0  Warnings: 0
OceanBase (root@test)> select * from t1 union select * from t2;
+------+------+------+
| a    | b    | c    |
+------+------+------+
|    1 |    1 |    1 |
|    2 |    2 |    2 |
|    3 |    3 |    3 |
|    4 |    4 |    4 |
+------+------+------+
4 rows in set (0.01 sec)
```

Example of the UNION ALL statement

This example returns all rows in t1 and t2 including duplicate rows.

```
OceanBase (root@test)> create table t1(a int, b int, c int);
Query OK, 0 rows affected (0.12 sec)
OceanBase (root@test)> create table t2(a int, b int, c int);
Query OK, 0 rows affected (0.11 sec)
OceanBase (root@test)> insert into t1 values (1,1,1),(2,2,2),(3,3,3);
Query OK, 3 rows affected (0.07 sec)
Records: 3  Duplicates: 0  Warnings: 0
OceanBase (root@test)> insert into t1 values (2,2,2),(3,3,3),(4,4,4);
Query OK, 3 rows affected (0.02 sec)
Records: 3  Duplicates: 0  Warnings: 0
OceanBase (root@test)> select * from t1 union all select * from t2;
+------+------+------+
| a    | b    | c    |
+------+------+------+
|    1 |    1 |    1 |
|    2 |    2 |    2 |
|    3 |    3 |    3 |
|    2 |    2 |    2 |
|    3 |    3 |    3 |
|    4 |    4 |    4 |
+------+------+------+
6 rows in set (0.02 sec)
```

Example of the INTERSECT statement

This example returns rows that appear in both t1 and t2 without duplicate rows.

```
OceanBase (root@test)> create table t1(a int, b int, c int);
Query OK, 0 rows affected (0.12 sec)
OceanBase (root@test)> create table t2(a int, b int, c int);
Query OK, 0 rows affected (0.12 sec)
OceanBase (root@test)> insert into t1 values (1,1,1),(2,2,2),(3,3,3);
Query OK, 3 rows affected (0.02 sec)
Records: 3  Duplicates: 0  Warnings: 0
OceanBase (root@test)> insert into t2 values (2,2,2),(3,3,3),(3,3,3),(4,4,4);
Query OK, 4 rows affected (0.01 sec)
Records: 4  Duplicates: 0  Warnings: 0
OceanBase (root@test)> select * from t1 intersect select * from t2;
+------+------+------+
| a    | b    | c    |
+------+------+------+
|    2 |    2 |    2 |
|    3 |    3 |    3 |
+------+------+------+
2 rows in set (0.01 sec)
```

Example of the EXCEPT or MINUS statement

This example returns rows that appear in t1 but do not appear in t2 without duplicate rows.

```
OceanBase (root@test)> create table t1(a int, b int, c int);
Query OK, 0 rows affected (0.12 sec)
OceanBase (root@test)> create table t2(a int, b int, c int);
Query OK, 0 rows affected (0.12 sec)
OceanBase (root@test)> insert into t1 values (1,1,1),(2,2,2),(3,3,3);
Query OK, 3 rows affected (0.02 sec)
Records: 3  Duplicates: 0  Warnings: 0
OceanBase (root@test)> insert into t2 values (2,2,2),(3,3,3),(3,3,3),(4,4,4);
Query OK, 4 rows affected (0.01 sec)
Records: 4  Duplicates: 0  Warnings: 0
OceanBase (root@test)> select * from t1 except select * from t2;
+------+------+------+
| a    | b    | c    |
+------+------+------+
|    1 |    1 |    1 |
+------+------+------+
1 row in set (0.02 sec)
```

17.1.4.5. SQL statements

17.1.4.5.1. General syntax

Constants

- `INT_VALUE` : integer constants. For example, `123` .
- `DECIMAL_VALUE` : fixed-point constants. For example, `123.456` .
- `STR_VALUE` : string constants. For example, `abc` .
- `NULL` : a NULL constant.
- `STORAGE_SIZE` : storage size constants. The default unit is bytes for integer constants. M and G are units for string constants. For example, `1024` or `500M` .

```
const_value:
      INT_VALUE
    | DECIMAL_VALUE
    | STR_VALUE
    | NULL
    | STORAGE_SIZE

STORAGE_SIZE:
      INT_VALUE
    | 'INT_VALUE[M|G]'
```

Character sets

```
charset:
      default_charset
    | column_charset

default_charset:
    [DEFAULT] {CHARSET | CHARACTER SET} [=] {UTF8 | UTF8MB4 | BINARY}

column_charset:
    {CHARSET | CHARACTER SET} {UTF8 | UTF8MB4 | BINARY}
```

Collations

```
collate:
      default_collate
    | column_collate

default_collate:
    [DEFAULT] COLLATE [=] {UTF8MB4_GENERAL_CI | UTF8MB4_BIN | BINARY}

column_collate:
    COLLATE {UTF8MB4_GENERAL_CI | UTF8MB4_BIN | BINARY}
```

Data types

```
data_type:
      TINYINT[(precision)] [UNSIGNED] [ZEROFILL]
    | SMALLINT[(precision)] [UNSIGNED] [ZEROFILL]
    | MEDIUMINT[(precision)] [UNSIGNED] [ZEROFILL]

    | INTEGER[(precision)] [UNSIGNED] [ZEROFILL]
    | BIGINT[(precision)] [UNSIGNED] [ZEROFILL]
    | FLOAT[(precision, scale)] [UNSIGNED] [ZEROFILL]
    | DOUBLE[(precision, scale)] [UNSIGNED] [ZEROFILL]
    | DECIMAL[(precision [, scale])] [UNSIGNED] [ZEROFILL]
    | NUMERIC[(precision [, scale])] [UNSIGNED] [ZEROFILL]
    | DATETIME[(scale)]
    | TIMESTAMP[(scale)]
    | DATE
    | TIME[(scale)]
    | YEAR
    | VARCHAR(length) column_charset column_collate
    | VARBINARY(length)
    | CHAR[(length)] column_charset column_collate
    | BINARY[(length)]
    | TINYTEXT column_charset column_collate
    | TINYLOB
    | TEXT[(length)] column_charset column_collate
    | BLOB[(length)]
    | MEDIUMTEXT column_charset column_collate
    | MEDIUMBLOB
    | LONGTEXT column_charset column_collate
    | LONGBLOB

precision | scale | length:
    INT_VALUE
```

SQL statement attributes

- Object names

```
tenant_name | pool_name | unit_name | zone_name | region_name:
    STR_VALUE

database_name | table_name | table_alias_name | column_name| column_alias_name  | partition_name | su
bpartition_name:
    STR_VALUE

index_name | view_name | object_name | constraint_name | tablegroup_name:
    STR_VALUE

outline_name | user_name:
    STR_VALUE

table_factor:
    [[database_name].] table_name

column_factor:
    [table_factor.] column_name
```

- Expressions

```
expression:
      const_value
    | column_factor
    | operator_expression
    | function_expression
```

- Comments

```
comment:
    COMMENT 'comment_text'

comment_text:
    STR_VALUE
```

Distributed architecture attributes

- `PRIMARY_ZONE` : the distribution strategy of the replica leader.

```
primary_zone:
    PRIMARY_ZONE [=] zone_name
```

- `ZONE_LIST` : the resource distribution strategy of the tenants.

```
zone_list:
    ZONE_LIST [=] (zone_name [, zone_name ...])
```

- `REPLICA_NUM` : the number of data replicas.

```
replica_num:
    REPLICA_NUM [=] INT_VALUE
```

- `TABLEGROUP` : the distribution strategy of the replica leader for multiple data sets.

```
tablegroup:
      default_tablegroup
    | table_tablegroup

default_tablegroup:
    DEFAULT TABLEGROUP [=] {tablegroup_name | NULL}

table_tablegroup:
    TABLEGROUP [=] {tablegroup_name | NULL}
```

Data storage attributes

- `BLOCK_SIZE` : the micro-block size for object storage.

```
block_size:
    BLOCK_SIZE [=] INT_VALUE
```

- `COMPRESSION` : the compression algorithm for object storage.

```
compression:
    COMPRESSION [=] {NONE | LZ4_1.0 | LZ0_1.0 | SNAPPY_1.0 | ZLIB_1.0}
```

- `PCTFREE` : the ratio of idle space reserved in a macro-block for object storage.

```
pctfree:
    PCTFREE [=] INT_VALUE
```

- `TABLET_SIZE` : the minimum size of each data shard for parallel compaction in a single task.

```
tablet_size:
    TABLET_SIZE [=] INT_VALUE
```

17.1.4.5.2. ALTER DATABASE

Description

You can execute the ALTER DATABASE statement to modify the attributes of a database.

Syntax

```
alter_database_stmt:
        ALTER DATABASE [database_name] [SET] alter_specification_list;

alter_specification_list:
    alter_specification [alter_specification ...]

alter_specification:
    [DEFAULT] {CHARACTER SET | CHARSET} [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
  | REPLICA_NUM [=] int_num
  | PRIMARY_ZONE [=] zone_name
  | {READ ONLY | READ WRITE}
    | DEFAULT TABLEGROUP [=] {NULL | table_group_name}
```

Parameters

Parameter	Description
database_name	The name of the database for which you want to modify attributes. The current default database is modified if you leave this parameter empty.
CHARSET charset_name	The character set that you want to modify.
COLLATE collation_name	The collation.
REPLICA_NUM int_num	The number of replicas.
PRIMARY_ZONE zone_name	The primary zone.
READ ONLY | READ WRITE	The attribute of the database. Valid values: READ ONLY and READ WRITE.
DEFAULT TABLEGROUP table_group_name	The default table group of the database. A NULL value indicates that no default table group is specified for the database.

Examples

- Execute the following statements to modify database test2. Set the character set to UTF8MB4 and the collation to UTF8MB4_BIN. Set the database attribute to READ WRITE.

```
OceanBase(admin@test)>alter database test2 DEFAULT CHARACTER SET UTF8MB4;
Query OK, 0 rows affected (0.03 sec)

OceanBase(admin@test)>alter database test2 DEFAULT COLLATE UTF8MB4_BIN;
Query OK, 0 rows affected (0.03 sec)

OceanBase(admin@test)>alter database test2 READ WRITE;
Query OK, 0 rows affected (0.02 sec)
```

17.1.4.5.3. ALTER OUTLINE

Description

You can execute the ALTER OUTLINE statement to modify outlines and configure throttling rules for SQL queries. This statement can be used only for outlines that are created based on SQL texts.

Syntax

```
ALTER OUTLINE outline_name ADD stmt [ TO target_stmt ]
```

Parameters

Parameter	Description
outline_name	The name of the outline that you want to modify.
stmt	The original data manipulation language (DML) statement that contains a hint and parameters.
TO target_stmt	You can leave TO target_stmt empty if the following requirements are met: The parameterized SQL statement is equivalent to the stmt value without the hint. In this case, the system generates an execution plan for the parameterized SQL statement that has the hint in stmt. To generate a fixed execution plan for a statement that contains a hint, specify the original SQL statement as TO target_stmt. **Notice** Make sure TO target_stmt you specify is the same as the stmt value without the hint.

Examples

- Execute the ALTER OUTLINE statement to add throttling rules.

```
OceanBase (root@oceanbase)> alter outline ol_1 add select /*+max_concurrent(1)*/ * from t1 where c1 =
1 and c2 = ? ;
OceanBase (root@oceanbase)> alter outline ol_1 add select /*+max_concurrent(1)*/ * from t1 where c1 =
? and c2 = 1;
```

- Execute the ALTER OUTLINE statement to add an execution plan.

```
OceanBase (root@oceanbase)> create outline ol_2 on select /*+max_concurrent(1)*/ * from t1,t2 where t
1.c1 = 1;
OceanBase (root@oceanbase)> alter outline ol_2 add select /*+use_nl(t2)*/ * from t1,t2 where t1.c1 =
1;
```

Notes

- One outline_name argument is associated with only one execution plan. If an execution plan is added by executing CREATE OUTLINE, you cannot execute ALTER OUTLINE to add an execution plan again.
- When you execute the ALTER OUTLINE statement, you can specify only a throttling rule or an execution plan for each execution. The similar rule applies to the CREATE OUTLINE statement.

17.1.4.5.4. ALTER RESOURCE POOL

Description

You can execute the ALTER RESOURCE POOL statement to modify a resource pool.

Syntax

```
ALTER RESOURCE POOL poolname
  UNIT [=] unitname,
  UNIT_NUM [=] unitnum,
  ZONE [=] ('zone' [, 'zone' …]) ;
```

Parameters

Parameter	Description
UNIT	The name of the resource unit that you want to use.
UNIT_NUM	The number of resource units that you want to create in a zone. The value must be smaller than the number of OBServers in the zone.
ZONE_LIST	The zones in which you want to create resource units.

Examples

- You cannot modify multiple attributes for a resource pool at a time, such as UNIT, UNIT_NUM, and ZONE_LIST. Otherwise, the system returns an error.

```
OceanBase(admin@test)> ALTER RESOURCE POOL pool1 unit='unit2', unit_num=1, zone_list=('zone1');
ERROR 1235 (0A000): alter unit_num, resource_unit, zone_list in one cmd not supported
```

- Modify the UNIT attribute for a resource pool.

```
OceanBase(admin@test)> ALTER RESOURCE POOL pool1 unit='unit2';
Query OK, 0 rows affected (0.00 sec)
```

17.1.4.5.5. ALTER RESOURCE UNIT

Description

You can execute the ALTER RESOURCE UNIT statement to modify a resource unit.

Syntax

```
ALTER RESOURCE UNIT unitname
  MAX_CPU [=] cpunum,
  MAX_MEMORY [=] memsize,
  MAX_IOPS [=] iopsnum,
  MAX_DISK_SIZE [=] disksize,
  MAX_SESSION_NUM [=] sessionnum,
  [MIN_CPU [=] cpunum,]
  [MIN_MEMORY [=] memsize,]
  [MIN_IOPS [=] iopsnum] ;
```

Parameters

Parameter	Description
MAX_CPU	The maximum number of CPUs.
MAX_MEMORY	The maximum memory size. Valid values: [1073741824,+∞). The unit is bytes. The minimum value 1073741824 bytes is equivalent to 1 GB.
MAX_IOPS	The maximum IOPS. Valid values: [128,+∞).
MAX_DISK_SIZE	The maximum disk capacity. Valid values: [536870912,+∞). The unit is bytes. The minimum value 536870912 bytes is equivalent to 512 MB.
MAX_SESSION_NUM	The maximum number of sessions. Valid values: [64,+∞).
MIN_CPU	The minimum number of CPUs.
MIN_MEMORY	The minimum memory size.
MIN_IOPS	The minimum IOPS.

Examples

- Modify resource unit unit1 by changing the maximum number of CPUs to two and memory size to 2 GB.

```
OceanBase(admin@test)> ALTER RESOURCE UNIT unit1 max_cpu 2, max_memory '2G';
Query OK, 0 rows affected (0.02 sec)
```

17.1.4.5.6. ALTER SYSTEM

You can execute the ALTER SYSTEM statement to send commands to the ApsaraDB for OceanBase system to perform specified operations.

BOOTSTRAP

Description

You can use this statement to bootstrap an ApsaraDB for OceanBase cluster.

Syntax

```
alter_system_bootstrap_stmt:
    ALTER SYSTEM BOOTSTRAP opt_cluster_type region_zone_server_list;

opt_cluster_type:
    [CLUSTER cluster_role]

cluster_role:
    PRIMARY | STANDBY

region_zone_server_list:
    region_zone_server [, region_zone_server ...]

region_zone_server:
    [region] zone server

region:
    REGION [=] region_name

zone:
    ZONE [=] zone_name

server:
    SERVER [=] ip_port

ip_port:
    'STR_VALUE:INT_VALUE'
```

Parameters

To bootstrap the system, specify the RootService nodes. Use commas (,) to separate multiple RootService nodes.

Parameter	Description
region_name	The region where the RootService node is deployed. Specify this parameter if the cluster is deployed across zones in multiple regions.
zone_name	The zone to which the RootService node belongs.
ip_port	The IP address and port number of the RootService node.

Parameter	Description
PRIMARY | STANDBY	Specifies whether to run the primary or secondary database. Use the PRIMARY or STANDBY keyword to specify the database that is used when the system is started. By default, if you do not use PRIMARY or STANDBY, the system runs the primary database.

Examples

- Specify a RootService node.

```
ALTER SYSTEM BOOTSTRAP ZONE 'zone1' SERVER '10.218.248.178:55410';
```

- Separate multiple RootService nodes with commas (,).

```
ALTER SYSTEM BOOTSTRAP ZONE 'zone1' SERVER '172.24.65.24:55410', ZONE 'zone2'
SERVER '172.24.65.114:55410';
```

- Run a secondary database.

```
ALTER SYSTEM BOOTSTRAP CLUSTER STANDBY ZONE 'zone1' SERVER '10.218.248.178:55410';
```

JOB

Description

You can use this statement to trigger a background job. You can configure parameters to specify a job.

Syntax

```
alter_system_job_stmt:
    ALTER SYSTEM RUN JOB job_name
    [zone | server];
```

Parameters

Parameter	Description

Parameter	Description
JOB job_name	The name of the job. If special characters are included, the job name must be enclosed in single quotation marks ('). If special characters are not included, you can determine whether to use single quotation marks (') as needed. ApsaraDB for OceanBase supports the following jobs: • check_partition_table: Check and delete partitioned tables on an OBServer. • root_inspection: Trigger a self-check job on a RootService node.
zone | server	Specifies whether to run the job in a specified zone or on a specified server.

Examples

- Trigger a self-check job on a RootService node.

```
ALTER SYSTEM RUN JOB "root_inspection";
```

MERGE

Description

You can use this statement to trigger major or minor freeze operations.

Syntax

```
alter_system_merge_stmt:
    ALTER SYSTEM merge_action;

merge_action:
      MAJOR FREEZE
    | MINOR FREEZE
      [tenant_list | replica] [server_list] [zone]
    | START MERGE
      zone
    | {SUSPEND | RESUME} MERGE
      [zone]
    | CLEAN MERGE ERROR

tenant_list:
    TENANT [=] (tenant_name_list)

tenant_name_list:
    tenant_name [, tenant_name ...]

replica:
    PARTITION_ID [=] 'partition_id%partition_count@table_id'

server_list:
    SERVER [=] ip_port_list
```

Parameters

Parameter	Description
MAJOR FREEZE	Trigger a daily major freeze operation.
MINOR FREEZE	Trigger a minor freeze operation.
START MERGE	Start a daily major freeze operation.
{SUSPEND | RESUME} MERGE	Suspend or resume a daily major freeze operation.
CLEAN MERGE ERROR	Clear errors that occur during major freeze operations.
tenant_name	The tenant on which minor freeze operations are performed.
PARTITION_ID	The partition in which minor freeze operations are performed.
SERVER	The OBServer on which minor freeze operations are performed.

Parameter	Description
zone	The zone in which major freeze operations are performed.

Examples

- Trigger a daily major freeze operation.

```
OceanBase(root@oceanbase)>alter system major freeze;
Query OK, 0 rows affected (0.06 sec)
```

PARAMETER

Description

You can use this statement to modify configuration items.

Syntax

```
alter_system_parameter_stmt:
    ALTER SYSTEM [SET]
    parameter_name = expression [SCOPE = {MEMORY | SPFILE | BOTH}] [COMMENT [=} 'text']
                                                                  {SERVER [=] 'ip:port' | ZONE [=] 'zone'};
```

Parameters

Parameter	Description
parameter_name	The name of the configuration item that you want to modify.
expression	The new value of the configuration item.
COMMENT 'text'	Add a comment about the modification. This parameter is optional. We recommend that you do not omit it.

Parameter	Description
SCOPE	The effective range of the modification. Valid values: • MEMORY: Only the configuration item in the memory is modified. The modification takes effect immediately but becomes invalid after the server is restarted. No configuration items support this option. • SPFILE: Only the configuration item in the configuration table is modified. The modification takes effect after the server is restarted. • BOTH: Both the configuration item in the configuration table and that in the memory are modified. The modification takes effect immediately and remains valid after the server is restarted. • The default value is BOTH. If you specify BOTH or MEMORY for a configuration item on which the modification cannot take effect immediately, the system returns an error.
SERVER	The configuration item of the specified server. This indicates that only the configuration item of the specified server is modified.
ZONE	The name of the zone. This indicates that the configuration item modification applies to the specified type of servers in the specified cluster. If you do not specify the zone name, the configuration item modification applies to the specified type of the servers in all clusters.

Note

To modify multiple system configuration items at a time, separate them with commas (,).

Execute the following statement to query system configuration items:

```
SHOW PARAMETERS [LIKE 'pattern' | WHERE expr];
```

Examples

- Modify the configuration item enable_sql_audit.

```
OceanBase(root@oceanbase)>show parameters like 'enable_sql_audit';
+------+----------+---------------+----------+-----------------+-----------+-------+----------------
----------------------------------------------------------------------------------------------------+-----
-----+---------+---------+-------------------+
| zone | svr_type | svr_ip        | svr_port | name            | data_type | value | info
| section  | scope   | source  | edit_level        |
+------+----------+---------------+----------+-----------------+-----------+-------+----------------
----------------------------------------------------------------------------------------------------+-----
-----+---------+---------+-------------------+
| z1   | observer | 11.11.111.111 |    19510 | enable_sql_audit | NULL      | True  | specifies wheth
er SQL audit is turned on. The default value is TRUE. Value: TRUE: turned on FALSE: turned off | OBSE
RVER | CLUSTER | DEFAULT | DYNAMIC_EFFECTIVE |
+------+----------+---------------+----------+-----------------+-----------+-------+----------------
----------------------------------------------------------------------------------------------------+-----
-----+---------+---------+-------------------+
1 rows in set (0.02 sec)

OceanBase(root@oceanbase)>alter system set enable_sql_audit = false scope = BOTH;
Query OK, 0 rows affected (0.05 sec)

OceanBase(root@oceanbase)>show parameters like 'enable_sql_audit';
+------+----------+---------------+----------+-----------------+-----------+-------+----------------
----------------------------------------------------------------------------------------------------+-----
-----+---------+---------+-------------------+
| zone | svr_type | svr_ip        | svr_port | name            | data_type | value | info
| section  | scope   | source  | edit_level        |
+------+----------+---------------+----------+-----------------+-----------+-------+----------------
----------------------------------------------------------------------------------------------------+-----
-----+---------+---------+-------------------+
| z1   | observer | 11.11.111.111 |    19510 | enable_sql_audit | NULL      | False | specifies wheth
er SQL audit is turned on. The default value is TRUE. Value: TRUE: turned on FALSE: turned off | OBSE
RVER | CLUSTER | DEFAULT | DYNAMIC_EFFECTIVE |
+------+----------+---------------+----------+-----------------+-----------+-------+----------------
----------------------------------------------------------------------------------------------------+-----
-----+---------+---------+-------------------+
1 rows in set (0.02 sec)
```

REFRESH

Description

You can use this statement to refresh database information, such as the schema, time zone, and caches.

Syntax

```
alter_system_refresh_stmt:
    ALTER SYSTEM refresh_action;

refresh_action:
      REFRESH SCHEMA
      [zone | server]
    | REFRESH TIME_ZONE_INFO
    | FLUSH cache_type CACHE
      [tenant_list] [GLOBAL]
    | FLUSH KVCACHE
      [tenant] [CACHE [=] cache_name]

cache_type:
      ALL
    | LOCATION
    | CLOG
    | ILOG
    | COLUMN_STAT
    | BLOCK_INDEX
    | BLOCK
    | ROW
    | BLOOM_FILTER
    | SCHEMA
    | PLAN

tenant:
    TENANT [=] tenant_name

cache_name:
```

Parameters

Parameter	Description
REFRESH SCHEMA	Refresh the schema. In normal cases, when the system executes a data definition language (DDL) statement, the RootService node notifies all OBServers to refresh the schemas. Assume that some OBServers are disconnected from the RootService node due to exceptions. In this case, you must manually refresh the schemas. You can refresh the schema for a single OBServer or refresh all the schemas in a cluster.
REFRESH TIME_ZONE_INFO	Refresh the local time zone of all servers in the cluster.
FLUSH cache_type CACHE	Clear the caches of the specified type.

Parameter	Description
FLUSH KVCACHE	Clear the KV caches. • If tenant and cache_name are specified, the system clears the specified KV cache under the specified tenant. • If only tenant is specified, the system clears all the KV cache under the specified tenant. • If you leave tenant and cache_name empty, the system clears all the KV cache under all tenants.

Examples

- Refresh the schema for a single OBServer:

```
ALTER SYSTEM REFRESH SCHEMA SERVER='172.24.65.24:55410';
```

- Refresh all schemas in a zone:

```
ALTER SYSTEM REFRESH SCHEMA ZONE='zone1';
```

REPLICA

Description

You can use this statement to migrate, replicate, or delete replicas. You can also change the replica type or switch replica roles.

Syntax

```
alter_system_replica_stmt:
    ALTER SYSTEM replica_action;

replica_action:
      SWITCH REPLICA
      {LEADER | FOLLOWER}
      {replica server | server [tenant_name] | zone [tenant_name]}
    | DROP REPLICA partition_id_desc
      replica server [create_timestamp] [zone] [FORCE]
    | {MOVE | COPY} REPLICA
      replica source destination
    | REPORT REPLICA partition_id_desc
         {zone | server}
      | RECYCLE REPLICA partition_id_desc
         {zone | server}
      | {ALTER | CHANGE | MODIFY} REPLICA
      replica server [set] REPLICA_TYPE = replica_type

source:
    SOURCE [=] 'ip:port'

destination:
    DESTINATION [=] 'ip:port'

partition_id_desc
    PARTITION_ID partition_id%partition_count@table_id

partition_idx | partition_count | table_id | task_id:
    INT_VALUE

create_timestamp:
    CREATE_TIMESTAMP [=] INT_VALUE

tenant_name_list:
    tenant_name [, tenant_name ...]

replica_type:
      {FULL | F}
    | {READONLY | R}
    | {LOGONLY | L}
```

Parameters

Parameter	Description
SWITCH REPLICA	Select a new replica leader.
DROP REPLICA	Delete a replica. To delete a replica on the specified OBServer, specify the following parameters: PARTITION_ID, SERVER, and CREATE_TIMESTAMP.

Parameter	Description
{MOVE | COPY} REPLICA	Migrate or replicate a replica. You must specify a source OBServer, a destination OBServer, and a partition ID.
REPORT REPLICA	Report replicas. This clause requires a single OBServer or all the OBServers in a zone to report replicas.
RECYCLE REPLICA	Recycle replicas that you no longer need.
{ALTER | CHANGE | MODIFY} REPLICA	Modify the replica attributes. You can modify the type of a specified replica. The following replica types are supported: FULL, READONLY, and LOGONLY. You can set REPLICA_TYPE to the full name or abbreviation of a valid replica type, such as F, R, or L. The value is case-insensitive.

Examples

- Migrate a replica.

```
ALTER SYSTEM MOVE REPLICA PARTITION_ID '0%4@1100611139403777'
SOURCE '172.24.65.24:55410'
DESTINATION '172.24.65.26:55410';
```

- Delete a replica.

```
ALTER SYSTEM DROP REPLICA PARTITION_ID '0%4@1100611139403777'
SERVER '172.24.65.26:55410';
```

- Modify the type of a replica.

```
ALTER SYSTEM CHANGE REPLICA PARTITION_ID '0%4@1100611139403777'
SERVER '172.24.65.26:55410';
CHANGE REPLICA_TYPE = 'L';
```

- Select a new replica leader.

```
ALTER SYSTEM SWITCH REPLICA LEADER PARTITION_ID '0%4@1100611139403777'
SERVER '172.24.65.26:55410';
```

ROOTSERVICE

Description

You can use this statement to change the role of a RootService node.

Syntax

```
alter_system_rootservice_stmt:
    ALTER SYSTEM SWITCH ROOTSERVICE {LEADER | FOLLOWER} {zone | server};
```

Parameters

Parameter	Description
LEADER | FOLLOWER	Set the role of a RootService node to LEADER or FOLLOWER.
zone | server	Change the role of a specified RootService node or a RootService node in a specified zone.

Examples

- Change the role of a RootService node in zone z1 to LEADER.

```
ALTER SYSTEM SWITCH ROOTSERVICE LEADER ZONE 'z1';
```

SERVER

Description

You can use this statement to maintain OBServers. For example, you can add, delete, start, or stop an OBServer.

Syntax

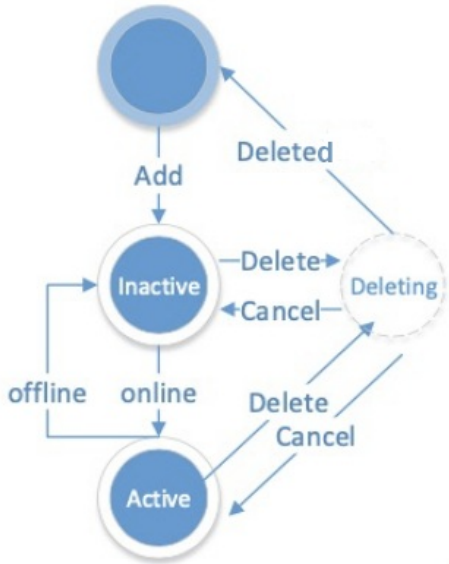
```
alter_system_server_stmt:
    ALTER SYSTEM server_action SERVER ip_port_list [zone];

server_action:
      ADD
    | DELETE
    | CANCEL DELETE
    | START
    | STOP
    | FORCE STOP

ip_port_list:
    ip_port [, ip_port ...]
```

Parameters

The following figure displays the OBServer status.



Parameter	Description
ip_port	The IP address and port number of the OBServer.
zone	If a zone is specified, the system checks whether the OBServer that you want to maintain is deployed in the specified zone.
ADD	Add an OBServer.
DELETE	Delete an OBServer.
CANCEL DELETE	Abort a DELETE operation on an OBServer.
START	Start an OBServer.
STOP	Stop an OBServer.
FORCE STOP	Forcibly stop an OBServer.

Examples

- Add an OBServer.

```
ALTER SYSTEM ADD SERVER '172.24.65.113:55410' ZONE 'zone1';
```

> **Notice**
>
> - You can execute the ALTER SYSTEM ADD SERVER or ALTER SYSTEM DELETE SERVER statement to add a server to or delete a server from the server list. Only servers on the server list can provide services.
> - When the ALTER SYSTEM DELETE SERVER statement is executed, the system selects a new replica leader and replicates replicas.
> - The ALTER SYSTEM DELETE SERVER statement is time-consuming. You can execute the ALTER SYSTEM CANCEL DELETE SERVER statement to abort this operation.

THROTTLE

Description

You can use this statement to configure throttling rules.

Syntax

```
alter_system_throttle_stmt:
    ALTER SYSTEM throttle_action;

throttle_action:
      ENABLE SQL THROTTLE [priority_option] [using_metric_option_list]
    | DISABLE SQL

priority_option:
    FOR PRIORITY <= INT_VALUE

using_metric_option_list:
    USING metric_option_list

metric_option_list:
    metric_option [metric_option ...]

metric_option:
      RT = {INT_VALUE | DECIMAL_VALUE}
    | CPU = {INT_VALUE | DECIMAL_VALUE}
    | IO = INT_VALUE
    | NETWORK = {INT_VALUE | DECIMAL_VALUE}
    | QUEUE_TIME = {INT_VALUE | DECIMAL_VALUE}
    | LOGICAL_READS = {INT_VALUE | DECIMAL_VALUE}
```

Parameters

Parameter	Description
ENABLE SQL	Enable throttling. You can configure the parameters to enable throttling based on the specified rules and metrics.
FOR PRIORITY	Configure the priority to throttle part of the sessions.

Parameter	Description
RT	Enable throttling based on the amount of time required for executing an SQL statement.
CPU	Enable throttling based on the CPU utilization. This option is not supported.
IO	Enable throttling based on the number of I/O operations. This option is not supported.
NETWORK	Enable throttling based on the network traffic during data transmission. This option is not supported.
QUEUE_TIME	Enable throttling based on the wait time for a query in the queue.
LOGICAL_READS	Enable throttling based on the number of logical reads. This option is not supported.
DISABLE SQL	Disable throttling.

Examples

- Assume that you want to throttle the sessions where the values for FOR PRIORITY are less than or equal to 100. Execute the following statement to throttle the sessions that wait longer than 0.1s in the queue:

```
alter system enable sql throttle for priority <= 100 using queue_time=0.1
```

UNIT

Description

You can use this statement to migrate units.

Syntax

```
alter_system_unit_stmt:
    ALTER SYSTEM MIGRATE
    UNIT [=] unit_id DESTINATION [=] ip_port

unit_id:
    INT_VALUE
```

Parameters

Parameter	Description
unit_id	The ID of the unit.
ip_port	The server IP address to which the unit is migrated.

Examples

- Migrate unit 1001 to 11.11.111.111:19510.

```
OceanBase(root@oceanbase)>alter system migrate unit = 1001 destination = '11.11.111.111:19510';
Query OK, 0 rows affected (0.05 sec)
```

ZONE

Description

You can use this statement to maintain zones. For example, you can add, delete, activate, or deactivate zones.

Syntax

```
alter_system_zone_stmt:
      ADD ZONE zone_name
      [zone_option_list]
    | {ALTER | CHANGE | MODIFY} ZONE zone_name
      [SET] zone_option_list
    | {DELETE | START | STOP | FORCE STOP} ZONE zone_name

zone_option_list:
    zone_option [, zone_option ...]

zone_option:
      region
    | idc
    | ZONE_TYPE {READONLY | READWRITE}

idc:
    STR_VALUE
```

Parameters

Parameter	Description
ADD ZONE	Add a zone.
{ALTER | CHANGE | MODIFY} ZONE	Modify the region property for a zone.
DELETE ZONE	Delete a zone. Before you delete a zone, ensure that no servers are available in the zone.

Parameter	Description
START | STOP	Activate or deactivate a zone.

Examples

- Delete a zone.

```
OceanBase(root@oceanbase)>alter system delete zone 'z1';
ERROR 4668 (HY000): The zone is not empty and can not be deleted. You should delete the servers of th
e zone. There are 1 servers alive and 0 not alive.
```

CLUSTER

Description

You can execute this statement to manage clusters. For example, you can add or delete a cluster, or modify cluster attributes.

Syntax

```
ALTER SYSTEM  cluster_action cluster_name CLUSTER_ID INTNUM;
cluster_action:
    ADD CLUSTER
    | REMOVE CLUSTER
    | ENABLE CLUSTER SYNCHRONIZATION
    | DISABLE CLUSTER SYNCHRONIZATION
```

Parameters

Parameter	Description
ADD CLUSTER	Add a secondary database.
REMOVE CLUSTER	Delete an existing secondary database.
ENABLE CLUSTER SYNCHRONIZATION	Enable data synchronization for a secondary database.
DISABLE CLUSTER SYNCHRONIZATION	Disable data synchronization for a secondary database.

Examples

- Add a secondary database.

```
ALTER SYSTEM ADD CLUSTER 'ob1.test' cluster_id = 1;
```

SWITCHOVER

Description

You can execute this statement to switch cluster roles. For example, you can switch a primary cluster to the secondary role, or switch a secondary cluster to the primary role.

Syntax

```
ALTER SYSTEM commit_switchover_clause;

commit_switchover_clause:
    COMMIT TO SWITCHOVER TO PRIMARY
    | COMMIT TO SWITCHOVER TO PHYSICAL STANDBY
    | ACTIVATE PHYSICAL STANDBY CLUSTER
    | CONVERT TO PHYSICAL STANDBY
```

Parameters

Parameter	Description
COMMIT TO SWITCHOVER TO PRIMARY	Switch a secondary cluster to the primary role. Execute this statement on a secondary cluster. Before you execute this statement, ensure that the original primary cluster is switched to the secondary role, and no another primary cluster exists.
COMMIT TO SWITCHOVER TO PHYSICAL STANDBY	Switch a primary cluster to the secondary role. Execute this statement on the primary cluster. Before you execute this statement, ensure that at least a secondary cluster is synchronized with the primary cluster. After you switch a primary cluster to the secondary role, you can also switch the cluster to the primary role again.
ACTIVATE PHYSICAL STANDBY CLUSTER	Switch a secondary cluster to the primary role if the primary cluster becomes faulty.
CONVERT TO PHYSICAL STANDBY	Switch a primary database to the secondary role.

Examples

- Switch a primary database to the secondary role.

```
ALTER SYSTEM COMMIT TO SWITCHOVER TO PHYSICAL STANDBY;
```

- Switch a secondary database to the primary role.

```
ALTER SYSTEM COMMIT TO SWITCHOVER TO PRIMARY;
```

- The primary cluster becomes faulty. Switch a secondary cluster to the primary role.

```
ALTER SYSTEM ACTIVATE PHYSICAL STANDBY CLUSTER;
```

- Restart the old primary database and switch it to the secondary role.

```
ALTER SYSTEM CONVERT TO PHYSICAL STANDBY;
```

BALANCE TASK

Description

You can use this statement to clear load balancing tasks that are not being scheduled.

Syntax

```
ALTER SYSTEM REMOVE BALANCE TASK opt_tenant_list opt_zone_list opt_balance_task_type;

opt_tenant_list
    TENANT [=] name,name_list

opt_zone_list
    ZONE [=] zone_name, zone_list

opt_balance_task_type
    ALL
    | MANUAL
    | AUTO
```

Parameters

Parameter	Description
opt_tenant_list	The tenants. If you leave this parameter empty, the tasks under all tenants are cleared.
opt_zone_list	The zones. This parameter is optional.
opt_balance_task_type	The type of the tasks to be cleared. Valid values: • ALL: all tasks. • AUTO: tasks that are automatically generated. • MANUAL: tasks that are manually generated.

Examples

- Clear the tasks that are not being scheduled under all tenants.

```
ALTER SYSTEM REMOVE BALANCE TASK;
```

CANCEL MIGRATE UNIT

Description

You can use this statement to cancel the migration of units.

Syntax

```
ALTER SYSTEM CANCEL MIGRATE UNIT unit_id;
```

Parameters

Parameter	Description
unit_id	The ID of the unit that is being migrated.

Examples

- Cancel the migration of unit 1001.

```
ALTER SYSTEM CANCEL MIGRATE UNIT 1001;
```

RESTORE

Description

You can use this statement to restore tenant data.

Syntax

```
alter system restore dest_tenant from source_tenant at 'uri' until 'timestamp' with 'restore_option';
```

Parameters

Parameter	Description
dest_tenant	The name of the new tenant to which the data is restored.
source_tenant	The name of the original tenant.
uri	The path from which the tenant data is restored.
timestamp	The timestamp to which the tenant data is restored. The value must be greater than or equal to START_TIME of baseline backup data in CDB_OB_BACKUP_SET_DETAILS, and less than or equal to MAX_NEXT_TIME of backup logs in CDB_OB_BACKUP_ARCHIVELOG_SUMMARY.

Parameter	Description
restore_option	The options for restoration. Valid values: • backup_cluster_name: the name of the source cluster. This parameter is required. • backup_cluster_id: the ID of the source cluster. This parameter is required. • pool_list: the resource pool of the user. This parameter is required. • locality: the locality of the tenant. This parameter is optional. • kms_encrypt: This parameter is optional. If you set kms_encrypt to true, specify kms_encrypt_info during restoration.

Examples

- Restore the tenant data.

```
alter system restore restored_trade from trade
    at 'oss://antsys-oceanbasebackup/backup_rd/20200323? host=cn-hangzhou-alipay-b.oss-cdn.aliyun-inc
.com&access_id=xxx&access_key=xxx'
  until ' 2020-03-23 08:59:45'
  with 'backup_cluster_name=ob20daily.backup&backup_cluster_id=1&pool_list=restore_pool';

alter system restore restored_trade from trade
  at 'file:///data/nfs/physical_backup_test/20200520'
  until '2020-05-21 09:39:54.071670'
  with 'backup_cluster_name=ob20daily.backup&backup_cluster_id=1&pool_list=restore_pool&locality=F@z1
,F@z2,F@z3';
```

CHANGE TENANT

Description

You can use this statement to switch to another tenant.

Syntax

```
ALTER SYSTEM CHANGE TENANT tenant_name;

ALTER SYSTEM CHANGE TENANT TENANT_ID [=] INTNUM;
```

Parameters

Parameter	Description
tenant_name	The name of the tenant that you want to switch to.
TENANT_ID	The ID of the tenant that you want to switch to.

Examples

- Switch to the tenant whose ID is 1001.

```
ALTER SYSTEM CHANGE TENANT TENANT_ID = 1001;
```

Notes

1. Log on to the database as a system tenant. A general tenant cannot execute this statement.
2. Execute this statement on an OBServer that is running properly. If an OBServer is disconnected, execute this statement again after the OBServer is recovered.
3. You cannot switch to another tenant when transactions are being processed.
4. If you switch to a non-system tenant, you cannot execute data definition language (DDL) statements.

BACKUP

Description

You can use this statement to trigger data backup.

Syntax

```
Specify a path to store the backup data: alter system set backup_dest = <backup_uri>
Enable log archiving: alter system archivelog
Disable log archiving: alter system noarchivelog
Back up baseline data for a cluster: alter system backup database;
Cancel the current backup task: alter system cancel backup
```

Parameters

Parameter	Description
backup_uri	The path to store the backup data. You can specify an Object Storage Service (OSS) path or a file system. For more information about the formats, see Examples.

Examples

- Set the path to store the backup data.

```
alter system set backup_dest='oss://antsys-oceanbasebackup/backup_dir? host=xxx&access_id=xxx&access_
key=xxx';
alter system set backup_dest='file:///data/nfs/physical_backup_dir';
```

Notes

Log on to the database as a system tenant. A general tenant cannot execute this statement.

17.1.4.5.7. ALTER TABLE

Description

You can execute the ALTER TABLE statement to update the schema of an existing table. For example, you can modify an existing table and table attributes, add columns, modify columns and column attributes, or delete columns.

Syntax

```
alter_table_stmt:
      ALTER TABLE table_name
      alter_table_action_list;
    | RENAME TABLE rename_table_action_list;

alter_table_action_list:
    alter_table_action [, alter_table_action ...]

alter_table_action:
      ADD [COLUMN] {column_definition | (column_definition_list)}
    | CHANGE [COLUMN] column_name column_definition
    | MODIFY [COLUMN] column_definition
    | ALTER [COLUMN] column_name {SET DEFAULT const_value | DROP DEFAULT}
    | DROP [COLUMN] column_name
    | ADD [CONSTRAINT [constraint_name]] UNIQUE {INDEX | KEY} [index_name] index_desc
    | ADD {INDEX | KEY} [index_name] index_desc
    | ADD FULLTEXT [INDEX | KEY] [index_name] fulltext_index_desc
    | ALTER INDEX index_name [VISIBLE | INVISIBLE]
    | DROP {INDEX | KEY} index_name
    | ADD PARTITION (range_partition_list)
    | DROP PARTITION (partition_name_list)
    | REORGANIZE PARTITION name_list INTO partition_range_or_list
    | TRUNCATE PARTITION name_list
    | [SET] table_option_list
    | RENAME [TO] table_name
    | DROP TABLEGROUP
    | DROP FOREIGN KEY fk_name

rename_table_action_list:
    rename_table_action [, rename_table_action ...]

rename_table_action:
    table_name TO table_name

column_definition_list:
    column_definition [, column_definition ...]

column_definition:
    column_name data_type
    [DEFAULT const_value] [AUTO_INCREMENT]

    INT_VALUE
```

Parameters

Parameter	Description
ADD [COLUMN]	Add the column. You cannot add a primary key column.
CHANGE [COLUMN]	Modify the column name and column attributes.
MODIFY [COLUMN]	Modify column attributes.
ALTER [COLUMN]	Modify the default value of the column.
DROP [COLUMN]	Delete the column. You cannot delete a primary key column or column that has indexes.
ADD [UNIQUE INDEX]	Add the unique index.
ADD [INDEX]	Add the common index.
ALTER [INDEX]	Modify index attributes.
ADD [PARTITION]	Add the partition.
DROP [PARTITION]	Delete the partition.
REORGANIZE [PARTITION]	Re-partition the table.
TRUNCATE [PARTITION]	Delete data from the partition.
RENAME [TO] table_name	Rename the table.
DROP [TABLEGROUP]	Delete the table group.
DROP [FOREIGN KEY]	Delete the foreign key.
SET BLOCK_SIZE	The block size for the partitioned table.

Parameter	Description
SET REPLICA_NUM	The number of replicas for the table.
SET COMPRESSION	The compression method for the table.
SET USE_BLOOM_FILTER	Specifies whether to use a Bloom filter.
SET COMMENT	Add comments.
SET PROGRESSIVE_MERGE_NUM	The number of macro-blocks that are to be merged at a time for progressive compaction. Valid values: 1 to 64.

Examples

- Change the field name d in the t2 table to c and change the data type of the field.

```
ALTER TABLE t2 CHANGE COLUMN d c CHAR(10);
```

- Add a column, and then delete it.
  - Before you add a column, execute the `DESCRIBE test;` statement to view the table. The following information appears:

```
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| c1    | int(11)     | NO   | PRI | NULL    |       |
| c2    | varchar(50) | YES  |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
2 rows in set (0.01 sec)
```

  - Execute the following statement to add the c3 column:

```
ALTER TABLE test ADD c3 int;
```

  - After you add the column, execute the `DESCRIBE test;` statement to view the table. The following information appears:

```
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| c1    | int(11)     | NO   | PRI | NULL    |       |
| c2    | varchar(50) | YES  |     | NULL    |       |
| c3    | int(11)     | YES  |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
3 rows in set (0.02 sec)
```

  - Execute the following statement to delete the c3 column:

```
ALTER TABLE test DROP c3;
```

- After you delete the column, execute the `DESCRIBE test;` statement to view the table. The following information appears:

```
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| c1    | int(11)     | NO   | PRI | NULL    |       |
| c2    | varchar(50) | YES  |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
2 rows in set (0.01 sec)
```

- Configure the number of replicas for the test table, and add the c5 column to the table.

```
ALTER TABLE test SET REPLICA_NUM=2, ADD COLUMN c5 INT;
```

17.1.4.5.8. ALTER TABLEGROUP

Description

You can execute the ALTER TABLEGROUP statement to perform the following operations:

- Add multiple tables to a table group.
- Modify partition rules for a table group.
- Modify the locality and primary zone for a table group.

Syntax

- Add multiple tables to a table group.

```
ALTER TABLEGROUP tablegroupname ADD [TABLE] tblname [, tblname…]
```

- Modify partition rules for a table group.

```
ALTER TABLEGROUP tablegroupname alter_tg_partition_option
alter_tg_partition_option:
DROP PARTITION '(' name_list ')'
| ADD PARTITION opt_range_partition_list
| modify_tg_partition_info
```

- Modify the locality and primary zone for a table group.

```
ALTER TABLEGROUP tablegroupname alter_tablegroup_actions
alter_tablegroup_actions:
alter_tablegroup_action
| alter_tablegroup_action, alter_tablegroup_action
alter_tablegroup_action:
SET LOCALITY [=] locality_name
|SET PRIMARY_ZONE [=] primary_zone_name
```

Parameters

Parameter	Description
tablegroupname	The name of the table group.

Parameter	Description
tblname	The name of the table. To add multiple tables to a table group, separate table names with commas (,). If you add multiple tables at a time, you can specify duplicate table names. If the table you want to add exists in the *specified table group*, the system does not return an error.
modify_tg_partition_info	Modify the partition rules for the table group.
LOCALITY locality_name	The locality of the table group.
PRIMARY_ZONE primary_zone_name	The primary zone of the table group.

Examples

Create table group tgh and two relational tables ttgh and ttgh2, and change the locality of the table group to F@z1.

```
OceanBase(admin@test)> create tablegroup tgh locality='F,R{ALL_SERVER}@z1' partition by hash partitio
ns 10;
Query OK, 0 rows affected (0.09 sec)

OceanBase(admin@test)> create table ttgh(c1 int, c2 int) tablegroup = tgh locality='F,R{ALL_SERVER}@z
1';
Query OK, 0 rows affected (0.55 sec)

OceanBase(admin@test)> create table ttgh2(c1 int, c2 int) tablegroup = tgh locality='F,R{ALL_SERVER}@
z1';
Query OK, 0 rows affected (0.39 sec)

OceanBase(admin@test)> alter tablegroup tgh set locality ='F@z1';
Query OK, 0 rows affected (0.09 sec)

OceanBase(admin@test)> select locality from oceanbase.__all_tablegroup where tablegroup_name ='tgh';
+------------+
| locality   |
+------------+
| FULL{1}@z1 |
+------------+
1 row in set (0.05 sec)

OceanBase(admin@test)> select locality from oceanbase.__all_table where tablegroup_id=(select tablegr
oup_id from oceanbase.__all_tablegroup where tablegroup_name ='tgh');
+------------+
| locality   |
+------------+
| FULL{1}@z1 |
| FULL{1}@z1 |
+------------+
2 rows in set (0.04 sec)
```

17.1.4.5.9. ALTER TENANT

Description

You can execute the ALTER TENANT statement to modify tenant information.

Syntax

```
ALTER TENANT {tenant_name | ALL}
    [SET] [tenant_option_list] [opt_global_sys_vars_set]

tenant_option_list:
    tenant_option [, tenant_option ...]

tenant_option:
            COMMENT [=]'string'
            |{CHARACTER SET | CHARSET} [=] charsetname
            |COLLATE [=]  collationname
            |REPLICA_NUM [=] num
            |ZONE_LIST [=] (zone [, zone…])
            |PRIMARY_ZONE [=] zone
            |RESOURCE_POOL_LIST [=](poolname [, poolname…])
            |DEFAULT TABLEGROUP [=] {NULL | tablegroupname}
            |{READ ONLY | READ WRITE}
      |LOGONLY_REPLICA_NUM [=] num
      |LOCALITY [=] 'locality description'
      |LOCK|UNLOCK;

opt_global_sys_vars_set:
      VARIABLES system_var_name = expr [,system_var_name = expr] ...
```

Parameters

Parameter	Description
tenant_name	The name of the tenant that you want to modify.
ALTER TENANT ALL	Modify information for all tenants at a time.
RESOURCE_POOL_LIST	The resource pools. This parameter is required when you create a tenant. You can specify only one resource pool.
DEFAULT TABLEGROUP	The default table group of the tenant. A NULL value specifies no default table group for the database.
LOCK|UNLOCK	Lock or unlock the tenant. After the tenant is locked, you cannot create sessions on the tenant. The existing sessions remain unchanged. You can lock a tenant if the subscription of the service is not renewed upon expiration. After the subscription is renewed, you can unlock the tenant.

Parameter	Description
COMMENT	The comments.
CHARACTER SET | CHARSET	The character set for the tenant.
COLLATE	The collation.
REPLICA_NUM	The number of replicas.
ZONE_LIST	The zones.
PRIMARY_ZONE	The primary zone.
READ ONLY | READ WRITE	The attribute of the tenant. Valid values: READ ONLY and READ WRITE.
LOGONLY_REPLICA_NUM	The number of log replicas.
LOCALITY	The distribution of replicas across zones. For example, the F@z1,F@z2,F@z3,R@z4 value specifies that replicas in the z1, z2, and z3 zones are FULL replicas, and replicas in the z4 zone are READONLY replicas.
system_var_name	The system variable for the tenant.

Examples

- Lock the TENANT1 tenant.

```
ALTER TENANT TENANT1 LOCK;
```

Notes

The system tenants and administrator of the current tenant have the permission to execute the ALTER TENANT statement.

17.1.4.5.10. ALTER USER

Description

You can execute the ALTER USER statement to perform the following operations:

- Change the password of a user that is used to log on to the ApsaraDB for OceanBase system.
- Lock or unlock a user. A locked user cannot log on to the ApsaraDB for OceanBase system.

> **Note**
>
> To execute the ALTER USER statement, ensure you have the global UPDATE USER permission.

Syntax

- Change the password of a user.

```
ALTER USER 'username' IDENTIFIED BY 'password';
```

- Lock a user.

```
ALTER USER user [lock_option]

lock_option:{
ACCOUNT LOCK
| ACCOUNT UNLOCK}
```

Parameters

Parameter	Description
ACCOUNT UNLOCK	Lock the user.
ACCOUNT UNLOCK	Unlock the user.

Examples

- Change a password.

Execute the following statement to change the password of the sqluser01 user to abc123:

```
ALTER USER 'sqluser01' IDENTIFIED BY 'abc123';
```

- Lock a user.

Lock the obsqluser01 user.

```
ALTER USER 'obsqluser01' ACCOUNT LOCK;
```

- Unlock a user.

Unlock the obsqluser01 user.

```
ALTER USER 'obsqluser01' ACCOUNT UNLOCK;
```

17.1.4.5.11. CREATE DATABASE

Description

You can execute the CREATE DATABASE statement to create a database. You can also specify default attributes for a database, such as the default character set and collation of the database.

Syntax

```
create_database_stmt:
    CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] database_name [database_option_list]

database_option_list:
    database_option [database_option ...]

database_option:
    [DEFAULT] {CHARACTER SET | CHARSET} [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
  | REPLICA_NUM [=] int_num
  | PRIMARY_ZONE [=] zone_name
  | {READ ONLY | READ WRITE}
  | DEFAULT TABLEGROUP [=] {NULL | table_group_name}
```

Parameters

Parameter	Description
database_name	The name of the database for which you want to modify attributes. By default, the current database is modified if you leave this parameter empty.
CHARSET charset_name	The character set that you want to modify.
COLLATE collation_name	The collation.
REPLICA_NUM int_num	The number of replicas.
PRIMARY_ZONE zone_name	The primary zone.
READ ONLY | READ WRITE	The attribute of the database. Valid values: READ ONLY and READ WRITE.
DEFAULT TABLEGROUP table_group_name	The default table group of the database. A NULL value specifies no default table group for the database.

Examples

- Create the test2 database that uses the UTF-8 character set.

```
OceanBase(admin@test)>create database test2 default CHARACTER SET UTF8;
Query OK, 1 row affected (0.00 sec)
```

- Create the test3 database in read/write mode.

```
OceanBase(admin@test)>create database test3 READ WRITE;
Query OK, 1 row affected (0.03 sec)
```

17.1.4.5.12. CREATE INDEX

Description

You can execute the CREATE INDEX statement to create an index. Indexes are created on tables to sort the values of one or more table columns. Indexes are used to reduce the query response time and performance overhead of database systems.

Syntax

```
CREATE [UNIQUE] INDEX indexname
         ON tblname (index_col_name,...)
      [index_type] [index_options]
index_type:
      USING BTREE

index_options:
      index_option [index_option…]

index_option:
    GLOBAL | LOCAL
    | COMMENT 'string'
    | COMPRESSION [=] {NONE | LZ4_1.0 | LZO_1.0 | SNAPPY_1.0 | ZLIB_1.0}
    | BLOCK_SIZE [=] size
    | STORING(columname_list)
    | VISIBLE | INVISIBLE

index_col_name:
    colname [(length)] [ASC | DESC]

columname_list:
    colname [, colname…]
```

Parameters

Parameter	Description
indexname	The name of the index that you want to create.
tblname	The name of the table to which the index belongs.
index_col_name	The name of the column on which the index is created. You can specify ASC that follows each column name. ASC indicates that the values are sorted in ascending order. DESC is not supported. By default, the values are sorted in ascending order. In the CREATE INDEX statement, the values of the first column in index_col_name are indexed. If the values in the first column are the same, the values in the next column are indexed. Similar rules apply to the other columns.
index_type	The type of the index. Set the value to USING BTREE.

Parameter	Description
UNIQUE	The unique index.
index_option	The index option. To specify multiple index options, separate them with spaces.
GLOBAL | LOCAL	Specifies whether the index is a global or local index. Default value: GLOBAL.
COMMENT	The comments.
COMPRESSION	The compression algorithm.
BLOCK_SIZE	The size of a micro-block.
STORING	Some columns are stored in the indexed table for redundant storage. This improves the system query performance.

Examples

1. Execute the following statement to create the test table:

```
CREATE TABLE test (c1 int primary key, c2 VARCHAR(10));
```

2. Execute the following statement to create indexes on the test table:

```
CREATE INDEX test_index ON test (c1, c2 DESC);
```

3. Execute the following statement to view the indexes of the test table:

```
SHOW INDEX FROM test;
```

17.1.4.5.13. CREATE OUTLINE

Description

You can execute the CREATE OUTLINE statement to create an outline. You can use an SQL text or SQL statement ID to create an outline. An SQL text indicates an original SQL statement that contains parameters.

> **Note**
>
> Before you create an outline, log on to the database for which you want to create the outline.

Syntax

- **Use an SQL text to create an outline.**

```
CREATE [OR REPLACE] OUTLINE outline_name ON stmt [ TO target_stmt ]
```

- **Use an SQL statement ID to create an outline.**

```
CREATE OUTLINE outline_name ON sql_id USING HINT  hint;
```

Parameters

Parameter	Description
outline_name	The name of the outline that you want to create.
OR REPLACE	Replace an existing outline with a new outline of the same name.
stmt	The original data manipulation language (DML) statement that contains hints and parameters.
TO target_stmt	You can leave TO target_stmt empty if the following requirements are met: The original parameterized SQL statement is equivalent to the stmt value without hints. In this case, the system generates an execution plan for the parameterized SQL statement that has the hints in stmt. To generate a fixed execution plan for a statement that contains hints, specify the original SQL statement as TO target_stmt. **Notice** Make sure TO target_stmt you specify is the same as the stmt value without hints.
sql_id	Assume that the SQL statement of the specified ID contains hints. When you create an outline, the hints you specify overwrite all existing hints in the original statement.
hint	The value must be in the /*+ xxx */ format.

Examples

- Use an SQL text to create an outline.

```
CREATE OUTLINE otl_idx_c2
       ON SELECT/*+ index(t1 idx_c2)*/ * FROM t1 WHERE c2 = 1;
```

- Use an SQL statement ID to create an outline.

```
CREATE OUTLINE otl_idx_c2
ON "ED570339F2C856BA96008A29EDF04C74"
USING HINT /*+ index(t1 idx_c2)*/ ;
```

Notes

The outline created by using an SQL text prevails and overwrites that created by using an SQL statement ID.

17.1.4.5.14. CREATE RESOURCE POOL

Description

You can execute the CREATE RESOURCE POOL statement to create a resource pool. A resource pool represents a set of resource units that can be assigned to tenants.

Syntax

```
CREATE RESOURCE POOL poolname
  UNIT [=] unitname,
  UNIT_NUM [=] unitnum,
  ZONE_LIST [=] ('zone' [, 'zone' …]) ;
```

Parameters

Parameter	Description
UNIT	The name of the resource unit that you want to create.
NIT_NUM	The number of resource units that you want to create in a zone. The value must be smaller than the number of OBServers in the zone.
ZONE_LIST	The cluster to which the resource pool that you want to create belongs.

Examples

- Create resource pool pool1 in cluster zone1.

```
OceanBase(admin@test)> CREATE RESOURCE POOL pool1 unit='unit1', unit_num=1, zone_list=('zone1');
Query OK, 0 rows affected (0.01 sec)
```

17.1.4.5.15. CREATE RESOURCE UNIT

Description

You can execute the CREATE RESOURCE UNIT statement to create a resource unit. In this statement, you can specify parameters to assign hardware resources to tenants.

Syntax

```
CREATE RESOURCE UNIT unitname
MAX_CPU [=] cpunum,
MAX_MEMORY [=] memsize,
MAX_IOPS [=] iopsnum,
MAX_DISK_SIZE [=] disksize,
MAX_SESSION_NUM [=] sessionnum,
[MIN_CPU [=] cpunum,]
[MIN_MEMORY [=] memsize,]
[MIN_IOPS [=] iopsnum] ;
```

Parameters

Parameter	Description
MAX_CPU	The maximum number of CPUs.
MAX_MEMORY	The maximum memory size. Valid values: [1073741824,+∞). The unit is bytes. The minimum value 1073741824 bytes is equivalent to 1 GB.
MAX_IOPS	The maximum IOPS. Valid values: [128,+∞).
MAX_DISK_SIZE	The maximum disk capacity. Valid values: [536870912,+∞). The unit is bytes. The minimum value 536870912 bytes is equivalent to 512 MB.
MAX_SESSION_NUM	The maximum number of sessions. Valid values: [64,+∞).
MIN_CPU	The minimum number of CPUs.
MIN_MEMORY	The minimum memory size.
MIN_IOPS	The minimum IOPS.

Examples

- Create resource unit unit1. The resource unit has one CPU, 1 GB memory, 128 IOPS, 10 GB disk capacity, and 64 sessions.

```
OceanBase(admin@test)> CREATE RESOURCE UNIT unit1 max_cpu 1, max_memory '1G', max_iops 128,max_disk_s
ize '10G', max_session_num 64, MIN_CPU=1, MIN_MEMORY= '1G', MIN_IOPS=128;
Query OK, 0 rows affected (0.02 sec)
```

- Create resource unit unit1. The resource unit has one CPU, 1 GB memory, 128 IOPS, 10 GB disk capacity, and 64 sessions.

```
OceanBase(admin@test)> CREATE RESOURCE UNIT unit1 max_cpu 1, max_memory 1073741824, max_iops 128, max
_disk_size 10737418240, max_session_num 64, MIN_CPU=1, MIN_MEMORY=1073741824, MIN_IOPS=128;
Query OK, 0 rows affected (0.01 sec)
```

17.1.4.5.16. CREATE SYNONYM

Description

You can execute the CREATE SYNONYM statement to create a synonym.

Syntax

```
CREATE [ OR REPLACE ] [ PUBLIC ]
SYNONYM [ DATABASE. ]synonym
FOR [ DATABASE. ]object;
```

Parameters

Parameter	Description
OR REPLACE	Create the synonym again if it already exists. You can use this clause to change the definition of an existing synonym.
PUBLIC	Add PUBLIC to the statement to create a public synonym. Public synonyms are accessible to all users. To use a public synonym, ensure you have appropriate permissions on the underlying object. The system uses a public synonym only if you do not specify the DataBase parameter for the object. If you do not use the PUBLIC keyword, the synonym is private and is accessible only in the current database. The name of a private synonym must be unique in the current database.
[DataBase.]synonym	DataBase specifies the database to which the current synonym belongs. If you add PUBLIC to the statement, you do not need to specify the database for the synonym. The synonym parameter specifies the name of the synonym.
[DataBase.]object	The name of the object for which the synonym is created.

Examples

- Create a synonym.

```
OceanBase(admin@test)>create table t1(c1 int);
Query OK, 0 rows affected (0.18 sec)

OceanBase(admin@test)>create synonym s1 for t1;
Query OK, 0 rows affected (0.05 sec)

OceanBase(admin@test)>insert into s1 values(1);
Query OK, 1 row affected (0.02 sec)

OceanBase(admin@test)>select * from s1;
+------+
| c1   |
+------+
|    1 |
+------+
1 row in set (0.01 sec)
```

- Create a public synonym.

```
OceanBase(admin@test)>create public synonym syn_pub for t1;
Query OK, 0 rows affected (0.03 sec)

OceanBase(admin@test)>select * from syn_pub;
+------+
| c1   |
+------+
|    1 |
+------+
1 row in set (0.01 sec)
```

Notes

To create a synonym, ensure that you have the following permissions:

- To create a private synonym for the current database, ensure that you have the CREATE SYNONYM permission.
- To create a private synonym for another database, ensure that you have the CREATE ANY SYNONYM permission.
- To create a public synonym, ensure that you have the CREATE PUBLIC SYNONYM permission.
- The object for which you want to create a synonym does not need to exist. Therefore, you do not need to have the permission to access the object.

```
Connect to the database as the syn_user user.
OceanBase(ADMIN@TEST)>CREATE USER syn_user IDENTIFIED BY syn_user;
Query OK, 0 rows affected (0.06 sec)

OceanBase(ADMIN@TEST)>grant CREATE on syn_user.* to syn_user;
Query OK, 0 rows affected (0.02 sec)

OceanBase(ADMIN@TEST)>grant SELECT on syn_user.* to syn_user;
Query OK, 0 rows affected (0.03 sec)

Connect to the database as the syn_user user.
//Failed to create a synonym.
OceanBase(SYN_USER@(none))>create synonym syn_1 for t1;
ERROR-00600: internal error code, arguments: -5036, Access denied; you need (at least one of) the CRE
ATE SYNONYM privilege(s) for this operation

Connect to the database as the syn_user user and grant the CREATE SYNONYM permission to the user.
OceanBase(ADMIN@TEST)>grant CREATE SYNONYM on *.* to syn_user;
Query OK, 0 rows affected (0.03 sec)

Connect to the database as the syn_user user.
OceanBase(SYN_USER@(none))>create synonym syn_1 for t1;
Query OK, 0 rows affected (0.05 sec)
```

17.1.4.5.17. CREATE TABLE

Description

You can execute the CREATE TABLE statement to create a table in a database.

Syntax

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] table_name
      (table_definition_list) [table_option_list] [partition_option] [AS] select;

CREATE [TEMPORARY] TABLE [IF NOT EXISTS] table_name
      LIKE table_name;

table_definition_list:
    table_definition [, table_definition ...]

table_definition:
      column_definition
    | [CONSTRAINT [constraint_name]] PRIMARY KEY index_desc
    | [CONSTRAINT [constraint_name]] UNIQUE {INDEX | KEY} [index_name] index_desc
    | {INDEX | KEY} [index_name] index_desc
    | FULLTEXT [INDEX | KEY] [index_name] fulltext_index_desc

column_definition_list:
    column_definition [, column_definition ...]

column_definition:
    column_name data_type
    [DEFAULT const_value] [AUTO_INCREMENT]
    [NULL | NOT NULL] [[PRIMARY] KEY] [UNIQUE [KEY]] comment

index_desc:
```

```
   (column_desc_list) [index_type] [index_option_list]

fulltext_index_desc:
   (column_desc_list) CTXCAT(column_desc_list) [index_option_list]

column_desc_list:
    column_desc [, column_desc ...]

column_desc:
     column_name [(length)] [ASC | DESC]

index_type:
    USING BTREE

index_option_list:
    index_option [ index_option ...]

index_option:
      [GLOBAL | LOCAL]
    | block_size
    | compression
    | STORING(column_name_list)
    | comment

table_option_list:
    table_option [ table_option ...]

table_option:
      [DEFAULT] {CHARSET | CHARACTER SET} [=] charset_name
    | [DEFAULT] COLLATE [=] collation_name

column_name_list:
    column_name [, column_name ...]

partition_name_list:
    partition_name [, partition_name ...]

partition_count | subpartition_count:
    INT_VALUE
```

Parameters

Parameter	Description
DUPLICATE_SCOPE	The attribute of the replicated table. Valid values: • none: The table is a standard table. • zone: The table is a replicated table. The replica leader must replicate transactions to all FULL (F) replicas and READONLY (R) replicas in the current zone. • region: The table is a replicated table. The replica leader must replicate transactions to all F replicas and R replicas in the current region. • cluster: The table is a replicated table. The replica leader must replicate transactions to all F replicas and R replicas in the current cluster. If you do not specify DUPLICATE_SCOPE, the default value is none.

Parameter	Description

ROW_FORMAT	Specifies whether to enable data encoding for the table.
	• redundant
	  ○ Disable data encoding.
	• compact
	  ○ Disable data encoding.
	• dynamic
	  ○ Enable data encoding.
	• compressed
	  ○ Enable data encoding.
	• default
	  ○ If you set the value to default, the dynamic mode is used.

BLOCK_SIZE	The micro-block size of the table.
COMPRESSION	The compression algorithm used by the table. Valid values: 1. none: No compression algorithms are used. 2. lz4_1.0: The lz4 compression algorithm is used. 3. zstd_1.0: The zstd compression algorithm is used. 4. snappy_1.0: The snappy compression algorithm is used.
CHARSET | CHARACTER SET	The default character set of the columns in the table. Valid values: utf8, utf8mb4, gbk, utf16, and gb18030.
COLLATE	The default comparison rules of the columns in the table. Valid values: utf8_bin, utf8_general_ci, utf8_unicode_ci, gbk_bin, gbk_chinese_ci, utf8mb4_general_ci, utf8mb4__general_cs, utf8mb4_bin, utf8mb4_unicode_ci, utf16_general_ci, utf16_bin, utf16_unicode_ci, gb18030_chinese_ci, gb18030_bin
primary_zone	The primary zone where the replica leader resides.
replica_num	The number of replicas.
table_tablegroup	The table group to which the table belongs.

Parameter	Description
AUTO_INCREMENT	The initial value of the auto-increment column in the table.
comment	The comments.
LOCALITY	A description about the distribution of replicas across zones. For example, the F@z1,F@z2,F@z3,R@z4 value specifies that replicas in the z1, z2, and z3 zones are F replicas and the replicas in the z4 zone are R replicas.
PCTFREE	The percentage of the idle space reserved in a macro-block.

Examples

- Create a table in a database.

```
CREATE TABLE test (c1 int primary key, c2 VARCHAR(50)) REPLICA_NUM = 3, PRIMARY_ZONE = 'zone1';
```

- Create a table and enable vertical partitioning for the table. The first partition contains only the c3 column. The second partition contains the c1 and c2 columns. The third partition contains the c4 and c5 columns that are not listed.

```
CREATE TABLE t1(c1 int,
                c2 int,
                c3 int,
                c4 int,
                c5 int)
                PARTITION BY CLOUMN ( c3, (c1, c2));
```

- Create a replicated table.

```
CREATE TABLE item() locality = 'F,R{all_server}@hz1, F,R{all_server}@hz2,
F,R{all_server}@hz3' DUPLICATE_SCOPE="cluster"
```

- Create a table that has an index.

```
create table t1 (c1 int primary key, c2 int, c3 int, index i1 (c2));
```

- Create an eight-partition table that uses hash partitioning.

```
create table t1 (c1 int primary key, c2 int) partition by hash(c1) partitions 8;
```

- Create a table that uses range partitioning to determine the partitions and uses key partitioning to determine the subpartitions.

```
 create table t1 (c1 int, c2 int, c3 int)
     partition by range(c1) subpartition by key(c2, c3) subpartitions 5
     (partition p0 values less than(0), partition p1 values less than(100));
```

- Create a table in which one column uses the GBK character set and the other column uses the UTF-8 character set.

```
create table t1 (c1 varchar(10),
                 c2 varchar(10) charset gbk collate gbk_bin)
  default charset utf8 collate utf8mb4_general_ci;
```

- Enable encoding, use the zstd compression algorithm, and reserve five percent of the space in a macro-block.

```
create table t1 (c1 int, c2 int, c3 varchar(64))
  compression 'zstd_1.0'
  ROW_FORMAT dynamic
  pctfree 5;
```

17.1.4.5.18. CREATE TABLEGROUP

Description

You can execute the CREATE TABLEGROUP statement to create a table group.

> **Note**
>
> Only an administrator under a tenant can create a table group.

Syntax

```
CREATE TABLEGROUP [IF NOT EXISTS] tablegroupname [opt_tablegroup_option_list] [opt_tg_partition_optio
n]

opt_tablegroup_option_list:
tablegroup_option [tablegroup_option]

tablegroup_option:
LOCALITY [=] locality_name
| PRIMARY_ZONE [=] primary_zone_name

opt_tg_partition_option:
PARTITION BY
 KEY COLUMN_NUM [tg_subpartition_option] PARTITIONS INTNUM
| HASH [tg_subpartition_option] PARTITIONS INTNUM
| RANGE [tg_subpartition_option] {PARTITION partition_name VALUES LESS THAN range_partition_expr, ...
}
| RANGE COLUMNS COLUMN_NUM [tg_subpartition_option] {PARTITION partition_name VALUES LESS THAN range_
partition_expr, ...}
| LIST [tg_subpartition_option] {PARTITION partition_name VALUES in list_partition_expr, ...}
| LIST COLUMNS COLUMN_NUM [tg_subpartition_option] {PARTITION partition_name VALUES in list_partition
_expr, ...}

tg_subpartition_option:
SUBPARTITION BY
 RANGE SUBPARTITION TEMPLATE {SUBPARTITION partition_name VALUES LESS THAN range_partition_expr, ...}
| RANGE COLUMNS COLUMN_NUM SUBPARTITION TEMPLATE {SUBPARTITION partition_name VALUES LESS THAN range_
partition_expr, ...}
| HASH [SUBPARTITIONS INTNUM]
| KEY COLUMN_NUM [SUBPARTITIONS INTNUM]
| LIST SUBPARTITION TEMPLATE {SUBPARTITION partition_name VALUES in list_partition_expr, ...}
| LIST COLUMNS COLUMN_NUM SUBPARTITION TEMPLATE {SUBPARTITION partition_name VALUES in list_partition
_expr, ...}
```

Parameters

Parameter	Description
tablegroupname	A table group name must be up to 64 characters in length and can contain letters, digits, and underscores (_). The name must start with a letter or an underscore (_) and cannot be a keyword that is reserved for ApsaraDB for OceanBase. If the specified tenant name is used and the IF NOT EXISTS option is not specified, the system returns an error.

Parameter	Description
opt_tablegroup_option_list	The partition mode, locality, and primary zone of a table group must be the same as those of the tables in the table group. You cannot modify a single table record in a table group. You can only modify a table group to modify multiple table records at a time. Tables in a table group must be in the same locality. The type, number, and locality of replicas must be the same. Tables in a table group must be in the same primary zone and have the same replica leader. The priority of the replicas is the same. Tables in a table group are partitioned in the same way. • Specify the same partitioning type for all tables. For example, partition all tables in hash-range partitioning mode. • To use key partitioning, reference the same number of columns in each table, and ensure that each table has the same number of partitions. • To use hash partitioning, ensure that each table has the same number of partitions. • To use range columns partitioning, reference the same number of columns in each table, and ensure that each table has the same number of partitions and uses the same partitioning column values. • To use range partitioning, ensure that each table has the same number of partitions and uses the same partitioning column values. • For sub-partitioning, follow the preceding rules based on the partitioning type.
opt_tg_partition_option	The partitioning rule of the table group. Use the partitioning rule that you specify when you create a table. A table group has no columns. Therefore, you do not need to specify column names for KEY, RANGE COLUMNS, and LIST COLUMNS. You only need to specify COLUMN_NUM.

Examples

- Create table group myTableGroup1.

```
OceanBase(admin@test)> CREATE TABLEGROUP myTableGroup1;
Query OK, 0 rows affected (0.07 sec)

OceanBase(admin@test)> create table myt1 (c1 int, c2 int ) tablegroup = myTableGroup1;
Query OK, 0 rows affected (0.28 sec)

OceanBase(admin@test)> create table myt2 (c1 int, c2 int ) tablegroup = myTableGroup1;
Query OK, 0 rows affected (0.26 sec)
```

- Create table group tgh and table ttgh. tgh and ttgh use hash partitioning and have the same number of partitions.

```
OceanBase(admin@test)> create tablegroup tgh locality='F,R{ALL_SERVER}@z1' partition by hash partitio
ns 10;
Query OK, 0 rows affected (0.09 sec)

OceanBase(admin@test)> create table ttgh(c1 int, c2 int) locality='F,R{ALL_SERVER}@z1' partition by h
ash(c1) partitions 10;
Query OK, 0 rows affected (0.55 sec)

OceanBase(admin@test)> create table ttgh2(c1 int, c2 int) locality='F,R{ALL_SERVER}@z1' partition by
hash(c2) partitions 10;
Query OK, 0 rows affected (0.39 sec)
```

17.1.4.5.19. CREATE TENANT

Description

You can execute the CREATE TENANT statement to create a tenant.

Syntax

```
CREATE TENANT [IF NOT EXISTS] tenantname
     [tenant_characteristic_list] [opt_set_sys_var]

tenant_characteristic_list:
tenant_characteristic [, tenant_characteristic...]

tenant_characteristic:
COMMENT 'string'
|{CHARACTER SET | CHARSET} [=] charsetname
|COLLATE [=]  collationname
|REPLICA_NUM [=] num
|ZONE_LIST [=] (zone [, zone…])
|PRIMARY_ZONE [=] zone
|DEFAULT TABLEGROUP [=] {NULL | tablegroup}
|RESOURCE_POOL_LIST [=](poolname [, poolname…])
|LOGONLY_REPLICA_NUM [=] num
|LOCALITY [=] 'locality description'

opt_set_sys_var:
{ SET | SET VARIABLES | VARIABLES } system_var_name = expr [,system_var_name = expr] ...
```

Parameters

Parameter	Description
tenant_name	The name of the tenant. The name must be a maximum of 64 bytes in length and can contain only letters, digits, and underscores (_). The name must start with a letter or an underscore (_) and cannot be a keyword that is reserved for ApsaraDB for OceanBase.
IF NOT EXISTS	If the specified tenant name is used and the IF NOT EXISTS option is added, the system returns an error.
RESOURCE_POOL_LIST	The resource pools. This parameter is required when you create a tenant. You can specify only one resource pool.
DEFAULT TABLEGROUP	The default table group of the tenant. A NULL value specifies no default table group for the database. If you do not specify this option, the default value is NULL.
COMMENT	The comments.
CHARACTER SET | CHARSET	The character set for the tenant.
COLLATE	The collation.
REPLICA_NUM	The number of replicas.
ZONE_LIST	The zones.
PRIMARY_ZONE	The primary zone.
LOGONLY_REPLICA_NUM	The number of log replicas.
LOCALITY	The distribution of replicas across zones. For example, the F@z1,F@z2,F@z3,R@z4 value specifies that replicas in the z1, z2, and z3 zones are FULL replicas, and replicas in the z4 zone are READONLY replicas.
system_var_name	The system variable of the tenant. The system variable ob_compatibility_mode specifies the compatibility mode of the tenant. You can set the tenant to be compatible with MySQL or Oracle. You can set the value only when you create a tenant. By default, the tenant is compatible with MySQL if you leave ob_compatibility_mode empty.

Examples

- Create a tenant.

```
CREATE TENANT IF NOT EXISTS t1 charset='utf8mb4', replica_num=1, zone_list=('zone1'), primary_zone='zone1', resource_pool_list=('pool1');
```

- Create a tenant that is compatible with Oracle.

```
CREATE TENANT IF NOT EXISTS t1 zone_list=('zone1'), primary_zone='zone1', resource_pool_list=('pool1') SET ob_compatibility_mode='oracle';
```

Notes

Before you execute the CREATE TENANT statement to create a tenant, connect your root user to the root tenant root@ROOT.

17.1.4.5.20. CREATE USER

Description

You can execute the CREATE USER statement to create a user in ApsaraDB for OceanBase. After a user is created, you can use the user to connect to ApsaraDB for OceanBase.

> **Note**
>
> To execute the CREATE USER statement, ensure you have the global CREATE USER permission.

Syntax

```
create_user_stmt:
    CREATE USER [IF NOT EXISTS] user_name [IDENTIFIED BY 'password'];

alter_user_stmt:
      ALTER USER user_name ACCOUNT {LOCK | UNLOCK};
    | ALTER USER user_name IDENTIFIED BY 'password';
    | SET PASSWORD [FOR user_name] = PASSWORD('password');
    | RENAME USER rename_user_action_list;

drop_user_stmt:
    DROP USER user_name_list;

rename_user_action_list:
    rename_user_action [, rename_user_action ...]

rename_user_action:
    user_name TO user_name

user_name_list:
    user_name [, user_name ...]

password:
    STR_VALUE

CREATE USER [IF NOT EXISTS] user_specification_list;

user_specification_list:
user_specification [, user_specification ...]

user_specification:
user IDENTIFIED BY 'authstring'
| user IDENTIFIED BY PASSWORD 'hashstring'
```

Parameters

Parameter	Description
user_name	The username. After a user is created, a new row is added for the user to the mysql.user table. If the username is used, the system returns an error.
IDENTIFIED BY	Set a password for the user.
user_name [, user_name ...]	To create multiple users at a time, separate them with commas (,).
user IDENTIFIED BY 'authstring'	The plaintext password. After the password is saved to the mysql.user table, the password is stored in ciphertext on the server.
user IDENTIFIED BY PASSWORD 'hashstring'	The ciphertext password.

Examples

1. Create users sqluser01 and sqluser02, and set their password to 123456.

```
CREATE USER 'sqluser01' IDENTIFIED BY '123456', 'sqluser02' IDENTIFIED BY '123456';
```

2. View the users you create.

```
SELECT user FROM mysql.user;
```

Output:

```
mysql> CREATE USER 'sqluser01' IDENTIFIED BY '123456', 'sqluser02' IDENTIFIED BY '123456';
Query OK, 0 rows affected (0.12 sec)
mysql> select user from mysql.user;
+-----------+
| user      |
+-----------+
| root      |
| admin     |
| sqluser01 |
| sqluser02 |
+-----------+
4 rows in set (0.00 sec)
```

17.1.4.5.21. CREATE VIEW

Description

You can execute the CREATE VIEW statement to create a view. If you add the OR REPLACE clause to the statement, you can execute the statement to replace an existing view.

Views are not stored as physical tables in databases. Views are generated each time you send a request to access the views. Views are created based on the outputs of the SELECT statements that are specified in the CREATE VIEW statements.

ApsaraDB for OceanBase V2.2.50 supports updatable views.

Syntax

```
create_view_stmt:
  CREATE [OR REPLACE] VIEW view_name [(column_name_list)] AS select_stmt;

column_name_list:
    column_name [, column_name ...]
```

Parameters

Parameter	Description
OR REPLACE	Create the view again if it exists. You can use this clause to change the definition of an existing view.
view_name	The name of the view.

Parameter	Description
select_stmt	The SELECT statement. This statement defines the view by selecting data from base tables or other views.
column_name_list	In views, column names must be unique. This rule for views is the same as that for base tables. By default, the column names that are returned by the SELECT statement are used as the column names for the view. To specify the column names of the view, use the optional column_name_list clause. You can use this clause to specify the column names. Separate column names with commas (,). The number of the column names in the column_name_list clause must be equal to the number of columns that are returned by the SELECT statement. The columns that are returned by the SELECT statement can be the specified table columns. The columns that are returned by the SELECT statement can also store the computing results of the expressions that use functions, constant values, or operators.

Examples

Create view v by using columns c1 and c2 in table t.

```
create or replace view v(vc1, vc2) as select c1, c2 from t;
```

17.1.4.5.22. DELETE

Description

You can execute the DELETE statement to delete rows that can satisfy specified conditions from one or more tables.

Syntax

```
Single-Table-Delete Syntax:
    DELETE [hint_options] FROM tbl_name
    [PARTITION (partition_name,...)]
    [WHERE where_condition]
    [ORDER BY order_expression_list]
    [LIMIT row_count]

Multiple-Table-Delete Syntax:
    DELETE [hint_options] tbl_name[.*] [, tbl_name[. *]] ...
    FROM table_references
    [WHERE where_condition]
Or:
    DELETE [hint_options] FROM tbl_name[.*] [, tbl_name[. *]] ...
    USING table_references
    [WHERE where_condition]

where_condition:
    expression

order_expression_list:
    order_expression [, order_expression ...]

order_expression:
    expression [ASC | DESC]

limit_row_count:
    INT_VALUE

table_references:
    {tbl_name | joined_table | table_subquery | select_with_parens} [, ...]
```

Parameters

Parameter	Description
hint_options	The hint.
tbl_name	The name of the table that you want to delete.
partition_name	The name of the table partition from which you want to delete data.
where_condition	The filter conditions. The system deletes the table rows that can satisfy the specified conditions.
order_expression_list	Sort the column values of the table from which you want to delete data. The values are sorted based on the sort keys.

Parameter	Description
row_count	The number of table rows that you want to delete. The value must be an integer.
table_references	The tables from which you want to delete data.

Examples

The following examples are based on tables t1 and t2.

```
OceanBase(admin@test)>create table t1(c1 int primary key, c2 int);
Query OK, 0 rows affected (0.16 sec)
OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |    1 |
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
4 rows in set (0.06 sec)

OceanBase(admin@test)>create table t2(c1 int primary key, c2 int) partition by key(c1) partitions 4;
Query OK, 0 rows affected (0.19 sec)
OceanBase(admin@test)>select * from t2;
+----+------+
| c1 | c2   |
+----+------+
|  5 |    5 |
|  1 |    1 |
|  2 |    2 |
|  3 |    3 |
+----+------+
4 rows in set (0.02 sec)
```

- Delete a row from a table: Delete a row where the value for the c1 column is equal to 2. The c1 column is the primary key of the t1 table.

```
OceanBase(admin@test)>DELETE FROM t1 WHERE c1 = 2;
Query OK, 1 row affected (0.02 sec)

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |    1 |
|  3 |    3 |
|  4 |    4 |
+----+------+
3 rows in set (0.01 sec)
```

- Delete a row from a table: Sort the rows in the t2 table by the c2 column, and delete the first row.

```
OceanBase(admin@test)>DELETE FROM t1 ORDER BY c2 LIMIT 1;
Query OK, 1 row affected (0.01 sec)

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
3 rows in set (0.00 sec)
```

- Delete a row from a table: Delete the p2 partition data from the t2 table.

```
OceanBase(admin@test)>DELETE FROM t2 PARTITION(p2);
Query OK, 3 rows affected (0.02 sec)

OceanBase(admin@test)>select * from t2;
+----+------+
| c1 | c2   |
+----+------+
|  5 |    5 |
+----+------+
1 row in set (0.02 sec)
```

- Delete rows from multiple tables: In the t1 and t2 tables, find the rows where the value for the c1 column in t1 is equal to that in t2, and delete the rows from t1 and t2.

```
OceanBase(admin@test)>DELETE t1, t2 FROM t1, t2 WHERE t1.c1 = t2.c1;
Query OK, 3 rows affected (0.02 sec)

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  4 |    4 |
+----+------+
1 row in set (0.01 sec)

OceanBase(admin@test)>select * from t2;
+----+------+
| c1 | c2   |
+----+------+
|  5 |    5 |
+----+------+
1 row in set (0.01 sec)
```

- Delete rows from multiple tables: In the t1 and t2 tables, find the rows where the value for the c1 column in t1 is equal to that in t2, and delete the rows from t1 and t2.

```
OceanBase(admin@test)>DELETE FROM t1, t2 USING t1, t2 WHERE t1.c1 = t2.c1;
Query OK, 4 rows affected (0.02 sec)

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  4 |    4 |
+----+------+
1 row in set (0.01 sec)

OceanBase(admin@test)>select * from t2;
Empty set (0.01 sec)
```

- Delete rows from multiple tables: In the t1 table and the p2 partition of the t2 table, find the rows where the value for the c1 column in t1 is equal to that in t2, and delete the rows from t1 and t2.

```
OceanBase(admin@test)>DELETE t2 FROM t1,t2 PARTITION(p2) WHERE t1.c1 = t2.c1;
Query OK, 3 rows affected (0.02 sec)

OceanBase(admin@test)>select * from t2;
+----+------+
| c1 | c2   |
+----+------+
|  5 |    5 |
+----+------+
1 row in set (0.01 sec)
```

- Delete a row from updatable view v.

```
OceanBase(admin@test)>create view v as select * from t1;
Query OK, 0 rows affected (0.07 sec)

OceanBase(admin@test)>delete from v where v.c1 = 1;
Query OK, 1 row affected (0.02 sec)

OceanBase(admin@test)>select * from v;
+----+------+
| c1 | c2   |
+----+------+
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
3 rows in set (0.01 sec)
```

Notes

You cannot use subqueries to delete rows from one or more tables. For example, you cannot execute the following statement:

```
delete from (select * from t1);
```

17.1.4.5.23. DROP DATABASE

Description

You can execute the DROP DATABASE statement to delete a database.

Syntax

```
drop_database_stmt:
    DROP DATABASE [IF EXISTS] database_name;
```

Parameters

Parameter	Description
IF EXISTS	Prevent errors that occur when you attempt to delete a database that does not exist.
database_name	The name of the database that you want to delete.

Examples

- Delete database test2.

```
OceanBase(admin@test)>drop database test2;
Query OK, 0 rows affected (0.03 sec)
```

- Delete database notest that does not exist.

```
OceanBase(admin@test)>drop database notest;
ERROR 1008 (HY000): Can't drop database 'notest'; database doesn't exist

OceanBase(admin@test)>drop database if exists notest;
Query OK, 0 rows affected, 1 warning (0.00 sec)

OceanBase(admin@test)>show warnings;
+-------+------+-----------------------------------------------------+
| Level | Code | Message                                             |
+-------+------+-----------------------------------------------------+
| Note  | 1008 | Can't drop database 'notest'; database doesn't exist |
+-------+------+-----------------------------------------------------+
1 row in set (0.00 sec)
```

17.1.4.5.24. DROP INDEX

Description

You can execute the DROP INDEX statement to delete an index. A large number of indexes require high maintenance overheads. We recommend that you delete the indexes that are not required.

After you execute the DROP INDEX statement to delete an index, the index cannot be immediately deleted. Wait for a period before the index is deleted.

Syntax

```
DROP INDEX indexname
     ON tblname;
```

Parameters

Parameter	Description
indexname	The name of the index.
tblname	The name of the table.

Examples

- Delete index test_index.

```
DROP INDEX test_index ON test;
```

17.1.4.5.25. DROP OUTLINE

Description

You can execute the DROP OUTLINE statement to delete an outline from an ApsaraDB for OceanBase database.

Syntax

```
DROP OUTLINE outline_name;
```

Parameters

Parameter	Description
outline_name	The name of the outline that you want to delete.

Examples

- Delete outline ol_1.

```
DROP OUTLINE ol_1;
```

17.1.4.5.26. DROP RESOURCE POOL

Description

You can execute the DROP RESOURCE POOL statement to delete a resource pool.

Syntax

```
DROP RESOURCE POOL poolname;
```

Parameters

Parameter	Description
poolname	The name of the resource pool that you want to delete.

Examples

- Delete resource pool pool1.

```
OceanBase(admin@test)> DROP RESOURCE POOL pool1;
Query OK, 0 rows affected (0.00 sec)
```

17.1.4.5.27. DROP RESOURCE UNIT

Description

You can execute the DROP RESOURCE UNIT statement to delete a resource unit.

Syntax

```
DROP RESOURCE UNIT unitname
```

Parameters

Parameter	Description
unitname	The name of the resource unit that you want to delete.

Examples

- Delete resource unit unit1.

```
OceanBase(admin@test)> DROP RESOURCE UNIT unit1;
Query OK, 0 rows affected (0.00 sec)
```

17.1.4.5.28. DROP TABLE

Description

You can execute the DROP TABLE statement to delete tables from an ApsaraDB for OceanBase database.

Syntax

```
DROP [TEMPORARY] {TABLE | TABLES} [IF EXISTS]
    table_name [,table_name]...
    [RESTRICT | CASCADE]
```

Parameters

Parameter	Description
table_name	The name of the table that you want to delete. To delete multiple tables at a time, separate the table names with commas (,).
IF EXISTS	If you add IF EXISTS to the statement and the table that you want to delete does not exist, the system does not return an error. If you do not add IF EXISTS to the statement and the table that you want to delete does not exist, the system returns an error.
TEMPORARY	Delete a temporary table.
RESTRICT | CASCADE	This parameter is required if you migrate data from other databases to ApsaraDB for OceanBase.

Examples

- Delete table test.

```
DROP TABLE IF EXISTS test;
```

17.1.4.5.29. DROP TABLEGROUP

Description

You can execute the DROP TABLEGROUP statement to delete a table group.

Syntax

```
DROP TABLEGROUP [IF EXISTS] tablegroupname
```

Parameters

Parameter	Description
tablegroupname	The name of the table group. Assume that the table group that you want to delete does not exist. If you do not use the IF EXISTS clause, the system returns an error.

Examples

Delete table group myTableGroup1.

```
OceanBase(admin@test)> DROP TABLEGROUP myTableGroup1;
```

17.1.4.5.30. DROP TENANT

Description

You can execute the DROP TENANT statement to delete a tenant from the ApsaraDB for OceanBase system.

Syntax

```
drop_tenant_stmt:
    DROP TENANT [IF EXISTS] tenant_name;
```

Parameters

Parameter	Description
tenant_name	The name of the tenant that you want to delete. Only a locked tenant can be deleted. If you execute this statement to delete an unlocked tenant, the system returns an error.

Examples

- Delete tenant TENANT1.

```
DROP TENANT TENANT1;
```

Notes

Before you execute the DROP TENANT statement to delete a tenant, connect your root user to the root tenant root@ROOT.

17.1.4.5.31. DROP SYNONYM

Description

You can execute the DROP SYNONYM statement to delete a synonym.

Syntax

```
DROP [PUBLIC] SYNONYM [ DATABASE. ]synonym;
```

Parameters

- PUBLIC

  Delete a public synonym. If you do not use PUBLIC, a private synonym is deleted.

- [DATABASE.]synonym

  The database to which the current synonym belongs. If you add PUBLIC to the statement, you do not need to specify the database for the synonym. synonym specifies the name of the synonym.

Examples

- Delete a synonym.

```
OceanBase(admin@test)>drop synonym test.s1;
Query OK, 0 rows affected (0.03 sec)
```

- Delete a public synonym.

```
OceanBase(admin@test)>drop public synonym syn_pub;
Query OK, 0 rows affected (0.02 sec)
```

Notes

Notice

- To delete a private synonym, ensure that the synonym belongs to the specified database and you have the DROP ANY SYNONYM permission.
- To delete a public synonym, ensure that you have the DROP PUBLIC SYNONYM permission.
- To delete a public synonym, make sure that you add PUBLIC to the statement and do not specify the database.

17.1.4.5.32. DROP USER

Description

You can execute the DROP USER statement to delete one or more users from ApsaraDB for OceanBase.

Note

- To execute the DROP USER statement, ensure that you have the global permission to execute the CREATE USER statement.
- You cannot execute a DELETE statement to manage permissions on the mysql.user table.
- After a user is deleted, all permissions of the user are removed.

Syntax

```
DROP USER username [, username...] ;
```

Parameters

Parameter	Description
username	The username. To delete multiple users at a time, separate the usernames with commas (,).

Examples

Run the following command to delete user sqluser02:

```
oceanBase(admin@TEST)>drop user sqluser02;
Query OK, 0 rows affected (0.02 sec)
```

17.1.4.5.33. DROP VIEW

Description

You can execute the DROP VIEW statement to delete one or more views.

> **Note**
>
> Before you execute this statement, ensure you have the global DROP permission.

Syntax

```
drop_view_stmt:
    DROP VIEW [IF EXISTS] view_name_list [CASCADE | RESTRICT];

view_name_list:
    view_name [, view_name_list]
```

Parameters

Parameter	Description
IF EXISTS	If you add IF EXISTS to the statement and the specified views do not exist, the system does not return an error.
view_name_list	If some views you specify in view_name_list do not exist, the system may return an error. However, the system still deletes the views that exist.
CASCADE | RESTRICT	CASCADE and RESTRICT are parsed and ignored.

Examples

Execute the following statements to delete views v1 and v2: Assume that v1 or v2 does not exist. If you execute the first statement, the system returns an error.

```
drop view v1, v2;

drop view if exists v1, v2;
```

17.1.4.5.34. EXPLAIN

Description

You can execute the EXPLAIN statement to query the execution plans for SQL statements. EXPLAIN supports the SELECT, DELETE, INSERT, REPLACE, and UPDATE statements.

Syntax

```
Query a table or a column:
{EXPLAIN | DESCRIBE | DESC} tbl_name [col_name | wild]

Query the execution plan for an SQL statement:
{EXPLAIN | DESCRIBE | DESC}
[BASIC | OUTLINE | EXTENDED | EXTENDED_NOADDR | PARTITIONS | FORMAT = {TRADITIONAL| JSON}]
{SELECT statement | DELETE statement | INSERT statement | REPLACE statement| UPDATE statement}
```

Parameters

Parameter	Description
tbl_name	The name of the table.
col_name	The name of the table column.
BASIC	Query the basic information about the execution plan, such as the operator IDs, the operator names, and the names of the tables that are referenced.
OUTLINE	Query the information about the execution plan, including the outline.
EXTENDED	Query the additional information generated by the EXPLAIN statement. The information includes the input and output columns of each operator, the partitions of the referenced tables, and the specified filter conditions. If the current operator uses an index, the system returns the index columns and query range.
EXTENDED_NOADDR	Display the additional information in a clear way.
PARTITIONS	Query the partition information.
FORMAT = {TRADITIONAL| JSON}	The output format of the EXPLAIN statement. Valid values: • TRADITIONAL: displays the output in a tabular format. • JSON: displays the output in a JSON string that contains key-value pairs. The output information includes the additional information and partition information.

Examples

- **Leave the parameters that specify the output type empty.**

```
OceanBase(admin@test)>explain select * from t1,t2 where t1.c2=t2.c2 and t2.c1 > 4\G
*************************** 1. row ***************************
Query Plan: ========================================
|ID|OPERATOR   |NAME|EST. ROWS|COST   |
----------------------------------------
|0 |HASH JOIN  |    |9801000  |5933109|
|1 | TABLE SCAN|t2  |10000    |6219   |
|2 | TABLE SCAN|t1  |100000   |68478  |
========================================

Outputs & filters:
-------------------------------------
  0 - output([t1.c1], [t1.c2], [t2.c1], [t2.c2]), filter(nil),
      equal_conds([t1.c2 = t2.c2]), other_conds(nil)
  1 - output([t2.c2], [t2.c1]), filter(nil),
      access([t2.c2], [t2.c1]), partitions(p0)
  2 - output([t1.c2], [t1.c1]), filter(nil),
      access([t1.c2], [t1.c1]), partitions(p0)
```

- **EXTENDED**

```
OceanBase(admin@test)>explain extended_noaddr select * from t1,t2 where t1.c2=t2.c2 and t2.c1 > 4\G
*************************** 1. row ***************************
Query Plan: ========================================
|ID|OPERATOR   |NAME|EST. ROWS|COST   |
----------------------------------------
|0 |HASH JOIN  |    |9801000  |5933109|
|1 | TABLE SCAN|t2  |10000    |6219   |
|2 | TABLE SCAN|t1  |100000   |68478  |
========================================

Outputs & filters:
-------------------------------------
  0 - output([t1.c1], [t1.c2], [t2.c1], [t2.c2]), filter(nil),
      equal_conds([t1.c2 = t2.c2]), other_conds(nil)
  1 - output([t2.c2], [t2.c1]), filter(nil),
      access([t2.c2], [t2.c1]), partitions(p0),
      is_index_back=false,
      range_key([t2.c1]), range(4 ; MAX),
      range_cond([t2.c1 > 4])
  2 - output([t1.c2], [t1.c1]), filter(nil),
      access([t1.c2], [t1.c1]), partitions(p0),
      is_index_back=false,
      range_key([t1.__pk_increment], [t1.__pk_cluster_id], [t1.__pk_partition_id]), range(MIN,MIN,MIN
; MAX,MAX,MAX)always true
```

- **TRADITIONAL format**

```
OceanBase(admin@test)>explain format=TRADITIONAL select * from t1,t2 where t1.c2=t2.c2 and t2.c1 > 4\
G
*************************** 1. row ***************************
Query Plan: ========================================
|ID|OPERATOR   |NAME|EST. ROWS|COST   |
----------------------------------------
|0 |HASH JOIN  |    |9801000  |5933109|
|1 | TABLE SCAN|t2  |10000    |6219   |
|2 | TABLE SCAN|t1  |100000   |68478  |
========================================

Outputs & filters:
-------------------------------------
  0 - output([t1.c1], [t1.c2], [t2.c1], [t2.c2]), filter(nil),
      equal_conds([t1.c2 = t2.c2]), other_conds(nil)
  1 - output([t2.c2], [t2.c1]), filter(nil),
      access([t2.c2], [t2.c1]), partitions(p0)
  2 - output([t1.c2], [t1.c1]), filter(nil),
      access([t1.c2], [t1.c1]), partitions(p0)
```

- **JSON format**

```
OceanBase(admin@test)>explain format=JSON select * from t1,t2 where t1.c2=t2.c2 and t2.c1 > 4\G
*************************** 1. row ***************************
Query Plan: {
  "ID":2,
  "OPERATOR":"JOIN",
  "NAME":"JOIN",
  "EST.ROWS":9800999,
  "COST":5933108,
  "output": [
    "t1.c1",
    "t1.c2",
    "t2.c1",
    "t2.c2"
  ],
  "TABLE SCAN": {
    "ID":0,
    "OPERATOR":"TABLE SCAN",
    "NAME":"TABLE SCAN",
    "EST.ROWS":10000,
    "COST":6218,
    "output": [
      "t2.c2",
      "t2.c1"
    ]
  },
  "TABLE SCAN": {
    "ID":1,
    "OPERATOR":"TABLE SCAN",
    "NAME":"TABLE SCAN",
    "EST.ROWS":100000,
    "COST":68477,
    "output": [
      "t1.c2",
      "t1.c1"
    ]
  }
}
```

Each row in the output of the EXPLAIN statement contains the following columns.

Column	Description
ID	The sequential number of the execution plan.
OPERATOR	The operator in the execution plan.
NAME	The table referenced by the operator.
EST.ROWS	The estimated number of rows in the output of the operator.
COST	The CPU time consumed by the operator.

17.1.4.5.35. FLASHBACK DATABASE

Description

You can execute the FLASHBACK DATABASE statement to restore a deleted database from the recycle bin.

Prerequisites

The recycle bin is enabled. You can execute the following statement to check whether the recycle bin is enabled:

```
show variables like 'recyclebin';
```

```
OceanBase(admin@test)> show variables like 'recyclebin';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| recyclebin    | ON    |
+---------------+-------+
1 row in set (0.00 sec)
```

If the recycle bin is disabled, you can execute the following statement to enable it:

```
set recyclebin = on;
```

Databases in the recycle bin are not deleted from the system and still consume resources. To delete them from the system, execute the following statement:

```
purge recyclebin;
```

Syntax

```
 FLASHBACK DATABASE object_name TO BEFORE DROP [RENAME TO db_name];
```

Parameters

Parameter	Description
object_name	The name of the object that you want to restore. You cannot specify a database name. If you restore a database, the tables and indexes in the database are also restored.
RENAME to	Rename the database that you want to restore.

Examples

- Restore a deleted database from the recycle bin.

```
OceanBase(admin@test)> create database da;
Query OK, 1 row affected (0.03 sec)

OceanBase(admin@test)> drop database da;
Query OK, 0 rows affected (0.04 sec)

OceanBase(admin@test)> show recyclebin;
+-------------------------------------------------+---------------+----------+---------------------
------+
| OBJECT_NAME                                     | ORIGINAL_NAME | TYPE     | CREATETIME
|
+-------------------------------------------------+---------------+----------+---------------------
------+
| __recycle_$_1_1099511628829_18446744073709551615 | da            | DATABASE | 2017-10-20 17:36:15.8
38771 |
+-------------------------------------------------+---------------+----------+---------------------
------+
1 row in set (0.02 sec)

OceanBase(admin@test)> flashback database __recycle_$_1_1099511628829_18446744073709551615 to before
drop;
Query OK, 0 rows affected (0.03 sec)
```

17.1.4.5.36. FLASHBACK TABLE

Description

You can execute the FLASHBACK TABLE statement to restore a deleted table from the recycle bin.

Prerequisites

The recycle bin is enabled. You can execute the following statement to check whether the recycle bin is enabled:

```
show variables like 'recyclebin';
```

```
OceanBase(admin@test)> show variables like 'recyclebin';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| recyclebin    | ON    |
+---------------+-------+
1 row in set (0.00 sec)
```

If the recycle bin is disabled, you can execute the following statement to enable it:

```
set recyclebin = on;
```

Tables in the recycle bin are not deleted from the database and still consume resources. To delete them from the database, execute the following statement:

```
purge recyclebin;
```

Syntax

```
 FLASHBACK TABLE object_name TO BEFORE DROP [RENAME to db_name.table_name];
```

Parameters

Parameter	Description
object_name	The name of the object or table that you want to restore. Before you execute FLASHBACK TABLE to restore a table, log on to the database where the table is stored. When you restore a table, the index of the table is also restored.
RENAME to	Rename the table and database to which the table belongs.

Examples

- Restore deleted table t from the recycle bin.

```
OceanBase(admin@test)> create table t(id int primary key, k int);
Query OK, 0 rows affected (0.04 sec)

OceanBase(admin@test)> insert into t values(1,1);
Query OK, 1 row affected (0.00 sec)

OceanBase(admin@test)> select * from t;
+----+------+
| id | k    |
+----+------+
|  1 |    1 |
+----+------+
1 row in set (0.00 sec)

OceanBase(admin@test)> drop table t;
Query OK, 0 rows affected (0.01 sec)

OceanBase(admin@test)> select * from t;
ERROR 1146 (42S02): Table 'test.t' does not exist
OceanBase(admin@test)> show recyclebin;
+--------------------------------+---------------+-------+----------------------------+
| OBJECT_NAME                    | ORIGINAL_NAME | TYPE  | CREATETIME                 |
+--------------------------------+---------------+-------+----------------------------+
| __recycle_$_1_1597028971700936 | t             | TABLE | 2020-08-10 11:09:31.701033 |
+--------------------------------+---------------+-------+----------------------------+
1 row in set (0.00 sec)

OceanBase(admin@test)> flashback table t to before drop;
Query OK, 0 rows affected (0.01 sec)

OceanBase(admin@test)> select * from t;
+----+------+
| id | k    |
+----+------+
|  1 |    1 |
+----+------+
1 row in set (0.00 sec)
```

17.1.4.5.37. GRANT

Description

You can execute the GRANT statement to grant permissions to a user as a system administrator.

> **Note**
>
> - Before you grant permissions to a user, ensure that you have the permissions. For example, to grant User 2 the SELECT permission on Table 1 as User 1, ensure that User 1 has the permission to be granted and the GRANT OPTION permission. Otherwise, you cannot grant the permission to User 2.
> - After you grant a permission to a user, the user must log on to the ApsaraDB for OceanBase system again to ensure that the permission takes effect.

Syntax

```
GRANT priv_type
       ON priv_level
       TO user_specification [, user_specification]...
     [WITH with_option ...]

privilege_type:
      ALTER
    | CREATE
    | CREATE USER
    | CREATE VIEW
    | DELETE
    | DROP
    | GRANT OPTION
    | INDEX
    | INSERT
    | PROCESS
    | SELECT
    | SHOW DATABASES
    | SHOW VIEW
    | SUPER
    | UPDATE
    | USAGE
    | CREATE SYNONYM

priv_level:
     *
    | *.*
    | db_name.*
    | db_name.tbl_name
    | tbl_name
    | db_name.rountine_name

user_specification:
user [IDENTIFIED BY [PASSWORD] 'Password']

with_option:
 GRANT OPTION
```

Parameters

Parameter	Description
priv_type	The permission to be granted. For more information, see the Permissions table in the following description. To grant multiple permissions to a user at a time, separate the permissions with commas (,).
priv_level	The level of the permission to be granted. Permissions can be divided into the following levels: • Global level: The permissions apply to all the databases. Use GRANT ALL ON *.* to grant global permissions. • Database level: The permissions apply to all the objects in the specified database. Use GRANT ALL ON db_name.* to assign database-level permissions. • Table level: The permissions apply to all the columns in the specified table. Use GRANT ALL ON db_name.tbl_name to assign table-level permissions. You can use an asterisk (*) instead of specifying a table name to assign permissions on all tables in the specified database.
user_specification	Grant permissions to the specified user. If the specified user does not exist, the system can create a user. If sql_mode is set to no_auto_create_user and you do not specify a password by using IDENTIFIED BY, the system does not automatically create a user. To grant permissions to multiple users at a time, separate the usernames with commas (,).
user IDENTIFIED BY 'Password'	Specifies a plaintext password.
user IDENTIFIED BY PASSWORD 'Password'	Specifies a ciphertext password.
with_option	Specifies whether to allow authorized users to grant permissions to other users.

The following table lists the permissions that can be assigned.

Permissions

Permission	Description
ALL PRIVILEGES	All permissions except GRANT OPTION.
ALTER	The permission to execute the ALTER TABLE statement.

Permission	Description
CREATE	The permission to execute the CREATE TABLE statement.
CREATE USER	The permission to execute the CREATE USER, DROP USER, RENAME USER, and REVOKE ALL PRIVILEGES statements.
CREATE TABLEGROUP	The global permission to execute the CREATE TABLEGROUP statement.
DELETE	The permission to execute the DELETE statement.
DROP	The permission to execute the DROP statement.
GRANT OPTION	The permission to execute the GRANT OPTION statement.
INSERT	The permission to execute the INSERT statement.
SELECT	The permission to execute the SELECT statement.
UPDATE	The permission to execute the UPDATE statement.
SUPER	The permission to execute the SET GLOBAL statement to modify global system parameters.
SHOW DATABASES	The global permission to execute the SHOW DATABASES statement.
INDEX	The permission to execute the CREATE INDEX and DROP INDEX statements.
CREATE VIEW	The permission to create or delete a view.
SHOW VIEW	The permission to execute the SHOW CREATE VIEW statement.
CREATE SYNONYM	The permission to create a synonym.

Note

The permission to execute the CHANGE EFFECTIVE TENANT statement is not limited. Therefore, all users under the system tenant can grant this permission to other users.

Examples

- Run the following command to grant ALL PRIVILEGES to the obsqluser01 user:

```
OceanBase(admin@TEST)>GRANT ALL PRIVILEGES ON *. * TO obsqluser01 with grant option;
Query OK, 0 rows affected (0.03 sec)
```

17.1.4.5.38. INSERT

Description

You can execute the INSERT statement to add one or more records to a table.

Syntax

```
INSERT [IGNORE] [INTO]
       single_table_insert
       [ON DUPLICATE KEY UPDATE update_asgn_list]

single_table_insert:
    {dml_table_name values_clause
     | dml_table_name '(' ')' values_clause
     | dml_table_name '(' column_list ')' values_clause
     | dml_table_name SET update_asgn_list}

dml_table_name:
    tbl_name [PARTITION (partition_name,...)]

values_clause:
     {{VALUES | VALUE} ({expr | DEFAULT},...) [, ...]
      | select_stmt}

column_list
    column_name [, ...]

update_asgn_list:
     column_name = expr [, ...]
```

Parameters

If you execute the INSERT...ON DUPLICATE KEY UPDATE... statement, the number of affected rows is calculated based on the following rules:

- If you do not specify the CLIENT_FOUND_ROWS flag in client_capabilities, the number of affected rows is calculated based on the following rules:
  - If a new row is inserted, one row is affected.
  - If an inserted row conflicts with an existing row in the table and the data in the table remains the same after the update, no row is affected. If the data in the table before the update is different from that after the update, two rows are affected.
- If you specify the CLIENT_FOUND_ROWS flag, the number of affected rows is calculated based on the following rules:
  - If a new row is inserted, one row is affected.
  - If the data in the table remains the same after the update, one row is affected.
  - If the data in the table before the update is different from that after the update, two rows are affected.
- If you do not specify the CLIENT_FOUND_ROWS flag, the number of affected rows equals the number of

updated rows. If you specify the CLIENT_FOUND_ROWS flag, the number of affected rows equals the number of touched rows that conflict with existing rows. The data in the touched rows may not be modified.

Parameter	Description
IGNORE	Ignore the errors that occur when the INSERT statement is executed.
column_list	The columns to insert. Separate multiple columns with commas (,).
tbl_name	The name of the table to insert.
partition_name	The partition name of the table to insert.
update_asgn_list	Assign values to the column. For example, c1 = 2.
ON DUPLICATE KEY UPDATE	Specifies whether to update duplicate primary key or unique key values. Assume that a value you insert conflicts with an existing primary key or unique key value. In this case, if you have added ON DUPLICATE KEY UPDATE to the statement, the new value overwrites the existing value. If you do not add ON DUPLICATE KEY UPDATE, the system returns an error when duplicate primary key or unique key values exist.

Examples

The following examples are based on tables t1 and t2.

```
OceanBase(admin@test)>create table t1(c1 int primary key, c2 int) partition by key(c1) partitions 4;
Query OK, 0 rows affected (0.16 sec)

OceanBase(admin@test)>create table t2(c1 int primary key, c2 int);
Query OK, 0 rows affected (0.16 sec)
OceanBase(admin@test)>select * from t2;
+----+------+
| c1 | c2   |
+----+------+
|  1 |    1 |
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
4 rows in set (0.06 sec)
```

- Insert a row into table t1.

```
OceanBase(admin@test)>insert into t1 values(1,1);
Query OK, 1 row affected (0.01 sec)

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |    1 |
+----+------+
1 row in set (0.04 sec)
```

- Insert multiple rows into table t1.

```
OceanBase(admin@test)>insert t1 values(1,1),(2,default),(2+2,3*4);
Query OK, 3 rows affected (0.02 sec)
Records: 3  Duplicates: 0  Warnings: 0

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |    1 |
|  2 | NULL |
|  4 |   12 |
+----+------+
3 rows in set (0.02 sec)
```

- Insert a row into partition p0 in table t1.

```
OceanBase(admin@test)>insert into t1 partition(p0) (c1) values(5);
Query OK, 1 row affected (0.02 sec)
OceanBase(admin@test)>select * from t1 partition(p0);
+----+------+
| c1 | c2   |
+----+------+
|  5 | NULL |
+----+------+
1 row in set (0.01 sec)
```

- Insert the query results from table t2 into table t1.

```
OceanBase(admin@test)>insert into t1 select * from t2;
Query OK, 4 rows affected (0.02 sec)
Records: 4  Duplicates: 0  Warnings: 0

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |    1 |
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
4 rows in set (0.01 sec)
```

- Insert data into table t1 and add ON DUPLICATE KEY UPDATE to the statement to update duplicate primary key

values.

```
OceanBase(admin@test)>insert into t1 values(1,1),(1,2) ON DUPLICATE KEY UPDATE c1=100;
Query OK, 3 rows affected (0.01 sec)
Records: 2  Duplicates: 1  Warnings: 0

OceanBase(admin@test)>select * from t1;
+-----+------+
| c1  | c2   |
+-----+------+
| 100 |    1 |
+-----+------+
1 row in set (0.02 sec)
```

- Insert data into updatable view v.

```
OceanBase(admin@test)>create view v as select * from t1;
Query OK, 0 rows affected (0.07 sec)
OceanBase(admin@test)>insert into v values(1,1);
Query OK, 1 row affected (0.01 sec)

OceanBase(admin@test)>select * from v;
+----+------+
| c1 | c2   |
+----+------+
|  1 |    1 |
+----+------+
1 row in set (0.02 sec)
```

Notes

You cannot use subqueries in the INSERT statement to insert rows. For example, you cannot execute the following statement:

```
insert into (select * from t1) values(1, 1);
```

17.1.4.5.39. KILL

Description

You can execute the KILL statement to close a session.

> **Note**
>
> If you have the PROCESS permission, you can view all sessions. If you have the SUPER permission, you can close all sessions and statements. If you do not have the PROCESS or SUPER permission, you can view or close only your own sessions and statements.

Syntax

```
KILL [CONNECTION | QUERY] 'sessionid'
```

Parameters

Parameter	Description
KILL CONNECTION	This statement performs the same operation as a KILL statement that does not contain a modifier. This statement closes the connection that is associated with the specified *sessionid*.
KILL QUERY	Stop the execution of statements that are being executed in the connection, but leaves the connection intact.

Examples

Stop the execution of the statement that is being executed in session 3221638213, and then close the session.

```
OceanBase(admin@test)>show processlist;
+------------+-------+--------------------+------+---------+------+--------+------------------+
| Id         | User  | Host               | db   | Command | Time | State  | Info             |
+------------+-------+--------------------+------+---------+------+--------+------------------+
| 3221638212 | admin | 1.11.111.127:11161 | test | Query   |    0 | ACTIVE | show processlist |
| 3221638213 | admin | 1.11.111.127:11161 | test | Query   |    0 | ACTIVE | select "abcedfg" |
+------------+-------+--------------------+------+---------+------+--------+------------------+
1 row in set (0.03 sec)

OceanBase(admin@test)>kill query 3221638213;
Query OK, 0 rows affected (0.01 sec)

OceanBase(admin@test)>kill 3221638212;
Query OK, 0 rows affected (0.01 sec)
```

17.1.4.5.40. PURGE DATABASE

Description

You can execute the PURGE DATABASE statement to delete a database from the recycle bin.

Syntax

```
PURGE DATABASE object_name;
```

Parameters

Parameter	Description
object_name	The name of the object in the recycle bin. After an object is moved to the recycle bin, the system renames the object.

Examples

- Delete database __recycle_$_1_1597384386029184 from the recycle bin.

```
OceanBase(admin@test)> create database db1;
Query OK, 1 row affected (0.03 sec)

OceanBase(admin@test)> drop database db1;
Query OK, 0 rows affected (0.04 sec)

OceanBase(admin@test)> show recyclebin;
+--------------------------------+---------------+----------+----------------------------+
| OBJECT_NAME                    | ORIGINAL_NAME | TYPE     | CREATETIME                 |
+--------------------------------+---------------+----------+----------------------------+
| __recycle_$_1_1597384386029184 | db1           | DATABASE | 2020-08-14 13:53:06.029367 |
+--------------------------------+---------------+----------+----------------------------+
1 row in set (0.01 sec)

OceanBase(admin@test)> purge database __recycle_$_1_1597384386029184;
Query OK, 0 rows affected (0.03 sec)

OceanBase(admin@test)> show recyclebin;
```

17.1.4.5.41. PURGE INDEX

Description

You can execute the PURGE INDEX statement to delete an indexed table from the recycle bin.

Syntax

```
PURGE INDEX object_name;
```

Parameters

Parameter	Description
object_name	The name of the object in the recycle bin. After an object is moved to the recycle bin, the system renames the object.

Examples

- Delete indexed table __recycle_$_1_1597387726700872 from the recycle bin.

```
OceanBase(admin@test)> create table t1(c1 int);
Query OK, 0 rows affected (0.09 sec)

OceanBase(admin@test)> create index idx on t1(c1);
Query OK, 0 rows affected (0.48 sec)

OceanBase(admin@test)> drop table t1;
Query OK, 0 rows affected (0.03 sec)

OceanBase(admin@test)> show recyclebin;
+--------------------------------+----------------------------+-------+----------------------------+
| OBJECT_NAME                    | ORIGINAL_NAME              | TYPE  | CREATETIME                 |
+--------------------------------+----------------------------+-------+----------------------------+
| __recycle_$_1_1597387726700872 | __idx_1101710651081557_idx | INDEX | 2020-08-14 14:48:46.699145 |
| __recycle_$_1_1597387726712976 | t1                         | TABLE | 2020-08-14 14:48:46.712643 |
+--------------------------------+----------------------------+-------+----------------------------+
5 rows in set (0.01 sec)

OceanBase(admin@test)> purge index __recycle_$_1_1597387726700872;
Query OK, 0 rows affected (0.04 sec)
```

17.1.4.5.42. PURGE RECYCLEBIN

Description

You can execute the PURGE RECYCLEBIN statement to empty the recycle bin as the root user.

> **Notice**
>
> The PURGE RECYCLEBIN statement clears all objects in the recycle bin. You can execute this statement only as the root user. Proceed with caution.

Syntax

```
PURGE RECYCLEBIN;
```

Parameters

None.

Examples

- Empty the recycle bin as the root user.

```
OceanBase(admin@test)> purge recyclebin;
Query OK, 0 rows affected (0.03 sec)
```

17.1.4.5.43. PURGE TABLE

Description

You can execute the PURGE TABLE statement to delete a table from the recycle bin.

Syntax

```
PURGE TABLE object_name;
```

Parameters

Parameter	Description
object_name	The name of the object in the recycle bin. After an object is moved to the recycle bin, the system renames the object.

Examples

- Delete table __recycle_$_1_1099511628776_1099511677778 from the recycle bin.

```
OceanBase(admin@test)> create table test(c1 int);
Query OK, 0 rows affected (0.16 sec)

OceanBase(admin@test)> drop table test;
Query OK, 0 rows affected (0.03 sec)

OceanBase(admin@test)> show recyclebin;
+-------------------------------------------+---------------+-------+----------------------------+
| OBJECT_NAME                               | ORIGINAL_NAME | TYPE  | CREATETIME                 |
+-------------------------------------------+---------------+-------+----------------------------+
| __recycle_$_1_1099511628776_1099511677778 | test          | TABLE | 2017-10-20 17:40:22.304025 |
+-------------------------------------------+---------------+-------+----------------------------+
1 row in set (0.02 sec)

OceanBase(admin@test)> purge table __recycle_$_1_1099511628776_1099511677778;
Query OK, 0 rows affected (0.04 sec)
```

17.1.4.5.44. RENAME TABLE

Description

You can execute the RENAME TABLE statement to rename one or more tables.

Syntax

```
RENAME TABLE tblname TO newtblname
     [, tblname2 TO newtblname …] ;
```

Parameters

Parameter	Description
tblname	The name of the original table.
newtblname	The name of the new table.

Parameter	Description
tblname TO newtblname [, tb1name2 TO newtblname ...] ;	To rename multiple tables at a time, separate the table names with commas (,).

Notes

- After you execute the RENAME TABLE statement, the specified tables are automatically renamed. When the tables are being renamed, other threads cannot read data from the tables.
- If you execute this statement to rename multiple tables, the tables are renamed in the left-to-right order.
- To execute the RENAME TABLE statement, ensure that no tables are locked or involved in active transactions. To execute the RENAME TABLE statement, ensure that you have the ALTER and DROP permissions on the original table and the CREATE and INSERT permissions on the new table.
- You can execute the RENAME TABLE statement to rename views.

Examples

1. Create tables t1 and t2.

```
create table t1(c1 int);

create table t2(c1 int);
```

2. Rename table t1 to t11.

```
rename table t1 to t11;
```

3. Rename table t11 to t111 and table t2 to t22.

```
rename table t11 to t111, t2 to t22;
```

4. Rename table t111 to t1111, and then rename table t1111 to t1.

```
rename table t111 to t1111, t1111 to t1;
```

17.1.4.5.45. RENAME USER

Description

You can execute the RENAME USER statement to change the username that is used to log on to the ApsaraDB for OceanBase system.

> **Note**
>
> To execute this statement, ensure you have the global CREATE USER permission.

Syntax

```
RENAME USER
'oldusername' TO 'newusername'
[,'oldusername' TO 'newusername'...] ;
```

Parameters

Parameter	Description
oldusername	The old username.
newusername	The new username. The name must be a maximum of 16 bytes in length.
'oldusername' TO 'newusername'	Changes the username. To change multiple usernames at a time, separate them with commas (,). After you change the username, the permissions of the user remain unchanged.

Examples

1. Before you change a username, execute the following statement to view users:

```
SELECT user FROM mysql.user;
```

Output:

```
mysql> SELECT user FROM mysql.user;
+-----------+
| user      |
+-----------+
| root      |
| admin     |
| sqluser01 |
| sqluser02 |
+-----------+
4 rows in set (0.00 sec)
```

2. Execute the following statement to change username sqluser01 to obsqluser01.

```
RENAME USER 'sqluser01' TO 'obsqluser01';
```

3. After you change the username, execute the following statement to view users:

```
SELECT user FROM mysql.user;
```

Output: Username sqluser01 is changed to obsqluser01.

```
mysql> RENAME USER 'sqluser01' TO 'obsqluser01';
Query OK, 0 rows affected (0.04 sec)

mysql> SELECT user FROM mysql.user;
+-------------+
| user        |
+-------------+
| root        |
| admin       |
| obsqluser01 |
| sqluser02   |
+-------------+
4 rows in set (0.00 sec)
```

17.1.4.5.46. REPLACE

Description

You can execute the REPLACE statement to replace one or more records in a table. If an old record has the same value as a new record in a primary or unique key column, the old record is deleted before the new record is inserted.

Syntax

```
replace_stmt:
    REPLACE [INTO] table_factor [PARTITION (partition_name_list)] [(column_name_list)]
    {VALUES | VALUE} column_value_lists;

partition_name_list:
        partition_name [, partition_name ...]

column_name_list:
    column_name [, column_name ...]

column_value_lists:
        (column_value_list) [, (column_value_list) ...]

column_value_list:
    column_value [, column_value ...]

column_value:
    {expression | DEFAULT}
```

Parameters

Parameter	Description
table_factor	The name of the table in which you want to replace records.
column_name_list	The columns in which you want to replace data.

Parameter	Description
partition_name_list	The table partitions in which you want to replace records.

Examples

The following statement defines a table named test. All the examples in this topic are based on the test table.

```
OceanBase(admin@test)>create table test (c1 int primary key, c2 varchar(40));
Query OK, 0 rows affected (0.23 sec)
```

1. Replace the value in row 1 in the test table with 'hello alibaba' and replace the value in row 2 with 'hello ob'.

```
OceanBase(admin@test)>REPLACE INTO test VALUES (1, 'hello alibaba'),(2, 'hello ob');
Query OK, 2 rows affected (0.01 sec)
Records: 2  Duplicates: 0  Warnings: 0
```

2. Query row 1 and row 2 in the test table.

```
OceanBase(admin@test)>SELECT * FROM test;
+----+---------------+
| c1 | c2            |
+----+---------------+
|  1 | hello alibaba |
|  2 | hello ob      |
+----+---------------+
2 rows in set (0.00 sec)
```

3. Replace the value in row 3 in the test table with 'hello alibaba' and replace the value in row 2 with 'hello oceanbase'.

```
OceanBase(admin@test)>REPLACE INTO test VALUES (3, 'hello alibaba'),(2, 'hello oceanbase');
Query OK, 3 rows affected (0.00 sec)
Records: 2  Duplicates: 1  Warnings: 0
```

4. Query row 1, row 2, and row 3 in the test table.

```
OceanBase(admin@test)>SELECT * FROM test;
+----+-----------------+
| c1 | c2              |
+----+-----------------+
|  1 | hello alibaba   |
|  2 | hello oceanbase |
|  3 | hello alibaba   |
+----+-----------------+
3 rows in set (0.00 sec)
```

17.1.4.5.47. REVOKE

Description

You can execute the REVOKE statement to revoke permissions from users as a system administrator.

Notes:

- To revoke permissions from a user, ensure that you have the permissions to be revoked. For example, to revoke the SELECT permission on Table 1 from User 2 as User 1, ensure that User 1 has this permission and the GRANT OPTION permission.
- To revoke the ALL PRIVILEGES or GRANT OPTION permission, ensure that you have the global permission to execute the GRANT OPTION statement or the UPDATE and DELETE permissions on the permission table.
- Revocations do not have cascading effects. Assume that User 1 has granted permissions to User 2. If you revoke permissions from User 1, the permissions are not revoked from User 2.

Syntax

```
REVOKE priv_type
         ON database.tblname
         FROM 'username';

privilege_type:
      ALTER
    | CREATE
    | CREATE USER
    | CREATE VIEW
    | DELETE
    | DROP
    | GRANT OPTION
    | INDEX
    | INSERT
    | PROCESS
    | SELECT
    | SHOW DATABASES
    | SHOW VIEW
    | SUPER
    | UPDATE
    | USAGE
```

Parameters

Parameter	Description
priv_type	The permission that you want to revoke. For more information, see the Permissions table in the following description. To revoke multiple permissions from a user, separate the permissions with commas (,).
database.tblname	The table in the database. To revoke permissions on all tables in the database, use an asterisk (*) to replace database or *table_name*.
username	The user from which the permissions are revoked. To revoke permissions from multiple users at a time, separate the usernames with commas (,).

The following table lists the permissions that can be revoked.

Permissions

Permission	Description
ALL PRIVILEGES	All permissions except GRANT OPTION.
ALTER	The permission to execute the ALTER TABLE statement.
CREATE	The permission to execute the CREATE TABLE statement.
CREATE USER	The permission to execute the CREATE USER, DROP USER, RENAME USER, and REVOKE ALL PRIVILEGES statements.
CREATE TABLEGROUP	The global permission to execute the CREATE TABLEGROUP statement.
DELETE	The permission to execute the DELETE statement.
DROP	The permission to execute the DROP statement.
GRANT OPTION	The permission to execute the GRANT OPTION statement.
INSERT	The permission to execute the INSERT statement.
SELECT	The permission to execute the SELECT statement.
UPDATE	The permission to execute the UPDATE statement.
SUPER	The permission to execute the SET GLOBAL statement to modify global system parameters.
SHOW DATABASES	The global permission to execute the SHOW DATABASES statement.
INDEX	The permission to execute the CREATE INDEX and DROP INDEX statements.
CREATE VIEW	The permission to create or delete a view.
SHOW VIEW	The permission to execute the SHOW CREATE VIEW statement.
CREATE SYNONYM	The permission to create a synonym.

> **Note**
>
> The permission to execute the CHANGE EFFECTIVE TENANT statement is not limited. Therefore, all users under the system tenant can revoke this permission from other users.

Examples

Run the following command to revoke all permissions from the obsqluser01 user:

```
OceanBase(admin@TEST)>REVOKE ALL PRIVILEGES, GRANT OPTION FROM 'obsqluser01';
Query OK, 0 rows affected (0.03 sec)
```

17.1.4.5.48. SAVEPOINT

Description

You can execute the SAVEPOINT statement to perform a partial rollback of a transaction.

Syntax

1. Create a savepoint:

```
SAVEPOINT spname
```

2. Roll back to a savepoint:

```
ROLLBACK [WORK] to [SAVEPOINT] spname
```

3. Delete a savepoint:

```
RELEASE SAVEPOINT spname
```

Parameters

- spname: specifies the name of the savepoint. Savepoints are unique within a transaction. If the specified name of a savepoint already exists, the new savepoint overwrites the existing savepoint. After a savepoint is created, the transaction can be rolled back to the savepoint. You can also execute the `ROLLBACK` statement to roll back the entire transaction.

Examples

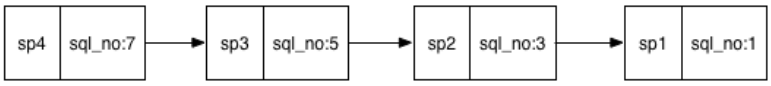
Assume that a transaction has executed the following statements:

sql_no	Statement	Partition
1	update...	p1, p4
	savepoint sp1	
2	update...	p2, p4

sql_no	Statement	Partition
3	update...	p3, p5
	savepoint sp2	
4	update...	p1, p3, p6
5	update...	p1, p5
	savepoint sp3	
6	select...	
7	update...	p5, p6
	savepoint sp4	

Record a savepoint

You can create savepoints before you submit transactions. You must connect the transaction savepoints into a linked list based on the order in which the savepoints are created. The preceding transaction contains seven SQL statements and four savepoints. The following figure shows the linked list of savepoints, where each node records a mapping from the spname to the sql_no.



List of transaction participants

To roll back all changes after an SQL statement is executed in a transaction, the participants and sql_no of each statement must be recorded. The preceding transaction executes seven SQL statements and involves six partitions from p1 to p6.

p1	p2	p3	p4	p5	p6
1,4,5	2	2,3,4	1,2	3,5,7	4,7

Roll back to a savepoint

1. Find the sql_no that corresponds to the spname based on the savepoint linked list.

Assume that you have executed the `ROLLBACK to SAVEPOINT sp2` statement. In the linked list of savepoints, sp2 corresponds to sql_no:3.

2. Find the partitions that correspond to the sql_no based on the list of transaction participants.

The query result shows that the statements whose sql_no values are greater than 3 involve partitions p1, p3, p5, and p6.

3. Roll back the data in partitions

The scheduler initiates a rollback request to the partitions obtained in Step 2. All changes caused by the transaction after sp2 are rolled back in these partitions. Some changes caused by this transaction in p1, p3, and p5 are rolled back, and all changes in p6 are rolled back.

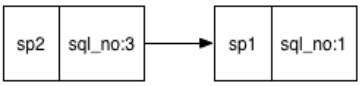
4. Update the transaction participant list

ApsaraDB for OceanBase modifies the transaction participant list and deletes the information about operations that have sql_no greater than 3 from the transaction participant list. p6 is deleted from the transaction participant list because all changes in p6 are rolled back.

p1	p2	p3	p4	p5	p6
1	2	2, 3	1, 2	3	

5. Delete an invalid savepoint

After you execute the `ROLLBACK to SAVEPOINT sp2` statement, the system deletes savepoints sp3 and sp4. In this case, you cannot roll back to sp3 or sp4.



17.1.4.5.49. SCHEMA

You can execute statements that include `SCHEMA` in the same way as you execute the statements that include `DATABASE`. For more information, see the descriptions about the CREATE DATABASE, ALTER DATABASE, and DROP DATABASE statements.

17.1.4.5.50. SELECT

The syntax of SELECT statements is complex. This topic describes the syntax of simple SELECT statements and the SELECT statements that contain set operators.

SIMPLE SELECT

Description

You can execute a simple SELECT statement to query table data.

Syntax

```
simple_select:
SELECT [/*+ hint statement */] [ALL | DISTINCT | UNIQUE | SQL_CALC_FOUND_ROWS]
 select_expr_list FROM from_list [WHERE condition]
  [GROUP BY group_expression_list [WITH ROLLUP] [HAVING condition]]
  [ORDER BY order_expression_list]
  [limit_clause]
  [FOR UPDATE]

select_expr:
 table_name.*
  | table_alias_name.*
  | expr [[AS] column_alias_name]

from_list:
    table_reference [, table_reference ...]

table_reference:
      simple_table
    | joined_table

simple_table:
    table_factor [partition_option] [[AS] table_alias_name]
    | (select_stmt) [AS] table_alias_name
    | (table_reference_list)

joined_table:
      table_reference [INNER] JOIN simple_table [join_condition]
    | table_reference outer_join_type JOIN simple_table join_condition

partition_option:
    PARTITION (partition_name_list)

partition_name_list:
    partition_name [, partition_name ...]

outer_join_type:
    {LEFT | RIGHT | FULL} [OUTER]

join_condition:
    ON expression

condition:
    expression

group_expression_list:
    group_expression [, group_expression ...]

group_expression:
    expression [ASC | DESC]

order_expression_list:
    order_expression [, order_expression ...]

order_expression:
    expression [ASC | DESC]

limit_clause:
  LIMIT {[offset,] row_count |row_count OFFSET offset}
```

Parameters

Parameter	Description
ALL | DISTINCT | UNIQUE | SQL_CALC_FOUND_ROWS	Specifies whether to return distinct table rows. A database table may contain duplicate values. • If you add DISTINCT to the statement, only distinct rows are returned in the query results. • If you add ALL to the statement, all the matched rows are returned. • If you add SQL_CALC_FOUND_ROWS to the statement, only the number of rows is returned. • If you do not add ALL, DISTINCT, UNIQUE, or SQL_CALC_FOUND_ROWS to the statement, the default setting ALL is used.
select_expr	The expressions or column names to query. To specify multiple expressions or column names, separate them with commas (,). You can use an asterisk (*) to indicate that all the columns are queried.
AS othername	Rename the output fields.
FROM table_references	The tables from which data is queried. You can query data from multiple tables.
WHERE where_conditions	The filter conditions. The query results contain the data that can satisfy the filter conditions. This clause is optional. where_conditions specifies an expression.
GROUP BY group_by_list	Divide data into groups.
HAVING search_confitions	The filter conditions. HAVING clauses are similar to WHERE clauses. The difference between HAVING and WHERE clauses is that you can use aggregate functions in HAVING clauses, such as SUM and AVG.
ORDER BY order_list order_list : colname [ASC | DESC] [,colname [ASC | DESC]...]	Display the query results in ascending or descending order. ASC indicates the ascending order and DESC indicates the descending order. If you do not specify the order, the default order ASC is used.

Parameter	Description
[LIMIT {[offset,] row_count |row_count OFFSET offset}]	Limit the number of rows that are returned by the SELECT statement. You can specify one or two arguments of the numeric data type for the LIMIT clause. The arguments must be integer constants. • If you specify two arguments, the first argument specifies the offset for the first row to be returned and the second argument specifies the maximum number of rows to be returned. The initial offset for the first row is 0 instead of 1. • If you specify only one argument, the argument specifies the maximum number of rows to be returned and the offset is 0.
FOR UPDATE	Apply an exclusive lock on each row of the query results. This prevents other transactions from concurrently updating the rows. This also prevents other transactions from concurrently reading the rows for which some transaction isolation levels are specified.
PARTITION(partition_list)	The partition information of the specified tables. For example, partition(p0,p1...).

Examples

The following examples are based on table a.

Table a

id	name	num
1	a	100
2	b	200
3	a	50

- Query the name column from table a.

```
SELECT name FROM a;
```

```
+------+
| name |
+------+
| a    |
| b    |
| a    |
+------+
3 rows in set (0.01 sec)
```

- Return the distinct rows for the name column.

```
SELECT DISTINCT name FROM a;
```

```
+------+
| name |
+------+
| a    |
| b    |
+------+
2 rows in set (0.01 sec)
```

- In table a, query the id, name, and num columns, divide the num column values by 2, and return the calculation result of the num column in a column named avg.

```
SELECT id, name, num/2 AS avg FROM a;
```

```
+------+------+------+
| id   | name | avg  |
+------+------+------+
|    1 | a    |   50 |
|    2 | b    |  100 |
|    3 | a    |   25 |
+------+------+------+
3 rows in set (0.00 sec)
```

- In table a, find the 'a' value for the name column, and return the values for the id, name, and num columns.

```
SELECT id, name, num FROM a WHERE name = 'a';
```

```
+------+------+------+
| id   | name | num  |
+------+------+------+
|    1 | a    |  100 |
|    3 | a    |   50 |
+------+------+------+
2 rows in set (0.01 sec)
```

- In table a, query the id and name columns, group the num column values by name, and return the sum of the num column values.

```
SELECT id, name, SUM(num) FROM a GROUP BY name;
```

```
+------+------+----------+
| id   | name | SUM(num) |
+------+------+----------+
|    1 | a    |      150 |
|    2 | b    |      200 |
+------+------+----------+
2 rows in set (0.00 sec)
```

- In table a, query the id and name columns, group the num column values by name, and calculate the sum of the num column values. Then, return the sum value that is less than 160.

```
SELECT id, name, SUM(num) as sum FROM a GROUP BY name HAVING SUM(num) < 160;
```

```
+------+------+------+
| id   | name | sum  |
+------+------+------+
|    1 | a    |  150 |
+------+------+------+
1 row in set (0.01 sec)
```

- In table a, query the id, name, and num columns, and sort and return the result set by the num column in ascending order.

```
SELECT * FROM a ORDER BY num ASC;
```

```
+------+------+------+
| id   | name | num  |
+------+------+------+
|    3 | a    |   50 |
|    1 | a    |  100 |
|    2 | b    |  200 |
+------+------+------+
3 rows in set (0.00 sec)
```

- In table a, query the id, name, and num columns, and sort and return the result set by the num column in descending order.

```
SELECT * FROM a ORDER BY num DESC;
```

- In table a, query the id, name, and num columns, and use the LIMIT clause to return two rows that start from the second row.

```
SELECT * FROM a LIMIT 1,2;
```

```
+------+------+------+
| id   | name | num  |
+------+------+------+
|    2 | b    |  200 |
|    3 | a    |   50 |
+------+------+------+
2 rows in set (0.00 sec)
```

SELECT statements that contain set operators

Description

You can execute the SELECT statement that contains the UNION, MINUS, or INTERSECT operator to combine query results.

Syntax

```
select_clause_set:
    simple_select [ UNION | UNION ALL | EXCEPT | INTERSECT] select_clause_set_left
  [ORDER BY sort_list_columns] [limit_clause]
select_clause_set_right:
    simple_select |
  select_caluse_set
```

Parameters

Parameter	Description
UNION ALL	Combine the results of two queries and return all rows.
UNION	Combine the results of two queries and return distinct rows.
EXCEPT	Return the distinct rows in the left query that are not selected by the right query.
INTERSECT	Return the distinct rows that are selected by the left and right queries.

Examples

The following examples are based on tables t1 and t2.

```
create table t1 (c1 int, c2 int);
create table t2 (c1 int, c2 int);
insert into t1 values (1, -1), (2, -2);
insert into t2 values (1, 1), (2, -2), (3, 3);
```

- Query all rows from t1 and t2.

```
SELECT C1, C2 FROM T1 UNION ALL SELECT C1, C2 FROM T2;
+------+------+
| C1   | C2   |
+------+------+
|    1 |   -1 |
|    2 |   -2 |
|    1 |    1 |
|    2 |   -2 |
|    3 |    3 |
+------+------+
```

- Query all distinct rows from t1 and t2.

```
SELECT C1, C2 FROM T1 UNION SELECT C1, C2 FROM T2;
+------+------+
| C1   | C2   |
+------+------+
|    1 |   -1 |
|    2 |   -2 |
|    1 |    1 |
|    3 |    3 |
+------+------+
```

- Query the rows that exist in t1 and t2.

```
SELECT C1, C2 FROM T1 INTERSECT SELECT C1, C2 FROM T2;
+------+------+
| C1   | C2   |
+------+------+
|    2 |   -2 |
+------+------+
```

- Query the rows that exist in t1 but do not exist in t2.

```
SELECT C1, C2 FROM T1 EXCEPT SELECT C1, C2 FROM T2;
+------+------+
| C1   | C2   |
+------+------+
|    1 |   -1 |
+------+------+
```

- Query all the distinct rows from t1 and t2, and return the first two rows ordered by the c2 column in descending order.

```
SELECT C1, C2 FROM T1 UNION SELECT C1, C2 FROM T2 ORDER BY C2 DESC LIMIT 2;
+------+------+
| C1   | C2   |
+------+------+
|    3 |    3 |
|    1 |    1 |
+------+------+
```

17.1.4.5.51. SESSION

Description

You can execute the SESSION statement to close a session.

Syntax

```
session_stmt:
    KILL [CONNECTION] session_id;

session_id:
    INT_VALUE
```

Parameters

Parameter	Description
session_id	The ID of the session that you want to close.

Examples

- Close sessions 3221502221 and 3221750376.

```
OceanBase(admin@test)>show processlist;
+------------+-------+--------------------+------+---------+------+--------+-----------------------
----------+
| Id         | User  | Host               | db   | Command | Time | State  | Info
|
+------------+-------+--------------------+------+---------+------+--------+-----------------------
----------+
| 3221502221 | admin | 100.xx.xx.xx:44775 | test | Sleep   |   10 | SLEEP  | NULL
|
| 3221502083 | admin | 100.xx.xx.xx:44720 | test | Query   |    0 | ACTIVE | show processlist
|
| 3221502317 | NULL  | 100.xx.xx.xx:41414 | test | Query   |    0 | ACTIVE | REMOTE/DISTRIBUTE PLAN
EXECUTING |
| 3221750377 | NULL  | 100.xx.xx.xx:41414 | test | Query   |    0 | ACTIVE | REMOTE/DISTRIBUTE PLAN
EXECUTING |
| 3221750376 | admin | 100.xx.xx.xx:43783 | test | Sleep   |    4 | SLEEP  | NULL
|
+------------+-------+--------------------+------+---------+------+--------+-----------------------
----------+
5 rows in set (0.04 sec)

OceanBase(admin@test)>kill 3221502221;
Query OK, 0 rows affected (0.00 sec)

OceanBase(admin@test)>kill connection 3221750376;
Query OK, 0 rows affected (0.05 sec)
```

17.1.4.5.52. SET PASSWORD

Description

You can execute the SET PASSWORD statement to change the password for the current user or another user.

Syntax

```
SET PASSWORD [FOR user] = password_option;

password_option: {
PASSWORD('authstring')
|'hashstring'
}
```

Parameters

Parameter	Description
FOR user	If you do not use the FOR user clause, the statement changes the password for the current user. After a user logs on to the ApsaraDB for OceanBase system, the user can change its own password. If you use the FOR user clause, the statement changes the password for a specified user. To change the password for a specified user, ensure that you have the global permission to execute the CREATE USER statement.

Examples

Run the following command to change the password of the sqluser01 user to abc123:

```
oceanBase(admin@TEST)>set password for sqluser01 = password('abc123');
Query OK, 0 rows affected (0.02 sec)
```

17.1.4.5.53. SHOW GRANTS

Description

You can execute the SHOW GRANTS statement to view user permissions as a system administrator.

Syntax

```
SHOW GRANTS [FOR username];
```

Parameters

Parameter	Description
FOR username	If you do not specify the username, this statement returns the permissions that have been granted to the current user. You can view the permissions of the current user. To view the permissions of another specified user, ensure you have the SELECT permission on the mysql.user table.

Examples

View the permissions of the obsqluser01 user.

```
oceanBase(admin@TEST)>show grants for obsqluser01;
+-------------------------------------+
| Grants for obsqluser01@%            |
+-------------------------------------+
| GRANT USAGE ON *. * TO 'obsqluser01' |
+-------------------------------------+
1 row in set (0.02 sec)
```

17.1.4.5.54. SHOW RECYCLEBIN

Description

You can execute the SHOW RECYCLEBIN statement to view objects in the recycle bin.

Syntax

```
 SHOW RECYCLEBIN;
```

Parameters

None.

Examples

- View objects in the recycle bin.

```
OceanBase(admin@test)> create table t1(c1 int);
Query OK, 0 rows affected (0.24 sec)

OceanBase(admin@test)> drop table t1;
Query OK, 0 rows affected (0.07 sec)

OceanBase(admin@test)> show recyclebin;
+-------------------------------------------+---------------+-------+----------------------------+
| OBJECT_NAME                               | ORIGINAL_NAME | TYPE  | CREATETIME                 |
+-------------------------------------------+---------------+-------+----------------------------+
| __recycle_$_1_1099511628776_1099511677777 | t1            | TABLE | 2017-10-20 17:27:40.881506 |
+-------------------------------------------+---------------+-------+----------------------------+
1 row in set (0.02 sec)
```

17.1.4.5.55. TRANSACTION

Description

You can execute the TRANSACTION statement to start a transaction.

A database transaction is a single logical unit of work that consists of a collection of operations. Transaction processing ensures that SQL operations in a batch are all executed or are not executed at all. You can use transactions to maintain the data integrity of databases.

An explicit transaction is a user-defined or user-specified transaction. An explicit transaction is a transaction that starts with the BEGIN TRANSACTION, BEGIN, or BEGIN WORK statement and ends with the COMMIT or ROLLBACK statement. BEGIN and BEGIN WORK are supported as aliases of the START TRANSACTION statement.

Syntax

```
transaction_stmt:
      START TRANSACTION [READ ONLY | READ WRITE];
    | BEGIN [WORK];
    | COMMIT [WORK];
    | ROLLBACK [WORK];
    | SET TRANSACTION {READ ONLY | READ WRITE};
```

Parameters

Parameter	Description
START TRANSACTION [READ ONLY | READ WRITE]	Start a transaction. After a transaction is started, the SQL statements that follow the START TRANSACTION statement, such as INSERT, UPDATE, and DELETE, take effect only when the transaction is explicitly committed. The READ ONLY clause specifies that the transaction is started in read-only mode. This prevents you from modifying the transaction after the transaction is started. The READ WRITE clause specifies that the transaction is started in read/write mode. By default, the read/write mode is used.

Parameter	Description
BEGIN	BEGIN and BEGIN WORK are supported as aliases of the START TRANSACTION statement.
COMMIT	Commit the current transaction.
ROLLBACK	Roll back the current transaction.
SET TRANSACTION {READ ONLY | READ WRITE}	Set the current transaction mode. Valid values: READ ONLY and READ WRITE.

Examples

Assume that table a is created, as shown in the following table.

id	name	num	sell_date
1	a	100	2013-06-21 10:06:43
2	b	200	2013-06-21 13:07:21
3	a	50	2013-06-21 13:08:15

1. Run the following commands in sequence to start a transaction. The transaction completes the following operations: Find the row where the value for the id column is 3, change the value for the name column to c, and then insert a row that contains a sale record of product a.

```
OceanBase(admin@test)> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

OceanBase(admin@test)> UPDATE a SET name = 'c' WHERE id = 3;
Query OK, 1 rows affected (0.00 sec)

OceanBase(admin@test)> INSERT INTO a VALUES (4, 'a', 30, '2013-06-21 16:09:13');
Query OK, 1 rows affected (0.00 sec)

OceanBase(admin@test)> COMMIT;
Query OK, 0 rows affected (0.00 sec)
```

2. After you commit the transaction, run the following command to view table a:

```
SELECT * FROM a;
```

Return result:

id	name	num	sell_date
1	a	100	2013-06-21 10:06:43
2	b	200	2013-06-21 13:07:21
3	c	50	2013-06-21 13:08:15
4	a	30	2013-06-21 16:09:13

> **Notice**
>
> Before you commit a transaction, you can check whether the operations in the transaction have taken effect. For example, you can insert **SELECT * FROM a;** before you execute the COMMIT statement. The session within which this transaction is executed can read the updated result. A session outside this transaction cannot read the updated result. Before the transaction is committed, your previous operations are invisible outside the transaction session. To roll back a transaction, replace COMMIT with ROLLBACK.

17.1.4.5.56. TRUNCATE TABLE

Description

You can execute the TRUNCATE TABLE statement to delete all data in a specified table and retain the table schema, including the partition information of the table. The TRUNCATE TABLE statement implements the same logic as the DELETE FROM statement. You can use DELETE FROM to delete all rows. To execute the TRUNCATE TABLE statement, ensure that you have the permissions to create and delete tables. The TRUNCATE TABLE statement is a Data Definition Language (DDL) statement.

The TRUNCATE TABLE and DELETE FROM statements have the following differences:

- The TRUNCATE TABLE statement deletes and creates the table again, whereas the DELETE FROM statement deletes rows one after another. Therefore, The response time for the TRUNCATE TABLE statement is shorter than that for the DELETE FROM statement.
- The output of the TRUNCATE TABLE statement shows that the number of affected rows is always 0.
- If you execute the TRUNCATE TABLE statement, each auto-incremented value is reset to the start value. The table manager does not store the latest auto-incremented value.
- You cannot execute the TRUNCATE TABLE statement when a transaction is being processed or the table is locked. If you execute the statement in these scenarios, the system returns errors.
- If the file that defines the table is valid, you can execute the TRUNCATE TABLE statement to create the table again as an empty table. This applies even if the data or the index file is corrupted.

Syntax

```
TRUNCATE [TABLE] table_name;
```

Parameters

Parameter	Description
table_name	The name of the table.

Examples

Remove all records from the tb1 table.

```
TRUNCATE [TABLE] tb1;
```

17.1.4.5.57. UPDATE

Description

You can execute the UPDATE statement to change field values in a table.

Syntax

```
UPDATE [IGNORE] table_references
    SET update_asgn_list
    [WHERE where_condition]
    [ORDER BY order_list]
    [LIMIT row_count];

table_references:
    tbl_name [PARTITION (partition_name,...)] [, ...]

update_asgn_list:
    column_name = expr [, ...]

order_list:
    column_name [ASC|DESC] [, column_name [ASC|DESC]…]
```

Parameters

Parameter	Description
IGNORE	Ignore the errors that occur when the INSERT statement is being executed.
table_references	The name of the table that you want to update. To update multiple tables at a time, separate the table names with commas (,).
where_condition	The filter conditions.
row_count	The maximum number of rows that can be updated.

Parameter	Description
tbl_name	The name of the table.
partition_name	The name of the partition.
column_name	The name of the column.
column_name ASC	Sort the table by values in a specified column in ascending order and then update the table.
column_name DESC	Sort the table by values in a specified column in descending order and then update the table.

Notes

You cannot execute the UPDATE statement on the output value of a subquery. This rule applies regardless of the number of tables that you want to update. For example, this statement is not allowed:

`update (select * from t1) set c1 = 100;` .

Examples

1. Create sample tables t1 and t2.

```
OceanBase(admin@test)>create table t1(c1 int primary key, c2 int);
Query OK, 0 rows affected (0.16 sec)
OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |    1 |
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
4 rows in set (0.06 sec)

OceanBase(admin@test)>create table t2(c1 int primary key, c2 int) partition by key(c1) partitions 4;
Query OK, 0 rows affected (0.19 sec)
OceanBase(admin@test)>select * from t2;
+----+------+
| c1 | c2   |
+----+------+
|  5 |    5 |
|  1 |    1 |
|  2 |    2 |
|  3 |    3 |
+----+------+
4 rows in set (0.02 sec)
```

2. In the t1 table, find the row that matches the t1.c1 = 1 condition, and change the value at the intersection of this row and the c2 column to 100.

```
OceanBase(admin@test)>update t1 set t1.c2 = 100 where t1.c1 = 1;
Query OK, 1 row affected (0.02 sec)
Rows matched: 1  Changed: 1  Warnings: 0

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |  100 |
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
4 rows in set (0.01 sec)
```

3. Sort the t1 table by the values in column c2, and change the first two values in column c2 to 100.

```
OceanBase(admin@test)>update t1 set t1.c2 = 100 order by c2 limit 2;
Query OK, 2 rows affected (0.02 sec)
Rows matched: 2  Changed: 2  Warnings: 0

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |  100 |
|  2 |  100 |
|  3 |    3 |
|  4 |    4 |
+----+------+
4 rows in set (0.01 sec)
```

4. In the p2 partition of the t2 table, find the row that matches the t2.c1 > 2 condition. Then, change the value at the intersection of this row and the c2 column to 100.

```
OceanBase(admin@test)>update t2 partition(p2) set t2.c2 = 100 where t2.c1 > 2;
Query OK, 1 row affected (0.02 sec)
Rows matched: 1  Changed: 1  Warnings: 0

OceanBase(admin@test)>select * from t2;
+----+------+
| c1 | c2   |
+----+------+
|  5 |    5 |
|  1 |    1 |
|  2 |    2 |
|  3 |  100 |
+----+------+
4 rows in set (0.06 sec)
```

5. Update multiple tables. In the t1 and t2 tables, find the rows that match the t1.c1 = t2.c1 condition. Change the value at the intersection of the matching row in the t1 table and the c2 column to 100. Change the value at the intersection of the matching row in the t2 table and the c2 column to 200.

```
OceanBase(admin@test)>update t1,t2 set t1.c2 = 100, t2.c2 = 200 where t1.c2 = t2.c2;
Query OK, 6 rows affected (0.03 sec)
Rows matched: 6  Changed: 6  Warnings: 0

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |  100 |
|  2 |  100 |
|  3 |  100 |
|  4 |    4 |
+----+------+
4 rows in set (0.00 sec)

OceanBase(admin@test)>select * from t2;
+----+------+
| c1 | c2   |
+----+------+
|  5 |    5 |
|  1 |  200 |
|  2 |  200 |
|  3 |  200 |
+----+------+
4 rows in set (0.01 sec)
```

6. Update multiple tables. In the p2 partition in the t1 and t2 tables, find the rows that match the t1.c1 = t2.c1 condition. Change the value at the intersection of the matching row in the t1 table and the c2 column to 100. Change the value at the intersection of the matching row in the t2 table and the c2 column to 200.

```
OceanBase(admin@test)>update t1,t2 partition(p2) set t1.c2 = 100, t2.c2 = 200 where t1.c2 = t2.c2;
Query OK, 6 rows affected (0.02 sec)
Rows matched: 6  Changed: 6  Warnings: 0

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |  100 |
|  2 |  100 |
|  3 |  100 |
|  4 |    4 |
+----+------+
4 rows in set (0.01 sec)

OceanBase(admin@test)>select * from t2;
+----+------+
| c1 | c2   |
+----+------+
|  5 |    5 |
|  1 |  200 |
|  2 |  200 |
|  3 |  200 |
+----+------+
4 rows in set (0.01 sec)
```

7. Update the values in updatable view v.

```
OceanBase(admin@test)>create view v as select * from t1;
Query OK, 0 rows affected (0.07 sec)

OceanBase(admin@test)>update v set v.c2 = 100 where v.c1 = 1;
Query OK, 1 row affected (0.02 sec)
Rows matched: 1  Changed: 1  Warnings: 0

OceanBase(admin@test)>select * from v;
+----+------+
| c1 | c2   |
+----+------+
|  1 |  100 |
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
4 rows in set (0.01 sec)
```

17.1.5. SQL Reference (Oracle Mode)

17.1.5.1. Compatibility with Oracle

ApsaraDB for OceanBase supports most of the basic SQL syntax in Oracle. This indicates that when your business is transferred from Oracle to ApsaraDB for OceanBase, you do not need to spend a large amount of time learning new syntax. In addition, your business can be smoothly migrated from Oracle to ApsaraDB for OceanBase.

For optimization and development reasons, ApsaraDB for OceanBase does not support some features or the effect of some features in ApsaraDB for OceanBase is different from that in Oracle. This document describes the compatibility between ApsaraDB for OceanBase and Oracle by topic.

SQL syntax

- ApsaraDB for OceanBase supports the basic SQL syntax in Oracle.
- If some features are unavailable, the system reports errors that indicate that the syntax is not supported. For example, when hierarchical queries include multi-table joins, the system reports the errors.
- ApsaraDB for OceanBase does not support some complex online analytical processing (OLAP) syntax of Oracle, such as pattern matching, `PIVOT`, and `UNPIVOT` functions, polymorphic table functions, and frequent itemset computing.

SQL data types

- Oracle supports 24 data types. ApsaraDB for OceanBase supports 18 data types. For more information, see Built-in data types.
- For the optimization reason, the `LONG` and `LONG RAW` data types are obsolete. Therefore, ApsaraDB for OceanBase does not support these two data types.
- In ApsaraDB for OceanBase, a large object data type stores a maximum of 48 MB data and the performance is low. Therefore, we recommend that you do not use large object data types in complex scenarios. For more information, see Large object data types.

Character sets and collations

- ApsaraDB for OceanBase supports the UTF-8, GBK, GB18030, and national character set.
- ApsaraDB for OceanBase supports only case-sensitive collations.

- ApsaraDB for OceanBase does not support the collations of multilingual semantics.

Built-in functions

Oracle supports 117 built-in functions. ApsaraDB for OceanBase supports 103 built-in functions. For more information, see Functions.

System views

- Oracle supports more than 400 dictionary views. ApsaraDB for OceanBase is compatible with 17 of the 400 dictionary views.
  - ALL_CONS_COLUMNS
  - ALL_CONSTRAINTS
  - ALL_IND_COLUMNS
  - ALL_INDEX
  - ALL_OBJECTS
  - ALL_PART_KEY_COLUMNS
  - ALL_PART_TABLES
  - ALL_SEQUENCE
  - ALL_SOURCE
  - ALL_SUBPART_KEY_COLUMNS
  - ALL_SYNONYMS
  - ALL_TAB_COLUMNS
  - ALL_TAB_PARTITIONS
  - ALL_TABLES
  - ALL_TYPES
  - ALL_USERS
  - ALL_VIEWS
- Oracle supports more than 700 performance views. ApsaraDB for OceanBase is compatible with 3 of the 700 performance views.
  - V$SYSTEM_EVENT
  - V$SESSION_WAIT
  - V$NLS_PARAMETERS

SQL features

ApsaraDB for OceanBase supports the following core SQL features in Oracle:

- Plan cache
- Outline binding
- Plan management evolution
- Cost-based optimizer
- Cost-based rewriting
- Prepared statements
- Global indexes
- Function-based indexes

Foreign keys

- ApsaraDB for OceanBase supports foreign keys.
- In ApsaraDB for OceanBase, you cannot add the following foreign key constraints: `DISABLE` and `ENABLE`.
- In ApsaraDB for OceanBase, you cannot add foreign key constraints in `ALTER TABLR` statements.
- ApsaraDB for OceanBase does not support `SET NULL` in cascade clauses.

Triggers

- ApsaraDB for OceanBase supports only row-level triggers.
- In ApsaraDB for OceanBase, you can create triggers on only tables. You cannot create triggers on views.
- In ApsaraDB for OceanBase, you cannot perform the `DISABLE` or `ENABLE` operation on triggers.

Database links

- ApsaraDB for OceanBase does not support database links.

Synonyms

In ApsaraDB for OceanBase, you can create synonyms for objects, such as tables, views, synonyms, and sequences. You can also create public synonyms.

Updatable views

ApsaraDB for OceanBase does not support the `WITH CHECK OPTION` clauses.

Constraints

- ApsaraDB for OceanBase supports the `CHECK`, `UNIQUE`, and `NOT NULL` constraints.
- ApsaraDB for OceanBase does not support the `DISABLE` operation on the `UNIQUE` constraint.

Hint

Oracle has 73 hints. ApsaraDB for OceanBase is compatible with 25 of the 73 hints. In addition, the number of hints that are specific to ApsaraDB for OceanBase is 20.

Oracle hint with which ApsaraDB for OceanBase is compatible	Hint specific to ApsaraDB for OceanBase
USE_BNL	INDEX Hint
NO_USE_BNL Hint	FULL Hint
USE_PX Hint	LEADING Hint

Security-related items

TDE

ApsaraDB for OceanBase supports the transparent data encryption (TDE) feature that is compatible with Oracle and does not allow you to encrypt redo log files.

Auditing

- ApsaraDB for OceanBase supports standard auditing of Oracle but does not support unified auditing.
- You can store the audit results of ApsaraDB for OceanBase in files or internal audit tables.
- ApsaraDB for OceanBase supports two types of auditing: statement auditing and object auditing. Object auditing supports only tables, sequences, and package objects.
- ApsaraDB for OceanBase does not support network auditing or Fine Grained Auditing (FGA).

Label Security

- ApsaraDB for OceanBase supports the Label Security feature of Oracle.
- In ApsaraDB for OceanBase, you cannot perform a `DISABLE` operation on a created policy that has taken effect or perform an `ENABLE` operation on this policy after a `DISABLE` operation.

SSL encryption for transmission links

ApsaraDB for OceanBase allows you to encrypt transmission links between clients and ApsaraDB for OceanBase servers.

Partitioning support

ApsaraDB for OceanBase supports partitioning and subpartitioning and the following partitioning methods: hash partitioning, range partitioning, and list partitioning.

The following table lists the details about the support for subpartitioning.

Partition or subpartition	Hash	Range	List
Hash	Not supported	Supported	Supported
Range	Supported	Not supported	Supported
List	Supported	Supported	Not supported

- ApsaraDB for OceanBase supports only basic operation commands for partition maintenance, such as the `ADD PARTITION` operation for partitions.

- ApsaraDB for OceanBase does not support complex operations for partition maintenance, such as `SPLIT`, `MERGE`, and `EXCHANGE` operations on partitions.
- ApsaraDB for OceanBase does not support the `TRUNCATE` operation on partitions.
- ApsaraDB for OceanBase supports only homogeneous subpartitioning and does not support heterogeneous subpartitioning.

Parallel queries

- ApsaraDB for OceanBase supports parallel queries that are similar to those of Oracle. In ApsaraDB for OceanBase, you need to manually specify the degree of parallelism (DOP). ApsaraDB for OceanBase does not support the Auto DOP feature.
- ApsaraDB for OceanBase does not support Product Data Markup Language (PDML).

17.1.5.2. SQL overview

Structured Query Language (SQL) is a programming language that is used for specific purposes. All the programs and users can use SQL to access data in ApsaraDB for OceanBase in the same way as access to other current popular relational databases. Even if some platforms and tools allow users to directly access the database through interfaces or UIs, the underlying layers of these platforms and tools still use SQL to access databases.

SQL history

In June 1970, Dr. E. F. Codd in the laboratory of IBM in San Jose, California published the paper A Relational Model of Data for Large Shared Data Banks in the Association for Computing Machinery (ACM) journal. He proposed the concept of the relational model.

In 1974, D.D.Chamberlin and R.F.Boyce in the same laboratory developed a set of Structured English Query Language (SEQUEL) in the relational database system SystemR that was developed by IBM. In IBM Journal of R&D of November 1976, they published a new version of SQL that was named SEQUEL/2. In 1980, SEQUEL/2 was renamed as SQL.

In 1979, Oracle first provided SQL for commercial use and IBM also implemented SQL in the DB2 and SQL/DS database systems.

Nowadays, SQL has become the standard language for relational database management systems (RDBMSs).

SQL standards

In October 1986, the American National Standards Institute (ANSI) adopted SQL as the standard language for RDBMSs and named the language ANSI X3. 135-1986. The International Organization for Standardization (ISO) also adopted SQL as the international standard.

In 1989, ANSI adopted the SQL standard language that was defined in the ANSI X3.135-1989 report, and named the language ANSI SQL 89. This standard replaced the previous version ANSI X3.135-1986.

The following list provides a brief history for SQL development:

- 1986, ANSI X3.135-1986, ISO/IEC 9075:1986, SQL-86
- 1989, ANSI X3.135-1989, ISO/IEC 9075:1989, SQL-89
- 1992, ANSI X3.135-1992, ISO/IEC 9075:1992, SQL-92 (SQL2)
- 1999, ISO/IEC 9075:1999, SQL:1999 (SQL3)
- 2003, ISO/IEC 9075:2003, SQL:2003
- 2008, ISO/IEC 9075:2008, SQL:2008
- 2011, ISO/IEC 9075:2011, SQL:2011

Nowadays, the content in most of mentioned SQL standards is actually the basic and core part of SQL-92. ApsaraDB for OceanBase also complies with the SQL-92 standard.

Running of SQL

SQL is an interface that is used to access a relational database, such as the interfaces of ApsaraDB for OceanBase an Oracle, and MySQL. All the SQL statements are the instructions for databases.

Generally, SQL includes the following five parts:

1. Data Query Language (DQL): also known as the data retrieval language. It is used to retrieve data from tables and describe how to return the data to programs for output. DQL does not change the data content that is stored in databases.
2. Data Manipulation Language (DML): changes the data content that is stored in databases. This indicates that the language adds, modifies, and deletes data.
3. Transaction Control Language (TCL): ensures the integrity and consistency of databases. The DML statements in the same transaction must be all successful or fail.
4. Data Control Language (DCL): the commands that control the permissions to access data. This language controls the permission of a specified account to access the specified database resources.
5. Data Definition Language (DDL): defines, modifies, and deletes the database resources, such as creating and deleting tables.

Portability of SQL

SQL is a standard language for accessing databases. All the major relational databases support SQL. Therefore, all the programs that are written in SQL are portable. Typically, you can migrate a program from one relational database to the other relational database only after you make only a few modifications.

Vocabulary conventions

- **Bold** indicates the graphical user interface (GUI) elements associated with operations or the terms that are defined in text or a vocabulary.
- Reserved words, keywords, identifiers, and parameters are not case-sensitive. These items are written in uppercase to facilitate reading and identification.
- The ways in which SQL statements are terminated vary based on the programming environments. In this document, a semicolon (;) is used to identify the end of an SQL statement.
- `Inline code` indicates the code that is referenced in the document.
- To highlight the important information, the text, such as description, notes, and importance, are written in bold in this document.
- The text of optional parameters in this document is enclosed in square brackets, such as [-n, -quiet].

17.1.5.3. Pseudocolumns

Pseudocolumns behave the same as table columns, but do not store values. Therefore, pseudocolumns have only the read attribute. You cannot perform operations on pseudocolumns, such as inserting, updating, and deleting data.

> **Notice**
>
> ApsaraDB for OceanBase does not support the `ROWID` pseudocolumn.

Hierarchical query pseudocolumns

Hierarchical query pseudocolumns are valid only in hierarchical queries. To define hierarchical relationships in queries, you must use a `CONNECT BY` clause.

CONNECT_BY_ISCYCLE pseudocolumn

The `CONNECT_BY_ISCYCLE` pseudocolumn is used to assist in marking the row from which a loop starts. If the child node of the current row is also one of the ancestor nodes of the current row, `CONNECT_BY_ISCYCLE` returns 1. Otherwise, 0 is returned.

`CONNECT_BY_ISCYCLE` must be used in conjunction with `NOCYCLE` of the `CONNECT BY` clause. Otherwise, an error is reported for the query result because a loop exists in the tree structure result.

CONNECT_BY_ISLEAF pseudocolumn

The `CONNECT_BY_ISLEAF` pseudocolumn is used to assist in marking leaf nodes in a hierarchy structure. If the current row does not have a child node, that is, the current row is the leaf node of the tree, 1 is returned. Otherwise, 0 is returned.

LEVEL pseudocolumn

The `LEVEL` pseudocolumn is used to assist in marking the hierarchy of nodes. In the hierarchy structure, the root is at level 1, the child nodes of the root is at level 2, and so on. For example, the return value of `LEVEL` for the root node is 1, the return value of `LEVEL` for the child node of the root node is 2, and so on.

Sequence pseudocolumns

A sequence pseudocolumn is an auto-increment numeric sequence that is generated by the database based on specific rules. The sequence pseudocolumn is often used as primary keys and unique keys due to its auto-increment characteristics. You can use the following two methods to obtain the values of the sequence pseudocolumn:

- `CURRVAL`: returns the current value of the sequence.
- `NEXTVAL`: returns the next auto-increment value of the sequence.

When you use a sequence pseudocolumn, you must add the sequence name before `CURRVAL` or `NEXTVAL` and use a period (.) for reference. For example, if the name of a sequence is **SEQ_FOO**, you can use `SEQ_FOO.CURRVAL` to obtain the current value of the **SEQ_FOO** sequence. You can also use `SEQ_FOO.NEXTVAL` to obtain the next auto-increment value of the **SEQ_FOO** sequence.

Application scenarios of sequence pseudocolumns

You can use the `CURRVAL` and `NEXTVAL` values of the sequence pseudocolumns in the following positions:

- The select lists of `SELECT` statements that are in subqueries, materialized views, or views
- The select lists of subqueries in `INSERT` statements
- The `VALUES` clauses in `INSERT` statements
- The `SET` clauses in `UPDATE` statements

You cannot use the `CURRVAL` and `NEXTVAL` values of the sequence pseudocolumns in the following positions:

- The subqueries in `DELETE`, `SELECT`, or `UPDATE` statements
- The queries of views or materialized views
- The `SELECT` statements that contain the `DISTINCT` operator
- The `SELECT` statements that contain the `GROUP BY` or `ORDER BY` clause
- The `SELECT` statement that is combined with another `SELECT` statement by using the `UNION`, `INTERSECT`, or `MINUS` set operator
- The `WHERE` clauses in `SELECT` statements
- The `DEFAULT` values of columns in `CREATE TABLE` or `ALTER TABLE` statements
- The conditions of `CHECK` constraints

How to use sequence pseudocolumns

When you create a sequence, you must specify its initial value and step size. When you reference `NEXTVAL` for the first time, the initial value of the sequence is returned. When you subsequently reference `NEXTVAL`, a new value is returned after the return value of the previous sequence plus the step size that is specified for the sequence. When you reference `CURRVAL` at any time, the current value of the sequence, that is, the return value for the last reference to `NEXTVAL`, is returned.

Before you reference the `CURRVAL` pseudocolumn of a sequence in a session, you must first initialize the sequence value for the current session by using the `NEXTVAL` pseudocolumn of the sequence.

When you create a sequence, you can define its initial value and the increment between values of the sequence. When you reference `NEXTVAL` for the first time, the initial value of the sequence is returned. When you subsequently reference `NEXTVAL`, the sequence value is incremented by the defined increment and a new value is returned. For any reference to `CURRVAL`, the current value of the sequence, that is, the return value for the last reference to `NEXTVAL`, is always returned. For more information about how to create sequences, see CREATE SEQUENCE.

If you reference `NEXTVAL` in a single SQL statement, ApsaraDB for OceanBase increments the sequence in the following ways:

- Each time the outer query block of a `SELECT` statement returns one row, the sequence is incremented once. Such a query block can appear in the following positions:
  - Top-level `SELECT` statements.
  - `INSERT... SELECT` statements. If data is inserted into multiple tables, `NEXTVAL` must be placed in the `VALUES` clause. Each time the subquery returns one row, the sequence is incremented once, even if multiple branches reference `NEXTVAL`.
  - `CREATE TABLE ... AS SELECT` statements.
  - `CREATE MATERIALIZED VIEW ... AS SELECT` statements.

- Each time an `UPDATE` statement updates one row, the sequence is incremented once.
- For each `INSERT` statement that contains a `VALUES` clause, the sequence is incremented once.
- Each time a `MERGE` statement merges one row, the sequence is incremented once. `NEXTVAL` can appear in the `merge_insert_clause` or `merge_update_clause` clause or both. `NEXTVAL` is incremented as each row is updated and inserted, even if the sequence values are not used for the update or insert operation. If `NEXTVAL` is specified multiple times in these positions, the sequence is incremented once for each row. The same value is returned for all the occurrences of `NEXTVAL` in the row.

If the `NEXTVAL` pseudocolumn of a sequence is referenced multiple times in these positions, the sequence is incremented only once. That is, the next sequence value of the current sequence is returned for all the `NEXTVAL` pseudocolumns that are referenced.

If both `CURRVAL` and `NEXTVAL` pseudocolumns of a sequence are referenced in these positions, ApsaraDB for OceanBase increments the sequence. That is, the next sequence value of the current sequence is returned for the `CURRVAL` and `NEXTVAL` pseudocolumns that are referenced.

Multiple users can access a sequence at the same time without waiting and locking.

ROWSCN pseudocolumn

The `ORA_ROWSCN` pseudocolumn reflects the latest System Change Number (SCN) to a row. The SCN indicates the commit time of the transaction that modifies the data of this row.

ROWNUM pseudocolumn

The `ROWNUM` pseudocolumn numbers each row in the query result. The value indicates the specific position of the row in the query result set. The value 1 is returned for the first row, 2 for the second row, and so on.

Instructions on the usage of ROWNUM

`ROWNUM` can limit the number of returned rows. In the following example, five data records in the **employees** table are returned.

```
SELECT * FROM employees WHERE rownum <=5;
```

If an `ORDER BY` clause follows `ROWNUM`, the results that meet the `WHERE` conditions are resorted. Assume that you embed an `ORDER BY` clause in a subquery and use the `ROWNUM` pseudocolumn as a condition in the top-level query. In this case, you can force the `ROWNUM` condition to be applied after the rows are sorted. For example, you cannot obtain the expected result if you execute the following statement to query information about the five oldest employees. The statement only sorts the first five employee information entries in the query result by age:

```
SELECT * FROM employees WHERE rownum <=5 ORDER BY age DESC;
```

The following statement is valid:

```
SELECT * FROM (SELECT * FROM employees ORDER BY age DESC) WHERE rownum <= 5;
```

If you specify that `ROWNUM` is greater than a positive integer in the `WHERE` clause, **FALSE** is always returned. For example, the following SQL statement returns no information:

```
SELECT * FROM employees WHERE rownum > 1;
```

This is because when the result of the first row in the table is retrieved, the value of the `ROWNUM` pseudocolumn of this row is assigned 1. In this case, the result is **FALSE** when the `WHERE` condition is checked. This row is discarded. When the result of the second row is retrieved, the value of the `ROWNUM` pseudocolumn of this row is still assigned 1. The result is still **FALSE** when the `WHERE` condition is checked. This row is also discarded. This way, all the rows fail to meet the condition. Therefore, no data is returned.

You can also assign the `ROWNUM` values to a column in the table by executing a `UPDATE` statement, as shown in the following example.

```
UPDATE employees SET id = rownum;
```

The statement assigns the `ROWNUM` values to the **id** column in the **employees** table. The **id** column is assigned values 1, 2,... until the total number of rows in the table is reached.

> **Notice**
>
> If you use `ROWNUM` in queries, view optimization may be affected.

17.1.5.4. Elements

17.1.5.4.1. Built-in data types

17.1.5.4.1.1. Overview of built-in data types

Each value manipulated by ApsaraDB for OceanBase has a data type. The value's data type associates a fixed set of attributes with the value. These attributes cause ApsaraDB for OceanBase to treat values of one data type differently from values of another. ApsaraDB for OceanBase provides a number of built-in data types. They are also called basic data types of ApsaraDB for OceanBase.

Data types

ApsaraDB for OceanBase supports the following data types, which are consistent with the Oracle data types:

- Character data types
- Numeric data types
- Date and time data types
- RAW data types
- Large object data types

17.1.5.4.1.2. Character data types

Overview of character data types

Character data types store character (alphanumeric) data, which are words and free-form text, in the database character set or national character set. Character data types are subject to more limits than other data types. Therefore, character data types have fewer attributes.

Character data is stored in strings with byte values that correspond to one of the character sets. The character sets are specified when a database is created. ApsaraDB for OceanBase supports both single-byte and multibyte character sets.

> **Note**
>
> The columns of character data types can store all alphanumeric values. But the columns of `NUMBER` data types can store only numeric values.

Data type	Length	Description	Length description
CHAR(size [BYTE | CHAR])	Fixed length	High index efficiency. The program uses the `trim` function to remove white spaces.	Set the `size` parameter to a numeric value between 1 and 2000. The number of bytes for storage is the value of the `size` parameter.
NCHAR[(size)]	Fixed length	Use the Unicode character set. Two bytes are required to represent all characters.	Set the `size` parameter to a numeric value between 1 and 2000. The number of bytes for storage is twice the value of the `size` parameter.
NVARCHAR2(size)	Variable length	Use the Unicode character set. Two bytes are required to represent all characters.	Set the `size` parameter to a value between 1 and 32767. The number of bytes for storage is twice that of input characters.
VARCHAR2(size [BYTE | CHAR])	Variable length	Use the Unicode character set. Two bytes are required to represent all characters.	Set the `size` parameter to a numeric value between 1 and 32767. The number of bytes for storage is that of bytes for input characters rather than the value of the `size` parameter.

Data type	Length	Description	Length description
VARCHAR(size [BYTE | CHAR])	Variable length	In ApsaraDB for OceanBase, `VARCHAR` functions the same as `VARCHAR2`.	Set the `size` parameter to a numeric value between 1 and 32767. The number of bytes for storage is that of bytes for input characters rather than the value of the `size` parameter.

You must specify the `length` semantics for the `CHAR` and `VARCHAR2` data types. The default length semantics is defined by the `NLS_LENGTH_SEMANTICS` system variable.

CHAR data type

The `CHAR` data type stores fixed-length strings. ApsaraDB for OceanBase ensures that all values stored in a `CHAR` column have the fixed length specified by `size`. If you insert a value that is shorter than the specified length, ApsaraDB for OceanBase pads the value to the specified length with spaces. If you insert a value that exceeds the specified length, ApsaraDB for OceanBase returns an error.

The `BYTE` and `CHAR` qualifiers override the semantics specified by the `NLS_LENGTH_SEMANTICS` parameter, which defaults to the BYTE semantics. To ensure proper data conversion between databases that use different character sets, the `CHAR` data must consist of well-formed strings.

Syntax

```
CHAR [(size [BYTE | CHAR])]
```

Parameters

Parameter	Description
size	A fixed length.
BYTE	Specifies that the column length is measured in bytes.
CHAR	Specifies that the column length is measured in characters.

The default length of a `CHAR` column is 1 byte. The maximum length is 2,000 bytes.

Examples

By default, when you create a table that contains a `CHAR` column, you specify the column length in bytes. `BYTE` is the default qualifier.

If you use the `CHAR` qualifier, you specify the column length in characters.

- **Example 1**

Assume that you insert a 1-byte string into the `CHAR(10)` column. Before the string is stored, the system pads the string to 10 bytes with spaces.

- **Example 2**

`CHAR(10 CHAR)` indicates that you specify the column length in characters.

NCHAR data type

The `NCHAR` data type specifies the fixed-length `UNICODE` character data. When you create a database, the national character set defines the maximum column length. When you create a table that contains an `NCHAR` column, you define the column length in characters. Width specifications of the character data type `NCHAR` indicate the number of characters. The maximum column length is 2,000 bytes.

If you want to use less space to store Chinese characters, choose the `NCHAR` data type.

When you use an `NCHAR` column to store values, the database automatically pads the values that are shorter than the specified length with spaces to the specified length. When you specify lengths, `CHAR` is used as the unit of measurement. You cannot specify other units.

> **Notice**
>
> You cannot insert a `CHAR` value into an `NCHAR` column or insert an `NCHAR` value into a `CHAR` column.

Syntax

```
NCHAR[(size)]
```

Parameters

Parameter	Description
`size`	The length of a fixed-length character string. Based on the national character set, the maximum length is set to 2,000 bytes. By default, the minimum length of a fixed-length character string is one character.

More information

Unicode character set

The Unicode character set is an encoding of characters. It provides UTF-8, UTF-16, UTF-32, and other compression and conversion encoding methods. An encoding method determines the size required to store a character. Chinese characters and English characters take up different spaces varying from storage methods.

Comparison of three encoding methods

Encoding method	Number of bytes for encoding characters	BOM	Advantage	Disadvantage
UTF-8	A variable-length encoding method that provides single-byte encoding for ASCII characters and multibyte encoding for non-ASCII characters. The minimum code unit is eight bits.	Without BOM: If a byte stream starts with EF BB BF at the beginning of a text, the text is encoded in UTF-8.	An ideal Unicode encoding method: This method is fully compatible with ASCII encoding, requires no BOM, features strong self-synchronization and error correction capabilities for network transmission and communication, and provides high scalability.	The variable-length encoding makes internal processing of the program more difficult.
UTF-16	Two or four bytes. The minimum code unit is 16 bits.	With BOM: UTF-16LE (little-endian) is represented by FF FE, and UTF-16BE (big-endian) is represented by FE FF.	The earliest Unicode encoding method that has been applied to various scenarios. This method is suitable for Unicode processing in memory, and is used to encode strings in APIs across multiple programming languages.	This method is not compatible with ASCII encoding, and has poor scalability. The encoding is complex when surrogate pairs are used to encode code points in the supplementary planes.
UTF-32	A fixed length of four bytes. The minimum code unit is 16 bits.	With BOM: UTF-16LE (little-endian) is represented by FF FE, and UTF-16BE (big-endian) is represented by FE FF.	A fixed-byte encoding that is easy to read and is internally processed by a compiler. This method provides a one-to-one mapping between Unicode code points and code units.	All characters are encoded in a fixed length of four bytes, which wastes storage space and bandwidth. This method is not compatible with ASCII encoding, has a poor scalability, and is not used in most cases.

Database character set

- Used to store the data types such as `CHAR`, `VARCHAR2`, and `CLOB`
- Used to identify the information such as table names, column names, and PL/SQL variables
- Used to store SQL and PL/SQL program units

National character set

- Used to store the data types such as `NCHAR`, `NVARCHAR2`, and `NCLOB`
- The national character set is essentially an additional character set that is selected for ApsaraDB for OceanBase. The national character set is mainly used to enhance the character processing capability of ApsaraDB for OceanBase. The `NCHAR` data type uses the national character set. While using the database character set provided by the `CHAR` data type, the `NCHAR` data type provides an alternative to the database character set.

NVARCHAR2 data type

The `NVARCHAR2` data type stores `UNICODE` characters. An NVARCHAR2 column stores variable-length values. The maximum length of an NVARCHAR2 column is 32,767 bytes. The minimum length of an NVARCHAR2 column is 1 byte. When you create a table that contains an `NVARCHAR2` column, you must specify the maximum number of characters that a value in the `NVARCHAR2` column can contain. By default, `CHAR` is the unit that is used to measure the column length. You cannot specify other units.

If the values to be stored have uncertain lengths, you can choose the `NVARCHAR2` type.

Format

```
NVARCHAR2(size)
```

Parameters

Parameter	Description
size	A variable column length. You must specify the size of `NVARCHAR2`. The number of bytes can be up to two times the specified size if AL16UTF16 encoding is used and three times the specified size if UTF8 encoding is used. The national character set defines the number of bytes. The upper limit is 32,767 bytes.

VARCHAR2 data type

The `VARCHAR2` data type stores variable-length strings. The maximum string length is 32,767 bytes. When you create a `VARCHAR2` column, you must specify the maximum length for the `VARCHAR2` column. Although you can store a zero-length string (''), the maximum value must be at least 1 byte. ApsaraDB for OceanBase stores each value in the column in the way as you specify.

Notice

- From a technical point of view, a character is a code point of the database character set.
- Assume that you create a database object with a VARCHAR2 column or attribute. If you specify no explicit qualifiers in the column or attribute definition, the value of the `NLS_LENGTH_SEMANTICS` parameter of the session determines the length semantics.
- ApsaraDB for OceanBase compares the `VARCHAR2` values by using non-padded comparison semantics.
- When you convert data between databases that use different character sets, you must ensure that the `VARCHAR2` data consists of well-formed strings.

Syntax

```
VARCHAR2(size [BYTE | CHAR])
```

Parameters

Parameter	Description
size	The number of the stored bytes or characters.
BYTE	Specifies that the column length is measured in bytes.
CHAR	Specifies that the column length is measured in characters.

Examples

You can specify the maximum length in characters by using the `CHAR` qualifier.

```
VARCHAR2(10 CHAR)
```

You can specify the maximum length in bytes by using the `BYTE` qualifier.

```
VARCHAR2(10 BYTE)
```

VARCHAR data type

The `VARCHAR` data type is used to store variable-length strings. When you create a `VARCHAR` column, you must specify the maximum length for the `VARCHAR` column. Although you can store a zero-length string (''), the maximum length must be at least 1 byte. ApsaraDB for OceanBase stores each value in the column in the way as you specify. If you insert a value that exceeds the specified length, ApsaraDB for OceanBase returns an error.

In ApsaraDB for OceanBase, the `VARCHAR` data type is synonymous with the `VARCHAR2` data type. In most cases, `VARCHAR2` is used.

Syntax

```
VARCHAR(size [BYTE | CHAR])
```

Parameters

Parameter	Description
size	The number of the stored bytes or characters.
BYTE	Specifies that the column length is measured in bytes.
CHAR	Specifies that the column length is measured in characters.

17.1.5.4.1.3. Numeric data types

Overview of numeric data types

ApsaraDB for OceanBase allows you to store numeric values in the `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE` data types. You can store fixed-point numbers, floating-point numbers, and zero by using these numeric data types. In numeric calculations, the numeric data types have different operator precedence values. For more information, see Precedence of numeric data types.

Data type	Length (bytes)	Description
NUMBER	4~40	`NUMBER(p,s)` stores variable-length fixed-point numbers that have decimal precisions. You can also store floating-point numbers by using `NUMBER` where `p` and `s` are not specified.
FLOAT	4~40	`FLOAT(p)` is a subtype of the `NUMBER` data type. The binary precision ranges from 1 to 126. A value of `FLOAT` is not a floating-point number.
BINARY_FLOAT	4	This data type stores 32-bit single-precision floating-point numbers that have binary precisions.
BINARY_DOUBLE	8	This data type stores 64-bit double-precision floating-point numbers that have binary precisions.

NUMBER data type

`NUMBER` is a numeric data type that stores variable-length and exact values. Each value of this data type occupies 4 to 40 bytes of storage space. The storage space of 4 bytes is used to store `NUMBER` metadata and the storage space of 36 bytes is used to store specific `NUMBER` values. The NUMBER data type can store zeros, floating-point numbers, positive fixed-point numbers, and negative fixed-point numbers. The absolute values that can be stored range from 1.0×10^{-130} to 1.0×10^{126} (excluding 1.0×10^{126}). ApsaraDB for OceanBase returns an error if the absolute value of the specified arithmetic expression is greater than or equal to 1.0×10^{-130}.

The `NUMBER` data type provides higher data accuracy and is more general and portable than the floating-point data type. The floating-point data type enables more efficient arithmetic operations than the NUMBER data type.

Syntax

```
NUMBER [(p[s])]
```

Parameters

Parameter	Value range	Description
p	1~38	Specifies the precision. The value of this parameter is the maximum number of significant decimal digits. The most significant digit is the leftmost non-zero digit and the least significant digit is the rightmost known digit.
s	-84~127	Specifies the number of digits in the fractional part. The value of this parameter is the number of digits from the decimal point to the least significant digit. The scale range is from -84 to 127.

Note

- If s is greater than 0, the value is rounded to `s` digits on the right of the decimal point. Then, the system checks whether the number of significant digits is smaller than or equal to `p`.
- If s is smaller than 0, the value is rounded to `s` digits on the left of the decimal point. Then, the system checks whether the number of significant digits is smaller than or equal to `p + |s|`.
- If s is equal to 0, the value is an integer.

> **Notice**
>
> - The positive scale for decimal places is the number of significant digits from the first digit on the right of the decimal point to the least significant digit. Precisions and decimal places are represented by decimal digits.
> - The negative scale for decimal places is the number of significant digits on the left of the decimal point, excluding the least significant digit. For the negative scale, the least significant digit is on the left of the decimal point because the actual data is rounded to the specified number of digits on the left of the decimal point.

Examples

- **Example 1:** Use the following format to specify an integer:

`NUMBER(p)` specifies a fixed-point number with a precision of `p` and a scale of 0. NUMBER(p) is equivalent to `NUMBER(p,0)`.

`NUMBER` specifies a floating-point number. In this format, the designators for precisions and decimal places are absent.

- **Example 2:** Store data that has different precisions and different numbers of decimal places. To prevent the precisions of the data stored in ApsaraDB for OceanBase from exceeding the specified precisions, specify the precisions and the number of decimal places for fixed-point number columns. You must also perform integrity checks on the input data. However, this does not enforce a fixed length of the values in the fixed-point number columns. If the precisions of the actual data to be stored exceed the specified precisions, ApsaraDB for OceanBase returns an error. If the number of decimal places of the actual data to be stored exceeds the specified value, ApsaraDB for OceanBase rounds the data.

Actual data	Specified As	Stored As
123.89	`NUMBER`	123.89
123.89	`NUMBER(3)`	124
123.89	`NUMBER(3,2)`	Exceeds the specified precision
123.89	`NUMBER(4,2)`	Exceeds the specified precision
123.89	`NUMBER(5,2)`	123.89
123.89	`NUMBER(6,1)`	123.9
123.89	`NUMBER(6,-2)`	100
.01234	`NUMBER(4,5)`	.01234
.00012	`NUMBER(4,5)`	.00012

Actual data	Specified As	Stored As
.000127	`NUMBER(4,5)`	.00013
.000012	`NUMBER(2,7)`	.000012
.0000123	`NUMBER(2,7)`	.000012
1.2e-4	`NUMBER(2,5)`	.00012
1.2e-5	`NUMBER(2,5)`	.00001

FLOAT data type

The `FLOAT` data type is a subtype of the `NUMBER` data type that is specified with precision. This data type occupies 4 bytes to 40 bytes of storage space. The precision is calculated based on the number of significant binary digits which ranges from 1 to 126. The number of decimal places is not user-defined. The `FLOAT` data type specifies the variable-length non-exact numeric data.

Syntax

```
FLOAT [(p)]
```

Parameters

Parameter	Definition	Value range	Description
p	Precision	1~126	The precision for numeric values. The precision is calculated based on the number of significant binary digits. To convert from binary precision to decimal precision, you must multiply the binary precision by 0.30103.

Note

- Binary-to-decimal precision conversion: `Binary precision = int(Decimal precision x 0.30103)`
- Decimal-to-binary precision conversion: `Decimal precision = int(Binary precision x 3.32193)`

Examples

- **Example 1**: Assume that you set the binary precision to 2 by using `FLOAT`, convert the binary precision to the decimal precision by using the following function: int(2 x 0.30103) = 0.6, and round down the result to an integer. The decimal precision of `FLOAT(2)` is 0.

```
FLOAT(2)
```

- **Example 2**: Assume that you create a table named **test**, and insert data into the table. The **col1** column is of the `NUMBER` data type, and the **col2** column is of the `FLOAT` data type. `NUMBER(5,2)` represents a fixed-point value with decimal precision. The result is limited to five significant digits, and is returned with two decimal places. `FLOAT(5)` represents the binary precision of 5. This value is converted to the decimal precision by using the following function: `int(5 x 0.30103) = 1.50515`. After the result is rounded down to an integer, the decimal precision is 1. For example, 123.45 is expressed as 1.2345×10^2 in scientific notation. If one decimal place is required, the value of 1.2345 is rounded to 1.2. The following result is finally displayed: $1.2 \times 10^2 = 120$. Execute the following statement:

```
CREATE TABLE test (col1 NUMBER(5,2), col2 FLOAT(5));
INSERT INTO test VALUES (1.23, 1.23);
INSERT INTO test VALUES (7.89, 7.89);
INSERT INTO test VALUES (12.79, 12.79);
INSERT INTO test VALUES (123.45, 123.45);
```

Execute the following statement to query the **test** table:

```
SELECT * FROM test;
```

The following result is returned:

```
+-----------+----------+
| col1          |   col2   |
+-----------+----------+
|    1.23   |   1.2    |
+-----------+----------+
|    7.89   |   7.9    |
+-----------+----------+
|    12.79  |   13     |
+-----------+----------+
|    123.45 |   120    |
+-----------+----------+
```

> **Note**
>
> When you convert the `ANSI FLOAT` data, you can use the `FLOAT` data type that is used by ApsaraDB for OceanBase. However, we recommend that you use `BINARY_FLOAT` and `BINARY_DOUBLE` for floating-point numbers in ApsaraDB for OceanBase.

Floating-point numbers

Floating-point numbers can have a decimal point anywhere from the first to the last digit, or can have no decimal point at all. You can choose to optionally use an exponent following the number to increase the range, for example, 1.666 e^{-20}. Decimal places are not applicable to floating-point numbers, because the number of digits that can appear after the decimal point is not limited.

> **Notice**
>
> Binary floating-point numbers differ from `NUMBER` in the way where the values are internally stored by ApsaraDB for OceanBase. All values of the `NUMBER` data type are exactly stored with decimal precision. Binary floating-point numbers are stored with binary precision by using the digits 0 and 1. Such a storage method cannot exactly represent all values that use decimal precision.

Syntax

ApsaraDB for OceanBase provides two numeric data types for floating-point numbers:

- `BINARY_FLOAT` is a 32-bit single-precision floating-point number data type. Each `BINARY_FLOAT` value requires 4 bytes.
- `BINARY_DOUBLE` is a 64-bit double-precision floating-point number data type. Each `BINARY_DOUBLE` value requires 8 bytes.

> **Note**
>
> - In a `NUMBER` column, floating-point numbers have decimal precision.
> - In a `BINARY_FLOAT` or `BINARY_DOUBLE` column, floating-point numbers have binary precision.
> - The binary floating-point numbers do not support the special values `infinity` and `NaN` (not a number).

Value range

You can specify floating-point numbers within the value range.

Value	BINARY_FLOAT	BINARY_DOUBLE
Maximum positive finite value	3.40282E+38F	1.79769313486231E+308
Minimum positive finite value	1.17549E-38F	2.22507485850720E-308

More information

IEEE754 conformance

- IEEE Standard 754-1985 (IEEE754)

The implementation of floating-point data types in ApsaraDB for OceanBase conforms substantially with the Institute of Electrical and Electronics Engineers (IEEE) Standard for Binary Floating-Point Arithmetic.

- The floating-point data types conform to `IEEE754` in the following areas:
  - The SQL function `SQRT` returns the square root.

- The SQL function `REMAINDER` returns the remainder.
- Arithmetic operators conform to the standard.
- Comparison operators conform to the standard.
- Conversion operators conform to the standard.
- The default rounding mode is supported.
- The default exception handling mode is supported.
- ApsaraDB for OceanBase does not support the special constants such as `INF`, `-INF`, `NaN`, `BINARY_FLOAT_NAN`, and `BINARY_DOUBLE_NAN`.
- The SQL functions `ROUND`, `TRUNC`, `CEIL`, and `FLOOR` enable the rounding of binary floating-point numbers of `BINARY_FLOAT` and `BINARY_DOUBLE` to integer values of `BINARY_FLOAT` and `BINARY_DOUBLE`.
- The SQL functions `TO_CHAR`, `TO_NUMBER`, `TO_NCHAR`, `TO_BINARY_FLOAT`, `TO_BINARY_DOUBLE`, and `CAST` enable the rounding of binary floating-point numbers of `BINARY_FLOAT` and `BINARY_DOUBLE` to decimal values, and the rounding of decimal values to binary floating-point numbers of `BINARY_FLOAT` and `BINARY_DOUBLE`.

- The floating-point data types do not conform to IEEE754 in the following areas:
  - The value of -0 is coerced to that of +0.
  - Comparison with `NaN` is not supported.
  - Non-default rounding modes are not supported.
  - Non-default exception handling modes are not supported.

Numeric precedence

Different numeric data types have different levels of precedence in operations. In ApsaraDB for OceanBase, `BINARY_DOUBLE` has the highest precedence, followed by `BINARY_FLOAT`, and finally by `NUMBER`.

In any operation on multiple numeric values:

- If an operand is `BINARY_DOUBLE`, ApsaraDB for OceanBase converts all operands to `BINARY_DOUBLE` before performing the operation.
- If an operand is `BINARY_FLOAT`, ApsaraDB for OceanBase converts all operands to `BINARY_FLOAT` before performing the operation.
- If none of the operands is `BINARY_DOUBLE` or `BINARY_FLOAT`, ApsaraDB for OceanBase converts all operands to `NUMBER` before performing the operation.
- If the required conversion fails, the operation fails.
- In the context of other data types, numeric data types have lower precedence than the date, time, and interval data types, and have higher precedence than character and all other data types.

17.1.5.4.1.4. Date, time, and interval data types

Overview of datetime and interval data types

ApsaraDB for OceanBase supports datetime and interval data types. These data types are the same as those in Oracle.

Datetime data types

The datetime data types are used to store date and time data that is stored in databases. This category consists of the following data types.

Data type	Description
DATE	Stores date and time information. The precision is seconds. The information about time zones is excluded.
TIMESTAMP	Serves as an extension of the `DATE` data type. The precision is nanoseconds. The information about time zones is excluded.
TIMESTAMP WITH TIME ZONE	Serves as an extension of the `DATE` data type. The precision is nanoseconds. The information about time zones is included.
TIMESTAMP WITH LOCAL TIME ZONE	Stores the information about database time zones. This data type stores `TIMESTAMP` values that contain the information about the local time zone.

Interval data types

Interval data types are different from datetime data types in the following aspect: Datetime data types store specific time points and interval data types store time periods. Interval data types provide an effective way to store the difference between each two datetime values. This category consists of the following data types.

Data type	Description
INTERVAL YEAR TO MONTH	Stores time periods that are measured in years and months.
INTERVAL DAY TO SECOND	Stores time periods that are measured in days, hours, minutes, and seconds.

More information

- Daylight saving time
- Calculation of DATE and INTERVAL values

DATE data type

The `DATE` data type stores the date and time information. Although you can use both character and numeric data types to represent the date and time information, the `DATE` data type has special associated properties.timetime For each `DATE` value, ApsaraDB for OceanBase stores the information about year, month, day, hour, minute, and second, but does not contain the time zone information.time zoneinfo

Format

`NLS_DATE_FORMAT` determines the default input and output formats of the `DATE` data type. Run the following SQL statement to query the default format:

```
SELECT @@NLS_DATE_FORMAT FROM DUAL;
```

Return result:

```
DD-MON-RR
```

To customize data formats, you can use conversion functions. When you insert data, you can use the `TO_DATE(char,fmt)` function to specify the input format of the data. When you query data, you can use the `TO_CHAR(datetime,fmt)` function to specify the output format of the data. These two conversion functions convert a string to the format defined by the `fmt` parameter. If you do not specify `fmt`, the default format is used.

> **Notice**
>
> The `DATE` data type stores the time information such as the hour, minute, and second. However, the default format does not contain the time information.

Value range

`0001-01-01 00:00:00` ~ `9999-12-31 23:59:59`

Examples

- **Example 1**: This example returns the current system date. Assume that you do not specify the `fmt` parameter, the `TO_CHAR` function returns a value in the default format of the data type.

```
SELECT TO_CHAR(sysdate) FROM DUAL;
```

Return result:

```
+------------------+
| TO_CHAR(SYSDATE) |
+------------------+
| 24-FEB-20        |
+------------------+
```

- **Example 2**: Assume that you do not specify the `DATE` value as a literal, the database returns the system default value:

- Year: indicates the current year, which is returned by `SYSDATE`.
- Month: indicates the current month, which is returned by `SYSDATE`.
- Day: defaults to 01 that indicates the first day of the current month.
- The hour, minute, and second values are all 0.

This example uses the `TO_DATE(string,format)` function to insert date data. `TO_DATE` converts the characters in the `string` parameter to a value in the format specified in the `format` parameter.

Assume that you issue the following query in February 2020:

```
SELECT TO_CHAR(TO_DATE('2020', 'YYYY'),'YYYY-MM-DD HH24:MI:SS') FROM DUAL;
```

Return result:

```
+-----------------------------------------------------------+
| TO_CHAR(TO_DATE('2020', 'YYYY'),'YYYY-MM-DD HH24:MI:SS') |
+-----------------------------------------------------------+
|                                      2020-02-01 00:00:00|
+-----------------------------------------------------------+
```

TIMESTAMP data type

In addition to the `DATE` data type, the date and time data types also include the `TIMESTAMP[(scale)]` data type. The TIMESTAMP data type is an extension of the `DATE` data type. The TIMESTAMP data type stores some information that the `DATE` data type stores, such as the year, month, day, hour, minute, and second values. However, the TIMESTAMP data type does not store the time zone information. The highest precision of a TIMESTAMP value is nanosecond precision. Therefore, this data type is often used to store the data that has a high time precision and does not require time zone conversion.

Syntax

```
TIMESTAMP [(scale)]
```

Parameters

Parameter	Value range	Description
scale	0~9	The value of `scale` determines the range and precision of `TIMESTAMP[(scale)]`. The maximum value of scale is 9, which means nanosecond precision. If scale is 9, nine digits appear after the decimal point of the second value. The minimum value of scale is 0, which indicates second precision. If scale is 0, no digits appear after the decimal point of the second value. The default value of scale is 6.

Format

`NLS_TIMESTAMP_FORMAT` determines the default input and output formats of the `TIMESTAMP` data type. Execute the following SQL statement to query the default format:

```
SELECT @@NLS_TIMESTAMP_FORMAT FROM DUAL;
```

The following result is returned:

```
DD-MON-RR HH.MI.SSXFF AM
```

To customize data formats, use conversion functions. When you insert data, you can use the `TO_TIMESTAMP(char,fmt)` function to specify the input format of the data. When you query data, you can use the `TO_CHAR(datetime,fmt)` function to specify the output format of the data. These two conversion functions convert a string to the format defined by the `fmt` parameter. If you do not specify `fmt`, the default format is used.

Value range

`0001-01-01 00:00:00.000000000` ~ `9999-12-31 23:59:59.999999999`

Examples

- **Example 1**: You can run the following code to create two **TIMESTAMP** columns named **timestp1** and **timestp2** in the `Timestamp_Sample` table and set scale to 3 for the **timestp2** column. The date value **2020-01-01 11:00:00** is inserted into both columns in the format of `TO_TIMESTAMP(string,format)`.

```
CREATE TABLE Timestamp_Sample(timestp1 TIMESTAMP, timestp2 TIMESTAMP(3));
INSERT INTO Timestamp_Sample(timestp1,timestp2) VALUES(TO_TIMESTAMP('2020-01-01 11:00:00','YYYY-MM-DD
HH24:MI:SS'),TO_TIMESTAMP('2020-01-01 11:00:00','YYYY-MM-DD HH24:MI:SS'));
SELECT * FROM Timestamp_Sample;
```

The following result is returned. The **timestp1** column uses the default time precision because the value of `scale` is not specified. Six digits appear after the decimal point of the second value. However, in the **timestp2** column, three digits appear after the decimal point of the second value because scale is set to 3.

```
+-----------------------------+----------------------------+
| timestamp1                  | timestamp2                 |
+-----------------------------+----------------------------+
| 01-JAN-20 11.00.00.000000 AM | 01-JAN-20 11.00.00.000 AM |
+-----------------------------+----------------------------+
```

- **Example 2**: In the following statement, the `TO_CHAR(datetime,fmt)` function is used to specify the output format:

```
SELECT TO_CHAR(TO_TIMESTAMP_TZ('25-FEB-20 11:00:00 AM America/Los_Angeles','DD-MON-RR HH:MI:SSXFF PM
TZR'),'YYYY-MM-DD HH:MI:SSXFF PM TZR') Timestamp
FROM DUAL;
```

The following result is returned:

```
+-----------------------------------------------------+
| Timestamp                                           |
+-----------------------------------------------------+
| 2020-02-25 11:00:00.000000000 AM America/Los_Angeles |
+-----------------------------------------------------+
```

TIMESTAMP WITH TIME ZONE data type

`TIMESTAMP [(scale)] WITH TIME ZONE` is a variant of `TIMASTAMP [(scale)]`. TIMESTAMP [(scale)] WITH TIME ZONE stores all the time information that is stored in a `TIMASTAMP [(scale)]` value, such as the year, month, day, hour, minute, and second values. The value of `scale` determines the bounds and precision of TIMESTAMP [(scale)] WITH TIME ZONE. The TIMESTAMP [(scale)] WITH TIME ZONE data type also stores the time zone information that `TIMASTAMP [(scale)]` does not store. Therefore, TIMESTAMP [(scale)] WITH TIME ZONE is often used to store the date and time information across geographical regions.

Syntax

```
TIMESTAMP [(scale)] WITH TIME ZONE
```

Parameters

Parameter	Value range	Description
scale	0~9	The value of `scale` determines the bounds and precision of `TIMESTAMP [(scale)] WITH TIME ZONE`. The maximum value of scale is 9, which indicates nanosecond precision. If scale is 9, nine digits appear after the decimal point of the second value. The minimum value of scale is 0, which indicates second precision. If scale is 0, no digits appear after the decimal point of the second value. The default value of scale is 6.

Format

`NLS_TIMESTAMP_TZ_FORMAT` determines the default input and output formats of the `TIMESTAMP WITH TIME ZONE` data type. Execute the following SQL statement to query the default formats:

```
SELECT @@NLS_TIMESTAMP_TZ_FORMAT FROM DUAL;
```

The following result is returned:

```
DD-MON-RR HH.MI.SSXFF AM TZR
```

To customize data formats, use conversion functions. When you insert data, you can use the `TO_TIMESTAMP_TZ(char,fmt)` function to specify the input format of the data. When you query data, you can use the `TO_CHAR(datetime,fmt)` function to specify the output format of the data. These two conversion functions convert a string to the format defined by the `fmt` parameter. If you do not specify `fmt`, the default format is used.

Value range

`0001-01-01 00:00:00.000000000` ~ `9999-12-31 23:59:59.999999999`

Examples

In the following examples, `TO_TIMESTAMP_TZ(char,fmt)` is used to insert a timestamp value.

When you insert a time zone, ApsaraDB for OceanBase allows you to use the offset and region name of the time zone.

- The time zone offset is the difference (in hours and minutes) between the local time zone and the UTC+0 time zone.
- Specify the time zone region name (TZR) and time zone abbreviation (TZD) in this format: Country/City Time zone abbreviation.

Use the time zone offset

Execute the following statement to insert a value by using the time zone offset:

```
SELECT TO_TIMESTAMP_TZ('2020-01-01 11:00:00 -05:00','YYYY-MM-DD HH:MI:SS TZH:TZM') FROM DUAL;
```

The following result is returned:

```
01-JUN-20 11.00.00.000000000 AM AMERICA/LOS_ANGELES
```

Use the region name and abbreviation of the time zone

Execute the following statement to insert a value by using the region name and abbreviation of the time zone:

```
SELECT TO_TIMESTAMP_TZ('2020-01-01 11:00:00 America/Los_Angeles PST','YYYY-MM-DD HH:MI:SS TZR TZD') F
ROM DUAL;
```

The following result is returned:

```
01-JUN-20 11.00.00.000000000 AM America/Los_Angeles PST
```

Daylight saving time

ApsaraDB for OceanBase supports daylight saving time and uses time zone abbreviations to indicate the information about daylight saving time. For example, in the time zone region America/Los_Angeles, the daylight saving time is Pacific Daylight Time (PDT). PDT is in effect from the second Sunday in March to the first Sunday in November each year. Pacific Standard Time (PST) is in effect in the other periods of each year. If an inserted value contains only the name of the time zone region, ApsaraDB for OceanBase determines whether PDT applies to the inserted time zone region based on the inserted time information. The output includes the time zone abbreviation to indicate whether the current time is in PDT.

You can run the following sample code:

```
SELECT TO_TIMESTAMP_TZ('2020-02-01 11:00:00 America/Los_Angeles','YYYY-MM-DD HH:MI:SS TZR') FROM DUAL
;
SELECT TO_TIMESTAMP_TZ('2020-06-01 11:00:00 America/Los_Angeles','YYYY-MM-DD HH:MI:SS TZR') FROM DUAL
;
```

The following result is returned:

```
01-JUN-20 11.00.00.000000000 AM America/Los_Angeles PST
01-JUN-20 11.00.00.000000000 AM America/Los_Angeles PDT
```

TIMESTAMP WITH LOCAL TIME ZONE data type

The time zone in a value of the `TIMESTAMP [(scale)] WITH LOCAL TIME ZONE` data type is the time zone where the current session occurs. When you specify a `TIMASTAMP [(scale)] WITH TIME ZONE` value, you must specify the time zone. However, when you specify a TIMESTAMP [(scale)] WITH LOCAL TIME ZONE value, ApsaraDB for OceanBase automatically stores the default database time zone (UTC+0). You cannot change the time zone. When you retrieve data, ApsaraDB for OceanBase returns the time zone of the current session and you can change the time zone. This data type is often used to store the date information that is always displayed in the time zone of the client system in a two-tier application.

Syntax

```
TIMASTAMP [(scale)] WITH TIME ZONE
```

Parameters

Parameter	Value range	Description
scale	0~9	The value of `scale` determines the bounds and precision of `TIMESTAMP [(scale)]`. The maximum value is 9, which indicates nanosecond precision. The minimum value is 0, which indicates second precision. The default value is 6.

Format

`NLS_TIMESTAMP_FORMAT` determines the default input and output formats of the `TIMESTAMP WITH LOCAL TIME ZONE` data type. Execute the following SQL statement to query the date and time format:

```
SELECT @@NLS_TIMESTAMP_FORMAT FROM DUAL;
```

The following result is returned:

```
DD-MON-RR HH.MI.SSXFF AM
```

To customize data formats, use conversion functions. You can use the `TO_CHAR(datetime,fmt)` function to specify the output data format. The conversion function converts a string to the format defined by the fmt parameter. If you do not specify `fmt`, `TO_CHAR` returns data in the default format of the data type. For more information about the input formats of the `TIMESTAMP WITH TIME ZONE` data type, see Timestamp literals.

Value range

`0001-01-01 00:00:00.000000000` ~ `9999-12-31 23:59:59.999999999`

Examples

No literals can be used to specify a `TIMESTAMP WITH TIME ZONE` value. **SESSIONTIMEZONE** returns the information of the local session time zone. The value of **SESSIONTIMEZONE** is the same as the value of the custom parameter **TIME_ZONE**.

```
CREATE TABLE LocalTZ ( ltzcol TIMESTAMP WITH LOCAL TIME ZONE);
INSERT INTO LocalTZ VALUES (TIMESTAMP '2020-02-25 11:10:08.123');
ALTER SESSION SET TIME_ZONE='+08:00';
SELECT SESSIONTIMEZONE, ltzcol FROM LocalTZ;
```

The following result is returned:

```
+-----------------+-------------------------------+
| SESSIONTIMEZONE | ltzcol                        |
+-----------------+-------------------------------+
| +08:00          | 25-FEB-20 11:10:08.123000 AM |
+-----------------+-------------------------------+
```

You can change **SESSIONTIMEZONE** by changing the value of the custom parameter **TIME_ZONE**:

```
ALTER SESSION SET TIME_ZONE='+00:00';
SELECT SESSIONTIMEZONE, ltzcol FROM LocalTZ;
```

The following result is returned:

```
+-----------------+-------------------------------+
| SESSIONTIMEZONE | ltzcol                        |
+-----------------+-------------------------------+
| +00:00          | 25-FEB-20 03:10:08.123000 AM |
+-----------------+-------------------------------+
```

INTERVAL YEAR TO MONTH data type

The INTERVAL YEAR TO MONTH data type stores different objects from the DATE and TIMESTAMP data types. The `TIMESTAMP` data type stores specific timestamps. The `DATE` data type stores specific dates. The `INTERVAL YEAR TO MONTH` data type uses the `YEAR` and `MONTH` elements to store a period of time. This data type can be used to indicate the difference between two date and time values.

Syntax

```
INTERVAL YEAR [(percision)] TO MONTH
```

Parameter

Parameter	Value	Description
percision	0~9	The precision in the `YEAR` element. The default value is 2. That is, if you do not specify this parameter, you can store a maximum interval value of 99 years and 11 months because the maximum interval value cannot exceed 100 years. If you want to store data with the precision that exceeds the default precision of 2 digits, you must explicitly specify this parameter with a value rather than leave this parameter empty.

Date formats

You can use the following formats when you insert a value of the `INTERVAL YEAR TO MONTH` data type. For more information about how to specify the values of interval data types, see Interval literals.

Syntax	Example	Description
INTERVAL 'year-month' YEAR(percision) TO MONTH	INTERVAL '120-3' YEAR(3) TO MONTH	The interval is 120 years and 3 months. Because the value of the `YEAR` element is greater than the default precision of 2, you must set the precision of the `YEAR` element to 3.
INTERVAL 'year' YEAR(percision)	INTERVAL '50' YEAR	The interval is 50 years.
INTERVAL 'month' MONTH	INTERVAL '500' MONTH	The interval is 500 months or 41 years and 8 months.

Examples

Assume that you write the following codes to create three `INTERVAL YEAR TO MONTH` columns named **interval1**, **interval2**, and **interval3** in a table named **Interval_Sample**, and insert numeric values into the columns.

```
CREATE TABLE Interval_Sample (
    interval1 INTERVAL YEAR TO MONTH,
    interval2 INTERVAL YEAR(3) TO MONTH,
    interval3 INTERVAL YEAR TO MONTH
);
INSERT INTO Interval_Sample (interval1, interval2, interval3)
VALUES (INTERVAL '12-3' YEAR TO MONTH, INTERVAL '120-3' YEAR(3) TO MONTH, INTERVAL '40' MONTH);
SELECT * FROM Interval_Sample;
```

Return result:

```
+-----------+-----------+-----------+
| interval1 | interval2 | interval3 |
+-----------+-----------+-----------+
| +12-03    | +120-03   | +03-04    |
+-----------+-----------+-----------+
```

Calculations between interval and other date and time types

ApsaraDB for OceanBase supports the conversion between data types. Therefore, you can perform calculations between interval values and other date values. However, the database allows you to perform addition, subtraction, multiplication, and division between data types by following rules. For more information about the matrix of calculations between date types that are currently supported, see Calculation of DATE and INTERVAL values. For more information about data type conversion, see Data type conversion.

- **Example 1**: When a calculation is performed between interval values, an interval value is returned.

```
SELECT INTERVAL '2-2' YEAR TO MONTH -INTERVAL '1-1' YEAR  TO MONTH calculate1, INTERVAL '2-2' YEAR TO
MONTH + INTERVAL '1-1' YEAR TO MONTH calculate2 FROM DUAL;
```

Return result:

```
+---------------+----------------+
| calculate1    | calculate2     |
+--------------------------------+
| +000000001-01 | +000000003-03  |
+---------------+----------------+
```

- **Example 2**: When a calculation is performed between interval and date and time values, a date value is returned. `SYSDATE` returns the current time **2020-02-27 16:13:50**. The following example returns the date value two months after the current time. The database only supports the format of an interval value plus a date and time value. The format of an interval value minus a date and time value is invalid for the calculation. However, a date time value plus an interval value and a date and time value minus an interval value are valid formats for calculations.

```
SELECT TO_CHAR(INTERVAL '2' MONTH +SYSDATE,'YYYY-MM-DD HH24:MI:SS') calculate3 FROM DUAL;
```

Return result:

```
+---------------------+
| calculate3          |
+---------------------+
| 2020-04-27 16:13:50 |
+---------------------+
```

- **Example 3**: When a calculation is performed between interval and numeric values, an interval value is returned.

Interval values can be multiplied and divided with numeric values. The following example calculates the 2-month interval multiplied by 2 and the 2-day interval divided by 3.

```
SELECT INTERVAL '2' MONTH*2 calculate4, INTERVAL '2' DAY/3 calculate5 FROM DUAL;
```

The intervals of 4 months and 16 hours are returned.

```
+---------------+-------------------------------+
| calculate4    | calculate5                    |
+---------------+-------------------------------+
| +000000000-04 | +000000000 16:00:00.000000000 |
+---------------+-------------------------------+
```

INTERVAL DAY TO SECOND data type

`INTERVAL DAY TO SECOND` stores time periods that are measured in days, hours, minutes, and seconds. This data type is useful for storing a value that represents the precise difference between two date and time values.

Syntax

```
INTERVAL DAY [(precision)] TO SECOND [(fractional_seconds_precision)]
```

Parameters

Parameter	Value	Description
precision	0~9	The precision of the `DAY` element. The default value is 2.
fractional_seconds_precision	0~9	The precision of the fractional part of the `SECOND` element. The default value is 6.

Examples

You can use the following formats when you insert a value of the `INTERVAL DAY TO SECOND` data type. For more information about how to specify values of interval data types, see Interval literals.

Syntax	Examples	Description
INTERVAL 'dd hh:mm:ss' DAY(precision) TO SECOND(fractional_seconds_precision)	INTERVAL '140 5:12:10.2222222' DAY(3) TO SECOND(7)	The interval is 140 days, 5 hours, 12 minutes, and 10.2222222 seconds.
INTERVAL 'dd hh'DAY(precision) TO HOUR	INTERVAL '400 5' DAY(3) TO HOUR	The interval is 400 days and 5 hours.
INTERVAL 'dd hh:mm'DAY(precision) TO MINUTE	INTERVAL '4 5:12' DAY TO MINUTE	The interval is four days, 5 hours, and 12 minutes.
INTERVAL 'hh:mm' HOUR TO MINUTE	INTERVAL '11:20' HOUR TO MINUTE	The interval is 11 hours and 20 minutes.

Syntax	Examples	Description
INTERVAL 'hh:mm:ss' HOUR TO SECOND(fractional_seconds_precision)	INTERVAL '11:12:10.2222222' HOUR TO SECOND(7)	The interval is 11 hours, 12 minutes, and 10.2222222 seconds.
INTERVAL 'dd' DAY(precision)	INTERVAL '14' DAY	The interval is 14 days.
INTERVAL 'hh' HOUR	INTERVAL '160' HOUR	The interval is 160 hours.
INTERVAL 'mm' MINUTE	INTERVAL '14' MINUTE	The interval is 14 minutes.
INTERVAL 'ss' SECOND(fractional_seconds_precision)	INTERVAL '14.666' SECOND(2, 3)	The interval is 14.666 seconds.

The following code can be used to create two `INTERVAL DAY TO SECOND` columns named **interval1** and **interval2** in the **Interval_Sample** table and insert values into these columns.

```
CREATE TABLE Interval_Sample (interval1 INTERVAL DAY TO SECOND, interval2 INTERVAL DAY(3) TO SECOND(3
));
INSERT INTO Interval_Sample (interval1, interval2) VALUES ( INTERVAL '15 06:10:08' DAY TO SECOND, INT
ERVAL '150 06:10:08' DAY(3) TO SECOND(3));
SELECT * FROM Interval_Sample;
```

The following result is returned:

```
+---------------------+-------------------+
| interval1           | interval2         |
+---------------------+-------------------+
| +15 06:10:08.000000 | +150 06:10:08.000 |
+---------------------+-------------------+
```

Calculations on interval data types and other date and time types

ApsaraDB for OceanBase supports the conversion between data types. Therefore, mathematical operations on interval data types and other date and time data types are supported. However, ApsaraDB for OceanBase does not support all addition, subtraction, multiplication, and division operations on two random data types. For more information about the matrix diagram that lists the supported calculations on DATE values, see Calculations on DATE and INTERVAL values. For more information about data type conversion, see Data type conversion.

For more information about examples of calculations on interval data types and other data types, see INTERVAL YEAR TO MONTH data type.

Calculation of DATE and INTERVAL values

You can perform multiple arithmetic operations on the following types of values: dates (`DATE`), timestamps (`TIMESTAMP` , `TIMESTAMP WITH TIME ZONE` , and `TIMESTAMP WITH LOCAL TIME ZONE`), and intervals (`INTERVAL YEAR TO MONTH` and `INTERVAL DAY TO SECOND`).

ApsaraDB for OceanBase calculates results based on the following rules:

- You can use `NUMBER` constants in arithmetic operations that are performed on date and timestamp values instead of interval values. In ApsaraDB for OceanBase, timestamp values are internally converted to date values and `NUMBER` constants in arithmetic datetime and interval expressions are interpreted as the number of days. For example, `SYSDATE` + 1 represents tomorrow. `SYSDATE` - 7 represents a week ago. `SYSDATE` + (10/1440) represents 10 minutes later.

  > **Notice**
  > You cannot multiply or divide date or timestamp values.

- ApsaraDB for OceanBase converts `BINARY_FLOAT` and `BINARY_DOUBLE` operands to `NUMBER` data.
- Each `DATE` value includes a time component and the results of multiple DATE operations include fractions. Each of the fractions represents a portion of a day. For example, 1.5 days is equal to 36 hours. ApsaraDB for OceanBase provides built-in functions to return these fractions for general operations on `DATE` data. For example, the `MONTHS_BETWEEN` function returns the number of months between two dates. The fractional part of the result represents the part of a 31-day month.
- If an operand is a `DATE` or numeric value but contains neither the time zone component nor the fractional second component, the following operations are performed:
  - ApsaraDB for OceanBase converts the other operands to `DATE` data. The exception is the multiplication of a numeric value by an interval. In this case, an interval is returned.
  - If another operand contains a time zone value, ApsaraDB for OceanBase uses the time zone of the current session in the return value.
  - If another operand contains a fractional second value, the fractional second value is lost.
- Assume that you pass timestamps, time intervals, or numeric values to built-in functions that apply to only the `DATE` data type. In this case, ApsaraDB for OceanBase converts non-`DATE` values to `DATE` values.
- When interval calculations return datetime values, the results must be actual datetime values. Otherwise, the database returns errors. For example, errors are returned for the following two statements:

```
SELECT TO_DATE("31-AUG-2004','DD-MON-YYYY") + TO_YMINTERVAL("0-1") FROM DUAL;
SELECT TO_DATE("29-FEB-2004','DD-MON-YYYY") + TO_YMINTERVAL("1-0") FROM DUAL;
```

The first statement fails because the operation of adding a month to a 31-day month results in an invalid date: September 31. The second statement fails because the operation of adding a year to a date that occurs only every four years is invalid. However, the operation of adding four years to February 29 is valid and the calculation result is February 29, 2008:

```
SELECT TO_DATE("29-FEB-2004", "DD-MON-YYYY") + TO_YMINTERVAL("4-0") FROM DUAL;
```

17.1.5.4.1.5. RAW data type

The `RAW` data type stores variable-length binary data. The data is transferred in binary mode across different platforms. The binary data does not need to be converted even if the platforms use different character sets. In ApsaraDB for OceanBase, this data type is used to store binary data or byte strings.

`RAW` is similar to `VARCHAR2`. The RAW data type is declared by using `RAW(length)`. The `length` parameter specifies the value length in bytes. A value in a database column of the RAW data type can be up to 2,000 bytes. A variable of the RAW data type can be up to 2,000 bytes.

Syntax

```
RAW(length)
```

Parameters

Parameter	Description
length	The length of the value. The length is measured in bytes. A value in a database column of the RAW data type can be up to 2,000 bytes. A variable of the RAW data type can be up to 2,000 bytes.

Examples

- **Example 1**: Assume that you declare a column of the `RAW` data type in the **test_raw** table and insert a record into the table.

```
CREATE TABLE test_raw (c1 RAW(10));
INSERT INTO test_raw VALUES (utl_raw.cast_to_raw('1234567890'));
```

Execute the following statement:

```
SELECT utl_raw.cast_to_varchar2(c1) FROM test_raw;
```

The following result is returned:

```
+------------------------------+
|    UTL_RAW.CAST_TO_RAW(C1)   |
+------------------------------+
|          1234567890          |
+------------------------------+
```

- **Example 2**: Assume that you insert two records into the **raw_test** table.

```
CREATE TABLE raw_test (id number, raw_date raw(10));
INSERT INTO raw_test VALUES  (1, hextoraw('ff'));
INSERT INTO raw_test VALUES  (2, utl_raw.cast_to_raw('051'));
```

Execute the following statement:

```
SELECT * FROM raw_test;
```

The following result is returned:

```
+-----------+----------+
|    ID     | RAW_DATE |
+-----------+----------+
|      1    |     ff   |
+-----------+----------+
|      2    |   303531 |
+-----------+----------+
```

The SQL function `HEXTORAW()` converts the data in a string to a hexadecimal value. The SQL function `UTL_RAW.CAST_TO_RAW([VARCHAR2])` stores the ASCII code of each character in a string into a `RAW` field. In this example, **051** is converted to **303531**.

- **Example 3**: ApsaraDB for OceanBase converts a value of the `RAW` type to a value of a character data type. Each character in the result represents the hexadecimal value for four consecutive bits in the value of the `RAW` type. The hexadecimal values can be digits 0 to 9 and letters A to F (or a to f).

For example, the binary number 11001011 of the `RAW` data type is converted to the **CB** string.

To convert character data to a `RAW` value, ApsaraDB for OceanBase interprets each consecutive input character as four consecutive bits of binary data. Then, ApsaraDB for OceanBase builds the resulting `RAW` value by concatenating those bits.

> **Notice**
>
> If an input character is not a hexadecimal value, an error is reported. Hexadecimal values include digits 0 to 9 and letters A to F (or a to f). If the number of characters is odd, the result is undefined.

More information

Character conversion

When data is transferred between databases or between the database character set and the client character set, ApsaraDB for OceanBase automatically converts the `CHAR` and `VARCHAR2` data across database character sets. When the `RAW` data is transferred, ApsaraDB for OceanBase does not convert the characters.

RAW functions

Function	Description
HEXTORAW()	`HEXTORAW()` converts the data in a string to a hexadecimal string. Every two characters in the source string corresponds to 1 byte of the resulting `RAW` value.

Function	Description
RAWTOHEX(rawvalue)	This function converts `rawvalue` of the `RAW` type to a hexadecimal string. Each byte of `rawvalue` is converted to a double-byte string.
UTL_RAW_CAST_TO_RAW([VARCHAR2])	This function only converts the data type from `VARCHAR2` to `RAW`. The content stored in the data remains unchanged.
UTL_RAW_CAST_TO_VARCHAR2([RAW])	This function only converts the data type from `RAW` to `VARCHAR2`. The content stored in the data remains unchanged.
UTL_RAW.BIT_OR(), UTL_RAW.BIT_AND(), and UTL_RAW.BIT_XOR()	Bitwise operation.

17.1.5.4.1.6. Large object data types

Overview of large object data types

The large object (LOB) data types are used to store large amounts of unstructured data, such as texts, images, videos, and spatial data. The LOB data types include binary LOB (`BLOB`) and character LOB (`CLOB`).

When you create a table, you can specify tablespaces and storage characteristics for LOB columns or LOB object attributes. The specified tablespaces and storage characteristics can be different from those specified in the table.

ApsaraDB for OceanBase supports the following LOB data types:

Type	Length	Maximum length (characters)	Character set
BLOB	Variable length	48M	BINARY
CLOB	Variable length	48M	UTF8MB4

BLOB data type

The binary large object (`BLOB`) data type is used to store large amounts of binary objects in a database. You can regard `BLOB` objects as bitstreams that do not have character set semantics. A `BLOB` object has a maximum length of 48 MB and uses the `BINARY` character set.

`BLOB` objects have full transaction support. The changes that you make by using `SQL` statements or the `DBMS_LOB` package participate fully in the transaction. You can submit and roll back operations on `BLOB` values. However, you cannot save a `BLOB` locator in PL/SQL in one transaction and then use it in another transaction or session.

> **Notice**
> If you store an oversized binary file, the database performance is degraded.

In most cases, the `BLOB` fields are used to store the information about large files in a database, such as images, files, and music files. The database converts large files to binary files and then stores the binary files.

In the following example, a table named **blob_table** is created, and the `BLOB` data type is specified for the **blob_cl** column.

```
CREATE TABLE blob_table (blob_cl BLOB);
```

CLOB data type

`CLOB` is short for character large object. The CLOB data type stores single-byte and multi-byte character data. Fixed-width and variable-width character sets are supported. Single-byte and multi-byte character data use the database character set. `CLOB` does not support character sets that have different widths. The maximum length (characters) of bytes that can be stored is 48 MB and the character set is `UTF8MB4` .

`CLOB` objects provide full transactional support. Changes that are made by using `DBMS_ LOB` packages and `SQL` are fully involved in transactions. You can commit and roll back `CLOB` value operations. However, you cannot save a `CLOB` locator to PostgreSQL or SQL Server in one transaction and then use the locator in another transaction or session.

A field of the `VARCHAR2` data type can be a maximum of 32,767 characters in length. If you need to store a field that is more than 32,767 characters in length, you can use the `CLOB` data type. In addition, you can use the `CLOB` data type to store `CHAR` data. For example, XML documents use `CLOB` data to store content.

In the following example, the table named **temp** is created and the data type of the **temp_clob** column is set to `CLOB` :

```
CREATE TABLE temp (temp_clob CLOB);
```

17.1.5.4.2. Comparison rules of data types

17.1.5.4.2.1. Overview of data type comparison rules

The data type comparison rules specify how ApsaraDB for OceanBase compares the values of each data type. The data type comparison rules in ApsaraDB for OceanBase support the following data values:

- Numeric values

- Date values
- Character values

More information

- Data type precedences
- Data type conversions
- Security notes for data conversions

17.1.5.4.2.2. Numeric values

Numeric data includes fixed-point numbers, floating-point numbers, and zeros.

The following list provides the comparison rules for numeric data:

- Larger values are larger than smaller values. For example, 5.5 is larger than 2.1.
- Negative values are smaller than zeros. For example, -3 is smaller than 0 and -200 is smaller than -1.
- Positive values are larger than zeros. For example, 20 is larger than 0 and 100 is larger than 1.

17.1.5.4.2.3. Date values

The `DATE` data type stores date and time information. Each `DATE` value in ApsaraDB for OceanBase stores the following information: year, month, day, hour, minute, and second, but the value does not contain time zone information.

The following list provides the comparison rules for date data:

- The current time is greater than the past time. For example, the date value of May 1, 2018 is greater than the date value of May 1, 2012.
- The time in the afternoon is greater than that in the morning. For example, the date and time value of 15:30:00 on February 2, 2019 is greater than the date and time value of 10:30:00 on February 2, 2019.
- The time in the morning is greater than the time of the previous day. For example, the date and time value of 02:30:00 on March 5, 2019 is greater than the date and time value of 23:30:00 on March 4, 2019.

17.1.5.4.2.4. Character values

Character data is compared by using character values. Character values are compared by using the following two measures:

- Binary and linguistic comparisons
- Blank-padded or nonpadded comparison semantics

Binary and linguistic comparisons

Binary comparison

In the default binary comparison, ApsaraDB for OceanBase compares strings by using the cascaded values of the numeric codes for the characters in the character set of the database. If the numeric value of a character in the character set is larger than the numeric value of another character, the former character is larger. ApsaraDB for OceanBase does not support the American Standard Code for Information Interchange (ASCII) or Extended Binary Coded Decimal Interchange Code (EBCDIC) character set.

Linguistic comparison

In linguistic sorting, both SQL sorting and comparison are performed by using the linguistic rules that are specified by `NLS_SORT`. If the binary sequence of the character encoding does not match the language sequence that is required by the character set, linguistic comparison is used. If the `NLS_SORT` parameter is not set to `BINARY` and the `NLS_COMP` parameter is set to `LINGUISTIC`, language comparison is used.

Blank-padded and nonpadded comparison semantics

Blank-padded comparison semantics

If the blank-padded comparison semantics is used and two values are different in length, ApsaraDB for OceanBase first adds blanks to the end of the shorter value. This ensures that the two values are the same in length. ApsaraDB for OceanBase compares the values character by character until the first different character is identified. The value that has a larger character at the first difference position is considered larger. If the two values do not have different characters, they are considered equal. This rule indicates that the two values are equal only if they are different in the number of trailing blanks.

> **Notice**
>
> ApsaraDB for OceanBase uses the blank-padded comparison semantics only if both values in the comparison are the values of the `CHAR` or `NCHAR` data type, text literals, or the values that are returned by the `USER` function.

Nonpadded comparison semantics

In the blank-padded comparison semantics, ApsaraDB for OceanBase compares two values character by character until the first different character is identified. The value that has a larger character at the position is considered larger. If the two values in different lengths are the same up to the end of the shorter value, the longer value is considered larger. If the two values whose lengths are equal do not have different characters, the two values are considered equal.

> **Notice**
>
> If the data type of one or two values in the comparison is `VARCHAR2` or `NVARCHAR2`, ApsaraDB for OceanBase uses the nonpadded comparison semantics.

Examples

If you compare two character values by using different comparison semantics, the results are different. In the following example, the blank-padded comparison semantics and the nonpadded comparison semantics are used for comparison.

Blank-padded	Nonpadded
'ac' > 'ab'	'ac' > 'ab'
'ab' > 'a '	'ab' > 'a '
'ab' > 'a'	'ab' > 'a'

Blank-padded	Nonpadded
'ab' = 'ab'	'ab' = 'ab'
'ac' > 'ab'	'ac' > 'ab'
'a ' = 'a'	'a ' > 'a'

The results of blank-padded and nonpadded comparisons are generally the same. The comparison example of the last row illustrates the difference between the blank-padded comparison semantics and the nonpadded comparison semantics.

17.1.5.4.2.5. Data type precedence

ApsaraDB for OceanBase uses the data type precedence to specify the order in which data types are implicitly converted.

The following list provides the precedence from highest to lowest for converting data types in ApsaraDB for OceanBase.

1. DATETIME and INTERVAL data types
2. `BINARY_DOUBLE` data type
3. `BINARY_FLOAT` data type
4. `NUMBER` data type
5. Character data types
6. All the other built-in data types

17.1.5.4.2.6. Data type conversion

Generally, an expression cannot contain values of different data types. However, to enable expressions to be calculated, ApsaraDB for OceanBase allows you to implicitly and explicitly convert values from one data type to another.

Implicitly convert data types

If a conversion makes sense, ApsaraDB for OceanBase automatically converts values from one data type to another. Rules of implicitly converting data types are:

- For `INSERT` and `UPDATE` operations, ApsaraDB for OceanBase converts variable values into the column type.
- For `SELECT FROM` operations, ApsaraDB for OceanBase converts the column data type into the destination variable type.
- When character values are compared with numeric values, ApsaraDB for OceanBase converts the character values into numeric values.
- When numeric values are processed, ApsaraDB for OceanBase adjusts the precision and decimal places. The generated numeric data type is different from the numeric data type that is found in the base table.
- Conversions between character values or numeric values and floating-point numbers can be inexact. This is because character types and numeric types use decimal precision to represent numeric values but floating-point numbers use binary precision.

- Assume that a value is converted from `CLOB` to a character type, such as `VARCHAR2`, or from `BLOB` to `RAW`. If the size of data to be converted is larger than the size of the destination data type, the database returns an error.
- When timestamp values are converted into `DATE` values, the fractional second portion of the timestamp values is truncated and rounded.
- The result of converting `BINARY_FLOAT` to `BINARY_DOUBLE` is exact.
- If the number of digits of precision for `BINARY_DOUBLE` exceeds the number of digits supported by `BINARY_FLOAT`, the result of converting `BINARY_DOUBLE` to `BINARY_FLOAT` is inexact.
- When character values are compared with `DATE` values, ApsaraDB for OceanBase converts character data into `DATE` values.
- When a value is assigned, ApsaraDB for OceanBase converts the value on the right side of the equal sign into the data type of the object to which the value is assigned on the left.
- ApsaraDB for OceanBase converts non-character types into character types or national character types during join operations.

Matrix of implicit data type conversions

The following table lists all implicit conversions between data types. You do not need to consider the directions or contexts of conversions. Hyphens (-) indicate that the conversion is not supported.

Data type	CHAR	VARCHAR2	NCHAR	NVARCHAR2	DATE	DATETIME / INTERVAL	NUMBER	BINARY_FLOAT	BINARY_DOUBLE	RAW	CLOB	BLOB
CHAR	-	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
VARCHAR2	Yes	-	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	-
NCHAR	Yes	Yes	-	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	-
NVARCHAR2	Yes	Yes	Yes	-	Yes	Yes	Yes	Yes	Yes	Yes	Yes	-
DATE	Yes	Yes	Yes	Yes	-	-	-	-	-	-	-	-
DATETIME / INTERVAL	Yes	Yes	Yes	Yes	-	-	-	-	-	-	-	-

NUMBER	Yes	Yes	Yes	Yes	-	-	-	Yes	Yes	-	-	-
BINARY_FLOAT	Yes	Yes	Yes	Yes	-	-	Yes	-	Yes	-	-	-
BINARY_DOUBLE	Yes	Yes	Yes	Yes	-	-	Yes	Yes	-	-	-	-
RAW	Yes	Yes	Yes	Yes	-	Yes [1]	-	-	-	-	Yes	-
CLOB	Yes	Yes	Yes	Yes	-	-	-	-	-	-	-	Yes
BLOB	-	-	-	-	-	-	-	-	-	Yes	-	-

[1] You cannot directly convert from `RAW` to `INTERVAL`. However, you can use `UTL_RAW.CAST_TO_VARCHAR2([RAW])` to convert from `RAW` to `VARCHAR2`. Then, convert the generated `VARCHAR2` value to `INTERVAL`.

Directions of implicit conversions between different character types

Data type	TO_CHAR	TO_VARCHAR2	TO_NCHAR	TO_NVARCHAR2
from CHAR	-	VARCHAR2	NCHAR	NVARCHAR2
from VARCHAR2	VARCHAR2	-	NVARCHAR2	NVARCHAR2
from NCHAR	NCHAR	NCHAR	-	NCHAR2
from NVARCHAR2	NVARCHAR2	NVARCHAR2	NVARCHAR2	-

Examples of implicit data type conversions

Execute the following statement:

```
SELECT 5 * 10 + 'james' FROM DUAL;
```

The statement fails to be executed and you receive the following error message:

```
invalid number
```

This is because ApsaraDB for OceanBase implicitly converts `'james'` into the numeric type, but fails to convert it.

In this example, the string **'2'** is implicitly converted from the `CHAR` data type into the value **2** of the numeric data type. The calculation result is **52**.

Execute the following statement:

```
SELECT 5 * 10 + '2' FROM  DUAL;
```

The following query result is returned:

```
+---------------------+
|     5 * 10 + '2'    |
+---------------------+
|          52         |
+---------------------+
```

Explicitly convert data types

You can use SQL conversion functions to convert data types. SQL functions explicitly convert one data type to another.

Matrix of explicit data type conversions

Data type	To CHAR, VARCHAR2, NCHAR, and NVARCHAR2	To NUMBER	To Datetime/ Interval	To RAW	To CLOB and BLOB	To_BINARY_FLOAT	To_BINARY_DOUBLE
From CHAR, VARCHAR2, NCHAR, and NVARCHAR2	TO_CHAR(char .) and TO_NCHAR(char .)	TO_NUMBER	TO_DATE, TO_TIMESTAMP, TO_TIMESTAMP_TZ, TO_YMINTERVAL, and TO_DSINTERVAL	HEXTORAW	TO_CLOB	TO_BINARY_FLOAT	TO_BINARY_DOUBLE
From NUMBER	TO_CHAR(number) and TO_NCHAR(number)	--	TO_DATE, NUMTOYM_INTERVAL, and NUMTOOLS_INTERVAL	--	--	TO_BINARY_FLOAT	TO_BINARY_DOUBLE
From Datetime/ Interval	TO_CHAR(date) and TO_NCHAR(date)	--	--	--	--	--	--

From RAW	RAWTOHEX and RAWTONHEX	--	--	--	TO_BLOB	--	--
From CLOB and BLOB	TO_CHAR and TO_NCHAR	--	--	--	TO_CLOB	--	--
From BINARY_FLOAT	TO_CHAR(char .) and TO_NCHAR(char .)	TO_NUMBER	--	--	--	TO_BINARY_FLOAT	TO_BINARY_DOUBLE
From BINARY_DOUBLE	TO_CHAR(char .) and TO_NCHAR(char .)	TO_NUMBER	--	--	--	TO_BINARY_FLOAT	TO_BINARY_DOUBLE

Examples of explicit data type conversions

You can use the `TO_CHAR` function to explicitly convert the current time into the desired format for output.

Execute the following statement:

```
SELECT TO_CHAR(SYSDATE, 'YYYY_MM_DD') FROM DUAL;
```

The following query result is returned:

```
+-------------------------------+
| TO_CHAR(SYSDATE,'YYYY_MM_DD') |
+-------------------------------+
| 2020_02_27                    |
+-------------------------------+
```

17.1.5.4.2.7. Security notes for data conversions

If date and time values are implicitly converted to text or explicitly converted to text without specifying a format model, the format model is defined by a global session parameter. The name of the parameter can be `NLS_DATE_FORMAT`, `NLS_TIMESTAMP_FORMAT`, or `NLS_TIMESTAMP_TZ_ FORMAT`. This depends on the type of source data. The values of these parameters can be specified in the client environment or the `ALTER SESSION` statement.

If date and time values in dynamically constructed SQL statements are explicitly converted without specifying a format model, database security is negatively affected when the format model selects a session parameter.

The dynamically constructed SQL statements are those generated by programs or stored procedures. To execute dynamically constructed SQL statements, the built-in procedural language (PL) package `DBMS_SQL` in ApsaraDB for OceanBase is required, or the SQL statement is relevant to the PL statement `EXECUTE IMMEDIATE`. However, these are not the only methods to execute the dynamically constructed SQL text.

In the following example, the data type of `start_date` is `DATE`. The format model that is specified in the session parameter `NLS_DATE_FORMAT` is used to convert the value of `start_date` to text. Then, the result is passed to the SQL text. The date and time format model can consist of text that is enclosed in double quotation marks (").

```
SELECT last_name FROM employees WHERE hire_date > '' || start_date || '';
```

> **Note**
>
> The user who sets globalization parameters for the format model that is used for explicit conversion can determine what text is generated by the previous conversion.
>
> If the SQL statement is executed by a procedure, SQL injection may occur during the execution because the session variables are modified. Procedures that have higher permissions, such as Definer's Rights Procedure, may cause more impact on security.

17.1.5.4.3. Literals

17.1.5.4.3.1. Literal overview

A literal is a notation for representing a fixed value. For most functions and SQL statements, you must specify literals. Literals can also serve as a part of expressions and conditions. ApsaraDB for OceanBase supports the following literals:

- Text literals
- Numeric literals
- Datetime literals
- Interval literals

17.1.5.4.3.2. Text literals

Text literals are strings that are enclosed in single quotation marks `(')` and are used to specify the values of strings in expressions, conditions, SQL functions, and SQL statements.

Text literals have the attributes of the `CHAR` and `VARCHAR2` data types.

- In expressions and conditions, ApsaraDB for OceanBase uses blank-padded comparison semantics for comparison and considers text literals as the `CHAR` data type.
- When you specify text literals, a value of the `CHAR` data type can be up to 2,000 bytes in length. A value of the `VARCHAR2` data type can be up to 32,767 bytes in length.

The following examples show some valid text literals. To show a single quotation mark (') in a string, you must insert a single quotation mark (') before the single quotation mark (') in the string.

```
'Jackie''s raincoat'
'Hello'
'09-MAR-98'
'It's a nice day today'
```

17.1.5.4.3.3. Numeric literals

Numeric literals allow you to use numeric values to specify the fixed number and floating-point number values.

Integer literals

If integers appear in expressions, conditions, SQL functions, and SQL statements, you must use integer literals to specify values.

The following integer literals are valid:

```
8
+186
-15
```

Number literals and floating-point literals

If numbers appear in expressions, conditions, SQL functions, and SQL statements, you must use number or floating-point literals to specify values.

The following number literals are valid:

```
12
+6.87
0.5
25e-03
-9
```

The following floating-point literals are valid:

```
25f
+6.34F
0.5d
-1D
```

A number literal can store a number whose maximum precision is 38 digits. If a literal requires a higher precision than that provided by `NUMBER`, `BINARY_FLOAT`, or `BINARY_DOUBLE`, ApsaraDB for OceanBase truncates the value. If the range of the literal exceeds the range that is supported by `NUMBER` `BINARY_FLOAT`, or `BINARY_DOUBLE`, ApsaraDB for OceanBase reports an error.

Examples

The decimal point delimiter in a numeric literal is always a dot (.). If you specify a text literal in a position where a numeric literal is expected, the text literal is converted to a numeric literal.

In the following example, **2** is multiplied by the numeric literal **2.2** and **2** is multiplied by the text literal **'3.3'**:

```
SELECT 2*2.2, 2*'3.3' FROM DUAL;
```

The following result is returned:

```
+-------+---------+
| 2*2.2 | 2*'3.3' |
+-------+---------+
|   4.4 |     6.6 |
+-------+---------+
```

17.1.5.4.3.4. Datetime literals

Date literals

You can use a string to specify a date literal. You can also use a `TO_DATE` function to convert a character or numeric value to a date value. You can use a `TO_DATE` expression in place of a string to specify a date literal. This applies to only date literals.

```
TO_DATE('2020-03-25 11:05:00', 'YYYY-MM-DD HH24:MI:SS')
```

When you use a date value to specify a date literal, you must use the date value of the Gregorian calendar. You can also use the ANSI format to specify a date literal, as shown in the following example. The ANSI date literal does not contain the time information and must be specified in the **YYYY-MM-DD** format.

```
DATE '2020-03-25'
```

You can also use the default date value of the database to specify a date literal. If the default value is used in a date expression, ApsaraDB for OceanBase automatically converts the character value in the default date format to a date value. The default date value of the database is specified by the initialization parameter `NLS_DATE_FORMAT`. In this example, the default format is **DD-MON-RR**.

```
TO_DATE('25-FEB-20', 'DD-MON-RR')
```

If you specify a date value that does not include the time part, the default time is midnight (00:00:00 in the 24-hour clock and 12:00:00 in the 12-hour clock). If a specified date value does not include the date part, the default date is the first day of the current month.

The `DATE` column of a table in ApsaraDB for OceanBase always contains both the date and time fields. Therefore, if you query the `DATE` column, you must specify the time field in the query or make sure that the time field in the `DATE` column is specified as midnight. Otherwise, the database may not return the query result that you expect. For example, create a **Date_Literals** table that contains the **id** column and the date column **datecol**.

```
CREATE TABLE Date_Literals (id NUMBER, datecol DATE);
```

Insert the system date and time **SYSDATE** of the current session into the table. In this example, the `TRUNC` function is used to set the time field to midnight. The `TRUNC` function truncates the date part of **SYSDATE**. This way, the time in the **datecol** column is automatically filled with the default midnight time:

```
INSERT INTO Date_Literals VALUES (1,SYSDATE);
INSERT INTO Date_Literals VALUES (2,TRUNC(SYSDATE));
```

The following data in the table is available:

```
+------+---------------------+
| id   | datecol             |
+------+---------------------+
|    1 | 25-FEB-20 11:28:16  |
|    2 | 25-FEB-20 00:00:00  |
+------+---------------------+
```

If the query does not contain the time information, you can use the greater than or less than condition instead of the equal to or not equal to condition in the query:

```
SELECT * FROM Date_Literals WHERE datecol > TO_DATE('2020-02-24', 'YYYY-MM-DD');
```

The following result is returned:

```
+------+---------------------+
| id   | datecol             |
+------+---------------------+
|    1 | 25-FEB-20 11:28:16  |
|    2 | 25-FEB-20 00:00:00  |
+------+---------------------+
```

If you use the equal to condition, only the date whose time information is midnight is returned because the query does not contain the time information.

```
SELECT * FROM Date_Literals WHERE datecol = TO_DATE('2020-02-25', 'YYYY-MM-DD');
```

The following result is returned:

```
+------+---------------------+
| id   | datecol             |
+------+---------------------+
|    2 | 25-FEB-20 00:00:00  |
+------+---------------------+
```

You can also filter out the time field in the **datecol** column and query only the date field:

```
SELECT * FROM Date_Literals WHERE TRUNC(datecol) = DATE '2020-02-25';
```

The following result is returned:

```
+------+---------------------+
| id   | detacol             |
+------+---------------------+
|    1 | 25-FEB-20 11:28:16  |
|    2 | 25-FEB-20 00:00:00  |
+------+---------------------+
```

Timestamp literals

ApsaraDB for OceanBase supports the following three types of timestamp literals:

- TIMESTAMP
- TIMESTAMP WITH TIME ZONE
- TIMESTAMP WITH LOCAL TIME ZONE

TIMESTAMP literals

The `TIMESTAMP[(scale)]` data type stores year, month, day, hour, minute, and second, and fractional second values. When you specify a TIMESTAMP literal, you can set the maximum precision of the second field to the nanosecond that lies in the ninth digit.

```
TIMESTAMP '2020-02-25 11:26:18.316'
```

TIMESTAMP WITH TIME ZONE literals

TIMESTAMP WITH TIME ZONE literals are timestamp literals that include time zone information.

The `TIMESTAMP [(scale)] WITH TIME ZONE` data type is a variant of the `TIMESTAMP[(scale)]` data type. The TIMESTAMP [(scale)] WITH TIME ZONE data type stores the information, such as time zone offsets and the names of time zone regions (TZRs), in addition to the information that the `TIMESTAMP[(scale)]` data type stores.

When you specify a TIMESTAMP WITH TIME ZONE literal, you must specify the time zone information. You can also set the maximum precision of the second field to the nanosecond that lies in the ninth digit. In the following example, the time zone offset is used to specify the value of the time zone field.

```
TIMESTAMP '2020-02-25 11:26:18.316 +08:00'
```

Assume that the values of two TIMESTAMP WITH TIME ZONE literals represent the same point in time in the Greenwich Mean Time (GMT) time zone. The two literals are considered as the same literals even if the values of the time zone fields for these two literals are different. In the following example, 08:00:00 in the GMT-8 time zone and 11:00:00 in the GMT-5 time zone are actually the same point in time:

```
TIMESTAMP '2020-04-25 08:26:18.316 -08:00'
TIMESTAMP '2020-04-25 11:26:18.316 -05:00'
```

In a literal, we can replace the time zone offset with the name of a TZR. In the following example, **-08:00** is replaced with **America/Los_Angeles**.

```
TIMESTAMP '2020-02-01 11:00:00 America/Los_Angeles'
```

In some regions, the daylight saving time (DST) switches. To eliminate the time ambiguity when the DST switches, you can use both the TZR name and a corresponding abbreviation TZD. This ensures that the literal value is the daylight saving time.

```
TIMESTAMP '2020-06-01 11:00:00 America/Los_Angeles PDT'
```

TIMESTAMP WITH LOCAL TIME ZONE literals

`TIMESTAMP [(scale)] WITH LOCAL TIME ZONE` is a data type that contains the information about the local time zone. In ApsaraDB for OceanBase, specific TIMESTAMP WITH LOCAL TIME ZONE literals are unavailable. The `TIMESTAMP [(scale)] WITH LOCAL TIME ZONE` literals are assigned values by using other valid date and time literals. The following table shows some formats that can be used to insert values into the TIMESTAMP WITH LOCAL TIME ZONE column, and the return values of queries:

Value specified in the INSERT statement	Return value of the query
'25-FEB-20'	25-FEB-20 00.00.000000
SYSTIMESTAMP	25-FEB-20 14:28:41.264258
TO_TIMESTAMP('25-FEB-2020', 'DD-MON-YYYY')	25-FEB-20 00.00.000000
SYSDATE	25-FEB-20 02.55.29.000000 PM

Value specified in the INSERT statement	Return value of the query
TO_DATE('25-FEB-20', 'DD-MON-YYYY')	25-FEB-20 12.00.00.000000 AM
TIMESTAMP'2020-02-25 8:00:00 America/Los_Angeles'	25-FEB-20 08.00.00.000000 AM

17.1.5.4.3.5. Interval literals

An interval literal specifies the value of a period of time. ApsaraDB for OceanBase supports the following two types of interval literals:

- INTERVAL YEAR TO MONTH
- INTERVA DAY TO SECOND

Leading and trailing fields

Each type of interval literal contains a leading field and an optional trailing field. The leading field defines the basic unit of measured date or time. The trailing field defines the smallest increment of the considered basic unit. For example, DAY TO MINUTE is used to specify an interval literal whose minimum unit is month. The leading field is `YEAR` and the trailing field is `MINUTE`. The trailing field is optional. When you specify the interval literal, the trailing field can be omitted.

Interval literals have the following fields: `YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, and `SECOND`. The weights of these fields are in descending order. The weight of the `YEAR` field is the largest. If you need to specify a trailing field, the weight of the trailing field in the literal must be lower than that of the leading field. Otherwise, the specified trailing field is invalid. For example, `INTERVAL '1-2' DAY TO YEAR` is an invalid literal.

The number of digits in the value of the leading field ranges from 0 to 9. The default value is 2. The `SECOND` field specifies the number of seconds. This field value can be accurate to at most nine decimal places and at least zero decimal place. The default precision is six decimal places. When a field value exceeds the specified range, the database returns an error. If the number of decimal places of the `SECOND` field exceeds the specified precision, the field value is rounded to the value that is a specified precision.

INTERVAL YEAR TO MONTH literals

The `INTERVAL YEAR TO MONTH` literal specifies a period of time in the unit of year and month.

The following examples show you some `INTERVAL YEAR TO MONTH` literals:

Example	Description
INTERVAL '265-2' YEAR(3) TO MONTH	An interval of 265 years and two months. The precision of the leading field `YEAR` is greater than the default precision: two digits. The specified precision must match the number of digits of the value.
INTERVAL '265' YEAR(3)	An interval of 265 years.

Example	Description
INTERVAL '500' MONTH(3)	An interval of 500 months or an interval of 41 years and eight months.
INTERVAL '10' MONTH	An interval of 10 months.
INTERVAL '123' YEAR	Returns an error. The value 123 exceeds the default precision: two digits.

You can add one `INTERVAL YEAR TO MONTH` literal to another `INTERVAL YEAR TO MONTH` literal or subtract one INTERVAL YEAR TO MONTH literal from another INTERVAL YEAR TO MONTH literal. For example: `INTERVAL '6-2' YEAR TO MONTH` plus `INTERVAL'21' MONTH` equals to `INTERVAL '7-11' YEAR TO MONTH`.

INTERVAL DAY TO SECOND literals

The `INTERVAL DAY TO SECOND` literal specifies a period of time for which the day and the specific time are used as the unit.

The following examples show some `INTERVAL DAY TO SECOND` literals:

Example	Description
INTERVAL '4 5:12:10.222' DAY TO SECOND(3)	An interval of four days, 5 hours, 12 minutes, and 10.222 seconds. The default decimal point precision of the `SECOND` field is 6. If you do not manually set the precision to 3, the system pads the decimal places of the returned result with zeros.
INTERVAL '4 5:12' DAY TO MINUTE	An interval of four days, 5 hours, and 12 minutes.
INTERVAL '400 5' DAY(3) TO HOUR	An interval of 400 days and 5 hours. The precision of the leading field `DAY` exceeds the default precision: two digits. Manually specify the precision as 3.
INTERVAL '400' DAY(3)	An interval of 400 days.
INTERVAL '11:12:10.2222222' HOUR TO SECOND(7)	An interval of 11 hours, 12 minutes, and 10.2222222 seconds. The precision for the value of the `SECOND` field value exceeds the default precision: six digits. The precision that matches the value is manually specified here.

Example	Description
INTERVAL '11:20' HOUR TO MINUTE	An interval of 11 hours and 20 minutes.
INTERVAL '10' HOUR	An interval of 10 hours.
INTERVAL '10:22' MINUTE TO SECOND	An interval of 10 minutes and 22 seconds.
INTERVAL '10' MINUTE	An interval of 10 minutes.
INTERVAL '4' DAY	An interval of four days.
INTERVAL '25' HOUR	Indicates an interval of 25 hours.
INTERVAL '40' MINUTE	An interval of 40 minutes.
INTERVAL '120' HOUR(3)	An interval of 120 hours.
INTERVAL '30.12345' SECOND(2,4)	An interval of 30.1235 seconds. The number of decimal places of the SECOND value exceeds the specified precision. Therefore, this value is rounded to the fourth decimal place.

You can perform an addition or subtraction operation on an `INTERVAL DAY TO SECOND` literal and another `INTERVAL DAY TO SECOND` literal. For example, `INTERVAL'20' DAY` minus `INTERVAL'239' HOUR` is equal to `INTERVAL'10-1' DAY TO SECOND`.

17.1.5.4.4. Formatting

17.1.5.4.4.1. Formatting overview

Formatting specifies the format of datetime or numeric data that is stored in databases. When you convert a string to a datetime or numeric value, the formatting determines how ApsaraDB for OceanBase converts and stores the string. In an SQL statement, you can set the parameters of the `TO_CHAR`, `TO_NUMBER`, and `TO_DATE` functions to specify the following items:

- The format of the values that are returned by ApsaraDB for OceanBase
- The format of the values that are stored in ApsaraDB for OceanBase

ApsaraDB for OceanBase supports the following types of data formatting:

Number formatting

Number formatting specifies the formats of fixed-point and floating-point numbers that are stored in databases. When you need to convert `NUMBER`, `BINARY_FLOAT`, or `BINARY_ DOUBLE` values in an SQL statement to `VARCHAR2` values, you can use number formatting in functions. A number formatting model consists of one or more number format elements. For more information, see Number formatting.

Datetime formatting

Datetime formatting specifies the format of date and time data that is stored in databases. The total length of a string that is obtained after datetime formatting cannot exceed 22 characters. When you need to convert character values in a non-default format to values in the datetime format, you can use datetime formatting in functions. A datetime formatting model consists of one or more datetime format elements. For more information, see Datetime formatting. For more information about the rules for converting strings to date values, see String-to-date conversion rules.

The `RR` datetime format element is similar to the `YY` datetime format element. However, the RR element offers additional flexibility for storing the values of dates that are not covered by the current century. For more information about RR, see RR datetime format element.

Formatting modifiers

ApsaraDB for OceanBase does not support `FX` or `FM` formatting modifiers.

17.1.5.4.4.2. Number formatting

Number formatting specifies the formats of fixed-point and floating-point numbers that are stored in databases.

Number formatting in functions

The following functions for numeric type conversion use number formatting:

- Assume that `NUMBER`, `BINARY_FLOAT`, or `BINARY_ DOUBLE` values appear in expressions, conditions, SQL functions, and SQL statements. If you need to convert these values to `VARCHAR2` values, set the corresponding parameters of the `TO_CHAR` function to specify the formats of these numeric values.
- Assume that `CHAR` or `VARCHAR2` values appear in expressions, conditions, SQL functions, and SQL statements. If you need to convert these values to `NUMBER` values, set the corresponding parameters of the `TO_NUMBER` function to specify the formats of these numeric values. The `NLS_NUMERIC_CHARACTERS` parameter is not supported. If you need to convert the values to `BINARY_FLOAT` or `BINARY_DOUBLE` values, set the corresponding parameters of `TO_BINARY_FLOAT` and `TO_BINARY_DOUBLE` functions to specify the formats of these numeric values.

Number formatting rounds a value to the specified number of significant digits. If a value has a decimal part and the number of significant digits to the left is greater than that specified in the format, the value is replaced with `#`. If the positive value of the `NUMBER` type is extremely large and cannot be represented in the specified format, the value is replaced with the infinity symbol (~). If the negative value of the `NUMBER` type is extremely small and cannot be represented in the specified format, the value is replaced with the negative infinity symbol (-~).

Number format elements

ApsaraDB for OceanBase is different from Oracle databases because the number format elements in ApsaraDB for OceanBase support only standard numeric formats. The following table lists the number format elements that are supported by ApsaraDB for OceanBase.

Element	Example	Description
. (decimal point)	99.99	Returns a decimal number where the decimal point is in the specified place. **Constraint**: In number formatting, you can specify only one decimal point.
0	0999 9990	For 0999, leading zero values are returned. For 9990, trailing zero values are returned.
9	9999	Returns a value that has the specified number of digits. If the value is positive, a number with leading white-space characters is returned. If the value is negative, a number with a leading minus sign (-) is returned. Leading zeros are not displayed and are replaced with white-space characters for all of the numeric values except zero values. A zero is returned for each non-leading zero value that is included in the integer part of the fixed-point number.

If the format parameter is omitted, ApsaraDB for OceanBase converts the numeric value to a `VARCHAR2` value of a sufficient length to retain all of the significant digits of the value.

Examples

Execute the following statement:

```
SELECT TO_CHAR(0, '99.99') FROM DUAL;
```

The following query result is returned:

```
+--------------------+
| TO_CHAR(0,'99.99') |
+--------------------+
|    .00             |
+--------------------+
```

The following table lists the results of queries where **number** is set to different values and the 'fmt' format element is used.

```
SELECT TO_CHAR(number, 'fmt')  FROM DUAL;
```

number	'fmt'	Result
0	99.99	' .00'
+0.1	99.99	' .10'
-0.2	99.99	' -.20'
0	90.99	' 0.00'
+0.1	90.99	' 0.10'
-0.2	90.99	' -0.20'
0	9999	' 0'
1	9999	' 1'
+123.456	999.999	' 123.456'
-123.456	999.999	'-123.456'

When the 'fmt' parameter is omitted, the following statement is executed:

```
SELECT TO_CHAR(123.456) FROM DUAL;
```

The following result is displayed:

```
+------------------+
| TO_CHAR(123.456) |
+------------------+
| 123.456          |
+------------------+
```

When the `TO_CHAR` result is more than 40 bytes in length or the input parameter is of the BINARY_DOUBLE or BINARY_FLOAT type, the result is in the scientific notation format.

Example:

```
SELECT TO_CHAR(12355555555555555555555555555555555555555555555555555) FROM DUAL;
```

The following result is displayed:

```
+-----------------------------------------------------------------+
| TO_CHAR(123555555555555555555555555555555555555555555555555) |
+-----------------------------------------------------------------+
| 1.235555555555555555555555555555556E+49                         |
+-----------------------------------------------------------------+
```

17.1.5.4.4.3. Datetime formatting

Datetime formatting specifies the format of date and time data that is stored in databases. The total length of a string that is obtained after datetime formatting cannot exceed 22 characters.

Datetime formatting in functions

Datetime formatting appears in the following data type conversions:

- When you use the `TO_DATE`, `TO_TIMESTAMP`, or `TO_TIMESTAMP_TZ` function to convert a character value in a non-default format to a datetime value, specify the datetime format. To specify the datetime format, set the corresponding parameter of the function that you use.
- When you use the `TO_CHAR` function to convert a datetime value to a character value in a non-default format, set the corresponding parameter of the function to specify the format.

You can use the following methods to specify the datetime format:

- Explicitly specify the datetime format by using the `NLS_DATE_FORMAT`, `NLS_TIMESTAMP_FORMAT`, or `NLS_TIMESTAMP_TZ_FORMAT` session parameter.
- Implicitly specify the datetime format by using the `NLS_TERRITORY` session parameter
- Change the default datetime format of a session by executing the `ALTER SESSION` statement.

Datetime formatting

A datetime formatting model consists of one or more datetime format elements. For more information about the format elements that are supported by ApsaraDB for OceanBase, see the table of datetime format elements.

- In a formatting string, the same format element cannot appear twice, and format elements that represent similar information cannot be combined. For example, you cannot use `SYYYY` and `BC` elements in the same formatting string.
- All of the format elements can be used in `TO_CHAR`, `TO_DATE`, `TO_TIMESTAMP`, and `TO_TIMESTAMP_TZ` functions.
- The following datetime format elements can be used in timestamp and interval formatting, but not in `DATE` formatting: `FF`, `TZD`, `TZH`, `TZM`, and `TZR`.
- Many datetime format elements are padded with blank spaces or zero values to a specified length.

> **Notice**
>
> In ApsaraDB for OceanBase, we recommend that you use the four-digit year element (`YYYY`). The year element with a shorter length affects query optimization because the year can be determined only at the runtime.

Table of datetime format elements

Element	Supported by datetime functions	Description
- / , . ; : "text"	Yes	Punctuations and quoted text are copied to the result.
AD A.D.	Yes	The anno domini (A.D.) year. The periods (.) can be retained or removed.
AMA.M.	Yes	The morning. The periods (.) can be retained or removed.
BCB.C.	Yes	The before Christ (B.C.) year. The periods (.) can be retained or removed.
D	Yes	The day (1 to 7) of the week.
DAY	Yes	The name of the day.
DD	Yes	The day (1 to 31) of the month.
DDD	Yes	The day (1 to 366) of the year.
DL	Yes	Date and time data is printed only in the fixed format. For example, "Monday, January, 01, 1996" is in the fixed format.
DS	Yes	Date and time data is printed only in the fixed format. For example, "10-10-1996" is in the fixed format.
DY	Yes	The abbreviated name of the date. The day of the week is returned.

Element	Supported by datetime functions	Description
FF [1..9]	Yes	The fractional seconds. Use the numbers 1 to 9 to specify the number of digits in the fractional second portion of the return value. By default, the precision that is specified by the datetime data type is used. This element is valid in timestamp and interval formatting, but invalid in `DATE` formatting.
FX	Yes	Requires an exact match between character data and the format model.
HHHH12	Yes	The hour (1 to 12). The 12-hour clock is used.
HH24	Yes	The hour (0 to 23) The 24-hour clock is used.
YYYY	Yes	The year in the four-digit format.
MI	Yes	The minute (0 to 59)
MM	Yes	The month (01 to 12). The value 01 represents January.
MON	Yes	The abbreviated name of the month.
MONTH	Yes	The name of the month.
PMP.M.	Yes	The afternoon. The periods (.) can be retained or removed.
Q	Yes	The quarter (1, 2, 3, and 4). The first quarter lasts from January to March.
RR	Yes	The year in the two-digit format.

Element	Supported by datetime functions	Description
RRRR	Yes	The year. Four-digit or two-digit inputs can be entered.
SS	Yes	The second (0 to 59).
SSSSS	Yes	The number of seconds (0 to 86400) after midnight.
TZD	Yes	The daylight saving time (DST) information. The TZD value is an abbreviated time zone string that contains the DST information. This element is valid in timestamp and interval formatting, but invalid in `DATE` formatting.
TZH	Yes	The time zone hour. This element is valid in timestamp and interval formatting, but invalid in `DATE` formatting.
TZM	Yes	The time zone minute. This element is valid in timestamp and interval formatting, but invalid in `DATE` formatting.
TZR	Yes	The region information about the time zone. This element is valid in timestamp and interval formatting, but invalid in `DATE` formatting.
X	Yes	The decimal point, which is always a period (.).
Y,YYY	Yes	The year with a comma (,).
YYYYSYYYY	Yes	The year in the four-digit format. S means that a minus sign (-) is used to represent a B.C. date.
YYYYYY	Yes	The last one, two, or three digits of the year.

> **Note**
>
> Datetime functions are `TO_CHAR`, `TO_DATE`, `TO_TIMESTAMP`, and `TO_TIMESTAMP_TZ`.

Take note of the following point: In the preceding conversions, the input date string must match the format elements. Otherwise, an error is returned. The following example is provided:

```
SELECT TO_DATE( '31 Aug 2020', 'DD MON YYYY' ) FROM DUAL;

+-----------------------------------+
| TO_DATE('31AUG2020','DDMONYYYY') |
+-----------------------------------+
| 2020-08-31 00:00:00               |
+-----------------------------------+
```

If some elements are missing from your formatting string, the system returns an error:

```
SELECT TO_DATE( '31 Aug 2020', 'DD MON YYY' ) FROM DUAL;

ORA-01830: date format picture ends before converting entire input string
```

Uppercase letters in date format elements

Uppercase letters in spelled-out words, abbreviations, or Roman numerals are also capitalized in the corresponding format elements. For example, the `DAY` date format element generates `MONDAY` where every letter is capitalized. `Day` generates `Monday` that is in the same format as the Day element. `day` generates `monday` that is in the same format as the day element.

```
OceanBase(SYS@SYS)>SELECT TO_CHAR(sysdate,'mon')  AS nowMonth FROM DUAL;
+-----------+
| NOWMONTH |
+-----------+
| sep      |
+-----------+

OceanBase(SYS@SYS)>SELECT TO_CHAR(sysdate,'MON')  AS nowMonth FROM DUAL;
+-----------+
| NOWMONTH |
+-----------+
| SEP      |
+-----------+
```

Punctuations and character literals in datetime formatting

Date formatting is required for the following characters. These characters appear in the return value in the same positions as they appear in the formatting string:

- Punctuations, such as hyphens (-), slashes (/), commas (,), periods (.), and colons (:)
- Character literals, which are enclosed in double quotation marks (")

ApsaraDB for OceanBase can convert strings to dates based on your business needs. If you use the `TO_DATE` function and each numeric element of the input string contains the maximum number of digits allowed for formatting, the formatting string matches the input string.

- **Example 1**: In the **MM/YY** format element, **02** corresponds to **MM** and **07** corresponds to **YY**.

Execute the following statement:

```
SELECT TO_CHAR(TO_DATE('0207','MM/YY'),'MM/YY') FROM DUAL;
```

The following query result is returned:

```
+-----------------------------------------+
| TO_CHAR(TO_DATE('0207','MM/YY'),'MM/YY') |
+-----------------------------------------+
| 02/07                                   |
+-----------------------------------------+
```

- **Example 2**: ApsaraDB for OceanBase allows matching between punctuation characters in formatting and non-alphanumeric characters. For example, **#** corresponds to **/**.

Execute the following statement:

```
 SELECT TO_CHAR (TO_DATE('02#07','MM/YY'), 'MM/YY') FROM DUAL;
```

The following query result is returned:

```
+-----------------------------------------+
| TO_CHAR(TO_DATE('02#07','MM/YY'),'MM/YY') |
+-----------------------------------------+
| 02/07                                   |
+-----------------------------------------+
```

Date format elements and globalization support

In ApsaraDB for OceanBase, you can use the `NLS_DATE_LANGUAGE` and `NLS_LANGUAGE` parameters to specify the language for datetime format elements. The default value is `AMERICAN`. The value cannot be changed. Therefore, globalization is not supported.

Example: By default, the language for datetime format elements is `American`. The other languages are not supported.

```
SELECT TO_CHAR (SYSDATE, 'DD/MON/YYYY', 'nls_date_language=''Traditional Chinese'' ') FROM DUAL;
```

An error is returned in the query result because the specified value for the language parameter is not supported.

```
ERROR-12702: invalid NLS parameter string used in SQL function
```

More information

- String-to-date conversion rules

17.1.5.4.4.4. RR datetime format element

The `RR` datetime format element is similar to the `YY` datetime format element. However, the RR element offers additional flexibility for storing the values of dates that are not covered by the current century. In the `YY` datetime format element, you must specify all of the digits of the year. In the `RR` datetime format element, you need only to specify the last two digits of the year to store a date value.

Assume that the `RR` datetime format element is used in conjunction with the `TO_DATE` function. In this case, the century of the return value varies based on the specified two-digit year and the last two digits of the current year. If the `YY` datetime format element is used in conjunction with the `TO_DATE` function, the returned year always has the same first two digits as the current year.

Assume that the specified two-digit year ranges from 00 to 49. In this case, if the last two digits of the current year ranges from 00 to 49, the returned year has the same first two digits as the current year. If the last two digits of the current year ranges from 50 to 99, the first two digits of the returned year indicate the next century.

Assume that the specified two-digit year ranges from 50 to 99. In this case, if the last two digits of the current year ranges from 00 to 49, the first two digits of the returned year indicate the previous century. The previous century is the one before the century of the current year. If the last two digits of the current year ranges from 50 to 99, the returned year has the same first two digits as the current year.

The `RR` datetime format element returns the same value for the years whose first two digits are different, as shown in the following examples: Assume that these queries were run during the period from 1950 to 1999. Execute the following statement:

```
SELECT TO_CHAR(TO_DATE('27-OCT-98', 'DD-MON-RR'), 'YYYY') "Year1" ,
TO_CHAR(TO_DATE('27-OCT-17', 'DD-MON-RR'), 'YYYY') "Year2"  FROM DUAL;
```

The following query result is returned:

```
+-------+-------+
| Year1 | Year2 |
+-------+-------+
| 2017  | 1998  |
+-------+-------+
```

Assume that these queries were run during the period from 2000 to 2049. Execute the following statement:

```
SELECT TO_CHAR(TO_DATE('27-OCT-98', 'DD-MON-RR'), 'YYYY') "Year1" ,
TO_CHAR(TO_DATE('27-OCT-17', 'DD-MON-RR'), 'YYYY') "Year2"  FROM DUAL;
```

The following query result is returned:

```
+-------+-------+
| Year1 | Year2 |
+-------+-------+
| 2017  | 1998  |
+-------+-------+
```

Notice

The same value is returned regardless of whether queries were run before or after 2000.

17.1.5.4.4.5. String-to-date conversion rules

The following conversion rules govern the conversion from a string value to a date value:

- If you specify all numeric values for numeric format elements, including leading zeros, you can omit punctuation marks contained in the format string from the date string. Specify 02 instead of 2 for the two-digit format elements such as `MM`, `DD`, and `YY`.
- You can omit time fields found at the end of the format string from the date string.
- You can use any non-alphanumeric character in the date string to match the punctuation mark in the format string.

17.1.5.4.5. Null values

17.1.5.4.5.1. Null value overview

Null values are invalid, unspecified, unknown, or unpredictable values in database tables. The occurrences of null values are not restricted by the `NOT NULL` or `PRIMARY KEY` constraint. The result of each arithmetic expression that contains `NULL` is `NULL`.

ApsaraDB for OceanBase supports the following three types of null values:

Null values in SQL functions

The null values of this type are the null values of the parameters in SQL functions. When the parameters of SQL functions have null values, most scalar functions return `NULL` and analytic functions ignore null values. Null values in SQL functions are divided into two types. The following table describes the two types.

Null value	Description
Null values in NVL functions	If `expr1` in the `NVL(expr1,expr2)` expression is not NULL, the expression returns `expr1`. Otherwise, the expression returns `expr2`.
Null values in analytic functions	When an analytic function such as `AVG`, `MAX`, `SUM`, or `COUNT` is used, NULL records are ignored.

Null values in comparison conditions

The null values of this type are the `NULL` values that are found in comparison conditions and used for comparison. Only `IS NULL` and `IS NOT NULL` comparators can be used to test for null values. `NULL` is incomparable to other values because it indicates that data is missing. This means that `NULL` cannot be equal to, unequal to, greater than, or smaller than another numeric value or another null value.

Null values in conditional expressions

Null values in conditional expressions are the NULL values in the `= NULL`, `! = NULL`, `NULL =`, and `NULL ! =` conditions. These `NULL` values are used for logical evaluation. If conditions evaluate to `UNKNOWN`, no rows are returned.

17.1.5.4.5.2. Null values in SQL functions

Null values in SQL functions refer to the null arguments in the functions. If you pass null arguments to SQL functions, most scalar functions return `NULL`, and analytic functions ignore the null arguments. You can determine whether a null value occurs based on the return value of the `NVL` function.

Null value in the NVL function

`NVL(expr1,expr2)` is the expression of the `NVL` function. If `expr1` is not `NULL`, `expr1` is returned. Otherwise, `expr2.` is returned.

In the following example, the statement is used to query the return value of the `NVL(expr1,0)` expression when the `expr1` parameter is set to `NULL`.

Execute the following statement:

```
SELECT NVL(NULL,0) FROM DUAL;
```

The following result is returned:

```
+-------------+
| NVL(NULL,0) |
+-------------+
|           0 |
+-------------+
```

If `expr1` is `NULL`, the `NVL(expr1,0)` expression returns 0. If `expr1` is not `NULL`, the expression returns `NULL`.

Null values in analytic functions

When you use analytic functions such as `AVG`, `MAX`, `SUM`, and `COUNT`, `NULL` records are ignored.

In the following example, the data is inserted into the **tbl_a** table, and the following statement is executed:

```
CREATE TABLE tbl_a (col_a varchar2(1),  col_b int );
INSERT INTO tbl_a VALUES (NULL, 3);
INSERT INTO tbl_a VALUES (NULL, NULL);
INSERT INTO tbl_a VALUES (NULL, 1);
```

Execute the following statement:

```
SELECT * FROM tb1_a;
```

The following result is returned:

```
+-------+-------+
| COL_A | COL_B |
+-------+-------+
|  NULL |   3   |
+-------+-------+
|  NULL |  NULL |
+-------+-------+
|  NULL |   1   |
+-------+-------+
```

The following result is returned:

```
SELECT AVG(col_b) FROM tbl_a; -- The result is 2.
SELECT MAX(col_b) FROM tbl_a; -- The result is 3.
SELECT SUM(col_b) FROM tbl_a; -- The result is 4.
SELECT COUNT(col_b) FROM tbl_a; -- The result is 2.
SELECT COUNT(col_a) FROM tbl_a; -- The result is 0.
SELECT COUNT(*) FROM tbl_a; -- The result is 3.
```

`NULL` records are ignored.

17.1.5.4.5.3. Null values in comparison conditions

Null values in comparison conditions are `NULL` compared to other conditions. To test for nulls, you can use only the comparison operators `IS NULL` and `IS NOT NULL`. `NULL` is not comparable to other values because it indicates a lack of data. That is, `NULL` cannot be compared to other values, including null values, by using "equal to", "not equal to", "greater than", or "smaller than".

In addition, ApsaraDB for OceanBase considers two null values to be equal when it performs calculations by using the `DECODE` function. Two null values are also considered to be equal if they appear in compound keys.

The following example shows that you judge the results of comparison conditions based on the values of A:

Condition	Value of A	Result
A IS NULL	10	FALSE
A IS NOT NULL	10	TRUE
A IS NULL	NULL	TRUE
A IS NOT NULL	NULL	FALSE

17.1.5.4.5.4. Null values in conditional expressions

Null values in conditional expressions are the NULL values in `= NULL`, `! = NULL`, `NULL =`, and `NULL ! =` conditions. These `NULL` values are used for logical evaluation. If conditions evaluate to `UNKNOWN`, no rows are returned.

In ApsaraDB for OceanBase, use the `IS NULL` comparison operator to test for null values. This operator returns `TRUE` or `FALSE`. However, `UNKNOWN` that is returned for null values in conditional expressions is different from `FALSE`. `NOT FALSE` evaluates to `TRUE`, but `NOT UNKNOWN` still evaluates to `UNKNOWN`.

The following table lists the results that are returned for conditional expressions based on the A value.

Condition	A value	Result
A = NULL	10	UNKNOWN
A ! = NULL	10	UNKNOWN
A = NULL	NULL	UNKNOWN
A ! = NULL	NULL	UNKNOWN
A = 10	NULL	UNKNOWN
A ! = 10	NULL	UNKNOWN

No rows are returned if a condition that evaluates to `UNKNOWN` is used in the `WHERE` clause of a `SELECT` statement.

17.1.5.4.6. Comments

17.1.5.4.6.1. Overview

In ApsaraDB for OceanBase, you can create three types of comments:

- Comments in SQL statements: The comments of this type are stored as part of the application code that is used to execute the SQL statements.
- Comments on schema and non-schema objects: The comments of this type and the object metadata are stored in a data dictionary.
- Hints: Hints are comments that are located in SQL statements and pass instructions to the ApsaraDB for OceanBase optimizer.

17.1.5.4.6.2. Comments in SQL statements

Comments make applications easier to read and maintain. For example, you can create a comment in a statement to describe the purpose of the statement in an application. Only hints in SQL statements affect how the statements are executed. The other comments in SQL statements do not affect how the statements are affected.

You can add a comment between keywords, parameters, or punctuations in a statement. You can use two methods to add a comment:

- Add a comment that starts with a slash and an asterisk (/*). The text of the comment follows the slash and the asterisk (/*). The text can be distributed across multiple lines. The comment must end with an asterisk and a slash (*/). You do not need to use white-space characters or line feeds to separate the start and end symbols from the text.
- Add a comment that starts with two hyphens (--). The text of the comment follows the hyphens (--). The text can be distributed in only one line. The comment must end with a line feed.

An SQL statement can contain multiple comments of the preceding two styles. The comment text can contain all of the printable characters in your database character set.

The following example is used to demonstrate multiple forms of comments, each of which starts with a slash and an asterisk (/*):

```
SELECT last_name, employee_id, salary + NVL(commission_pct, 0),
            job_id, e.department_id
  /* Select all employees whose compensation is
  greater than that of Pataballa. */
  FROM employees e, departments d
  /*The DEPARTMENTS table is used to get the department name. */
  WHERE e.department_id = d.department_id
    AND salary + NVL(commission_pct,0) >   /* Subquery:       */
        (SELECT salary + NVL(commission_pct,0)
          /* total compensation is salary + commission_pct */
          FROM employees
          WHERE last_name = 'Pataballa')
  ORDER BY last_name, employee_id;
```

The statement in the following example contains multiple forms of comments, each of which starts with two hyphens (--):

```
SELECT last_name,                                  -- select the name
       employee_id                                 -- employee id
       salary + NVL(commission_pct, 0),            -- total compensation
       job_id,                                     -- job
       e.department_id                             -- and department
  FROM employees e,                                -- of all employees
       departments d
  WHERE e.department_id = d.department_id
    AND salary + NVL(commission_pct, 0) >          -- whose compensation
                                                   -- is greater than
        (SELECT salary + NVL(commission_pct,0)     -- the compensation
          FROM employees
          WHERE last_name = 'Pataballa')           -- of Pataballa
  ORDER BY last_name                               -- and order by last name
           employee_id                             -- and employee id.
;
```

17.1.5.4.6.3. Comments on schema objects and non-schema objects

You can execute the `COMMENT` statement to associate comments with schema objects (tables, views, materialized views, operators, and index types) or non-schema objects (editions). You can also create comments for columns of table schema objects. Comments associated with schema objects and non-schema objects are stored in your data dictionary.

```
Syntax:
COMMENT ON {TABLE table | COLUMN column | INDEXTYPE indextype
    | OPERATOR operator | VIEW view} IS string
```

For example, you want to associate a comment with the table named user:

```
COMMENT ON TABLE test.user is "This is a table that records user information";
```

For example, you want to create a comment for the user_name column:

```
COMMENT ON COLUMN test.user.user_name is "The user names are recorded";
```

17.1.5.4.6.4. Hint

Hint overview

Hints are comments that are located in SQL statements and pass instructions to the ApsaraDB for OceanBase optimizer or server. The optimizer or the server can generate specific execution plans based on hints. In general, the optimizer chooses the optimal execution plan for your query without the need to use hints. However, in some scenarios, the optimizer-generated execution plan may not meet your requirements. In these scenarios, you can use hints to specify the execution plans that are to be generated.

We recommend that you do not use hints if possible. Use hints only after you have collected statistics about the relevant tables and have executed the `EXPLAIN PLAN` statement to evaluate the optimizer-generated plan that is not affected by hints. Query performance improvements in subsequent versions and changes to database conditions may cause hints in your code to have a significant impact on performance.

Use hints

In a statement block, only one comment can contain hints and the comment must follow the `SELECT`, `UPDATE`, `INSERT`, `MERGE`, or `DELETE` keyword.

The following hint syntax applies to comments in statement blocks:

```
/*+[hint text]*/
```

In terms of syntax, hints are a special type of SQL comments. The difference between comments and hints is that their marks are different. If a plus sign (+) is appended to the left mark of a comment, the comment is interpreted as a hint. If the server cannot recognize hints in SQL statements, the optimizer ignores the specified hints and uses the logic that is generated by the default execution plan. In addition, take note of the following point: Hints affect only the logic of optimizer-generated plans and do not affect the semantics of SQL statements.

Take note of the following rules when you define hints:

- The plus sign (+) causes the database to interpret a comment as a list of hints. The plus sign (+) must immediately follow the left mark of the comment. No white-space character is allowed.
- The white-space character between the plus sign (+) and the hint text is optional. If a comment contains multiple hints, use at least one white-space character to separate hints.

- Hints that contain spelling or syntax errors are ignored. However, the database does not ignore the other hints that are correctly specified in the same comment.
- Hints that do not follow the `DELETE`, `INSERT`, `MERGE`, `SELECT`, or `UPDATE` keyword are invalid.
- In a combination of hints, the hints that conflict with each other are invalid. However, the database does not ignore the other hints in the same comment.
- Hints are invalid when the database environment uses PostgreSQL version 1 or SQL Server version 1. For example, when the database environment uses triggers in Forms version 3, hints are invalid.

Specify query blocks in hints

You can specify an optional query block name in multiple hints to specify the query block on which the hint takes effect. In an outer query, you can use this syntax to specify a hint that applies to an inline view.

The parameters of a query block use the `@queryblock` syntax. In this syntax, `queryblock` is the identifier of the query block that is specified in your query. The `queryblock` identifier can be customized or system-generated. When you directly specify a hint to be applied in a query block, `@queryblock` is ignored.

- You can obtain the system-generated identifier by executing the `EXPLAIN PLAN` statement for your query.

  You can obtain the names of pre-transformation query blocks by executing the `EXPLAIN PLAN` statement for your query that uses the `NO_QUERY_TRANSFORMATION` hint.
- You can use `QB_NAME` to specify a custom name.

Specify global hints

Many hints can be applied to specific tables or indexes and more globally to the tables in a view or to some columns that are part of indexes. These global hints are specified by using the `tablespec` and `indexspec` syntax elements.

`tablespec` uses the following syntax:

```
[ view.[ view. ]... ]table
```

You must specify the table that you want to access exactly as it appears in the statement. If the statement uses a table alias, use the alias instead of the table name in the hint. However, even if the schema name appears in the statement, do not include the schema name in the table name that is used in the hint.

> **Notice**
>
> If you use the `tablespec` clause to specify global hints, the global hints do not take effect on the queries that use ANSI joins. This is because the optimizer generates additional views in the parsing process. Instead, you can use `@queryblock` to specify the query block to which the hint applies.

`indexspec` uses the following syntax:

```
{ index
| ( [ table. ]column [ [ table. ]column ]...)
}
```

When `tablespec` is followed by `indexspec` in the description of a hint, commas (,) that separate table names and index names are allowed but not required. Commas (,) that separate multiple occurrences of `indexspec` are also allowed but not required.

Lists of hints

Hints related to access paths

INDEX Hint

The `INDEX` hint instructs the optimizer to scan a specified table based on the index. You can use the `INDEX` hint for function-based, domain, B-tree, bitmap, and bitmap join indexes.

The `INDEX` hint uses the following syntax:

```
/*+ INDEX ( [ @ queryblock ] tablespec [ indexspec [ indexspec ]... ] ) */
```

The behavior of the hint depends on the `indexspec` specification:

- If the `INDEX` hint specifies a single available index, the database scans based on this index. The optimizer does not consider a full table scan or a scan on another index on the table.
- If the `INDEX` hint specifies multiple available indexes, the optimizer compares the costs of scans base on each index in the list. Then, the optimizer performs an index scan at the lowest cost. If an access path that is generated based on multiple indexes cause the lowest cost among all table scan plans, this access path is used. The database does not consider a full table scan or a scan on an index that is not specified in the hint.
- If the `INDEX` hint specifies no indexes, the optimizer compares the costs of scans on each available index on the table. Then, the optimizer performs an index scan at the lowest cost. If an access path that is generated based on multiple indexes cause the lowest cost among all table scan plans, this access path is used. The optimizer does not consider a full table scan.

The following statement provides an example:

```
SELECT /*+ INDEX (employees emp_department_ix)*/ employee_id, department_id
  FROM employees
  WHERE department_id > 50;
```

FULL Hint

The `FULL` hint instructs the optimizer to perform a full table scan on the specified table.

The `FULL` hint uses the following syntax:

```
/*+ FULL ( [ @ queryblock ] tablespec ) */
```

The following statement provides an example:

```
SELECT /*+ FULL(e) */ employee_id, last_name
  FROM hr.employees e
  WHERE last_name LIKE :b1;
```

The database performs a full table scan on the **employees** table to execute this statement, even if an index on the **last_name** column is listed in the condition in the `WHERE` clause.

The **employees** table has an alias **e** in the `FROM` clause. Therefore, the hint must reference the table by using its alias rather than its name. Do not reference schema names in the hint even if the schema names are specified in the `FROM` clause.

Hints related to join orders

LEADING Hint

The `LEADING` hint instructs the optimizer to use the specified set of tables as the prefix in the execution plan. This hint can be used to specify the join order of tables. This hint is more versatile than the `ORDERED` hint.

The `LEADING` hint uses the following syntax:

```
/*+ LEADING ( [ @ queryblock ] tablespec [ tablespec ]...  ) */
```

The `LEADING` hint performs strict checks to ensure that tables are joined in the specified order. If the `table_name` that is specified in a `LEADING` hint does not exist, the hint is ignored. If duplicate tables are found in a `LEADING` hint, the hint is ignored. If the optimizer attempts to join tables but cannot locate a table to be joined, the join orders specified for this table and the tables after the table become invalid. The join orders specified for the tables before this table remain valid. If the specified table cannot be first joined in the specified order due to the dependencies in the join graph, the `LEADING` hint is ignored. If you specify two or more conflicting `LEADING` hints, these `LEADING` hints are ignored. If you specify an `ORDERED` hint, it overrides all `LEADING` hints.

The following statement provides an example:

```
SELECT /*+ LEADING(e j) */ *
    FROM employees e, departments d, job_history j
    WHERE e.department_id = d.department_id
      AND e.hire_date = j.start_date;
```

ORDERED Hint

The `ORDERED` hint instructs a database to join tables in the order in which they appear in the `FROM` clause. We recommend that you use the `LEADING` hint. It is more versatile than the `ORDERED` hint.

The `ORDERED` hint uses the following syntax:

```
/*+ ORDERED */
```

When you omit the `ORDERED` hint in an SQL statement that performs a join operation, the optimizer chooses the order in which the tables are joined. However, the optimizer does not know the number of rows to be selected from each table. In this case, you can use the `ORDERED` hint to specify a join order. This allows you to select internal and external tables in a better way than the optimizer. If you rewrite the specified `ORDERED` hint, the tables are joined in the order as you rewrite in the `FROM` clause of the statement.

Hints related to join operations

USE_MERGE Hint

The `USE_MERGE` hint instructs the optimizer to join each specified table with another row resource by using a `sort-merge` join. We recommend that you use the `USE_NL` and `USE_MERG` hints when you use the `LEADING` and `ORDERED` hints. The optimizer uses these hints if the referenced table is the internal table of a join operation. The hints are ignored if the referenced table is an external table.

The `USE_MERGE` hint uses the following syntax:

```
/*+ USE_MERGE ( [ @ queryblock ] tablespec [ tablespec ]... ) */
```

The `USE_MERGE` hint uses the MERGE-JOIN algorithm if a table is specified as an internal table. ApsaraDB for OceanBase allows you to use the MERGE-JOIN algorithm only if a `join condition` is used to specify the equivalence relation between two fields in the two tables. If you attempt to join two tables without such join conditions, the `USE_MERGE` hint is invalid.

The following statement provides an example of the `USE_MERGE` hint:

```
SELECT /*+ USE_MERGE(employees departments) */ *
  FROM employees, departments
  WHERE employees.department_id = departments.department_id;
```

NO_USE_MERGE Hint

The `NO_USE_MERGE` hint instructs the optimizer to exclude the joins specified in the `USE_MERGE` hint when the optimizer uses a specified table as an internal table and joins the specified table with another row resource.

The `NO_USE_MERGE` hint uses the following syntax:

```
/*+ NO_USE_MERGE ( [ @ queryblock ] tablespec [ tablespec ]... ) */
```

The following statement provides an example of the `NO_USE_MERGE` hint:

```
SELECT /*+ NO_USE_MERGE(e d) */ *
  FROM employees e, departments d
  WHERE e.department_id = d.department_id;
```

USE_HASH Hint

The `USE_HASH` hint instructs the optimizer to join each specified table with another row resource by using the HASH-JOIN algorithm.

The `USE_HASH` hint uses the following syntax:

```
/*+ USE_HASH ( [ @ queryblock ] tablespec [ tablespec ]... ) */
```

The following statement provides an example of the `USE_HASH` hint:

```
SELECT /*+ USE_HASH(l h) */ *
  FROM orders h, order_items l
  WHERE l.order_id = h.order_id
    AND l.order_id > 2400;
```

NO_USE_HASH Hint

The `NO_USE_HASH` hint instructs the optimizer to exclude the joins specified in the `USE_HASH` hint when the optimizer uses a specified table as an internal table and joins the specified table to another row resource.

The `NO_USE_HASH` hint uses the following syntax:

```
/*+ NO_USE_HASH ( [ @ queryblock ] tablespec [ tablespec ]... ) */
```

The following statement provides an example of the `NO_USE_HASH` hint:

```
SELECT /*+ NO_USE_HASH(e d) */ *
  FROM employees e, departments d
  WHERE e.department_id = d.department_id;
```

USE_NL Hint

The `USE_NL` hint instructs the optimizer to join each specified table to another row resource by using a nested loop join. This hint also instructs the optimizer to use the specified table as an internal table by using the NL-JOIN algorithm. We recommend that you use the `USE_NL` and `USE_MERG` hints together with the `LEADING` and `ORDERED` hints. The optimizer uses these hints when the referenced table is the internal table of a join. The hints are ignored if the referenced table is an external table.

The `USE_NL` hint uses the following syntax:

```
/*+ USE_NL ( [ @ queryblock ] tablespec [ tablespec ]... ) */
```

In the following example, a hint is used to forcibly execute a nested loop and access **orders** through a full table scan. The filter condition `l.order_id = h.order_id` is applied to every row. If a row meets the filter condition, **order_items** is queried through the index **order_id**:

```
SELECT /*+ USE_NL(l h) */ h.customer_id, l.unit_price * l.quantity
  FROM orders h, order_items l
  WHERE l.order_id = h.order_id;
```

NO_USE_NL Hint

The `NO_USE_NL` hint instructs the optimizer to exclude nested loop joins when the optimizer uses a specified table as an internal table and joins the specified table to another row resource.

The `NO_USE_NL` hint uses the following syntax:

```
/*+ NO_USE_NL ( [ @ queryblock ] tablespec [ tablespec ]... ) */
```

The following statement provides an example of the `NO_USE_NL` hint:

```
SELECT /*+ NO_USE_NL(e d) */ *
  FROM employees e, departments d
  WHERE e.department_id = d.department_id;
```

USE_BNL Hint

The `USE_BNL` hint instructs the optimizer to join each specified table to another row resource by using a block-nested loop join. The hint also instructs the optimizer to use the specified table as an internal table by using the BNL-JOIN algorithm. We recommend that you use the `USE_BN` hint together with the `LEADING` and `ORDERED` hints. The optimizer uses these hints when the referenced table is the internal table of a join. The hints are ignored if the referenced table is an external table.

The `USE_BNL` hint uses the following syntax:

```
/*+ USE_BNL ( [ @ queryblock ] tablespec [ tablespec ]... ) */
```

In the following example, a hint is used to forcibly execute a block nested loop and access **orders** through a full table scan. The filter condition `l.order_id = h.order_id` is applied to every row. If a row meets the filter condition, **order_items** is queried through the index **order_id**:

```
SELECT /*+ USE_BNL(l h) */ h.customer_id, l.unit_price * l.quantity
  FROM orders h, order_items l
  WHERE l.order_id = h.order_id;
```

NO_USE_BNL Hint

The `NO_USE_BNL` hint instructs the optimizer to exclude the joins specified in the `USE_BNL` hint when the optimizer uses a specified table as an internal table and joins the specified table to another row resource.

The `NO_USE_BNL` hint uses the following syntax:

```
/*+ NO_USE_BNL ( [ @ queryblock ] tablespec [ tablespec ]... ) */
```

The following statement provides an example of the `NO_USE_BNL` hint:

```
SELECT /*+ NO_USE_BNL(e d) */ *
  FROM employees e, departments d
  WHERE e.department_id = d.department_id;
```

Hints related to parallel execution

PARALLEL Hint

The `PARALLEL` hint is a statement-level hint that instructs the optimizer to specify the number of parallel servers that can be used for parallel operations. The PARALLEL hint overwrites the value of the `PARALLEL_DEGREE_ POLICY` initialization parameter. The PARALLEL hint is applicable to the `SELECT`, `INSERT`, `MERGE`, `UPDATE`, and `DELETE` portions of a statement and to the table scan portion. If a parallel constraint is violated, the `PARALLEL` hint is ignored.

The `PARALLEL` hint uses the following syntax:

```
/*+ PARALLEL [ ( DEFAULT | AUTO | MANUAL | integer ) ] */
```

> **Notice**
>
> If sorting or grouping is also performed, the number of servers that can be used is twice the value specified in the `PARALLEL` hint.

You can set the following parameters in the `PARALLEL` hint:

- `PARALLEL`: the degree of parallelism that is calculated by the database. The value can be 2 or a greater value. The statement is always executed as a set of operations that are performed in parallel.
- `PARALLEL(DEFAULT)`: the degree of parallelism that is calculated by the optimizer. The parameter value is equal to the product of the value of the `PARALLEL_THREADS_PER_CPU` initialization parameter and the number of CPUs available on all of the participating instances.
- `PARALLEL(AUTO)`: the degree of parallelism that is calculated by the database. The value can be greater than or equal to 1. If the calculated degree of parallelism is 1, the statement is executed as a set of operations that are performed in sequence.
- `PARALLEL(MANUAL)`: the degree of parallelism that the optimizer is forced to use. The degree of parallelism is specified by the parallel settings of the objects in the statement.
- `PARALLEL(integer)`: the degree of parallelism that is used by the optimizer and specified by the `integer` parameter. The value of the integer parameter is an integer.

In the following example, the database calculates the degree of parallelism and the statement is always executed as a set of operations that are performed in parallel:

```
SELECT /*+ PARALLEL */ last_name
  FROM employees;
```

In the following example, the database calculates the degree of parallelism, but the degree of parallelism is 1. Therefore, the statement is executed as a set of operations that are performed in sequence:

```
SELECT /*+ PARALLEL (AUTO) */ last_name
  FROM employees;
```

In the following example, 5 is specified in the statement as the degree of parallelism and takes effect on the current table. The `PARALLEL` hint recommends that the optimizer use 5 as the degree of parallelism:

```
CREATE TABLE parallel_table (col1 number, col2 VARCHAR2(10)) PARALLEL 5;
SELECT /*+ PARALLEL (MANUAL) */ col2
 FROM parallel_table;
```

USE_PX Hint

The `USE_PX` hint instructs the server to execute SQL statements in PX mode. In PX mode, multithreading is allowed when statements are executed. In general, the `USE_PX` hint is used in conjunction with the `PARALLEL` hint.

The `USE_PX` hint uses the following syntax:

```
/*+ USE_PX  */
```

Example:

```
SELECT /*+ USE_PX PARALLEL(4)*/ e.department_id, sum(e.salary)
 FROM employees e
 WHERE e.department_id = 1001;
 GROUP BY e.department_id;
```

NO_USE_PX Hint

The `NO_USE_PX` hint instructs the server not to use the PX mode to execute SQL statements.

The `NO_USE_PX` hint uses the following syntax:

```
/*+ NO_USE_PX  */
```

Example:

```
SELECT /*+ NO_USE_PX*/ e.department_id, sum(e.salary)
 FROM employees e
 WHERE e.department_id = 1001;
 GROUP BY e.department_id;
```

PQ_DISTRIBUTE Hint

The `PQ_DISTRIBUTE` hint instructs the optimizer on how to distribute rows between producer (query) servers and consumer (load) servers. You can use this hint to control row distribution for joins or loads. The `PQ_DISTRIBUTE` hint uses the following syntax:

```
/*+ PQ_DISTRIBUTE
  ( [ @ queryblock ] tablespec
    { distribution | outer_distribution inner_distribution }
  ) */
```

Control load distribution

You can control the row distribution for parallel `INSERT ... SELECT` and `CREATE TABLE ... AS SELECT` statements to determine how rows are distributed between producer (query) servers and consumer (load) servers. Use the upper branch of the syntax to specify a distribution method. The following table lists the values and semantics of distribution methods.

Distribution method	Description
NONE	Row distribution is not performed. This means that query and load operations are combined on each query server. Each server loads all of the partitions. In this distribution method, row distribution is not performed. This helps you avoid the overhead of row distribution when no skew occurs. Skew may occur due to null fields. Skew may also occur because a predicate in the statement filters out all of the rows that are evaluated by the query. If skew occurs due to this distribution method, use `RANDOM` or `RANDOM_ LOCAL` distribution instead. **Notice** Use this distribution method with caution. A minimum of 512 KB Program Global Area (PGA) memory is required for the loading of each process. If compression is also used, each server consumes about 1.5 MB PGA memory.
PARTITION	This method uses the partition information of `tablespec` to distribute rows from query servers to consumer servers. Use this method when the action of combining query and load operations is not possible or expected. Use this method also when the number of partitions being loaded is greater than or equal to the number of load servers and no skew occurs. If no skew occurs, the input data is evenly distributed across the partitions being loaded.
RANDOM	This method distributes rows from producer servers to consumer servers in a round-robin manner. Use this method when the input data is highly skewed.
RANDOM_LOCAL	This method distributes rows from producer servers to a group of servers that are responsible for maintaining a given group of servers. Two or more servers can load the same partition, but none of the servers loads all of the partitions. Use this distribution method when the input data is skewed and query and load operations cannot be combined due to memory limits.

For example, in the following direct-load INSERT operation, the query and load portions of the operation are combined on each query server:

```
INSERT /*+ APPEND PARALLEL(target_table, 16) PQ_DISTRIBUTE(target_table, NONE) */
  INTO target_table
  SELECT * FROM source_table;
```

In the following example, the optimizer uses the partitioning of the **target_table** table to distribute rows when the table is created:

```
CREATE /*+ PQ_DISTRIBUTE(target_table, PARTITION) */ TABLE target_table
  NOLOGGING PARALLEL 16
  PARTITION BY HASH (l_orderkey) PARTITIONS 512
  AS SELECT * FROM source_table;
```

Control the distribution for joins

You can specify two methods to control the distribution for joins. In the lower branch of the syntax, one of the distribution methods is for the outer table and the other distribution method is for the inner table:

- `outside_distribution` specifies the distribution method for the outer table.
- `inner_distribution` specifies the distribution method for the inner table.

The values for distribution methods are `HASH`, `BROADCAST`, `PARTITION`, and `NONE`. Only the six combinations of distribution methods in the following table are valid.

Distribution method	Description
HASH, HASH	The rows of each table are mapped to consumer query servers by using a hash function on the join keys. After the mapping is completed, each query server performs a join operation on a pair of result partitions. We recommend that you use this distribution method when the sizes of tables are comparable and the join operation is implemented by using a hash join or a sort merge join.
BROADCAST, NONE	All of the rows in the outer table are broadcast to each producer query server. The rows in the inner table are randomly distributed across partitions. We recommend that you use this distribution method when the size of the outer table is extremely smaller than that of the inner table. In some scenarios, the product of the inner table size and the number of query servers is greater than the outer table size. In general, we also recommend that you use this distribution method in these scenarios.
NONE, BROADCAST	All of the rows in the inner table are broadcast to each consumer query server. The rows in the outer table are randomly distributed across partitions. We recommend that you use this distribution method when the size of the inner table is extremely smaller than that of the outer table. In some scenarios, the product of the inner table size and the number of query servers is smaller than the outer table size. In general, we also recommend that you use this distribution method in these scenarios.

Distribution method	Description
PARTITION, NONE	The rows in the outer table are mapped based on the partitioning of the inner table. The inner table must be partitioned based on the join key. We recommend that you use this distribution method when the number of outer table partitions is equal to or nearly equal to a multiple of the number of query servers. For example, the number of partitions is 14 and the number of query servers is 15. **Notice** If the inner table is not partitioned or an equijoin is not performed on the inner table based on the partition key, the optimizer ignores this hint.
NONE, PARTITION	The rows in the inner table are mapped based on the partitioning of the outer table. The outer table must be partitioned based on the join key. We recommend that you use this distribution method when the number of outer table partitions is equal to or nearly equal to a multiple of the number of query servers. For example, the number of partitions is 14 and the number of query servers is 15. **Notice** If the outer table is not partitioned or an equijoin is not performed on the outer table based on the partition key, the optimizer ignores this hint.
NONE, NONE	Each query server performs a join operation on a pair of matching partitions. Each table contains a partition that consists of the pair. The two tables must be equally joined based on the join keys.

In the following example, a hash join is implemented on the two given tables **r** and **s** and the query contains a hint that instructs the system to use hash distribution:

```
SELECT /*+ORDERED PQ_DISTRIBUTE(s HASH, HASH) USE_HASH (s)*/ column_list
  FROM r,s
  WHERE r.c=s.c;
```

To broadcast the outer table **r**, execute the following query statement:

```
SELECT /*+ORDERED PQ_DISTRIBUTE(s BROADCAST, NONE) USE_HASH (s) */ column_list
  FROM r,s
  WHERE r.c=s.c;
```

Hints related to query policies

USE_JIT Hint

The `USE_JIT` hint instructs the server to forcibly execute expressions by using the JIT compilation when the server is executing SQL statements.

The `USE_JIT` hint uses the following syntax:

```
/*+ USE_JIT  */
```

The following statement provides an example:

```
SELECT /*+ USE_JIT*/ e.department_id, sum(e.salary)
 FROM employees e
 WHERE e.department_id = 1001;
 GROUP BY e.department_id;
```

NO_USE_JIT Hint

The `NO_USE_JIT` hint prevents the server from using the JIT compilation to execute expressions when the server is executing SQL statements.

The `NO_USE_JIT` hint uses the following syntax:

```
/*+ NO_USE_JIT*/
```

The following statement provides an example:

```
SELECT /*+NO_USE_JIT*/ e.department_id, sum(e.salary)
 FROM employees e
 WHERE e.department_id = 1001;
 GROUP BY e.department_id;
```

USE_HASH_AGGREGATION Hint

The `USE_HASH_AGGREGATION` hint instructs the optimizer to forcibly execute the SQL statement by using the hash aggregation algorithm when the optimizer is generating a plan.

The `USE_HASH_AGGREGATION` hint uses the following syntax:

```
/*+ USE_HASH_AGGREGATION */
```

The following statement provides an example:

```
SELECT /*+ USE_HASH_AGGREGATION */ e.department_id, sum(e.salary)
 FROM employees e
 WHERE e.department_id = 1001;
 GROUP BY e.department_id;
```

NO_USE_HASH_AGGREGATION Hint

The `NO_USE_HASH_AGGREGATION` hint prevents the optimizer from using the hash aggregation algorithm to run an SQL statement when the optimizer is executing the statement.

The `NO_USE_HASH_AGGREGATION` hint uses the following syntax:

```
/*+ NO_USE_HASH_AGGREGATION */
```

The following statement provides an example:

```
SELECT /*+ NO_USE_HASH_AGGREGATION */ e.department_id, sum(e.salary)
 FROM employees e
 WHERE e.department_id = 1001;
 GROUP BY e.department_id;
```

USE_LATE_MATERIALIZATION Hint

The `USE_LATE_MATERIALIZATION` hint instructs the optimizer to delay view materialization.

The `USE_LATE_MATERIALIZATION` hint uses the following syntax:

```
/*+ USE_LATE_MATERIALIZATION  */
```

The following statement provides an example:

```
SELECT /*+ USE_LATE_MATERIALIZATION*/ e.department_id, sum(e.salary)
 FROM employees e
 WHERE e.department_id = 1001;
 GROUP BY e.department_id;
```

NO_USE_LATE_MATERIALIZATION Hint

The `NO_USE_LATE_MATERIALIZATION` hint instructs the optimizer to disable the delay of view materialization.

The `NO_USE_LATE_MATERIALIZATION` hint uses the following syntax:

```
/*+ NO_USE_LATE_MATERIALIZATION  */
```

The following statement provides an example:

```
SELECT /*+ NO_USE_LATE_MATERIALIZATION*/ e.department_id, sum(e.salary)
 FROM employees e
 WHERE e.department_id = 1001;
 GROUP BY e.department_id;
```

USE_NL_MATERIALIZATION Hint

The `USE_NL_MATERIALIZATION` hint forcibly instructs the optimizer to generate a materialize operator to cache data when the optimizer specifies a table as an internal table or a subtree.

The `USE_NL_MATERIALIZATION` hint uses the following syntax:

```
/*+ USE_NL_MATERIALIZATION ( [ @ queryblock ] tablespec [ tablespec ]... ) */
```

The following statement provides an example:

```
SELECT /*+ USE_NL_MATERIALIZATION(departments) */ *
  FROM employees, departments
  WHERE employees.department_id = departments.department_id;
```

NO_USE_NL_MATERIALIZATION Hint

The `NO_USE_NL_MATERIALIZATION` hint prevents the optimizer from generating a materialize operator to cache data when the optimizer specifies a table as an internal table or a subtree.

The `NO_USE_NL_MATERIALIZATION` hint uses the following syntax:

```
/*+ NO_USE_NL_MATERIALIZATION ( [ @ queryblock ] tablespec [ tablespec ]... ) */
```

The following statement provides an example:

```
SELECT /*+ NO_USE_NL_MATERIALIZATION(departments) */ *
  FROM employees, departments
  WHERE employees.department_id = departments.department_id;
```

Hints related to query transformation

NO_REWRITE Hint

The `NO_REWRITE` hint instructs the optimizer to disable query rewrites for the query block and override the setting of the `QUERY_REWRITE_ENABLED` parameter.

The `NO_REWRITE` hint uses the following syntax:

```
/*+ NO_REWRITE [ ( @ queryblock ) ] */
```

The following statement provides an example:

```
SELECT /*+ NO_REWRITE */ sum(s.amount_sold) AS dollars
  FROM sales s, times t
  WHERE s.time_id = t.time_id
  GROUP BY t.calendar_month_desc;
```

NO_EXPAND Hint

The `NO_EXPAND` hint prevents the optimizer from considering `OR` expansion for queries that have `OR` conditions or `IN` lists in the `WHERE` clause. Usually, the optimizer uses `OR` expansion when the optimizer decides that the cost of using `OR` extension is lower than not using it.

The `NO_EXPAND` hint uses the following syntax:

```
/*+ NO_EXPAND [ ( @ queryblock ) ] */
```

The following statement provides an example:

```
SELECT /*+ NO_EXPAND */ *
  FROM employees e, departments d
  WHERE e.manager_id = 108
     OR d.department_id = 110;
```

USE_CONCAT Hint

The `USE_CONCAT` hint instructs the optimizer to transform combined `OR` conditions in the `WHERE` clause of a query into a compound query by using the `UNION ALL` operator. If this hint is not used, this transformation occurs only if the cost of the query based on concatenations is lower than that without concatenations. The `USE_CONCAT` hint overrides the cost consideration.

The `USE_CONCAT` hint uses the following syntax:

```
/*+ USE_CONCAT [ ( @ queryblock ) ] */
```

The following statement provides an example:

```
SELECT /*+ USE_CONCAT */ *
  FROM employees e
  WHERE manager_id = 108
     OR department_id = 110;
```

MERGE Hint

The `MERGE` hint allows you to merge views in a query.

The `MERGE` hint uses the following syntax:

```
/*+ MERGE [ ( @ queryblock )  | ( [ @ queryblock ] tablespec ) ] */
```

If the query block of a view includes the `GROUP BY` clause or `DISTINCT` operator in the `SELECT` list, the optimizer can merge the view into the accessing statement only if complex view merging is enabled. If an `IN` subquery is uncorrelated, you can also use complex merging to merge the subquery into the accessing statement. The following statement provides an example:

```
SELECT /*+ MERGE(v) */ e1.last_name, e1.salary, v.avg_salary
   FROM employees e1,
        (SELECT department_id, avg(salary) avg_salary
           FROM employees e2
           GROUP BY department_id) v
   WHERE e1.department_id = v.department_id
     AND e1.salary > v.avg_salary
   ORDER BY e1.last_name;
```

When you use the `MERGE` hint without an argument, you must place the hint in the query block of a view. When you use

the `MERGE` hint with the view name as an argument, you must place the hint in the surrounding query.

NO_MERGE Hint

The `NO_MERGE` hint instructs the optimizer not to combine the outer query and inline view queries into a single query.

The `NO_MERGE` hint uses the following syntax:

```
/*+ NO_MERGE [ ( @ queryblock )  | ( [ @ queryblock ] tablespec ) ] */
```

This hint affects how you access the view. For example, if you execute the following statement, the view **seattle_dept** cannot be merged:

```
SELECT /*+ NO_MERGE(seattle_dept) */ e1.last_name, seattle_dept.department_name
  FROM employees e1,
       (SELECT location_id, department_id, department_name
          FROM departments
          WHERE location_id = 1700) seattle_dept
  WHERE e1.department_id = seattle_dept.department_id;
```

When you use the `NO_MERGE` hint in the view query block, you do not need to specify arguments for the hint.

When you specify the `NO_MERGE` hint in the surrounding query, you must specify the hint with the view name as an argument.

UNNEST Hint

The `UNNEST` hint instructs the optimizer not to nest but to merge the body of the subquery into the body of the query block that contains the hint. This allows the optimizer to consider the subquery and the hint together when the optimizer evaluates access paths and joins.

The `UNNEST` hint uses the following syntax:

```
/*+ UNNEST [ ( @ queryblock ) ] */
```

Before a subquery is unnested, the optimizer first verifies whether the subquery is valid. The subquery must pass heuristic and query optimization tests. When you use the `UNNEST` hint, the optimizer verifies the validity of only the subquery block. If the subquery block is valid, subquery unnesting is enabled even if heuristic and query optimization tests are not passed.

The following statement provides an example:

```
SELECT AVG(t1.c) FROM t1
WHERE t1.b >=
    (SELECT /*+unnest*/AVG(t2.b)
     FROM t2
     WHERE t1.a = t2.a);
```

NO_UNNEST Hint

The `NO_UNNEST` hint is used to disable subquery unnesting.

The `NO_UNNEST` hint uses the following syntax:

```
/*+ NO_UNNEST [ ( @ queryblock ) ] */
```

The following statement provides an example:

```
SELECT /*+no_unnest(@qb1)*/AVG(t1.c)
FROM t1 WHERE t1.b >=
    (SELECT /*+qb_name(qb1)*/AVG(t2.b)
     FROM t2)
     WHERE t1.a = t2.a);
```

PLACE_GROUP_BY Hint

The `PLACE_GROUP_BY` hint instructs the optimizer to use sequence replacement rules that are specified in the GROUP BY clause. In this case, the optimizer does not consider the cost increase caused by the transformation.

The `PLACE_GROUP_BY` hint uses the following syntax:

```
/*+ PLACE_GROUP_BY [ ( @ queryblock ) ] */
```

The following statement provides an example:

```
SELECT /*+place_group_by*/SUM(t1.c),SUM(t2.c) FROM t1, t2
WHERE t1.a = t2.a AND t1.b > 10 AND t2.b > 10
GROUP BY  t1.a;
```

NO_PLACE_GROUP_BY Hint

The `NO_PLACE_GROUP_BY` hint is used to disable the sequence transformation that is specified in the GROUP BY clause.

The `NO_PLACE_GROUP_BY` hint uses the following syntax:

```
/*+ NO_PLACE_GROUP_BY [ ( @ queryblock ) ] */
```

The following statement provides an example:

```
SELECT /*+no_place_group_by*/SUM(t1.c),SUM(t2.c) FROM t1, t2
WHERE t1.a = t2.a AND t1.b > 10 AND t2.b > 10
GROUP BY  t1.a;
```

NO_PRED_DEDUCE Hint

The `NO_PRED_DEDUCE` hint instructs the optimizer not to use predicates to deduce the transformation rules.

The `NO_PRED_DEDUCE` hint uses the following syntax:

```
/*+ NO_PRED_DEDUCE [ ( @ queryblock ) ] */
```

The following statement provides an example:

```
SELECT /*+no_pred_deduce(@qb1)*/ *
FROM  (
  SELECT /*+no_merge qb_name(qb1)*/ t1.a, t2.b
  FROM t1, t2
  WHERE t1.a = t2.a) v, t3
WHERE t3.a = 1 AND t3.a = v.a;
```

Other hints

QB_NAME Hint

Use the `QB_NAME` hint to specify a name for a query block. Then, you can use this name in the hint of an outer query or in the hint of an inline view to affect how queries are run on the tables that appear in the named query block. For more information about query block names, see the section "Specify query blocks in hints" in Hint overview.

The `QB_NAME` hint uses the following syntax:

```
/*+ QB_NAME ( queryblock ) */
```

Assume that two or more query blocks have the same name or different names are specified by two hints for the same query block. In this case, the optimizer ignores all of the names and hints that reference the query blocks. The system generates unique names for the query blocks that are not named by using the `QB_NAME` hint. These names can be displayed in plan tables and can also be used in the other query block hints.

In the following example, the `QB_NAME` hint is used:

```
SELECT /*+ QB_NAME(qb) FULL(@qb e) */ employee_id, last_name
  FROM employees e
  WHERE last_name = 'Smith';
```

READ_CONSISTENCY Hint

The `READ_CONSISTENCY` hint instructs a server to specify the mode of table reading for an SQL statement as weak consistency (specified by the

`WEAK` parameter) or strong consistency (specified by the `STRONG` parameter).

The `READ_CONSISTENCY` hint uses the following syntax:

```
/*+ READ_CONSISTENCY(WEAK[STRONG]) */
```

Example:

```
SELECT /*+ READ_CONSISTENCY(WEAK) */ *
  FROM employees
  WHERE employees.department_id = 1001;
```

FROZEN_VERSION Hint

The `FROZEN_VERSION` hint instructs a server to read the baseline data of a specified version.

The `FROZEN_VERSION` hint uses the following syntax:

```
/*+ FROZEN_VERSION (intnum) */
```

Example:

```
SELECT /*+ FROZEN_VERSION(1000) */ *
  FROM employees e
  WHERE e.department_id = 1001;
```

QUERY_TIMEOUT Hint

The `QUERY_TIMEOUT` hint instructs a server to specify the time-out period of executing an SQL statement. The unit for the time-out period is microseconds.

The `QUERY_TIMEOUT` hint uses the following syntax:

```
/*+ QUERY_TIMEOUT (intnum) */
```

In the following example, a time-out error is returned when the statement in the query fails to be fully executed within a second:

```
SELECT /*+ QUERY_TIMEOUT(1000000) */ *
  FROM employees e
  WHERE e.department_id = 1001;
```

LOG_LEVEL Hint

The `LOG_LEVEL` hint instructs a server to use a specified log level when an SQL statement is executed.

The `LOG_LEVEL` hint uses the following syntax:

```
/*+ LOG_LEVEL (']log_level[']) */
```

In the following example, the `DEBUG` log level is used for executing the SQL statement:

```
SELECT /*+ LOG_LEVEL(DEBUG) */ *
  FROM employees e
  WHERE e.department_id = 1001;
```

USE_PLAN_CACHE Hint

The `USE_PLAN_CACHE` hint specifies whether to use the plan cache mechanism when a server executes an SQL statement. The `NONE` parameter specifies that the plan cache mechanism is not used. The `DEFAULT` parameter specifies that the server settings determine whether to use the plan cache mechanism.

The `USE_PLAN_CACHE` hint uses the following syntax:

```
/*+ USE_PLAN_CACHE (NONE[DEFAULT]) */
```

In the following example, the plan cache mechanism is not implemented for the statement:

```
SELECT /*+ USE_PLAN_CACHE(NONE) */ *
  FROM employees e
  WHERE e.department_id = 1001;
```

TRANS_PARAM Hint

The `TRANS_PARAM` hint specifies whether to use the parameters that are specified by the `param` parameter when a server performs a transaction. Only the `FORCE_EARLY_LOCK_FREE` parameter at the transaction level is supported. The FORCE_EARLY_LOCK_FREE parameter specifies the setting of releasing row locks in advance. When `FORCE_EARLY_LOCK_FREE` is set to **TRUE**, the parameters that are specified by param are used. When FORCE_EARLY_LOCK_FREE is set to **FALSE**, the parameters that are specified by param are not used. Take note of the following point: The parameter names must be enclosed in single quotation marks ('). The parameter values must be also enclosed in single quotation marks ('), except when the parameter values are numeric values.

The `TRANS_PARAM` hint uses the following syntax:

```
/*+ TRANS_PARAM ['param' , 'param_value'] */
```

Example:

```
SELECT /*+ TRANS_PARAM('FORCE_EARLY_LOCK_FREE' 'TRUE') */ *
  FROM employees e
  WHERE e.department_id = 1001;
```

TRACING Hint

The `TRACING` hint instructs a server to implement `TRACING` for some operators in execution plans.

The `TRACING` hint uses the following syntax:

```
/*+ TRACING(TRACING_NUM_LIST)*/
```

Example:

```
SELECT /*+ TRACING(1) */ *
  FROM employees e
  WHERE e.department_id = 1001;
```

STAT Hint

The `STAT` hint specifies that `STAT` is used to display the information about some operators in execution plans.

The `STAT` hint uses the following syntax:

```
/*+ STAT(TRACING_NUM_LIST) */
```

Example:

```
SELECT /*+ STAT(1) */ *
  FROM employees e
  WHERE e.department_id = 1001;
```

TOPK Hint

The `TOPK` hint instructs a server to set the precision and the minimum number of rows for a fuzzy match. The value of the `PRECISION` parameter is an integer that ranges from 0 to 100. This parameter specifies the percentage of rows that are returned for a fuzzy match. The `MINIMUM_ROWS` parameter specifies the minimum number of rows that are returned.

The `TOPK` hint uses the following syntax:

```
/*+ TOPK(PRECISION MINIMUM_ROWS) */
```

Example:

```
SELECT /*+ TOPK(1,10) */ *
  FROM employees e
  WHERE e.department_id = 1001;
```

TRACE_LOG Hint

The `TRACE_LOG` hint instructs a server to collect trace logs. The trace logs are displayed when you run the `SHOW TRACE` command.

The `TRACE_LOG` hint uses the following syntax:

```
/*+ TRACE_LOG */
```

Example:

```
SELECT /*+ TRACE_LOG */ *
  FROM employees e
  WHERE e.department_id = 1001;
```

17.1.5.4.7. Database objects

17.1.5.4.7.1. Schema objects

A schema is a collection of data logical structures and schema objects. Each user of ApsaraDB for OceanBase has a schema and the schema has the same name as the user.

You can use SQL to create and process your database objects. Schema objects are divided into the following types:

- Constraints
- Database links
- Database triggers
- Indexes

- Object tables
- Object types
- Object views
- Packages
- Sequences
- Stored functions
- Stored procedures
- Synonyms
- Tables
- Views

17.1.5.4.8. Database naming conventions

17.1.5.4.8.1. Overview of the naming conventions of database objects

Some database objects consist of parts that you can or must name. For example, the columns in a table or view, indexes, table partitions and subpartitions, table integrity constraints, and objects that are stored within packages, including procedures and stored functions. This topic discusses the following content:

• Naming rules of database objects

• Examples of naming schema objects

• Naming guidelines of schema objects

17.1.5.4.8.2. Naming rules of database objects

Database object identifiers

Every database object has a name. In an SQL statement, you can use a quoted identifier or a nonquoted identifier to name a database object.

- A quoted identifier starts and ends with double quotation marks (`"`). If you name a schema object by using a quoted identifier, you must use double quotation marks (") when you reference this object.
- A nonquoted identifier does not contain punctuation marks.

However, database names, global database names, database link names, disk group names, and pluggable database (PDB) names are not case-sensitive and are stored in uppercase. If you specify such names by using quoted identifiers, the quotation marks are ignored.

> **Notice**
>
> We do not recommend that you use quoted identifiers to name database objects in ApsaraDB for OceanBase. These quoted identifiers are compatible with SQL Plus. However, other tools that manage database objects may fail to recognize these quoted identifiers.

Identifier usage rules

The following rules apply to both quoted and nonquoted identifiers unless otherwise specified:

Identifier length

An identifier is 1 to 128 bytes in length.

If an identifier contains multiple parts separated by periods (.), each part can be up to 128 bytes in length. Each period delimiter consumes one byte. Each double quotation mark consumes 1 byte. The following string provides an example:

```
"schema"."table"."column"
```

The string contains three parts: **schema**, **table**, and **column**. Each part can be up to 128 bytes in length. Each of the quotation marks and periods is a single-byte character. Therefore, the total length of the identifier in this example can be up to 392 bytes in length.

Use reserved words as identifiers

Nonquoted identifiers cannot be SQL reserved words in ApsaraDB for OceanBase. Quoted identifiers can be reserved words. However, we recommend that you do not use reserved words as quoted identifiers. Based on the tools that you plan to use to access database objects, the names may be further limited by other product-specific reserved words.

> **Notice**
>
> The reserved word `ROWID` is an exception to this rule. You cannot use the uppercase word `ROWID` as a column name, regardless of whether the word is quoted or nonquoted. You cannot use an all-caps quoted identifier as a column name. However, you can use a quoted identifier that contains one or more lowercase letters as a column name, for example, "Rowid" or "Rowid".

Use words with special meanings as identifiers

In ApsaraDB for OceanBase, the SQL language contains other words that have special meanings. These words include data types, schema names, function names, the virtual system table `DUAL`, and keywords. The keywords are the all-caps words in SQL statements, such as `DIMENSION`, `SEGMENT`, `ALLOCATE`, and `DISABLE`. These words are not reserved. However, ApsaraDB for OceanBase uses them inside the system in specific ways. Therefore, if you use these words as the names of objects and object parts, your SQL statements may be difficult to read and may lead to unpredictable results. In particular, do not use the names of SQL built-in functions as the names of schema objects and user-defined functions.

Use ASCII characters as identifiers

Characters in the ASCII character set provide optimal compatibility across different platforms and operating systems. Therefore, we recommend that you use these characters in database names, global database names, and database link names. You can use only the characters from the ASCII character set in the names of common users and common roles in a multitenant container database (CDB).

Characters in passwords

Passwords can contain multibyte characters, such as Chinese characters or Chinese punctuation marks.

Beginning of identifiers

Nonquoted identifiers must start with an alphabetic character from the database character set. Quoted identifiers can start with all characters.

Signs in identifiers

Nonquoted identifiers can contain only alphanumeric characters from the database character set and underscores (_). However, nonquoted identifiers that are used in database link names can contain periods (.) and at signs (@). Quoted identifiers can contain all characters, punctuation marks, and spaces. However, both quoted and nonquoted identifiers cannot contain double quotation marks (") or the null character (\0).

Limits of object names in namespaces

Tables, views, and private synonyms in the same namespace cannot have the same name.

Identifier case sensitivity

Nonquoted identifiers are not case-sensitive. ApsaraDB for OceanBase stores them in uppercase. Quoted identifiers are case-sensitive. By enclosing names in double quotation marks, you can assign the following names to different objects in the same namespace:

```
"employees"
"Employees"
"EMPLOYEES"
```

Nonquoted identifiers are not case-sensitive. Therefore, ApsaraDB for OceanBase considers the following names the same. You cannot use these names for different objects in the same namespace:

```
employees
EMPLOYEES
"EMPLOYEES"
```

Uppercase identifiers

When you store or compare all-caps identifiers, the uppercase form of each character in the identifiers is determined by applying the capitalization rules of the database character set. The language rules that are specified in the session setting `NLS_SORT` are not considered. The SQL function `UPPER`, rather than the function `NLS_UPPER`, is applied to the identifiers.

If you apply the capitalization rules of the database character set to natural languages, the capitalization result may be incorrect. For example, based on the capitalization rules of the database character set, the German lowercase letter `ß` does not have an uppercase form. Therefore, this letter does not change when you convert an identifier that contains this letter to an all-caps word.

The capitalization rules of the database character set ensure that identifiers are displayed in the same form regardless of the session language. To display an identifier correctly in a specific natural language, quote the identifier to keep the lowercase form or convert the letters to the correct uppercase letters in this language.

Column names

Columns in the same table or view cannot have the same name. However, columns in different tables or views can have the same name.

Procedure and function names

If the parameters in two procedures or functions in the same package have different quantities and data types, the procedures or functions can have the same name. Creating multiple procedures or functions with the same name using different parameters in the same package is called overloaded procedures or functions.

17.1.5.4.8.3. Examples of schema object names

The following examples provide some valid schema object names:

- `last_name`
- `horse`
- `hr.hire_date`
- `"EVEN THIS & THAT!"`
- `a_very_long_and_valid_name`

All the examples follow the rule illustrated in Rules for naming database objects.

17.1.5.4.8.4. Rules for naming schema objects

The following rules are useful for naming objects and their parts:

- Use full, descriptive, and pronounceable names or well-known abbreviations.
- Use the same naming rule for all objects.
- Assign the same name to the same object or attribute in different tables.

Make sure that you assign names that are both simple and descriptive to objects. If these objectives cannot be balanced, ensure that the name is descriptive. This is because database objects may be used for a long time. Assume that a table column is named **pmdd**. Users that use the database ten years later may not understand what information this column stores. However, the table column named **payment_due_date** is clearer to the users.

The object names based on the same naming rule help users understand the role that each table plays in your application. For example, assign names that start with **fin_** to all tables that belong to the **FINANCE** application.

Assign the same name to the same object in different tables. For example, if both the employee table and the department table have a column that stores the same department IDs, name the column **department_id** in both tables.

17.1.5.4.9. Methods of referencing database objects

17.1.5.4.9.1. Overview of database object references

This topic discusses how to reference schema objects and parts of them in the context of SQL statements. This topic provides:

- Reference schema objects
- Reference objects in a remote database
- Reference partition tables and indexes
- Reference object type attributes and methods
- Create remote database links

17.1.5.4.9.2. Reference schema objects

When an object is referenced in an SQL statement, ApsaraDB for OceanBase considers the context of the SQL statement and locates the object in the appropriate namespace. After the object is located, ApsaraDB for OceanBase executes the SQL statement to perform the specified operation on the object. If the named object cannot be located in the appropriate namespace, an error is returned.

Reference objects in users' schemas

The following example is used to illustrate how ApsaraDB for OceanBase resolves object references in SQL statements:

Execute the following statement to add a row of data to the table named **departments**:

```
INSERT INTO departments
VALUES (280, 'ENTERTAINMENT_CLERK', 206, 1700);
```

Based on the context of the SQL statement, **departments** may represent one of the following items in the database:

- A table in your schema

- A view in your schema
- A private synonym of a table or a view
- A public synonym

ApsaraDB for OceanBase always attempts to resolve the referenced objects in the namespaces of your schema before it considers the namespaces outside your schema. In this example, ApsaraDB for OceanBase attempts to resolve the object:

1. Firstly, ApsaraDB for OceanBase attempts to locate the object in the namespace of your schema that contains tables, views, and private synonyms. If the object is a private synonym, ApsaraDB for OceanBase locates the object that the synonym represents. The object can be in your own schema, another schema, or another database. The object can also be another synonym. In this case, ApsaraDB for OceanBase locates the object that the synonym represents.
2. If the object is located in the namespace, ApsaraDB for OceanBase attempts to execute the SQL statement on the object. In this example, ApsaraDB for OceanBase attempts to add a row of data to **departments**. If the type of the object is not the required type of the SQL statement, ApsaraDB for OceanBase returns an error. In this example, **departments** must be a table, view, or private synonym that can be resolved as a table or a view. If **departments** is a sequence, ApsaraDB for OceanBase returns an error.
3. If the object is not found in all of the namespaces that have been searched so far, ApsaraDB for OceanBase searches the namespace that contains public synonyms. If the object is in the namespace that contains public synonyms, ApsaraDB for OceanBase attempts to execute the statement on the object. If the type of the object is not the required type of the SQL statement, ApsaraDB for OceanBase returns an error. In this example, if **departments** is a public synonym that represents a sequence, ApsaraDB for OceanBase returns an error.

Assume that the public synonym has dependent tables or user-defined types. In this case, you cannot create an object with the same name as the synonym in the same schema as that of the dependent object.

On the contrary, assume that the synonym does not have dependent tables or user-defined types. In this case, you can create an object with the same name as the synonym in the same schema as that of the dependent object. ApsaraDB for OceanBase invalidates all of the dependent objects, and revalidates them when they are accessed the next time.

Reference objects in other schemas

To reference objects in schemas other than your schema, add the schema name to the beginning of the object name:

```
schema.object
```

In the following example, the **employees** table is deleted from the schema named **hr**:

```
DROP TABLE hr.employees;
```

17.1.5.4.9.3. Reference objects in a remote database

Create database links

To reference an object in a database other than the local database, specify the name of the database link that points to the desired database after the object name. A database link is a schema object that enables ApsaraDB for OceanBase to connect to a remote database and access the objects in the remote database.

You can use the CREATE DATABASE LINK statement to create a database link. When you use this statement, you must specify the following database link information:

- The tenant name, username, and password.
- The network address and port number.

ApsaraDB for OceanBase stores the preceding information in a data dictionary.

Limits on creating links

1. You can only create database links to connect an Oracle tenant to another Oracle tenant in ApsaraDB for OceanBase. Currently, ApsaraDB for OceanBase does not allow you to create a link that connect an ApsaraDB for OceanBase database to an external Oracle database.
2. A tenant can create and delete database links for multiple times. However, a maximum of 15 database links are allowed under a tenant at the same time.

Format of database connection strings

```
user_name@tenant_name IDENTIFIED BY password HOST 'ip:port'
```

- **user_name**: The username.
- **tenant_name**: The tenant name.
- **password**: The password.
- **ip**: The network address.
- **port**: The port number.

For example, you can execute the following statement to create a database link:

```
CREATE DATABASE LINK my_link CONNECT TO
root@oracle  IDENTIFIED BY abcdef HOST '192.168.0.0:1521';
```

Reference database links

When you issue an SQL statement that contains a database link, you need to use the complete database link name as stored in the data dictionary. For more information about database link names, see Create database links.

When ApsaraDB for OceanBase connects to a remote database, ApsaraDB for OceanBase uses a database connection string to access the remote database. If the connection succeeds by using the database string, username, and password, ApsaraDB for OceanBase follows the rules in Reference schema objects to access the specified object in the remote database. However, take note of the following limits:

1. You can only execute read-only statements.
2. You can only access table objects but not other objects such as views and sequences.
3. When you access a table object, you must explicitly specify the database name, for example, `test.t1@my_link`.
4. The following plans and operators are not supported:
   - You cannot perform the `RESCAN` operation on the remote database.
   - You cannot execute the operators such as `NESTED LOOP JOIN`, `SEMI JOIN`, `ANTI JOIN`, and `SUBPLAN FILTER` on the remote database.
   - If the preceding problems occur, you can attempt to run the `EXPLAIN PLAN` statement to view the original plan and the SQL statements sent to the remote cluster for execution, and adjust the plan by using a hint.

17.1.5.4.9.4. Reference partitioned tables and indexes

You can partition tables and indexes. When you partition a table, these schema objects consist of a number of parts called partitions. All the partitions have the same logical attributes. For example, all partitions in a table share the same column and constraint definitions, whereas all partitions in an index share the same index columns.

Partition-extended and subpartition-extended names allow you to perform some partition-level and subpartition-level operations. For example, you can delete all rows from only one partition or subpartition. To manage partitions or subpartitions that do not have extended names, specify a range by using the `WHERE` clause. For range-partitioned and list-partitioned tables, you may encounter difficulties when you attempt to use conditional statements to phrase a partition-level operation. The difficulty increases if multiple columns are used as the range partition keys. Hash partitions and subpartitions are based on system-defined hash functions. Therefore, you may encounter more difficulties in using conditional statements on these partitions and subpartitions.

Partition-extended names allow you to use partitions in the same way as you use tables. This method allows you to build partition-level access control mechanisms by granting (or revoking) permissions on these views to (or from) other users or roles. This feature is useful when you query data in range-partitioned tables. To use a partition as a table, create a view by selecting data from the partition, and then use the view as a table.

Syntax

If the `partition_extended_name` or `subpartition_extended_name` element appears in the syntax of an SQL statement, you can use these elements to specify partition-extended or subpartition-extended table names.
Syntax of `partition_extended_name`:

```
PARTITION partition
|
PARTITION FOR ( partition_key_value [, partition_key_value]... )
```

Syntax of `subpartition_extended_name`:

```
SUBPARTITION subpartition
|
SUBPARTITION FOR ( subpartition_key_value [, subpartition_key_value]... )
```

Partition or subpartition names in data manipulation language (DML) statements, such as `INSERT`, `UPDATE`, `DELETE`, and `ANALYZE`, must be included in parentheses (). This small distinction is reflected in the `partition_extension_clause` element: In `partition_extended_name`, `subpartition_extended_name`, and `partition_extension_clause`, the `PARTITION FOR` and `SUBPARTITION FOR` clauses allow you to reference partitions without using their names. They are valid for all partition types, and are especially useful for interval partitions. When you insert data into a table, interval partitions are automatically created as needed.

For each `partition_key_value` or `subpartition_key_value` of the preceding elements, a value is specified for each partition key column. If multiple columns are used as partition keys, you must specify a value for each partition key. If a composite partitioning scheme is used, you must specify a value for each subpartition key after you specify a value for a partition key. Separate all partition key values with commas (,). If an interval partitioning scheme is used, you can specify only one `partition_key_value`. The specified value must be a valid value of the `NUMBER` or a date and time data type. Your SQL statements operate on the partitions or subpartitions that contain the specified values.

Limits on extended names

The use of partition-extended and subpartition-extended table names is subject to the following limits:

- No remote tables in names: Partition-extended and subpartition-extended table names cannot contain database links or synonyms that can be translated to tables that contain database links. To use remote partitions and subpartitions, create a view at the remote site by using the extended table name syntax and then reference the remote view.
- No synonyms in names: You must use base tables to specify partition-extended and subpartition-extended names. You cannot use synonyms, views, or other objects.
- In the `PARTITION FOR` and `SUBPARTITION FOR` clauses, you cannot specify the `DEFAULT` or `MAXVALUE` keyword, or a bind variable for `partition_key_value` or `subpartition_key_value`.
- In the `PARTITION` and `SUBPARTITION` clauses, you cannot specify a bind variable for the partition or subpartition name.

Examples

In the following example, **sales** is a partitioned table with the **sales_q1_2000** partition. You can execute the following statement to create a view of the **sales_q1_2000** partition, and then use the view in the same way as you use a table. In this example, some rows are deleted from the partition.

```
/*Create the Q1_2000_sales view for the sales_q1_2000 partition.*/
CREATE VIEW Q1_2000_sales
AS
SELECT *
FROM sales PARTITION (SALES_Q1_2000);
/*Delete the record in which the value in the amount_sold column is less than 0 from the Q1_2000_sale
s view.*/
DELETE FROM Q1_2000_sales
WHERE amount_sold < 0;
```

17.1.5.4.9.5. Reference object type attributes and methods

To reference object type attributes or methods in an SQL statement, qualify the reference by using a table alias. In the following example, the sample schema **ob** contains the **cust_address_typ** type and the **customers** table, and the **customers** table has a **cust_address_typ** column named **cust_address**.

```
CREATE TYPE cust_address_typ
  OID '82A4AF6A4CD1656DE034080020E0EE3D'
AS OBJECT
    (street_address    VARCHAR2(40),
     postal_code       VARCHAR2(10),
     city              VARCHAR2(30),
     state_province    VARCHAR2(10),
     country_id        CHAR(2));
/
CREATE TABLE customers
  (customer_id        NUMBER(6),
   cust_first_name    VARCHAR2(20) CONSTRAINT cust_fname_nn NOT NULL,
   cust_last_name     VARCHAR2(20) CONSTRAINT cust_lname_nn NOT NULL,
   cust_address       cust_address_typ,
. . .
```

In an SQL statement, you must qualify the reference to the **postal_code** attribute by using a table alias, as shown in the following example:

```
SELECT c.cust_address.postal_code
FROM customers c;

UPDATE customers c
SET c.cust_address.postal_code = '610000'
WHERE c.cust_address.city = 'chengdu'
AND c.cust_address.state_province = 'SICHUAN';
```

To reference a member method that does not accept arguments, provide empty parentheses. For example, the **ob** sample schema contains the **category_tab** object table based on **catalog_typ**, and this table contains the `getCatalogName` member function. To call this method in an SQL statement, provide empty parentheses, as shown in the following example:

```
SELECT TREAT(VALUE(c) AS catalog_typ).getCatalogName() "Catalog Type"
FROM categories_tab c
WHERE category_id = 10;
```

The following result is returned:

```
+----------------+
| Catalog Type   |
+----------------+
| online catalog |
+----------------+
```

17.1.5.5. Operators

17.1.5.5.1. Operator overview

Operators generally connect individual data items, such as operands or parameters, and return the results. In terms of syntax, an operator can appear before or after an operand, or between two operands. Special characters or keywords are generally used to represent operators. For example, slashes (/) are used to represent division operators. This topic discusses the operators that excludes logical or BOOLEAN operators. You cannot use these operators as the `WHERE` or `HAVING` conditions for queries or subqueries.

This topic describes the following operators in detail:

- Arithmetic operators
- Concatenation operators
- Hierarchical query operators
- Set operators

Unary and binary operators

Operators can be divided into two categories:

- Unary operators: A unary operator performs an operation on only one operand. The following general format is used for unary operators:

```
operator operand
```

- Binary operators: A binary operator performs an operation on two operands. The following general format is used for binary operators:

```
operand 1 operator operand 2
```

Other operators in the special formats can accept more than two operands. If a NULL operand is provided for an operator, the result is always null. The only operator that does not comply with this rule is the concatenation (||) operator.

Operator precedences

The precedences affect the order in which ApsaraDB for OceanBase calculates different operators in the same expression. When an expression that contains multiple operators is calculated, ApsaraDB for OceanBase first calculates the operator that has a higher precedence and then calculates the operator that has a lower precedence. If the precedences of two operators are equal, the operators that have the same precedence in the expression are calculated from left to right.

The following table lists the precedences of SQL operators from highest to lowest. Operators that are listed on the same line have the same precedence.

Operator	Operation method
+, - (it is used as an unary operator), PRIOR, and CONNECT_BY_ROOT	Plus sign, unary minus, and the position in a hierarchy.
* and /	Multiplication and division.
+, - (it is used as a binary operator), and ||	Addition, subtraction, and concatenation.
After the database evaluates operators, it evaluates case expressions.	For more information, see SQL condition overview.

In the following example, multiplication takes precedence over addition. The database first multiplies 2 by 3 and then adds 1 to the result.

```
1+2*3
```

You can also use parentheses in an expression to limit operator precedences. ApsaraDB for OceanBase evaluates the expressions that are enclosed in parentheses, and then evaluates the expressions that are outside the parentheses.

SQL also supports the set operators `UNION` , `UNION ALL` , `INTERSECT` , and `MINUS` . Set operators merge rowsets that are returned by queries instead of individual data items. All the set operators have equal precedence.

17.1.5.5.2. Arithmetic operators

Arithmetic operators perform operations, such as negation, addition, subtraction, multiplication, and division, on one or two parameters. Some of arithmetic operators are also used to calculate date and time and interval values. The parameters of arithmetic operators must be resolved to the numeric data type or a data type that can be directly converted into the numeric data type by the database.

Unary arithmetic operators return the same data type as the data type of the parameters. For binary arithmetic operators, ApsaraDB for OceanBase determines the parameter that has the highest numeric precedence in the expression, and then converts the remaining parameters to the data type of this parameter.

The following table describes arithmetic operators.

Operator	Description
+, -	If the operators represent positive and negative, they are unary operators.
+, -	If the operators represent addition and subtraction operations, they are binary operators.
*, /	The binary operators. They represent multiplication and division operations.

Two consecutive minus signs (--) cannot be used in arithmetic expressions to indicate double negation or the subtraction of a negative value. This is because the characters -- are used to specify comments in SQL statements. You can separate two consecutive minus signs with spaces or parentheses. For more information about the comments in SQL statements, see Comments.

The following example shows an SQL query that uses the + and - operators to represent positive and negative:

```
SELECT * FROM order_items WHERE quantity = -1 ORDER BY order_id, line_item_id, product_id;
SELECT * FROM employees WHERE -salary < 0 ORDER BY employee_id;
```

The following example shows an SQL query that uses the + and - operators to represent addition and subtraction operations:

```
SELECT hire_date FROM employees WHERE SYSDATE - hire_date > 365 ORDER BY hire_date;
```

The following example shows an SQL query that uses the * and / operators to represent multiplication and division operations:

```
UPDATE employees SET salary = salary * 1.1;
UPDATE employees SET salary = salary / 2;
```

17.1.5.5.3. Concatenation operators

The concatenation operator || is used to concatenate strings and data of the `CLOB` type.

After two strings are concatenated, another string is generated. If the data types of the two strings are `CHAR`, the returned result is of the `CHAR` data type and can be at most 2,000 characters in length. If the data type of one of the concatenated strings is `VARCHAR2`, the returned result is of the `VARCHAR2` data type and can be at most 4,000 characters in length. If one of the parameters on the two sides of the concatenation operator is a value of the `CLOB` data type, the returned result is of a temporary `CLOB` data type. The trailing spaces in the strings are preserved by concatenation, regardless of the data types of the parameters on both sides of the concatenation operator.

Although ApsaraDB for OceanBase regards a zero-length string as NULL, an operand that contains values is generated after an operand that contains values is concatenated with another zero-length string. Therefore, NULL can be generated only if two NULL strings are concatenated. However, this may not continue to be true in future ApsaraDB for OceanBase database versions. To concatenate expressions that may be NULL, use the `NVL` function to directly convert the expressions to zero-length strings.

In the following example, a table that contains columns of the `CHAR` and `VARCHAR2` types is created. Values that have and do not have trailing spaces are inserted and concatenated.

```
CREATE TABLE tab1 (col1 VARCHAR2(6), col2 CHAR(10), col3 VARCHAR2(10), col4 CHAR(6));
INSERT INTO tab1 (col1, col2, col3, col4) VALUES ('abc', 'def    ', 'ghi    ', 'jkl');
SELECT col1 || col2 || col3 || col4 "Concatenation" FROM tab1;
```

The following result is returned:

```
+----------------------------+
| Concatenation              |
+----------------------------+
| abcdef       ghi    jkl    |
+----------------------------+
```

17.1.5.5.4. Hierarchical query operators

The `PRIOR` and `CONNECT_BY_ROOT` operators are valid in only hierarchical queries.

PRIOR operator

In a hierarchical query, the `CONNECT BY` condition must contain at least one expression that is qualified by the `PRIOR` operator. The result of the `PRIOR` operator is obtained by using the parent row of the current row to compute the expression that immediately follows the operator.

`PRIOR` is most commonly used in an equality comparison of columns. `PRIOR` can be placed on either side of the comparison operator. Theoretically, operators other than the equal sign (=) can be used in `CONNECT BY` clauses. However, the conditions that are created by these other operators may cause loops. In this case, ApsaraDB for OceanBase detects the loops at runtime and returns an error.

CONNECT_BY_ROOT operator

`CONNECT_BY_ROOT` is a unary operator and is valid in only hierarchical queries. The parameters of `CONNECT_BY_ROOT` can be columns and most expressions. The result of the `CONNECT_BY_ROOT` operator equals to the value that is obtained by using the data of the root row to calculate the parameter.

You cannot specify this operator in a `START WITH` or `CONNECT BY` condition.

17.1.5.5.5. Set operators

A set operator merges two query results into one result. The queries that contain set operators are compound queries.

Operator	Return value
UNION	Returns all the distinct rows that are selected by a query.
UNION ALL	Returns all the rows that are selected by a query. The return result includes all the duplicates.
INTERSECT	Returns all the distinct rows that are selected by both queries.
MINUS	Returns all the distinct rows that are selected by the first query. The return result excludes the rows that are included in the result of the second query.

For more information and examples about the set operators, see the descriptions of the UNION ALL, INTERSECT, and MINUS operators in the Queries and subqueries topic.

17.1.5.5.6. Collations

Collations (COLLATE operators) allow you to specify a collation and reset the collation of the character type or specify the collation of a single expression.

COLLATE is a postfix unary operator. It has the same precedence as other unary operators, but it is executed after all the prefix unary operators are executed. The COLLATE operator can be applied to the expressions of the VARCHAR2, CHAR, LONG, NVARCHAR, or NCHAR type.

The collation_name parameter that follows the COLLATE operator is the collation that is to be specified or used. When the collation name includes spaces, you must enclose the name in double quotation marks ('').

Example:

```
obclient> create table t1(c1 varchar(20));
obclient> insert into t1 values('a');
obclient> insert into t1 values('b');
obclient> insert into t1 values(1);
obclient> select * from t1 order by c1 collate utf8mb4_general_ci;
+------+
| C1   |
+------+
| 1    |
| a    |
| b    |
+------+
3 rows in set (0.00 sec)
```

The following collations are supported:

```
obclient> show collation;
+--------------------+---------+-----+---------+----------+---------+
| COLLATION          | CHARSET | ID  | DEFAULT | COMPILED | SORTLEN |
+--------------------+---------+-----+---------+----------+---------+
| utf8mb4_general_ci | utf8mb4 |  45 | Yes     | Yes      |       1 |
| utf8mb4_bin        | utf8mb4 |  46 | NULL    | Yes      |       1 |
| binary             | binary  |  63 | Yes     | Yes      |       1 |
| gbk_chinese_ci     | gbk     |  28 | Yes     | Yes      |       1 |
| gbk_bin            | gbk     |  87 | NULL    | Yes      |       1 |
| utf16_general_ci   | utf16   |  54 | Yes     | Yes      |       1 |
| utf16_bin          | utf16   |  55 | NULL    | Yes      |       1 |
| utf8mb4_unicode_ci | utf8mb4 | 224 | NULL    | Yes      |       1 |
| utf16_unicode_ci   | utf16   | 101 | NULL    | Yes      |       1 |
| gb18030_chinese_ci | gb18030 | 248 | Yes     | Yes      |       1 |
| gb18030_bin        | gb18030 | 249 | NULL    | Yes      |       1 |
+--------------------+---------+-----+---------+----------+---------+
11 rows in set (0.01 sec)
```

17.1.5.6. Functions

17.1.5.6.1. Function overview

Functions work in a similar way as operators. After data elements are passed to a function as the input of parameters, the function returns a result. However, functions differ from operators in the format of input parameters. Functions can contain a variable number of parameters. A function can contain one, two, or more parameters.

```
Function name (parameter, parameter, ...)
```

A function without parameters is similar to a pseudocolumn. For more information, see Pseudo columns. A pseudocolumn returns a different value for each row in the result set. However, a function without variables returns the same value for all rows.

About functions

Built-in functions of ApsaraDB for OceanBase can be used in SQL statements. An expected data type is specified for each parameter of a function. If the data type of an input argument is expected, ApsaraDB for OceanBase attempts to convert the data type to the expected one and then executes the SQL statement.

Null values in functions

If the input argument is NULL, most functions return NULL as the result. In this case, you can use the `NVL` function to return a non-null value. For example, assume that a table is created to store commission data and the **commission_pct** column stores the commission values. If the value in the commission_pct column is NULL, the `NVL(commission_pct,0)` expression returns 0. If the value in the **commission_pct** column is not NULL, the expression returns the actual commission value.

Function types and lists

In the following function lists, each parameter or return value of each function has a specific data type.

> **Notice**
>
> When you apply a function to a `LOB` column in an SQL statement, ApsaraDB for OceanBase creates a temporary `LOB` column during SQL processing or PL/SQL processing. Some limits are set for using the column. For more information, see Compatibility with Oracle databases.

This topic describes two categories of functions:

- **Single-row functions**: include numeric functions, string functions that return strings, string functions that return numbers, date and time functions, general comparison functions, conversion functions, encoding and decoding functions, and null-related functions.
- **Statistical functions**: include aggregate functions and analytic functions.

A single-row function returns a result value for each row of a queried table or view. These functions can be used in SQL clauses such as `SELECT`, `WHERE`, `START WITH`, `CONNECT BY`, and `HAVING`.

Aggregate functions and analytic functions perform aggregate calculations on a group of rows. An aggregate function returns only a single row for each group of rows. However, an analytic function returns multiple rows for each group of rows. A group of rows is also called a window. In most cases, aggregate functions are used in combination with the `GROUP BY` clause in the `SELECT` statement. When you use an aggregate function, the database divides the rows of a queried table or view into groups and applies the aggregate function to each group of rows. Then, one result row is returned for each group of rows.

When you use analytic functions, you must use the special keyword `OVER` to specify a window. For more information about window functions, see Window functions.

Numeric functions

Numeric functions accept numeric values as the input and return numeric values. Most numeric functions return values of

the `NUMBER` data type. The return values can be accurate to 38 decimal places. Some functions are related to advanced algebra. Some of these functions, such as `COS`, `COSH`, `EXP`, `LN`, `LOG`, `SIN`, `SINH`, `SQRT`, `TAN`, and `TANH`, return values that are accurate to 36 decimal points. Other functions that are related to advanced algebra, such as `ACOS`, `ASIN`, `ATAN`, and `ATAN2`, return values that are accurate to 30 decimal places.

Function category	Function subcategory	Function name	Description
Single-row function	Numeric function	ABS	A mathematical function that returns the absolute (positive) value of the specified numeric expression.

Function category	Function subcategory	Function name	Description
Single-row function	Numeric function	ACOS	Returns the angle that is represented in radians, whose cosine is specified by using the `NUMBER` expression. This angle is also called arccosine.
Single-row function	Numeric function	ASIN	ApsaraDB for OceanBase does not support this function.
Single-row function	Numeric function	ATAN	ApsaraDB for OceanBase does not support this function.
Single-row function	Numeric function	ATAN2	ApsaraDB for OceanBase does not support this function.
Single-row function	Numeric function	BITAND	Performs a bitwise operation by using the bitwise AND operator. Both the input and output values are of the same `INT` type.
Single-row function	Numeric function	CEIL	Returns the smallest integer that is greater than or equal to the value of `numeric_expression` .
Single-row function	Numeric function	COS	ApsaraDB for OceanBase does not support this function.
Single-row function	Numeric function	COSH	ApsaraDB for OceanBase does not support this function.

Function category	Function subcategory	Function name	Description
Single-row function	Numeric function	EXP	Returns e raised to the power of numeric_expression.
Single-row function	Numeric function	FLOOR	Returns the largest integer that is equal to or less than the value of `numeric_expression`.
Single-row function	Numeric function	LN	Returns the e-based logarithm of `numeric_expression`.
Single-row function	Numeric function	LOG	Returns the `x`-based logarithm of `y`.
Single-row function	Numeric function	MOD	Returns the remainder that is produced when `x` is divided by `y`.
Single-row function	Numeric function	POWER	Returns `x` raised to the power of `y`.
Single-row function	Numeric function	REMAINDER	Returns the remainder that is produced when `x` is divided by `y`.
Single-row function	Numeric function	ROUND	Returns the rounded value of `numeric`.

Function category	Function subcategory	Function name	Description
Single-row function	Numeric function	SIGN	Returns the sign of the number `n`. This function returns 1 if n is greater than 0, returns -1 if n is less than 0, and returns 0 if n is equal to 0.
Single-row function	Numeric function	SIN	ApsaraDB for OceanBase does not support this function.
Single-row function	Numeric function	SINH	ApsaraDB for OceanBase does not support this function.
Single-row function	Numeric function	SQRT	Returns the square root of `n`.
Single-row function	Numeric function	TAN	ApsaraDB for OceanBase does not support this function.
Single-row function	Numeric function	TANH	ApsaraDB for OceanBase does not support this function.
Single-row function	Numeric function	TRUNC	Truncates `numeric` to the specified `precision` and returns the result value.
Single-row function	Numeric function	WIDTH_BUCKET	ApsaraDB for OceanBase does not support this function.

String functions that return strings

The maximum length of the value returned by a function varies based on the data type of the value. For example, assume that a function returns a `VARCHAR2` value whose length exceeds the maximum length of a `VARCHAR2` value. In this case, ApsaraDB for OceanBase truncates the value and returns the truncated value without displaying a prompt on the client.

Notice

If a function returns a `CLOB` value whose length exceeds the maximum length of a CLOB value, ApsaraDB for OceanBase returns no data and displays an error message.

Function category	Function subcategory	Function name	Description
Single-row function	String functions that return strings	CHR	Converts `n` to one or more equivalent characters. The return value is related to the current system character set.
Single-row function	String functions that return strings	CONCAT	Concatenates two strings.
Single-row function	String functions that return strings	INITCAP	Returns a string in which the first letter of each word is uppercase and other letters are lowercase.
Single-row function	String functions that return strings	LOWER	Converts all letters in a string to lowercase letters.
Single-row function	String functions that return strings	LPAD	Left-pads the `c1` string to the given length `n` with the `c2` string.
Single-row function	String functions that return strings	LTRIM	Trims the string that appears on the left.
Single-row function	String functions that return strings	REGEXP_REPLACE	Replaces an object with a regular expression.
Single-row function	String functions that return strings	REGEXP_SUBSTR	ApsaraDB for OceanBase does not support this function.
Single-row function	String functions that return strings	REPLACE	Replaces a specified string with a new string in a character expression.

Function category	Function subcategory	Function name	Description
Single-row function	String functions that return strings	RPAD	Right-pads the `c1` string to the given length `n` with the `c2` string.
Single-row function	String functions that return strings	RTRIM	Trims a string that appears on the right. This function is useful for formatting the output of a query.
Single-row function	String functions that return strings	SUBSTR	Extracts a substring. A multibyte character, such as a full-width character, is counted as one character.
Single-row function	String functions that return strings	TRANSLATE	Replaces a specified character with a new character in a character expression. A multibyte character, such as a full-width character, is counted as one character.
Single-row function	String functions that return strings	TRIM	Trims leading characters, trailing characters, or both of them from a string.
Single-row function	String functions that return strings	UPPER	Converts all letters in a string to uppercase letters.

String functions that return numbers

Function category	Function subcategory	Function name	Description
Single-row function	String functions that return numbers	ASCII	Returns the ASCII value of the leftmost character in a character expression.

Single-row function	String functions that return numbers	INSTR	Searches for a specified character in a string, and returns the position where the specified character is found.
Single-row function	String functions that return numbers	LENGTH	Returns the length of a string.
Single-row function	String functions that return numbers	REGEXP_COUNT	ApsaraDB for OceanBase does not support this function.
Single-row function	String functions that return numbers	REGEXP_INSTR	ApsaraDB for OceanBase does not support this function.

Date and time functions

Date and time functions support input parameters of the following data types: date-related data types (`DATE`), timestamp-related data types (`TIMESTAMP` , `TIMESTAMP WITH TIME ZONE` , and `TIMESTAMP WITH LOCAL TIME ZONE`), and interval-related data types (`INTERVAL DAY TO SECOND` and `INTERVAL YEAR TO MONTH`).

The following functions support input parameters of only the `DATE` data type: `ADD_MONTHS` , `CURRENT_DATE, LAST_DAY` , `NEW_TIME` , and `NEXT_DAY` .

Assume that you attempt to insert a `TIMESTAMP` value as an argument into the preceding functions. ApsaraDB for OceanBase implicitly converts the data type, passes the converted data to the function for calculations, and then returns a `DATE` value.

> **Notice**
>
> `MONTHS_BETWEEN` returns a number.
>
> `ROUND` and `TRUNC` cannot implicitly convert data types and support input parameter of only the `DATE` type. If you pass values of other data types to these functions, errors are reported.

The other date and time functions support input parameters of the three data types and return values of the same data types as the input parameters.

Function category	Function subcategory	Function name	Description
Single-row function	Date and time function	ADD_MONTHS	Returns the date value that is `n` months after `date`. If `n` is a negative number, this function returns the date value that is `n` months before `date`.
Single-row function	Date and time function	CURRENT_DATE	Returns the current date in the session time zone.
Single-row function	Date and time function	CURRENT_TIMESTAMP	Returns a value of the `TIMESTAMP WITH TIME ZONE` data type. The return value indicates the current date in the session time zone and contains the information of the current time zone.
Single-row function	Date and time function	DBTIMEZONE	Returns the time zone of the current database instance. In ApsaraDB for OceanBase, the database time zone is UTC+0 and cannot be changed.
Single-row function	Date and time function	EXTRACT (datetime)	Extracts elements such as the year, month, day, hour, minute, and second values from a specified time field or expression.
Single-row function	Date and time function	FROM_TZ	Combines a value of the `TIMESTAMP` data type with the time zone information into a time value of the `TIMESTAMP WITH TIME ZONE` data type.

Function category	Function subcategory	Function name	Description
Single-row function	Date and time function	LAST_DAY	Returns the date of the last day of the month in which the specified `date` falls.
Single-row function	Date and time function	LOCALTIMESTAMP	Returns a value of the `TIMESTAMP` data type. The return value indicates the current date in the session time zone.
Single-row function	Date and time function	MONTHS_BETWEEN	Returns the number of months between `date1` and `date2`.
Single-row function	Date and time function	NEW_TIME	ApsaraDB for OceanBase does not support this function.
Single-row function	Date and time function	NEXT_DAY	Returns the date value of the weekday `c1` in the week following `d1`.
Single-row function	Date and time function	NUMTODSINTERVAL	Converts the argument `n` to a value of the `INTERVAL DAY TO SECOND` data type. The `interval_unit` parameter specifies the measurement unit.
Single-row function	Date and time function	NUMTOYMINTERVAL	Converts the argument `n` to a value of the `INTERVAL YEAR TO MONTH` data type. The `interval_unit` parameter specifies the measurement unit.

Function category	Function subcategory	Function name	Description
Single-row function	Date and time function	ROUND (date)	Returns a date and time value that is nearest to the specified `date`. The `fmt` parameter specifies the unit that is used to measure the interval between the returned date and the specified date.
Single-row function	Date and time function	SESSIONTIMEZONE	Returns the time zone of the current session.
Single-row function	Date and time function	SYS_EXTRACT_UTC	Returns the UTC time that corresponds to the specified time.
Single-row function	Date and time function	SYSDATE	Returns the current date.
Single-row function	Date and time function	SYSTIMESTAMP	Returns the current system date which contains the current time zone information. Six digits appear after the decimal point of the second value.
Single-row function	Date and time function	TO_CHAR (datetime)	Converts a value of the `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `TIMESTAMP WITH LOCAL TIME ZONE`, `INTERVAL DAY TO SECOND`, or `INTERVAL YEAR TO MONTH` data type to a value of the `VARCHAR2` data type. The `fmt` parameter specifies the format of the return value.

Function category	Function subcategory	Function name	Description
Single-row function	Date and time function	TO_DSINTERVAL	Converts a string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type to a value of the `INTERVAL DAY TO SECOND` data type. You can perform the addition and subtraction arithmetic operations on date and time values by using this function.
Single-row function	Date and time function	TO_TIMESTAMP	Converts a string to a value of the `TIMESTAMP` data type.
Single-row function	Date and time function	TO_TIMESTAMP_TZ	Converts a string to a value of the `TIMESTAMP WITH TIME ZONE` data type, which contains the time zone information.
Single-row function	Date and time function	TO_YMINTERVAL	Converts a string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type to a value of the `INTERVAL YEAR TO MONTH` data type. You can perform the addition and subtraction arithmetic operations on date and time values by using this function.

Function category	Function subcategory	Function name	Description
Single-row function	Date and time function	TRUNC (date)	Returns a date and time value that is nearest to the specified `date`. The `fmt` parameter specifies the unit in which the interval between the return value and the specified date is measured. The returned date value precedes `date`.
Single-row function	Date and time function	TZ_OFFSET	Returns the offset of the `n` time zone. The time zone offset is the difference between a time zone and the UTC+0 time zone in hours and minutes.

General comparison functions

You can use this type of functions to locate the maximum and minimum values in a set of values in a short time.

Function category	Function subcategory	Function name	Description
Single-row function	General comparison function	GREATEST	Returns the maximum value in a list of one or more expressions.
Single-row function	General comparison function	LEAST	Returns the minimum value in a list of one or more expressions.

Conversion functions

You can convert a value from one data type to another data type by using this type of functions.

Function category	Function subcategory	Function name	Description
Function category	**Function subcategory**	**Function name**	**Description**
Single-row function	Conversion function	ASCIISTR	ApsaraDB for OceanBase does not support this function.

Function category	Function subcategory	Function name	Description
Single-row function	Conversion function	BIN_TO_NUM	ApsaraDB for OceanBase does not support this function.
Single-row function	Conversion function	CHARTOROWID	ApsaraDB for OceanBase does not support this function.
Single-row function	Conversion function	HEXTORAW	Converts a character that contains hexadecimal numbers and is of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type to a value of the RAW data type.
Single-row function	Conversion function	RAWTOHEX	Converts a binary number to a hexadecimal format string.
Single-row function	Conversion function	TO_BINARY_DOUBLE	Returns a 64-bit double-precision floating-point number.
Single-row function	Conversion function	TO_BINARY_FLOAT	Returns a 32-bit single-precision floating-point number.
Single-row function	Conversion function	TO_CHAR (character)	Converts an `NCHAR`, `NVARCHAR2`, or `CLOB` character to a database character set.

Function category	Function subcategory	Function name	Description
Single-row function	Conversion function	TO_CHAR (datetime)	Converts a value of the `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `TIMESTAMP WITH LOCAL TIME ZONE`, `INTERVAL DAY TO SECOND`, or `INTERVAL YEAR TO MONTH` data type to a value of the `VARCHAR2` data type. The `fmt` parameter specifies the format of the return value.
Single-row function	Conversion function	TO_CHAR (number)	Converts the value `n` of the `NUMBER`, `BINARY_FLOAT`, or `BINARY_DOUBLE` data type to a value of the `VARCHAR2` data type in the format specified by `fmt`.
Single-row function	Conversion function	TO_DATE	Converts a character of the `CHAR`, `VARCHAR`, `NCHAR`, or `NVARCHAR2` data type to a value of the DATE data type.

Function category	Function subcategory	Function name	Description
Single-row function	Conversion function	TO_DSINTERVAL	Converts a string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type to a value of the `INTERVAL DAY TO SECOND` data type. You can perform the addition and subtraction arithmetic operations on a date and time value by using this function.
Single-row function	Conversion function	TO_NUMBER	Converts `expr` to a numeric value.
Single-row function	Conversion function	TO_TIMESTAMP	Converts a string to a value of the `TIMESTAMP` data type.
Single-row function	Conversion function	TO_TIMESTAMP_TZ	Converts a string to a value of the `TIMESTAMP WITH TIME ZONE` data type, which contains the time zone information.

Function category	Function subcategory	Function name	Description
Single-row function	Conversion function	TO_YMINTERVAL	Converts a string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type to a value of the `INTERVAL YEAR TO MONTH` data type. You can perform the addition and subtraction arithmetic operations on a date and time value by using this function.

Encoding and decoding functions

You can encode and decode data in ApsaraDB for OceanBase by using this type of functions.

Function category	Function subcategory	Function name	Description
Single-row function	Encoding and decoding function	DECODE	Returns a value that matches the specified conditions.
Single-row function	Encoding and decoding function	ORA_HASH	Retrieves the hash value of a corresponding expression.
Single-row function	Encoding and decoding function	VSIZE	Returns the size of `X` in bytes.

Null value-related functions

Function category	Function subcategory	Function name	Description
Single-row function	Null value-related function	COALESCE	Returns the first non-null expression in a parameter list. You must specify at least two parameters.

Function category	Function subcategory	Function name	Description
Single-row function	Null value-related function	LNNVL	Determines whether one or two operands in a condition are `NULL`.
Single-row function	Null value-related function	NULLIF	ApsaraDB for OceanBase does not support this function.
Single-row function	Null value-related function	NVL	Returns a non-NULL value from two expressions. If `expr1` and `expr2` return NULL, the NVL function returns NULL.
Single-row function	Null value-related function	NVL2	Returns different values based on whether an expression is null. If `expr1` is not null, this function returns the value of `expr2`. If `expr1` is null, this function returns the value of `expr3`. If `expr2` and `expr3` are of different data types, this function converts the data type of `expr3` to that of `expr1`.

Environment-related functions

Functions of this type provide the environment information about sessions or tenants.

Function category	Function subcategory	Function name	Description
Single-row function	Environment-related function	SYS_CONTEXT	ApsaraDB for OceanBase does not support this function.
Single-row function	Environment-related function	UID	ApsaraDB for OceanBase does not support this function.

Function category	Function subcategory	Function name	Description
Single-row function	Environment-related function	USER	ApsaraDB for OceanBase does not support this function.

Aggregate functions

Function category	Function subcategory	Function name	Description
Statistical function	Aggregate function	AVG	Returns the average value of all values in a numeric column.
Statistical function	Aggregate function	COUNT	Queries the number of rows for the `expr` parameter.
Statistical function	Aggregate function	SUM	Returns the sum of all values in a specified column.
Statistical function	Aggregate function	GROUPING	ApsaraDB for OceanBase does not support this function.
Statistical function	Aggregate function	MAX	Returns the maximum value of a specified column.
Statistical function	Aggregate function	MIN	Returns the minimum value of a specified column.
Statistical function	Aggregate function	LISTAGG	Converts a column to a row. The `LISTAGG` function sorts the data within each group that is specified in the `ORDER BY` clause and merges the values in the measure column.

Function category	Function subcategory	Function name	Description
Statistical function	Aggregate function	ROLLUP	Returns a subtotal for each group and a grand total for all groups during data statistical analysis and report generation.
Statistical function	Aggregate function	STDDEV	Calculates the population standard deviation.
Statistical function	Aggregate function	STDDEV_POP	Calculates the population standard deviation.
Statistical function	Aggregate function	STDDEV_SAMP	Calculates the sample standard deviation.
Statistical function	Aggregate function	VARIANCE	Returns the variance of a specified column.
Statistical function	Aggregate function	APPROX_COUNT_DISTINCT	Calculates the number of rows in a column where duplicates are removed, and can return only an approximate value. You can use this function to further calculate the selectivity of the referenced column.

Analytic functions

Function category	Function subcategory	Function name	Description
Statistical function	Analytic function	AVG	Returns the average value of all values in a numeric column.
Statistical function	Analytic function	COUNT	Queries the number of rows for the `expr` parameter.

Function category	Function subcategory	Function name	Description
Statistical function	Analytic function	CUME_DIST	Calculates the cumulative distribution of a value in a group of values.
Statistical function	Analytic function	DENSE_RANK	Calculates the rank of a row in an ordered group of rows and returns the rank as `NUMBER`.
Statistical function	Analytic function	MAX	Returns the maximum value of a specified column.
Statistical function	Analytic function	MIN	Returns the minimum value of a specified column.
Statistical function	Analytic function	SUM	Returns the sum of all values in a specified column.
Statistical function	Analytic function	FIRST_VALUE	Returns the first value in a set of ordered values.
Statistical function	Analytic function	LAG	Provides access to a multi-row table without a self join.
Statistical function	Analytic function	LAST_VALUE	Returns the last value in a set of ordered values.
Statistical function	Analytic function	LEAD	Provides access to multiple rows of a table without a self join. Given a set of rows returned from a query and the position of the cursor, `LEAD` provides access to a row at a given physical offset beyond that position.
Statistical function	Analytic function	LISTAGG	Converts a column to a row.

Function category	Function subcategory	Function name	Description
Statistical function	Analytic function	NTH_VALUE	Returns the value of `measure_expr` in the `n` th row of the window defined by `analytic_clause`.
Statistical function	Analytic function	NTILE	Divides an ordered dataset into several buckets and assigns an appropriate bucket number to each row. `expr` specifies the number of buckets.
Statistical function	Analytic function	PERCENT_RANK	This function is similar to the `CUME_DIST` function that calculates the cumulative distribution. The return value ranges from 0 to 1. The `PERCENT_RANK` function of the first row in a set is 0. The return value is NUMBER.
Statistical function	Analytic function	SUM	Returns the sum of all values in a specified column.
Statistical function	Analytic function	RANK	Determines the rank of a group of values based on the `ORDER BY` expression in the `OVER` clause.
Statistical function	Analytic function	RATIO_TO_REPORT	Calculates the ratio of a value to the sum of a group of values.
Statistical function	Analytic function	ROW_NUMBER	Assigns a unique number to each row to which the function is applied.

Function category	Function subcategory	Function name	Description
Statistical function	Analytic function	STDDEV	Calculates the population standard deviation.
Statistical function	Analytic function	STDDEV_POP	Calculates the population standard deviation.
Statistical function	Analytic function	STDDEV_SAMP	Calculates the sample standard deviation.
Statistical function	Analytic function	VARIANCE	Returns the variance of a specified column.

More information

For more information about the `OVER` keyword of analytic functions, see Window function description.

17.1.5.6.2. Single-row functions

17.1.5.6.2.1. Numeric functions

ABS

The `ABS` function is a mathematical function that returns the absolute value of the specified numeric expression. The absolute value is a positive value. `ABS` changes negative values to positive values and does not affect zero or positive values.

Syntax

```
ABS (numeric_expression)
```

Parameters

Parameter	Description
numeric_expression	The expression of the exact numeric data types or the approximate numeric data types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`.

Return type

The return type is the same as the data type of `numeric_expression`.

Examples

This example shows the results of using the `ABS` function for three different numbers.

Execute the following statement:

```
SELECT ABS(-1.0), ABS(0.0), ABS(1.0), ABS(1.666) FROM DUAL;
```

The following query result is returned:

```
+-----------+----------+----------+------------+
| ABS(-1.0) | ABS(0.0) | ABS(1.0) | ABS(1.666) |
+-----------+----------+----------+------------+
|         1 |        0 |        1 |      1.666 |
+-----------+----------+----------+------------+
```

ACOS

The `ACOS` function returns an angle that is expressed in radians. The cosine of the angle is a specified `NUMBER` expression. It is also called the arc cosine.

Syntax

```
ACOS (num_expression)
```

Parameters

Parameter	Value	Description
num_expression	-1.00~1.00	The expression of the `NUMBER` type or the types that can be implicitly converted to the `NUMBER` type. Only the values from -1.00 to 1.00 are valid. For values beyond this range, the function returns `NULL` and reports an error.

Return type

`NUMBER` data type

Examples

This example returns the value of `ACOS` for the specified number.

Execute the following statement:

```
SELECT ACOS(0.3)"acos_test" FROM DUAL;
```

The following query result is returned:

```
+-----------+
| acos_test |
+-----------+
|1.26610367 |
+-----------+
```

BITAND

The operator performs a bitwise AND operation. The input and output types are the `NUMBER` data type.

Syntax

```
BITAND (nExpression1, nExpression2)
```

Parameters

Parameter	Description
nExpression1, nExpression2	Specifies two numeric values for the bitwise `AND` operation. If `nExpression1` and `nExpression2` are not the integer type, they are converted to integers before the bitwise `AND` operation is performed.

Return type

`NUMBER` data type

Examples

a is 0100 in binary.

b is 0110 in binary.

Compare the binary numbers. If the digits in corresponding positions are all 1, the value of this bit is 1. Otherwise, the value is 0. Therefore, the result is BITAND(2 , 3) = 0100 = 2.

Execute the following statement:

```
SELECT BITAND(2,3) FROM DUAL;
```

The following query result is returned:

```
+-------------+
| BITAND(2,3) |
+-------------+
|           2 |
+-------------+
```

CEIL

The `CEIL` function returns the smallest integer that is greater than or equal to the numeric value of `numeric_expression` .

Syntax

```
CEIL (numeric_expression)
```

Parameters

Parameter	Description
numeric_expression	The expression of the exact numeric data types or the approximate numeric data types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`.

Return type

The return type is the same as the data type of the `numeric_expression` parameter.

Examples

This example shows the result of using the `CEIL` function for three different numbers.

Execute the following statement:

```
SELECT CEIL(1.2), CEIL(2), CEIL(-12.1) FROM DUAL;
```

The following query result is returned:

```
+-----------+---------+-------------+
| CEIL(1.2) | CEIL(2) | CEIL(-12.1) |
+-----------+---------+-------------+
|         2 |       2 |         -12 |
+-----------+---------+-------------+
```

EXP

The `EXP` function returns e that is raised to the power of `numeric_expression`. e is a mathematical constant and is equal to 2.71828183....

Syntax

```
EXP (numeric_expression)
```

Parameters

Parameter	Description
numeric_expression	The expression of the exact numeric data types or the approximate numeric data types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`.

Return type

The return type is the same as the data type of the `numeric_expression` parameter.

Examples

This example shows the result of querying e that is raised to the power of 4.

Execute the following statement:

```
SELECT EXP(4) "e to the 4th power" FROM DUAL;
```

The following query result is returned:

```
+-------------------------------------------+
| e to the 4th power                        |
+-------------------------------------------+
| 54.59815003314423907811026120286087840279 |
+-------------------------------------------+
```

FLOOR

The `FLOOR` function returns the largest integer that is less than or equal to the numeric value of `numeric_expression` .

Syntax

```
FLOOR (numeric_expression)
```

Parameters

Parameter	Description
numeric_expression	The expression of the exact numeric data types or the approximate numeric data types: `NUMBER` , `FLOAT` , `BINARY_FLOAT` , and `BINARY_DOUBLE` .

Return type

The return type is the same as the data type of the `numeric_expression` parameter.

Examples

This example shows the results of using the `FLOOR` function for three different numbers.

Execute the following statement:

```
SELECT FLOOR(1.2), FLOOR(2), FLOOR(-12.1) FROM DUAL;
```

The following query result is returned:

```
+------------+----------+--------------+
| FLOOR(1.2) | FLOOR(2) | FLOOR(-12.1) |
+------------+----------+--------------+
|          1 |        2 |          -13 |
+------------+----------+--------------+
```

LN

The `LN` function returns the logarithm of `numeric_expression` to the base of e. e is a mathematical constant and is equal to 2.71828183....

Syntax

```
LN (numeric_expression)
```

Parameters

Parameter	Description
numeric_expression	The expression of the exact numeric data types or the approximate numeric data types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`.

Return type

When the data type of the parameter is `BINARY_FLOAT`, the return type is `BINARY_DOUBLE`. In other cases, the return type is the same as the data type of the `numeric_expression` parameter.

Examples

This example shows the result of calculating the logarithm of 4 to the base of e.

Execute the following statement:

```
SELECT LN(4) "Natural log of 4" FROM DUAL;
```

The following query result is returned:

```
+-----------------------------------------+
| Natural log of 4                        |
+-----------------------------------------+
| 1.3862943611198906188344642429163531361 5 |
+-----------------------------------------+
```

LOG

The `LOG` function returns the logarithm of `y` to the base of `x`.

Syntax

```
LOG (x,y)
```

Parameters

Parameter	Description
x,y	The expression of the numeric types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`. `x` and `y` must be greater than 0.

Return type

If the data types of the parameters are `BINARY_FLOAT` and `BINARY_DOUBLE`, the return type is `BINARY_DOUBLE`. In other cases, the return type is `NUMBER`.

Examples

This example shows the logarithm of 8 to the base of 2.

```
SELECT LOG(2,8) FROM DUAL;
```

The following query result is returned:

```
+-----------+
| LOG(2,8) |
+-----------+
|         3 |
+-----------+
```

MOD

The `MOD` function returns the remainder of `x` that is divided by `y`.

> **Notice**
>
> When the `REMAINDER (x,y)` and `MOD (x,y)` functions perform operations, the same formula result=x-y*(x/y) is used. The difference between MOD (x,y) and REMAINDER (x,y) is that the processing methods are different when x/y is calculated. `ROUND(x/y)` is used in the `REMAINDER (x,y)` function, whereas `FLOOR(x/y)` is used in the `MOD (x,y)` function.

Syntax

```
MOD (x,y)
```

Parameters

Parameter	Description
x,y	`x` and `y` are the expressions of the numeric types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`.

Return type

The return type is the same as the data type of the parameter that has higher numeric precedence.

Examples

This example shows the result of calculating the remainder of 23/8 and 24/8.

Execute the following statement:

```
SELECT MOD(23,8), MOD(24,8) FROM DUAL;
```

The following query result is returned:

```
+-----------+-----------+
| MOD(23,8) | MOD(24,8) |
+-----------+-----------+
|         7 |         0 |
+-----------+-----------+
```

POWER

The `POWER` function returns `x` that is raised to the `y` power.

Syntax

```
POWER (x, y)
```

Parameters

Parameter	Description
x,y	`x` and `y` are the expressions of the numeric types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`.

Return type

If the data types of the parameters are `BINARY_FLOAT` and `BINARY_DOUBLE`, the return type is `BINARY_DOUBLE`. In other cases, the return type is `NUMBER`.

Examples

This example shows the results of using the `POWER` function for three different groups of numbers.

Execute the following statement:

```
SELECT POWER(2,2), POWER(1.5,0), POWER(20, -1) FROM DUAL;
```

The following query result is returned:

```
+------------+--------------+--------------+
| POWER(2,2) | POWER(1.5,0) | POWER(20,-1) |
+------------+--------------+--------------+
|          4 |            1 |          .05 |
+------------+--------------+--------------+
```

REMAINDER

The `REMAINDER` function returns the remainder of `x` that is divided by `y`.

> **Notice**
>
> Difference between the REMAINDER function and the MOD function:
>
> When the `REMAINDER (x,y)` and `MOD (x,y)` functions perform operations, the same formula result=x-y*(x/y) is used. The difference is that the processing methods are different when x/y is calculated. `ROUND(x/y)` is used in the `REMAINDER (x,y)` function, whereas `FLOOR(x/y)` is used in the `MOD (x,y)` function. Assume that the decimal part of the value of the x/y parameter in `ROUND(x/y)` is 0.5 in the `REMAINDER` function. If the integer part of the value of x/y is an even number, the value is rounded down to the nearest integer. If the integer part of the value of x/y is an odd number, the value is rounded up the nearest integer. For example, `ROUND(1.5)` is equal to 2, `ROUND(2.5)` is equal to 2, `ROUND(3.5)` is equal to 4, and `ROUND(4.5)` is equal to 4.

Syntax

```
REMAINDER (x, y)
```

Parameter

Parameter	Description
x,y	`x` and `y` are the expressions of the numeric types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`.

Return type

The return type is the same as the data type of the parameter that has higher numeric precedence.

Examples

This example shows the results of using the `MOD` and `REMAINDER` functions to calculate the remainder of 1.5/1. Take note of the difference between the two functions.

Execute the following statement:

```
SELECT MOD(1.5,1), REMAINDER(1.5,1) FROM DUAL;
```

The following query result is returned:

```
+------------+------------------+
| MOD(1.5,1) | REMAINDER(1.5,1) |
+------------+------------------+
|      0.5   |      -0.5        |
+------------+------------------+
```

ROUND

The `ROUND` function returns the rounded value of the `numeric` parameter.

Syntax

```
ROUND (numeric[,decimal])
```

Parameters

Parameter	Description
numeric	The expression of the numeric types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`.
decimal	If `decimal` is greater than or equal to 0, `numeric` is rounded to the number of decimal places specified by `decimal`. If `decimal` is less than 0, the numeric value is rounded to the specified number of digits to the left of the decimal point. The number of digits is specified by `decimal`. If `decimal` is not an integer, the integer part of `decimal` is truncated. If you do not specify `decimal`, `numeric` is rounded to the integer.

Return type

If you do not specify `decimal`, the return type is the same as the data type of the `numeric` parameter. If you specify `decimal`, the return type is the `NUMBER` data type.

Examples

This example shows the results of rounding 5555.6666 under different values of `decimal`.

Execute the following statement:

```
SELECT ROUND(5555.6666, 2.1), ROUND(5555.6666, -2.6), ROUND(5555.6666) FROM DUAL;
```

The following query result is returned:

```
+----------------------+-----------------------+------------------+
| ROUND(5555.6666,2.1) | ROUND(5555.6666,-2.6) | ROUND(5555.6666) |
+----------------------+-----------------------+------------------+
|              5555.67 |                  5600 |             5556 |
+----------------------+-----------------------+------------------+
```

SIGN

The `SIGN` function returns the sign of the number `n`. If n is greater than 0, 1 is returned. If n is smaller than 0, -1 is returned. If n is equal to 0, 0 is returned.

Syntax

```
SIGN (n)
```

Parameters

Parameter	Description
n	The expression of the exact numeric data types or the approximate numeric data types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`.

Return type

The numeric values 0, 1, and -1 are returned.

Examples

This example shows the results of using the `SIGN` function for three different numbers.

Execute the following statement:

```
SELECT SIGN(100), SIGN(-100), SIGN(0) FROM DUAL;
```

The following query result is returned:

```
+-----------+------------+---------+
| SIGN(100) | SIGN(-100) | SIGN(0) |
+-----------+------------+---------+
|         1 |         -1 |       0 |
+-----------+------------+---------+
```

SQRT

The `SQRT` function returns the square root of `n`.

Syntax

```
SQRT (n)
```

Parameters

Parameter	Description
n	The expression of the numeric types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`. `n` cannot be a negative number.

Return type

The return type is the same as the data type of the `n` parameter.

Examples

This example shows the results of using the `SQRT` function to calculate the square roots of two different numbers.

Execute the following statement:

```
SELECT SQRT(64), SQRT(10) FROM DUAL;
```

The following query result is returned:

```
+----------+-----------------------------------------+
| SQRT(64) | SQRT(10)                                |
+----------+-----------------------------------------+
|        8 | 3.16227766016837933199889354443271853372 |
+----------+-----------------------------------------+
```

TRUNC

The `TRUNC` function returns the `numeric` value that is truncated based on `precision`.

Syntax

```
TRUNC (numberic[,precision])
```

Parameters

Parameter	Description
numeric,precision	The expression of the numeric types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`. If `precision` is not an integer, `precision` is truncated to its integer part. If `precision` is greater than or equal to 0, `numeric` is truncated to the number of decimal places specified by `precision`. If `precision` is less than 0, `numeric` is truncated to `precision` digits to the left of the decimal point, and other data before the decimal point is represented by zero. The default value of `precision` is 0.

Return type

If `precision` is not specified, the return type is the same as the data type of the `numeric` parameter. If `precision` is specified, the return type is `NUMBER`.

Examples

This example shows the results of calculating 5555.66666 under different values of `precision`.

Execute the following statement:

```
SELECT TRUNC(5555.66666, 2.1), TRUNC(5555.66666, -2.6), TRUNC(5555.66666) FROM DUAL;
```

The following query result is returned:

```
+----------------------+-----------------------+--------------------+
| TRUNC(5555.66666,2.1) | TRUNC(5555.66666,-2.6) | TRUNC(5555.033333) |
+----------------------+-----------------------+--------------------+
|               5555.66 |                  5500 |               5555 |
+----------------------+-----------------------+--------------------+
```

17.1.5.6.2.2. String functions that return strings

CHR

The `CHR` function converts `n` to one or more equivalent characters. The return value is relevant to the character sets of the current system.

Syntax

```
CHR ( n )
```

Parameters

Parameter	Value range
n	0~4294967295

Return type

The return value is relevant to the character sets of the current system. The character sets that ApsaraDB for OceanBase supports are `UTF-8`, `UTF-16`, `GBK`, and `GB18030`.

Examples

Decimal (25700) > Hexadecimal (0x6464) > `UTF-8` encoding (dd)

Execute the following statement:

```
SELECT CHR(25700) AS str FROM DUAL;
```

The following query result is returned:

```
+------+
| STR  |
+------+
| dd   |
+------+
```

Decimal (50318) > Hexadecimal (0xC48E) > `UTF-8` encoding (Ď)

Execute the following statement:

```
SELECT CHR(50318) AS str FROM DUAL;
```

The following query result is returned:

```
+------+
| STR  |
+------+
| Ď    |
+------+
```

Decimal > `UTF-8` encoding

```
SELECT CHR(67)||CHR(65)||CHR(84) "Dog" FROM DUAL;
```

The following query result is returned:

```
+------+
| Dog  |
+------+
| CAT  |
+------+
```

CONCAT

The `CONCAT` function can concatenate two strings.

Syntax

```
CONCAT(c1,c2)
```

Parameters

Parameter	Description
c1	The string. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.
c1	The string. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.

Return type

The return type is the same as the data type of `c1`.

Examples

In this example, the `CONCAT` function is used to concatenate the `'010-'` character and the `'88888888'` character.

Execute the following statement:

```
SELECT concat('010-','88888888')||'to 23'XXXX phone FROM DUAL;
```

The following query result is returned:

```
+-------------------+
| XXXX phone        |
+-------------------+
| 010-88888888 to 23  |
+-------------------+
```

INITCAP

The `INITCAP` function returns a string where the initial letter of each word is in uppercase and the other letters are in lowercase.

Syntax

```
INITCAP(c1)
```

Parameters

Parameter	Description
c1	The string. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2`.

Return type

The data of the `CHAR` type is returned.

Examples

Execute the following statement:

```
SELECT initcap('smith abc aBC') upp FROM DUAL;
```

The following query result is returned:

```
+------------------+
|   UPP            |
+------------------+
|   Smith Abc Abc  |
+------------------+
```

LOWER

The `LOWER` function converts a string to lowercase.

Syntax

```
LOWER(c1)
```

Parameters

Parameter	Description
c1	The string. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.

Return type

The return type is the same as the data type of `c1`.

Examples

Execute the following statement:

```
SELECT  lower('AaBbCcDd')AaBbCcDd FROM DUAL;
```

The following query result is returned:

```
+-----------+
| AABBCCDD |
+-----------+
| aabbccdd |
+-----------+
```

LPAD

The `LPAD` function left-pads the `c1` string with the `c2` string until the length reaches `n`.

Syntax

```
LPAD(c1,n[,c2])
```

Parameters

Parameter	Description
c1	The string. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.
n	The total length of characters after the string is padded. The type must be the `NUMBER` integer type or the type that can be implicitly converted to the `NUMBER` integer type.
c2	The padding string. The default value is a space. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.

Return type

If `c1` is the data of the character type, the return type is `VARCHAR2`. If `c1` is of the national character data type, the return type is `NVARCHAR2`. If the data type of `c1` is `CLOB`, the return type is `CLOB`.

> **Notice**
>
> If the length of `c1` is greater than `n`, the function returns the leftmost `n` characters of `c1`. If the length of `c1` is less than `n` and the length of `c1` that is left-padded with `c2` is greater than `n`, the function returns the rightmost `n` characters of c1 that is left-padded with c2.

Examples

Execute the following statement:

```
SELECT  lpad('gao',10,'*') FROM DUAL;
```

The following query result is returned:

```
+--------------------+
| LPAD('GAO',10,'*') |
+--------------------+
| *******gao         |
+--------------------+
```

LTRIM

The `LTRIM` function removes the string that appears on the left.

Syntax

```
LTRIM(c1 [,c2])
```

The `LTRIM` function removes all the `c2` characters that are included in `c1` from the left end. If you do not specify `c2`, the default value is a single space.

Parameters

Parameter	Description
c1	The string. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.
c2	The string to be removed. The default value is a space. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.

Return type

If the data type of `c1` is `CHAR` or `VARCHAR2`, the function returns the `VARCHAR2` data type. If the data type of `c1` is `NCHAR` or `NVARCHAR2`, the function returns the `NVARCHAR2` data type. If the data type of `c1` is `CLOB`, the data type of the returned string is `CLOB`.

Examples

Execute the following statement:

```
SELECT LTRIM('   gao qian jing',' ') text FROM DUAL;
```

The following query result is returned:

```
+------------------+
|   TEXT           |
+------------------+
|   gao qian jing  |
+------------------+
```

REGEXP_REPLACE

The `REGEXP_REPLACE` function replaces regular expressions.

Syntax

```
REGEXP_REPLACE (source_char, pattern [,replace_string [, position [, occurrence [, match_param ]  ]
]  ])
```

Parameters

Parameter	Description
source_char	The character expression that is used as a search value. It is generally a character column and its data type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.
pattern	The regular expression. It is generally a text literal and its data type can be `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2`.
replace_string	The replacement character. The type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.
position	The positive integer type. It indicates the ordinal number of the character from which ApsaraDB for OceanBase starts to search the character of `source_char`. The default value is 1 and indicates that ApsaraDB for OceanBase starts to search `source_char` from the first character.

Parameter	Description
occurrence	The non-negative integer. It indicates that the replacement operation occurs. If you specify this parameter as 0, ApsaraDB for OceanBase replaces all the matching items. If you specify this parameter as a positive integer n, ApsaraDB for OceanBase replaces the matching items that occur for the nth time. By default, all the matching items are replaced. If you specify this parameter as 0, all the matching items are also replaced.
match_param	The character expression of the `VARCHAR2` or `CHAR` data type. It allows you to change the default matching behavior of the function. `i` indicates that the match is not case-sensitive. `c` indicates that the match is case-sensitive. `n` represents periods (.). The period (`.`) indicates that line feeds are not matched. `m` indicates the multi-line mode. `x` indicates that space characters are ignored. By default, space characters match with each other.

Return type

The returned result has the same data type as `source_char` .

Examples

The following example checks the string to search for two or more spaces. ApsaraDB for OceanBase replaces each occurrence of two or more spaces with one space. Execute the following statement:

```
SELECT REGEXP_REPLACE('500   OceanBase     Parkway,    Redwood  Shores, CA', '( ){2,}', ' ') "REGEXP_
REPLACE"
FROM DUAL;
```

The following query result is returned:

```
REGEXP_REPLACE
--------------------------------------
500 OceanBase Parkway, Redwood Shores, CA
```

REPLACE

The `REPLACE` function replaces some identical strings in the value of a character expression with new strings.

Syntax

```
REPLACE(c1,c2[,c3])
```

Parameters

Parameter	Description
c1	The CHAR string to be replaced.
c2	The string to be searched for and replaced.
c3	The replacement string. By default, this parameter is empty. This indicates the deletion instead of using spaces.

The data types of c1, c2, and c3 can be CHAR, VARCHAR2, NCHAR, NVARCHAR2, and CLOB.

Return type

The character set of the returned string is the same as that of c1. If c3 is the default or NULL, all the occurrences of c2 in c1 are removed. If c2 is NULL, the result is c1. If the data type of c1 is CLOB, the function returns the CLOB data type. If the data type of c1 is not CLOB, the function returns the VARCHA2 data type.

Examples

Execute the following statement:

```
SELECT replace('he love you','he','i') test FROM DUAL;
```

The following query result is returned:

```
+------------+
| TEST       |
+------------+
| i love you |
+------------+
```

RPAD

The RPAD function right-pads the c1 string with the c2 string until the length reaches n.

Syntax

```
RPAD(c1,n[,c2])
```

Parameters

Parameter	Description

Parameter	Description
c1	The string. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.
n	The total length of characters after the string is padded. The type must be the `NUMBER` integer type or the type that can be implicitly converted to the `NUMBER` integer type.
c2	The padding string. The default value is a space. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.

Return type

If `c1` is the data of the character type, the return type is `VARCHAR2`. If `c1` is of the national character data type, the return type is `NVARCHAR2`. If the data type of `c1` is `CLOB`, the return type is `CLOB`.

> **Note**
>
> - If the length of `c1` is greater than `n`, the function returns the leftmost `n` characters of `c1`.
> - If the length of `c1` is less than `n` and the length of `c1` that is right-padded with `c2` is greater than `n`, the function returns the leftmost `n` characters of c1 that is right-padded with c2.
> - If the length of `c1` is less than n and the length of the `c1` that is right-padded with `c2` is also less than `n`, the function returns the leftmost `n` characters of `c1` that is right-padded with multiple replicated `c2` (the total length of c1 after padding is greater than or equal to `n`).

Examples

Execute the following statement:

```
SELECT rpad('gao',10,'*a') FROM DUAL;
```

The following query result is returned:

```
+----------------------+
| RPAD('GAO',10,'*A') |
+----------------------+
| gao*a*a*a*           |
+----------------------+
```

RTRIM

The `RTRIM` function deletes a string that appears on the right side. This function is useful for formatting the output of a query.

Syntax

```
RTRIM(c1 [,c2])
```

`RTRIM` deletes `c2` from the right end of all the characters that appear in `c1`. If you do not specify `c2`, the default value is a single space.

Parameters

Parameter	Description
c1	The string.
c2	The string to be deleted. The default value is a space.

The data types of `c1` and `c2` can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, and `CLOB`.

Return type

If the data type of `c1` is `CHAR` or `VARCHAR2`, the function returns the `VARCHAR2` data type.

If the data type of `c1` is `NCHAR` or `NVARCHAR2`, the function returns the `NVARCHAR2` data type.

If the data type of `c1` is `CLOB`, the data type of the returned string is `CLOB`.

Examples

Execute the following statement:

```
SELECT RTRIM('gao qian jingXXXX','X') text FROM DUAL;
```

The following query result is returned:

```
+------------------+
|   TEXT           |
+------------------+
|   gao qian jing  |
+------------------+
```

SUBSTR

The `SUBSTR` function extracts a substring. A multibyte character, such as a Chinese character and a full-width character, is calculated as one character.

Syntax

```
SUBSTR(c1,n1[,n2])
```

Parameters

Parameter	Description
c1	The string to be truncated. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.
n1	The start position for truncating the string. If n1 is equal to 0 or 1, the string is truncated from the first character.
n2	The length of the truncated string. If you do not specify `n2`, the truncated string starts from the `n1` th character to the end.

Return type

The data that has the same type as `c1` is returned. If `n2` is 0, it is considered as 1. If `n2` is positive, ApsaraDB for OceanBase searches for the first character from the beginning of `c1`. If `n2` is negative, ApsaraDB for OceanBase counts backward `c1` from the end of `c1`. If `n3` is omitted, ApsaraDB for OceanBase returns all the characters of `c1`. If `n3` is less than 1, ApsaraDB for OceanBase returns `NULL`.

Examples

Execute the following statement:

```
SELECT SUBSTR('13088888888',3,8) test FROM DUAL;
```

The following query result is returned:

```
+----------+
| TEST     |
+----------+
| 08888888 |
+----------+
```

TRANSLATE

The `TRANSLATE` function replaces specified characters in the value of a character expression with new characters. A multibyte character, such as a Chinese character and a full-width character, is calculated as one character.

Syntax

```
TRANSLATE(c1,c2,c3)
```

Parameters

Parameter	Description
c1	The character or the variable that you want to replace.
c2	The original character set to be queried.
c3	The new character set for replacement. Characters in a sequence in `c2` are replaced with characters in the corresponding sequence in `c3`.

Note

- The data types of `c1`, `c2`, and `c3` can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.
- If the length of `c3` is greater than that of `c2`, the extra characters in `c3` are invalid.
- If the length of `c3` is less than that of `c2`, extra characters in `c2` are replaced with null. This indicates that extra characters are deleted.
- If the length of `c3` is 0, an empty string is returned.
- If `c2` contains duplicate characters, the character in the position of the first occurrence is replaced.

Return type

The characters of the `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB` type are returned.

Examples

Execute the following statement:

```
SELECT TRANSLATE('he love you','he','i') FROM DUAL;
```

The following query result is returned:

```
+------------------+
|   TRANSLATE      |
+------------------+
|   i love you     |
+------------------+
```

TRIM

The `TRIM` function deletes leading or trailing characters (or both) from a string.

Syntax

```
TRIM([ { { LEADING | TRAILING | BOTH } [ trim_character ] | trim_character } FROM ] trim_source)
```

Parameters

Parameter	Description
LEADING	The leading characters.
TRAILING	The trailing characters.
BOTH	The leading and trailing characters.
trim_character	The characters to be deleted.
trim_source	The trim source.

The data type of `trim_char` and `trim_source` can be `VARCHAR2` or data types that can be implicitly converted to `VARCHAR2`. If you specify `LEADING`, ApsaraDB for OceanBase deletes all the leading characters that are equal to `trim_character`. If you specify `TRAILING`, ApsaraDB for OceanBase deletes all the trailing characters that are equal to `trim_character`. If you specify `BOTH` or none of the three parameters, ApsaraDB for OceanBase deletes the leading and trailing characters that are equal to `trim_character`. If you do not specify `trim_character`, the default value is a blank space. If you specify only `trim_source`, ApsaraDB for OceanBase deletes the leading and trailing spaces. If the value that is returned by the function is of the `VARCHAR2` data type, the maximum length of the value is `trim_source`.

Return type

If the data type of `trim_source` is `CHAR` or `VARCHAR2`, the function returns the `VARCHAR2` data type.

If the data type of `trim_source` is `NCHAR` or `NVARCHAR2`, the function returns the `NVARCHAR2` data type.

If the data type of `trim_source` is `CLOB`, the function returns the `CLOB` data type.

If `trim_source` or `trim_character` is `NULL`, the `TRIM` function returns `NULL`.

Examples

Execute the following statement:

```
SELECT TRIM('X' from 'XXXgao qian jingXXXX'),TRIM('X' from 'XXXgaoXXjingXXXX') text FROM DUAL;
```

The following query result is returned:

```
+-----------------------------------+-----------+
| TRIM('X'FROM'XXXGAOQIANJINGXXXX') | TEXT      |
+-----------------------------------+-----------+
| gao qian jing                     | gaoXXjing |
+-----------------------------------+-----------+
```

UPPER

The `UPPER` function converts a string to uppercase.

Syntax

```
UPPER(c1)
```

Parameters

Parameter	Description
c1	The string. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.

Return type

The characters of the `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB` type are returned.

Examples

Execute the following statement:

```
SELECT UPPER('AaBbCcDd') upper FROM DUAL;
```

The following query result is returned:

```
+----------+
| UPPER    |
+----------+
| AABBCCDD |
+----------+
```

17.1.5.6.2.3. String functions that return numbers

ASCII

The `ASCII` function returns the ASCII code value of the leftmost character of a character expression.

Syntax

```
ASCII(x)
```

Parameters

Parameter	Description
x	The expression of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type.

Return type

`NUMBER` data type

Examples

In this example, the `ASCII` function returns the ASCII code values of **A**, **a**, **Medium**, and spaces.

```
SELECT ASCII('A') A, ASCII('a') a, ASCII(' ') space,ASCII('Medium') hz FROM DUAL;
```

The following result is returned:

```
+----+----+-------+-----+
| A  | a  | space |  hz |
+----+----+-------+-----+
| 65 | 97 |    32 | 228 |
+----+----+-------+-----+
```

INSTR

The `INSTR` function searches for a specified character in a string and returns the position of the specified character.

> **Notice**
> A multibyte character, such as a Chinese character and a full-width character, is calculated as one character.

Syntax

```
INSTR(c1,c2[,i[,j]])
```

Parameters

Parameter	Description
c1	The string to be searched. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.

Parameter	Description
c2	The string that you want to search for. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.
i	The position where the search starts. Default value: 1. If the value is less than 0, the search starts from the opposite direction, but the function returns the left-to-right position of the searched characters.
j	The position of the `j` th occurrence. Default value: 1.

Return type

`NUMBER` data type

Examples

In this example, the function needs to return the position of the second ce occurrence for **instring1** when the function searches forward for **ce**. The function needs to return the position of the second ce occurrence for **instring2** when the function searches backward for **ce**.

```
SELECT INSTR ('oceanbase pratice','ce',1,2) instring1,INSTR ('oceanbase pratice','ce',-1,2) instring2
FROM DUAL;
```

The result is returned. For the forward search, the second occurrence of **ce** lies in the sixteenth character. For the backward search, the second occurrence of **ce** lies in the second character.

```
+----------+------------+
| instring1 | instring2 |
+----------+------------+
|       16 |          2 |
+----------+------------+
```

LENGTH

The `LENGTH` function returns the length of a string.

> **Notice**
> A multibyte character, such as a Chinese character and a full-width character, is calculated as one character.

Syntax

```
LENGTH(c1)
```

Parameters

Parameter	Description
c1	The string of the `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB` data type.

Return type

`NUMBER` data type

Examples

This example shows the lengths of the strings: **Test**, **Haidian District of Beijing**, and **Beijing TO_CHAR**.

```
SELECT LENGTH ('Test'), LENGTH('Haidian District of Beijing'), LENGTH('Beijing TO_CHAR') FROM DUAL;
```

The following result is returned:

```
+------------------+------------------------------+-------------------------+
|    LENGTH('Test')|         LENGTH('Haidian District of Beijing') |   LENGTH('Bejing TO_CHAR') |
+------------------+------------------------------+-------------------------+
|                2 |                            6 |                       9 |
+------------------+------------------------------+-------------------------+
```

17.1.5.6.2.4. Datetime functions

ADD_MONTHS

The `ADD_MONTHS` function returns a date value that is `n` months after `date`. If `n` is a negative value, this function returns a date value that is `n` months before `date`.

> **Notice**
>
> Different months have different numbers of days. If `date` is the last day of a month, this function returns the last day of the resulting month. For example, if you use `ADD_MONTHS` to calculate the date one month before March 31, 2020, the function returns February 29, 2020.

Syntax

```
ADD_MONTHS (date,n)
```

Parameters

Parameter	Description
date	A value of the `DATE` data type.
n	A value of the `NUMBER` data type.

Return type

The return type is `DATE`.

Examples

Example 1: In the following example, the date that is three months after the system date is queried.

Execute the following statement:

```
SELECT SYSDATE, ADD_MONTHS(SYSDATE,3) FROM DUAL;
```

The following result is returned:

```
+---------------------+-----------------------+
| SYSDATE             | ADD_MONTHS(SYSDATE,3) |
+---------------------+-----------------------+
| 2020-03-26 12:21:40 | 2020-06-26 12:21:40   |
+---------------------+-----------------------+
```

Example 2: In the following example, the date that is three months before the system date is queried.

Execute the following statement:

```
SELECT SYSDATE, ADD_MONTHS(SYSDATE,-3) FROM DUAL;
```

The following result is returned:

```
+---------------------+-----------------------+
| SYSDATE             | ADD_MONTHS(SYSDATE,-3) |
+---------------------+-----------------------+
| 2020-03-26 12:21:04 | 2019-12-26 12:21:04    |
+---------------------+-----------------------+
```

CURRENT_DATE

The `CURRENT_DATE` function returns the current date in the session time zone.

Syntax

```
CURRENT_DATE
```

Parameters

No parameters are involved.

Return type

The return type is `DATE`.

Examples

In the following examples, the `CURRENT_DATE` function returns the current date in different session time zones.

Set the current time zone to the UTC-5 time zone:

```
ALTER SESSION SET TIME_ZONE = '-05:00';
```

Execute the following statement to call the function:

```
SELECT CURRENT_DATE FROM DUAL;
```

The following result is returned:

```
+---------------------+
| CURRENT_DATE        |
+---------------------+
| 2020-03-08 01:40:11 |
+---------------------+
```

Change the current time zone to the UTC+8 time zone:

```
ALTER SESSION SET TIME_ZONE = '+08:00';
```

Execute the following statement to call the function:

```
SELECT CURRENT_DATE FROM DUAL;
```

The following result is returned:

```
+---------------------+
| CURRENT_DATE        |
+---------------------+
| 2020-03-08 14:40:11 |
+---------------------+
```

CURRENT_TIMESTAMP

The `CURRENT_TIMESTAMP` function returns the current date in the time zone of the current session. The return value is of the `TIMESTAMP WITH TIME ZONE` data type and contains the information about the current time zone.

Syntax

```
CURRENT_TIMESTAMP (precision)
```

Parameters

Parameter	Description

precision	The precision of the fractional part of seconds. Default value: 6. Valid values: 0 to 9.

Return type

`TIMESTAMP WITH TIME ZONE` data type that includes the information about the current time zone in its value

Examples

In the following examples, the `CURRENT_TIMESTAMP` function returns different results for different time zones of sessions.

Set the current time zone to GMT-5:

```
ALTER SESSION SET TIME_ZONE = '-05:00';
```

Execute the following statement to call the function:

```
SELECT CURRENT_TIMESTAMP FROM DUAL;
```

The following query result is returned:

```
+-----------------------------------+
| CURRENT_TIMESTAMP                 |
+-----------------------------------+
| 2020-03-08 01:49:31.219066 -05:00  |
+-----------------------------------+
```

Change the current time zone to GMT+8 and change the precision of the fractional part of seconds to 3:

```
ALTER SESSION SET TIME_ZONE = '+08:00';
```

Execute the following statement to call the function:

```
SELECT CURRENT_TIMESTAMP(3) FROM DUAL;
```

The following query result is returned:

```
+---------------------------------+
| CURRENT_TIMESTAMP(3)            |
+---------------------------------+
| 2020-03-08 14:50:32.499 +08:00  |
+---------------------------------+
```

DBTIMEZONE

The `DBTIMEZONE` function returns the time zone of the current database instance. In ApsaraDB for OceanBase, the time zone is always +00:00 and cannot be changed.

Syntax

```
DBTIMEZONE
```

Parameters

None

Return type

`VARCHAR2` data type

Examples

Execute the following statement:

```
SELECT DBTIMEZONE FROM DUAL;
```

The following query result is returned:

```
+------------+
| DBTIMEZONE |
+------------+
| +00:00     |
+------------+
```

EXTRACT(datetime)

The `EXTRACT(datetime)` function extracts elements such as the year, month, day, hour, minute, and second values from a specified time field or expression.

Syntax

```
EXTRACT  (fields FROM datetime)
```

Parameters

Parameter	Description
fields	The name of the element to be extracted. Valid values: `YEAR`, `MONTH`, `DAY`, `HOUR`, `MINUTE`, `SECOND`, `TIMEZONE_HOUR`, `TIMEZONE_MINUTE`, `TIMEZONE_REGION`, and `TIMEZONE_ABBR`.
datetime	A value of the data types such as `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `TIMESTAMP WITH LOCAL TIME ZONE`, `INTERVAL YEAR TO MONTH`, and `INTERVAL DAY TO SECOND`.

Return type

When this function extracts the `TIMEZONE_REGION` and `TIMEZONE_ABBR` elements, the return type is `VARCHAR2`. When this function extracts other elements, the return type is `NUMBER`.

Examples

Execute the following statement:

```
SELECT EXTRACT(HOUR FROM TIMESTAMP '2001-2-16 2:38:40') Hour,
        EXTRACT(MINUTE FROM TIMESTAMP '2001-2-16 2:38:40 ') Minute,
            EXTRACT(SECOND FROM TIMESTAMP '2001-2-16 2:38:40 ') Second,
            EXTRACT(DAY FROM TIMESTAMP '2001-2-16 2:38:40 ') Day,
            EXTRACT(MONTH FROM TIMESTAMP '2001-2-16 2:38:40 ') Month,
            EXTRACT(YEAR FROM TIMESTAMP '2001-2-16 2:38:40 ') Year
FROM DUAL;
```

The following result is returned:

```
+--------+--------+------+------+------+------+
| Hour   | Minute   | Second   | Day   | Month   | Year   |
+--------+--------+------+------+------+------+
|      2 |     38 |   40 |   16 |    2 | 2001 |
+--------+--------+------+------+------+------+
```

FROM_TZ

The `FROM_TZ` function combines a `TIMSTAMP` value with the time zone information into a time value of the `TIMESTAMP WITH TIME ZONE` data type.

Syntax

```
FROM_TZ (timestamp_value,time_zone_value)
```

Parameters

Parameter	Description
timestamp_value	A time value of the `TIMSTAMP` data type.
time_zone_value	The time zone information.

Return type

`TIMESTAMP WITH TIME ZONE` data type

Examples

Execute the following statement:

```
SELECT FROM_TZ(TIMESTAMP '2020-03-28 08:00:00', '-03:00') FROM DUAL;
```

The following query result is returned:

```
+-----------------------------------------------+
| FROM_TZ(TIMESTAMP'2020-03-2808:00:00','-03:00') |
+-----------------------------------------------+
| 2020-03-28 08:00:00.000000000 -03:00          |
+-----------------------------------------------+
```

LAST_DAY

The `LAST_DAY` function returns the date of the last day of the month that contains `date`.

Syntax

```
LAST_DAY (date)
```

Parameters

Parameter	Description
date	A value of a data type that contains the date information, such as `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, and `TIMESTAMP WITH LOCAL TIME ZONE`.

Return type

`DATE` data type

Examples

In this example, the following information is queried: the current date, the last day of the current month, and the number of the remaining days in the current month.

Execute the following statement:

```
SELECT SYSDATE, LAST_DAY(SYSDATE)Last, LAST_DAY(SYSDATE)-SYSDATE "Left" FROM DUAL;
```

The following query result is returned:

```
+---------------------+---------------------+------+
| SYSDATE             | LAST                | Left |
+---------------------+---------------------+------+
| 2020-03-08 15:23:33 | 2020-03-31 15:23:33 |   23 |
+---------------------+---------------------+------+
```

LOCALTIMESTAMP

The `LOCALTIMESTAMP` function returns the current date in the time zone of the current session. The return type is `TIMESTAMP`. This function and the CURRENT_TIMESTAMP function return different data types. The `CURRENT_TIMESTAMP` function returns a value of the `TIMESTAMP WITH TIME ZONE` data type.

Syntax

```
LOCALTIMESTAMP (timestamp_precision)
```

Parameters

Parameter	Description
timestamp_precision	The precision of fractional seconds. The value ranges from 0 to 9, and the default value is 6.

Return type

`TIMESTAMP` data type

Examples

The following examples show the results that the `LOCALTIMESTAMP` function returns in different session time zones.

Set the current time zone to the UTC-5 time zone:

```
ALTER SESSION SET TIME_ZONE = '-05:00';
```

Execute the following statement to call the function:

```
SELECT LOCALTIMESTAMP FROM DUAL;
```

The following query result is returned:

```
+----------------------------+
| LOCALTIMESTAMP             |
+----------------------------+
| 2020-03-08 02:30:20.062104 |
+----------------------------+
```

Change the current time zone to the UTC+8 time zone and change the precision of fractional seconds to 3:

```
ALTER SESSION SET TIME_ZONE = '+08:00';
```

Execute the following statement to call the function:

```
SELECT LOCALTIMESTAMP(3) FROM DUAL;
```

The following query result is returned:

```
+-------------------------+
| LOCALTIMESTAMP(3)       |
+-------------------------+
| 2020-03-08 15:30:54.500 |
+-------------------------+
```

MONTHS_BETWEEN

The `MONTHS_BETWEEN` function returns the number of months between `date1` and `date2`.

Syntax

```
MONTHS_BETWEEN(date1,date2)
```

Parameters

Parameter	Description
date1	A value of the `DATE` data type.
date2	A value of the `DATE` data type.

Return type

The return type is `NUMBER`. If `date1` is greater than `date2`, this function returns a positive number. If `date1` is less than `date2`, this function returns a negative number.

Examples

The following statement queries the number of months between the current time and a specified time:

```
SELECT SYSDATE,
MONTHS_BETWEEN(SYSDATE,TO_DATE('2006-01-01','YYYY-MM-DD')),
MONTHS_BETWEEN(SYSDATE,TO_DATE('2022-01-01','YYYY-MM-DD'))
FROM DUAL;
```

The following result is returned:

```
+---------------------+-----------------------------------------------------------------+-----------------
-----------------------------------------+
| SYSDATE             | MONTHS_BETWEEN(SYSDATE,TO_DATE('2006-01-01','YYYY-MM-DD')) | MONTHS_BETWEEN(S
YSDATE,TO_DATE('2022-01-01','YYYY-MM-DD')) |
+---------------------+-----------------------------------------------------------------+-----------------
-----------------------------------------+
| 2020-03-08 15:38:35 |                   170.24683206391875746714456391875746714 5 |
-21.753167936081242532855436081242532855544 |
+---------------------+-----------------------------------------------------------------+-----------------
-----------------------------------------+
```

NEXT_DAY

The `NEXT_DAY` function returns the date value of the weekday `c1` in the week following the date `d1`.

Syntax

```
NEXT_DAY (d1[,c1])
```

Parameters

Parameter	Description
d1	A value of the `DATE` data type.
c1	A weekday value. Valid values: `MONDAY`, `TUESDAY`, `WEDNESDAY`, `THURSDAY`, `FRIDAY`, `SATURDAY`, and `SUNDAY`.

Return type

`DATE` data type

Examples

The following statements are used to query the date values that correspond to each weekday value in the next week:

```
SELECT SYSDATE Current date,
NEXT_DAY(SYSDATE,'MONDAY') Next Monday,
NEXT_DAY(SYSDATE,'TUESDAY') Next Tuesday,
NEXT_DAY(SYSDATE,'WEDNESDAY') Next Wednesday,
NEXT_DAY(SYSDATE,'THURSDAY') Next Thursday,
NEXT_DAY(SYSDATE,'FRIDAY') Next Friday,
NEXT_DAY(SYSDATE, 'Saturn ') Next Saturday,
NEXT_DAY(SYSDATE,'SUNDAY') Next Sunday
FROM DUAL;
```

The following query result is returned:

```
+---------------------+---------------------+---------------------+---------------------+-----------
---------+---------------------+---------------------+---------------------+
| Current date            | Next Monday           | Next Tuesday          | Next Wednesday          |
Next Thursday           | Next Friday          | Next Saturday           | Next Sunday          |
+---------------------+---------------------+---------------------+---------------------+-----------
---------+---------------------+---------------------+---------------------+
| 2020-03-08 15:47:57 | 2020-03-09 15:47:57 | 2020-03-10 15:47:57 | 2020-03-11 15:47:57 | 2020-03-12
15:47:57 | 2020-03-13 15:47:57 | 2020-03-14 15:47:57 | 2020-03-15 15:47:57 |
+---------------------+---------------------+---------------------+---------------------+-----------
---------+---------------------+---------------------+---------------------+
```

NUMTODSINTERVAL

The `NUMTODSINTERVAL` function converts the `n` parameter value to a value of the `INTERVAL DAY TO SECOND` data type. The `interval_unit` parameter specifies the unit of the result value.

Syntax

```
NUMTODSINTERVAL (n,interval_unit)
```

Parameters

Parameter	Description
n	The value of the `NUMBER` data type.
interval_unit	Valid values for the unit: `DAY`, `HOUR`, `MINUTE`, and `MINUTE`.

Return type

`INTERVAL DAY TO SECOND` data type

Examples

In the following example, the statement returns a datetime value and the value indicates the date and time that is 3 hours after the current date:

```
SELECT SYSDATE,SYSDATE+NUMTODSINTERVAL(3,'HOUR') AS RES FROM DUAL;
```

The following query result is returned:

```
+---------------------+---------------------+
| SYSDATE             | RES                 |
+---------------------+---------------------+
| 2020-03-08 16:01:40 | 2020-03-08 19:01:40 |
+---------------------+---------------------+
```

NUMTOYMINTERVAL

The `NUMTOYMINTERVAL` function converts the `n` parameter value to a value of the `INTERVAL YEAR TO MONTH` data type in the unit specified by `interval_unit`.

Syntax

```
NUMTOYMINTERVAL (n,interval_unit)
```

Parameters

Parameter	Description
n	A value of the `NUMBER` data type.
interval_unit	The unit. Valid values: `YEAR` and `MONTH`.

Return type

The return type is `INTERVAL YEAR TO MONTH`.

Examples

In the following example, a date and time value that is three years after the current date is returned:

```
SELECT SYSDATE,SYSDATE+NUMTOYMINTERVAL(3,'YEAR') AS RES FROM DUAL;
```

The following result is returned:

```
+---------------------+---------------------+
| SYSDATE             | RES                 |
+---------------------+---------------------+
| 2020-03-08 16:03:58 | 2023-03-08 16:03:58 |
+---------------------+---------------------+
```

ROUND (date)

The `ROUND(date)` function returns a date and time value that is nearest to the specified `date`. The `fmt` parameter specifies the unit in which the interval between the return value and the specified date is measured.

Syntax

```
ROUND(date,[fmt])
```

Parameters

Parameter	Description
date	A value of the following data types: `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, and `TIMESTAMP WITH LOCAL TIME ZONE`. The values of all these data types include date values.
fmt	The unit in which the interval between the return value and the specified `date` is measured. The following table lists the valid values of this parameter, which are not case-sensitive.

Values of the fmt parameter	Description
j	The date and time value that corresponds to the nearest 00:00:00 is returned. This is the default value.
day, dy, and d	The nearest Sunday of the specified date is returned.

Values of the fmt parameter	Description
month, mon, mm, and rm	The first date of the month nearest to the specified date is returned.
q	The first date of the quarter nearest to the specified date is returned.
syear, year, yyyy, yyy, yy, and y	The first date of the year nearest to the specified date. The number of the y letters determines the precision of the interval value.
cc and scc	The first date of the century nearest to the specified date.

Return type

The return type is `DATE`.

Examples

Execute the following statement:

```
SELECT SYSDATE Current date,
ROUND(SYSDATE) The date and time value of the nearest 00:00:00,
ROUND(SYSDATE,'DAY') The nearest Sunday,
ROUND(SYSDATE,'MONTH') The first date of the nearest month,
ROUND(SYSDATE,'Q') The first date of the nearest quarter,
ROUND(SYSDATE,'YEAR') The first date of the nearest year
FROM DUAL;
```

The following result is returned:

```
+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
| Current date            | The date and time value of the nearest 00:00:00        | The nearest Sunday          | The first date of the nearest month            | The first date of the nearest quarter | The first date of the nearest year        |
+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
| 2020-03-08 20:24:53 | 2020-03-09 00:00:00 | 2020-03-08 00:00:00 | 2020-03-01 00:00:00 | 2020-04-01 00:00:00 | 2020-01-01 00:00:00 |
+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
```

SESSIONTIMEZONE

The `SESSIONTIMEZONE` function returns the time zone of the current session.

Syntax

```
SESSIONTIMEZONE
```

Parameters

None

Return type

`VARCHAR2` data type

Examples

The following statement is used to query the database time zone and the time zone of the current session:

```
SELECT DBTIMEZONE,SESSIONTIMEZONE FROM DUAL;
```

The following query result is returned:

```
+------------+-----------------+
| DBTIMEZONE | SESSIONTIMEZONE |
+------------+-----------------+
| +00:00     | +08:00          |
+------------+-----------------+
```

You can change the time zone of the current session by using the `ALTER SESSION` statement, but you cannot change the database time zone.

```
ALTER SESSION SET TIME_ZONE = '+05:00';
```

Execute the following statement to query the time zone of the current session after the change:

```
SELECT DBTIMEZONE,SESSIONTIMEZONE FROM DUAL;
```

The following query result is returned:

```
+------------+-----------------+
| DBTIMEZONE | SESSIONTIMEZONE |
+------------+-----------------+
| +00:00     | +05:00          |
+------------+-----------------+
```

SYS_EXTRACT_UTC

The `SYS_EXTRACT_UTC` function returns the standard Coordinated Universal Time (UTC) time that corresponds to the specified time.

Syntax

```
SYS_EXTRACT_UTC (datetime_with_timezone)
```

> **Notice**
>
> UTC is short for Coordinated Universal Time. The UTC and Greenwich Mean Time (GMT) are the same as the local time in London, UK.

Parameters

Parameter	Description
datetime_with_timezone	The values of the `TIMESTAMP WITH TIME ZONE` and `TIMESTAMP WITH LOCAL TIME ZONE` data types.

Return type

`TIMESTAMP` data type

Examples

Execute the following statement:

```
SELECT SYS_EXTRACT_UTC(TIMESTAMP '2020-03-28 11:30:00.00 -08:00')
FROM DUAL;
```

The following query result is returned:

```
+-----------------------------------------------------------+
| SYS_EXTRACT_UTC(TIMESTAMP'2020-03-2811:30:00.00-08:00') |
+-----------------------------------------------------------+
| 2020-03-28 19:30:00.000000000                             |
+-----------------------------------------------------------+
```

SYSDATE

The `SYSDATE` function returns the current date and time.

> **Notice**
>
> This function is not dependent on the time zone of the current session but on the time zone of the Linux operating system that runs on the database host.

Syntax

```
SYSDATE
```

Parameters

None

Return type

`DATE` data type

Examples

In the following example, the current time is returned in the specified format:

```
SELECT TO_CHAR
(SYSDATE, 'MM-DD-YYYY HH24:MI:SS') "NOW"
FROM DUAL;
```

The following query result is returned:

```
+---------------------+
| NOW                 |
+---------------------+
| 03-08-2020 20:44:04 |
+---------------------+
```

SYSTIMESTAMP

The `SYSTIMESTAMP` function returns the current date of the system. The return value contains the information about the current time zone. The fractional part of seconds in the return value consists of six digits and the six digits specify the precision.

> **Notice**
>
> This function is not dependent on the time zone of the current session but on the time zone of the Linux operating system that runs on the database host.

Syntax

```
SYSTIMESTAMP
```

Parameter

None

Return type

`TIMESTAMP WITH TIME ZONE` data type

Examples

Execute the following statement:

```
SELECT SYSTIMESTAMP FROM DUAL;
```

The following query result is returned:

```
+-----------------------------------+
| SYSTIMESTAMP                      |
+-----------------------------------+
| 2020-03-08 20:47:08.254086 +08:00  |
+-----------------------------------+
```

TO_CHAR (datetime)

The `TO_CHAR` function converts a value of the data types such as `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `TIMESTAMP WITH LOCAL TIME ZONE`, `INTERVAL DAY TO SECOND`, and `INTERVAL YEAR TO MONTH` to a value of the `VARCHAR2` data type in the format specified by the `fmt` parameter. If you do not specify the `fmt` parameter, this function converts the `datetime` parameter value to a value of the `VARCHAR2` data type in the following format:

- The values of the `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, and `TIMESTAMP WITH LOCAL TIME ZONE` data types are converted to the default format of date and time values in the database. You can view the default format for values of each date and time data type in the "Data types" section.
- The values of the `INTERVAL DAY TO SECOND` and `INTERVAL YEAR TO MONTH` data types are converted to interval values in the numeric format.

Syntax

```
TO_CHAR({ datetime | interval } [, fmt [, 'nlsparam' ] ])
```

Parameters

Parameter	Description
datetime	A value of the data types such as `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `TIMESTAMP WITH LOCAL TIME ZONE`, `INTERVAL DAY TO SECOND`, and `INTERVAL YEAR TO MONTH`.
fmt	The output format.
nlsparam	The language in which the month and day values are returned.

Return type

The return type is `VARCHAR2`.

Examples

Example 1: The following statement uses the TO_CHAR function to return the current system date and convert the date and time value to a result in the **DS DL** format:

```
SELECT TO_CHAR(SYSDATE,'DS DL') FROM DUAL;
```

The following result is returned:

```
+-----------------------------------+
| TO_CHAR(SYSDATE,'DSDL')           |
+-----------------------------------+
| 03/08/2020 Sunday, March 08, 2020 |
+-----------------------------------+
```

Example 2: The following statement converts an interval value to a result in a specified format and sets the return language to **AMERICAN**:

```
SELECT TO_CHAR(interval'1' year, 'SS-MI-HH', 'nls_language = AMERICAN') FROM DUAL;
```

The following result is returned:

```
+------------------------------------------------------------+
| TO_CHAR(INTERVAL'1'YEAR,'SS-MI-HH','NLS_LANGUAGE=AMERICAN') |
+------------------------------------------------------------+
| +01-00                                                     |
+------------------------------------------------------------+
```

TO_DSINTERVAL

The `TO_DSINTERVAL` function converts a string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type to a value of the `INTERVAL DAY TO SECOND` data type. You can add and subtract a date and time value by using this function.

Syntax

```
TO_DSINTERVAL(days hours:minutes:seconds[.frac_secs])
```

Parameters

Parameter	Description
days hours:minutes:seconds[.frac_secs]	A string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type in the format specified by this parameter.

Return type

`INTERVAL DAY TO SECOND` data type

Examples

The following example returns the date and time value that is 100 days after the current time:

```
SELECT SYSDATE, SYSDATE+TO_DSINTERVAL('100 00:00:00') FROM DUAL;
```

The following query result is returned:

```
+---------------------+---------------------------------------+
| SYSDATE             | SYSDATE+TO_DSINTERVAL('10000:00:00') |
+---------------------+---------------------------------------+
| 2020-03-26 12:40:39 | 2020-07-04 12:40:39                   |
+---------------------+---------------------------------------+
```

TO_TIMESTAMP

The `TO_TIMESTAMP` function converts a string to a value of the `TIMESTAMP` data type.

Syntax

```
TO_TIMESTAMP(char,[fmt],['nlsparam'])
```

Parameters

	Description
char	A string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type.
fmt	The format of the return value.
nlsparam	The language that is used to return the month and day values.

Return type

`TIMESTAMP` data type

Examples

Execute the following statement:

```
SELECT TO_TIMESTAMP ('10-Sep-02 14:10:10.123000', 'DD-Mon-RR HH24:MI:SS.FF')
FROM DUAL;
```

The following query result is returned:

```
+---------------------------------------------------------------------+
| TO_TIMESTAMP('10-SEP-0214:10:10.123000','DD-MON-RRHH24:MI:SS.FF') |
+---------------------------------------------------------------------+
| 2002-09-10 14:10:10.123000000                                       |
+---------------------------------------------------------------------+
```

TO_TIMESTAMP_TZ

The `TO_TIMESTAMP_TZ` function converts a string to a value that is of the `TIMESTAMP WITH TIME ZONE` data type and contains the time zone information.

Syntax

```
TO_TIMESTAMP_TZ (char,[fmt],['nlsparam'])
```

Parameters

Parameter	Description

char	Specifies the string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type.
fmt	Specifies the output format.
nlsparam	Specifies the language that is used for the returned month and day.

Return type

`TIMESTAMP WITH TIME ZONE` data type

Examples

Execute the following statement:

```
SELECT TO_TIMESTAMP_TZ ('10-Sep-02 14:10:10.123000', 'DD-Mon-RR HH24:MI:SS.FF') FROM DUAL;
```

The following query result is returned:

```
+---------------------------------------------------------------------------+
| TO_TIMESTAMP_TZ('10-SEP-0214:10:10.123000','DD-MON-RRHH24:MI:SS.FF') |
+---------------------------------------------------------------------------+
| 2002-09-10 14:10:10.123000000 +08:00                                      |
+---------------------------------------------------------------------------+
```

TO_YMINTERVAL

The `TO_YMINTERVAL` function converts a string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type to a value of the `INTERVAL YEAR TO MONTH` data type. You can use this function to add a time interval to or subtract a time interval from a datetime value.

Syntax

```
TO_YMINTERVAL (years-months)
```

Parameters

Parameter	Description
years-months	The string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type. The string must meet the format requirements of this parameter.

Return type

`INTERVAL YEAR TO MONTH` data type

Examples

In the following example, the statement returns a datetime value and the value indicates the date and time that is one year and two months later than the current time:

```
SELECT SYSDATE,SYSDATE+TO_YMINTERVAL('01-02') FROM DUAL;
```

The following query result is returned:

```
+---------------------+---------------------------------+
| SYSDATE             | SYSDATE+TO_YMINTERVAL('01-02') |
+---------------------+---------------------------------+
| 2020-03-08 22:32:01 | 2021-05-08 22:32:01            |
+---------------------+---------------------------------+
```

TRUNC (date)

The `TRUNC` function truncates an input value based on the specified unit. This function returns a datetime value that indicates the nearest date and time to the specified `date` based on the specified interval requirement. The `fmt` parameter specifies the unit for the time interval between the return value and the specified date. The returned date occurs before the date that is specified by `date`.

> **Notice**
>
> `TRUNC` is different from `ROUND` in the following aspect: The TRUNC function returns the nearest date to the specified `date` and the nearest date occurs before the specified `date`. `ROUND` returns the nearest date to the specified `date` and the nearest date occurs before or after the specified `date`.

Syntax

```
TRUNC (date,[fmt])
```

Parameters

Parameter	Description
date	The `DATE` data type.
fmt	The unit for the time interval between the return value of the function and the specified `date`. The following table lists the valid values of this parameter. The values of this parameter are not case-sensitive.

fmt parameter	Description
j	The default value. The function returns the nearest date to 00:00.
day, dy, or d	Returns the nearest Sunday to the specified date.
month, mon, mm, or rm	Returns the first date of the nearest month to the specified date.
q	Returns the first date of the nearest quarter to the specified date.
yyyy, yyy, yy, or y	Returns the first date of the nearest year to the specified date. yyyy, yyy, yy, and y correspond to different precisions.
cc or scc	Returns the first date of the nearest century to the specified date.

Return type

`DATE` data type

Examples

In the following example, the `TRUNC` function calculates the nearest dates to the **SYSDATE** based on the specified requirements:

```
SELECT SYSDATE The current date,
TRUNC(SYSDATE) The date of today,
TRUNC(SYSDATE,'DAY') The Sunday of this week,
TRUNC(SYSDATE,'MONTH') The first date of this month,
TRUNC(SYSDATE,'Q') The first date of this quarter,
TRUNC(SYSDATE,'YEAR') The first date of this year FROM DUAL;
```

The following query result is returned:

```
+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
| The current date    | The date of today   | The Sunday of this week | The first date of this month | The first date of this quarter | The first date of this year |
+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
| 2020-03-08 22:41:46 | 2020-03-08 00:00:00 | 2020-03-08 00:00:00 | 2020-03-01 00:00:00 | 2020-01-01 00:00:00 | 2020-01-01 00:00:00 |
+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
```

In the following example, `ROUND` calculates the nearest dates that meet the different specified requirements when the input date is the same:

```
SELECT SYSDATE The current date,
ROUND(SYSDATE) The nearest date to 00:00,
ROUND(SYSDATE,'DAY') The nearest Sunday,
ROUND(SYSDATE,'MONTH') The first date of the nearest month,
ROUND(SYSDATE,'Q') The first date of the nearest quarter,
ROUND(SYSDATE,'YEAR') The first date of the nearest year FROM DUAL;
```

The following query result is returned:

```
+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
| The current date            | The nearest date to 00:00          | The nearest Sunday          | The first date of the nearest month            | The first date of the nearest quarter         | The first date of the nearest year        |
+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
| 2020-03-08 22:41:02 | 2020-03-09 00:00:00 | 2020-03-08 00:00:00 | 2020-03-01 00:00:00 | 2020-04-01 00:00:00 | 2020-01-01 00:00:00 |
+---------------------+---------------------+---------------------+---------------------+---------------------+---------------------+
```

TZ_OFFSET

The `TZ_OFFSET` function returns the time zone offset of the `n` time zone. The time zone offset is the difference (in hours and minutes) between a specified time zone and the UTC+0 time zone.

Syntax

```
TZ_OFFSET (n)
```

Parameters

Parameter	Description
n	The name of the time zone region.

Return type

`VARCHAR2` data type

Examples

The following example returns the time zone offsets of the current session time zone specified by `SESSIONTIMEZONE`, the database time zone specified by `DBTIMEZONE`, and the US/Eastern time zone:

```
SELECT TZ_OFFSET(SESSIONTIMEZONE),TZ_OFFSET(DBTIMEZONE),TZ_OFFSET('US/Eastern') FROM DUAL;
```

The following query result is returned:

```
+-----------------------------+-----------------------+-------------------------+
| TZ_OFFSET(SESSIONTIMEZONE) | TZ_OFFSET(DBTIMEZONE) | TZ_OFFSET('US/EASTERN') |
+-----------------------------+-----------------------+-------------------------+
| +08:00                      | +00:00                | -04:00                  |
+-----------------------------+-----------------------+-------------------------+
```

17.1.5.6.2.5. General comparison functions

GREATEST

The `GREATEST` function returns the maximum value in a list of one or more expressions. The database uses the first parameter `expr` to determine the return type. If the data type of the remaining parameters is different from that of the first parameter `expr`, ApsaraDB for OceanBase implicitly converts each parameter that follows the first parameter `expr` to the data type of the first parameter `expr` before the comparison.

Syntax

```
GREATEST(expr [, expr ]...)
```

Parameters

Parameter	Description
expr	An expression or an expression list. The data type can be `NUMBER`, `FLOAT`, `BINARY_FLOAT`, `BINARY_DOUBLE`, `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.

Return type

If the data type of the first parameter `expr` is `NUMBER`, `FLOAT`, `BINARY_FLOAT`, or `BINARY_DOUBLE`, the function returns the data type that is the same as the data type of the first parameter `expr`. If the data type of the first parameter `expr` is `CHAR`, `VARCHAR2`, or `CLOB`, the function returns the `VARCHAR2` type. If the data type of the first parameter `expr` is `NCHAR` or `NVARCHAR2`, the function returns the `NVARCHAR2` type.

Examples

The following statement compares the sizes of strings and returns the maximum string:

```
SELECT GREATEST('HAPPY', 'HAPPEN', 'HAPPINESS') "Greatest"
  FROM DUAL;
```

The following result is returned:

```
+-----------+
| Greatest |
+-----------+
|    HAPPY |
+-----------+
```

The following statement compares the sizes of the **1** integer, the **3.925** string, and the **2.4** string. The sizes can be compared after the remaining parameters are implicitly converted to the numeric data type. This is because the data type of the first parameter is the numeric data type.

```
SELECT GREATEST (1, '3.935', '2.4') "Greatest"
  FROM DUAL;
```

The following result is returned:

```
+-----------+
| Greatest |
+-----------+
|    3.935 |
+-----------+
```

LEAST

The `LEAST` function returns the minimum value in a list of one or more expressions. The database uses the first parameter `expr` to determine the return type. If the data type of the remaining parameters is different from that of the first parameter `expr`, ApsaraDB for OceanBase implicitly converts each parameter that follows the first parameter `expr` to the data type of the first parameter `expr` before the comparison.

Syntax

```
LEAST(expr [, expr ]...)
```

Parameters

Parameter	Description
expr	An expression or an expression list. The data type can be `NUMBER`, `FLOAT`, `BINARY_FLOAT`, `BINARY_DOUBLE`, `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.

Return type

If the data type of the first parameter `expr` is `NUMBER`, `FLOAT`, `BINARY_FLOAT`, or `BINARY_DOUBLE`, the function returns the data type that is the same as the data type of the first parameter `expr`. If the data type of the first parameter `expr` is `CHAR`, `VARCHAR2`, or `CLOB`, the function returns the `VARCHAR2` type. If the data type of the first parameter `expr` is `NCHAR` or `NVARCHAR2`, the function returns the `NVARCHAR2` type.

Examples

The following statement compares the sizes of strings and returns the minimum string:

```
SELECT LEAST('HAPPY', 'HAPPEN', 'HAPPINESS') "Least"
  FROM DUAL;
```

The following result is returned:

```
+--------+
| Least  |
+--------+
| HAPPEN |
+--------+
```

The following statement compares the sizes of the **1** integer, the **3.925** string, and the **2.4** string. The sizes can be compared after the remaining parameters are implicitly converted to the numeric data type. This is because the data type of the first parameter is the numeric data type.

```
SELECT LEAST (1, '3.925', '2.4') "Least"
  FROM DUAL;
```

The following result is returned:

```
+-------+
| Least |
+-------+
|     1 |
+-------+
```

17.1.5.6.2.6. Conversion functions

CAST

The `CAST` function explicitly converts the expression of a source data type to another data type.

Syntax

```
CAST (expr AS type_name )
```

Parameters

Parameter	Description
expr	The column name or the expression.
AS	Separates two parameters. The parameter before `AS` specifies the data to be processed. The parameter after `AS` specifies the data type to be converted to.
type_name	The data type is the built-in data type of ApsaraDB for OceanBase. For more information, see Built-in data types.

Return type

The return type is the same as the data type of `type_name` .

The following table lists which data types can be converted to other built-in data types.

	from BINARY_FLOAT, BINARY_DOUBLE	from CHAR, VARCHAR2	from NUMBER	[1] from DATETIME/INTERVAL	from RAW	from NCHAR, NVARCHAR2
to BINARY_FLOAT, BINARY_DOUBLE	yes	yes	yes	no	no	yes
to CHAR, VARCHAR2	yes	yes	yes	yes	yes	no
to NUMBER	yes	yes	yes	no	no	yes
to DATETIME, INTERVAL	no	yes	no	yes	no	no
to RAW	yes	yes	yes	no	yes	no
to NCHAR, NVARCHAR2	yes	no	yes	yes	yes	yes

[1] `To DATETIME/INTERVAL` data types include `DATE` , `TIMESTAMP` , `TIMESTAMP WITH TIMEZONE` , `INTERVAL DAY TO SECOND` , and `INTERVAL YEAR TO MONTH` .

Examples

Execute the following statement:

```
SELECT CAST('123' AS INT),CAST(1 AS VARCHAR2(10)),CAST('22-OCT-1997' AS TIMESTAMP WITH LOCAL TIME ZONE)
AS RESULT FROM DUAL;
```

The following query result is returned:

```
+------------------+----------------------+----------------------------+
| CAST('123'ASINT) | CAST(1ASVARCHAR2(10)) | RESULT                     |
+------------------+----------------------+----------------------------+
|              123 | 1                    | 1997-10-22 00:00:00.000000 |
+------------------+----------------------+----------------------------+
```

HEXTORAW

The `HEXTORAW` function converts a character that contains hexadecimal digits in the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type to the `RAW` data type.

Syntax

```
HEXTORAW (char)
```

Parameters

Parameter	Description
char	The hexadecimal string. The string type can be `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2`.

Return type

The data of the `RAW` data type is returned.

Examples

Execute the following statement:

```
select HEXTORAW('A123')  from dual;
```

The following query result is returned:

```
+------------------+
| HEXTORAW('A123') |
+------------------+
| A123             |
+------------------+
```

RAWTOHEX

The `RAWTOHEX` function converts a binary number to a corresponding hexadecimal string.

Syntax

```
RAWTOHEX (raw)
```

Parameters

Parameter	Description
raw	The binary string.

Return type

The hexadecimal string

Examples

Execute the following statement:

```
SELECT RAWTOHEX('AB')  FROM DUAL;
```

The following query result is returned:

```
+-----------------+
| RAWTOHEX('AB') |
+-----------------+
| 4142           |
+-----------------+
```

TO_BINARY_DOUBLE

The `TO_BINARY_DOUBLE` function returns a 64-bit double-precision floating-point number.

Syntax

```
TO_BINARY_DOUBLE(expr [, fmt [, 'nlsparam' ] ])
```

Parameters

Parameter	Description
expr	The string or the numeric data type: `NUMBER`, `BINARY_FLOAT`, or `BINARY_DOUBLE`.

The optional parameters `fmt` and `nlsparam` are valid only if `expr` is a string. They serve the same purpose as the `TO_CHAR(number)` feature. If `expr` is `BINARY_DOUBLE`, the function returns `expr`.

Return type

A 64-bit double-precision floating-point number is returned. The result of converting a string or `NUMBER` to `BINARY_DOUBLE` may be inexact. This is because `NUMBER` and character types use decimal precision to represent numeric values, but `BINARY_DOUBLE` uses binary precision. The result of converting `BINARY_FLOAT` to `BINARY_DOUBLE` is exact.

Examples

Execute the following statement:

```
SELECT TO_BINARY_DOUBLE(1222.111) FROM DUAL;
```

The following query result is returned:

```
+----------------------------+
| TO_BINARY_DOUBLE(1222.111) |
+----------------------------+
|              1.222111E+003 |
+----------------------------+
```

You can refer to TO_BINARY_FLOAT and TO_CHAR(number).

TO_BINARY_FLOAT

The `TO_BINARY_FLOAT` function returns a 32-bit single-precision floating-point number.

Syntax

```
TO_BINARY_FLOAT(expr [, fmt [, 'nlsparam' ] ])
```

Parameters

Parameter	Description
expr	The string or the numeric data type: `NUMBER`, `BINARY_FLOAT`, or `BINARY_DOUBLE`.

The optional parameters `fmt` and `nlsparam` are valid only if `expr` is a string. They serve the same purpose as the `TO_CHAR(number)` feature. If `expr` is `BINARY_FLOAT`, the function returns `expr`.

Return type

A 32-bit single-precision floating-point number is returned. The result of converting a string or `NUMBER` to `BINARY_FLOAT` may be inexact. This is because `NUMBER` and character types use decimal precision to represent numeric values, but `BINARY_FLOAT` uses binary precision. If a `BINARY_DOUBLE` value uses higher precision than the precision that is supported by `BINARY_FLOAT`, the result of converting `BINARY_DOUBLE` to `BINARY_FLOAT` is inexact.

Examples

Execute the following statement:

```
SELECT TO_BINARY_FLOAT(1222.111) from dual;
```

The following query result is returned:

```
+---------------------------+
| TO_BINARY_FLOAT(1222.111) |
+---------------------------+
|           1.22211096E+003 |
+---------------------------+
```

You can refer to TO_BINARY_DOUBLE and TO_CHAR(number).

TO_CHAR (character)

The `TO_CHAR (character)` function converts the data of `NCHAR`, `NVARCHAR2`, or `CLOB` to a database character set.

Syntax

```
TO_CHAR(character )
```

Parameter

	Description
character	The data type can be `NCHAR`, `NVARCHAR2`, or `CLOB`.

Return type

The return type is `VARCHAR2`. When the function converts a character `CLOB` to a database character set, the database returns an error if the `CLOB` value to be converted is greater than the desired type.

Examples

Create the **CLOBTEST** table and insert data to the column of the `RAW` data type.

```
CREATE TABLE CLOBTEST(TEXT CLOB);
INSERT INTO CLOBTEST VALUES('DWUIDBWUIDBWIOBFWUIOBFIOWBFWUIOBFUWIFB') ;
```

Execute the following statements:

```
SELECT TO_CHAR(TEXT) FROM CLOBTEST;
```

The following query result is returned:

```
+----------------------------------------+
| TO_CHAR(TEXT)                          |
+----------------------------------------+
| dwuidbwuidbwiobfwuiobfiowbfwuiobfuwifb |
+----------------------------------------+
```

TO_CHAR (datetime)

The `TO_CHAR` function converts a value of a data type to a value of the `VARCHAR2` data type based on the format that is specified by the `fmt` parameter. The data types of which values can be converted include `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `TIMESTAMP WITH LOCAL TIME ZONE`, `INTERVAL DAY TO SECOND`, and `INTERVAL YEAR TO MONTH`. If you do not specify the `fmt` parameter, the value of the `datetime` parameter is converted to a value of the `VARCHAR2` data type based on the following formats.

- The values of `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, and `TIMESTAMP WITH LOCAL TIME ZONE` are converted to the values that are in the default format of date and time values in the database. In the Data types topic, you can view the default format for each date and time type.
- The values of the `INTERVAL DAY TO SECOND` and `INTERVAL YEAR TO MONTH` data types are converted to the interval values in the numeric format.

Syntax

```
TO_CHAR({ datetime | interval } [, fmt [, 'nlsparam' ] ])
```

Parameters

Parameter	Description
datetime	The values of the data types, such as `DATE`, `TIMESTAMP`, `TIMESTAMP WITH TIME ZONE`, `TIMESTAMP WITH LOCAL TIME ZONE`, `INTERVAL DAY TO SECOND`, and `INTERVAL YEAR TO MONTH`.
fmt	The output format parameter.
nlsparam	Controls the language of the returned month and day.

Return type

`VARCHAR2` data type

Examples

Example 1: The following statement returns the current system date and converts the date and time value to the value in the **DS DL** format by using the TO_CHAR function.

```
SELECT TO_CHAR(SYSDATE,'DS DL') FROM DUAL;
```

The following query result is returned:

```
+-----------------------------------+
| TO_CHAR(SYSDATE,'DSDL')           |
+-----------------------------------+
| 03/08/2020 Sunday, March 08, 2020 |
+-----------------------------------+
```

Example 2: In the following statement, the interval value is converted to the value in the specified format and the language of the returned result is specified as **AMERICAN**.

```
SELECT TO_CHAR(interval'1' year, 'SS-MI-HH', 'nls_language = AMERICAN') FROM DUAL;
```

The following query result is returned:

```
+-------------------------------------------------------------+
| TO_CHAR(INTERVAL'1'YEAR,'SS-MI-HH','NLS_LANGUAGE=AMERICAN') |
+-------------------------------------------------------------+
| +01-00                                                      |
+-------------------------------------------------------------+
```

TO_CHAR (number)

The `TO_CHAR` function converts the numeric value `n` of the `NUMBER`, `BINARY_FLOAT`, or `BINARY_DOUBLE` type to a value of the `varchar2` data type based on the specified numeric format `fmt`. If you omit `fmt`, `n` is converted to a `VARCHAR2` value and the value is long enough to hold valid digits. If `n` is negative, the negative sign is displayed on the leftmost side of the output value. For example, `TO_CHAR(-1,'$9')` returns `-$1` instead of `$-1`.

Syntax

```
TO_CHAR(n [, fmt [, 'nlsparam' ] ])
```

Parameters

Parameter	Description
n	The expression of exact numeric data types or approximate numeric data types. The numeric data type can be `NUMBER`, `BINARY_FLOAT`, or `BINARY_DOUBLE`.

Parameter	Description
fmt	The output format parameter.
nlsparam	The supported language is obtained from `sys.V_$NLS_VALID_VALUES`.

fmt parameter list

fmt parameter	Description
9	Returns the value for which the number of digits is specified.
0	It returns leading zeros. It returns trailing zeros.
, (Comma)	Returns the comma in the specified position. You can specify multiple commas when you format the number. **Limits**: You cannot start to format a numeric value from a comma, and the comma cannot appear to the right of a decimal character or a period.
. (Decimal point)	Returns a decimal where the decimal point is in the specified position. **Limits**: You can specify only one decimal point when you format the number.

Return type

`VARCHAR2` data type

Examples

Execute the following statement:

```
SELECT TO_CHAR(123.456,'999') FROM DUAL;
```

The following query result is returned:

```
+------------------------+
| TO_CHAR(123.456,'999') |
+------------------------+
|  123                   |
+----------------------
```

TO_DATE

The `TO_DATE` function converts a character of the `CHAR`, `VARCHAR`, `NCHAR`, or `NVARCHAR2` data type to a value of the date data type.

Syntax

```
TO_DATE(char [, fmt [, 'nlsparam' ] ])
```

Parameters

Parameter	Description
char	The data of the `CHAR`, `VARCHAR`, `NCHAR`, or `NVARCHAR2` character type.
fmt	The date and time format.
nlsparam	The value is implicitly specified by the `nls_territory` initialization parameter or explicitly specified by the `nls_date_format` parameter.

Return type

The return type is the `DATE` type.

Examples

Execute the following statement:

```
SELECT TO_DATE('199912','YYYYMM'),TO_DATE('2000.05.20','YYYY.MM.DD'),
(DATE '2008-12-31') XXDATE,
TO_DATE('2008-12-31 12:31:30','YYYY-MM-DD HH24:MI:SS'),
(TIMESTAMP '2008-12-31 12:31:30') XXTIMESTAMP
FROM DUAL;
```

The following query result is returned:

```
+---------------------------+-----------------------------------+---------------------+------------
-----------------------------------------+-------------------------------+
| TO_DATE('199912','YYYYMM') | TO_DATE('2000.05.20','YYYY.MM.DD') | XXDATE              | TO_DATE('20
08-12-3112:31:30','YYYY-MM-DDHH24:MI:SS') | XXTIMESTAMP                   |
+---------------------------+-----------------------------------+---------------------+------------
-----------------------------------------+-------------------------------+
| 1999-12-01 00:00:00        | 2000-05-20 00:00:00               | 2008-12-31 00:00:00 | 2008-12-31
12:31:30                                | 2008-12-31 12:31:30.000000000 |
+---------------------------+-----------------------------------+---------------------+------------
-----------------------------------------+-------------------------------+
```

TO_DSINTERVAL

The `TO_DSINTERVAL` function converts a string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type to a value of the `INTERVAL DAY TO SECOND` data type. You can use this function to add or subtract a date and time value.

Syntax

```
TO_DSINTERVAL (days hours:minutes:seconds[.frac_secs])
```

Parameters

Parameter	Description
days hours:minutes:seconds[.frac_secs]	The string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type in compliance with the format of this parameter.

Return type

`INTERVAL DAY TO SECOND` data type

Examples

The following example returns a date and time value 100 days later than the current time:

```
SELECT SYSDATE, SYSDATE+TO_DSINTERVAL('100 00:00:00') FROM DUAL;
```

The following query result is returned:

```
+---------------------+---------------------------------------+
| SYSDATE             | SYSDATE+TO_DSINTERVAL('10000:00:00') |
+---------------------+---------------------------------------+
| 2020-03-26 12:40:39 | 2020-07-04 12:40:39                   |
+---------------------+---------------------------------------+
```

TO_NUMBER

The `TO_NUMBER` function converts `expr` to a value of the numeric data type. `expr` can be a value of the `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, `BINARY_FLOAT`, or `BINARY_DOUBLE` data type.

Syntax

```
TO_NUMBER(expr [, fmt [, 'nlsparam' ] ])
```

Parameters

Parameter	Description

Parameter	Description
expr	The value of the `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, `BINARY_FLOAT`, or `BINARY_DOUBLE` data type.
fmt	The format model.
nlsparam	The supported language is obtained from `sys.V_$NLS_VALID_VALUES`.

Return type

The data of the `NUMBER` type is returned.

Examples

Execute the following statement:

```
SELECT TO_NUMBER('199912'),TO_NUMBER('450.05') FROM DUAL;
```

The following query result is returned:

```
+---------------------+---------------------+
| TO_NUMBER('199912') | TO_NUMBER('450.05') |
+---------------------+---------------------+
|              199912 |              450.05 |
+---------------------+---------------------+
```

TO_TIMESTAMP

The `TO_TIMESTAMP` function converts a string to the `TIMESTAMP` data type.

Syntax

```
TO_TIMESTAMP (char,[fmt],['nlsparam'])
```

Parameters

Parameter	Description
char	The string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type.

Parameter	Description
fmt	Specifies the format of the return value.
nlsparam	Controls the language of the returned month and day.

Return type

`TIMESTAMP` data type

Examples

Execute the following statement:

```
SELECT TO_TIMESTAMP ('10-Sep-02 14:10:10.123000', 'DD-Mon-RR HH24:MI:SS.FF')
FROM DUAL;
```

The following query result is returned:

```
+---------------------------------------------------------------------+
| TO_TIMESTAMP('10-SEP-0214:10:10.123000','DD-MON-RRHH24:MI:SS.FF') |
+---------------------------------------------------------------------+
| 2002-09-10 14:10:10.123000000                                       |
+---------------------------------------------------------------------+
```

TO_TIMESTAMP_TZ

The `TO_TIMESTAMP` function converts a string to the `TIMESTAMP WITH TIME ZONE` data type, including information about time zones.

Syntax

```
TO_TIMESTAMP_TZ (char,[fmt],['nlsparam'])
```

Parameters

Parameter	Description
char	The string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type.
fmt	Specifies the output format.
nlsparam	Controls the language of the returned month and day.

Return type

`TIMESTAMP WITH TIME ZONE` data type

Examples

Execute the following statement:

```
SELECT TO_TIMESTAMP_TZ ('10-Sep-02 14:10:10.123000', 'DD-Mon-RR HH24:MI:SS.FF') FROM DUAL;
```

The following query result is returned:

```
+---------------------------------------------------------------------+
| TO_TIMESTAMP_TZ('10-SEP-0214:10:10.123000','DD-MON-RRHH24:MI:SS.FF') |
+---------------------------------------------------------------------+
| 2002-09-10 14:10:10.123000000 +08:00                                |
+---------------------------------------------------------------------+
```

TO_YMINTERVAL

The `TO_YMINTERVAL` function converts a string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type to a value of the `INTERVAL YEAR TO MONTH` data type. You can use this function to add or subtract a date and time value.

Syntax

```
TO_YMINTERVAL (years-months)
```

Parameters

Parameter	Description
years-months	The string of the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` data type in compliance with the format of this parameter.

Return type

`INTERVAL YEAR TO MONTH` data type

Examples

The following example shows that the date and time value one year and two months later than the current time is returned:

```
SELECT SYSDATE,SYSDATE+TO_YMINTERVAL('01-02') FROM DUAL;
```

The following query result is returned:

```
+---------------------+--------------------------------+
| SYSDATE             | SYSDATE+TO_YMINTERVAL('01-02') |
+---------------------+--------------------------------+
| 2020-03-08 22:32:01 | 2021-05-08 22:32:01            |
+---------------------+--------------------------------+
```

17.1.5.6.2.7. Encoding and decoding functions

DECODE

The `DECODE` function compares the `search` parameter with `condition` in sequence until the value of `condition` is equal to that of `search`. Then, the function returns the value of the `result` parameter that follows the corresponding `search`. If no `search` is equal to `condition`, the function returns the value of the `default` parameter.

Syntax

```
DECODE (condition, search 1, result 1, search 2, result 2 ... search n, result n, default)
```

The meaning of the `DECODE` function can be interpreted by using the `IF...ELSE IF...END` statement.

```
IF condition = search 1 THEN
RETURN(result 1)
ELSE IF condition = search 2 THEN
RETURN(result 2)
......
ELSE IF condition = search n THEN
RETURN(result n)
ELSE
RETURN(default)
END IF
```

Parameters

Parameter	Description
condition, search 1...search n, result 1...result n, default	The expression of the `NUMBER`, `FLOAT`, `BINARY_FLOAT`, or `BINARY_DOUBLE` numeric type or the `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2` character type.

> **Notice**
>
> `search 1` to `search n` cannot be conditional expressions. In this case, you can execute only the `CASE WHEN THEN END` statement to resolve the issue.

```
WHEN CASE condition = search 1 THEN
RETURN(result 1)
ELSE CASE condition = search 2 THEN
RETURN(result 2)
......
ELSE CASE condition = search n THEN
RETURN(result n)
ELSE
RETURN(default)
END
```

Examples

Example 1: Use `DECODE` to compare numeric values.

The following statement uses the `DECODE` function to return a smaller number between 10 and 20. The `SIGN()` function is used to calculate the sign of the difference between two values. The difference is a negative number and `SIGN()` returns -1 because 10 is less than 20. In this case, the `DECODE` function compares the -1 argument with the return value of the `SIGN()` function. If they are equal, 10 is returned. If they are not equal, 20 is returned.

```
SELECT DECODE(SIGN(10-20),-1,10,20) FROM DUAL;
```

The following result is returned:

```
+------------------------------+
| DECODE(SIGN(10-20),-1,10,20) |
+------------------------------+
|                           10 |
+------------------------------+
```

Example 2: Run the `DECODE` function to check whether the data includes the **S** character.

The following statements create the **EMP** table that contains the **ename** and **sal** columns and insert values into the table:

```
CREATE TABLE EMP(ename VARCHAR(30),sal NUMBER);
INSERT INTO EMP VALUES('CLARK', 2750);
INSERT INTO EMP VALUES('KING', 5300);
INSERT INTO EMP VALUES('MILLER', 1600);
INSERT INTO EMP VALUES('ADAMS', 1400);
INSERT INTO EMP VALUES('FORD', 3300);
INSERT INTO EMP VALUES('JONES', 3275);
INSERT INTO EMP VALUES('SCOTT', 3300);
INSERT INTO EMP VALUES('SMITH', 1100);
INSERT INTO EMP VALUES('ALLEN', 1900);
INSERT INTO EMP VALUES('BLAKE', 3150);
INSERT INTO EMP VALUES('JAMES', 1250);
INSERT INTO EMP VALUES('MARTIN', 1550);
INSERT INTO EMP VALUES('TURNER', 1800);
INSERT INTO EMP VALUES('WARD', 1550);
```

The following statement returns the occurrence position of the **S** character in the values of the **ename** column by using the `INSTR()` function. If the S character does not occur, 0 is returned. In this case, the `DECODE` function compares the return value of the `INSTR` function with 0. If they are equal, the **S** character does not occur in the values and the `DECODE` function returns **S excluded**. Otherwise, it returns **S included**.

```
SELECT ENAME, SAL, DECODE(INSTR(ename, 'S'), 0, 'S excluded', 'S included') AS INFO FROM EMP;
```

The following query result is returned:

```
+--------+------+------------+
| ENAME  | SAL  | INFO       |
+--------+------+------------+
| CLARK  | 2750 | S excluded    |
| KING   | 5300 | S excluded    |
| MILLER | 1600 | S excluded    |
| ADAMS  | 1400 | S included      |
| FORD   | 3300 | S excluded    |
| JONES  | 3275 | S included      |
| SCOTT  | 3300 | S included      |
| SMITH  | 1100 | S included      |
| ALLEN  | 1900 | S excluded    |
| BLAKE  | 3150 | S excluded    |
| JAMES  | 1250 | S included      |
| MARTIN | 1550 | S excluded    |
| TURNER | 1800 | S excluded    |
| WARD   | 1550 | S excluded    |
+--------+------+------------+
```

ORA_HASH

The `ORA_HASH` function retrieves the hash value of a corresponding expression.

Syntax

```
ORA_HASH(expr [, max_bucket [, seed_value ] ])
```

Parameters

Parameter	Description
expr	The value is generally a column name in the database table. The data type can be the numeric type, character type, date and time type, or `RAW` type.
max_bucket	The optional `max_bucket` parameter determines the maximum number of buckets that the hash function can return. Valid values: 0 to 4294967295. Default value: 4294967295.
seed_value	The optional `seed_value` parameter enables ApsaraDB for OceanBase to produce a number of different results for the same group of data. You can specify a value from 0 to 4294967295. Default value: 0.

Return type

Data of the `NUMBER` type

Examples

To create the **SALE** table and insert data into the table, execute the following statements:

```
CREATE TABLE SALE(MONTH CHAR(6), SELL NUMBER(10,2));
INSERT INTO SALE VALUES(200001, 1000);
INSERT INTO SALE VALUES(200002, 1100);
INSERT INTO SALE VALUES(200003, 1200);
INSERT INTO SALE VALUES(200004, 1300);
INSERT INTO SALE VALUES(200005, 1400);
INSERT INTO SALE VALUES(200006, 1500);
INSERT INTO SALE VALUES(200007, 1600);
INSERT INTO SALE VALUES(200101, 1100);
INSERT INTO SALE VALUES(200202, 1200);
INSERT INTO SALE VALUES(200301, 1300);
```

To use the `ORA_HASH` function to query the **SALE** table, execute the following statement:

```
SELECT ORA_HASH(CONCAT(month,sell),12,0), month, sell FROM Sale;
```

The following query result is returned:

```
+-----------------------------------+--------+------+
| ORA_HASH(CONCAT(MONTH,SELL),12,0) | MONTH  | SELL |
+-----------------------------------+--------+------+
|                                 1 | 200001 | 1000 |
|                                 6 | 200002 | 1100 |
|                                 5 | 200003 | 1200 |
|                                 4 | 200004 | 1300 |
|                                 5 | 200005 | 1400 |
|                                 2 | 200006 | 1500 |
|                                 7 | 200007 | 1600 |
|                                10 | 200101 | 1100 |
|                                 7 | 200202 | 1200 |
|                                 4 | 200301 | 1300 |
+-----------------------------------+--------+------+
```

VSIZE

The `VSIZE` function returns the number of bytes for `X`.

Syntax

```
VSIZE(X)
```

Return type

The number of bytes for x is returned. If x is `NULL`, the function returns `NULL`.

Examples

To create the **employees** table and insert data to the table, execute the following statements:

```
CREATE TABLE employees(manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(300, 'Wei',  '2019-09-11',23600);
INSERT INTO employees VALUES(200, 'Red', '2019-11-05', 23800);
INSERT INTO employees VALUES(100, 'Part',  '2018-10-01',24000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',23500);
COMMIT;
```

To use the `VSIZE` function to query the number of bytes for **manager_id = 300** in the **last_name** column, execute the following statement:

```
SELECT last_name, VSIZE (last_name) "BYTES" FROM employees WHERE manager_id = 300;
```

The following query result is returned:

```
+-----------+-------+
| LAST_NAME | BYTES |
+-----------+-------+
| Wei       |     3 |
+-----------+-------+
```

17.1.5.6.2.8. Null value-related functions

COALESCE

The `COALESCE` function returns the first non-null expression in a parameter list. You must specify at least two parameters.

Syntax

```
COALESCE(expr1, expr2[,…, exprn])
```

Parameters

Parameter	Description
expr1, expr2[,..., exprn]	The non-null expressions. You must specify at least two non-null expressions.

Return type

The first non-null expression in the parameter list is returned. If all the parameters are `NULL`, `NULL` is returned.

Examples

Assume that a **product_information** table is available. In the table, **product_id** indicates a product ID, **list_price** indicates the original price of the product, **min_price** indicates the lowest price of the product, and **Sale** indicates the actual sale price of the product. Specify the product discount as 10% and calculate the actual sale price of each product. In this case, you can use the `COALESCE` function. If **list_price** is empty, perform calculations based on **min_price**. If **min_price** is also empty, perform calculations based on **5**.

You can execute the following statements to create the **product_information** data table and insert data into the table:

```
CREATE TABLE product_information(supplier_id INT, product_id INT,list_price numeric, min_price numeri
c);
INSERT INTO PRODUCT_INFORMATION VALUES ('102050', '1659', '45', NULL);
INSERT INTO PRODUCT_INFORMATION VALUES ('102050', '1770', NULL, '70');
INSERT INTO PRODUCT_INFORMATION VALUES ('102050', '2370', '305', '247');
INSERT INTO PRODUCT_INFORMATION VALUES ('102050', '2380', '750', '731');
INSERT INTO PRODUCT_INFORMATION VALUES ('102050', '3255', NULL, NULL);
```

Execute the following query statement:

```
SELECT product_id, list_price,min_price,COALESCE(0.9*list_price, min_price, 5) "Sale"
FROM product_information WHERE supplier_id = 102050 ORDER BY product_id;
```

The following query result is returned:

```
+--------------+--------------+------------+--------+
|  PRODUCT_ID  |  LIST_PRICE  |  MIN_PRICE |  Sale  |
+--------------+--------------+------------+--------+
|        1659  |       45     |            |  40.5  |
+--------------+--------------+------------+--------+
|        1770  |              |     70     |    70  |
+--------------+--------------+------------+--------+
|        2370  |      305     |    247     | 274.5  |
+--------------+--------------+------------+--------+
|        2380  |      750     |    731     |   675  |
+--------------+--------------+------------+--------+
|        3255  |              |            |     5  |
+--------------+--------------+------------+--------+
```

LNNVL

The `LNNVL` function determines whether one or two operands in a condition are `NULL`. You can use this function in a `WHERE` clause or use the function as the `WHEN` condition in a `CASE` expression. A condition is used as a parameter. If the condition is `FALSE` or `UNKNOWN`, `TRUE` is returned. If the condition is `TRUE`, `FALSE` is returned.

Syntax

```
LNNVL(condition)
```

Parameters

Parameter	Description
condition	The condition.

Assume that a is equal to 2 and the value of b is **NULL**. The following table lists the return values of the `LNNVL` function.

Condition	Check result of the condition	Return value of LNNVL
a = 1	FALSE	TRUE
a = 2	TRUE	FALSE
a IS NULL	FALSE	TRUE
b = 1	UNKNOWN	TRUE
b IS NULL	TRUE	FALSE

Condition	Check result of the condition	Return value of LNNVL
a = b	UNKNOWN	TRUE

Return type

`TRUE` or `FALSE` of the BOOLEAN type is returned.

Examples

Assume that data is inserted into the employee name column **name** and the commission column **commission_pct** in an **EMPLOYEES** table. Execute the following statements:

```
CREATE TABLE EMPLOYEES (name VARCHAR(20), commission_pct numeric);
INSERT INTO EMPLOYEEs VALUES ('Baer', null);
INSERT INTO EMPLOYEEs VALUES ('Bada', null);
INSERT INTO EMPLOYEEs VALUES ('Boll', 0.1);
INSERT INTO EMPLOYEEs VALUES ('Bates', 0.15);
INSERT INTO EMPLOYEEs VALUES ('Eros', null);
INSERT INTO EMPLOYEEs VALUES ('Girl', 0.25);
```

You want to know the number of employees whose commission rates are less than 20%, including the employees who do not receive commissions. You can query only the number of employees whose actual commission rates are less than 20% by executing the following statement:

```
SELECT COUNT(*) FROM employees WHERE commission_pct < .2;
```

The following query result is returned:

```
+------------+
|  COUNT(*)  |
+------------+
|        2   |
+------------+
```

To include another three employees who do not receive commissions, you must rewrite the query by using the `INNVL` function. Execute the following statement:

```
SELECT COUNT(*) FROM employees WHERE LNNVL(commission_pct >= .2);
```

The following query result is returned:

```
+------------+
|  COUNT(*)  |
+------------+
|      4     |
+------------+
```

NVL

The `NVL` function returns a non-`NULL` value from two expressions. If the results of `expr1` and `expr2` are `NULL` values, the `NVL` function returns `NULL`.

Syntax

```
NVL(expr1, expr2)
```

Parameters

Parameter	Description
expr1	The expression. The data type can be one of the built-in data types of ApsaraDB for OceanBase.
expr2	The expression. The data type can be one of the built-in data types of ApsaraDB for OceanBase.

`expr1` and `expr2` must be the same type or can be implicitly converted to the same type. If they cannot be implicitly converted, ApsaraDB for OceanBase returns an error. Implicit conversions are implemented in the following ways:

- If `expr1` is the data of the `CHAR`, `NCHAR`, `NVARCHAR`, `VARCHAR2`, or `VARCHAR` character type, ApsaraDB for OceanBase converts `expr2` to the data type of `expr1` before it compares `expr1`. Then, ApsaraDB for OceanBase returns `VARCHAR2` in the character set of `expr1`.
- If `expr1` is the data of the `NUMBER`, `FLOAT`, `BINARY_FLOAT`, or `BINARY_DOUBLE` numeric type, ApsaraDB for OceanBase determines the parameter that has the highest numeric precedence. ApsaraDB for OceanBase implicitly converts the other parameter to this data type and returns the data type.

Return type

If `expr1` and `expr2` are `NULL`, `NULL` is returned. If `expr1` is the data of the `CHAR`, `NCHAR`, `NVARCHAR`, `VARCHAR2`, or `VARCHAR` character type, `VARCHAR2` in the character set of `expr1` is returned. If `expr1` is the data of the `NUMBER`, `FLOAT`, `BINARY_FLOAT`, or `BINARY_DOUBLE` numeric type, the data type that has the highest numeric precedence in `expr1` is returned.

Examples

Assume that data is inserted into the employee name column **name** and the commission column **commission_pct** in an **EMPLOYEES** table. Execute the following statements:

```
CREATE TABLE EMPLOYEES (name VARCHAR(20),commission_pct float(3));
INSERT INTO EMPLOYEEs VALUES ('Baer', null);
INSERT INTO EMPLOYEEs VALUES ('Bada', null);
INSERT INTO EMPLOYEEs VALUES ('Boll', 0.1);
INSERT INTO EMPLOYEEs VALUES ('Bates', 0.15);
INSERT INTO EMPLOYEEs VALUES ('Eric', null);
```

Query the name and the commission of an employee. If the employee does not receive the commission, **Not Applicable** appears. Execute the following statement:

```
SELECT name, NVL(TO_CHAR(commission_pct), 'Not Applicable') commission
FROM employees WHERE name LIKE 'B%' ORDER BY name;
```

The following query result is returned:

```
+--------------+----------------+
|        NAME  |     COMMISSION |
+--------------+----------------+
|        Baer  | Not Applicable |
+--------------+----------------+
|        Bada  | Not Applicable |
+--------------+----------------+
|        Boll  |             .1 |
+--------------+----------------+
|       Bates  |            .15 |
+--------------+----------------+
```

NVL2

The `NVL2` function returns different values based on whether an expression is null. If `expr1` is not null, the value of `expr2` is returned. If `expr1` is null, the value of `expr3` is returned. If the types of `expr2` and `expr3` are different, `expr3` is converted to the type of `expr1`.

Syntax

```
NVL2(expr1, expr2, expr3)
```

Parameters

Parameter	Description
expr1	The expression. The data type can be one of the built-in data types of ApsaraDB for OceanBase.
expr2	The expression. The data type can be one of the built-in data types of ApsaraDB for OceanBase.
expr3	The expression. The data type can be one of the built-in data types of ApsaraDB for OceanBase.

If the data types of `expr2` and `expr3` are different, ApsaraDB for OceanBase implicitly converts one data type to the other data type. If the data types cannot be implicitly converted, the database returns an error. If `expr2` is character or numeric data, the following implicit conversion rules are used:

- If `expr2` is the data of the `CHAR`, `NCHAR`, `NVARCHAR`, `VARCHAR2`, or `VARCHAR` character type, ApsaraDB for OceanBase converts `expr3` to the data type of `expr2` before the value is returned unless `expr3` is `NULL`. In this case, the data types do not need to be converted, and the database returns `VARCHAR2` in the character set of `expr2`.
- If `expr2` is the data of the `NUMBER`, `FLOAT`, `BINARY_FLOAT`, or `BINARY_DOUBL` numeric type, ApsaraDB for OceanBase determines the parameter that has the highest numeric precedence. ApsaraDB for OceanBase implicitly converts the other parameter to this data type and returns the data type.

Return type

If `expr1` and `expr2` are `NULL`, `NULL` is returned. If `expr1` is the data of the `CHAR`, `NCHAR`, `NVARCHAR`, `VARCHAR2`, or `VARCHAR` character type, `VARCHAR2` in the character set of `expr1` is returned. If `expr1` is the data of the `NUMBER`, `FLOAT`, `BINARY_FLOAT`, or `BINARY_DOUBLE` numeric type, the data type that has the highest numeric precedence in `expr1` is returned.

Examples

Assume that data is inserted into the employee name column **name**, the salary name **salary**, and the commission column **commission_pct** in the **EMPLOYEES** table. Execute the following statements:

```
CREATE TABLE EMPLOYEES (name VARCHAR(20),commission_pct numeric);
INSERT INTO EMPLOYEEs VALUES ('Baer', 10000, null);
INSERT INTO EMPLOYEEs VALUES ('Bada', 2800, null);
INSERT INTO EMPLOYEEs VALUES ('Boll', 5600, .25);
INSERT INTO EMPLOYEEs VALUES ('Bates', 7300, .39);
INSERT INTO EMPLOYEEs VALUES ('Broll', 4000, null);
```

Use the `NVL2` function to query the total income of employees. If the **commission_pct** column is not empty for an employee, the income of the employee consists of the salary and the commission. Otherwise, the income of the employee is only the salary. Execute the following statement:

```
SELECT name, salary,NVL2(commission_pct, salary + (salary * commission_pct), salary) income
FROM employees WHERE name like 'B%' ORDER BY name;
```

The following query result is returned:

```
+--------------+----------------+----------------+
|        NAME  |        SALARY  |        INCOME  |
+--------------+----------------+----------------+
|        Bear  |         10000  |         10000  |
+--------------+----------------+----------------+
|        Bada  |          2800  |          2800  |
+--------------+----------------+----------------+
|        Boll  |          5600  |          7280  |
+--------------+----------------+----------------+
|       Bates  |          7300  |         10220  |
+--------------+----------------+----------------+
|       Broll  |          4000  |          4000  |
+--------------+----------------+----------------+
```

17.1.5.6.3. Aggregate functions

17.1.5.6.3.1. AVG

The `AVG` function returns the average value of a numeric column.

Syntax

```
AVG([ DISTINCT | UNIQUE | ALL ] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
DISTINCT	Removes duplicate values from the data and ignores NULL values in the data during the query.
UNIQUE	Removes duplicate values from the data and ignores NULL values in the data during the query.
ALL	Retains duplicate values in the data and ignores NULL values in the data during the query. Default value: `ALL` .
expr	The expression of the numeric type or the types that can be converted to the numeric type. The numeric type can be `NUMBER` , `FLOAT` , `BINARY_FLOAT` , or `BINARY_DOUBLE` .
OVER	Uses the `OVER` clause to define a window for calculation.

Notice

If you specify the `DISTINCT` or `UNIQUE` keyword, `order_by_clause` and `windowing_clause` cannot appear in `analytic_clause` .

Return type

The return type is the same as the data type of the `expr` parameter.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT, last_name varchar(50), hiredate varchar(50), SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
COMMIT;
```

Execute the following statement to calculate the average value of each column:

```
SELECT manager_id, last_name, hiredate, salary, AVG(salary) OVER (PARTITION BY manager_id
ORDER BY hiredate ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING) AS c_mavg
FROM employees ORDER BY manager_id, hiredate, salary;
```

The following result is returned:

```
+------------+-----------+------------+---------+-----------------------------------------+
| MANAGER_ID | LAST_NAME | HIREDATE   | SALARY | C_MAVG                                   |
+------------+-----------+------------+---------+-----------------------------------------+
|        100 | Errazuriz | 2017-07-21 |   1400 |                                   1550 |
|        100 | Raphaely  | 2017-07-22 |   1700 |                                   4700 |
|        100 | De Haan   | 2018-05-01 |  11000 |                                   8900 |
|        100 | Partners  | 2018-12-01 |  14000 |                                  13000 |
|        100 | Hartstein | 2019-05-01 |  14000 |                                13833.333 |
|        100 | Weiss     | 2019-07-11 |  13500 |                                  13500 |
|        100 | Russell   | 2019-10-05 |  13000 |                                  13250 |
|        200 | Part      | 2018-08-11 |  14000 |                                  13500 |
|        200 | Bell      | 2019-05-25 |  13000 |                                  13500 |
|        200 | Ross      | 2019-06-11 |  13500 |                                  13250 |
+------------+-----------+------------+---------+-----------------------------------------+
```

Examples of the aggregate function

Execute the following statement to calculate the average value of **salary**:

```
SELECT AVG(salary) FROM employees;
```

The following query result is returned:

```
+-----------------------------------------+
| AVG(SALARY)                             |
+-----------------------------------------+
| 10072.727272727272727272727272727273 |
+-----------------------------------------+
```

17.1.5.6.3.2. COUNT

The `COUNT` function queries the number of rows for `expr`.

Syntax

```
COUNT({ * | [ DISTINCT | UNIQUE | ALL ] expr }) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
*	All the rows that meet the conditions and include the rows whose values are NULL.
DISTINCT	Removes duplicate rows from returned rows and ignores the rows whose values are NULL.
UNIQUE	Removes duplicate rows from returned rows and ignores the rows whose values are NULL.
ALL	Returns all the values, including duplicate rows, and ignores the rows whose values are NULL.
expr	The expression of the numeric type or the types that can be converted to the numeric type. The numeric type can be `NUMBER`, `FLOAT`, `BINARY_FLOAT`, or `BINARY_DOUBLE`.
OVER	Uses the OVER clause to define a window for calculation.

> **Notice**
>
> - The `COUNT` function never returns `NULL`. If you specify `expr`, the function returns the number of rows where `expr` is not `NULL`. If you specify `COUNT(*)`, the function returns the number of all the rows. If you use the `DISTINCT`, `UNIQUE`, or `ALL` parameter, separate the parameter and `expr` with a space.
> - If you specify the `DISTINCT` or `UNIQUE` keyword, `order_by_clause` and `windowing_clause` cannot appear in `analytic_clause`.

Return type

The return type is the same as the data type of the `expr` parameter.

Examples

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees(manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(300, 'Wei',  '2019-09-11',23600);
INSERT INTO employees VALUES(200, 'Red', '2019-11-05', 23800);
INSERT INTO employees VALUES(100, 'Part',  '2018-10-01',24000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',23500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 23000);
INSERT INTO employees VALUES(200, 'Part',  '2018-06-11',24500);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
COMMIT;
```

Examples of the analytic function

Execute the following statement to query the number of rows in the table:

```
SELECT last_name, salary,COUNT(*) OVER (ORDER BY salary RANGE BETWEEN 50 PRECEDING
AND 150 FOLLOWING) AS mov_count FROM employees ORDER BY salary, last_name;
```

The following query result is returned:

```
+-----------+--------+-----------+
| LAST_NAME | SALARY | MOV_COUNT |
+-----------+--------+-----------+
| Errazuriz |   1400 |         1 |
| De Haan   |  11000 |         1 |
| Hartstein |  14000 |         1 |
| Bell      |  23000 |         1 |
| Ross      |  23500 |         2 |
| Wei       |  23600 |         1 |
| Red       |  23800 |         1 |
| Part      |  24000 |         1 |
| Part      |  24500 |         1 |
+-----------+--------+-----------+
```

Examples of the aggregate function

To create a table named **a** and insert data into the table, execute the following statements:

```
CREATE TABLE a (
b INT
);
INSERT INTO a VALUES (1);
INSERT INTO a VALUES (null);
INSERT INTO a VALUES (null);
INSERT INTO a VALUES (1);
INSERT INTO a VALUES (null);
INSERT INTO a VALUES (1);
INSERT INTO a VALUES (1);
```

To return the number of rows whose values are not NULL in table **a**, execute the following statement:

```
SELECT COUNT(b) FROM a;
```

The following query result is returned:

```
+----------+
| COUNT(B) |
+----------+
|        4 |
+----------+
```

To specify `COUNT(*)` to return the number of all the rows, execute the following statement:

```
SELECT COUNT(*) FROM a;
```

The following query result is returned:

```
+----------+
| COUNT(*) |
+----------+
|        7 |
+----------+
```

17.1.5.6.3.3. SUM

The `SUM` function returns the sum of values in a column that is specified by a parameter. This function uses the numeric or non-numeric data types that can be implicitly converted to numeric data types as parameters. The function returns the data type that is the same as the numeric data type of the parameter.

Syntax

```
SUM([ DISTINCT | UNQIUE | ALL ] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
DISTINCT	Removes duplicate rows and ignores the rows whose values are NULL.
UNQIUE	Removes duplicate rows and ignores the rows whose values are NULL.
ALL	Returns all the values, including duplicate rows, and ignores the rows whose values are NULL.
expr	The data column or expression of the numeric type, character type, date type, or other types.
OVER	Uses the `OVER` clause to define a window for calculation.

> **Notice**
>
> :
>
> If you specify the `DISTINCT` or `UNIQUE` keyword, `order_by_clause` and `windowing_clause` cannot appear in `analytic_clause`.

Return type

The value of the data type same as the data type of `expr` is returned.

Examples

Examples of the analytic function

To create the **employees** table and insert data into the table, execute the following statements:

```
CREATE TABLE employees(manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(300, 'Wei',  '2019-09-11',23600);
INSERT INTO employees VALUES(200, 'Red', '2019-11-05', 23800);
INSERT INTO employees VALUES(100, 'Part',  '2018-10-01',24000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',23500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 23000);
INSERT INTO employees VALUES(200, 'Part',  '2018-06-11',24500);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
COMMIT;
```

To calculate the sum of salaries, execute the following statement:

```
SELECT manager_id, last_name, salary, SUM(salary) OVER (PARTITION BY manager_id
ORDER BY salary RANGE UNBOUNDED PRECEDING) l_csum
FROM employees ORDER BY manager_id, last_name, salary, l_csum;
```

The following query result is returned:

```
+------------+-----------+--------+--------+
| MANAGER_ID | LAST_NAME | SALARY | L_CSUM |
+------------+-----------+--------+--------+
|        100 | De Haan   |  11000 |  12400 |
|        100 | Errazuriz |   1400 |   1400 |
|        100 | Hartstein |  14000 |  26400 |
|        100 | Part      |  24000 |  50400 |
|        200 | Bell      |  23000 |  23000 |
|        200 | Part      |  24500 |  94800 |
|        200 | Red       |  23800 |  70300 |
|        200 | Ross      |  23500 |  46500 |
|        300 | Wei       |  23600 |  23600 |
+------------+-----------+--------+--------+
```

Examples of the aggregate function

To calculate the sum of salaries, execute the following statement:

```
SELECT SUM(salary) FROM employees;
```

The following query result is returned:

```
+-------------+
| SUM(SALARY) |
+-------------+
|      168800 |
+-------------+
```

17.1.5.6.3.4. MAX

The `MAX` function returns the maximum value in the column that is specified by a parameter.

Syntax

```
MAX([ DISTINCT | UNIQUE | ALL ] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
DISTINCT	Removes duplicate rows from returned rows and ignores the rows whose values are NULL.

Parameter	Description
UNIQUE	Removes duplicate rows from returned rows and ignores the rows whose values are NULL.
ALL	Returns all the values, including duplicate rows, and ignores the rows whose values are NULL.
expr	The data column or expression of the numeric type, character type, date type, or other types.
OVER	Uses the `OVER` clause to define a window for calculation.

Return type

The value of the data type same as the data type of `expr` is returned.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT, last_name varchar(50), hiredate varchar(50), SALARY INT);
INSERT INTO employees VALUES(100, 'Wei',  '2019-09-11',17000);
INSERT INTO employees VALUES(100, 'Red', '2019-11-05', 17000);
INSERT INTO employees VALUES(101, 'Part',  '2018-10-01',12008);
INSERT INTO employees VALUES(102, 'Wei',  '2019-09-11',9000);
INSERT INTO employees VALUES(103, 'Red', '2019-11-05', 6000);
INSERT INTO employees VALUES(104, 'Part',  '2018-10-01',8000);
COMMIT;
```

Execute the following statement to query the maximum value in the **SALARY** column:

```
SELECT manager_id, last_name, salary FROM (SELECT manager_id, last_name, salary,
MAX(salary) OVER (PARTITION BY manager_id) AS rmax_sal
FROM employees) WHERE salary = rmax_sal ORDER BY manager_id, last_name, salary;
```

The following query result is returned:

```
+------------+-----------+--------+
| MANAGER_ID | LAST_NAME | SALARY |
+------------+-----------+--------+
|        100 | Red       |  17000 |
|        100 | Wei       |  17000 |
|        101 | Part      |  12008 |
|        102 | Wei       |   9000 |
|        103 | Red       |   6000 |
|        104 | Part      |   8000 |
+------------+-----------+--------+
```

Examples of the aggregate function

Execute the following statement to query the maximum value in the **SALARY** column:

```
SELECT MAX(salary) FROM employees;
```

The following query result is returned:

```
+-------------+
| MAX(SALARY) |
+-------------+
|       17000 |
+-------------+
```

17.1.5.6.3.5. MIN

The `MIN` function returns the minimum value of a specified column.

Syntax

```
MIN([ DISTINCT | UNIQUE | ALL ] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
DISTINCT	Removes duplicate rows from returned rows and ignores the rows whose values are NULL.
UNIQUE	Removes duplicate rows from returned rows and ignores the rows whose values are NULL.
ALL	Returns all the values, including duplicate rows, and ignores the rows whose values are NULL.
expr	The data column or expression of the numeric type, character type, date type, or other types.
OVER	Uses the OVER clause to define a window for calculation.

Return type

The value of the data type same as the data type of `expr` is returned.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
```

Execute the following statement to query the minimum value of the **SALARY** column:

```
SELECT manager_id, last_name, hiredate, salary, MIN(salary) OVER(PARTITION BY manager_id
ORDER BY hiredate RANGE UNBOUNDED PRECEDING) AS p_cmin
FROM employees ORDER BY manager_id, last_name, hiredate, salary;
COMMIT;
```

The following query result is returned:

```
+------------+-----------+------------+--------+--------+
| MANAGER_ID | LAST_NAME | HIREDATE   | SALARY | P_CMIN |
+------------+-----------+------------+--------+--------+
|        100 | De Haan   | 2018-05-01 |  11000 |   1400 |
|        100 | Errazuriz | 2017-07-21 |   1400 |   1400 |
|        100 | Hartstein | 2019-05-01 |  14000 |   1400 |
|        100 | Partners  | 2018-12-01 |  14000 |   1400 |
|        100 | Raphaely  | 2017-07-01 |   1700 |   1700 |
|        100 | Raphaely  | 2017-07-22 |   1700 |   1400 |
|        100 | Russell   | 2019-10-05 |  13000 |   1400 |
|        100 | Weiss     | 2019-07-11 |  13500 |   1400 |
|        200 | Bell      | 2019-05-25 |  13000 |  13000 |
|        200 | Part      | 2018-08-11 |  14000 |  14000 |
|        200 | Ross      | 2019-06-11 |  13500 |  13000 |
+------------+-----------+------------+--------+--------+
```

Examples of the aggregate function

Execute the following statement to query the minimum value of the **SALARY** column:

```
SELECT MIN(salary)  FROM employees ;
```

The following query result is returned:

```
+-------------+
| MIN(SALARY) |
+-------------+
|        1400 |
+-------------+
```

17.1.5.6.3.6. LISTAGG

The `LISTAGG` function converts columns to rows. `LISTAGG` sorts the data in each group that is specified in the `ORDER BY` clause and merges the values of the measure column. When `LISTAGG` serves as a single-set aggregate function, it performs operations on all the rows and returns a single output row. When `LISTAGG` serves as a group-set aggregate, it performs operations on each group that is defined by the `GROUP BY` clause and returns an output row for each group. When `LISTAGG` serves as an analytic function, it divides the query result set into groups based on one or more expressions in `query_partition_clause`.

Syntax

```
LISTAGG(measure_expr [,'delimiter'])WITHIN GROUP (order_by_clause)
[OVER query_partition_clause]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
OVER	Uses the `OVER` clause to define a window for calculation.
measure_expr	The value can be an expression. Null values in the measure column are ignored.
delimiter	The string that is used to separate the measure values. This clause is optional. Default value: NULL.

Return type

If the data type of the measure column is `RAW`, the returned data type is `RAW`. Otherwise, the return value is of the `VARCHAR2` type.

Examples

Examples of the analytic function

To create the **employees** table and insert data into the table, execute the following statements:

```
CREATE TABLE employees (department_id INT,manager_id INT,last_name varchar(50),hiredate varchar(50),S
ALARY INT);
INSERT INTO employees VALUES(30, 100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(30, 100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(40, 100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(50, 100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(50, 100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(70, 100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(90, 100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(90,100, 'Partners',  '2018-12-01',14000);
```

Query the employees that were hired before October 10, 2019, the departments and hire dates of the employees, and the other employees in the departments. Execute the following statement:

```
SELECT department_id "Dept", hiredate "Date", last_name "Name",LISTAGG(last_name, '; ') WITHIN GROUP
(ORDER BY hiredate, last_name) OVER (PARTITION BY department_id) as "Emp_list"
FROM employees WHERE hiredate < '2019-10-10' ORDER BY "Dept", "Date", "Name";
```

The following query result is returned:

```
+------+------------+-----------+--------------------+
| Dept | Date       | Name      | Emp_list           |
+------+------------+-----------+--------------------+
|   30 | 2017-07-01 | Raphaely  | Raphaely; De Haan  |
|   30 | 2018-05-01 | De Haan   | Raphaely; De Haan  |
|   40 | 2017-07-21 | Errazuriz | Errazuriz          |
|   50 | 2017-07-22 | Raphaely  | Raphaely; Hartstein |
|   50 | 2019-05-01 | Hartstein | Raphaely; Hartstein |
|   70 | 2019-07-11 | Weiss     | Weiss              |
|   90 | 2018-12-01 | Partners  | Partners; Russell  |
|   90 | 2019-10-05 | Russell   | Partners; Russell  |
+------+------------+-----------+--------------------+
```

Examples of the aggregate function

To create the **employees** table and insert data into the table, execute the following statements:

```
CREATE TABLE employees (department_id INT,manager_id INT,last_name varchar(50),hiredate varchar(50),S
ALARY INT);
INSERT INTO employees VALUES(30, 100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(30, 100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(30, 100, 'Errazuriz', '2017-07-01', 1400);
INSERT INTO employees VALUES(30, 100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(30, 100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(30, 100, 'Weiss',  '2019-07-01',13500);
INSERT INTO employees VALUES(30, 100, 'Russell', '2019-07-01', 13000);
INSERT INTO employees VALUES(30,100, 'Partners',  '2018-12-01',14000);
```

To query all the employees in the thirtieth department and sort the employees by hire date and last name, execute the following statement:

```
SELECT LISTAGG(last_name, '; ') WITHIN GROUP (ORDER BY hiredate, last_name)  as "Emp_list",
MIN(hiredate) as "Earliest" FROM employees WHERE department_id = 30;
```

The following query result is returned:

```
+-------------------------------------------------------------------------------+------------+
| Emp_list                                                                      | Earliest   |
+-------------------------------------------------------------------------------+------------+
| Errazuriz; Raphaely; Raphaely; De Haan; Partners; Hartstein; Russell; Weiss | 2017-07-01 |
+-------------------------------------------------------------------------------+------------+
```

17.1.5.6.3.7. ROLLUP

The `ROLLUP` function is an aggregate function. It is a simple extension to the `GROUP BY` statement. When data statistics and reports are being generated, the function returns a subtotal for each group and a grand total for all the groups. This function is more efficient than the combination of `GROUP BY` and `UNION` .

The `ROLLUP` function runs in a simple way. The function runs in the following sequence:

- Group data from right to left in descending order based on the column that is specified by the parameter.
- Calculate a subtotal for each group, and then calculate a grand total for all the groups.
- Sort the data by `ORDER BY col1 (,col2,col3,col4 ...)` .

If the number of parameters in `ROLLUP` is `N` , the result of this function is equivalent to `UNION` of `N+1` `GROUP BY` groups.

The `ROLLUP` function makes tasks that involve group statistics efficient. For example, to calculate subtotals along a hierarchical dimension, such as time or geography, you need only to use `ROLLUP(y, m, day)` or `ROLLUP(country, state, city)` for the query. Data warehouse administrators can simplify and speed up the maintenance of aggregate tables by using the `ROLLUP` function.

Syntax

```
SELECT ... GROUP BY ROLLUP(col1 [,col2...])
```

Parameters

Parameter	Description
col1	The name of the column by which data is grouped. The number of columns refers to the number of rows in the database.

Examples

To create the **group_test** table and insert data into the table, execute the following statements:

```
CREATE TABLE group_test (group_id int, job varchar2(10), name varchar2(10), salary int);
INSERT INTO group_test VALUES (10, 'Coding', 'Bruce', 1000);
INSERT INTO group_test VALUES (10, 'Programmer', 'Clair', 1000);
INSERT INTO group_test VALUES (20, 'Coding', 'Jason', 2000);
INSERT INTO group_test VALUES (20, 'Programmer', 'Joey', 2000);
INSERT INTO group_test VALUES (30, 'Coding', 'Rebecca', 3000);
INSERT INTO group_test VALUES (30, 'Programmer', 'Rex', 3000);
INSERT INTO group_test VALUES (40, 'Coding', 'Samuel', 4000);
INSERT INTO group_test VALUES (40, 'Programmer', 'Susy', 4000);
COMMIT;
```

To use `GROUP BY` to group data by **group_id**, execute the following statement:

```
SELECT group_id, SUM(salary) FROM group_test GROUP BY group_id;
```

The following query result is returned:

```
+----------+-------------+
| GROUP_ID | SUM(SALARY) |
+----------+-------------+
|       10 |        2000 |
|       20 |        4000 |
|       30 |        6000 |
|       40 |        8000 |
+----------+-------------+
```

To use the `ROLLUP` function to group data by **group_id** and calculate a grand total, execute the following statement:

```
SELECT group_id, SUM(salary) FROM group_test GROUP BY ROLLUP (group_id);
```

The following query result is returned:

```
+----------+-------------+
| GROUP_ID | SUM(SALARY) |
+----------+-------------+
|       10 |        2000 |
|       20 |        4000 |
|       30 |        6000 |
|       40 |        8000 |
|     NULL |       20000 |
+----------+-------------+
```

To use the `ROLLUP` function to group data by the **group_id** and **job** columns and calculate a grand total, execute the following statement:

```
SELECT group_id, job, SUM(salary) FROM group_test GROUP BY ROLLUP (group_id, job);
```

The following query result is returned:

```
+----------+------------+-------------+
| GROUP_ID | JOB        | SUM(SALARY) |
+----------+------------+-------------+
|       10 | Coding     |        1000 |
|       10 | Programmer |        1000 |
|       10 | NULL       |        2000 |
|       20 | Coding     |        2000 |
|       20 | Programmer |        2000 |
|       20 | NULL       |        4000 |
|       30 | Coding     |        3000 |
|       30 | Programmer |        3000 |
|       30 | NULL       |        6000 |
|       40 | Coding     |        4000 |
|       40 | Programmer |        4000 |
|       40 | NULL       |        8000 |
|     NULL | NULL       |       20000 |
+----------+------------+-------------+
```

To replace the preceding SQL statement with the combination of `GROUP BY` and `UNION`, execute the following statement:

```
SELECT group_id, job, SUM(salary) FROM group_test GROUP BY group_id, job
UNION ALL
SELECT group_id, NULL, SUM(salary) FROM group_test GROUP BY group_id
UNION ALL
SELECT NULL, NULL, SUM(salary) FROM group_test ORDER BY 1, 2;
```

The following query result is returned:

```
+----------+------------+-------------+
| GROUP_ID | JOB        | SUM(SALARY) |
+----------+------------+-------------+
|       10 | Coding     |        1000 |
|       10 | Programmer |        1000 |
|       10 | NULL       |        2000 |
|       20 | Coding     |        2000 |
|       20 | Programmer |        2000 |
|       20 | NULL       |        4000 |
|       30 | Coding     |        3000 |
|       30 | Programmer |        3000 |
|       30 | NULL       |        6000 |
|       40 | Coding     |        4000 |
|       40 | Programmer |        4000 |
|       40 | NULL       |        8000 |
|     NULL | NULL       |       20000 |
+----------+------------+-------------+
```

The output result is the same as that of the `ROLLUP` function. However, the `ROLLUP` function is simpler and more efficient.

17.1.5.6.3.8. STDDEV

The `STDDEV` function calculates the population standard deviation. The `STDDEV` function uses numeric data as arguments and returns numeric data. The difference between this function and the `STDDEV_SAMP` function is that if only one row of input data is available, `STDDEV` returns 0 but `STDDEV_SAMP` returns NULL.

In ApsaraDB for OceanBase, the value of the standard deviation is the arithmetic square root of the variance that is calculated by the `VARIANCE` function.

Syntax

```
STDDEV([ DISTINCT | UNIQUE | ALL ] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
DISTINCT	Removes duplicate keywords. This indicates that the population standard deviation of unique values is calculated.
UNIQUE	Removes duplicate keywords. This indicates that the population standard deviation of unique values is calculated.
ALL	All the numeric columns.
expr	The numeric type or the types that can be converted to the numeric type.
OVER	Uses the `OVER` clause to define a window for calculation.

> **Notice**
>
> If you specify the `DISTINCT` or `UNIQUE` keyword, `order_by_clause` and `windowing_clause` cannot appear in `analytic_clause`.

Return type

The data of the `NUMBER` type is returned.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees(manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
COMMIT;
```

Call the function and execute the following statement:

```
SELECT last_name, salary, STDDEV(salary) OVER (ORDER BY hiredate) "StdDev"
FROM employees WHERE manager_id = 100 ORDER BY last_name, salary, "StdDev";
```

The following query result is returned:

```
+-----------+--------+-----------------------------------------+
| LAST_NAME | SALARY | StdDev                                  |
+-----------+--------+-----------------------------------------+
| De Haan   |  11000 | 4702.127178203498995615489088200868644482 |
| Errazuriz |   1400 |  212.132034355964257320253308631454711785 |
| Hartstein |  14000 | 6340.346993658943269176828928801701088079 |
| Partners  |  14000 | 6064.899009876421676804205219406952308814 |
| Raphaely  |   1700 |                                       0 |
| Raphaely  |   1700 |  173.205080756887729352744634150587236694 |
| Russell   |  13000 | 6026.474330580265330900400184969999384459 |
| Weiss     |  13500 | 6244.311697171159907069428668980211861012 |
+-----------+--------+-----------------------------------------+
```

Examples of the aggregate function

Call the function and execute the following statement:

```
SELECT STDDEV(salary) FROM employees WHERE manager_id = 100 ;
```

The following query result is returned:

```
+-----------------------------------------+
| STDDEV(SALARY)                          |
+-----------------------------------------+
| 6026.474330580265330900400184969999384459 |
+-----------------------------------------+
```

17.1.5.6.3.9. STDDEV_POP

The `STDDEV_POP` function calculates population standard deviation. The `STDDEV_POP` function uses numeric data as parameters and returns numeric data.

> **Notice**
> The population standard deviation is the arithmetic square root of a population variance.

Syntax

```
STDDEV_POP([ALL] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
ALL	All the numeric columns.
OVER	Uses the `OVER` clause to define a window for calculation.
expr	The expression of the numeric data types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`.

Return type

The return type is the same as the data type of the `expr` parameter.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
COMMIT;
```

Call the function and execute the following statement:

```
SELECT manager_id, last_name, salary, STDDEV_POP(salary) OVER (PARTITION BY manager_id) AS pop_std
FROM employees ORDER BY manager_id, last_name, salary, pop_std;
```

The following query result is returned:

```
+------------+-----------+--------+-----------------------------------------+
| MANAGER_ID | LAST_NAME | SALARY | POP_STD                                 |
+------------+-----------+--------+-----------------------------------------+
|        100 | De Haan   |  11000 | 5637.250548804798333699350384281939588505 |
|        100 | Errazuriz |   1400 | 5637.250548804798333699350384281939588505 |
|        100 | Hartstein |  14000 | 5637.250548804798333699350384281939588505 |
|        100 | Partners  |  14000 | 5637.250548804798333699350384281939588505 |
|        100 | Raphaely  |   1700 | 5637.250548804798333699350384281939588505 |
|        100 | Raphaely  |   1700 | 5637.250548804798333699350384281939588505 |
|        100 | Russell   |  13000 | 5637.250548804798333699350384281939588505 |
|        100 | Weiss     |  13500 | 5637.250548804798333699350384281939588505 |
|        200 | Bell      |  13000 |  408.248290463863016366214012450981899069 |
|        200 | Part      |  14000 |  408.248290463863016366214012450981899069 |
|        200 | Ross      |  13500 |  408.248290463863016366214012450981899069 |
+------------+-----------+--------+-----------------------------------------+
```

Examples of the aggregate function

Call the function and execute the following statement:

```
SELECT STDDEV_POP(salary) FROM employees ;
```

The following query result is returned:

```
+-----------------------------------------+
| STDDEV_POP(SALARY)                      |
+-----------------------------------------+
| 5249.950806538512715446505486136315088416 |
+-----------------------------------------+
```

17.1.5.6.3.10. STDDEV_SAMP

The `STDDEV_SAMP` function calculates the sample standard deviation. The `STDDEV_SAMP` function uses numeric data as arguments and returns numeric data. The difference between this function and the `STDDEV` function is that if only one row of input data is available, `STDDEV` returns 0 but `STDDEV_SAMP` returns NULL.

> **Note**
>
> The sample standard deviation is the square root of a sample variance.

Syntax

```
STDDEV_SAMP([ALL] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the OVER keyword.

Parameters

Parameter	Description
ALL	All the numeric columns.
expr	The expression of the numeric types (`NUMBER` , `FLOAT` , `BINARY_FLOAT` , and `BINARY_DOUBLE`) or the data types that can be converted to the numeric types.
OVER	Uses the `OVER` clause to define a window for calculation.

Return type

The return type is the same as the data type of the `expr` parameter.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
COMMIT;
```

Call the function and execute the following statement:

```
SELECT manager_id, last_name, hiredate, salary,STDDEV_SAMP(salary) OVER (PARTITION BY manager_id
ORDER BY hiredate ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) AS cum_sdev
FROM employees ORDER BY manager_id, last_name, hiredate, salary, cum_sdev;
```

The following result is returned:

```
+------------+-----------+------------+---------+-----------------------------------------+
| MANAGER_ID | LAST_NAME | HIREDATE   | SALARY | CUM_SDEV                                 |
+------------+-----------+------------+---------+-----------------------------------------+
|        100 | De Haan   | 2018-05-01 |  11000 | 4702.127178203498995615489088200868644482 |
|        100 | Errazuriz | 2017-07-21 |   1400 |  212.13203435596425732025330863145471785 |
|        100 | Hartstein | 2019-05-01 |  14000 | 6340.346993658943269176828928801701088079 |
|        100 | Partners  | 2018-12-01 |  14000 | 6064.899009876421676804205219406952308814 |
|        100 | Raphaely  | 2017-07-01 |   1700 |                                     NULL |
|        100 | Raphaely  | 2017-07-22 |   1700 |  173.20508075688772935274463415058723669 4 |
|        100 | Russell   | 2019-10-05 |  13000 | 6026.474330580265330900400184969999384459 |
|        100 | Weiss     | 2019-07-11 |  13500 | 6244.311697171159907069428668980211861012 |
|        200 | Bell      | 2019-05-25 |  13000 |  707.106781186547524400844362104849039285 |
|        200 | Part      | 2018-08-11 |  14000 |                                     NULL |
|        200 | Ross      | 2019-06-11 |  13500 |                                      500 |
+------------+-----------+------------+---------+-----------------------------------------+
```

Examples of the aggregate function

Call the function and execute the following statement:

```
SELECT STDDEV_SAMP(salary) FROM employees ;
```

The following query result is returned:

```
+-----------------------------------------+
| STDDEV_SAMP(SALARY)                     |
+-----------------------------------------+
| 5506.194858355615640082358245403620332764 |
+-----------------------------------------+
```

17.1.5.6.3.11. VARIANCE

The `VARIANCE` function returns the variance of the column that is specified by a parameter.

Syntax

```
VARIANCE([ DISTINCT | UNIQUE | ALL ] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
DISTINCT	Removes duplicate values from the column and ignores NULL values in the column during the query.
UNIQUE	Removes duplicate values from the column and ignores NULL values in the column during the query.

Parameter	Description
ALL	Retains duplicate values in the column and ignores NULL values in the column during the query. Default value: `ALL`.
expr	The data column or expression of the numeric type, character type, date type, or other types.
OVER	Uses the `OVER` clause to define a window for calculation.

> **Notice**
>
> If you specify the `DISTINCT` or `UNIQUE` keyword, `order_by_clause` and `windowing_clause` cannot appear in `analytic_clause`.

Return type

The data of the `NUMBER` type is returned.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
COMMIT;
```

Execute the following statement to calculate the variance of the **salary** column:

```
SELECT last_name, salary, VARIANCE(salary)  OVER (ORDER BY hiredate) "Variance"
FROM employees WHERE manager_id = 100 ORDER BY last_name, salary, "Variance";
```

The following query result is returned:

```
+-----------+--------+-----------------------------------------+
| LAST_NAME | SALARY | Variance                                |
+-----------+--------+-----------------------------------------+
| De Haan   |  11000 |                                22110000 |
| Errazuriz |   1400 |                                   45000 |
| Hartstein |  14000 |                                40200000 |
| Partners  |  14000 |                                36783000 |
| Raphaely  |   1700 |                                       0 |
| Raphaely  |   1700 |                                   30000 |
| Russell   |  13000 | 36318392.857142857142857142857142857142 |
| Weiss     |  13500 | 38991428.571428571428571428571428571428 |
+-----------+--------+-----------------------------------------+
```

Examples of the aggregate function

Execute the following statement to calculate the variance of the **salary** column:

```
SELECT VARIANCE(salary)  FROM employees;
```

The following query result is returned:

```
+----------------------------------------+
| VARIANCE(SALARY)                       |
+----------------------------------------+
| 30318181.818181818181818181818181818182 |
+----------------------------------------+
```

17.1.5.6.3.12. APPROX_COUNT_DISTINCT

The `APPROX_COUNT_DISTINCT` function is an aggregate function. It calculates the number of rows in a column where duplicates are removed, and can return only one approximate value. You can use this function to further calculate the selectivity of the referenced column.

Compared with the `COUNT(DISTINCT x)` function, `APPROX_COUNT_DISTINCT` returns an approximate value. Therefore, the calculation speed of APPROX_COUNT_DISTINCT is super high. It often takes a long time for `COUNT(DISTINCT x)` to process a large amount of data. `APPROX_COUNT_DISTINCT` sacrifices a small amount of accuracy for a significant increase in computational efficiency.

Syntax

```
APPROX_COUNT_DISTINCT(expr)
```

Parameters

Parameter	Description
expr	The numeric column.

Return type

The data of the `NUMBER` type is returned.

Examples

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
COMMIT;
```

Execute the following statement:

```
SELECT last_name, salary, APPROX_COUNT_DISTINCT(salary) OVER (ORDER BY hiredate) "Variance"
FROM employees WHERE manager_id = 100 ORDER BY last_name, salary, "Variance";
```

The following query result is returned:

```
+-----------+--------+----------+
| LAST_NAME | SALARY | Variance |
+-----------+--------+----------+
| De Haan   |  11000 |        3 |
| Errazuriz |   1400 |        2 |
| Hartstein |  14000 |        4 |
| Partners  |  14000 |        4 |
| Raphaely  |   1700 |        1 |
| Raphaely  |   1700 |        2 |
| Russell   |  13000 |        6 |
| Weiss     |  13500 |        5 |
+-----------+--------+----------+
```

17.1.5.6.4. Analytic functions

17.1.5.6.4.1. Description of window functions

Analytic functions (also called window functions) and aggregate functions perform aggregate operations on a group of rows (a set of rows). The difference is that aggregate functions return a value (a row) for each group, but window functions return multiple values (multiple rows) for each group. A group of rows is also known as a window and is defined by `analytic_clause`. Window sizes depend on the actual number of rows or a logical interval, such as time.

To trigger an analytic function, you must use a special keyword `OVER` to specify a window. A window consists of three parts:

- Partitioning specifications: used to split input rows into different partitions. This process is similar to the splitting process of the `GROUP BY` clause.

- Sorting specifications: used to determine the order in which input data rows are executed in the window function.
- Window boundary: specifies a window boundary for calculating data. The default value is `RANGE UNBOUNDED PRECEDING`. This boundary contains all data in all the rows that range from the start row to the current row in the current partition.

Analytic functions are the last group of operations that are performed in a query except for the final `ORDER BY` clause. Before window functions are processed, all the `JOIN` operations and `WHERE`, `GROUP BY`, and `HAVING` clauses must be completed. Therefore, window functions can appear in only the select list or the `ORDER BY` clause.

Analytic functions are generally used to calculate cumulative, moving, centered, and reporting aggregates.

Syntax

analytic_function

```
analytic_function([ arguments ]) OVER (analytic_clause)
```

analytic_clause

```
[ query_partition_clause ] [ order_by_clause [ windowing_clause ] ]
```

query_partition_clause

```
PARTITION BY { expr[, expr ]... | ( expr[, expr ]... ) }
```

order_by_clause

```
ORDER [ SIBLINGS ] BY{ expr | position | c_alias } [ ASC | DESC ] [ NULLS FIRST | NULLS LAST ] [, { e
xpr | position | c_alias } [ ASC | DESC ][ NULLS FIRST | NULLS LAST ]]...
```

windowing_clause

```
{ ROWS | RANGE } { BETWEEN { UNBOUNDED PRECEDING | CURRENT ROW | value_expr { PRECEDING | FOLLOWING }
} AND{ UNBOUNDED FOLLOWING | CURRENT ROW | value_expr { PRECEDING | FOLLOWING } } | { UNBOUNDED PRECE
DING | CURRENT ROW| value_expr PRECEDING}}
```

The following sections describe the semantics of the syntax.

analytic_function

analytic_function specifies the name of an analytic function.

arguments

The parameters (arguments). Analytic functions use 0 to 3 parameters. The parameters can be numeric data types or non-numeric data types that can be implicitly converted to numeric data types. ApsaraDB for OceanBase determines the parameter that has the highest numeric precedence based on the precedence of data types. Then, it implicitly converts the remaining parameters to the data type of the parameter that has the highest numeric precedence. The return type is also the data type of the parameter that has the highest numeric precedence, unless otherwise noted for a single function.

analytic_clause

The analytic clause (analytic_clause). Use `OVER analytic_clause` to indicate that the function performs operations on a query result set. This clause is calculated after the `FROM`, `WHERE`, `GROUP BY`, and `HAVING` clauses. You can use this clause to specify analytic functions in the select list or the ORDER BY clause. If you need to filter the results of a query based on an analytic function, nest these functions in the parent query and filter the results of the nested subquery.

> **Notice**
>
> - You cannot nest analytic functions by specifying analytic functions in analytic_clause. However, you can specify an analytic function in a subquery and calculate another analytic function over the subquery.
> - You can use user-defined analytic functions and built-in analytic functions to specify `analytic_clause`.

query_partition_clause

The partitioning clause (query_partition_clause). Use the `PARTITION BY` clause to partition a query result set to groups based on one or more `value_expr`. If you omit this clause, the function considers all the rows in the query result set as a single group.

You can specify multiple analytic functions in the same query. Each function has the same or different PARTITION BY keys. If you use `query_partition_clause` to specify an analytic function and the queried objects have the parallel attribute, the function calculations are also parallelized.

Valid values of `value_expr` are constants, columns, non-analytic functions, function expressions, or expressions that involve one of them.

order_by_clause

Use the sorting clause `order_by_clause` to specify how data is sorted in a partition. For all the analytic functions, you can sort values in a partition on multiple keys. Each key is defined by `value_expr` and is qualified by a sorting sequence.

In each function, you can specify multiple sorting expressions. This is especially useful when you use the functions that sort values.

When `order_by_clause` generates the identical values for multiple rows, the function has the following behavior:

- `CUME_DIST`, `DENSE_RANK`, `NTILE`, `PERCENT_RANK`, and `RANK` return the same result for each row.
- `ROW_NUMBER` assigns a distinct value to each row even if a value that is based on `order_by_clause` is available. The value is based on the order in which the row is processed. This order may be nondeterministic if `ORDER BY` cannot implement a total sorting.
- For other analytic functions, the result depends on the window rules. If you specify a logical window that has the `RANGE` keyword, the function returns the same result for each row. If you use the `ROWS` keyword to specify a physical window, the result is nondeterministic.

Limits on the ORDER BY clause

The `ORDER BY` clause is subject to the following limits:

- In analytic functions, `order_by_clause` must use an expression (expr). The `SIBLINGS` keyword is invalid. This keyword is relevant in only hierarchical queries. Position (position) and column aliases (c_alias) are also invalid. Otherwise, this `order_by_clause` clause is the same as the sorting command of an overall query or a subquery.
- An analytic function that uses the RANGE keyword can use multiple sort keys in the `ORDER BY` clause of this function. You must specify the following windows:
  - `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`, `RANGE UNBOUNDED PRECEDING` for short
  - `RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING`
  - `RANGE BETWEEN CURRENT ROW AND CURRENT ROW`
  - `RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING`

Window boundaries other than the preceding four windows can have only one sort key in the `ORDER BY` clause of the analytic function. This limit does not apply to the window boundaries that are specified by the `ROW` keyword.

ASC or DESC keyword

Specify the sorting sequence. `ASC` refers to the ascending order and `DESC` refers to the descending order. The default value is the ascending order (ASC).

NULLS FIRST or NULLS LAST keyword

`nulls first` and `nulls last` in `order_by_clause`. `nulls first` indicates that NULL values are processed as minimum values during sorting. `nulls last` indicates that NULL values are processed as maximum values during sorting.

windowing_clause

The window function clause (windowing_clause). You can use `windowing_clause` in some analytic functions. The following keywords are relevant:

ROWS or RANGE keyword

These keywords define a window for calculating the function result for each row. Then, the function is applied to all the rows in the window. The window moves through a query result set or a partition from top to bottom. A window is also called `FRAME`. ApsaraDB for OceanBase supports the following window statements:

- `ROWS`: specifies the window in physical units (rows).
- `RANGE`: specifies the window as a logical offset. The default method is `RANGE UNBOUNDED PRECEDING`. You can use window functions in analytic functions. To use `windowing_clause`, you must add `order_by_clause`.

If the window boundaries are defined by the `RANGE` clause in `windowing_clause`, you can specify only one expression in `order_by_clause`. For more information, see the limits on the ORDER BY clause. The value returned by an analytic function that has a logical offset is always deterministic. However, the value returned by an analytic function that has a physical offset may generate nondeterministic results. An analytic function that has a physical offset can return a deterministic value only when the sorting expression returns a unique sorting. Therefore, you must specify multiple columns in `order_by_clause` to implement the unique sorting.

BETWEEN ... AND keyword

Use the `BETWEEN ... AND` clause to specify the start point and end point of the window. The first expression (before AND) defines the start point. The second expression (after AND) defines the end point. If you omit `BETWEEN` and specify only one end point, ApsaraDB for OceanBase considers this point as the start point and the current row as the default end point.

UNBOUNDED PRECEDING keyword

`UNBOUNDED PRECEDING` indicates that the window starts at the first row of the partition. This is the start point instead of the end point.

UNBOUNDED FOLLOWING keyword

`UNBOUNDED FOLLOWING` indicates that the window ends at the last row of the partition. This is the end point instead of the start point.

CURRENT ROW keyword

If `CURRENT ROW` serves as a start point, it specifies that the window starts from the current row or the current value. This depends on whether you have specified `ROW` or `RANGE`. In this case, the end point cannot be `value_expr PRECEDING`. If `CURRENT ROW` serves as an end point, it specifies that the window ends at the current row or the current value. This depends on whether you have specified `ROW` or `RANGE`. In this case, the start point cannot be `value_expr FOLLOWING`.

value_expr PRECEDING or value_expr FOLLOWING keyword

- If `value_expr FOLLOWING` is the start point, the end point must be `value_expr FOLLOWING`.
- If `value_expr PRECEDING` is the end point, the start point must be `value_expr PRECEDING`.

If you need to define a logical window that is defined by a time interval in the numeric format, you may need to use conversion functions.

If you specify `ROWS`:

- `value_expr` is a physical offset. It must be a constant or an expression and must be calculated as a positive number.
- If `value_expr` is part of the start point, it must calculate the part that precedes the start point and the end point as a row.

If you specify `RANGE`:

- `value_expr` is a logical offset. It must be a constant or an expression whose result is a positive numeric value or an interval literal.
- You can specify only one expression in `order_by_clause`.
- If `value_expr` is a numeric value, `ORDER BY expr` must be the numeric or `DATE` data type.
- If `value_expr` is an interval value, `ORDER BY expr` must be the `DATE` data type. If you completely omit `windowing_clause`, the default value is `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`.

17.1.5.6.4.2. AVG

The `AVG` function returns the average value of a numeric column.

Syntax

```
AVG([ DISTINCT | UNIQUE | ALL ] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
DISTINCT	Removes duplicate values from the data and ignores NULL values in the data during the query.
UNIQUE	Removes duplicate values from the data and ignores NULL values in the data during the query.
ALL	Retains duplicate values in the data and ignores NULL values in the data during the query. Default value: `ALL`.
expr	The expression of the numeric type or the types that can be converted to the numeric type. The numeric type can be `NUMBER`, `FLOAT`, `BINARY_FLOAT`, or `BINARY_DOUBLE`.
OVER	Uses the `OVER` clause to define a window for calculation.

> **Notice**
>
> If you specify the `DISTINCT` or `UNIQUE` keyword, `order_by_clause` and `windowing_clause` cannot appear in `analytic_clause`.

Return type

The return type is the same as the data type of the `expr` parameter.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT, last_name varchar(50), hiredate varchar(50), SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
COMMIT;
```

Execute the following statement to calculate the average value of each column:

```
SELECT manager_id, last_name, hiredate, salary, AVG(salary) OVER (PARTITION BY manager_id
ORDER BY hiredate ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING) AS c_mavg
FROM employees ORDER BY manager_id, hiredate, salary;
```

The following result is returned:

```
+------------+-----------+------------+---------+-----------------------------------------+
| MANAGER_ID | LAST_NAME | HIREDATE   | SALARY | C_MAVG                                   |
+------------+-----------+------------+---------+-----------------------------------------+
|        100 | Errazuriz | 2017-07-21 |   1400 |                                   1550 |
|        100 | Raphaely  | 2017-07-22 |   1700 |                                   4700 |
|        100 | De Haan   | 2018-05-01 |  11000 |                                   8900 |
|        100 | Partners  | 2018-12-01 |  14000 |                                  13000 |
|        100 | Hartstein | 2019-05-01 |  14000 |                                13833.333 |
|        100 | Weiss     | 2019-07-11 |  13500 |                                  13500 |
|        100 | Russell   | 2019-10-05 |  13000 |                                  13250 |
|        200 | Part      | 2018-08-11 |  14000 |                                  13500 |
|        200 | Bell      | 2019-05-25 |  13000 |                                  13500 |
|        200 | Ross      | 2019-06-11 |  13500 |                                  13250 |
+------------+-----------+------------+---------+-----------------------------------------+
```

Examples of the aggregate function

Execute the following statement to calculate the average value of **salary**:

```
SELECT AVG(salary) FROM employees;
```

The following query result is returned:

```
+-----------------------------------------+
| AVG(SALARY)                             |
+-----------------------------------------+
| 10072.727272727272727272727272727273 |
+-----------------------------------------+
```

17.1.5.6.4.3. COUNT

The `COUNT` function queries the number of rows for `expr`.

Syntax

```
COUNT({ * | [ DISTINCT | UNIQUE | ALL ] expr }) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
*	All the rows that meet the conditions and include the rows whose values are NULL.
DISTINCT	Removes duplicate rows from returned rows and ignores the rows whose values are NULL.
UNIQUE	Removes duplicate rows from returned rows and ignores the rows whose values are NULL.
ALL	Returns all the values, including duplicate rows, and ignores the rows whose values are NULL.
expr	The expression of the numeric type or the types that can be converted to the numeric type. The numeric type can be `NUMBER`, `FLOAT`, `BINARY_FLOAT`, or `BINARY_DOUBLE`.
OVER	Uses the OVER clause to define a window for calculation.

> **Notice**
>
> - The `COUNT` function never returns `NULL`. If you specify `expr`, the function returns the number of rows where `expr` is not `NULL`. If you specify `COUNT(*)`, the function returns the number of all the rows. If you use the `DISTINCT`, `UNIQUE`, or `ALL` parameter, separate the parameter and `expr` with a space.
> - If you specify the `DISTINCT` or `UNIQUE` keyword, `order_by_clause` and `windowing_clause` cannot appear in `analytic_clause`.

Return type

The return type is the same as the data type of the `expr` parameter.

Examples

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees(manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(300, 'Wei',  '2019-09-11',23600);
INSERT INTO employees VALUES(200, 'Red', '2019-11-05', 23800);
INSERT INTO employees VALUES(100, 'Part',  '2018-10-01',24000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',23500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 23000);
INSERT INTO employees VALUES(200, 'Part',  '2018-06-11',24500);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
COMMIT;
```

Examples of the analytic function

Execute the following statement to query the number of rows in the table:

```
SELECT last_name, salary,COUNT(*) OVER (ORDER BY salary RANGE BETWEEN 50 PRECEDING
AND 150 FOLLOWING) AS mov_count FROM employees ORDER BY salary, last_name;
```

The following query result is returned:

```
+-----------+--------+-----------+
| LAST_NAME | SALARY | MOV_COUNT |
+-----------+--------+-----------+
| Errazuriz |   1400 |         1 |
| De Haan   |  11000 |         1 |
| Hartstein |  14000 |         1 |
| Bell      |  23000 |         1 |
| Ross      |  23500 |         2 |
| Wei       |  23600 |         1 |
| Red       |  23800 |         1 |
| Part      |  24000 |         1 |
| Part      |  24500 |         1 |
+-----------+--------+-----------+
```

Examples of the aggregate function

To create a table named **a** and insert data into the table, execute the following statements:

```
CREATE TABLE a (
b INT
);
INSERT INTO a VALUES (1);
INSERT INTO a VALUES (null);
INSERT INTO a VALUES (null);
INSERT INTO a VALUES (1);
INSERT INTO a VALUES (null);
INSERT INTO a VALUES (1);
INSERT INTO a VALUES (1);
```

To return the number of rows whose values are not NULL in table **a**, execute the following statement:

```
SELECT COUNT(b) FROM a;
```

The following query result is returned:

```
+----------+
| COUNT(B) |
+----------+
|        4 |
+----------+
```

To specify `COUNT(*)` to return the number of all the rows, execute the following statement:

```
SELECT COUNT(*) FROM a;
```

The following query result is returned:

```
+----------+
| COUNT(*) |
+----------+
|        7 |
+----------+
```

17.1.5.6.4.4. SUM

The `SUM` function returns the sum of values in a column that is specified by a parameter. This function uses the numeric or non-numeric data types that can be implicitly converted to numeric data types as parameters. The function returns the data type that is the same as the numeric data type of the parameter.

Syntax

```
SUM([ DISTINCT | UNQIUE | ALL ] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
DISTINCT	Removes duplicate rows and ignores the rows whose values are NULL.
UNQIUE	Removes duplicate rows and ignores the rows whose values are NULL.
ALL	Returns all the values, including duplicate rows, and ignores the rows whose values are NULL.
expr	The data column or expression of the numeric type, character type, date type, or other types.
OVER	Uses the `OVER` clause to define a window for calculation.

> **Notice**
>
> :
>
> If you specify the `DISTINCT` or `UNIQUE` keyword, `order_by_clause` and `windowing_clause` cannot appear in `analytic_clause`.

Return type

The value of the data type same as the data type of `expr` is returned.

Examples

Examples of the analytic function

To create the **employees** table and insert data into the table, execute the following statements:

```
CREATE TABLE employees(manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(300, 'Wei',  '2019-09-11',23600);
INSERT INTO employees VALUES(200, 'Red', '2019-11-05', 23800);
INSERT INTO employees VALUES(100, 'Part',  '2018-10-01',24000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',23500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 23000);
INSERT INTO employees VALUES(200, 'Part',  '2018-06-11',24500);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
COMMIT;
```

To calculate the sum of salaries, execute the following statement:

```
SELECT manager_id, last_name, salary, SUM(salary) OVER (PARTITION BY manager_id
ORDER BY salary RANGE UNBOUNDED PRECEDING) l_csum
FROM employees ORDER BY manager_id, last_name, salary, l_csum;
```

The following query result is returned:

```
+------------+-----------+--------+--------+
| MANAGER_ID | LAST_NAME | SALARY | L_CSUM |
+------------+-----------+--------+--------+
|        100 | De Haan   |  11000 |  12400 |
|        100 | Errazuriz |   1400 |   1400 |
|        100 | Hartstein |  14000 |  26400 |
|        100 | Part      |  24000 |  50400 |
|        200 | Bell      |  23000 |  23000 |
|        200 | Part      |  24500 |  94800 |
|        200 | Red       |  23800 |  70300 |
|        200 | Ross      |  23500 |  46500 |
|        300 | Wei       |  23600 |  23600 |
+------------+-----------+--------+--------+
```

Examples of the aggregate function

To calculate the sum of salaries, execute the following statement:

```
SELECT SUM(salary) FROM employees;
```

The following query result is returned:

```
+-------------+
| SUM(SALARY) |
+-------------+
|      168800 |
+-------------+
```

17.1.5.6.4.5. MAX

The `MAX` function returns the maximum value in the column that is specified by a parameter.

Syntax

```
MAX([ DISTINCT | UNIQUE | ALL ] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
DISTINCT	Removes duplicate rows from returned rows and ignores the rows whose values are NULL.

Parameter	Description
UNIQUE	Removes duplicate rows from returned rows and ignores the rows whose values are NULL.
ALL	Returns all the values, including duplicate rows, and ignores the rows whose values are NULL.
expr	The data column or expression of the numeric type, character type, date type, or other types.
OVER	Uses the `OVER` clause to define a window for calculation.

Return type

The value of the data type same as the data type of `expr` is returned.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT, last_name varchar(50), hiredate varchar(50), SALARY INT);
INSERT INTO employees VALUES(100, 'Wei',  '2019-09-11',17000);
INSERT INTO employees VALUES(100, 'Red', '2019-11-05', 17000);
INSERT INTO employees VALUES(101, 'Part',  '2018-10-01',12008);
INSERT INTO employees VALUES(102, 'Wei',  '2019-09-11',9000);
INSERT INTO employees VALUES(103, 'Red', '2019-11-05', 6000);
INSERT INTO employees VALUES(104, 'Part',  '2018-10-01',8000);
COMMIT;
```

Execute the following statement to query the maximum value in the **SALARY** column:

```
SELECT manager_id, last_name, salary FROM (SELECT manager_id, last_name, salary,
MAX(salary) OVER (PARTITION BY manager_id) AS rmax_sal
FROM employees) WHERE salary = rmax_sal ORDER BY manager_id, last_name, salary;
```

The following query result is returned:

```
+------------+-----------+--------+
| MANAGER_ID | LAST_NAME | SALARY |
+------------+-----------+--------+
|        100 | Red       |  17000 |
|        100 | Wei       |  17000 |
|        101 | Part      |  12008 |
|        102 | Wei       |   9000 |
|        103 | Red       |   6000 |
|        104 | Part      |   8000 |
+------------+-----------+--------+
```

Examples of the aggregate function

Execute the following statement to query the maximum value in the **SALARY** column:

```
SELECT MAX(salary) FROM employees;
```

The following query result is returned:

```
+-------------+
| MAX(SALARY) |
+-------------+
|       17000 |
+-------------+
```

17.1.5.6.4.6. MIN

The `MIN` function returns the minimum value of a specified column.

Syntax

```
MIN([ DISTINCT | UNIQUE | ALL ] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
DISTINCT	Removes duplicate rows from returned rows and ignores the rows whose values are NULL.
UNIQUE	Removes duplicate rows from returned rows and ignores the rows whose values are NULL.
ALL	Returns all the values, including duplicate rows, and ignores the rows whose values are NULL.
expr	The data column or expression of the numeric type, character type, date type, or other types.
OVER	Uses the OVER clause to define a window for calculation.

Return type

The value of the data type same as the data type of `expr` is returned.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
```

Execute the following statement to query the minimum value of the **SALARY** column:

```
SELECT manager_id, last_name, hiredate, salary, MIN(salary) OVER(PARTITION BY manager_id
ORDER BY hiredate RANGE UNBOUNDED PRECEDING) AS p_cmin
FROM employees ORDER BY manager_id, last_name, hiredate, salary;
COMMIT;
```

The following query result is returned:

```
+------------+-----------+------------+--------+--------+
| MANAGER_ID | LAST_NAME | HIREDATE   | SALARY | P_CMIN |
+------------+-----------+------------+--------+--------+
|        100 | De Haan   | 2018-05-01 |  11000 |   1400 |
|        100 | Errazuriz | 2017-07-21 |   1400 |   1400 |
|        100 | Hartstein | 2019-05-01 |  14000 |   1400 |
|        100 | Partners  | 2018-12-01 |  14000 |   1400 |
|        100 | Raphaely  | 2017-07-01 |   1700 |   1700 |
|        100 | Raphaely  | 2017-07-22 |   1700 |   1400 |
|        100 | Russell   | 2019-10-05 |  13000 |   1400 |
|        100 | Weiss     | 2019-07-11 |  13500 |   1400 |
|        200 | Bell      | 2019-05-25 |  13000 |  13000 |
|        200 | Part      | 2018-08-11 |  14000 |  14000 |
|        200 | Ross      | 2019-06-11 |  13500 |  13000 |
+------------+-----------+------------+--------+--------+
```

Examples of the aggregate function

Execute the following statement to query the minimum value of the **SALARY** column:

```
SELECT MIN(salary)  FROM employees ;
```

The following query result is returned:

```
+-------------+
| MIN(SALARY) |
+-------------+
|        1400 |
+-------------+
```

17.1.5.6.4.7. LISTAGG

The `LISTAGG` function converts columns to rows. `LISTAGG` sorts the data in each group that is specified in the `ORDER BY` clause and merges the values of the measure column. When `LISTAGG` serves as a single-set aggregate function, it performs operations on all the rows and returns a single output row. When `LISTAGG` serves as a group-set aggregate, it performs operations on each group that is defined by the `GROUP BY` clause and returns an output row for each group. When `LISTAGG` serves as an analytic function, it divides the query result set into groups based on one or more expressions in `query_partition_clause`.

Syntax

```
LISTAGG(measure_expr [,'delimiter'])WITHIN GROUP (order_by_clause)
[OVER query_partition_clause]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
OVER	Uses the `OVER` clause to define a window for calculation.
measure_expr	The value can be an expression. Null values in the measure column are ignored.
delimiter	The string that is used to separate the measure values. This clause is optional. Default value: NULL.

Return type

If the data type of the measure column is `RAW`, the returned data type is `RAW`. Otherwise, the return value is of the `VARCHAR2` type.

Examples

Examples of the analytic function

To create the **employees** table and insert data into the table, execute the following statements:

```
CREATE TABLE employees (department_id INT,manager_id INT,last_name varchar(50),hiredate varchar(50),S
ALARY INT);
INSERT INTO employees VALUES(30, 100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(30, 100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(40, 100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(50, 100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(50, 100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(70, 100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(90, 100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(90,100, 'Partners',  '2018-12-01',14000);
```

Query the employees that were hired before October 10, 2019, the departments and hire dates of the employees, and the other employees in the departments. Execute the following statement:

```
SELECT department_id "Dept", hiredate "Date", last_name "Name",LISTAGG(last_name, '; ') WITHIN GROUP
(ORDER BY hiredate, last_name) OVER (PARTITION BY department_id) as "Emp_list"
FROM employees WHERE hiredate < '2019-10-10' ORDER BY "Dept", "Date", "Name";
```

The following query result is returned:

```
+------+------------+-----------+--------------------+
| Dept | Date       | Name      | Emp_list           |
+------+------------+-----------+--------------------+
|   30 | 2017-07-01 | Raphaely  | Raphaely; De Haan  |
|   30 | 2018-05-01 | De Haan   | Raphaely; De Haan  |
|   40 | 2017-07-21 | Errazuriz | Errazuriz          |
|   50 | 2017-07-22 | Raphaely  | Raphaely; Hartstein |
|   50 | 2019-05-01 | Hartstein | Raphaely; Hartstein |
|   70 | 2019-07-11 | Weiss     | Weiss              |
|   90 | 2018-12-01 | Partners  | Partners; Russell  |
|   90 | 2019-10-05 | Russell   | Partners; Russell  |
+------+------------+-----------+--------------------+
```

Examples of the aggregate function

To create the **employees** table and insert data into the table, execute the following statements:

```
CREATE TABLE employees (department_id INT,manager_id INT,last_name varchar(50),hiredate varchar(50),S
ALARY INT);
INSERT INTO employees VALUES(30, 100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(30, 100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(30, 100, 'Errazuriz', '2017-07-01', 1400);
INSERT INTO employees VALUES(30, 100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(30, 100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(30, 100, 'Weiss',  '2019-07-01',13500);
INSERT INTO employees VALUES(30, 100, 'Russell', '2019-07-01', 13000);
INSERT INTO employees VALUES(30,100, 'Partners',  '2018-12-01',14000);
```

To query all the employees in the thirtieth department and sort the employees by hire date and last name, execute the following statement:

```
SELECT LISTAGG(last_name, '; ') WITHIN GROUP (ORDER BY hiredate, last_name)  as "Emp_list",
MIN(hiredate) as "Earliest" FROM employees WHERE department_id = 30;
```

The following query result is returned:

```
+--------------------------------------------------------------------------------+------------+
| Emp_list                                                                       | Earliest   |
+--------------------------------------------------------------------------------+------------+
| Errazuriz; Raphaely; Raphaely; De Haan; Partners; Hartstein; Russell; Weiss | 2017-07-01 |
+--------------------------------------------------------------------------------+------------+
```

17.1.5.6.4.8. STDDEV

The `STDDEV` function calculates the population standard deviation. The `STDDEV` function uses numeric data as arguments and returns numeric data. The difference between this function and the `STDDEV_SAMP` function is that if only one row of input data is available, `STDDEV` returns 0 but `STDDEV_SAMP` returns NULL.

In ApsaraDB for OceanBase, the value of the standard deviation is the arithmetic square root of the variance that is calculated by the `VARIANCE` function.

Syntax

```
STDDEV([ DISTINCT | UNIQUE | ALL ] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
DISTINCT	Removes duplicate keywords. This indicates that the population standard deviation of unique values is calculated.
UNIQUE	Removes duplicate keywords. This indicates that the population standard deviation of unique values is calculated.
ALL	All the numeric columns.
expr	The numeric type or the types that can be converted to the numeric type.
OVER	Uses the `OVER` clause to define a window for calculation.

> **Notice**
>
> If you specify the `DISTINCT` or `UNIQUE` keyword, `order_by_clause` and `windowing_clause` cannot appear in `analytic_clause`.

Return type

The data of the `NUMBER` type is returned.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees(manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
COMMIT;
```

Call the function and execute the following statement:

```
SELECT last_name, salary, STDDEV(salary) OVER (ORDER BY hiredate) "StdDev"
FROM employees WHERE manager_id = 100 ORDER BY last_name, salary, "StdDev";
```

The following query result is returned:

```
+-----------+--------+-----------------------------------------+
| LAST_NAME | SALARY | StdDev                                  |
+-----------+--------+-----------------------------------------+
| De Haan   |  11000 | 4702.127178203498995615489088200868644482 |
| Errazuriz |   1400 |  212.132034355964257320253308631454711785 |
| Hartstein |  14000 | 6340.346993658943269176828928801701088079 |
| Partners  |  14000 | 6064.899009876421676804205219406952308814 |
| Raphaely  |   1700 |                                       0 |
| Raphaely  |   1700 |  173.205080756887729352744634150587236694 |
| Russell   |  13000 | 6026.474330580265330900400184969999384459 |
| Weiss     |  13500 | 6244.311697171159907069428668980211861012 |
+-----------+--------+-----------------------------------------+
```

Examples of the aggregate function

Call the function and execute the following statement:

```
SELECT STDDEV(salary) FROM employees WHERE manager_id = 100 ;
```

The following query result is returned:

```
+-----------------------------------------+
| STDDEV(SALARY)                          |
+-----------------------------------------+
| 6026.474330580265330900400184969999384459 |
+-----------------------------------------+
```

17.1.5.6.4.9. STDDEV_POP

The `STDDEV_POP` function calculates population standard deviation. The `STDDEV_POP` function uses numeric data as parameters and returns numeric data.

> **Notice**
> The population standard deviation is the arithmetic square root of a population variance.

Syntax

```
STDDEV_POP([ALL] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
ALL	All the numeric columns.
OVER	Uses the `OVER` clause to define a window for calculation.
expr	The expression of the numeric data types: `NUMBER`, `FLOAT`, `BINARY_FLOAT`, and `BINARY_DOUBLE`.

Return type

The return type is the same as the data type of the `expr` parameter.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
COMMIT;
```

Call the function and execute the following statement:

```
SELECT manager_id, last_name, salary, STDDEV_POP(salary) OVER (PARTITION BY manager_id) AS pop_std
FROM employees ORDER BY manager_id, last_name, salary, pop_std;
```

The following query result is returned:

```
+------------+-----------+--------+-----------------------------------------+
| MANAGER_ID | LAST_NAME | SALARY | POP_STD                                 |
+------------+-----------+--------+-----------------------------------------+
|        100 | De Haan   |  11000 | 5637.250548804798333699350384281939588505 |
|        100 | Errazuriz |   1400 | 5637.250548804798333699350384281939588505 |
|        100 | Hartstein |  14000 | 5637.250548804798333699350384281939588505 |
|        100 | Partners  |  14000 | 5637.250548804798333699350384281939588505 |
|        100 | Raphaely  |   1700 | 5637.250548804798333699350384281939588505 |
|        100 | Raphaely  |   1700 | 5637.250548804798333699350384281939588505 |
|        100 | Russell   |  13000 | 5637.250548804798333699350384281939588505 |
|        100 | Weiss     |  13500 | 5637.250548804798333699350384281939588505 |
|        200 | Bell      |  13000 |  408.248290463863016366214012450981899069 |
|        200 | Part      |  14000 |  408.248290463863016366214012450981899069 |
|        200 | Ross      |  13500 |  408.248290463863016366214012450981899069 |
+------------+-----------+--------+-----------------------------------------+
```

Examples of the aggregate function

Call the function and execute the following statement:

```
SELECT STDDEV_POP(salary) FROM employees ;
```

The following query result is returned:

```
+-----------------------------------------+
| STDDEV_POP(SALARY)                      |
+-----------------------------------------+
| 5249.950806538512715446505486136315088416 |
+-----------------------------------------+
```

17.1.5.6.4.10. STDDEV_SAMP

The `STDDEV_SAMP` function calculates the sample standard deviation. The `STDDEV_SAMP` function uses numeric data as arguments and returns numeric data. The difference between this function and the `STDDEV` function is that if only one row of input data is available, `STDDEV` returns 0 but `STDDEV_SAMP` returns NULL.

> **Note**
> The sample standard deviation is the square root of a sample variance.

Syntax

```
STDDEV_SAMP([ALL] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the OVER keyword.

Parameters

Parameter	Description
ALL	All the numeric columns.
expr	The expression of the numeric types (`NUMBER` , `FLOAT` , `BINARY_FLOAT` , and `BINARY_DOUBLE`) or the data types that can be converted to the numeric types.
OVER	Uses the `OVER` clause to define a window for calculation.

Return type

The return type is the same as the data type of the `expr` parameter.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
COMMIT;
```

Call the function and execute the following statement:

```
SELECT manager_id, last_name, hiredate, salary,STDDEV_SAMP(salary) OVER (PARTITION BY manager_id
ORDER BY hiredate ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) AS cum_sdev
FROM employees ORDER BY manager_id, last_name, hiredate, salary, cum_sdev;
```

The following result is returned:

```
+------------+-----------+------------+--------+-----------------------------------------+
| MANAGER_ID | LAST_NAME | HIREDATE   | SALARY | CUM_SDEV                                |
+------------+-----------+------------+--------+-----------------------------------------+
|        100 | De Haan   | 2018-05-01 |  11000 | 4702.127178203498995615489088200868644482 |
|        100 | Errazuriz | 2017-07-21 |   1400 |  212.13203435596425732025330863145471178 5 |
|        100 | Hartstein | 2019-05-01 |  14000 | 6340.346993658943269176828928801701088079 |
|        100 | Partners  | 2018-12-01 |  14000 | 6064.899009876421676804205219406952308814 |
|        100 | Raphaely  | 2017-07-01 |   1700 |                                    NULL |

|        200 | Part      | 2018-08-11 |  14000 |                                    NULL |
|        200 | Ross      | 2019-06-11 |  13500 |                                     500 |
+------------+-----------+------------+--------+-----------------------------------------+
```

Examples of the aggregate function

Call the function and execute the following statement:

```
SELECT STDDEV_SAMP(salary) FROM employees ;
```

The following query result is returned:

```
+-----------------------------------------+
| STDDEV_SAMP(SALARY)                     |
+-----------------------------------------+
| 5506.194858355615640082358245403620332764 |
+-----------------------------------------+
```

17.1.5.6.4.11. VARIANCE

The `VARIANCE` function returns the variance of the column that is specified by a parameter.

Syntax

```
VARIANCE([ DISTINCT | UNIQUE | ALL ] expr) [ OVER (analytic_clause) ]
```

If the function is used as an analytic function, you must use the full syntax of a window function. The function calculates a set of rows and returns multiple values. If the function is used as an aggregate function, the function aggregates a set of rows and returns only one value. In this case, you do not need to add the `OVER` keyword.

Parameters

Parameter	Description
DISTINCT	Removes duplicate values from the column and ignores NULL values in the column during the query.
UNIQUE	Removes duplicate values from the column and ignores NULL values in the column during the query.
ALL	Retains duplicate values in the column and ignores NULL values in the column during the query. Default value: `ALL`.
expr	The data column or expression of the numeric type, character type, date type, or other types.
OVER	Uses the `OVER` clause to define a window for calculation.

Notice

If you specify the `DISTINCT` or `UNIQUE` keyword, `order_by_clause` and `windowing_clause` cannot appear in `analytic_clause`.

Return type

The data of the `NUMBER` type is returned.

Examples

Examples of the analytic function

The following statements create the **employees** table and insert data into the table:

```
CREATE TABLE employees (manager_id INT,last_name varchar(50),hiredate varchar(50),SALARY INT);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-01', 1700);
INSERT INTO employees VALUES(100, 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Errazuriz', '2017-07-21', 1400);
INSERT INTO employees VALUES(100, 'Hartstein', '2019-05-01',14000);
INSERT INTO employees VALUES(100, 'Raphaely', '2017-07-22', 1700);
INSERT INTO employees VALUES(100, 'Weiss',  '2019-07-11',13500);
INSERT INTO employees VALUES(100, 'Russell', '2019-10-05', 13000);
INSERT INTO employees VALUES(100, 'Partners',  '2018-12-01',14000);
INSERT INTO employees VALUES(200, 'Ross',  '2019-06-11',13500);
INSERT INTO employees VALUES(200, 'Bell', '2019-05-25', 13000);
INSERT INTO employees VALUES(200, 'Part',  '2018-08-11',14000);
COMMIT;
```

Execute the following statement to calculate the variance of the **salary** column:

```
SELECT last_name, salary, VARIANCE(salary)  OVER (ORDER BY hiredate) "Variance"
FROM employees WHERE manager_id = 100 ORDER BY last_name, salary, "Variance";
```

The following query result is returned:

```
+-----------+--------+-----------------------------------------+
| LAST_NAME | SALARY | Variance                                |
+-----------+--------+-----------------------------------------+
| De Haan   |  11000 |                                22110000 |
| Errazuriz |   1400 |                                   45000 |
| Hartstein |  14000 |                                40200000 |
| Partners  |  14000 |                                36783000 |
| Raphaely  |   1700 |                                       0 |
| Raphaely  |   1700 |                                   30000 |
| Russell   |  13000 | 36318392.857142857142857142857142857286 |
| Weiss     |  13500 | 38991428.571428571428571428571428571857 |
+-----------+--------+-----------------------------------------+
```

Examples of the aggregate function

Execute the following statement to calculate the variance of the **salary** column:

```
SELECT VARIANCE(salary)  FROM employees;
```

The following query result is returned:

```
+----------------------------------------+
| VARIANCE(SALARY)                       |
+----------------------------------------+
| 30318181.818181818181818181818181818182 |
+----------------------------------------+
```

17.1.5.6.4.12. RANK

The `RANK` function determines the rank of a group of values based on the `ORDER BY` expression in the `OVER` clause. If the same sort values are available, the same rank is generated, and the number of rows that have the same values is recorded to the next rank.

Syntax

```
RANK()  OVER ( [ PARTITION BY expr_list ] [ ORDER BY order_list ])
```

Parameters

Parameter	Description
OVER	Uses the `OVER` clause to define a window for calculation.
PARTITION BY [col1, col2..]	Specifies the column for which the window is opened.
ORDER BY col1[asc|desc]	Specifies the value by which data is ranked.
expr_list	The numeric type or the types that can be converted to the numeric type.
order_list	Defines the data column based on which values are ranked.

Examples

To create the **course** table and insert data into the **name** and **grade** columns, execute the following statements:

```
CREATE TABLE course
(
  name VARCHAR(8),
  grade NUMBER
);
INSERT INTO course VALUES('Linda',50);
INSERT INTO course VALUES('Tan',85);
INSERT INTO course VALUES('Tom',90);
INSERT INTO course VALUES('John',95);
INSERT INTO course VALUES('Mery',55);
INSERT INTO course VALUES('Peter',60);
INSERT INTO course VALUES('Jack',65);
INSERT INTO course VALUES('Rose',70);
INSERT INTO course VALUES('Tonny',75);
INSERT INTO course VALUES('Apple',80);
COMMIT;
```

Execute the following statement:

```
SELECT name,grade ,RANK() over(ORDER BY grade DESC) FROM course;
```

The following query result is returned:

```
+-------+-------+------------------------------+
| NAME  | GRADE | RANK()OVER(ORDERBYGRADEDESC) |
+-------+-------+------------------------------+
| John  |    95 |                            1 |
| Tom   |    90 |                            2 |
| Tan   |    85 |                            3 |
| Apple |    80 |                            4 |
| Tonny |    75 |                            5 |
| Rose  |    70 |                            6 |
| Jack  |    65 |                            7 |
| Peter |    60 |                            8 |
| Mery  |    55 |                            9 |
| Linda |    50 |                           10 |
+-------+-------+------------------------------+
```

17.1.5.6.4.13. LEAD

`LEAD` is an analytic function. It provides access to multiple rows of a table without a self join. Given a series of rows that are returned from a query and a cursor position, `LEAD` provides access to a row at a physical offset beyond this position.

Syntax

```
LEAD { (value_expr [,offset [,default]]) [RESPECT|IGNORE] NULLS
|(value_expr [RESPECT|IGNORE] NULLS [,offset [,default]]) }
OVER([query_partition_clause] order_by_clause)
```

Parameters

Parameter	Description
OVER	Uses the `OVER` clause to define a window for calculation.
offset	The offset of value_expr. This parameter is optional.
default	If you do not specify the default value, the default value is `null`. If the default value is not explicitly specified in `LEAD`, the return value is `NULL`.
{RESPECT | IGNORE} NULLS	Specifies whether to ignore `NULL` values. The default value is `RESPECT NULLS` and indicates that `NULL` values are taken into consideration.

Parameter	Description
value_expr	The field to be compared. You cannot use the `LEAD` function or other analytic functions to nest `value_expr`.

> **Notice**
>
> The `LEAD` function must be followed by order_by_clause. query_partition_clause is optional.

Return type

The returned data type is not limited.

Examples

To create the **emp_msg** table and insert data into columns, execute the following statements:

```
CREATE TABLE emp_msg(deptno INT, ename VARCHAR(30),sal INT);
INSERT INTO emp_msg VALUES(20,'ADAMS',1400);
INSERT INTO emp_msg VALUES(30,'ALLEN',1900);
INSERT INTO emp_msg VALUES(30,'BLAKE',3135);
INSERT INTO emp_msg VALUES(10,'CLARK',2750);
INSERT INTO emp_msg VALUES(20,'FORD',3300);
INSERT INTO emp_msg VALUES(30,'JAMES',1250);
INSERT INTO emp_msg VALUES(20,'JONES',3275);
INSERT INTO emp_msg VALUES(10,'KING',5300);
INSERT INTO emp_msg VALUES(30,'MARTIN',1550);
INSERT INTO emp_msg VALUES(10,'MILLER',1600);
INSERT INTO emp_msg VALUES(20,'SCOTT',3300);
INSERT INTO emp_msg VALUES(20,'SWITH',1100);
INSERT INTO emp_msg VALUES(30,'TURNER',1800);
INSERT INTO emp_msg VALUES(30,'WARD',1550);
```

Query the **emp_msg** table. Replace the last five values with **Jane**. Start to append the values that are sorted by the **ename** field in ascending order from the last but five value.

```
SELECT  deptno, ename, sal, LEAD(ename,5,'Jane') OVER (ORDER BY ename) AS new_ename
FROM emp_msg;
```

The following query result is returned:

```
+--------+--------+------+-----------+
| DEPTNO | ENAME  | SAL  | NEW_ENAME |
+--------+--------+------+-----------+
|     20 | ADAMS  | 1400 | JAMES     |
|     30 | ALLEN  | 1900 | JONES     |
|     30 | BLAKE  | 3135 | KING      |
|     10 | CLARK  | 2750 | MARTIN    |
|     20 | FORD   | 3300 | MILLER    |
|     30 | JAMES  | 1250 | SCOTT     |
|     20 | JONES  | 3275 | SWITH     |
|     10 | KING   | 5300 | TURNER    |
|     30 | MARTIN | 1550 | WARD      |
|     10 | MILLER | 1600 | Jane      |
|     20 | SCOTT  | 3300 | Jane      |
|     20 | SWITH  | 1100 | Jane      |
|     30 | TURNER | 1800 | Jane      |
|     30 | WARD   | 1550 | Jane      |
+--------+--------+------+-----------+
```

17.1.5.6.4.14. LAG

`LAG` is an analytic function. It provides access to a multi-row table at the same time without a self join. Given a series of rows that are returned from a query and a cursor position, `LAG` can access a row at a given physical offset prior to the position. You can specify the offset parameter as an integer that is greater than zero. If you do not specify an offset, its default value is 1. If the offset exceeds the scope of the window, an optional value is returned. If you do not specify the default value, the default value is `NULL`.

Syntax

```
LAG { (value_expr [,offset [,default]]) [RESPECT|IGNORE] NULLS
|(value_expr [RESPECT | IGNORE] NULLS [,offset [,default] ]) }
OVER([query_partition_clause] order_by_clause)
```

Parameters

Parameter	Description
value_expr	The field to be compared. You cannot use the `LAG` function or other analytic functions to nest `value_expr`.
offset	The offset of value_expr. This parameter is optional.
default	If you do not specify the default value, the default value is `NULL`. If the default value is not explicitly specified in `LAG`, the return value is `NULL`.

Parameter	Description
{RESPECT | IGNORE} NULLS	Specifies whether to ignore `NULL` values. The default value is `RESPECT NULLS` and indicates that `NULL` values are taken into consideration.
OVER	Uses the OVER clause to define a window for calculation.

Notice

The `LAG` function must be followed by order_by_clause. query_partition_clause is optional.

Return type

The data type of the return value is not limited.

Examples

To create the **emp_msg** table and insert data into the table, execute the following statements:

```
CREATE TABLE emp_msg(deptno INT, ename varchar(30),sal INT);
INSERT INTO emp_msg VALUES(20,'ADAMS',1400);
INSERT INTO emp_msg VALUES(30,'ALLEN',1900);
INSERT INTO emp_msg VALUES(30,'BLAKE',3135);
INSERT INTO emp_msg VALUES(10,'CLARK',2750);
INSERT INTO emp_msg VALUES(20,'FORD',3300);
INSERT INTO emp_msg VALUES(30,'JAMES',1250);
INSERT INTO emp_msg VALUES(20,'JONES',3275);
INSERT INTO emp_msg VALUES(10,'KING',5300);
INSERT INTO emp_msg VALUES(30,'MARTIN',1550);
INSERT INTO emp_msg VALUES(10,'MILLER',1600);
INSERT INTO emp_msg VALUES(20,'SCOTT',3300);
INSERT INTO emp_msg VALUES(20,'SWITH',1100);
INSERT INTO emp_msg VALUES(30,'TURNER',1800);
INSERT INTO emp_msg VALUES(30,'WARD',1550);
```

Query the **emp_msg** table. Replace the last five values with **Jane**. Start to append the values that are sorted by the **ename** field in ascending order from the last but five value. Execute the following statement:

```
SELECT deptno, ename, sal, LAG(ename,5,'Jane') OVER (ORDER BY ename) AS new_ename
FROM emp_msg;
```

The following query result is returned:

```
+--------+--------+------+-----------+
| DEPTNO | ENAME  | SAL  | NEW_ENAME |
+--------+--------+------+-----------+
|     20 | ADAMS  | 1400 | Jane      |
|     30 | ALLEN  | 1900 | Jane      |
|     30 | BLAKE  | 3135 | Jane      |
|     10 | CLARK  | 2750 | Jane      |
|     20 | FORD   | 3300 | Jane      |
|     30 | JAMES  | 1250 | ADAMS     |
|     20 | JONES  | 3275 | ALLEN     |
|     10 | KING   | 5300 | BLAKE     |
|     30 | MARTIN | 1550 | CLARK     |
|     10 | MILLER | 1600 | FORD      |
|     20 | SCOTT  | 3300 | JAMES     |
|     20 | SWITH  | 1100 | JONES     |
|     30 | TURNER | 1800 | KING      |
|     30 | WARD   | 1550 | MARTIN    |
+--------+--------+------+-----------+
```

17.1.5.6.4.15. FIRST_VALUE

`FIRST_VALUE` is an analytic function. It returns the first value in a set of the ordered values. If the first value in the set is `NULL`, the function returns `NULL` unless you specify `IGNORE NULLS`. This configuration is useful for data densification.

Syntax

```
FIRST_VALUE { (expr) [ {RESPECT | IGNORE} NULLS ] | (expr [ {RESPECT | IGNORE} NULLS ]) } OVER (analytic_clause)
```

Parameters

Parameter	Description
expr	The parameter type is not limited.
OVER	Uses the `OVER` clause to define a window for calculation.
{RESPECT | IGNORE} NULLS	Specifies whether to ignore `NULL` values. The default value is `RESPECT NULLS` and indicates that `NULL` values are taken into consideration.

Parameter	Description
FROM { FIRST | LAST }	Specifies whether the calculation starts from the first or last row of the window. The default value is `FROM FIRST`. If you specify `IGNORE NULLS`, `FIRST_VALUE` returns the first non-null value in the set. If all the values are `NULL`, `NULL` is returned.

Return type

The data type is not limited.

Examples

To create the **emp_msg** table and insert data into the table, execute the following statements:

```
CREATE TABLE emp_msg(deptno INT, ename VARCHAR(30), sal INT, MGR VARCHAR(30));
INSERT INTO emp_msg VALUES(10,'CLARK', 2750, 7839);
INSERT INTO emp_msg VALUES(10,'KING', 5300, NULL);
INSERT INTO emp_msg VALUES(10,'MILLER', 1600, 7782);
INSERT INTO emp_msg VALUES(20,'ADAMS', 1400, 7788);
INSERT INTO emp_msg VALUES(20,'FORD', 3300, 7566);
INSERT INTO emp_msg VALUES(20,'JONES', 3275, 7839);
INSERT INTO emp_msg VALUES(20,'SCOTT', 3300, 7566);
INSERT INTO emp_msg VALUES(20,'SMITH', 1100, 7902);
INSERT INTO emp_msg VALUES(30,'ALLEN', 1900, 7698);
INSERT INTO emp_msg VALUES(30,'BLAKE', 3150, 7839);
INSERT INTO emp_msg VALUES(30,'JAMES', 1250, 7698);
INSERT INTO emp_msg VALUES(30,'MARTIN', 1550, 7698);
INSERT INTO emp_msg VALUES(30,'TURNER', 1800, 7698);
INSERT INTO emp_msg VALUES(30,'WARD', 1550, 7698);
```

Query the highest and the first non-null **MGR** value in the **sal** column in the **emp_msg** table and use the queried value as the **first_MGR** column.

```
SELECT deptno , ename , sal , MGR ,
FIRST_VALUE ( MGR ) IGNORE NULLS over ( ORDER BY sal DESC ROWS UNBOUNDED PRECEDING ) AS first_MGR
FROM emp_msg ORDER BY deptno , ename;
```

The following query result is returned:

```
+--------+--------+------+------+-----------+
| DEPTNO | ENAME  | SAL  | MGR  | FIRST_MGR |
+--------+--------+------+------+-----------+
|     10 | CLARK  | 2750 | 7839 | 7566      |
|     10 | KING   | 5300 | NULL | NULL      |
|     10 | MILLER | 1600 | 7782 | 7566      |
|     20 | ADAMS  | 1400 | 7788 | 7566      |
|     20 | FORD   | 3300 | 7566 | 7566      |
|     20 | JONES  | 3275 | 7839 | 7566      |
|     20 | SCOTT  | 3300 | 7566 | 7566      |
|     20 | SMITH  | 1100 | 7902 | 7566      |
|     30 | ALLEN  | 1900 | 7698 | 7566      |
|     30 | BLAKE  | 3150 | 7839 | 7566      |
|     30 | JAMES  | 1250 | 7698 | 7566      |
|     30 | MARTIN | 1550 | 7698 | 7566      |
|     30 | TURNER | 1800 | 7698 | 7566      |
|     30 | WARD   | 1550 | 7698 | 7566      |
+--------+--------+------+------+-----------+
```

17.1.5.6.4.16. LAST_VALUE

The `LAST_VALUE` function is an analytic function. It returns the last value in a set of the ordered values. If the last value in the set is `NULL`, the function returns `NULL` unless you specify `IGNORE NULLS`. This configuration is useful for data densification.

Syntax

```
LAST_VALUE {(expr) [RESPECT|IGNORE NULLS] | (expr [RESPECT|IGNORE NULLS])}
OVER (analytic_clause)
```

Parameters

Parameter	Description
OVER	Uses the `OVER` clause to define a window for calculation.
expr	You cannot use `LAST_VALUE` or other analytic functions for `expr` to nest analytic functions.
FROM { FIRST | LAST }	Specifies whether the calculation starts from the first or last row of the window. The default value is `FROM FIRST`.

Parameter	Description
{RESPECT | IGNORE} NULLS	Specifies whether to ignore `NULL` values. The default value is `RESPECT NULLS` and indicates that `NULL` values are taken into consideration. If you specify `IGNORE NULLS`, `LAST_VALUE` returns the last non-null value in the set. If all the values are `NULL`, `NULL` is returned.

Return type

The data type of the return value is not limited.

Examples

To create the **emp_msg** table and insert data into the table, execute the following statements:

```
CREATE TABLE emp_msg(deptno INT, ename varchar(30),sal INT, MGR varchar(30));
INSERT INTO emp_msg VALUES(10,'CLARK', 2750, 7839);
INSERT INTO emp_msg VALUES(10,'KING', 5300, NULL);
INSERT INTO emp_msg VALUES(10,'MILLER', 1600, 7782);
INSERT INTO emp_msg VALUES(20,'ADAMS', 1400, 7788);
INSERT INTO emp_msg VALUES(20,'FORD', 3300, 7566);
INSERT INTO emp_msg VALUES(20,'JONES', 3275, 7839);
INSERT INTO emp_msg VALUES(20,'SCOTT', 3300, 7566);
INSERT INTO emp_msg VALUES(20,'SMITH', 1100, 7902);
INSERT INTO emp_msg VALUES(30,'ALLEN', 1900, 7698);
INSERT INTO emp_msg VALUES(30,'BLAKE', 3150, 7839);
INSERT INTO emp_msg VALUES(30,'JAMES', 1250, 7698);
INSERT INTO emp_msg VALUES(30,'MARTIN', 1550, 7698);
INSERT INTO emp_msg VALUES(30,'TURNER', 1800, 7698);
INSERT INTO emp_msg VALUES(30,'WARD', 1550, 7698);
```

To query the lowest and the last non-null **MGR** value in the **sal** column in the **emp_msg** table and use the queried value as the **last_MGR** column, execute the following statement:

```
SELECT deptno , ename , sal , MGR ,
LAST_VALUE ( MGR ) IGNORE NULLS OVER (ORDER BY sal DESC ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDE
D FOLLOWING ) AS last_MGR
FROM emp_msg ORDER BY deptno , ename ;
```

The following query result is returned:

```
+--------+--------+------+------+-----------+
| DEPTNO | ENAME  | SAL  | MGR  | FIRST_MGR |
+--------+--------+------+------+-----------+
|     10 | CLARK  | 2750 | 7839 | 7839      |
|     10 | KING   | 5300 | NULL | NULL      |
|     10 | MILLER | 1600 | 7782 | 7782      |
|     20 | ADAMS  | 1400 | 7788 | 7788      |
|     20 | FORD   | 3300 | 7566 | 7566      |
|     20 | JONES  | 3275 | 7839 | 7839      |
|     20 | SCOTT  | 3300 | 7566 | 7566      |
|     20 | SMITH  | 1100 | 7902 | 7902      |
|     30 | ALLEN  | 1900 | 7698 | 7698      |
|     30 | BLAKE  | 3150 | 7839 | 7839      |
|     30 | JAMES  | 1250 | 7698 | 7698      |
|     30 | MARTIN | 1550 | 7698 | 7698      |
|     30 | TURNER | 1800 | 7698 | 7698      |
|     30 | WARD   | 1550 | 7698 | 7698      |
+--------+--------+------+------+-----------+
```

17.1.5.6.4.17. NTH_VALUE

`NTH_VALUE` returns the value of `measure_expr` in the `n` th row of the window that is defined by `analytic_clause`. The return value is of the data type of `measure_expr`.

Syntax

```
NTH_VALUE (measure_expr, n) [ FROM { FIRST | LAST } ][ { RESPECT | IGNORE } NULLS ] OVER (analytic_clause)
```

Parameters

Parameter	Description
OVER	Uses the `OVER` clause to define a window for calculation.
measure_expr	The field name.
n	n is a positive number and determines the nth row for which the measurement value is to be returned. If n is NULL, the function returns an error. If n is greater than the number of all the rows in the window, the function returns NULL.

Parameter	Description
FROM { FIRST | LAST }	Specifies whether the calculation starts from the first or last row of the window. The default value is `FROM FIRST`.
{RESPECT | IGNORE} NULLS	Specifies whether to ignore `NULL` values. The default value is `RESPECT NULLS` and indicates that `NULL` values are taken into consideration.

Return type

The data type of the return value is not limited.

Examples

To create the **emp_msg** table and insert data into the table, execute the following statements:

```
CREATE TABLE emp_msg(deptno INT, ename VARCHAR(30),sal INT, MGR VARCHAR(30), hiredate VARCHAR(50));
INSERT INTO emp_msg VALUES(10,'CLARK', 2750, 7839, '2018-05-01');
INSERT INTO emp_msg VALUES(10,'KING', 5300, NULL, '2018-05-10');
INSERT INTO emp_msg VALUES(10,'MILLER', 1600, 7782, '2018-06-01');
INSERT INTO emp_msg VALUES(20,'ADAMS', 1400, 7788, '2018-05-21');
INSERT INTO emp_msg VALUES(20,'FORD', 3300, 7566, '2018-06-01');
INSERT INTO emp_msg VALUES(20,'JONES', 3275, 7839, '2018-06-20');
INSERT INTO emp_msg VALUES(20,'SCOTT', 3300, 7566, '2018-07-01');
INSERT INTO emp_msg VALUES(20,'SMITH', 1100, 7902, '2018-07-10');
INSERT INTO emp_msg VALUES(30,'ALLEN', 1900, 7698, '2018-08-05');
INSERT INTO emp_msg VALUES(30,'BLAKE', 3150, 7839, '2018-06-10');
INSERT INTO emp_msg VALUES(30,'JAMES', 1250, 7698, '2018-09-05');
INSERT INTO emp_msg VALUES(30,'MARTIN', 1550, 7698, '2018-10-01');
INSERT INTO emp_msg VALUES(30,'TURNER', 1800, 7698, '2019-05-01');
INSERT INTO emp_msg VALUES(30,'WARD', 1550, 7698, '2019-05-10');
```

Group data by department **deptno** and query the result of the comparison between the salaries of personnel in each department and the salary amount that ranks third in this department. Execute the following statement:

```
SELECT deptno, ename, sal, nth_value(sal, 3) OVER (PARTITION BY deptno ORDER BY sal DESC
rows BETWEEN unbounded preceding AND unbounded following)  AS third_most_sal
FROM emp_msg ORDER BY deptno,sal DESC;
```

The following query result is returned:

```
+--------+--------+------+----------------+
| DEPTNO | ENAME  | SAL  | THIRD_MOST_SAL |
+--------+--------+------+----------------+
|     10 | KING   | 5300 |           1600 |
|     10 | CLARK  | 2750 |           1600 |
|     10 | MILLER | 1600 |           1600 |
|     20 | FORD   | 3300 |           3275 |
|     20 | SCOTT  | 3300 |           3275 |
|     20 | JONES  | 3275 |           3275 |

+--------+--------+------+----------------+
```

17.1.5.6.4.18. CUME_DIST

The `CUME_DIST` function calculates the cumulative distribution of a value in a group of values. The range of the return value is `0 < CUME_DIST <= 1` Tie values always evaluate to the same cumulative distribution value. This function uses the numeric or non-numeric data types that can be implicitly converted to numeric data types as parameters. ApsaraDB for OceanBase determines the parameter that has the highest numeric precedence, implicitly converts the remaining parameters to that data type, performs calculations, and returns `NUMBER`.

`CUME_DIST` that serves as an analytic function calculates the relative position of a specified value in a group of values. Assume that the ascending order is used for row r. The cume_dist of r is obtained by dividing the number of rows whose values are less than or equal to the value of r by the number of the calculated rows (the entire query result set or a partition).

Syntax

```
CUME_DIST() OVER ([ query_partition_clause ] order_by_clause)
```

Parameters

Parameter	Description
expr	The expression of the `NUMBER` type or the types that can be implicitly converted to the `NUMBER` data type.

Parameter	Description
{RESPECT | IGNORE} NULLS	Specifies whether to ignore `NULL` values. The default value is `RESPECT NULLS` and indicates that `NULL` values are taken into consideration.

Return type

The return value is of the `NUMBER` data type.

Examples

To create the **emp_msg** table and insert data into the table, execute the following statements:

```
CREATE TABLE emp_msg(deptno INT, ename varchar(30), sal INT, MGR varchar(30));
INSERT INTO emp_msg VALUES(10,'CLARK', 2750, 7839);
INSERT INTO emp_msg VALUES(10,'KING', 5300, NULL);
INSERT INTO emp_msg VALUES(10,'MILLER', 1600, 7782);
INSERT INTO emp_msg VALUES(20,'ADAMS', 1400, 7788);
INSERT INTO emp_msg VALUES(20,'FORD', 3300, 7566);
INSERT INTO emp_msg VALUES(20,'JONES', 3275, 7839);
INSERT INTO emp_msg VALUES(20,'SCOTT', 3300, 7566);
INSERT INTO emp_msg VALUES(20,'SMITH', 1100, 7902);
INSERT INTO emp_msg VALUES(30,'ALLEN', 1900, 7698);
INSERT INTO emp_msg VALUES(30,'BLAKE', 3150, 7839);
INSERT INTO emp_msg VALUES(30,'JAMES', 1250, 7698);
INSERT INTO emp_msg VALUES(30,'MARTIN', 1550, 7698);
INSERT INTO emp_msg VALUES(30,'TURNER', 1800, 7698);
INSERT INTO emp_msg VALUES(30,'WARD', 1550, 7698);
```

To return the `CUME_DIST` value of the specified column **sal** in the same **deptno**, execute the following statement:

```
SELECT deptno , ename , sal, cume_dist ( ) over ( partition BY deptno ORDER BY sal DESC ) "RANK"
FROM emp_msg WHERE sal>2000;
```

The following query result is returned:

```
+--------+-------+------+-------------------------------------------+
| DEPTNO | ENAME | SAL  | RANK                                      |
+--------+-------+------+-------------------------------------------+
|     10 | KING  | 5300 |                                        .5 |
|     10 | CLARK | 2750 |                                         1 |
|     20 | FORD  | 3300 | .666666666666666666666666666666666666667 |
|     20 | SCOTT | 3300 | .666666666666666666666666666666666666667 |
|     20 | JONES | 3275 |                                         1 |
|     30 | BLAKE | 3150 |                                         1 |
+--------+-------+------+-------------------------------------------+
```

17.1.5.6.4.19. DENSE_RANK

`DENSE_RANK` calculates the rank of a row in an ordered group of rows and returns the rank as `NUMBER`. Ranks are consecutive integers that start from 1. The maximum rank value is the number of unique values that are returned by the query. Rank values are not skipped in the case of ties. The rows that have same values for the ranking criteria receive the same rank. This function is useful for top-N and bottom-N reporting.

When `DENSE_RANK` serves as an analytic function, it calculates the rank of each row that is returned by the query among other rows based on the value of `value_exprs` in `order_by_clause`.

Syntax

```
DENSE_RANK( ) OVER([ query_partition_clause ] order_by_clause)
```

Parameters

Parameter	Description
OVER	Uses the `OVER` clause to define a window for calculation.

Return type

The return value is of the `NUMBER` data type.

Examples

To create the **emp_msg** table and insert data into the table, execute the following statements:

```
CREATE TABLE emp_msg(deptno INT, ename varchar(30), sal INT, MGR varchar(30));
INSERT INTO emp_msg VALUES(10,'CLARK', 2750, 7839);
INSERT INTO emp_msg VALUES(10,'KING', 5300, NULL);
INSERT INTO emp_msg VALUES(10,'MILLER', 1600, 7782);
INSERT INTO emp_msg VALUES(20,'ADAMS', 1400, 7788);
INSERT INTO emp_msg VALUES(20,'FORD', 3300, 7566);
INSERT INTO emp_msg VALUES(20,'JONES', 3275, 7839);
INSERT INTO emp_msg VALUES(20,'SCOTT', 3300, 7566);
INSERT INTO emp_msg VALUES(20,'SMITH', 1100, 7902);
INSERT INTO emp_msg VALUES(30,'ALLEN', 1900, 7698);
INSERT INTO emp_msg VALUES(30,'BLAKE', 3150, 7839);
INSERT INTO emp_msg VALUES(30,'JAMES', 1250, 7698);
INSERT INTO emp_msg VALUES(30,'MARTIN', 1550, 7698);
INSERT INTO emp_msg VALUES(30,'TURNER', 1800, 7698);
INSERT INTO emp_msg VALUES(30,'WARD', 1550, 7698);
```

The following example shows the analytic function feature. Execute the following statement:

```
SELECT deptno, ename, sal, DENSE_RANK ( ) OVER ( partition BY deptno ORDER BY sal DESC ) "RANK"
FROM emp_msg WHERE sal>2000;
```

The following query result is returned:

```
+--------+-------+------+------+
| DEPTNO | ENAME | SAL  | RANK |
+--------+-------+------+------+
|     10 | KING  | 5300 |    1 |
|     10 | CLARK | 2750 |    2 |
|     20 | SCOTT | 3300 |    1 |
|     20 | FORD  | 3300 |    1 |
|     20 | JONES | 3275 |    2 |
|     30 | BLAKE | 3150 |    1 |
+--------+-------+------+------+
```

17.1.5.6.4.20. NTILE

The `NTILE` function divides an ordered dataset into a number of buckets that are indicated by `expr` and assigns an appropriate bucket number to each row. The bucket number ranges from 1 to `expr`. For each partition, the value of `expr` must be resolved to a positive constant. If `expr` is a non-integer constant, ApsaraDB for OceanBase truncates this value to an integer. The return value is `NUMBER`.

The number of rows in the buckets can differ by at most 1. Each bucket is assigned with a remainder value (the remainder of the number of rows divided by the number of buckets). This starts from bucket 1. If `expr` is greater than the number of rows, a number of buckets equal to the number of rows are filled and the remaining buckets are empty.

You cannot use `NTILE` or other analytic functions to nest analytic functions. However, you can use other built-in function expressions in `expr`.

Syntax

```
NTILE(expr) OVER ([query_partition_clause] order_by_clause)
```

Parameters

Parameter	Description
expr	The value can be only a positive constant.
OVER	Uses the `OVER` clause to define a window for calculation.

Return type

Data of the `NUMERIC` type is returned.

Examples

Categorize students to four levels based on scores to determine awards for students. To create the **course** table and insert data into the table, execute the following statements:

```
CREATE TABLE course
(
  name VARCHAR(8),
  grade NUMBER
);
INSERT INTO course VALUES('Linda',50);
INSERT INTO course VALUES('Tan',85);
INSERT INTO course VALUES('Tom',90);
INSERT INTO course VALUES('John',95);
INSERT INTO course VALUES('Mery',55);
INSERT INTO course VALUES('Peter',60);
INSERT INTO course VALUES('Jack',65);
INSERT INTO course VALUES('Rose',70);
INSERT INTO course VALUES('Tonny',75);
INSERT INTO course VALUES('Apple',80);
COMMIT;
```

Execute the following statement:

```
SELECT name, grade, ntile(4) OVER (ORDER BY grade DESC) til FROM course;
```

The following query result is returned:

```
+-------+-------+------+
| NAME  | GRADE | TIL  |
+-------+-------+------+
| John  |    95 |    1 |
| Tom   |    90 |    1 |
| Tan   |    85 |    1 |
| Apple |    80 |    2 |
| Tonny |    75 |    2 |
| Rose  |    70 |    2 |
| Jack  |    65 |    3 |
| Peter |    60 |    3 |
| Mery  |    55 |    4 |
| Linda |    50 |    4 |
+-------+-------+------+
```

17.1.5.6.4.21. PERCENT_RANK

The `PERCENT_RANK` function is similar to the `CUME_DIST` (cumulative distribution) function. The return value ranges from 0 to 1. The `PERCENT_RANK` function of the first row in a set is 0. The return value is `NUMBER`.

Syntax

```
PERCENT_RANK( ) OVER ([query_partition_clause] order_by_clause)
```

Parameters

Parameter	Description

Parameter	Description
OVER	Uses the `OVER` clause to define a window for calculation.

Return type

The numeric data type is returned.

Examples

Categorize students to four levels based on scores to determine the awards for the students. To create the **course_rank** table and insert data into the table, execute the following statements:

```
CREATE TABLE course_rank
(
  name VARCHAR(8),
    id NUMBER
);
INSERT INTO course_rank VALUES('Linda',1);
INSERT INTO course_rank VALUES('Tan',2);
INSERT INTO course_rank VALUES('Tom',3);
INSERT INTO course_rank VALUES('John',4);
INSERT INTO course_rank VALUES('Mery',5);
COMMIT;
```

Execute the following statement:

```
SELECT name, id ,percent_rank() OVER (ORDER BY id) AS pr1 FROM course_rank;
```

The following query result is returned:

```
+-------+------+------+
| NAME  | ID   | PR1  |
+-------+------+------+
| Linda |    1 |    0 |
| Tan   |    2 |  .25 |
| Tom   |    3 |   .5 |
| John  |    4 |  .75 |
| Mery  |    5 |    1 |
+-------+------+------+
```

17.1.5.6.4.22. RATIO_TO_REPORT

The `RATIO_TO_REPORT` function calculates the ratio of a value to the sum of a group of values.

Syntax

```
RATIO_TO_REPORT(expr) OVER ([query_partition_clause])
```

Parameter

Parameter	Description
expr	The value can be only a positive constant.
OVER	Uses the `OVER` clause to define a window for calculation.

Return type

The numeric data is returned.

Examples

The following example shows the ratio of the output of employees to the total output of the department. To create the **product** table and insert data into the data, execute the following statements:

```
CREATE TABLE product (name VARCHAR(8), deptno NUMBER, output NUMBER);
INSERT INTO product VALUES('Linda',100,5050);
INSERT INTO product VALUES('Tan',1001,8500);
INSERT INTO product VALUES('Tom',1001,3900);
INSERT INTO product VALUES('John',100,29500);
INSERT INTO product VALUES('Mery',1001,1500);
INSERT INTO product VALUES('Peter',100,1060);
COMMIT;
```

Execute the following statement:

```
SELECT name, OUTPUT, deptno, RATIO_TO_REPORT(output) OVER (partition BY deptno) FROM product;
```

The following query result is returned:

```
+-------+--------+--------+-----------------------------------------------+
| NAME  | OUTPUT | DEPTNO | RATIO_TO_REPORT(OUTPUT)OVER(PARTITIONBYDEPTNO) |
+-------+--------+--------+-----------------------------------------------+
| Linda |   5050 |    100 |      .141814097163718056725638865487222690255 |
| John  |  29500 |    100 |      .828418983431620331367593372648132547037 |
| Peter |   1060 |    100 |      .029766919404661611906767761864644762707 |
| Tan   |   8500 |   1001 |      .611510791366906474820143884892086330935 |
| Tom   |   3900 |   1001 |      .280575539568345323741007194244604316546 |
| Mery  |   1500 |   1001 |       .107913669064748201438848920863309352518 |
+-------+--------+--------+-----------------------------------------------+
```

17.1.5.6.4.23. ROW_NUMBER

The `ROW_NUMBER` function assigns a unique number to each row to which the function is applied, regardless of each row in the partition or each row returned by the query. The function returns values starting from 1 based on the ordered sequence of rows specified in the `order_by_clause`. You can use a subquery to nest another subquery in a query that retrieves `ROW_NUMBER` in a specified range. This way, you can find a precise subset of rows from the results of the inner query. You can use this function to implement `top-n`, `bottom-n`, and `inner-n` reporting. The query must ensure a deterministic sort order for consistent results.

Syntax

```
ROW_NUMBER( ) OVER ([ query_partition_clause ] order_by_clause)
```

Parameters

Parameter	Description
OVER	Uses the `OVER` clause to define a window for calculation.

Return type

The numeric data is returned.

Examples

Rank the employees by employee output in the unit of department. To create the **product** table and insert data into the table, execute the following statements:

```
CREATE TABLE product(name VARCHAR(8), deptno NUMBER, output NUMBER);
INSERT INTO product VALUES('Linda',100,5050);
INSERT INTO product VALUES('Tan',1001,8500);
INSERT INTO product VALUES('Tom',1001,3900);
INSERT INTO product VALUES('John',100,29500);
INSERT INTO product VALUES('Mery',1001,1500);
INSERT INTO product VALUES('Peter',100,1060);
COMMIT;
```

Execute the following statement:

```
SELECT name,OUTPUT,deptno,ROW_NUMBER() OVER (partition BY deptno ORDER BY OUTPUT DESC) FROM product;
```

The following query result is returned:

```
+-------+--------+--------+-----------------------------------------------------+
| NAME  | OUTPUT | DEPTNO | ROW_NUMBER()OVER(PARTITIONBYDEPTNOORDERBYOUTPUTDESC) |
+-------+--------+--------+-----------------------------------------------------+
| John  |  29500 |    100 |                                                   1 |
| Linda |   5050 |    100 |                                                   2 |
| Peter |   1060 |    100 |                                                   3 |
| Tan   |   8500 |   1001 |                                                   1 |
| Tom   |   3900 |   1001 |                                                   2 |
| Mery  |   1500 |   1001 |                                                   3 |
+-------+--------+--------+-----------------------------------------------------+
```

17.1.5.7. Expressions

17.1.5.7.1. Overview of SQL expressions

Expressions are used to calculate data values. An expression is a combination of one or more components, such as numeric values, operators, and SQL functions. In general, an expression assumes the data types of its components.

> **Notice**
>
> The values of the `NLS_COMP` and `NLS_SORT` parameters jointly affect the sorting and comparison of characters. If the `NLS_COMP` parameter in the database is set to `LINGUISTIC`, all the entities described in this chapter follow the rules that are specified by the `NLS_SORT` parameter. If the `NLS_COMP` parameter is not set to `LINGUISTIC`, the functions are not affected by `NLS_SORT`. You can directly specify the value of `NLS_SORT`. If you do not specify it, it inherits the value of `NLS_LANGUAGE`.

The result of the following simple expression is 4 and of the `NUMBER` data type. This data type is consistent with the data type of the components.

```
2*2
```

The following complex expression uses functions and operators. This expression adds seven days to the current date, removes the time portion, and then converts the result to the `CHAR` data type.

```
TO_CHAR(TRUNC(SYSDATE+7))
```

You can also use expressions in the following scenarios:

- The selected columns in `SELECT` statements
- The `WHERE` and `HAVING` clauses
- The `CONNECT BY`, `START WITH`, and `ORDER BY` clauses
- The `VALUES` clauses of `INSERT` statements
- The `SET` clauses of `UPDATE` statements

For example, you can use an expression to replace the string **Smith** in the `SET` clause of the following `UPDATE` statement:

```
SET last_name = 'Smith';
```

In the `SET` clause, the expression `INITCAP(last_name)` is used to replace the string **Smith**.

```
SET last_name = INITCAP(last_name);
```

In ApsaraDB for OceanBase, not all expressions can be directly used by SQL statements. For more information, see the limits on expressions in the SQL statements topic.

17.1.5.7.2. Simple expressions

A simple expression can be a column, pseudocolumn, constant, sequence number, or null value.

In addition to user schemas, `schema` can also be **PUBLIC** to specify the attribute of a synonym for a table or a view. You can use **PUBLIC** to specify a public synonym in only a DML statement. You cannot use PUBLIC in a DDL statement. `NCHAR` and `NVARCHAR2` are not valid pseudocolumn data types.

The following list provides some valid simple expressions:

- `employees.last_name`
- `'this is a text string'`
- `10`
- `N 'this is an NCHAR string'`

17.1.5.7.3. Compound expressions

A compound expression is an expression that is a combination of other types of expressions.

You can use a built-in function as an expression. However, in compound expressions, some combinations of functions are inappropriate and are discarded. For example, the `LENGTH` function is inapplicable in an aggregate function.

You can use the `PRIOR` operators in the `CONNECT BY` clauses of hierarchical queries.

The following list provides some valid compound expressions:

- `('CLARK' || 'SMITH')`
- `LENGTH('MOOSE') * 57`
- `SORT(144) + 72`
- `my_fun(TO_CHAR(sysdate, 'DD-MMM-YY'))`

17.1.5.7.4. Case expressions

A case expression allows you to use the `IF ... THEN ... ELSE` logic in SQL statements without calling a stored procedure.

Syntax

```
CASE { simple_case_expression
     | searched_case_expression
     }
     [ ELSE else_expr ]
     END
```

The following code provides the syntax of `simple_case_expression`.

```
expr
  { WHEN comparison_expr THEN return_expr }...
```

The following code provides the syntax for `searched_case_expression`:

```
{ WHEN condition THEN return_expr }...
```

Usage rules

Validation of conditions

For a simple case expression, ApsaraDB for OceanBase uses `expr` as a base and searches `WHEN ... THEN` for the first `comparison_expr` that is equal to expr. Then, ApsaraDB for OceanBase returns the corresponding `return_expr`. If no `WHEN ... THEN` meets the condition and an `ELSE` clause exists, ApsaraDB for OceanBase returns `else_expr`. Otherwise, ApsaraDB for OceanBase returns NULL.

In a searched case expression, ApsaraDB for OceanBase searches from left to right until the `condition` is met. Then, ApsaraDB for OceanBase returns `return_expr`. If no condition is met and an `ELSE` clause exists, the database returns `else_expr`. Otherwise, the database returns NULL.

Calculation of conditions

ApsaraDB for OceanBase uses the short-circuit calculation rule. For a simple case expression, the database calculates a `comparison_expr` value only before the database compares the value with `expr`. The database does not calculate all the `comparison_expr` values before the database compares a comparison_expr value with `expr`. Therefore, if the previous `comparison_expr` is equal to `expr`, ApsaraDB for OceanBase does not calculate the next `comparison_expr` value. For a searched case expression, the database performs serial computing for each condition to determine whether the condition is true. If the previous condition is true, ApsaraDB for OceanBase does not calculate the next condition.

Data types

For a simple case expression, the `expr` and all the `comparison_expr` values must have the same data type, such as `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2`, and `NUMBER`, `BINARY_FLOAT`, or `BINARY_DOUBLE`. Alternatively, they must all have the numeric type. If the data type of all the returned expressions is the numeric type, ApsaraDB for OceanBase selects the data type that has the highest precedence. ApsaraDB for OceanBase explicitly converts the other parameters to this data type and returns this data type.

For a simple case expression and a searched case expression, all the `return_exprs` must have the same data type, such as `CHAR`, `VARCHAR2`, `NCHAR`, or `NVARCHAR2`, and `NUMBER`, `BINARY_FLOAT`, or `BINARY_DOUBLE`. Alternatively, they must all have the numeric type. If the data type of all the returned expressions is the numeric type, ApsaraDB for OceanBase selects the data type that has the highest precedence. ApsaraDB for OceanBase explicitly converts the other parameters to this data type and returns this data type.

Examples

```
SELECT cust_last_name,
    CASE credit_limit
    WHEN 100 THEN 'Low'
    WHEN 5000 THEN 'High'
    ELSE 'Medium' END AS credit
FROM customer
ORDER BY cust_last_name, credit;
```

The following example shows a searched case expression:

```
SELECT AVG(CASE WHEN e.salary > 2000 THEN e.salary
          ELSE 2000 END) "Average Salary" FROM employee e;
```

17.1.5.7.5. Column expressions

Column expressions are a limited form of `expr`. A column expression is named `column_expression` in the syntax of other expressions in this chapter. Column expressions can be simple expressions, compound expressions, function expressions, or expression lists. Column expressions can contain only the following forms of expressions:

- Columns in the table that is created, changed, or indexed.
- Constants (strings or numbers).
- Deterministic functions, such as SQL built-in functions or user defined functions.

Other forms of expressions except the preceding forms of expressions are invalid column expressions. In addition, column expressions do not support compound expressions and aggregate functions that use the `PRIOR` keywords.

You can use column expressions to achieve the following purposes:

- Create a function-based index.
- Explicitly or implicitly define a virtual column. When you define a virtual column, `column_expression` applies to only the column of the table that has been defined in a previous statement.

The components of a column expression must be deterministic. This indicates that the same input values must return the same output values.

17.1.5.7.6. Datetime expressions

A datetime expression generates a value of the datetime data type.

The following syntax is provided:

```
{TIMESTAMP | DATE} string
```

You can combine TIMESTAMP or DATE and a string literal to generate a value of the TIMESTAMP or DATE type. The string format must be consistent with that of the system variables NLS_TIMESTAMP_FORMAT and NLS_DATE_FORMAT.

You can query the values of the system variables by executing the following SQL statement:

```
select * from v$nls_parameters where parameter like '%FORMAT';
```

For example, if the value of the system variable NLS_TIMESTAMP_FORMAT is YYYY-MM-DD HH24:MI:SS.FF, you can use the following expression to generate a value of the TIMESTAMP type.

```
select timestamp '2020-01-01 10:00:00' from dual;
+-------------------------------+
| TIMESTAMP'2020-01-0110:00:00' |
+-------------------------------+

```

17.1.5.7.7. Function expressions

Function expressions allow you to use a built-in SQL function expression or a user defined function expression.

The following list shows some valid built-in function expressions:

- `LENGTH('BLAKE')`
- `ROUND(1234.567*43)`
- `SYSDATE`

> **Notice**
>
> User-defined function expressions cannot pass the parameters of the object type or XMLType to remote functions or procedures.

A user defined function expression calls:

- A function in a custom package or type or in a standalone user defined function
- A user defined function or an operator

The following list shows some valid user defined function expressions:

- `circle_area(radius)`
- `payroll.tax_rate(empno)`
- `hr.employees.comm_pct@remote(dependents, empno)`
- `DBMS_LOB.getlength(column_name)`
- `my_function(a_column)`

If you use user defined functions as expressions, you can use positional notation, named notation, or mixed notation. For example, the following notations are valid:

```
CALL my_function(arg1 => 3, arg2 => 4) ...
CALL my_function(3, 4) ...
CALL my_function(3, arg2 => 4) ...
```

17.1.5.7.8. Interval expressions

An interval expression generates a value of the `INTERVAL YEAR TO MONTH` or `INTERVAL DAY TO SECOND` data type.

The following syntax is provided:

```
INTERVAL string
   { DAY [ (leading_field_precision) ] TO
     SECOND [ (fractional_second_precision) ]
   | YEAR [ (leading_field_precision) ] TO
     MONTH
   }
```

`leading_field_precision` and `fractional_second_precision` can be integers from 0 to 9. The two parameters specify the precisions of the corresponding element values. If you omit the `leading_field_precision` parameter when you specify the `DAY` and `YEAR` elements, the used default value is 2. The value 2 indicates that the value of the element cannot be an integer that has more than two digits. If you omit the following parameter for the `SECOND` element:

`fractional_second_ precision`, the default value is 6. The value 6 indicates that the element value is accurate to the sixth decimal place. If the return value of a query has more digits than the default precision, ApsaraDB for OceanBase returns an error.

For example, the following statement shows an INTERVAL value of the DAY TO SECOND type.

```
select INTERVAL '999999999 23:59:59.999' day(9) to second from dual;
```

17.1.5.7.9. Scalar subquery expressions

A scalar subquery expression is a subquery that returns a row. This row contains multiple column values. If a subquery returns zero rows, the value of the scalar subquery expression is NULL. If a subquery returns multiple rows, the scalar query expression returns an error. In most expressions, scalar subquery expressions can be used as parameters.

Scalar subqueries are not valid expressions in the following scenarios:

- As default values of columns
- In hash functions
- In the `RETURNING` clauses of DML statements
- In the definition of a function index
- In `CHECK` constraints
- In `GROUP BY` clauses
- In the statements that are irrelevant to queries, such as `CREATE PROFILE`

17.1.5.7.10. Expression lists

An expression list is a group of other expressions.

Expression lists can appear in comparison and membership conditions and in the `GROUP BY` clauses of queries and subqueries. Expression lists in comparison and membership conditions are called row value constructors or row constructors.

Comparison and membership conditions appear in the `WHERE` clauses. Comparison and membership conditions can contain one expression or multiple expressions that are separated by commas (,), or one or more groups of expressions. Each group of expressions contains one expression or multiple expressions that are separated by commas (,). In the following examples (multiple groups of expressions):

- Each group is enclosed in parentheses.
- Each group must contain the same number of expressions.
- The number of expressions in each group must match the number of expressions that precede the operator in the comparison condition. Alternatively, the number of expressions in each group must match the number of expressions that precede the `IN` keyword in the membership condition.

A comma-separated list of expressions can contain a maximum of 1,000 expressions. A comma-separated list of groups of expressions can contain expression groups whose quantity is not limited. However, each expression group can contain a maximum of 1,000 expressions.

The following examples show some valid expression lists:

```
(10, 20, 40)
('SCOTT', 'BLAKE', 'TAYLOR')
( ('Guy', 'Himuro', 'GHIMURO'),('Karen', 'Colmenares', 'KCOLMENA') )
```

In the third example, the number of expressions in each group must be the same as the number of expressions in the first part of the condition of the SQL statement. The following example shows the corresponding statement:

```
SELECT * FROM employees
    WHERE (first_name, last_name, email) IN
        (('Guy', 'Himuro', 'GHIMURO'),('Karen', 'Colmenares', 'KCOLMENA'));
```

In a simple `GROUP BY` clause, you can use the uppercase or lowercase expression list.

```
SELECT department_id, MIN(salary) min, MAX(salary) max FROM employees
    GROUP BY department_id, salary
    ORDER BY department_id, min, max;

SELECT department_id, MIN(salary) min, MAX(salary) max FROM employees
    GROUP BY (department_id, salary)
    ORDER BY department_id, min, max;
```

In the `ROLLUP` , `CUBE` , and `GROUPING SETS` clauses of a `GROUP BY` clause, you can combine individual expressions and expression groups in the same expression list. The following example shows some valid expression group lists in the SQL statement:

```
SELECT prod_category, prod_subcategory, country_id, cust_city, count(*)
    FROM products, sales, customers
    WHERE sales.prod_id = products.prod_id
        AND sales.cust_id=customers.cust_id
        AND sales.time_id = '01-oct-00'
        AND customers.cust_year_of_birth BETWEEN 1960 and 1970
    GROUP BY GROUPING SETS (
        (prod_category, prod_subcategory, country_id, cust_city), (prod_category, prod_subcategory, c
ountry_id),        (prod_category, prod_subcategory),
        country_id
        )
    ORDER BY prod_category, prod_subcategory, country_id, cust_city;
```

17.1.5.8. Conditions

17.1.5.8.1. Overview of SQL conditions

Conditions are used to determine data values and return `TRUE`, `FALSE`, or `UNKNOWN`. A condition is a combination of one or more components, such as expressions and logical (Boolean) operators. You must use valid syntax for conditions in SQL statements.

> **Notice**
>
> The `NLS_COMP` and `NLS_SORT` parameters jointly affect the sorting and comparison of characters. If the `NLS_COMP` parameter in the database is set to `LINGUISTIC`, all the entities that are described in this Developer Guide follow the rules that are specified by the `NLS_SORT` parameter. If the `NLS_COMP` parameter is not set to `LINGUISTIC`, the functions are not affected by `NLS_SORT`. You can directly specify the value of `NLS_SORT`. If you do not specify it, it inherits the value of `NLS_LANGUAGE1`.

You can use conditions in the `WHERE` clauses of these statements:

- `DELETE`
- `SELECT`
- `UPDATE`

You can use conditions in these clauses of the `SELECT` statements:

- `WHERE`
- `START WITH`
- `CONNECT BY`
- `HAVING`

A condition can be called a logical data type, although ApsaraDB for OceanBase does not officially support such a data type.

For example, the simple condition 1 = 1 returns the result of TRUE.

The following more complex condition adds the value of **salary** to the value of **commission_pct** and checks whether the sum is greater than 25,000. The `NVL` function replaces NULL values in **salary** with 0.

```
NVL(salary, 0) + NVL(salary + (salary * commission_pct, 0) > 25000)
```

The logical `AND` condition can combine multiple conditions into a single condition.

```
(1 = 1) AND (5 < 7)
```

The following conditions are valid in SQL statements:

```
name = 'SMITH'
employees.department_id = departments.department_id
hire_date > '01-JAN-08'
job_id IN ('SA_MAN', 'SA_REP')
salary BETWEEN 5000 AND 10000
commission_pct IS NULL AND salary = 2100
```

Condition precedence

Condition precedence indicates the order in which ApsaraDB for OceanBase checks different conditions in the same expression. When an expression that contains multiple conditions is computed, the conditions that have higher precedence are checked first, and then the conditions that have lower precedence. The conditions that have equal precedence are checked from left to right. For example, multiple conditions that are connected by `AND` and `OR` cannot be checked from left to right. The `AND` condition is computed first, and then the `OR` condition.

List of SQL condition precedence

Condition type	Functionality
=, ! =, <, >, <=, >=	Comparison
IS [NOT] NULL, LIKE, [NOT] BETWEEN, [NOT] IN, EXISTS, and IS OF	Comparison
NOT	Exponentiation and logical negation
AND	Conjunction
OR	Disjunction

The levels of precedence are listed from high to low. Conditions that are listed on the same line have the same precedence.

17.1.5.8.2. Comparison conditions

Comparison conditions are used to compare an expression with another expression. The result of the comparison is `TRUE`, `FALSE`, or `UNKNOWN`.

You cannot use comparison conditions to compare data of large object (LOB) data types. However, you can compare `CLOB` data by using PL programs.

When numeric expressions are compared, ApsaraDB for OceanBase uses numeric precedence to determine the order in which the numeric values in the conditions are compared. For example, the numeric values of different types appear on both sides of a comparison operator. In this case, if one of the types is `BINARY_DOUBLE`, `BINARY_DOUBLE` values are compared first. Then, `BINARY_FLOAT` values are compared, and finally `NUMBER` values are compared. ApsaraDB for OceanBase determines whether to compare `NUMBER`, `BINARY_FLOAT`, or `BINARY_DOUBLE` values.

When character expressions are compared, ApsaraDB for OceanBase uses specifications in comparison rules of character data types. The rules specify how the character sets of expressions are unified before they are compared, by binary and linguistic comparison, or by blank-padded and nonpadded comparison semantics.

When comparison conditions are used to perform a linguistic comparison on character values, the character values are first converted to sort keys and then compared. The comparison process is similar to that of the `RAW` data type. The sort keys are the values that are returned by the `NLSSORT` function. If the sort keys that are generated by two expressions have the same prefix, the expressions can be linguistically equal even if they differ in the rest of the value.

If two objects of the non-scalar type are of the same named type and a one-to-one correspondence exists between their elements, the two objects are comparable. When you use user-defined object types (nested tables) in equality or `IN` conditions, you must define the `MAP` method. The elements of the nested tables are comparable.

Simple comparison conditions

A simple comparison condition can compare a single expression with an expression list, or compare a single expression with the results of a subquery.

Simple comparison conditions have the following syntax:

```
expr   {= | ! = | ^= | <> | < | >= |}   ( expression_list | subquery )
```

Assume that a single expression is compared with an expression list in a simple comparison condition. The number and data type of the expressions in the expression list must match those of the expressions to the left of the operator. Assume that a single expression is compared with the results of a subquery. The number and data type of the values that are returned by the subquery must match those of the expressions to the left of the operator.

Group comparison conditions

A group comparison condition can compare a single expression with a member or all the members of expression lists or the results of a subquery. The group comparison condition can also compare multiple expressions with a member or all the members of expression lists or the results of a subquery.

Assume that a single expression or multiple expressions are compared with a member or all the members of expression lists in a group comparison condition. The number and data type of the expressions in each expression list must match those of the expressions to the left of the operator. Assume that a single expression or multiple expressions are compared with a member or all the members of the results of a subquery. The number and data type of the values that are returned by the subquery must match those of the expressions to the left of the operator.

Group comparison conditions have the following two types of syntax:

```
expr  {= | ! = | ^= | <> | < | >= | ANY | SOME | ALL } ({ expression_list | subquery})
```

```
(expr [, expr ]...){ = | ! = | ^= | ANY | SOME | ALL} ({expression_list  [, expression_list ]... |sub
query})
```

17.1.5.8.3. Logical conditions

Logical conditions combine two conditions to generate a single result or invert the result of a single condition.

Logical NOT condition

The logical `NOT` condition indicates "not" and can invert the result of a single condition. If the condition is `FALSE` , `TRUE` is returned. If the condition is `TRUE` , `FALSE` is returned. If the condition is `UNKNOWN` , `UNKNOWN` is returned.

Examples of the logical NOT condition

```
SELECT * FROM employees WHERE NOT (job_id IS NULL) ORDER BY employee_id;
SELECT * FROM employees WHERE NOT (salary BETWEEN 1000 AND 2000) ORDER BY employee_id;
```

Logical AND condition

The logical `AND` condition indicates "and". It connects two conditions. If both conditions are `TRUE` , `TRUE` is returned. If either condition is `FALSE` , `FALSE` is returned. Otherwise, `UNKNOWN` is returned.

Examples of the logical AND condition

```
SELECT * FROM employees WHERE job_id = 'PU_CLERK' AND department_id = 30 ORDER BY employee_id;
```

Logical OR condition

The logical `OR` condition indicates "or". This means that either condition is valid. If either condition is `TRUE` , `TRUE` is returned. If both conditions are `FALSE` , `FALSE` is returned. Otherwise, `UNKNOWN` is returned.

Examples of the logical OR condition

```
SELECT * FROM employees WHERE job_id = 'PU_CLERK' OR department_id = 10 ORDER BY employee_id;
```

17.1.5.8.4. Pattern-matching conditions

A pattern-matching condition compares character data.

LIKE condition

A `LIKE` condition is used for pattern matching. The equality operator (=) indicates that one character value exactly matches another character value. The `LIKE` condition matches a portion of one character value with another character value by searching the first value for the pattern that is specified by the second character value.

`LIKE` calculates strings by using the characters that are defined by the input character set.

Syntax

```
char1 [NOT] LIKE char2 [ ESCAPE esc_char ]
```

In addition to `LIKE`, the special pattern-matching character `_` indicates that one character in the value is exactly matched. `%` indicates that zero or multiple characters in the value are matched. The pattern `%` cannot match `NULL`.

Parameters

Parameter	Description
char1	The character expression, such as a character column. It is called the search value.
char2	The character expression that is generally a literal. It is called the pattern.
esc_char	The character expression that is generally a literal. `ESCAPE` converts the `esc_char` identity as an escape character. When an escape character is located before a pattern-matching character, the pattern-matching character is interpreted as a general character.

Examples

The following statement uses the `LIKE` condition:

```
SELECT last_name FROM employees WHERE last_name LIKE '%A\_B%' ESCAPE '\' ORDER BY last_name;
```

`ESCAPE '\'` interprets the pattern-matching character _ after `\` in `%A\_B%` as a general character.

```
SELECT salary FROM employees WHERE 'SM%' LIKE last_name ORDER BY salary;
```

REGEXP_LIKE condition

`REGEXP_LIKE` is used for regular expression matching. `REGEXP_LIKE` evaluates strings by using the characters that are defined by the input character set.

Syntax

```
REGEXP_LIKE(source_char, pattern [, match_param ])
```

Parameters

Parameter	Description
source_char	The string expression that is used as the search value. The data type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.
pattern	The regular expression. The data type can be `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, or `CLOB`.
source_char	The character expression of the `VARCHAR2` or `CHAR` data type. This expression allows you to change the default matching behavior of the condition.

If the data type of the pattern is different from that of `source_char`, ApsaraDB for OceanBase converts the pattern to the data type of `source_char`.

Examples

Create the **employees** table and insert data into the table. Execute the following statements:

```
CREATE TABLE employees(manager_id INT, first_name varchar(50), last_name varchar(50), hiredate varcha
r(50),SALARY INT);
INSERT INTO employees VALUES(300, 'Steven', 'King',  '2019-09-11',23600);
INSERT INTO employees VALUES(200, 'Steven', 'Markle', '2019-11-05', 23800);
INSERT INTO employees VALUES(100, 'Deven',  'Part',  '2018-10-01',24000);
INSERT INTO employees VALUES(200, 'Carlos', 'Ross',  '2019-06-11',23500);
INSERT INTO employees VALUES(200, 'Teven',  'Bell', '2019-05-25', 23000);
INSERT INTO employees VALUES(200, 'Stephen', 'Stiles',  '2018-06-11',24500);
INSERT INTO employees VALUES(100, 'Ame', 'De Haan', '2018-05-01',11000);
INSERT INTO employees VALUES(100, 'Jon', 'Errazuriz', '2017-07-21', 1400);
COMMIT;
```

Query the first names and the last names of the employees whose names contain **Steven** or **Stephen**. `first_name` starts with **Ste** and ends with **en**. **v** or **ph** is in the middle of the first name. Execute the following statement:

```
SELECT first_name, last_name FROM employees WHERE REGEXP_LIKE (first_name, '^Ste(v|ph)en$')
ORDER BY first_name, last_name;
```

The following query result is returned:

```
+------------+-----------+
| FIRST_NAME | LAST_NAME |
+------------+-----------+
| Stephen    | Stiles    |
| Steven     | King      |
| Steven     | Markle    |
+------------+-----------+
```

17.1.5.8.5. NULL conditions

A NULL condition tests null values. This is the only condition that is used to test for null values.

Syntax

```
expr IS [ NOT ] NULL
```

Examples

Execute the following statement:

```
SELECT last_name FROM employees WHERE commission_pct IS NULL
ORDER BY last_name;
```

17.1.5.8.6. Compound conditions

A composition condition is a combination of other conditions.

Syntax

```
{ (condition) | NOT condition | condition { AND | OR } condition }
```

For more information about the `NOT`, `AND`, and `OR` conditions, see the reference document Logical conditions.

17.1.5.8.7. BETWEEN conditions

A `BETWEEN` condition determines whether the value of an expression falls in the interval that is defined by other two expressions.

Syntax

```
expr1 [ NOT ] BETWEEN expr2 AND expr3

NOT (expr1 BETWEEN expr2 AND expr3)
```

The `expr1`, `expr2`, and `expr3` expressions must be the numeric, character, or datetime expressions. In SQL, `expr1` may be calculated for multiple times. If an expression appears in Procedural Language for SQL (PL/SQL), make sure that `expr1` is calculated only once. If the data types of expressions are not the same, ApsaraDB for OceanBase implicitly converts the expressions to the unified data type. Otherwise, the system returns an error.

Examples

Query the information about employees whose salary ranges from 2,000 to 3,000, and sort the result by using employee IDs.

```
SELECT * FROM employees WHERE salary BETWEEN 2000 AND 3000 ORDER BY employee_id;
```

17.1.5.8.8. EXISTS conditions

An EXISTS condition tests whether a specified row exists in a subquery.

Syntax

```
EXISTS (subquery)
```

If a subquery returns at least one row, your required data exists.

Examples

```
SELECT department_id FROM departments d WHERE EXISTS (SELECT * FROM employees e
WHERE d.department_id = e.department_id) ORDER BY department_id;
```

17.1.5.8.9. IN conditions

An `IN` condition is a membership condition. It tests a value or a member value that is in a subquery list.

Syntax

```
expr [ NOT ] IN  ({ expression_list | subquery })
|
( expr [, expr ]... ) [ NOT ]  IN  ( { expression_list [, expression_list ]... | subquery } )
```

An `IN` condition tests whether an expression is a member of an expression list or a subquery, or whether multiple expressions are members of expression lists or subqueries. The expressions in each expression list must match the expressions to the left of the `IN` operator in terms of quantity and data types.

Examples

IN example: equivalent to `=ANY`. It indicates all the members in the set.

```
SELECT * FROM employees WHERE job_id IN ('PU_CLERK','SH_CLERK') ORDER BY employee_id;

SELECT * FROM employees WHERE salary IN (SELECT salary  FROM employees
WHERE department_id =30) ORDER BY employee_id;
```

NOT IN example: equivalent to `! = ALL`. If a member in the set is `NULL`, the calculation result is `false`.

```
SELECT * FROM employees WHERE salary NOT IN (SELECT salary FROM employees
WHERE department_id = 30) ORDER BY employee_id;

SELECT * FROM employees WHERE job_id NOT IN ('PU_CLERK', 'SH_CLERK')
ORDER BY employee_id;
```

17.1.5.9. Queries and subqueries

17.1.5.9.1. Overview of queries and subqueries

A query is a method that is used to retrieve data from databases. It can be used with conditional clauses, such as `WHERE`, and clauses for sorting (such as `ORDER BY`), to retrieve query results. A subquery is a query that is nested in an upper-level query. An upper-level query is called a parent query or an outer query. The result value of the subquery is passed back as an input to the parent query or the outer query. The parent query uses this value in the computation to determine the final output. SQL supports multiple levels of nested queries. This indicates that you can nest other subqueries in a subquery. In addition, subqueries can appear in various clauses of SQL statements, such as `SELECT`, `FROM`, and `WHERE` statements. The following queries are common in SQL statements:

- Simple queries
- Hierarchical queries
- Sets
- Joins
- Subqueries

Simple queries

A simple query is an operation that retrieves data from one or more columns of data from one or more select lists or views in ApsaraDB for OceanBase. The number of columns and their data type and length depend on the elements in the select lists. Select lists are the expression lists that appear after the `SELECT` keyword and before the `FROM` clause.

Hierarchical queries

A hierarchical query is a query statement that has special features. You can use this query to obtain the hierarchical data that is displayed based on hierarchical relationships. Hierarchical data indicates that the data in a relational table has the hierarchical relationship.

Sets

You can use the following set operators to combine multiple queries: `UNION`, `UNION ALL`, `INTERSECT`, and `MINUS`. All the set operators have equal precedence. If an `SQL` statement contains multiple set operators, ApsaraDB for OceanBase checks them from left to right unless an order is specified in the parentheses. This section describes the following set operators.

Operator	Description
UNION	Returns the union of two result sets. The union does not include duplicates.
UNION ALL	Returns the union of two result sets. The union can include duplicates.
INTERSECT	Returns the intersection of two result sets.

Operator	Description
MINUS	Returns the difference of two result sets.

Joins

A join is a query that combines the rows from two or more tables, views, or materialized views. ApsaraDB for OceanBase performs a join when multiple tables appear in the `FROM` clause of the query. The select list of the query can select columns from all of the specified tables. If the same column name is used in the two tables, you must qualify all the references to these columns in the query process by using table names. This section describes the following joins.

Join type	Representation	Description
Equi join	Equijoins	A join that has a join condition in which an equality operator is contained.
Self join	SELF-JOIN	A join of a table to itself.
Inner join	INNER JOIN	An inner join. An inner join returns the matching rows in the two joined tables.
Left (outer) join	LEFT [OUTER] JOIN	The result includes all the rows from the left table (that appears at the leftmost position of the `JOIN` clause) and excludes the rows that do not match from the right table.
Right (outer) join	RIGHT [OUTER] JOIN	The result includes all the rows from the right table (that appears at the rightmost position of the `JOIN` clause) and excludes the rows that do not match from the left table.
Full (outer) join	FULL [OUTER] JOIN	The result includes all the rows from all the joined tables regardless of whether these rows are matched.
Semi join	SEMI-JOIN	You can obtain a semi join by only unnesting a subquery.
Anti join	ANTI-JOIN	Anti joins can be implemented by only subquery unnesting.

Join type	Representation	Description
Cartesian product	Cartesian Products	If two tables are not joined, the data that is retrieved by querying the two tables is the Cartesian product of the two tables.

Subqueries

A subquery is one or more `SELECT` statements that are nested in a `SELECT` query statement. A subquery can return a row, multiple rows, or no result. A subquery in the `FROM` clause of a `SELECT` statement is called an inline view. You can nest one or more subqueries in a nested view. A subquery in the `WHERE` clause of a `SELECT` statement is called a nested subquery.

17.1.5.9.2. Simple queries

A simple query is an operation that retrieves data from one or more columns of data from one or more tables or views in ApsaraDB for OceanBase. The number of columns and their data type and length depend on the schema. Select lists are the expression lists that appear after the `SELECT` keyword and before the `FROM` clause.

Syntax

```
SELECT column name 1,column name 2,column name 3,... FROM table;
```

Table names, field names, and keywords `SELECT` and `FROM` are not case-sensitive. The end of a query can be followed by a semicolon (;). Multiple SQL statements can be executed at the same time. You can use hints in a `SELECT` statement to pass instructions or hints to the ApsaraDB OceanBase database optimizer. The optimizer selects execution plans for statements by using hints.

Examples

Create an employee table **employee** and insert data into the **employee_id**, **first_name**, **last_name**, **manager_id**, and **salary** columns.

```
CREATE TABLE employee (
employee_id INT,
first_name VARCHAR(50),
last_name VARCHAR(50),
manager_id INT,
salary NUMERIC
);
INSERT INTO employee VALUES(111, 'DEL', 'FA BEN', 1, 1500);
INSERT INTO employee VALUES(112, 'AXEL', 'BELL', 1, 1000);
INSERT INTO employee VALUES(113, 'CRIS',  'RACHAR', 1, 1000);
```

Simple query example

- Query some columns:

```
SELECT first_name, last_name, salary FROM employee;
+------------+-----------+--------+
| FIRST_NAME | LAST_NAME | SALARY |
+------------+-----------+--------+
| DEL        | FA BEN    |   1500 |
| AXEL       | BELL      |   1000 |
| CRIS       | RACHAR    |   1000 |
+------------+-----------+--------+
```

- Query all the columns:

```
SELECT * FROM employee;
+-------------+------------+-----------+------------+--------+
| EMPLOYEE_ID | FIRST_NAME | LAST_NAME | MANAGER_ID | SALARY |
+-------------+------------+-----------+------------+--------+
|         111 | DEL        | FA BEN    |          1 |   1500 |
|         112 | AXEL       | BELL      |          1 |   1000 |
|         113 | CRIS       | RACHAR    |          1 |   1000 |
+-------------+------------+-----------+------------+--------+
```

- Perform a mathematical operation on a column:

```
SELECT salary+100 FROM employee;
+-------------+
| SALARY+100 |
+-------------+
|       1600 |
|       1100 |
|       1100 |
+-------------+
```

- Create an alias for a column:

```
SELECT salary*12 Annual salary FROM employee;
+---------+
| Annual salary   |
+---------+
|  18000 |
|  12000 |
|  12000 |
+---------+
```

- Concatenate strings:

```
SELECT first_name || '-' || last_name  AS Full name FROM employee;
+-------------+
| Full name        |
+-------------+
| DEL-FA BEN  |
| AXEL-BELL   |
| CRIS-RACHAR |
+-------------+
```

- Remove duplicates from data

```
SELECT DISTINCT MANAGER_ID FROM employee;
+------------+
| MANAGER_ID |
+------------+
|          1 |
+------------+
```

- `CASE WHEN` statement

```
SELECT salary, CASE WHEN salary >= 1000 then 'High salary >= 800 THEN 'General'
ELSE 'Keeping working hard' END AS typeFROM employee;
+--------+--------+
| SALARY | TYPE   |
+--------+--------+
|   1500 | High salary   |
|   1000 | High salary   |
|   1000 | High salary   |
+--------+--------+
```

17.1.5.9.3. Hierarchical queries

A hierarchical query is a query statement that has special features. You can use this query to display the hierarchical data based on the hierarchical relationship. Hierarchical data indicates that the data in a relational table has the hierarchical relationship. Hierarchical relationships are common in real life. For example, the following hierarchical relationships are common:

- Relationships between team leaders and team members in the organizational structure
- Relationships between superior and subordinate departments in an enterprise
- Relationships between page redirects in web pages

Syntax

```
SELECT [level], column, expr... FROM table [WHERE condition] [ START WITH start_expression ]
CONNECT BY [NOCYCLE] { PRIOR child_expr = parent_expr | parent_expr = PRIOR child_expr }
[ ORDER SIBLINGS BY …] [ GROUP BY … ] [ HAVING … ] [ ORDER BY … ]
```

Parameters

Parameter	Description
LEVEL	The node level. This parameter is a pseudocolumn and specifies the level. The level is counted from the beginning of a query and numbered as 1. The level of the second node in the query is 2, the level for the third node in the query is 3, and so on.
CONNECT_BY_ISLEAF	Specifies whether the current data row is a leaf node in the hierarchical relationship. This parameter is a pseudocolumn. The value 0 indicates that the row is not a leaf node. The value 1 indicates that the row is a leaf node.

Parameter	Description
CONNECT_BY_ISCYCLE	Specifies whether the current data row is in the loop. This parameter is a pseudocolumn. The value 0 indicates that the current data row is not in the loop. The value 1 indicates that the current data row is in the loop.
CONNECT_BY_ROOT operator	CONNECT_BY_ROOT is a unary operator and indicates that the columns in parameters come from the root node of a hierarchical query. This operator has the same precedence as the unary plus (+) and unary minus (-) operators.
condition	The condition.
CONNECT BY	Specifies how to determine the parent-child relationship. An equivalent expression is usually used. Other expressions are also supported.
START WITH	Specifies the root row in the hierarchical query.
PRIOR operator	`PRIOR` is a unary operator and indicates that the columns in parameters come from the parent row. This operator has the same precedence as the unary plus (+) and unary minus (-) operators.
NOCYCLE	When you specify this keyword, the result can still be returned even if the result contains a loop. You can use the `CONNECT_BY_ISCYCLE` virtual column to specify where the loop occurs. When you do not specify this keyword, the client receives an error if a loop occurs.
ORDER SIBLINGS BY	Specifies the order in which rows of the same level are sorted.

Execution process

The key to using and implementing hierarchical queries is to understand their execution processes. The following execution process for a hierarchical query is provided:

1. Perform the `SCAN` or `JOIN` operation that is after `FROM`.
2. Generate the hierarchical relationship results by using the content of `START WITH` and `CONNECT BY`.
3. Execute the remaining clauses, such as `WHERE`, `GROUP`, and `ORDER BY`, based on the regular query execution process. The following process explains how to generate hierarchical relationships in Step 2.
4. Obtain the root rows by using the expression in `START WITH`.
5. Select the child rows of each root row by using the expression in `CONNECT BY`.

6. Use the child rows generated in Step 2 as the new root rows and further generate child rows. This process is repeated until no new rows are generated.

Examples

The following example shows how to use hierarchical queries. Insert data into the **emp_id**, **position**, and **mgr_id** columns of the **emp** table. Execute the following statements:

```
CREATE TABLE emp(emp_id INT,position VARCHAR(50),mgr_id INT);
INSERT INTO emp VALUES (1,'Global Manager',NULL);
INSERT INTO emp VALUES (2,'Europe Regional Manager',1);
INSERT INTO emp VALUES (3,'Asia Pacific Regional Manager',1);
INSERT INTO emp VALUES (4,'Americas Regional Manager',1);
INSERT INTO emp VALUES (5,'Italy Regional Manager',2);
INSERT INTO emp VALUES (6,'France Regional Manager',2);
INSERT INTO emp VALUES (7,'China Regional Manager',3);
INSERT INTO emp VALUES (8,'Korea Regional Manager',3);
INSERT INTO emp VALUES (9,'Japan Regional Manager',3);
INSERT INTO emp VALUES (10,'US Regional Manager',4);
INSERT INTO emp VALUES (11,'Canada Regional Manager',4);
INSERT INTO emp VALUES (12,'Beijing Regional Manager',7);
```

The preceding content shows that data in the **position** column has a clear hierarchical relationship.

To display the results by using the hierarchy, execute the following statement:

```
SELECT emp_id, mgr_id, position, level FROM emp
START WITH mgr_id IS NULL CONNECT BY PRIOR emp_id = mgr_id;
```

The following query result is returned:

```
+--------+--------+-------------------+-------+
| EMP_ID | MGR_ID | POSITION          | LEVEL |
+--------+--------+-------------------+-------+
|      1 |    NULL| Global Manager           |     1 |
|      2 |      1 | Europe Regional Manager         |     2 |
|      5 |      2 | Italy Regional Manager       |     3 |
|      6 |      2 | France Regional Manager         |     3 |
|      3 |      1 | Asia Pacific Regional Manager         |     2 |
|      7 |      3 | China Regional Manager         |     3 |
|     12 |      7 | Beijing Regional Manager         |     4 |
|      8 |      3 | Korea Regional Manager         |     3 |
|      9 |      3 | Japan Regional Manager         |     3 |
|      4 |      1 | Americas Regional Manager         |     2 |
|     10 |      4 | US Regional Manager         |     3 |
|     11 |      4 | Canada Regional Manager       |     3 |
+--------+--------+-------------------+-------+
```

To query the hierarchy of only the Asia Pacific region, execute the following statement:

```
SELECT emp_id, mgr_id, position, level FROM emp START WITH position = 'Asia Pacific Regional Manager'
CONNECT BY PRIOR emp_id = mgr_id;
```

The following query result is returned:

```
+--------+--------+----------------+-------+
| EMP_ID | MGR_ID | POSITION       | LEVEL |
+--------+--------+----------------+-------+
|      3 |      1 | Asia Pacific Regional Manager      |     1 |
|      7 |      3 | China Regional Manager      |     2 |
|     12 |      7 | Beijing Regional Manager      |     3 |
|      8 |      3 | Korea Regional Manager      |     2 |
|      9 |      3 | Japan Regional Manager      |     2 |
+--------+--------+----------------+-------+
```

17.1.5.9.4. Sets

You can use the following set operators to combine multiple queries: `UNION` , `UNION ALL` , `INTERSECT` , and `MINUS` . All the set operators have equal precedence. If an `SQL` statement contains multiple set operators, ApsaraDB for OceanBase checks the operators in the left-to-right order unless an order is specified in the parentheses.

Rules and limits on set operators

You can specify the attribute of `UNION` as `ALL` and `DISTINCT` or `UNIQUE` . ALL indicates that duplicate values are allowed in a set. DISTINCT or UNIQUE indicates that duplicate values are not allowed in a set. However, you cannot specify the `ALL` attribute for other types of set operations. They have only the `DISTINCT` attribute. The default attribute of all set operations is `DISTINCT` . In ApsaraDB for OceanBase, you can specify `ORDER BY` and `LIMIT` clauses in set operations. However, other clauses are not allowed. Only `MINUS` is supported and `EXCEPT` is not supported, although both of them have the same semantics. The number of columns in each query result in a set operation must be the same as that of the corresponding expressions. The corresponding data types must be compatible, such as numeric or character.

Rules of set operators

If component queries query character data, the return values are of the following data types:

- If two values of the `VARCHAR2` type in equal length are queried, the return value is of the `CHAR` type in the same length. If the values of the `CHAR` type in different length are queried, the return value is of the `VARCHAR2` type. Its length is same as that of a larger `CHAR` value.
- If one or two of the queries query the values of the `VARCHAR2` data type, the return value is of the `VARCHAR2` type.

If component queries query numeric data, the data types of the return values are determined by numeric precedence.

- If the values of the `BINARY_DOUBLE` type are queried, the return value is of the `BINARY_DOUBLE` type.
- If the queries select values of the `BINARY_FLOAT` type, the return value is of the `BINARY_FLOAT` type.
- If all the queries select values of the `NUMBER` type, the return value is of the `NUMBER` type.

In queries that use set operators, ApsaraDB for OceanBase does not perform implicit conversion across data type groups. If the corresponding expressions of component queries are resolved into character data and numeric data at the same time, ApsaraDB for OceanBase returns an error.

Limits on set operators

Set operators are subject to the following limits:

- Set operators are invalid on columns of `BLOB` and `CLOB`.
- If the `SELECT` list before the set operator contains an expression, you must provide a column alias for the expression. Then, you can reference the column alias in the `ORDER BY` clause.
- You cannot use set operators to specify `UPDATE` statements.
- You cannot specify `ORDER BY` statements in the subqueries of these operators.
- You cannot use these operators in the `SELECT` statements that contain table collection expressions.

UNION and UNION ALL operators

The `UNION` operator combines the result sets of two or more `SELECT` statements. The `SELECT` statements inside `UNION` must have the same number of columns. The data types of the columns must be similar. In addition, the order of columns in each `SELECT` statement must be the same. By default, the `UNION` operator selects different values. To allow duplicate values, use `UNION ALL`.

Syntax

```
{ (< SQL- Statement 1>) }
UNION [ALL]
{ (< SQL- Statement 2>) }
```

INTERSECT operator

The INTERSECT operator returns the intersection of two result sets, that is, all the distinct values that are returned by both queries.

Syntax

```
{ (< SQL- Statement 1>) }
INTERSECT
{ (< SQL- Statement 2>) }
```

Limits

- The number and order of the columns in all the queries must be same.
- The column data types in the two query result sets that are compared can be different but must be compatible.
- The two query result sets that are compared cannot contain columns of incomparable data types, such as XML, TEXT, NTEXT, IMAGE, or non-binary CLR user-defined types.

- The column names of the returned result set are the same as those returned by the query to the left of the operand. The column names or aliases in `ORDER BY` clauses must reference the column names that are returned by the left-side query.
- The INTERSECT operator cannot be used together with `COMPUTE` and `COMPUTE BY` clauses.
- When rows are compared to determine distinct values, two NULL values are considered equal.

MINUS operator

The `MINUS` operator returns the difference between two result sets, that is, all the distinct values that are returned by the left-side query but not retrieved by the right-side query.

Syntax

```
{ (< SQL- Statement 1>) }
MINUS
{ (< SQL- Statement 2>) }
```

Execution sequence

The following execution sequence is applied when the MINUS operator is used together with other operators in expressions:

1. Expressions in parentheses

2. The `INTERSECT` operand

3. `MINUS` and `UNION` that are evaluated from left to right based on their positions in the expressions

If `MINUS` or `INTERSECT` is used to compare more than two query result sets, the data types are converted based on one comparison between two queries. The preceding rules for evaluating expressions are followed.

Examples

The following statements create tables **table_a** and **table_b** and insert data into the tables:

```
CREATE TABLE table_a(PK INT, name VARCHAR(25));
INSERT INTO table_a VALUES(1,'Fox');
INSERT INTO table_a VALUES(2,'Police');
INSERT INTO table_a VALUES(3,'Taxi');
INSERT INTO table_a VALUES(4,'Lincoln');
INSERT INTO table_a VALUES(5,'New York');
INSERT INTO table_a VALUES(6,'Washington');
INSERT INTO table_a VALUES(7,'Dell');
INSERT INTO table_a VALUES(10,'Lucent');
CREATE TABLE table_b(PK INT, name VARCHAR(25));
INSERT INTO table_b VALUES(1,'Fox');
INSERT INTO table_b VALUES(2,'Police');
INSERT INTO table_b VALUES(3,'Taxi');
INSERT INTO table_b VALUES(6,'Washington');
INSERT INTO table_b VALUES(7,'Dell');
INSERT INTO table_b VALUES(8,'Microsoft');
INSERT INTO table_b VALUES(9,'Apple');
INSERT INTO table_b VALUES(11,'Scotland');
```

Example of UNION:

```
SELECT PK, name FROM table_a
UNION
SELECT PK, name FROM table_b;
```

The following query result is returned:

```
+------+-----------+
| PK   | NAME      |
+------+-----------+
|    1 | Fox    |
|    2 | Police      |
|    3 | Taxi      |
|    4 | Lincoln      |
|    5 | New York      |
|    6 | Washington    |
|    7 | Dell      |
|   10 | Lucent      |
|    8 | Microsoft      |
|    9 | Apple      |
|   11 | Scotland    |
+------+-----------+
```

Example of UNION ALL:

```
SELECT PK, name FROM table_a
UNION ALL
SELECT PK, name FROM table_b;
```

The following query result is returned:

```
+------+-----------+
| PK   | NAME      |
+------+-----------+
|    1 | Fox    |
|    2 | Police      |
|    3 | Taxi      |
|    4 | Lincoln      |
|    5 | New York      |
|    6 | Washington    |
|    7 | Dell      |
|   10 | Lucent      |
|    1 | Fox    |
|    2 | Police      |
|    3 | Taxi      |
|    6 | Washington    |
|    7 | Dell      |
|    8 | Microsoft      |
|    9 | Apple      |
|   11 | Scotland    |
+------+-----------+
```

Example of INTERSECT:

```
SELECT PK, NAME FROM table_a
INTERSECT
SELECT PK, NAME FROM table_b;
```

The following query result is returned:

```
+------+-----------+
| PK   | NAME      |
+------+-----------+
|    1 | Fox       |
|    2 | Police    |
|    3 | Taxi      |
|    6 | Washington|
|    7 | Dell      |
+------+-----------+
```

Example of MINUS:

```
SELECT PK, NAME FROM table_a
MINUS
SELECT PK, NAME FROM table_b;
```

The following query result is returned:

```
+------+--------+
| PK   | NAME   |
+------+--------+
|    4 | Lincoln|
|    5 | New York|
|   10 | Lucent |
+------+--------+
```

17.1.5.9.5. Joins

A join is a query that combines two or more tables, views, or materialized views. If the `FROM` clause of a query contains multiple tables, ApsaraDB for OceanBase performs a join query. The output columns of the query can be selected from a table that is contained in the `FROM` clause. If multiple tables have a same column name, you must use table names to qualify all the references to these columns during the query. The join types in databases generally include `inner join`, `outer join`, `semi-join`, and `anti-join`. Among the preceding join types, you can obtain `semi-join` and `anti-join` by rewriting subqueries. ApsaraDB for OceanBase does not provide syntax for expressing `anti-join` and `semi-join`.

Join conditions

Join conditions are rules to combine multiple tables and exist in FROM clauses or `WHERE` clauses. A join condition is used to compare two columns from different tables. Most joins contain at least one join condition. Join conditions can be divided into equi joins (for example, t1.a = t2.b) and non-equi joins (for example, t1.a < t2.b). Compared with non-equi join conditions, equi join conditions allow databases to use efficient join algorithms, such as `Hash Join` and `Merge-Sort join`.

To perform a join, ApsaraDB for OceanBase retrieves rows from different tables to combine the rows into pairs and matches them based on join conditions. To perform a join on more than two tables, ApsaraDB for OceanBase first joins two of the tables based on the join conditions that compare their columns. Then, ApsaraDB for OceanBase joins the result to another table based on the join conditions that contain the columns of the joined tables and the new table. The optimizer determines the join order in ApsaraDB for OceanBase based on the join conditions, indexes on the base table, and available statistics.

A `WHERE` clause may contain other conditions in addition to join conditions. These conditions that reference only one table can further limit the number of rows returned by the join query.

Equi joins

Equi joins are joins for which join conditions contain equality operators. In an equi join, the rows that meet equality conditions for the specified columns are combined for output.

Self joins

A self join joins a table to itself. The table appears twice in the `FROM` clause and is followed by the table alias that qualify column names in the join condition. If you perform a self join, ApsaraDB for OceanBase combines and returns the rows that meet the join condition.

Cartesian products

If two tables in a join query have no join condition, ApsaraDB for OceanBase returns their Cartesian products. ApsaraDB for OceanBase combines each row of one table with each row of the other table for output. A Cartesian product always generates a number of rows. This is rarely useful. For example, the Cartesian product of two tables that each contain 100 rows is 10,000 rows. Always specify a join condition unless you particularly need a Cartesian product. If a query joins three or more tables and no join condition is specified for a specific pair, the optimizer can choose a join order that prevents from generating an intermediate Cartesian product.

Inner joins

Inner joins are the most basic joins in databases. An inner join combines the columns of two tables, such as Table A and Table B, based on join conditions to generate a new result table. The query compares each row of Table A with each row of Table B and finds combinations that meet the join conditions. If the join conditions are met, the matched rows in Table A and Table B are combined side by side based on columns into one row in the result set. The result set that is generated by the join equals to the result that is generated in the following process: The Cartesian products of the two tables are calculated first. Each row of Table A is combined with each row of Table B. Then, the records that meet the join conditions are returned.

Outer joins

An outer join returns all the rows that meet the join condition, also returns unused rows from one table, and fills in `NULL` at the corresponding positions in the other table. Outer joins can be further divided into left joins, right joins, and full joins. The join type depends on whether the joined table retains rows of the left table, right table, or both tables. In a LEFT [OUTER] JOIN, if the rows in the left table have no matching rows in the right table, the right table is automatically filled with `NULL`. In a RIGHT [OUTER] JOIN, if the rows in the right table have no matching rows in the left table, the left table is automatically filled with `NULL`. In a FULL [OUTER] JOIN, if the rows in the left or right table have no matching rows in the other table, both tables are automatically filled with `NULL`.

Semi-joins

A `LEFT` or `RIGHT ANTI-JOIN` on Table A and Table B returns only the rows in Table A or Table B that have matching rows in Table B or Table A. A `semi-join` can be implemented by only subquery unnesting.

Anti-joins

A `LEFT` or `RIGHT ANTI-JOIN` on Table A and Table B returns all the rows in Table A or Table B that have no matching rows in Table B or Table A. An `anti-join` can be implemented by only subquery unnesting. This is similar to the `semi-join`.

Examples

Create tables **table_a** and **table_b** and insert data. Execute the following statements:

```
CREATE TABLE table_a(PK INT, name VARCHAR(25));
INSERT INTO table_a VALUES(1,'Fox');
INSERT INTO table_a VALUES(2,'Police');
INSERT INTO table_a VALUES(3,'Taxi');
INSERT INTO table_a VALUES(4,'Lincoln');
INSERT INTO table_a VALUES(5,'Arizona');
INSERT INTO table_a VALUES(6,'Washington');
INSERT INTO table_a VALUES(7,'Dell');
INSERT INTO table_a VALUES(10,'Lucent');
CREATE TABLE table_b(PK INT, name VARCHAR(25));
INSERT INTO table_b VALUES(1,'Fox');
INSERT INTO table_b VALUES(2,'Police');
INSERT INTO table_b VALUES(3,'Taxi');
INSERT INTO table_b VALUES(6,'Washington');
INSERT INTO table_b VALUES(7,'Dell');
INSERT INTO table_b VALUES(8,'Microsoft');
INSERT INTO table_b VALUES(9,'Apple');
INSERT INTO table_b VALUES(11,'Scotch whisky');
```

Self join query:

```
SELECT * FROM table_a ta, table_a tb WHERE ta.NAME = tb.NAME;
```

The following query result is returned:

```
+------+-----------------+------+-----------------+
| PK   | NAME            | PK   | NAME            |
+------+-----------------+------+-----------------+
|    1 | Fox             |    1 | Fox             |
|    2 | Police          |    2 | Police          |
|    3 | Taxi            |    3 | Taxi            |
|    4 | Lincoln         |    4 | Lincoln         |
|    5 | Arizona         |    5 | Arizona         |
|    6 | Washington      |    6 | Washington      |
|    7 | Dell            |    7 | Dell            |
|   10 | Lucent          |   10 | Lucent          |
+------+-----------------+------+-----------------+
```

Inner join query:

```
SELECT A.PK AS A_PK, A.name AS A_Value, B.PK AS B_PK, B.name AS B_Value
FROM table_a A INNER JOIN table_b B ON A.PK = B.PK;
```

The following query result is returned:

```
+------+-----------+------+-----------+
| A_PK | A_VALUE   | B_PK | B_VALUE   |
+------+-----------+------+-----------+
|    1 | Fox       |    1 | Fox       |
|    2 | Police    |    2 | Police    |
|    3 | Taxi      |    3 | Taxi      |
|    6 | Washington|    6 | Washington|
|    7 | Dell      |    7 | Dell      |
+------+-----------+------+-----------+
```

Left join query:

```
SELECT  A.PK AS A_PK, A.name AS A_Value, B.PK AS B_PK, B.name AS B_Value
FROM table_a A LEFT JOIN  table_b B ON A.PK = B.PK;
```

The following query result is returned:

```
+------+-----------------+------+-----------+
| A_PK | A_VALUE         | B_PK | B_VALUE   |
+------+-----------------+------+-----------+
|    1 | Fox             |    1 | Fox       |
|    2 | Police          |    2 | Police    |
|    3 | Taxi            |    3 | Taxi      |
|    6 | Washington      |    6 | Washington|
|    7 | Dell            |    7 | Dell      |
|    4 | Lincoln         | NULL | NULL      |
|    5 | Arizona         | NULL | NULL      |
|   10 | Lucent          | NULL | NULL      |
+------+-----------------+------+-----------+
```

Right join query:

```
obclient> SELECT  A.PK AS A_PK, A.name AS A_Value, B.PK AS B_PK, B.name AS B_Value FROM table_a A RIG
HT JOIN   table_b B ON A.PK = B.PK;
```

The following query result is returned:

```
+------+-----------+------+--------------------+
| A_PK | A_VALUE   | B_PK | B_VALUE            |
+------+-----------+------+--------------------+
|    1 | Fox       |    1 | Fox                |
|    2 | Police    |    2 | Police             |
|    3 | Taxi      |    3 | Taxi               |
|    6 | Washington|    6 | Washington         |
|    7 | Dell      |    7 | Dell               |
| NULL | NULL      |    8 | Microsoft          |
| NULL | NULL      |   11 | Scotch whisky      |
| NULL | NULL      |    9 | Apple              |
+------+-----------+------+--------------------+
```

Full join query:

```
obclient> SELECT  A.PK AS A_PK,A.name AS A_Value,B.PK AS B_PK,B.name AS B_Value FROM table_a A FULL
JOIN table_b B ON A.PK = B.PK;
```

The following query result is returned:

```
+------+-----------------+------+--------------------+
| A_PK | A_VALUE         | B_PK | B_VALUE            |
+------+-----------------+------+--------------------+
|    1 | Fox             |    1 | Fox                |
|    2 | Police          |    2 | Police             |
|    3 | Taxi            |    3 | Taxi               |
|    6 | Washington      |    6 | Washington         |
|    7 | Dell            |    7 | Dell               |
| NULL | NULL            |    8 | Microsoft          |
| NULL | NULL            |    9 | Apple              |
| NULL | NULL            |   11 | Scotch whisky      |
|    4 | Lincoln         | NULL | NULL               |
|    5 | Arizona         | NULL | NULL               |
|   10 | Lucent          | NULL | NULL               |
+------+-----------------+------+--------------------+
```

Semi-join: A dependent subquery is unnested and rewritten into a **semi-join**.

```
explain SELECT * FROM table_a t1 WHERE t1.PK IN (SELECT t2.PK FROM table_b t2 WHERE t2.NAME = t1.NAME
);
```

The following query result is returned:

```
+---------------------------------------------+
| Query Plan                                  |
+---------------------------------------------+
======================================
|ID|OPERATOR      |NAME|EST. ROWS|COST|
--------------------------------------
|0 |HASH SEMI JOIN|    |8        |114 |
|1 | TABLE SCAN   |T1  |8        |38  |
|2 | TABLE SCAN   |T2  |8        |38  |
======================================

Outputs & filters:
-------------------------------------
  0 - output([T1.PK], [T1.NAME]), filter(nil),
      equal_conds([T1.PK = T2.PK], [T2.NAME = T1.NAME]), other_conds(nil)
  1 - output([T1.NAME], [T1.PK]), filter(nil),
      access([T1.NAME], [T1.PK]), partitions(p0)
  2 - output([T2.NAME], [T2.PK]), filter(nil),
      access([T2.NAME], [T2.PK]), partitions(p0)
+---------------------------------------------+
```

Anti-join: A dependent subquery is rewritten into an `anti-join`.

```
EXPLAIN SELECT * FROM table_a t1 WHERE t1.PK NOT IN (SELECT t2.PK
FROM table_b t2 WHERE t2.name = t1.name);
```

The following query result is returned:

```
+----------------------------------------------+
| Query Plan                                   |
+----------------------------------------------+
=======================================
|ID|OPERATOR      |NAME|EST. ROWS|COST|
---------------------------------------
|0 |HASH ANTI JOIN|    |0        |112 |
|1 | TABLE SCAN   |T1  |8        |38  |
|2 | TABLE SCAN   |T2  |8        |38  |
=======================================
Outputs & filters:
-------------------------------------
  0 - output([T1.PK], [T1.NAME]), filter(nil),
      equal_conds([T2.NAME = T1.NAME]), other_conds([(T_OP_OR, T1.PK = T2.PK,
      (T_OP_IS, T1.PK, NULL, 0), (T_OP_IS, T2.PK, NULL, 0))])
  1 - output([T1.NAME], [T1.PK]), filter(nil),
      access([T1.NAME], [T1.PK]), partitions(p0)
  2 - output([T2.NAME], [T2.PK]), filter(nil),
      access([T2.NAME], [T2.PK]), partitions(p0)
+----------------------------------------------------------+
```

17.1.5.9.6. Subqueries

A subquery is one or more `SELECT` statements that are nested in a `SELECT` query statement. A subquery can return a row, multiple rows, or no result. A subquery in the `FROM` clause of a `SELECT` statement is called an inline view. A subquery in the `WHERE` clause of a `SELECT` statement is called a nested subquery.

Subqueries are divided into correlated subqueries and uncorrelated subqueries. A correlated subquery is a subquery that depends on the variables of the outer query. This query is usually run for multiple times. An uncorrelated subquery is a subquery that does not depend on the variables of the outer query. This subquery is generally calculated only once. For uncorrelated subqueries and some correlated subqueries, you can rewrite the statements to eliminate subqueries. This achieves the unnesting of the nested subqueries.

Syntax

```
SELECT [ hint ] [ { { DISTINCT | UNIQUE } | ALL } ] select_list
FROM { table_reference | join_clause | ( join_clause ) }
  [ , { table_reference | join_clause | (join_clause) } ]
  [ where_clause ]
  [ hierarchical_query_clause ]
  [ group_by_clause ]
| subquery { UNION [ALL] | INTERSECT | MINUS } subquery [ { UNION [ALL] | INTERSECT | MINUS } subquer
y ]
| ( subquery ) [ order_by_clause ] [ row_limiting_clause ]
```

Parameters

Parameter	Description
select_list	The query list.

Parameter	Description
subquery	The subquery.
hint	The hint.
table_reference	The table to be queried.

If the column in the subquery has the same name as the column in the outer query, you must add a table name or an alias before the duplicate column name in the outer query.

If the upper-level query references the relevant columns in the subquery, the subquery is run. The upper-level query can be a `SELECT`, `UPDATE`, or `DELETE` statement. You can use subqueries in each statement in the following ways:

- Define the rowset that is to be inserted into the table in the `INSERT` or `CREATE TABLE` statement.
- In the `CREATE VIEW` or `CREATE MATERIALIZED VIEW` statement, define the rowset that is to be contained in the view or the materialized view.
- In the `UPDATE` statement, define one or more values to be assigned to the existing rows.
- In the `WHERE` clause, `HAVING` clause, or `START WITH` clause, provide condition values.
- Define the table that contains the query operation.

Unnesting of nested subqueries

Unnesting of nested subqueries is a database optimization strategy. It places some subqueries in the parent query of the outer layer. The essence of this operation is to convert some subqueries into equivalent multi-table join operations. One benefit of this strategy is that it can effectively use the access path, join method, and join order to minimize the number of query layers.

In the following cases, the nested subqueries in the database are unnested:

- Uncorrelated `IN` subqueries.
- The correlated subqueries in `IN` and `EXISTS` do not contain aggregate functions or the `GROUP BY` clauses.

You can use a `UNNEST` hint to control whether to unnest a nested subquery.

Examples

The following statements create the **table_a** table and the **table_b** table and insert data into the tables:

```
CREATE TABLE table_a(PK INT, name VARCHAR(25));
INSERT INTO table_a VALUES(1,'Fox');
INSERT INTO table_a VALUES(2,'Police');
INSERT INTO table_a VALUES(3,'Taxi');
INSERT INTO table_a VALUES(4,'Lincoln');
INSERT INTO table_a VALUES(5,'Arizona');
INSERT INTO table_a VALUES(6,'Washington');
INSERT INTO table_a VALUES(7,'Dell');
INSERT INTO table_a VALUES(10,'Lucent');
CREATE TABLE table_b(PK INT, name VARCHAR(25));
INSERT INTO table_b VALUES(1,'Fox');
INSERT INTO table_b VALUES(2,'Police');
INSERT INTO table_b VALUES(3,'Taxi');
INSERT INTO table_b VALUES(6,'Washington');
INSERT INTO table_b VALUES(7,'Dell');
INSERT INTO table_b VALUES(8,'Microsoft');
INSERT INTO table_b VALUES(9,'Apple');
INSERT INTO table_b VALUES(11,'Scotch whisky');
```

The subquery has no dependency relationship. Execute the following statement:

```
SELECT * FROM TABLE_A T1 WHERE T1.PK IN (SELECT T2.PK FROM TABLE_B T2);
```

The following query result is returned:

```
+------+-----------+
| PK   | NAME      |
+------+-----------+
|    1 | Fox    |
|    2 | Police      |
|    3 | Taxi      |
|    6 | Washington    |
|    7 | Dell      |
+------+-----------+
```

The subquery has the dependency relationship. The outer query variable **T1.PK** is used in the subquery. Execute the following statement:

```
SELECT * FROM TABLE_A T1 WHERE T1.PK IN (SELECT T2.PK FROM TABLE_B T2 WHERE T2.PK = T1.PK);
```

The following query result is returned:

```
+------+-----------+
| PK   | NAME      |
+------+-----------+
|    1 | Fox    |
|    2 | Police      |
|    3 | Taxi      |
|    6 | Washington    |
|    7 | Dell      |
+------+-----------+
```

The subquery that has the dependency relationship is unnested and rewritten as a join. Execute the following statement:

```
EXPLAIN SELECT * FROM TABLE_A T1 WHERE T1.PK IN (SELECT T2.NAME FROM TABLE_B T2 WHERE T2.NAME = T1.NAME);
```

The following query result is returned:

```
+------------------------------------+
| Query Plan                         |
+------------------------------------+
============================================
|ID|OPERATOR            |NAME|EST. ROWS|COST|
--------------------------------------------
|0 |HASH RIGHT SEMI JOIN|    |8        |107 |
|1 | TABLE SCAN         |T2  |8        |38  |
|2 | TABLE SCAN         |T1  |8        |38  |
============================================
Outputs & filters:
-------------------------------------
  0 - output([T1.PK], [T1.NAME]), filter(nil),
      equal_conds([T1.PK = T2.NAME], [T2.NAME = T1.NAME]), other_conds(nil)
  1 - output([T2.NAME]), filter(nil),
      access([T2.NAME]), partitions(p0)
  2 - output([T1.NAME], [T1.PK]), filter(nil),
      access([T1.NAME], [T1.PK]), partitions(p0)
+------------------------------------+
```

17.1.5.10. SQL statements

17.1.5.10.1. DDL

17.1.5.10.1.1. ALTER KEYSTORE

Description

The ALTER KEYSTORE statement modifies keystore attributes, such as enabling or disabling the keystore, changing the keystore password, and generating a secret key for the keystore.

Syntax

```
## Enable or disable KEYSTORE.
ADMINISTER KEY MANAGEMENT SET [keystore_name] OPEN IDENTIFIED BY [password];
ADMINISTER KEY MANAGEMENT SET [keystore_name] CLOSE IDENTIFIED BY [password];

## Set the secret key.
ADMINISTER KEY MANAGEMENT SET KEY IDENTIFIED BY [password]
```

Parameter description

Parameter	Description
keystore_name	Specifies the keystore name.

Parameter	Description
password	Specifies the password of the keystore for access control.

Examples

- Enable the keystore. You can access the encrypted table and set the key only when the keystore is in the open state.

```
ADMINISTER KEY MANAGEMENT SET my_keystore OPEN IDENTIFIED BY abcCBAK123;
```

- Update the master key that is stored in the keystore.

```
ADMINISTER KEY MANAGEMENT SET KEY IDENTIFIED BY abcCBAK123;
```

17.1.5.10.1.2. ALTER OUTLINE

Description

This statement supports only the outlines that you create by using SQL_TEXT. You can execute this statement to add and bind outlines and throttling rules.

Syntax

```
ALTER OUTLINE outline_name ADD stmt [ TO target_stmt ]
```

Parameter description

Parameter	Description
outline_name	The name of the outline to be created.
stmt	The value is generally a DML statement that contains hints and original parameters.

Parameter	Description
TO target_stmt	Assume that you do not specify TO target_stmt and the SQL statement accepted by the database is parameterized. If the parameterized SQL statement is the same as the parameterized text of stmt from which the hint is removed, the SQL statement is bound to the hint in stmt to generate an execution plan. If you need to generate a fixed plan for the statement that contains a hint, you must use TO target_stmt to specify the original SQL statement. **Notice** When target_stmt is used, it is strictly required that stmt exactly matches target_stMT from which the hint is removed.

Examples

- Execute ALTER OUTLINE to add throttling rules.

```
OceanBase (root@oceanbase)> alter outline ol_1 add select /*+max_concurrent(1)*/ * from t1 where c1 =
1 and c2 = ? ;
OceanBase (root@oceanbase)> alter outline ol_1 add select /*+max_concurrent(1)*/ * from t1 where c1 =
? and c2 = 1;
```

- Execute ALTER OUTLINE to add an execution plan.

```
OceanBase (root@oceanbase)> create outline ol_2 on select /*+max_concurrent(1)*/ * from t1,t2 where t
1.c1 = 1;
OceanBase (root@oceanbase)> alter outline ol_2 add select /*+use_nl(t2)*/ * from t1,t2 where t1.c1 =
1;
```

Notes

- You can specify only one execution plan for one outline_name. If you specify an execution plan by executing the create outline statement, you cannot add an execution plan by executing alter outline.
- When you execute alter outline, you can specify only a throttling rule or an execution plan. This is similar to the rule of executing create outline.
- When you execute alter outline, outline_name must match the signature.

17.1.5.10.1.3. ALTER SEQUENCE

Description

This statement modifies an auto-increment column.

Syntax

```
ALTER SEQUENCE sequence_name
  [MINVALUE value | NOMINVALUE]
  [MAXVALUE value | NOMAXVALUE]
  [INCREMENT BY value]
  [CACHE value | NOCACHE]
  [ORDER | NOORDER]
  [CYCLE | NOCYCLE];
```

Parameter description

Parameter	Description
MINVALUE value | NOMINVALUE	Specifies the minimum value of the auto-increment column. Valid values: -10^{27} to (10^{27}-1). If you set this parameter to NOMINVALUE, the minimum value is 1 for the ascending order and the minimum value is -(10^{27}-1) for the descending order. If no parameter is specified, the default value is NOMINVALUE.
MAXVALUE value | NOMAXVALUE	Specifies the maximum value of the auto-increment column. Valid values: (-10^{27}+1) to 10^{27}. If you set this parameter to NOMAXVALUE, the maximum value is (10^{28}-1) for the ascending order and the maximum value is -1 for the descending order. If no parameter is specified, the default value is NOMAXVALUE.
START WITH value	Specifies the start value of the auto-increment column. This value must be less than or equal to MAXVALUE and greater than or equal to MINVALUE. If no parameter is specified, the default value is the minimum value for the ascending order and the default value is the maximum value for the descending order.
INCREMENT BY value	Specifies the auto-increment step for the auto-increment column. The value cannot be 0. If you specify this parameter as a positive number, the auto-increment column is in ascending order. If you specify this parameter as a negative number, the auto-increment column is in descending order. If no parameter is specified, the default value is 1.
CACHE value | NOCACHE	Specifies the number of preassigned auto-increment values in the memory. Default value: 20.

Parameter	Description
ORDER | NOORDER	Specifies whether the values of the auto-increment column are generated in sequence. Default value: NOORDER.
CYCLE | NOCYCLE	Specifies whether the values of the auto-increment column are cyclically generated. Default value: NOCYCLE.

Examples

- Modify the maximum value of the auto-increment column my_sequence and specify that the values of the auto-increment column are cyclically generated.

```
OceanBase(root@oceanbase)>ALTER SEQUENCE my_sequence MAXVALUE 1024 CYCLE;
```

Considerations

- You cannot change the value of START WITH in `ALTER SEQUENCE`. If you need to modify the start position for the next sequence, you can modify `INCREMENT BY` to modify the start position.
- For other considerations of the auto-increment column values, see the CREATE SEQUENCE statement.

17.1.5.10.1.4. ALTER SESSION

Description

This statement modifies the status of a session.

ALTER SESSION has the statements of multiple features. ApsaraDB for OceanBase supports the following three features:

- Switching the database to which the current session connects.
- Modifying the isolation level of the current session.
- Specifying the session variables. You can specify multiple variables in the same statement.

Syntax

```
ALTER SESSION SET CURRENT_SCHEMA = current_schema;
ALTER SESSION SET ISOLATION_LEVEL = [READ UNCOMMITTED|READ COMMITTED|REPEATABLE READ|SERIALIZABLE];
ALTER SESSION SET var1_name = var1_value var2_name = var2_value ... ;
```

Parameter description

Parameter	Description
CURRENT_SCHEMA	Specifies the name of the database to which the connected session switches.

Parameter	Description
ISOLATION_LEVEL	Specifies the isolation level of the session.
var1_name = var1_value var2_name = var2_value ...	Specifies the name and the value of the session variable. When you specify multiple variables, the variables are not separated by commas (,).

Examples

- Change the values of the recyclebin, sql_warnings, and tx_isolation variables of a session.

```
OceanBase(TEST@TEST)>alter session set recyclebin = 'on' sql_warnings = 'on' tx_isolation = 'read-com
mitted';
Query OK, 0 rows affected (0.01 sec)
```

17.1.5.10.1.5. ALTER TABLE

Description

The ALTER TABLE statement changes the schema of an existing table. For example, you can modify a table and table attributes, add columns, modify columns and column attributes, and delete columns.

Syntax

```
alter_table_stmt:
      ALTER TABLE table_name
      alter_table_action_list;
    | RENAME TABLE rename_table_action_list;

alter_table_action_list:
    alter_table_action [, alter_table_action ...]

alter_table_action:
      ADD [COLUMN] {column_definition | (column_definition_list)}
    | MODIFY [COLUMN] column_definition
    | DROP [COLUMN] column_name
    | ADD [CONSTRAINT [constraint_name]] UNIQUE {INDEX | KEY} [index_name] index_desc
        | ADD [CONSTRAINT [constraint_name]] FOREIGN KEY (column_name_list) references_clause
    | ADD [CONSTRAINT [constraint_name]] CHECK (expr)
    | ADD {INDEX | KEY} [index_name] index_desc
    | ADD FULLTEXT [INDEX | KEY] [index_name] fulltext_index_desc
    | ALTER INDEX index_name [VISIBLE | INVISIBLE]
    | DROP {INDEX | KEY} index_name
    | ADD PARTITION (range_partition_list)
    | DROP PARTITION (partition_name_list)
    | REORGANIZE PARTITION name_list INTO partition_range_or_list
    | TRUNCATE PARTITION name_list
    | [SET] table_option_list
    | RENAME [TO] table_name
    | DROP TABLEGROUP
    | DROP CONSTRAINT constraint_name

rename_table_action_list:
    rename_table_action [, rename_table_action ...]
```

```
rename_table_action:
    table_name TO table_name

column_definition_list:
    column_definition [, column_definition ...]

column_definition:
    column_name data_type
    [DEFAULT const_value] [AUTO_INCREMENT]
    [NULL | NOT NULL] [[PRIMARY] KEY] [UNIQUE [KEY]] comment

index_desc:
   (column_desc_list) [index_type] [index_option_list]

fulltext_index_desc:
   (column_desc_list) CTXCAT(column_desc_list) [index_option_list]

column_desc_list:
    column_desc [, column_desc ...]

column_desc:
     column_name [(length)] [ASC | DESC]

index_type:
    USING BTREE

index_option_list:
    index_option [ index_option ...]

index_option:
      [GLOBAL | LOCAL]
    | block_size
    | compression
    | STORING(column_name_list)
    | comment

table_option_list:
    table_option [ table_option ...]

table_option:
    | primary_zone
    | replica_num
    | table_tablegroup
    | block_size
    | compression
    | AUTO_INCREMENT [=] INT_VALUE
    | comment
    | DUPLICATE_SCOPE [=] "none|zone|region|cluster"

partition_option:
      PARTITION BY HASH(expression)
      [subpartition_option] PARTITIONS partition_count
    | PARTITION BY KEY([column_name_list])
      [subpartition_option] PARTITIONS partition_count
    | PARTITION BY RANGE {(expression) | COLUMNS (column_name_list)}
      [subpartition_option] (range_partition_list)

subpartition_option:
      SUBPARTITION BY HASH(expression)
```

```
      SUBPARTITION BY HASH(expression)
      SUBPARTITIONS subpartition_count
    | SUBPARTITION BY KEY(column_name_list)
      SUBPARTITIONS subpartition_count
    | SUBPARTITION BY RANGE {(expression) | COLUMNS (column_name_list)}
      (range_subpartition_list)

range_partition_list:
    range_partition [, range_partition ...]

range_partition:
    PARTITION partition_name
    VALUES LESS THAN {(expression_list) | MAXVALUE}

range_subpartition_list:
    range_subpartition [, range_subpartition ...]

range_subpartition:
    SUBPARTITION subpartition_name
    VALUES LESS THAN {(expression_list) | MAXVALUE}

expression_list:
    expression [, expression ...]

column_name_list:
    column_name [, column_name ...]

partition_name_list:
    partition_name [, partition_name ...]

partition_count | subpartition_count:
    INT_VALUE
```

Parameter description

Parameter	Description
ADD [COLUMN]	Adds a column. You cannot add a primary key column.
MODIFY [COLUMN]	Modifies column attributes.
DROP [COLUMN]	Deletes a column. You are not allowed to delete the primary key column or a column that has indexes.
ADD [UNIQUE INDEX]	Adds a unique index.
ADD [INDEX]	Adds a general index.
ALTER [INDEX]	Modifies index attributes.
ADD [PARTITION]	Adds a partition.

Parameter	Description
DROP [PARTITION]	Deletes a partition.
REORGANIZE [PARTITION]	Reorganizes a partition.
TRUNCATE [PARTITION]	Deletes partition data.
RENAME [TO] table_name	Renames a table.
DROP [TABLEGROUP]	Deletes a table group.
DROP [CONSTRAINT]	Deletes a constraint.
SET BLOCK_SIZE	Specifies the block size of the partitioned table.
SET REPLICA_NUM	Specifies the number of replicas for the table. The value indicates the total number of replicas.
SET COMPRESSION	Specifies the compression method of the table.
SET USE_BLOOM_FILTER	Specifies whether to use BloomFilter.
SET COMMENT	Specifies comment information.
SET PROGRESSIVE_MERGE_NUM	Specifies the number of progressive merge rounds. Valid values: 1 to 64.

Examples

- Change the field type of the field d in table t2.

```
ALTER TABLE t2 MODIFY d CHAR(10);
```

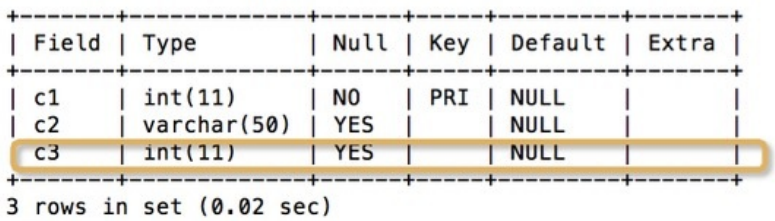
- Add and delete a column.
  - Before you add a column, run the `DESCRIBE test;` command to view table information. The following figure shows the result.

```
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| c1    | int(11)     | NO   | PRI | NULL    |       |
| c2    | varchar(50) | YES  |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
2 rows in set (0.01 sec)
```

- Run the following command to add the c3 column:

```
ALTER TABLE test ADD c3 int;
```

- After you add the column, run the `DESCRIBE test;` command to view the table information. The following figure shows the result.

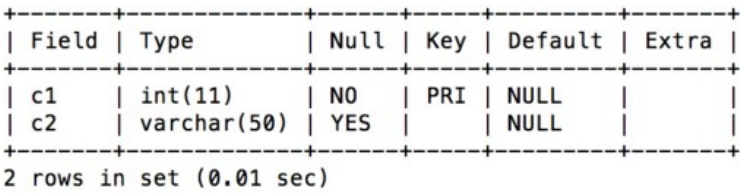


```
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| c1    | int(11)     | NO   | PRI | NULL    |       |
| c2    | varchar(50) | YES  |     | NULL    |       |
| c3    | int(11)     | YES  |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
3 rows in set (0.02 sec)
```

- Run the following command to delete the c3 column:

```
ALTER TABLE test DROP c3;
```

- After you delete the column, run the `DESCRIBE test;` command to view the table information. The following figure shows the result.



```
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| c1    | int(11)     | NO   | PRI | NULL    |       |
| c2    | varchar(50) | YES  |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
2 rows in set (0.01 sec)
```

- Set the number of replicas for the test table and add the c5 column.

```
ALTER TABLE test SET REPLICA_NUM=2, ADD COLUMN c5 INT;
```

17.1.5.10.1.6. ALTER TABLEGROUP

Description

This statement performs the following operations:

- Add multiple tables to a table group.
- Modify the partitioning rule of a table group.
- Modify the locality and the primary zone of a table group.

Syntax

- Add multiple tables to a table group.

```
ALTER TABLEGROUP tablegroupname ADD [TABLE] tblname [, tblname…]
```

- Modify the partitioning rule of a table group.

```
ALTER TABLEGROUP tablegroupname alter_tg_partition_option
alter_tg_partition_option:
DROP PARTITION '(' name_list ')'
| ADD PARTITION opt_range_partition_list
| modify_tg_partition_info
```

- Modify the locality and the primary zone of a table group.

```
ALTER TABLEGROUP tablegroupname alter_tablegroup_actions
alter_tablegroup_actions:
alter_tablegroup_action
| alter_tablegroup_action, alter_tablegroup_action
alter_tablegroup_action:
SET LOCALITY [=] locality_name
|SET PRIMARY_ZONE [=] primary_zone_name
```

Parameter description

Parameter	Description
tablegroupname	Specifies the table group.
tblname	The table name. If you add multiple tables to the table group, separate the tables with commas (,). If you add multiple tables, duplicate table names are allowed. If the table to be added already exists in the table group that is specified by *tablegroupname* , the system does not report an error.
modify_tg_partition_info	Modifies the partitioning rule of the table group.
LOCALITY locality_name	Specifies the locality of the table group.
PRIMARY_ZONE primary_zone_name	Specifies the primary zone of the table group.

Examples

- Create the table group tgh and two relational tables ttgh and ttgh2. Change the locality of the table group to F@z1.

```
OceanBase(admin@test)> create tablegroup tgh locality='F,R{ALL_SERVER}@z1' partition by hash partitio
ns 10;
Query OK, 0 rows affected (0.09 sec)

OceanBase(admin@test)> create table ttgh(c1 int, c2 int) tablegroup = tgh locality='F,R{ALL_SERVER}@z
1';
Query OK, 0 rows affected (0.55 sec)

OceanBase(admin@test)> create table ttgh2(c1 int, c2 int) tablegroup = tgh locality='F,R{ALL_SERVER}@
z1';
Query OK, 0 rows affected (0.39 sec)

OceanBase(admin@test)> alter tablegroup tgh set locality ='F@z1';
Query OK, 0 rows affected (0.09 sec)

OceanBase(admin@test)> select locality from oceanbase.__all_tablegroup where tablegroup_name ='tgh';
+------------+
| locality   |
+------------+
| FULL{1}@z1 |
+------------+
1 row in set (0.05 sec)

OceanBase(admin@test)> select locality from oceanbase.__all_table where tablegroup_id=(select tablegr
oup_id from oceanbase.__all_tablegroup where tablegroup_name ='tgh');
+------------+
| locality   |
+------------+
| FULL{1}@z1 |
| FULL{1}@z1 |
+------------+
2 rows in set (0.04 sec)
```

17.1.5.10.1.7. ALTER USER

Description

This statement performs the following operations:

- Change the password of an ApsaraDB for OceanBase user.
- Change the encryption method for an ApsaraDB for OceanBase user connection.

> **Note**
>
> To run this command, you must have the UPDATE USER permission.

Syntax

- Change the password of a user.

```
ALTER USER username IDENTIFIED BY password;
```

- Changes the encryption mode for a user connection.

```
ALTER USER user REQUIRE {NONE | SSL | x509 | tls_option_list}

tls_option_list:
  tls_option
  | tls_option_list tls_option

tls_option:
      CIPHER str_value
    | ISSUER str_value
    | SUBJECT str_value
```

Parameter description

Parameter	Description
REQUIRE	Specifies the encryption protocol.

Examples

- Change the password of the sqluser01 user to abc123.

```
ALTER USER sqluser01 IDENTIFIED BY abc123;
```

- Change the encryption protocol for the user connection to SSL.

```
ALTER USER sqluser REQUIRE SSL;
```

17.1.5.10.1.8. CREATE INDEX

Description

This statement creates an index. An index is a structure that is created on a table to sort the values of one or more columns of the database table. The main function of the index is to improve the query speed and reduce the performance cost of the database system.

Syntax

```
CREATE [UNIQUE] INDEX indexname
         ON tblname (index_col_name,...)
      [index_type] [index_options]
index_type:
      USING BTREE

index_options:
      index_option [index_option…]

index_option:
    GLOBAL | LOCAL
    | COMMENT 'string'
    | COMPRESSION [=] {NONE | LZ4_1.0 | LZO_1.0 | SNAPPY_1.0 | ZLIB_1.0}
    | BLOCK_SIZE [=] size
    | STORING(columname_list)
    | VISIBLE | INVISIBLE

index_col_name:
    colname [(length)] [ASC | DESC]

columname_list:
    colname [, colname…]
```

Parameter description

Parameter	Description
indexname	Specifies the name of the index to be created.
tblname	Specifies the name of the table to which the index belongs.
index_col_name	Specifies the column name of the index. Each column name can be followed by ASC that represents the ascending order, and cannot be followed by DESC that represents the descending order. By default, the ascending order is used. In the process of setting up the sorting method of indexes, records are first sorted by using the values of the first column in index_col_name. The records for which the values in the first column are the same are sorted by using the values in the next column. Similar rules apply to the other records.
index_type	The index type. Only USING BTREE is supported. This indicates that B-tree indexes are used.
UNIQUE	Specifies the index as a unique index.
index_option	Specifies the index option. Separate multiple values of index_option with spaces.

Parameter	Description
GLOBAL | LOCAL	Specifies whether the index is a global or local index. Default value: GLOBAL.
COMMENT	Specifies the comment.
COMPRESSION	Specifies the compression algorithm.
BLOCK_SIZE	Specifies the micro-block size.
STORING	Specifies that some columns are stored in the index table for redundant storage. This improves the query performance of systems.

Examples

1. Run the following command to create a table that is named test:

```
CREATE TABLE test (c1 int primary key, c2 VARCHAR(10));
```

2. Run the following command to create an index on the test table:

```
CREATE INDEX test_index ON test (c1, c2 DESC);
```

3. Run the following command to query the index on the test table:

```
SHOW INDEX FROM test;
```

17.1.5.10.1.9. CREATE KEYSTORE

Description

This statement creates a keystore object. This object stores keys. In TDE scenarios, you need to create a keystore object. Each tenant can create only one keystore object.

Syntax

```
ADMINISTER KEY MANAGEMENT CREATE KEYSTORE [KEYSTORE_NAME] IDENTIFIED BY [PASSSWORD] ;
```

Parameter description

Parameter	Description
KEYSTORE_NAME	Specifies the keystore name.

Parameter	Description
PASSWORD	Specifies the password of the keystore for access control.

Examples

Create a keystore object.

```
OceanBase(admin@test)>ADMINISTER KEY MANAGEMENT CREATE KEYSTORE my_keystore IDENTIFIED BY abcCBAK123;
```

17.1.5.10.1.10. CREATE OUTLINE

Description

This statement creates an outline. You can create an outline by using the two methods: SQL_TEXT and SQL_ID. SQL_TEXT is an original statement that contains parameters and is executed by a user.

> **Notice**
>
> To create an outline, you must use the corresponding user for execution.

Syntax

- **Create an outline by using SQL_TEXT.**

```
CREATE [OR REPLACE] OUTLINE outline_name ON stmt [ TO target_stmt ]
```

- **Create an outline by using SQL_ID.**

```
CREATE OUTLINE outline_name ON sql_id USING HINT  hint;
```

Parameter description

Parameter	Description
outline_name	The name of the outline to be created.
OR REPLACE	If the outline to be created already exists after you specify OR REPLACE, the original outline is replaced.
stmt	The value is generally a DML statement that contains hints and original parameters.

Parameter	Description
TO target_stmt	Assume that you do not specify TO target_stmt and the SQL statement accepted by the database is parameterized. If the parameterized SQL statement is the same as the parameterized text of stmt from which the hint is removed, the SQL statement is bound to the hint in stmt to generate an execution plan. If you need to generate a fixed plan for the statement that contains a hint, you must use TO target_stmt to specify the original SQL statement. **Notice** When target_stmt is used, it is strictly required that stmt exactly matches target_stMT from which the hint is removed.
sql_id	If the SQL statement that corresponds to sql_id has a hint, the hint that you specify when you create the outline overwrite all the hints in the original statement.
hint	The format is /*+ xxx */.

Examples

- Create an outline by using SQL_TEXT.

```
CREATE OUTLINE otl_idx_c2
       ON SELECT/*+ index(t1 idx_c2)*/ * FROM t1 WHERE c2 = 1;
```

- Create an outline by using SQL_ID.

```
CREATE OUTLINE otl_idx_c2
ON 'ED570339F2C856BA96008A29EDF04C74'
USING HINT /*+ index(t1 idx_c2)*/ ;
```

Considerations

An outline created by using SQL_TEXT overwrites an outline created by using SQL_ID. SQL_TEXT. The outline created by using SQL_TEXT has the higher precedence.

17.1.5.10.1.11. CREATE SEQUENCE

Description

This statement creates an auto-increment column.

Syntax

```
CREATE SEQUENCE sequence_name
  [MINVALUE value | NOMINVALUE]
  [MAXVALUE value | NOMAXVALUE]
  [START WITH value]
  [INCREMENT BY value]
  [CACHE value | NOCACHE]
  [ORDER | NOORDER]
  [CYCLE | NOCYCLE];
```

Parameter description

Parameter	Description
MINVALUE value | NOMINVALUE	Specifies the minimum value of the auto-increment column. Valid values: -10^{27} to (10^{27}-1). If you set this parameter to NOMINVALUE, the minimum value is 1 for the ascending order and the minimum value is -(10^{27}-1) for the descending order. If no parameter is specified, the default value is NOMINVALUE.
MAXVALUE value | NOMAXVALUE	Specifies the maximum value of the auto-increment column. Valid values: (-10^{27}+1) to 10^{27}. If you set this parameter to NOMAXVALUE, the maximum value is (10^{28}-1) for the ascending order and the maximum value is -1 for the descending order. If no parameter is specified, the default value is NOMAXVALUE.
START WITH value	Specifies the start value of the auto-increment column. This value must be less than or equal to MAXVALUE and greater than or equal to MINVALUE. If no parameter is specified, the default value is the minimum value for the ascending order and the default value is the maximum value for the descending order.
INCREMENT BY value	Specifies the auto-increment step for the auto-increment column. The value cannot be 0. If you specify this parameter as a positive number, the auto-increment column is in ascending order. If you specify this parameter as a negative number, the auto-increment column is in descending order. If no parameter is specified, the default value is 1.
CACHE value | NOCACHE	Specifies the number of preassigned auto-increment values in the memory. Default value: 20.

Parameter	Description
ORDER | NOORDER	Specifies whether the values of the auto-increment column are generated in sequence. Default value: NOORDER.
CYCLE | NOCYCLE	Specifies whether the values of the auto-increment column are cyclically generated. Default value: NOCYCLE.

Examples

- Create an auto-increment column s1.

```
OceanBase(ADMIN@TEST)>create sequence S1 minvalue 1 maxvalue 5 nocycle noorder cache 10240000;
```

Considerations

- If you specify both MINVALUE and MAXVALUE, MINVALUE must be smaller than MAXVALUE.
- The difference between MAXVALUE and MINVALUE must be greater than or equal to INCREMENT BY value.
- The value of the CACHE value must be greater than 1. If the value of CACHE value is 1, the value is equivalent to NOCACHE.
- If you specify CYCLE and INCREMENT BY value is smaller than 0, you must specify MINVALUE.
- If you specify CYCLE, the number of caches cannot exceed one cycle.

17.1.5.10.1.12. CREATE SYNONYM

Description

The CREATE SYNONYM statement creates a synonym.

Syntax

```
CREATE [ OR REPLACE ] [ PUBLIC ]
SYNONYM [ schema. ]synonym
FOR [ schema. ]object;
```

Parameter description

Parameter	Description
OR REPLACE	Specifies that if the name of the synonym to be created already exists, the synonym is recreated based on the new definition.

Parameter	Description
PUBLIC	Specify PUBLIC to create a public synonym that can be used by all users. To use the synonym, users must have the corresponding permission on the basic object. When the reference to an object is resolved, the public synonym is used only if no schema is specified for the object. If you do not specify PUBLIC, the synonym is private and can be accessed by only the current schema. In addition, the synonym name must be unique in the current schema.
[schema.]synonym	schema specifies the schema of the current synonym. If you specify PUBLIC, you do not need to specify a schema for the synonym. synonym specifies the name of the synonym.
[schema.]object	The name of the object that corresponds to the synonym.

Examples

- Create a synonym.

```
OceanBase(TEST@TEST)>create table t1(c1 int);
Query OK, 0 rows affected (0.11 sec)

OceanBase(TEST@TEST)>create synonym s1 for t1;
Query OK, 0 rows affected (0.04 sec)

OceanBase(TEST@TEST)>insert into s1 values(1);
Query OK, 1 row affected (0.04 sec)

OceanBase(TEST@TEST)>select * from s1;
+------+
| C1   |
+------+
|    1 |
+------+
1 row in set (0.02 sec)
```

- Create a public synonym.

```
OceanBase(TEST@TEST)>create public synonym syn_pub for t1;
Query OK, 0 rows affected (0.04 sec)

OceanBase(TEST@TEST)>select * from syn_pub;
+------+
| C1   |
+------+
|    1 |
+------+
1 row in set (0.01 sec)
```

Considerations

To create synonyms, the following permission requirements must be met:

- To create a private synonym in the current schema, you must have the CREATE SYNONYM permission.
- To create a private synonym in a schema that is not the current schema, you must have the CREATE ANY SYNONYM permission.
- To create a public synonym, you must have the CREATE PUBLIC SYNONYM permission.
- The object for which you need to create a synonym does not need to exist. Access permissions are not required.

```
// Create synonym_user.
OceanBase(TEST@TEST)>CREATE USER synonym_user IDENTIFIED BY synonym_user;
Query OK, 0 rows affected (0.04 sec)

OceanBase(TEST@TEST)>grant CREATE on test.* to synonym_user;
Query OK, 0 rows affected (0.05 sec)

OceanBase(TEST@TEST)>grant SELECT on test.* to synonym_user;
Query OK, 0 rows affected (0.02 sec)

// Connect to synonym_user.
OceanBase(SYNONYM_USER@TEST)>create or replace synonym s1 for t1;
ERROR-00600: internal error code, arguments: -5036, Access denied; you need (at least one of) the CRE
ATE SYNONYM privilege(s) for this operation

// Grant the CREATE SYNONYM permission again.
OceanBase(TEST@TEST)>grant CREATE SYNONYM on *.* to synonym_user;
Query OK, 0 rows affected (0.03 sec)

OceanBase(SYNONYM_USER@TEST)>create synonym s1 for t1;
Query OK, 0 rows affected (0.07 sec)
```

17.1.5.10.1.13. CREATE TABLE

Description

The CREATE TABLE statement creates a table in a database.

Syntax

```
CREATE [GLOBAL TEMPORARY] TABLE table_name
      (table_definition_list) [table_option_list] [partition_option] [on_commit_option]
CREATE [GLOBAL TEMPORARY] TABLE table_name
      (table_definition_list) [table_option_list] [partition_option] [AS] select;

table_definition_list:
    table_definition [, table_definition ...]

table_definition:
      column_definition
    | INDEX [index_name] index_desc
    | [CONSTRAINT [constraint_name]] [PRIMARY KEY|UNIQUE]  (column_desc_list) [USING INDEX index_opti
on_list]
    | [CONSTRAINT [constraint_name]] FOREIGN KEY (column_name, column_name ...) references_clause con
stranit_state
    | [CONSTRAINT [constraint_name]] CHECK(expression) constranit_state
```

```
column_definition_list:
    column_definition [, column_definition ...]

column_definition:
    column_name data_type
    [VISIBLE|INVISIBLE]
    {
    [DEFAULT expression]
    [NULL | NOT NULL]
    [CONSTRAINT [constraint_name] [PRIMARY] KEY] [UNIQUE [KEY]]
    [CONSTRAINT [constraint_name] CHECK(expression) constranit_state]
    [CONSTRAINT [constraint_name] references_clause
    |
    [GENERATED ALWAYS] AS (expression) [VIRTUAL]
    [NULL | NOT NULL] [UNIQUE KEY] [[PRIMARY] KEY] [UNIQUE LOWER_KEY] [COMMENT string]
    }

references_clause:
     REFERENCES table_name (column_name, column_name ...) [ON DELETE {CASCADE|SET NULL}]]

constranit_state:
    [RELY|NORELY] [USING INDEX index_option_list] [ENABLE|DISABLE] [VALIDATE|NOVALIDATE]

index_desc:
   (column_desc_list) [index_option_list]

column_desc_list:
    column_desc [, column_desc ...]

column_desc:
     column_name [ASC | DESC][NULL LAST|NULL FIRST]

index_option_list:
    index_option [ index_option ...]

index_option:
      [GLOBAL | LOCAL]
    | block_size
    | compression
    | STORING(column_name_list)
    | comment

table_option_list:
    table_option [ table_option ...]

table_option:
    primary_zone
    | replica_num
    | table_tablegroup
    | block_size

    PARTITION [partition_name] VALUES (DEFAULT|expression_list) [ID num] [physical_attribute_list] [c
ompression]

list_subpartition_list:
```

```
    list_subpartition [, list_subpartition] ...

list_subpartition:
    SUBPARTITION [partition_name] VALUES (DEFAULT|expression_list) [physical_attribute_list]

expression_list:
    expression [, expression ...]

column_name_list:
    column_name [, column_name ...]

partition_name_list:
    partition_name [, partition_name ...]

partition_count | subpartition_count:
    INT_VALUE

on_commit_option:
    ON COMMIT DELETE ROWS
    | ON COMMIT PRESERVE ROWS
```

Parameter description

Parameter	Description
DUPLICATE_SCOPE	Specifies the attributes of the replicated table. Valid values: • none: indicates that the table is a standard table. • zone: indicates that the table is a replicated table. The leader needs to replicate transactions to all the F replicas and R replicas of the current zone. • region: indicates that the table is a replicated table. The leader needs to replicate transactions to all the F replicas and R replicas of the current region. • cluster: indicates that the table is a replicated table. The leader needs to replicate transactions to all the F replicas and R replicas of the cluster. If DUPLICATE_SCOPE is not specified, the default value is none.
BLOCK_SIZE	Specifies the micro-block size of the table.

Parameter	Description
COMPRESSION	Specifies the flat or encoding storage format and the compression method. The following correspondence relationships are available: • nocompress: flat format, none compression • compress [basic]: flat format, lz4_1.0 compression • compress for oltp: flat format, zstd_1.0 compression • query [low|high]: encoding format, lz4_1.0 compression • archive [low|high]: encoding format, zstd_1.0 compression
primary_zone	Specifies the primary zone where the leader replica resides.
replica_num	Specifies the number of replicas.
table_tablegroup	Specifies the tablegroup to which the table belongs.
comment	The comment.
LOCALITY	Describes the distribution of replicas among zones. For example, F@z1,F@z2,F@z3,R@z4 indicates that z1, z2, and z3 are full-featured replicas and z4 is a read-only replica.
physical_attribute	PCTFREE: specifies the percentage of reserved macro block space. Other attributes: Attributes such as STORAGE and TABLESPACE are only for syntax compatibility to facilitate migration and do not take effect.
ENABLE/DISABLE ROW MOVEMENT	Specifies whether to allow data to be moved between partitions.
ON COMMIT DELETE ROWS	Transaction-level temporary tables: The data is deleted on commit.
ON COMMIT PRESERVE ROWS	Session-level temporary tables: The data is deleted when the session ends.

Examples

- Create a database table.

```
CREATE TABLE test (c1 int primary key, c2 VARCHAR(50)) REPLICA_NUM = 3, PRIMARY_ZONE = 'zone1';
```

- Create a replicated table.

```
CREATE TABLE item() locality = 'F,R{all_server}@hz1, F,R{all_server}@hz2,
F,R{all_server}@hz3' DUPLICATE_SCOPE="cluster"
```

- Create a table that has indexes.

```
create table t1 (c1 int primary key, c2 int, c3 int, index i1 (c2));
```

- Create a table that has eight hash partitions.

```
create table t1 (c1 int primary key, c2 int) partition by hash(c1) partitions 8;
```

- Create a table that has range partitions and hash subpartitions.

```
 create table t1 (c1 int, c2 int, c3 int)
     partition by range(c1) subpartition by hash(c2) subpartitions 5
     (partition p0 values less than(0), partition p1 values less than(100));
```

- Enable encoding and zstd compression. Set the percentage of reserved macro block space to 5%.

```
create table t1 (c1 int, c2 int, c3 varchar(64))
  COMPRESS FOR ARCHIVE
  PCTFREE 5;
```

- Create a transaction-level temporary table.

```
create global temporary table t1 (c1 int) on commit delete rows ;
```

- Create a table that has a constraint.

```
create table t1 (c1 int, c2 int, c3 int, CONSTRAINT equal_check CHECK(c2 = c3 * 2) ENABLE VALIDATE);
```

17.1.5.10.1.14. CREATE TABLEGROUP

Description

This statement creates a table group.

> **Note**
>
> Only the tenant administrator can create table groups.

Syntax

```
CREATE TABLEGROUP [IF NOT EXISTS] tablegroupname [opt_tablegroup_option_list] [opt_tg_partition_optio
n]

opt_tablegroup_option_list:
tablegroup_option [tablegroup_option]

tablegroup_option:
LOCALITY [=] locality_name
| PRIMARY_ZONE [=] primary_zone_name

opt_tg_partition_option:
PARTITION BY
 HASH COLUMN_NUM [tg_subpartition_option] PARTITIONS INTNUM
| RANGE COLUMNS COLUMN_NUM [tg_subpartition_option] {PARTITION partition_name VALUES LESS THAN range_
partition_expr, ...}
| LIST COLUMNS COLUMN_NUM [tg_subpartition_option] {PARTITION partition_name VALUES in list_partition
_expr, ...}

tg_subpartition_option:
SUBPARTITION BY
RANGE COLUMN_NUM SUBPARTITION TEMPLATE {SUBPARTITION partition_name VALUES LESS THAN range_partition_
expr, ...}
| HASH COLUMN_NUM [SUBPARTITIONS INTNUM]
| LIST COLUMN_NUM SUBPARTITION TEMPLATE {SUBPARTITION partition_name VALUES in list_partition_expr, .
..}
```

Parameter description

Parameter	Description
tablegroupname	The name of the table group. It must be up to 64 characters in length and can contain only letters, digits, and underscores (_). The name must start with a letter or an underscore (_) and cannot be a keyword that is reserved for ApsaraDB for OceanBase. If the specified table group name is already used and IF NOT EXISTS is not specified, an error occurs.

Parameter	Description
opt_tablegroup_option_list	The partitioning method, locality, and primary zone of the table group must be exactly consistent with those of the tables in the group. You cannot independently change an item of table information in the table group. You can perform only batch operations on the table group. Same locality: The types, quantities, and locations for replicas must be exactly consistent. Same primary zone: The locations and the precedences of leaders must be exactly consistent. Same partitioning method: • The partitioning types must be the same. For example, hash partitioning and range partitioning are used for each table. • If hash partitioning is used, the numbers of referenced columns must be the same and the numbers of partitions must be same. • If range partitioning is used, the number of referenced columns must be the same and the number of partitions must be the same. In addition, the range split points must be the same. • The subpartition requirements must be consistent with the preceding requirements based on the partitioning types.
opt_tg_partition_option	Specifies the partitioning rule for the table group. This rule is the same as the partitioning method that is used by CREATE TABLE. The table group does not have the specific column definition. Therefore, you do not need to write specific columns for HASH, RANGE, and LIST, and you need to specify only the number of columns (COLUMN_NUM).

Examples

- Create a table group that is named myTableGroup1.

```
OceanBase(admin@test)> CREATE TABLEGROUP myTableGroup1;
Query OK, 0 rows affected (0.07 sec)

OceanBase(admin@test)> create table myt1 (c1 int, c2 int ) tablegroup = myTableGroup1;
Query OK, 0 rows affected (0.28 sec)

OceanBase(admin@test)> create table myt2 (c1 int, c2 int ) tablegroup = myTableGroup1;
Query OK, 0 rows affected (0.26 sec)
```

- Create the table group tgh whose partitioning method is hash partitioning. Create the ttgh table whose partitioning method is hash partitioning. The number of partitions for the table group tgh is the same as that for the ttgh table.

```
OceanBase(admin@test)> create tablegroup tgh locality='F,R{ALL_SERVER}@z1' partition by hash partitio
ns 10;
Query OK, 0 rows affected (0.09 sec)

OceanBase(admin@test)> create table ttgh(c1 int, c2 int) locality='F,R{ALL_SERVER}@z1' partition by h
ash(c1) partitions 10;
Query OK, 0 rows affected (0.55 sec)

OceanBase(admin@test)> create table ttgh2(c1 int, c2 int) locality='F,R{ALL_SERVER}@z1' partition by
hash(c2) partitions 10;
Query OK, 0 rows affected (0.39 sec)
```

17.1.5.10.1.15. CREATE TABLESPACE

Description

The CREATE TABLESPACE statement creates a tablespace logical object. The tablespace attributes can be encrypted.

Syntax

```
CREATE TABLESPACE tablespace_name [ENCRYPTION USING 'AES-256|AES-128|AES-192|SM4']
```

Parameter description

Parameter	Description
tablespace_name	Specifies the name of the tablespace object to be created.
ENCRYPTION USING	The keyword for using encryption.
AES-256|AES-128|AES-192|SM4	Represents different encryption algorithms.

Examples

- Create a tablespace object.

```
CREATE TABLESPACE ob_tablespace;

CREATE TABLESPACE ob_tablespace ENCRYPTION USING 'AES-256';
```

17.1.5.10.1.16. CREATE USER

Description

This statement creates a new ApsaraDB for OceanBase user. After a user is created, you can use the user to connect to ApsaraDB for OceanBase.

> **Note**
>
> To use the CREATE USER command, you must have the CREATE USER system permission.

Syntax

```
create_user_stmt:
    CREATE USER user_name [host_name] IDENTIFIED BY password [REQUIRE {NONE | SSL | X509 | tls_option
_list}]
 [PROFILE user_profile] [DEFAULT TABLESPACE table_space]

password:
    STR_VALUE

tls_option_list:
        tls_option
    | tls_option_list, tls_option

tls_option:
          CIPHER STR_VALUE
    | ISSUER STR_VALUE
    | SUBJECT STR_VALUE
```

Parameter description

Parameter	Description
user_name	The username. After a new user is created, a new row for this user is added to the dba_users table. If the same username already exists, the system reports an error.
host_name	The hostname of the user. The value is in the @xxx.xxx.xx.x format.
IDENTIFIED BY	You must use an IDENTIFIED BY clause. You can specify a password for the account.
REQUIRE	Set the encryption protocol used by the user to NONE, SSL, X509, or tls_option_list.
PROFILE user_profile	Specifies a profile that is used by the user.
DEFAULT TABLESPACE table_space	Specifies the default tablespace for the user.

Examples

1. Run the following command to create a user named sqluser for which the password is 123456.

```
CREATE USER sqluser IDENTIFIED BY 123456;
```

2. Run the following command to query the created user.

```
SELECT username FROM dba_users;
```

The following execution result is displayed:

```
OceanBase(TEST@TEST)>CREATE USER sqluser IDENTIFIED BY 123456;
Query OK, 0 rows affected (0.05 sec)
OceanBase(TEST@TEST)>SELECT username FROM dba_users;
+------------+
| USERNAME   |
+------------+
| SYS        |
| LBACSYS    |
| ORAAUDITOR |
| ROOT       |
| TEST       |
| ADMIN      |
| SQLUSER    |
+------------+
7 rows in set (0.01 sec)
```

17.1.5.10.1.17. CREATE VIEW

Description

The CREATE VIEW statement creates a view. If you specify an OR REPLACE clause, you can execute the statement to replace an existing view.

Views actually do not exist in the form of tables in databases and are derived each time the views are used. A view is generated from the result of the SELECT statement that is specified in the CREATE VIEW statement.

Updatable views are supported.

Syntax

```
create_view_stmt:
  CREATE [OR REPLACE] VIEW view_name [(column_name_list)] AS select_stmt;

column_name_list:
    column_name [, column_name ...]
```

Parameter description

Parameter	Description
OR REPLACE	Specifies that if the name of the view to be created already exists, the view is recreated based on the new definition.
view_name	The name of the view.

Parameter	Description
select_stmt	A type of SELECT statements. It defines a view. This statement can select data from base tables or other views.
column_name_list	The view must have unique column names and do not have duplicate column names. This rule is the same as that for base tables. By default, the column names that are retrieved by the SELECT statement are used as the column names for the view. To specify the column names of the view, you can use the optional column_name_list clause and list comma-separated IDs. The number of the column names in the column_name_list clause must be equal to the number of columns that are retrieved by the SELECT statement. The columns that are retrieved by the SELECT statement can be simple references to table columns. They can also be expressions that use functions, constant values, and operators.

Examples

- Select columns c1 and c2 from table t to create a view named v.

```
create or replace view v(vc1, vc2) as select c1, c2 from t;
```

17.1.5.10.1.18. DROP INDEX

Description

The DROP INDEX statement deletes an index. Maintenance overheads increase if excessive indexes exist. Therefore, unnecessary indexes need to be deleted.

When you delete an index, you need to wait for a period before the index is completely deleted.

Syntax

```
DROP INDEX [schema.]indexname;
```

Parameter description

Parameter	Description
schema	Specifies the schema name.
indexname	Specifies the index name.

Examples

- Delete the index test_index.

```
DROP INDEX test_index;
```

17.1.5.10.1.19. DROP OUTLINE

Description

This statement deletes an outline from the ApsaraDB for OceanBase database.

Syntax

```
DROP OUTLINE outline_name;
```

Parameter description

Parameter	Description
outline_name	The name of the outline to be deleted.

Examples

- Delete OUTLINE ol_1.

```
DROP OUTLINE ol_1;
```

17.1.5.10.1.20. DROP SEQUENCE

Description

This statement deletes an auto-increment column.

Syntax

```
DROP SEQUENCE sequence_name
```

Parameter description

Parameter	Description
sequence_name	The name of the auto-increment column to be deleted.

Examples

- Delete the auto-increment column S1.

```
OceanBase(TEST@TEST)>drop sequence S1;
Query OK, 0 rows affected (0.16 sec)
```

17.1.5.10.1.21. DROP SYNONYM

Description

This statement deletes a synonym.

Syntax

```
DROP [PUBLIC] SYNONYM [ schema. ]synonym;
```

Parameter description

Parameter	Description
PUBLIC	Specify PUBLIC to delete a public synonym. If you do not specify PUBLIC, a private synonym is deleted.
[schema.]synonym	The schema field specifies the schema to which the current synonym belongs. If PUBLIC is specified, you do not need to specify the schema field for the synonym. The synonym field specifies the name of the synonym.

Examples

- Delete a synonym.

```
OceanBase(TEST@TEST)>drop synonym test.s1;
Query OK, 0 rows affected (0.04 sec)
```

- Delete a public synonym.

```
OceanBase(TEST@TEST)>drop public synonym syn_pub;
Query OK, 0 rows affected (0.03 sec)
```

Considerations

1. When you delete a synonym, you must have the following permissions:
   - If you need to delete a private synonym:
     - The synonym to be deleted must be under the corresponding schema.
     - You must have the DROP ANY SYNONYM permission.
   - When you delete a public synonym, you must have the DROP PUBLIC SYNONYM permission.
2. When you delete a public synonym, you must specify the PUBLIC keyword and do not specify the schema.

17.1.5.10.1.22. DROP TABLE

Description

This statement deletes tables from an ApsaraDB for OceanBase database.

Syntax

```
DROP TABLE table_name [CASCADE CONSTRAINTS] [PURGE]
```

Parameter description

Parameter	Description
table_name	The name of the table to be deleted.
CASCADE CONSTRAINTS	Performs a cascade delete for the constraints that are associated with table_name.
PURGE	Purges the table. The table is not recycled in the recycle bin.

Examples

- Delete the test table.

```
DROP TABLE test;
```

17.1.5.10.1.23. DROP TABLEGROUP

Description

The DROP TABLEGROUP statement deletes a table group.

Syntax

```
DROP TABLEGROUP [IF EXISTS] tablegroupname
```

Parameter description

Parameter	Description
tablegroupname	The name of the table group. If the name of the table group to be deleted does not exist and IF EXISTS is not specified, an error is reported.

Examples

- Delete the table group named myTableGroup1.

```
OceanBase(admin@test)> DROP TABLEGROUP myTableGroup1;
```

17.1.5.10.1.24. DROP TABLESPACE

Description

The DROP TABLESPACE statement deletes a tablespace logical object. The object can be deleted only if no table exists under the tablespace.

Syntax

```
DROP TABLESPACE tablespace_name;
```

Parameter description

Parameter	Description
tablespace_name	Specifies the name of the tablespace to be deleted.

Examples

- Delete the tablespace object ts.

```
OceanBase(root@oceanbase)>drop tablesapce ts;
```

17.1.5.10.1.25. DROP USER

Description

This statement deletes an ApsaraDB for OceanBase user.

> Note
>
> - To run the DROP USER command, you must have the CREATE USER system permission.
> - CASCADE specifies that before a user is deleted, all the objects for the user, such as permissions, databases, and tables, are deleted.

Syntax

```
DROP USER username CASCADE;
```

Parameter description

Parameter	Description
username	The username. Only a single user can be deleted.

Examples

- Run the following command to delete the user that is named sqluser.

```
oceanBase(admin@TEST)>DROP USER sqluser CASCADE;
Query OK, 0 rows affected (0.06 sec)
```

17.1.5.10.1.26. DROP VIEW

Description

This statement deletes one or more views.

> **Note**
> The current user must have the DROP permission on each view.

Syntax

```
drop_view_stmt:
    DROP VIEW view_name [CASCADE | RESTRICT];
```

Parameter description

Parameter	Description
view_name	The name of the view to be deleted.
CASCADE | RESTRICT	CASCADE and RESTRICT are parsed and ignored.

Examples

- Delete the view v1.

```
OceanBase(root@oceanbase)>drop view v1;
```

17.1.5.10.1.27. RENAME

Description

The RENAME statement renames an object.

Syntax

```
RENAME obj_name TO new_obj_name;
```

Parameter description

Parameter	Description
obj_name	The original name of the object.
new_obj_name	The new name of the object.

Examples

1. Create tables t1 and t2.

```
create table t1(c1 int);
```

2. Rename table t1 to t11.

```
rename t1 to t11;
```

Considerations

You can rename tables, views, private synonyms, and sequences.

17.1.5.10.1.28. TRUNCATE TABLE

Description

The TRUNCATE TABLE statement fully clears a specified table but retains the table schema that includes the defined partition information in the table. This statement is logically the same as the DELETE FROM statement that deletes all rows. To execute the TRUNCATE statement, you must have the permissions to delete and create tables.

The TRUNCATE TABLE and DELETE FROM statements have the following differences:

- The TRUNCATE TABLE operation cancels and recreates the table. This is much faster than deleting rows one after one.
- The result of the TRUNCATE TABLE statement shows that the number of affected rows is always 0.

Syntax

```
TRUNCATE [TABLE] table_name;
```

Parameter description

Parameter	Description
table_name	Specifies the table name.

Examples

- Fully clears table tb1.

```
OceanBase(root@oceanbase)>TRUNCATE TABLE tb1;
```

17.1.5.10.2. DML

17.1.5.10.2.1. DELETE

Description

You can execute the DELETE statement to delete rows that meet the specified conditions from one or more tables.

Syntax

```
DELETE [hint_options] [FROM] table_factor
       [WHERE where_condition]
       [{ RETURNING | RETURN } returning_exprs [into_clause]]

table_factor:
    {tbl_name | table_subquery | '(' table_reference ')' }

where_condition:
    expression

returning_exprs:
    projection [, ...]

into_clause:
{ INTO into_var_list | BULK COLLECT INTO into_var_list}

into_var_list:
{ USER_VARIABLE | ref_name } [, ...]
```

Parameters

Parameter	Description
hint_options	The hint.
table_factor	The name of the table from which you want to delete rows. You can specify a base table, an updatable view, or a special subquery.
where_condition	The filter conditions. The system deletes rows from tables that meet the specified conditions.
returning_exprs	Return the projection that is defined before rows are deleted.
into_clause	Insert the projection that is defined before rows are deleted into the specified table.

Notice

A special subquery is similar to a subquery in an updatable view. A special subquery cannot include complex operators, such as GROUP BY, DISTINCT, and WINDOW FUNCTION.

Examples

The following statements define a sample table and inserts data into the table:

```
OceanBase(admin@test)>create table t1(c1 int primary key, c2 int);
Query OK, 0 rows affected (0.16 sec)
OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |    1 |
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
4 rows in set (0.06 sec)
```

- Delete rows from a table: Delete the rows where the value in the c1 column is 2. The c1 column is the primary key of the t1 table.

```
OceanBase(admin@test)>DELETE FROM t1 WHERE c1 = 2;
Query OK, 1 row affected (0.02 sec)

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |    1 |
|  3 |    3 |
|  4 |    4 |
+----+------+
3 rows in set (0.01 sec)
```

- Delete rows from a table: Use a subquery to delete rows.

```
OceanBase(admin@test)>DELETE FROM (SELECT * FROM t1);
Query OK, 4 rows affected (0.04 sec)

OceanBase(admin@test)>select * from t1;
Empty set (0.01 sec)
```

- Delete rows from a table: Execute a statement that includes the RETURNING clause.

```
OceanBase(admin@test)>DELETE FROM t1 RETURNING c1;
+----+
| C1 |
+----+
|  1 |
|  2 |
|  3 |
|  4 |
+----+
4 rows in set (0.01 sec)

OceanBase(admin@test)>select * from t1;
Empty set (0.01 sec)
```

17.1.5.10.2.2. INSERT

Description

You can execute the INSERT statement to add one or more records to a table.

Syntax

```
INSERT [hint_options] single_table_insert

single_table_insert:
{ INTO insert_table_clause opt_nologging '(' column_list ')' values_clause [{ RETURNING | RETURN } re
turning_exprs [into_clause]]
| INTO insert_table_clause opt_nologging '(' ')' values_clause [{ RETURNING | RETURN } returning_expr
s [into_clause]]
| INTO insert_table_clause opt_nologging values_clause [{ RETURNING | RETURN } returning_exprs [into_
clause]]
}

opt_nologging: { NOLOGGING | /*EMPTY*/ }

returning_exprs:
    projection [, ...]

into_clause:
{ INTO into_var_list | BULK COLLECT INTO into_var_list}

into_var_list:
{ USER_VARIABLE | ref_name } [, ...]
```

Parameters

Parameter	Description
hint_options	The hint.
insert_table_clause	The table to insert. You can specify a base table, an updatable view, or a special subquery.
opt_nologging	Minimize the number of logs generated when you insert data.
column_list	The columns to insert.
returning_exprs	The projection after you insert data.
into_clause	Insert the updated column values to the specified table columns.

> **Notice**
>
> A special subquery is similar to a subquery in an updatable view. Such a subquery cannot include complex operators, such as GROUP BY, DISTINCT, and WINDOW FUNCTION.

Examples

In the following examples, table t1 is used to describe how to insert data into a single table.

```
OceanBase(admin@test)>create table t1(c1 int primary key, c2 int);
Query OK, 0 rows affected (0.16 sec)
OceanBase(admin@test)>select * from t1;
Empty set (0.02 sec)
```

- Insert a row into table t1.

```
OceanBase(admin@test)>insert into t1 values(1,1);
Query OK, 1 row affected (0.01 sec)

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |    1 |
+----+------+
1 row in set (0.04 sec)
```

- Use a subquery to insert data into table t1.

```
OceanBase(admin@test)>insert into (select * from t1) values(1,1);
Query OK, 1 row affected (0.01 sec)

OceanBase(admin@test)>select * from t1;
+----+------+
| C1 | C2   |
+----+------+
|  1 |    1 |
+----+------+
1 row in set (0.01 sec)
```

- Execute a statement that includes the RETURNING clause to insert data into table t1.

```
OceanBase(admin@test)>insert into t1 values(1,1) returning c1;
+----+
| C1 |
+----+
|  1 |
+----+
1 row in set (0.02 sec)

OceanBase(admin@test)>select * from t1;
+----+------+
| C1 | C2   |
+----+------+
|  1 |    1 |
+----+------+
1 row in set (0.01 sec)
```

17.1.5.10.2.3. MERGE

Description

You can execute the MERGE statement to update data for a destination table based on a source table. For example, you can insert, update, or delete rows.

Syntax

```
MERGE [hint_options]
         INTO table_factor [opt_alias]
        USING table_factor [opt_alias]
            ON '(' expr ')'
    [merge_update_clause]
        [merge_insert_clause]

merge_update_clause:
    WHEN MATCHED THEN UPDATE SET update_asgn_list [WHERE expr] [DELETE WHERE expr]

merge_insert_clause:
    WHEN NOT MATCHED THEN INSERT opt_insert_columns VALUES '(' insert_vals ')' [WHERE expr]
```

Parameters

Parameter	Description
hint_options	The hint.
table_factor	The names of source and destination tables.
ON expr	The JOIN conditions of source and destination tables.
update_asgn_list	Assign values for the update.

Parameter	Description
WHERE expr	The conditions required to trigger the update, delete, or insert operation.

Examples

The following examples are based on tables t1 and t2.

```
create table t1 (c1 int, c2 int);
create table t2 (c1 int, c2 int);

insert into t1 values (0, 0);
insert into t1 values (1, null);
insert into t1 values (2, null);
insert into t2 values (1, 1);
insert into t2 values (2, 20);
insert into t2 values (3, 3);
insert into t2 values (4, 40);
```

Update table t1 based on table t2.

1. Assume that a value in column c1 of table t1 is equal to a value in column c1 of table t2.
    i. If a value in column c2 of table t1 is NULL, the system updates the value by using the value in column c2 of table t2.
    ii. After the update, if the value in column c2 of table t1 is greater than or equal to 0, the system deletes the value.
2. Assume that values in column c1 of table t2 do not match those of table t1.
    i. Find the values in column c2 of table t2 that are less than 10, and insert them into table t1.

```
merge into t1 using t2 on (t1.c1 = t2.c1)
when matched then update set c2 = t2.c2 where t1.c2 is null delete where t1.c2 >= 10
when not matched then insert values (t2.c1, t2.c2) where t2.c2 < 10;
Query OK, 3 rows affected (0.02 sec)

select * from t1;
+------+------+
| C1   | C2   |
+------+------+
|    0 |    0 |
|    1 |    1 |
|    3 |    3 |
+------+------+
```

17.1.5.10.2.4. PURGE DATABASE

Description

You can execute the PURGE DATABASE statement to delete a database from the recycle bin.

Syntax

```
PURGE DATABASE object_name;
```

Parameters

Parameter	Description
object_name	The name of the object in the recycle bin. After an object is moved to the recycle bin, the system generates a new name for the object.

Examples

- Delete database __recycle_$_1_1597384386029184.

```
OceanBase(admin@test)> create database db1;
Query OK, 1 row affected (0.03 sec)

OceanBase(admin@test)> drop database db1;
Query OK, 0 rows affected (0.04 sec)

OceanBase(admin@test)> show recyclebin;
+--------------------------------+---------------+----------+----------------------------+
| OBJECT_NAME                    | ORIGINAL_NAME | TYPE     | CREATETIME                 |
+--------------------------------+---------------+----------+----------------------------+
| __recycle_$_1_1597384386029184 | db1           | DATABASE | 2020-08-14 13:53:06.029367 |
+--------------------------------+---------------+----------+----------------------------+
1 row in set (0.01 sec)

OceanBase(admin@test)> purge database __recycle_$_1_1597384386029184;
Query OK, 0 rows affected (0.03 sec)

OceanBase(admin@test)> show recyclebin;
```

17.1.5.10.2.5. PURGE INDEX

Description

You can execute the PURGE INDEX statement to delete an indexed table from the recycle bin.

Syntax

```
PURGE INDEX object_name;
```

Parameters

Parameter	Description
object_name	The name of the object in the recycle bin. After an object is moved to the recycle bin, the system generates a new name for the object.

Examples

- Delete indexed table __recycle_$_1_1597387726700872 from the recycle bin.

```
OceanBase(admin@test)> create table t1(c1 int);
Query OK, 0 rows affected (0.09 sec)

OceanBase(admin@test)> create index idx on t1(c1);
Query OK, 0 rows affected (0.48 sec)

OceanBase(admin@test)> drop table t1;
Query OK, 0 rows affected (0.03 sec)

OceanBase(admin@test)> show recyclebin;
+--------------------------------+----------------------------+-------+----------------------------+
| OBJECT_NAME                    | ORIGINAL_NAME              | TYPE  | CREATETIME                 |
+--------------------------------+----------------------------+-------+----------------------------+
| __recycle_$_1_1597387726700872 | __idx_1101710651081557_idx | INDEX | 2020-08-14 14:48:46.699145 |
| __recycle_$_1_1597387726712976 | t1                         | TABLE | 2020-08-14 14:48:46.712643 |
+--------------------------------+----------------------------+-------+----------------------------+
5 rows in set (0.01 sec)

OceanBase(admin@test)> purge index __recycle_$_1_1597387726700872;
Query OK, 0 rows affected (0.04 sec)
```

17.1.5.10.2.6. PURGE RECYCLEBIN

Description

You can execute the PURGE RECYCLEBIN statement to empty the recycle bin as the root user.

> **Notice**
>
> The PURGE RECYCLEBIN statement deletes all objects from the recycle bin. You can execute this statement as the root user only. Proceed with caution.

Syntax

```
PURGE RECYCLEBIN;
```

Parameters

None

Examples

- Empty the recycle bin as the root user.

```
OceanBase(admin@test)> purge recyclebin;
Query OK, 0 rows affected (0.03 sec)
```

17.1.5.10.2.7. PURGE TABLE

Description

You can execute the PURGE TABLE statement to delete a table from the recycle bin.

Syntax

```
PURGE TABLE object_name;
```

Parameters

Parameter	Description
object_name	The name of the object in the recycle bin. After an object is moved to the recycle bin, the system renames the object.

Examples

- Delete table __recycle_$_1_1099511628776_1099511677778 from the recycle bin.

```
OceanBase(admin@test)> create table test(c1 int);
Query OK, 0 rows affected (0.16 sec)

OceanBase(admin@test)> drop table test;
Query OK, 0 rows affected (0.03 sec)

OceanBase(admin@test)> show recyclebin;
+-------------------------------------------+---------------+-------+----------------------------+
| OBJECT_NAME                               | ORIGINAL_NAME | TYPE  | CREATETIME                 |
+-------------------------------------------+---------------+-------+----------------------------+
| __recycle_$_1_1099511628776_1099511677778 | test          | TABLE | 2017-10-20 17:40:22.304025 |
+-------------------------------------------+---------------+-------+----------------------------+
1 row in set (0.02 sec)

OceanBase(admin@test)> purge table __recycle_$_1_1099511628776_1099511677778;
Query OK, 0 rows affected (0.04 sec)
```

17.1.5.10.2.8. SELECT

The syntax of SELECT statements is complex. This topic describes the syntax of simple SELECT statements, SELECT statements that contain set operators, and SELECT statements that contain WITH clauses.

SIMPLE SELECT

Description

You can execute a simple SELECT statement to query table data.

Syntax

```
simple_select:
SELECT [/*+ hint statement */] [DISTINCT | UNIQUE | ALL]
    select_expr_list FROM from_list [WHERE condition]
  [GROUP BY group_expression_list] [ROLLUP group_expression_list] [HAVING condition]]
  [ORDER BY order_expression_list]
  [FOR UPDATE]

select_expr:
    table_name.*
  | table_alias_name.*
  | expr [[AS] column_alias_name]

from_list:
    table_reference [, table_reference ...]

table_reference:
      simple_table
    | joined_table

simple_table:
    table_factor [partition_option] [[AS] table_alias_name]
    | (select_stmt) [AS] table_alias_name
    | (table_reference_list)

joined_table:
      table_reference [INNER] JOIN simple_table [join_condition]
    | table_reference outer_join_type JOIN simple_table join_condition

partition_option:
    PARTITION (partition_name_list)

partition_name_list:
    partition_name [, partition_name ...]

outer_join_type:
    {LEFT | RIGHT | FULL} [OUTER]

join_condition:
    ON expression

condition:
    expression

group_expression_list:
    group_expression [, group_expression ...]

group_expression:
    expression [ASC | DESC]

order_expression_list:
    order_expression [, order_expression ...]

order_expression:
    expression [ASC | DESC]
```

Parameters

Parameter	Description
DISTINCT UNIQUE ALL	Specifies whether to return distinct table rows. A database table may contain duplicate rows. • If you add DISTINCT to the statement, only distinct rows are returned. • If you add UNIQUE to the statement, only distinct rows are returned. • If you add ALL to the statement, all the matched rows are returned, including the duplicate rows. By default, ALL is used.
select_expr	The expressions or column names to query. To specify multiple expressions or column names, separate them with commas (,). You can use an asterisk (*) to query all the columns.
AS othername	Rename the output fields.
FROM table_references	The tables from which you want to query data. You can query data from multiple tables.
WHERE where_conditions	The filter conditions. The query results contain the rows that match the filter conditions. This clause is optional. where_conditions specifies an expression.
GROUP BY group_by_list	Group data based on specified fields and generate statistics.
ROLLUP group_expression_list	Merge the groups generated by the Group By statement and generate statistics.
HAVING search_confitions	The filter conditions. HAVING clauses are similar to WHERE clauses. The difference between them is that you can use aggregate functions in HAVING clauses, such as SUM and AVG.
ORDER BY order_list order_list : colname [ASC | DESC] [,colname [ASC | DESC]...]	Display the query results in ascending or descending order. ASC indicates the ascending order and DESC indicates the descending order. If you do not specify the order, the default order ASC is used.

Parameter	Description
FOR UPDATE	Place an exclusive lock on each row of the query results. This prevents other transactions from concurrently updating the rows. This also prevents other transactions from concurrently reading the rows for which some transaction isolation levels are specified.
PARTITION(partition_list)	The partition information of the specified tables. Format: partition(p0,p1...)

Examples

The following examples are based on table a.

Table a

id	name	num
1	a	100
2	b	200
3	a	50

- Query the name column from table a.

```
SELECT name FROM a;
```

```
+------+
| name |
+------+
| a    |
| b    |
| a    |
+------+
3 rows in set (0.01 sec)
```

- Return the distinct rows for the name column.

```
SELECT DISTINCT name FROM a;
```

```
+------+
| name |
+------+
| a    |
| b    |
+------+
2 rows in set (0.01 sec)
```

- In table a, query the id, name, and num columns, divide the num column values by 2, and return the modified the num column as a column named avg.

```
SELECT id, name, num/2 AS avg FROM a;
```

```
+------+------+------+
| id   | name | avg  |
+------+------+------+
|    1 | a    |   50 |
|    2 | b    |  100 |
|    3 | a    |   25 |
+------+------+------+
3 rows in set (0.00 sec)
```

- In table a, find the rows in which the value for the name column is 'a'. Then, return the values at the intersections of this row and the id, name, and num columns.

```
SELECT id, name, num FROM a WHERE name = 'a';
```

```
+------+------+------+
| id   | name | num  |
+------+------+------+
|    1 | a    |  100 |
|    3 | a    |   50 |
+------+------+------+
2 rows in set (0.01 sec)
```

- In table a, query the id and name columns, and group the num column values by name. Then, return the sum of the num column values in each group.

```
SELECT id, name, SUM(num) FROM a GROUP BY name;
```

```
+------+------+----------+
| id   | name | SUM(num) |
+------+------+----------+
|    1 | a    |      150 |
|    2 | b    |      200 |
+------+------+----------+
2 rows in set (0.00 sec)
```

- In table a, query the id and name columns, group the num column values by name, and calculate the sum of the num column values in each group. Then, return the sum value that is less than 160.

```
SELECT id, name, SUM(num) as sum FROM a GROUP BY name HAVING SUM(num) < 160;
```

```
+------+------+------+
| id   | name | sum  |
+------+------+------+
|    1 | a    |  150 |
+------+------+------+
1 row in set (0.01 sec)
```

- In table a, query the id, name, and num columns. Then, sort the data by the num column in ascending order and return the result set.

```
SELECT * FROM a ORDER BY num ASC;
```

```
+------+------+------+
| id   | name | num  |
+------+------+------+
|    3 | a    |   50 |
|    1 | a    |  100 |
|    2 | b    |  200 |
+------+------+------+
3 rows in set (0.00 sec)
```

- In table a, query the id, name, and num columns. Then, sort the data by the num column in descending order and return the result set.

```
SELECT * FROM a ORDER BY num DESC;
```

```
+------+------+------+
| id   | name | num  |
+------+------+------+
|    2 | b    |  200 |
|    1 | a    |  100 |
|    3 | a    |   50 |
+------+------+------+
3 rows in set (0.01 sec)
```

SELECT statements that contain set operators

Description

You can execute the SELECT statement that contains the UNION, MINUS, or INTERSECT operator to combine query results.

Syntax

```
select_clause_set:
  simple_select [ UNION | UNION ALL |  | INTERSECT] select_clause_set_right
  [ORDER BY sort_list_columns]

select_clause_set_right:
  simple_select |
  select_caluse_set
```

Parameters

Parameter	Description
UNION ALL	Combine the results of two queries and return all rows.
UNION	Combine the results of two queries and return distinct rows.
MINUS	Return the distinct rows in the left query that are not selected by the right query.

Parameter	Description
INTERSECT	Return the distinct rows that are selected by the left and right queries.

Examples

The following examples are based on tables t1 and t2.

```
create table t1 (c1 int, c2 int);
create table t2 (c1 int, c2 int);
insert into t1 values (1, -1), (2, -2);
insert into t2 values (1, 1), (2, -2), (3, 3);
```

- Query all rows from t1 and t2.

```
SELECT C1, C2 FROM T1 UNION ALL SELECT C1, C2 FROM T2;
+------+------+
| C1   | C2   |
+------+------+
|    1 |   -1 |
|    2 |   -2 |
|    1 |    1 |
|    2 |   -2 |
|    3 |    3 |
+------+------+
```

- Query all distinct rows from t1 and t2.

```
SELECT C1, C2 FROM T1 UNION SELECT C1, C2 FROM T2;
+------+------+
| C1   | C2   |
+------+------+
|    1 |   -1 |
|    2 |   -2 |
|    1 |    1 |
|    3 |    3 |
+------+------+
```

- Query the rows that exist in t1 and t2.

```
SELECT C1, C2 FROM T1 INTERSECT SELECT C1, C2 FROM T2;
+------+------+
| C1   | C2   |
+------+------+
|    2 |   -2 |
+------+------+
```

- Query the rows that exist in t1 but do not exist in t2.

```
SELECT C1, C2 FROM T1 MINUS SELECT C1, C2 FROM T2;
+------+------+
| C1   | C2   |
+------+------+
|    1 |   -1 |
+------+------+
```

SELECT statements that contain WITH clauses

Description

You can execute the SELECT statement that contains a WITH clause to reduce duplicate subqueries. Subqueries in WITH clauses are used as common expressions that can be referenced by each query.

Syntax

```
with_clause_select:
    with_clause simple_select

with_clause:
    WITH table_name [opt_column_alias_name_list] AS ( select_clause )

select_clause:
    simple_select | select_clause_set

opt_column_alias_name_list:
    (column_name_list)

column_name_list:
    column_name | column_name , column_name_list
```

Parameters

None

Examples

- The following examples are based on tables t1 and t2. Execute the following SELECT statement to query t1 and t2:

```
create table t1(c1 int, c2 int, c3 int);
create table t2(c1 int);
insert into t1 values(1,1,1);
insert into t1 values(2,2,2);
insert into t1 values(3,3,3);
insert into t2 values(4);

select * from t1 where c1 > (select count(*) from t2)
                     and c2 > (select count(*) from t2)
                     and c3 > (select count(*) from t2);
+------+------+------+
| C1   | C2   | C3   |
+------+------+------+
|    2 |    2 |    2 |
|    3 |    3 |    3 |
+------+------+------+
```

Extract duplicate subqueries from the preceding SELECT statement, and add the subquery to a WITH clause.

```
with temp(cnt) as (select count(*) from t2)
select t1.* from t1, temp where c1 > temp.cnt and c2 > temp.cnt and c3 > temp.cnt;
+------+------+------+
| C1   | C2   | C3   |
+------+------+------+
|    2 |    2 |    2 |
|    3 |    3 |    3 |
+------+------+------+
```

17.1.5.10.2.9. UPDATE

Description

You can execute the UPDATE statement to change field values in a table.

Syntax

```
UPDATE [hint_options] dml_table_clause
       SET update_asgn_list
       [WHERE where_condition]
       [{ RETURNING | RETURN } returning_exprs [into_clause]]

dml_table_clause:
    dml_table_name opt_table_alias

update_asgn_list:
    column_name = expr [, ...]

where_condition:
    expression

returning_exprs:
    projection [, ...]

into_clause:
{ INTO into_var_list | BULK COLLECT INTO into_var_list}

into_var_list:
{ USER_VARIABLE | ref_name } [, ...]
```

Parameters

Parameter	Description
hint_options	The hint.
dml_table_clause	The name of the table that you want to update. You can specify a base table, an updatable view, or a special subquery.
where_condition	The filter conditions.

Parameter	Description
update_asgn_list	The columns to update.
returning_exprs	The projection after you update data.
into_clause	After you update the table, insert the projection into the specified table columns.

Notice

A special subquery is similar to a subquery in an updatable view. Such a subquery cannot include complex operators, such as GROUP BY, DISTINCT, or WINDOW FUNCTION.

Examples

Create sample tables t1 and t2.

```
OceanBase(admin@test)>create table t1(c1 int primary key, c2 int);
Query OK, 0 rows affected (0.16 sec)
OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |    1 |
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
4 rows in set (0.06 sec)
```

- Update a single table: In the t1 table, find the row that matches the t1.c1 = 1 condition, and change the value at the intersection of this row and the c2 column to 100.

```
OceanBase(admin@test)>update t1 set t1.c2 = 100 where t1.c1 = 1;
Query OK, 1 row affected (0.02 sec)
Rows matched: 1  Changed: 1  Warnings: 0

OceanBase(admin@test)>select * from t1;
+----+------+
| c1 | c2   |
+----+------+
|  1 |  100 |
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
4 rows in set (0.01 sec)
```

- Update a single table: Use a subquery to query table v. Find the row that matches the v.c1 = 1 condition in table v, and change the value at the intersection of this row and the c2 column to 100.

```
OceanBase(admin@test)>update (select * from t1)v set v.c2 = 100 where v.c1 = 1;
Query OK, 1 row affected (0.02 sec)
Rows matched: 1  Changed: 1  Warnings: 0

OceanBase(admin@test)>select * from t1;
+----+------+
| C1 | C2   |
+----+------+
|  1 |  100 |
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
4 rows in set (0.01 sec)
```

- Update a single table: Execute a statement that includes the RETURNING clause.

```
OceanBase(admin@test)>update t1 set t1.c2 = 100 where t1.c1 = 1 returning c2;
+------+
| C2   |
+------+
|  100 |
+------+
1 row in set (0.02 sec)

OceanBase(admin@test)>select * from t1;
+----+------+
| C1 | C2   |
+----+------+
|  1 |  100 |
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
+----+------+
4 rows in set (0.01 sec)
```

17.1.5.10.3. DCL

17.1.5.10.3.1. EXPLAIN

Description

This statement explains the execution plan of an SQL statement, such as a SELECT, DELETE, INSERT, REPLACE, or UPDATE statement.

Syntax

```
Retrieve the information about a table or a column:
{EXPLAIN | DESCRIBE | DESC} tbl_name [col_name | wild]

Retrieve the information about an SQL plan:
{EXPLAIN}
[BASIC | OUTLINE | EXTENDED | EXTENDED_NOADDR | PARTITIONS | FORMAT = {TRADITIONAL| JSON}]
{SELECT statement | DELETE statement | INSERT statement | UPDATE statement | MERGE statement}
```

Parameter description

Parameter	Description
tbl_name	Specifies the table name.
col_name	Specifies the column name of the table.
BASIC	Specifies the basic information about the output plan, such as the operator ID, operator name, and referenced table name.
OUTLINE	Specifies that the output plan information includes the outline information.
EXTENDED	Specifies that the EXPLAIN statement generates additional information. The additional information includes the input and output columns for each operator, the partition information about the accessed table, and the current used filter information. If the current operator uses an index, the used index column and the extracted query range appear.
EXTENDED_NOADDR	Displays the additional information in a simple way.
PARTITIONS	Displays the partition-related information.
FORMAT = {TRADITIONAL| JSON}	Specifies the output format of EXPLAIN: • TRADITIONAL: the table output format. • The KEY:VALUE output format. The output appears as JSON strings that contain EXTENDED and PARTITIONS information.

Examples

- Omit explain_type

```
OceanBase(admin@test)>explain select * from t1,t2 where t1.c2=t2.c2 and t2.c1 > 4\G
*************************** 1. row ***************************
Query Plan: ========================================
|ID|OPERATOR   |NAME|EST. ROWS|COST   |
----------------------------------------
|0 |HASH JOIN  |    |9801000  |5933109|
|1 | TABLE SCAN|t2  |10000    |6219   |
|2 | TABLE SCAN|t1  |100000   |68478  |
========================================

Outputs & filters:
-------------------------------------
  0 - output([t1.c1], [t1.c2], [t2.c1], [t2.c2]), filter(nil),
      equal_conds([t1.c2 = t2.c2]), other_conds(nil)
  1 - output([t2.c2], [t2.c1]), filter(nil),
      access([t2.c2], [t2.c1]), partitions(p0)
  2 - output([t1.c2], [t1.c1]), filter(nil),
      access([t1.c2], [t1.c1]), partitions(p0)
```

- EXTENDED

```
OceanBase(admin@test)>explain extended_noaddr select * from t1,t2 where t1.c2=t2.c2 and t2.c1 > 4\G
*************************** 1. row ***************************
Query Plan: ========================================
|ID|OPERATOR   |NAME|EST. ROWS|COST   |
----------------------------------------
|0 |HASH JOIN  |    |9801000  |5933109|
|1 | TABLE SCAN|t2  |10000    |6219   |
|2 | TABLE SCAN|t1  |100000   |68478  |
========================================

Outputs & filters:
-------------------------------------
  0 - output([t1.c1], [t1.c2], [t2.c1], [t2.c2]), filter(nil),
      equal_conds([t1.c2 = t2.c2]), other_conds(nil)
  1 - output([t2.c2], [t2.c1]), filter(nil),
      access([t2.c2], [t2.c1]), partitions(p0),
      is_index_back=false,
      range_key([t2.c1]), range(4 ; MAX),
      range_cond([t2.c1 > 4])
  2 - output([t1.c2], [t1.c1]), filter(nil),
      access([t1.c2], [t1.c1]), partitions(p0),
      is_index_back=false,
      range_key([t1.__pk_increment], [t1.__pk_cluster_id], [t1.__pk_partition_id]), range(MIN,MIN,MIN
; MAX,MAX,MAX)always true
```

- TRADITIONAL format

```
OceanBase(admin@test)>explain format=TRADITIONAL select * from t1,t2 where t1.c2=t2.c2 and t2.c1 > 4\
G
*************************** 1. row ***************************
Query Plan: ======================================
|ID|OPERATOR   |NAME|EST. ROWS|COST   |
--------------------------------------
|0 |HASH JOIN  |    |9801000  |5933109|
|1 | TABLE SCAN|t2  |10000    |6219   |
|2 | TABLE SCAN|t1  |100000   |68478  |
======================================

Outputs & filters:
-------------------------------------
  0 - output([t1.c1], [t1.c2], [t2.c1], [t2.c2]), filter(nil),
      equal_conds([t1.c2 = t2.c2]), other_conds(nil)
  1 - output([t2.c2], [t2.c1]), filter(nil),
      access([t2.c2], [t2.c1]), partitions(p0)
  2 - output([t1.c2], [t1.c1]), filter(nil),
      access([t1.c2], [t1.c1]), partitions(p0)
```

- JSON format

```
OceanBase(admin@test)>explain format=JSON select * from t1,t2 where t1.c2=t2.c2 and t2.c1 > 4\G
*************************** 1. row ***************************
Query Plan: {
  "ID":2,
  "OPERATOR":"JOIN",
  "NAME":"JOIN",
  "EST.ROWS":9800999,
  "COST":5933108,
  "output": [
    "t1.c1",
    "t1.c2",
    "t2.c1",
    "t2.c2"
  ],
  "TABLE SCAN": {
    "ID":0,
    "OPERATOR":"TABLE SCAN",
    "NAME":"TABLE SCAN",
    "EST.ROWS":10000,
    "COST":6218,
    "output": [
      "t2.c2",
      "t2.c1"
    ]
  },
  "TABLE SCAN": {
    "ID":1,
    "OPERATOR":"TABLE SCAN",
    "NAME":"TABLE SCAN",
    "EST.ROWS":100000,
    "COST":68477,
    "output": [
      "t1.c2",
      "t1.c1"
    ]
  }
}
```

Each output row of EXPLAIN provides the information about a table. Each row contains the following columns:

Column name	Description
ID	The execution serial number of the plan.
OPERATOR	The executed operator.
NAME	The table that is referenced by the operator.
EST.ROWS	The estimated number of rows that are returned by the current operator.

Column name	Description
COST	The CPU time that is consumed to execute the current operator.

17.1.5.10.3.2. FLASHBACK TABLE BEFORE DROP

Description

This statement restores the deleted tables from the recycle bin.

Prerequisites

The recycle bin is enabled. You can execute `show variables like 'recyclebin';` to check whether the recycle bin is enabled.

```
obclient> show variables like 'recyclebin';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| recyclebin    | ON    |
+---------------+-------+
1 row in set (0.00 sec)
```

If the recycle bin feature is in the disabled state, you can execute `set recyclebin = on;` to enable the recycle bin. The tables in the recycle bin are not actually deleted and still occupy resources. To completely delete these tables, execute `purge recyclebin;`.

Syntax

```
FLASHBACK TABLE object_name TO BEFORE DROP [RENAME to db_name.table_name];
```

Parameter description

Parameter	Description
object_name	Specifies the name of the object or the table to be restored. The object or the table can be restored in only the database where the table resides. When you restore a table, the indexes that are related to the table are also restored.
RENAME to	Modifies the table name and the database to which the table belongs.

Examples

- Restore the deleted table t from the recycle bin.

```
obclient> create table t(id int primary key, k int);
Query OK, 0 rows affected (0.04 sec)

obclient> insert into t values(1,1);
Query OK, 1 row affected (0.00 sec)

obclient> select * from t;
+----+------+
| id | k    |
+----+------+
|  1 |    1 |
+----+------+
1 row in set (0.00 sec)

obclient>> drop table t;
Query OK, 0 rows affected (0.01 sec)

obclient> select * from t;
ORA-00942: table or view 'SYS.T' does not exist
obclient> show recyclebin;
+--------------------------------+---------------+-------+----------------------------+
| OBJECT_NAME                    | ORIGINAL_NAME | TYPE  | CREATETIME                 |
+--------------------------------+---------------+-------+----------------------------+
| __recycle_$_1_1597028971700936 | T             | TABLE | 2020-08-10 11:09:31.701033 |
+--------------------------------+---------------+-------+----------------------------+
1 row in set (0.00 sec)

obclient> flashback table t to before drop;
Query OK, 0 rows affected (0.01 sec)

obclient> select * from t;
+----+------+
| id | k    |
+----+------+
|  1 |    1 |
+----+------+
1 row in set (0.00 sec)
```

17.1.5.10.3.3. GRANT

Description

This statement is used by the system administrator to grant a user some permissions, such as object permissions and system permissions and roles.

Note

- When a current user grants an object permission, the current user must be the object owner. For example, if user1 grants user2 the SELECT permission on table t1, user1 must have the SELECT permission on table t1. The current user must also have the GRANT OPTION permission.
- When a current user grants a system permission or a role, the current user must have the permission or the role to be granted and the GRANT OPTION permission. This way, the permission or the role can be granted.
- After the user is granted the permission, the permission can take effect only when the user reconnects to ApsaraDB for OceanBase.

Syntax

```
/*Grant object permissions*/
GRANT obj_with_col_priv_list
    ON obj_clause TO grant_user_list [WITH GRANT OPTION];

obj_with_col_priv_list:
  obj_with_col_priv
  | obj_with_col_priv_list, obj_with_col_priv

obj_with_col_priv:
  obj_privilege [column_list]

obj_privilege:
    ALTER
  | AUDIT
  | COMMENT
  | DELETE
  | GRANT
  | INDEX
  | INSERT
  | LOCK
  | RENAME
  | SELECT
  | UPDATE
  | REFERENCES
  | EXECUTE
  | CREATE
  | FLASHBACK
  | READ
  | WRITE
  | DEBUG

obj_clause:
  relation_name
  | relation_name '.' relation_name
  | DIRECTORY relation_name

grant_user_list:
    grant_user [, grant_user ...]

/*Grant system permissions*/
GRANT {system_privilege_list | ALL PRIVILEGES}
    TO grantee_user [IDENTIFIED BY password] [WITH {GRANT | ADMID} OPTION];

system_privilege_list:
  system_privilege [, system_privilege ...]

system_privilege:
  CREATE SESSION
  | EXEMPT REDACTION POLICY
  | SYSDBA
  | SYSOPER
  | SYSBACKUP
  | CREATE TABLE
  | CREATE ANY TABLE
  | ALTER ANY TABLE
  | BACKUP ANY TABLE
  | DROP ANY TABLE
```

```
| LOCK ANY TABLE
| COMMENT ANY TABLE
| SELECT ANY TABLE
| INSERT ANY TABLE
| UPDATE ANY TABLE
| DELETE ANY TABLE
| FLASHBACK ANY TABLE
| CREATE ROLE
| DROP ANY ROLE
| GRANT ANY ROLE
| ALTER ANY ROLE
| AUDIT ANY
| GRANT ANY PRIVILEGE
| GRANT ANY OBJECT PRIVILEGE
| CREATE ANY INDEX
| ALTER ANY INDEX
| DROP ANY INDEX
| CREATE ANY VIEW

| CREATE TABLESPACE
| ALTER TABLESPACE
| DROP TABLESPACE
```

```
  | SHOW PROCESS
  | ALTER SYSTEM
  | CREATE DATABASE LINK
  | CREATE PUBLIC DATABASE LINK
  | DROP DATABASE LINK
  | ALTER SESSION
  | ALTER DATABASE

/*Grant roles*/
GRANT role_list TO grantee_user [IDENTIFIED BY password] [WITH {GRANT | ADMID} OPTION];

role_list:
role [, role ...]
```

Parameter description

Parameter	Description
priv_type	Specifies the type of the permission to be granted. For more information about permission types and description, see the following table for permission type description. If you grant multiple permissions to a user at a time, separate the permission types with commas (,).
system_privilege	Specifies the type of the system permission to be granted. If you grant multiple permissions to a user at a time, separate the permission types with commas (,).
obj_clause	Specifies the level of the permission to be granted. Permissions can be divided into the following levels: • Global level: The permissions apply to all the databases. • Database level: The permissions apply to all the objects in a specified database. • Table level: The table permissions apply to all the columns in a specified table.
WITH GRANT OPTION	Specifies whether the permission can be granted to another user. When the permission is canceled, cascading is performed.
WITH ADMIN OPTION	Specifies whether the permission can be granted to another user. When the permission is canceled, cascading is not performed.

The following table describes the types of permissions that can be granted.

Table for permission type description

Permission	Description
ALL PRIVILEGES	All the permissions except the GRANT OPTION permission.
ALTER	The ALTER TABLE permission.
CREATE	The CREATE TABLE permission.
DELETE	The DELETE permission.
DROP	The DROP permission.
GRANT OPTION	The GRANT OPTION permission.
INSERT	The INSERT permission.
UPDATE	The UPDATE permission.
SELECT	The SELECT permission.
INDEX	The CREATE INDEX and DROP INDEX permissions.
SHOW VIEW	The SHOW CREATE VIEW permission.
SHOW DATABASES	The global SHOW DATABASES permission.
SUPER	The permission to execute the SET GLOBAL statement to modify global system parameters.
REFERENCES	The permission to create a constraint that refers to the table.
EXECUTE	The permission to execute the preprocessor program.
FLASHBACK	The FLASHBACK permission.
READ	The READ permission.
WRITE	The WRITE permission.

Permission	Description
CREATE SESSION	The permission to connect to the database.
EXEMPT REDACTION POLICY	The permission to bypass existing redaction policies and view data.
SYSDBA	The SYSDBA permission.
SYSOPER	The SYSOPER permission.
SYSBACKUP	The SYSBACKUP permission.
CREATE TABLE	The permission to create a table in the specified user schema.
CREATE ANY TABLE	The permission to create tables in all the user schemas except SYS.
ALTER ANY TABLE	The permission to modify tables in all the user schemas except SYS.
BACKUP ANY TABLE	The permission to create tables in all the user schemas except SYS.
DROP ANY TABLE	The permission to back up tables in all the user schemas except SYS.
LOCK ANY TABLE	The permission to lock tables in all the user schemas except SYS.
COMMENT ANY TABLE	The permission to comment tables in all the user schemas except SYS.
SELECT ANY TABLE	The permission to view tables in all the user schemas except SYS.
INSERT ANY TABLE	The permission to insert rows into tables in all the user schemas except SYS.
UPDATE ANY TABLE	The permission to update rows in tables in all the user schemas except SYS.

Permission	Description
DELETE ANY TABLE	The permission to delete tables in all the user schemas except SYS.
FLASHBACK ANY TABLE	The permission to flash back tables in all the user schemas except SYS.
CREATE ROLE	The permission to create a role.
DROP ANY ROLE	The permission to delete a role.
GRANT ANY ROLE	The permission to grant a role.
ALTER ANY ROLE	The permission to modify a role.
AUDIT ANY	The permission to modify objects in all the user schemas except SYS.
GRANT ANY PRIVILEGE	The permission to grant a system permission.
GRANT ANY OBJECT PRIVILEGE	The permission to grant an object permission.
CREATE ANY INDEX	The permission to create indexes in all the user schemas except SYS.
ALTER ANY INDEX	The permission to modify indexes in all the user schemas except SYS.
DROP ANY INDEX	The permission to delete indexes in all the user schemas except SYS.
CREATE ANY VIEW	The permission to create views in all the user schemas except SYS.
DROP ANY VIEW	The permission to delete indexes in all the user schemas except SYS.
CREATE VIEW	The permission to create a view in the specified user schema.

Permission	Description
SELECT ANY DICTIONARY	The permission to query a dictionary in the specified user schema.
CREATE PROCEDURE	The permission to create a procedure in the specified user schema.
CREATE ANY PROCEDURE	The permission to create procedures in all the user schemas except SYS.
ALTER ANY PROCEDURE	The permission to modify procedures in all the user schemas except SYS.
DROP ANY PROCEDURE	The permission to delete procedures in all the user schemas except SYS.
EXECUTE ANY PROCEDURE	The permission to perform procedures in all the user schemas except SYS.
CREATE SYNONYM	The permission to create a synonym in the specified user schema.
CREATE ANY SYNONYM	The permission to create synonyms in all the user schemas except SYS.
DROP ANY SYNONYM	The permission to delete synonyms in all the user schemas except SYS.
CREATE PUBLIC SYNONYM	The permission to create a public synonym.
DROP PUBLIC SYNONYM	The permission to delete a public synonym.
CREATE SEQUENCE	The permission to create a sequence in the specified user schema.
CREATE ANY SEQUENCE	The permission to create sequences in all the user schemas except SYS.
ALTER ANY SEQUENCE	The permission to modify sequences in all the user schemas except SYS.
DROP ANY SEQUENCE	The permission to delete sequences in all the user schemas except SYS.

Permission	Description
SELECT ANY SEQUENCE	The permission to query sequences in all the user schemas except SYS.
CREATE TRIGGER	The permission to create a trigger in the specified user schema.
CREATE ANY TRIGGER	The permission to create triggers in all the user schemas except SYS.
ALTER ANY TRIGGER	The permission to modify triggers in all the user schemas except SYS.
DROP ANY TRIGGER	The permission to delete triggers in all the user schemas except SYS.
CREATE PROFILE	The permission to create a profile.
ALTER PROFILE	The permission to modify a profile.
DROP PROFILE	The permission to delete a profile.
CREATE USER	The permission to create a user.
ALTER USER	The permission to modify a user.
DROP USER	The permission to delete a user.
CREATE TYPE	The permission to create a type in the specified user schema.
CREATE ANY TYPE	The permission to create types in all the user schemas except SYS.
ALTER ANY TYPE	The permission to modify types in all the user schemas except SYS.
DROP ANY TYPE	The permission to delete types in all the user schemas except SYS.
EXECUTE ANY TYPE	The permission to execute types in all the user schemas except SYS.

Permission	Description
UNDER ANY TYPE	The permission to create subtypes on the basis of the types in all the user schemas except SYS.
PURGE DBA_RECYCLEBIN	The permission to delete all the objects from the system recycle bin.
CREATE ANY OUTLINE	The permission to create outlines in all the user schemas except SYS.
ALTER ANY OUTLINE	The permission to modify outlines in all the user schemas except SYS.
DROP ANY OUTLINE	The permission to delete outlines in all the user schemas except SYS.
SYSKM	The SYSKM permission.
CREATE TABLESPACE	The permission to create a tablespace.
ALTER TABLESPACE	The permission to modify a tablespace.
DROP TABLESPACE	The permission to delete a tablespace.
ALTER SYSTEM	The ALTER SYSTEM permission.
CREATE DATABASE LINK	The permission to create a database link in the specified user schema.
CREATE PUBLIC DATABASE LINK	The permission to create a public database link.
DROP DATABASE LINK	The permission to delete a database link in the specified user schema.
ALTER SESSION	The permission to modify a session.
ALTER DATABASE	The permission to modify a database.

Examples

- Run the following command to grant the obsqluser01 user all the permissions.

```
OceanBase(admin@TEST)>GRANT ALL PRIVILEGES ON *. * TO obsqluser01 with grant option;
Query OK, 0 rows affected (0.03 sec)
```

17.1.5.10.3.4. KILL

Description

This statement terminates a session.

> **Note**
>
> If you have the PROCESS permission, you can view all the sessions. If you have the SUPER permission, you can terminate all the sessions and statements. Otherwise, you can view and terminate only your own sessions and statements.

Syntax

```
KILL [CONNECTION | QUERY] 'sessionid'
```

Parameter description

Parameter	Description
KILL	Terminates the specified threadid. This parameter is the same as KILL CONNECTION.
KILL CONNECTION	Terminates the specified threadid. This parameter is the same as the KILL statement that does not contain a modifier.
KILL QUERY	Terminates the statement that is being executed over the connection. The connection remains unchanged.

Examples

- Terminate the connection from the session whose sessionid is 3221638213 to the statement that is being executed, and then terminate the session.

```
OceanBase(admin@test)>show processlist;
+------------+-------+--------------------+------+---------+------+--------+------------------+
| Id         | User  | Host               | db   | Command | Time | State  | Info             |
+------------+-------+--------------------+------+---------+------+--------+------------------+
| 3221638212 | admin | 1.11.111.127:11161 | test | Query   |    0 | ACTIVE | show processlist |
| 3221638213 | admin | 1.11.111.127:11161 | test | Query   |    0 | ACTIVE | select "abcedfg" |
+------------+-------+--------------------+------+---------+------+--------+------------------+
1 row in set (0.03 sec)

OceanBase(admin@test)>kill query 3221638213;
Query OK, 0 rows affected (0.01 sec)

OceanBase(admin@test)>kill 3221638212;
Query OK, 0 rows affected (0.01 sec)
```

17.1.5.10.3.5. REVOKE

Description

This statement is used by the system administrator to revoke some permissions from a user.

The following usage description is provided:

- A user must have the permission to be revoked. For example, if user1 needs to revoke the SELECT permission on table t1 from user2, user1 must have the SELECT permission on table t1. The user must also have the GRANT OPTION permission.
- When the ALL PRIVILEGES and GRANT OPTION permissions are revoked, the current user must have the global GRANT OPTION permission or the UPDATE and DELETE permissions on the permission list.
- If the GRANT OPTION permission is unavailable, cascading is not performed for the revocation operation For example, user1 grants some permissions to user2. When the permissions are revoked from user1, the permissions are not revoked from user2. If the GRANT OPTION permission is available, cascading is performed for the revocation operation

Syntax

```
/*Revoke object permissions*/
REVOKE obj_privileges
  ON obj_clause FROM user_list;

user_list:
  user [, user ...]

obj_privileges:
  obj_privilege [, obj_privilege ...]

obj_privilege:
    ALTER
  | AUDIT
  | COMMENT
  | DELETE
  | GRANT
  | INDEX
  | INSERT
  | LOCK
  | RENAME
  | SELECT
  | UPDATE
  | REFERENCES
```

```
  | EXECUTE
  | CREATE
  | FLASHBACK
  | READ
  | WRITE
  | DEBUG

obj_clause:
  relation_name
  | relation_name '.' relation_name
  | DIRECTORY relation_name

relation_name:
  STR_VALUE

/*Revoke system permissions*/
REVOKE {system_privilege_list | ALL PRIVILEGES}
  FROM user_list;
REVOKE ALL [PRIVILEGES], GRANT_OPTION FROM user_list;

system_privilege_list:
  system_privilege [, system_privilege ...]

system_privilege:
  CREATE SESSION
  | EXEMPT REDACTION POLICY
  | SYSDBA
  | SYSOPER
  | SYSBACKUP
  | CREATE TABLE
  | CREATE ANY TABLE
  | ALTER ANY TABLE
  | BACKUP ANY TABLE
  | DROP ANY TABLE
  | LOCK ANY TABLE
  | COMMENT ANY TABLE
  | SELECT ANY TABLE
  | INSERT ANY TABLE
  | UPDATE ANY TABLE
  | DELETE ANY TABLE
  | FLASHBACK ANY TABLE
  | CREATE ROLE
  | DROP ANY ROLE
  | GRANT ANY ROLE
  | ALTER ANY ROLE
  | AUDIT ANY
  | GRANT ANY PRIVILEGE
  | GRANT ANY OBJECT PRIVILEGE
  | CREATE ANY INDEX
  | ALTER ANY INDEX
  | DROP ANY INDEX
  | CREATE ANY VIEW
  | DROP ANY VIEW
  | CREATE VIEW
  | SELECT ANY DICTIONARY
  | CREATE PROCEDURE
  | CREATE ANY PROCEDURE
  | ALTER ANY PROCEDURE
  | DROP ANY PROCEDURE
```

```
  | EXECUTE ANY PROCEDURE
  | CREATE SYNONYM
  | CREATE ANY SYNONYM
  | DROP ANY SYNONYM
  | CREATE PUBLIC SYNONYM
  | DROP PUBLIC SYNONYM
  | CREATE SEQUENCE
  | CREATE ANY SEQUENCE
  | ALTER ANY SEQUENCE
  | DROP ANY SEQUENCE
  | SELECT ANY SEQUENCE
  | CREATE TRIGGER
  | CREATE ANY TRIGGER
  | ALTER ANY TRIGGER
  | DROP ANY TRIGGER
  | CREATE PROFILE
  | ALTER PROFILE
  | DROP PROFILE
  | CREATE USER
  | ALTER USER
  | DROP USER
  | CREATE TYPE
  | CREATE ANY TYPE
  | ALTER ANY TYPE
  | DROP ANY TYPE
  | EXECUTE ANY TYPE
  | UNDER ANY TYPE
  | PURGE DBA_RECYCLEBIN
  | CREATE ANY OUTLINE
  | ALTER ANY OUTLINE
  | DROP ANY OUTLINE
  | SYSKM
  | CREATE TABLESPACE
  | ALTER TABLESPACE
  | DROP TABLESPACE
  | SHOW PROCESS
  | ALTER SYSTEM
  | CREATE DATABASE LINK
  | CREATE PUBLIC DATABASE LINK
  | DROP DATABASE LINK
  | ALTER SESSION
  | ALTER DATABASE

/*Revoke roles*/
REVOKE role_list FROM user;

role_list:
role [, role ...]
```

Parameter description

Parameter	Description

Parameter	Description
obj_privileges	Specifies the type of the object permission to be revoked. For more information about permission types and description, see the following table for permission type description. If you revoke multiple permissions at a time, separate the permission types with commas (,).
system_privilege	Specifies the type of the system permission to be revoked. If you revoke multiple permissions at a time, separate the permission types with commas (,).
obj_clause	Specifies the level of the permission to be revoked. relation_name specifies the name of the specific object. Permissions can be divided into the following levels: • Global level: The permissions apply to all the databases. • Database level: The permissions apply to all the objects in a specified database. • Table level: The permissions apply to all the columns in a specified table.

The following table describes the types of permissions that can be revoked.

Table for permission type description

Permission	Description
ALL PRIVILEGES	All the permissions except the GRANT OPTION permission.
ALTER	The ALTER TABLE permission.
CREATE	The CREATE TABLE permission.
DELETE	The DELETE permission.
DROP	The DROP permission.
GRANT OPTION	The GRANT OPTION permission.
INSERT	The INSERT permission.
UPDATE	The UPDATE permission.

Permission	Description
SELECT	The SELECT permission.
INDEX	The CREATE INDEX and DROP INDEX permissions.
SHOW VIEW	The SHOW CREATE VIEW permission.
SHOW DATABASES	The global SHOW DATABASES permission.
SUPER	The permission to execute the SET GLOBAL statement to modify global system parameters.
REFERENCES	The permission to create a constraint that refers to the table.
EXECUTE	The permission to execute the preprocessor program.
FLASHBACK	The FLASHBACK permission.
READ	The READ permission.
WRITE	The WRITE permission.
CREATE SESSION	The permission to connect to the database.
EXEMPT REDACTION POLICY	The permission to bypass existing redaction policies and view data.
SYSDBA	The SYSDBA permission.
SYSOPER	The SYSOPER permission.
SYSBACKUP	The SYSBACKUP permission.
CREATE TABLE	The permission to create a table in the specified user schema.
CREATE ANY TABLE	The permission to create tables in all the user schemas except SYS.

Permission	Description
ALTER ANY TABLE	The permission to modify tables in all the user schemas except SYS.
BACKUP ANY TABLE	The permission to create tables in all the user schemas except SYS.
DROP ANY TABLE	The permission to back up tables in all the user schemas except SYS.
LOCK ANY TABLE	The permission to lock tables in all the user schemas except SYS.
COMMENT ANY TABLE	The permission to comment tables in all the user schemas except SYS.
SELECT ANY TABLE	The permission to view tables in all the user schemas except SYS.
INSERT ANY TABLE	The permission to insert rows into tables in all the user schemas except SYS.
UPDATE ANY TABLE	The permission to update rows in tables in all the user schemas except SYS.
DELETE ANY TABLE	The permission to delete tables in all the user schemas except SYS.
FLASHBACK ANY TABLE	The permission to flash back tables in all the user schemas except SYS.
CREATE ROLE	The permission to create a role.
DROP ANY ROLE	The permission to delete a role.
GRANT ANY ROLE	The permission to grant a role.
ALTER ANY ROLE	The permission to modify a role.
AUDIT ANY	The permission to modify objects in all the user schemas except SYS.

Permission	Description
GRANT ANY PRIVILEGE	The permission to grant a system permission.
GRANT ANY OBJECT PRIVILEGE	The permission to grant an object permission.
CREATE ANY INDEX	The permission to create indexes in all the user schemas except SYS.
ALTER ANY INDEX	The permission to modify indexes in all the user schemas except SYS.
DROP ANY INDEX	The permission to delete indexes in all the user schemas except SYS.
CREATE ANY VIEW	The permission to create views in all the user schemas except SYS.
DROP ANY VIEW	The permission to delete indexes in all the user schemas except SYS.
CREATE VIEW	The permission to create a view in the specified user schema.
SELECT ANY DICTIONARY	The permission to query a dictionary in the specified user schema.
CREATE PROCEDURE	The permission to create a procedure in the specified user schema.
CREATE ANY PROCEDURE	The permission to create procedures in all the user schemas except SYS.
ALTER ANY PROCEDURE	The permission to modify procedures in all the user schemas except SYS.
DROP ANY PROCEDURE	The permission to delete procedures in all the user schemas except SYS.
EXECUTE ANY PROCEDURE	The permission to perform procedures in all the user schemas except SYS.
CREATE SYNONYM	The permission to create a synonym in the specified user schema.

Permission	Description
CREATE ANY SYNONYM	The permission to create synonyms in all the user schemas except SYS.
DROP ANY SYNONYM	The permission to delete synonyms in all the user schemas except SYS.
CREATE PUBLIC SYNONYM	The permission to create a public synonym.
DROP PUBLIC SYNONYM	The permission to delete a public synonym.
CREATE SEQUENCE	The permission to create a sequence in the specified user schema.
CREATE ANY SEQUENCE	The permission to create sequences in all the user schemas except SYS.
ALTER ANY SEQUENCE	The permission to modify sequences in all the user schemas except SYS.
DROP ANY SEQUENCE	The permission to delete sequences in all the user schemas except SYS.
SELECT ANY SEQUENCE	The permission to query sequences in all the user schemas except SYS.
CREATE TRIGGER	The permission to create a trigger in the specified user schema.
CREATE ANY TRIGGER	The permission to create triggers in all the user schemas except SYS.
ALTER ANY TRIGGER	The permission to modify triggers in all the user schemas except SYS.
DROP ANY TRIGGER	The permission to delete triggers in all the user schemas except SYS.
CREATE PROFILE	The permission to create a profile.
ALTER PROFILE	The permission to modify a profile.

Permission	Description
DROP PROFILE	The permission to delete a profile.
CREATE USER	The permission to create a user.
ALTER USER	The permission to modify a user.
DROP USER	The permission to delete a user.
CREATE TYPE	The permission to create a type in the specified user schema.
CREATE ANY TYPE	The permission to create types in all the user schemas except SYS.
ALTER ANY TYPE	The permission to modify types in all the user schemas except SYS.
DROP ANY TYPE	The permission to delete types in all the user schemas except SYS.
EXECUTE ANY TYPE	The permission to execute types in all the user schemas except SYS.
UNDER ANY TYPE	The permission to create subtypes on the basis of the types in all the user schemas except SYS.
PURGE DBA_RECYCLEBIN	The permission to delete all the objects from the system recycle bin.
CREATE ANY OUTLINE	The permission to create outlines in all the user schemas except SYS.
ALTER ANY OUTLINE	The permission to modify outlines in all the user schemas except SYS.
DROP ANY OUTLINE	The permission to delete outlines in all the user schemas except SYS.
SYSKM	The SYSKM permission.

Permission	Description
CREATE TABLESPACE	The permission to create a tablespace.
ALTER TABLESPACE	The permission to modify a tablespace.
DROP TABLESPACE	The permission to delete a tablespace.
ALTER SYSTEM	The ALTER SYSTEM permission.
CREATE DATABASE LINK	The permission to create a database link in the specified user schema.
CREATE PUBLIC DATABASE LINK	The permission to create a public database link.
DROP DATABASE LINK	The permission to delete a database link in the specified user schema.
ALTER SESSION	The permission to modify a session.
ALTER DATABASE	The permission to modify a database.

Examples

Run the following command to revoke all the permissions from the obsqluser01 user:

```
OceanBase(admin@TEST)>REVOKE ALL PRIVILEGES FROM sqluser;
Query OK, 0 rows affected (0.10 sec)
```

17.1.5.10.3.6. SAVEPOINT

Description

The SAVEPOINT statement performs a partial rollback of a transaction.

Syntax

1. Create a savepoint:

```
SAVEPOINT spname
```

2. Roll back to a savepoint:

```
ROLLBACK [WORK] to [SAVEPOINT] spname
```

3. Delete a savepoint:

```
RELEASE SAVEPOINT spname
```

Parameter description

Parameter	Description
spname	Specifies the name of the savepoint. Savepoints are unique in the transaction scope. A savepoint overwrites the preceding savepoint that has the same name as the save point. After you create a savepoint, you can roll back the transaction to the specified savepoint. You can also use the `ROLLBACK` statement to roll back the entire transaction.

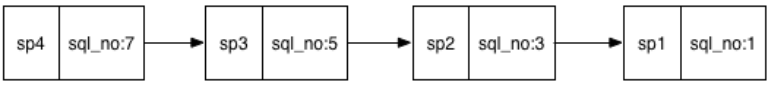
Examples

Assume that the following statements are executed in a transaction.

sql_no	Statement	Partition
1	update...	p1, p4
	savepoint sp1	
2	update...	p2, p4
3	update...	p3, p5
	savepoint sp2	
4	update...	p1, p3, p6
5	update...	p1, p5
	savepoint sp3	
6	select...	
7	update...	p5, p6
	savepoint sp4	

Record savepoints

You can create savepoints before you submit transactions. You must connect the transaction savepoints to a linked list by using the order in which they are created. The preceding transaction contains seven SQL statements and four savepoints. The linked list of savepoints is shown in the following figure where each node records a <spname, sql_no> mapping.



Transaction participant list

To roll back all the modifications that are made after an SQL statement in a transaction, the participants and sql_no that each statement involves are recorded. The preceding transaction contains seven SQL statements and six partitions that range from p1 to p6:

p1	p2	p3	p4	p5	p6
1,4,5	2	2,3,4	1,2	3,5,7	4,7

Savepoint rollback process

1. Query the sql_no that corresponds to spname by using the savepoint linked list

For example, the user executes the `ROLLBACK to SAVEPOINT sp2` statement. Based on the savepoint linked list, the queries sql_no that corresponds to sp2 is 3.

2. Query the partition that corresponds to sql_no by using the transaction participant list

Based on the transaction participant list, the partitions whose sql_no is larger than 3 involve p1, p3, p5, and p6.

3. Roll back the data of the partitions

The scheduler initiates a rollback request to these partitions that are queried in Step 2. This request rolls back all modifications that are made by the transaction after sp2 on these partitions. Some modifications that are related to this transaction on p1, p3, and p5 are rolled back, and all the modifications that are related to this transaction on p6 are rolled back.

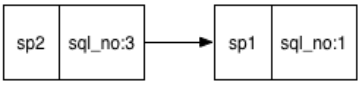
4. Update the information about the transaction participant list

Modify the transaction participant list and delete the operation information in which sql_no is larger than 3 from the transaction participant list. p6 can be deleted from the participant list because all the modifications on p6 are rolled back.

p1	p2	p3	p4	p5	p6
1	2	2, 3	1, 2	3	

5. Delete invalid savepoints

After the user executes the `ROLLBACK to SAVEPOINT sp2` statement, the system deletes the savepoints sp3 and sp4. Then, the transaction cannot be rolled back to sp3 and sp4.



17.1.5.10.3.7. SET NAMES

Description

This statement sets the character set encoding for the current connected database.

Syntax

```
SET NAMES 'charset_name' [COLLATE 'collation_name']
```

Parameter description

Parameter	Description
charset_name	Specifies a character set.
collation_name	Specifies a collation for the character set. If you do not specify this parameter, the default collation for the character set is used.

> **Note**
>
> This statement specifies three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` as the specified character set. This statement specifies `character_set_connection` as `charset_name`, and `collation_connection` as the default collation of `charset_name`.

Examples

- Specify the character set and collation of the database.

```
OceanBase(admin@test)>SET NAMES 'utf8mb4' COLLATE 'utf8mb4_general_ci';
Query OK, 0 rows affected (0.00 sec)

OceanBase(admin@test)>show variables like 'character_set_c%';
+--------------------------+---------+
| Variable_name            | Value   |
+--------------------------+---------+
| character_set_client     | utf8mb4 |
| character_set_connection | utf8mb4 |
+--------------------------+---------+
2 rows in set (0.01 sec)

OceanBase(admin@test)>show variables like 'collation_connection';
+----------------------+--------------------+
| Variable_name        | Value              |
+----------------------+--------------------+
| collation_connection | utf8mb4_general_ci |
+----------------------+--------------------+
1 row in set (0.05 sec)

OceanBase(admin@test)>SET NAMES 'gbk';
Query OK, 0 rows affected (0.02 sec)

OceanBase(admin@test)>show variables like 'character_set_c%';
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| character_set_client     | gbk   |
| character_set_connection | gbk   |
+--------------------------+-------+
2 rows in set (0.01 sec)

OceanBase(admin@test)>show variables like 'collation_connection';
+----------------------+----------------+
| Variable_name        | Value          |
+----------------------+----------------+
| collation_connection | gbk_chinese_ci |
+----------------------+----------------+
1 row in set (0.01 sec)
```

17.1.5.10.3.8. SET PASSWORD

Description

This statement changes the password of the current logon user or other users of ApsaraDB for OceanBase.

Syntax

```
SET PASSWORD [FOR user] = PASSWORD(password);
ALTER USER user IDENTIFIED BY password;

password:
  STR_VALUE
```

Parameter description

Parameter	Description
FOR user	If you do not specify the FOR user clause, the system changes the password for the current user. A user who logs on to ApsaraDB for OceanBase can change the password. If you specify the FOR user clause, the system changes the password for the specified user. To change the password for a specified user, you must have the CREATE USER system permission.

Examples

- Run the following command to change the password for the sqluser user to abc123:

```
oceanBase(admin@TEST)>SET PASSWORD for sqluser = PASSWORD(abc123);
Query OK, 0 rows affected (0.02 sec)
```

17.1.5.10.3.9. SET VARIABLE

Description

The SET VARIABLE statement is used to specify user-defined and system session variables.

Syntax

```
SET var1_name = var1_value, var2_name = var2_value, ... ;
```

Parameter description

Parameter	Description
var1_name	Specifies the variable to be specified. It can be a user-defined variable or a system variable. To set multiple variables, separate them with commas (,).

Examples

```
OceanBase(TEST@TEST)>set @a = 1, @b = 2, @c = 3;
Query OK, 0 rows affected (0.02 sec)

OceanBase(TEST@TEST)>set @@tx_isolation = 'read-what';
ORA-00600: internal error code, arguments: -5145, Variable 'tx_isolation' can't be set to the value o
f 'read-what'

OceanBase(TEST@TEST)>set @@tx_isolation = 'read-committed';
Query OK, 0 rows affected (0.01 sec)

OceanBase(TEST@TEST)>select @a,@b,@c,@@tx_isolation from dual;
+------+------+------+----------------+
| @A   | @B   | @C   | @@TX_ISOLATION |
+------+------+------+----------------+
|    1 |    2 |    3 | read-committed |
+------+------+------+----------------+
1 row in set (0.01 sec)
```

17.1.5.10.3.10. SHOW

Description

`show parameters` is used to show system variables.

`show errors` is used to show the error message of the current object.

Syntax

```
show parameters;
show errors;
```

Parameter description

None

Examples

- Show all system variables.

```
show parameters;
```

17.1.5.10.3.11. SHOW RECYCLEBIN

Description

The SHOW RECYCLEBIN statement is used to view content in the recycle bin.

Syntax

```
 SHOW RECYCLEBIN;
```

Parameter description

None

Examples

- View the content in the recycle bin.

```
OceanBase(admin@test)> create table t1(c1 int);
Query OK, 0 rows affected (0.24 sec)

OceanBase(admin@test)> drop table t1;
Query OK, 0 rows affected (0.07 sec)

OceanBase(admin@test)> show recyclebin;
+-----------------------------------------+---------------+-------+----------------------------+
| OBJECT_NAME                             | ORIGINAL_NAME | TYPE  | CREATETIME                 |
+-----------------------------------------+---------------+-------+----------------------------+
| __recycle_$_1_1099511628776_1099511677777 | t1            | TABLE | 2017-10-20 17:27:40.881506 |
+-----------------------------------------+---------------+-------+----------------------------+
1 row in set (0.02 sec)
```

17.1.5.10.3.12. SHRINK

Description

This statement reorganizes the data in the table. This indicates that the data is rewritten during the merge process.

Syntax

```
ALTER TABLE table_name SHRINK SPACE
```

Parameter description

Parameter	Description
table_name	The table name.

Examples

- Reorganize the data of table t1.

```
OceanBase(admin@test)>ALTER TABLE t1 SHRINK SPACE;
```

17.1.5.10.3.13. TRANSACTION

Description

The TRANSACTION statement starts a transaction.

A database transaction refers to a series of operations that are executed as a single logical unit of work. Transaction processing can be used to maintain the integrity of databases because it ensures that SQL operations in a batch are all executed or are not executed at all.

Explicit transactions are user-defined or user-specified transactions. The transactions explicitly start with a BEGIN TRANSACTION statement or BEGIN and BEGIN WORK statements (supported as the aliases of START TRANSACTION), and explicitly end with a COMMIT or ROLLBACK statement.

Syntax

```
transaction_stmt:
      START TRANSACTION [READ ONLY | READ WRITE];
    | BEGIN [WORK];
    | COMMIT [WORK];
    | ROLLBACK [WORK];
    | SET TRANSACTION {READ ONLY | READ WRITE};
```

Parameter description

Parameter	Description
START TRANSACTION [READ ONLY | READ WRITE]	The statement that is used to start a transaction. After the transaction is started, the subsequent SQL data manipulation language (DML) statements, such as INSERT, UPDATE, and DELETE, take effect only when the transaction is explicitly committed. The READ ONLY clause indicates that the transaction is started in READ ONLY mode. You cannot perform modifications within a transaction. The READ WRITE clause indicates that the transaction is started in READ WRITE mode. It is the default mode.
BEGIN	BEGIN and BEGIN WORK are supported as the aliases of START TRANSACTION.
COMMIT	Commits the current transaction.
ROLLBACK	Rolls back the current transaction.
SET TRANSACTION {READ ONLY | READ WRITE}	Sets the mode of the current transaction to READ ONLY or READ WRITE.

Examples

Assume that the following table a is available.

id	name	num	sell_date
1	a	100	2013-06-21 10:06:43
2	b	200	2013-06-21 13:07:21
3	a	50	2013-06-21 13:08:15

1. Run the following commands in sequence to start to execute the transaction, change the name of the row whose id is 3 to c, and insert a row of sales records of a.

```
OceanBase(admin@test)> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

OceanBase(admin@test)> UPDATE a SET name = 'c' WHERE id = 3;
Query OK, 1 rows affected (0.00 sec)

OceanBase(admin@test)> INSERT INTO a VALUES (4, 'a', 30, '2013-06-21 16:09:13');
Query OK, 1 rows affected (0.00 sec)

OceanBase(admin@test)> COMMIT;
Query OK, 0 rows affected (0.00 sec)
```

2. After you commit the transaction, run the following command to query information about table a:

```
SELECT * FROM a;
```

The following result is returned:

id	name	num	sell_date
1	a	100	2013-06-21 10:06:43
2	b	200	2013-06-21 13:07:21
3	c	50	2013-06-21 13:08:15
4	a	30	2013-06-21 16:09:13

Notice

Before the transaction is committed, you can check whether the operations in the current transaction have taken effect. For example, you can insert `SELECT * FROM a;` before the COMMIT keyword. The latest result can be retrieved for the access from the session of the current transaction. For the access from outside the session of the current transaction, the result does not take effect. Before the transaction is committed, your previous operations are invisible except the connection to the current transaction. To roll back the transaction, replace `COMMIT` with `ROLLBACK`.

18.Data Transmission Service (DTS)

18.1. User Guide

18.1.1. What is DTS?

Data Transmission Service (DTS) is a data service that is provided by Alibaba Cloud. DTS supports data transmission between various types of data sources, such as relational databases and big data systems.

Features

DTS has the following advantages over traditional data migration and synchronization tools: high compatibility, high performance, security, reliability, and ease of use. DTS allows you to simplify data transmission and focus on business development.

Feature	Description
Data migration	You can use DTS to migrate data between homogeneous and heterogeneous data sources. This feature applies to the following scenarios: data migration to Alibaba Cloud, data migration between instances within Alibaba Cloud, and database splitting and scale-out.
Data synchronization	You can use DTS to synchronize data between data sources. This feature applies to the following scenarios: disaster recovery, data backup, load balancing, cloud BI systems, and real-time data warehousing.
Change tracking	You can use DTS to track data changes from user-created MySQL databases, ApsaraDB RDS for MySQL instances, Cloud Native Distributed Database PolarDB-X instances (formerly known as DRDS), and user-created Oracle databases in real time. This feature applies to the following scenarios: cache updates, business decoupling, asynchronous data processing, synchronization of heterogeneous data, and synchronization of extract, transform, and load (ETL) operations.

18.1.2. Log on to the DTS console

This topic describes how to log on to the Data Transmission Service (DTS) console. Google Chrome is used in this example.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

> **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 10 to 32 characters in length and must contain at least two of the following character types:
>
> - Uppercase or lowercase letters
> - Digits
> - Special characters, which include ! @ # $ %

3. Click **Log On**.
4. In the top navigation bar, choose **Products > Data Transmission Service**.
5. Select an **organization** and **region**, and then click **DTS**.

18.1.3. Data migration

18.1.3.1. Supported databases and migration types

You can use Data Transmission Service (DTS) to migrate data between homogeneous and heterogeneous data sources. Typical scenarios include data migration to Alibaba Cloud, data migration between instances within Alibaba Cloud, and database splitting and scale-out. This topic describes the database types, database versions, or migration types that are supported by the data migration feature.

Source database	Destination database	Migration type
• User-created MySQL database Version 5.1, 5.5, 5.6, 5.7, or 8.0 • ApsaraDB RDS for MySQL All versions	User-created MySQL database Version 5.1, 5.5, 5.6, 5.7, or 8.0	• Schema migration • Full data migration • Incremental data migration
	ApsaraDB RDS for MySQL All versions	• Schema migration • Full data migration • Incremental data migration
	PolarDB-X (formerly known as DRDS) All versions	• Full data migration • Incremental data migration
	User-created Oracle database (RAC or non-RAC architecture) Version 9i, 10g, 11g, 12c, 18c, or 19c	• Full data migration • Incremental data migration

Source database	Destination database	Migration type
	User-created Kafka database Versions 0.1 to 2.0	• Schema migration • Full data migration • Incremental data migration
User-created SQL Server database Version 2005, 2008, 2008 R2, 2012, 2014, 2016, or 2017 **Note** • DTS does not support SQL Server clusters or SQL Server Always On availability groups (AOAGs). • If the version of the source database is 2005, incremental data migration is not supported.	• User-created SQL Server database Version 2005, 2008, 2008 R2, 2012, 2014, 2016, or 2017 **Note** DTS does not support SQL Server clusters or SQL Server Always On availability groups (AOAGs). • ApsaraDB RDS for SQL Server Version 2008, 2008 R2, 2012, 2014, 2016, or 2017	• Schema migration • Full data migration • Incremental data migration
User-created Oracle database (RAC or non-RAC architecture) Version 9i, 10g, 11g, 12c, 18c, or 19c	User-created Oracle database (RAC or non-RAC architecture) Version 9i, 10g, 11g, 12c, 18c, or 19c	• Schema migration • Full data migration • Incremental data migration
	PolarDB Version 9.3, 9.6, 10, or 11	• Schema migration • Full data migration • Incremental data migration
	User-created MySQL database Version 5.1, 5.5, 5.6, 5.7, or 8.0	• Schema migration • Full data migration • Incremental data migration
	ApsaraDB RDS for MySQL All versions	• Schema migration • Full data migration • Incremental data migration

Source database	Destination database	Migration type
	PolarDB-X All versions	• Full data migration • Incremental data migration
	AnalyticDB for MySQL Version 2.0 or 3.0	• Schema migration • Full data migration • Incremental data migration
• User-created PostgreSQL database Version 9.4, 9.5, 9.6, or 10.x • ApsaraDB RDS for PostgreSQL Version 9.4 or 10	• User-created PostgreSQL database Version 9.4, 9.5, 9.6, or 10.x • ApsaraDB RDS for PostgreSQL Version 9.4 or 10	• Schema migration • Full data migration • Incremental data migration
PolarDB Version 9.3, 9.6, 10, or 11	User-created Kafka database Versions 0.1 to 2.0	Incremental data migration
	User-created Oracle database (RAC or non-RAC architecture) Version 9i, 10g, 11g, 12c, 18c, or 19c	• Full data migration • Incremental data migration
	PolarDB Version 9.3, 9.6, 10, or 11	• Schema migration • Full data migration • Incremental data migration
User-created Redis database Version 2.8, 3.0, 3.2, 4.0, or 5.0	User-created Redis database Version 2.8, 3.0, 3.2, 4.0, or 5.0	• Full data migration • Incremental data migration
User-created MongoDB database Version 3.0, 3.2, 3.4, 3.6, 4.0 or 4.2	User-created MongoDB database Version 3.0, 3.2, 3.4, 3.6, 4.0 or 4.2	• Full data migration • Incremental data migration

18.1.3.2. Create a data migration instance

Before you configure a task to migrate data, you must create a data migration instance. This topic describes how to create a data migration instance in the Data Transmission Service (DTS) console.

Procedure

1. Log on to the DTS console.
2. In the left-side navigation pane, click **Data Migration**.
3. In the upper-right corner, click **Create Migration Task**.
4. In the Create DTS Instances dialog box, select a region, and enter the number of data migration instances that you want to create.

   > **Note** In the Create DTS Instances dialog box, you can view the total number of instances, the number of existing instances, and the number of instances that can be created.

5. Click **Create**.

18.1.3.3. Configure data migration tasks

18.1.3.3.1. Migrate data from a user-created MySQL database to an ApsaraDB RDS for MySQL instance

This topic describes how to migrate data from a user-created MySQL database to an ApsaraDB RDS for MySQL instance by using Data Transmission Service (DTS). DTS supports schema migration, full data migration, and incremental data migration. You can select all of the supported migration types to ensure service continuity.

Prerequisites

- The version of the user-created MySQL database is 5.1, 5.5, 5.6, 5.7, or 8.0.
- If you need to perform incremental data migration, binary logging must be enabled for the user-created MySQL database and the following requirements must be met:
  - The value of the binlog_format parameter is set to row.
  - The value of the binlog_row_image parameter is set to full.

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the loads of the database servers. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- DTS uses the `ROUND(COLUMN,PRECISION)` function to retrieve values from columns of the FLOAT or DOUBLE data type. If you do not specify a precision, DTS sets the precision for the FLOAT data type to 38 digits and the precision for the DOUBLE data type to 308 digits. You must check whether the precision settings meet your business requirements.
- DTS automatically creates a destination database in the ApsaraDB RDS for MySQL instance. However, if the name of the source database is invalid, you must manually create a database in the ApsaraDB RDS for MySQL instance before you configure the data migration task.
- If you perform a primary/secondary switchover on the source database when the data migration task is running, the task fails.
- Migration latency is the difference between the timestamp of the latest migrated data in the destination database and the current timestamp in the source database. If no data manipulation language (DML) operations are performed on the source database for a long time, the migration latency displayed in the DTS console may be inaccurate. If the latency of the migration task is too high, you can perform a DML operation on the source database to update the latency.

> **Note** If you select an entire database as the object to be migrated, you can create a heartbeat table. The heartbeat table is updated or receives data every second.

Migration types

- Schema migration

  DTS migrates the schemas of the required objects to the destination instance. DTS supports schema migration for the following types of objects: table, view, trigger, stored procedure, and function.

  > **Note**
  > - During schema migration, DTS changes the value of the SECURITY attribute in views, stored procedures, and functions from DEFINER to INVOKER.
  > - DTS does not migrate user information. Before a user can call views, stored procedures, and functions of the destination database, you must grant the read/write permissions to the user.

- Full data migration

  DTS migrates historical data of the required objects from the user-created MySQL database to the destination database in the ApsaraDB RDS for MySQL instance.

  > **Note** During full data migration, concurrent INSERT operations cause fragmentation in the tables of the destination instance. After full data migration is complete, the tablespace of the destination instance is larger than that of the source database.

- Incremental data migration

  After full data migration is complete, DTS retrieves binary log files from the user-created MySQL database. Then, DTS synchronizes incremental data from the user-created MySQL database to the destination ApsaraDB RDS for MySQL instance. Incremental data migration allows you to ensure service continuity when you migrate data from a user-created MySQL database to Alibaba Cloud.

Procedure

1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	If the instance type is set to **User-Created Database with Public IP Address**, you do not need to specify the **instance region**.
	Database Type	Select **MySQL**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the user-created MySQL database.

Source Section Database	Parameter	Description
	Port Number	Enter the service port number of the user-created MySQL database. The default port number is **3306**.
	Database Account	Enter the account of the user-created MySQL database. If you need to migrate incremental data, the account must have the SELECT permission on the objects to be migrated, the REPLICATION SLAVE permission, the REPLICATION CLIENT permission, and the SHOW VIEW permission. If you do not need to migrate incremental data, the account must have the SELECT permission on the objects to be migrated.
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select **RDS Instance**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	RDS Instance ID	Select the ID of the destination RDS instance.
	Database Account	Enter the database account of the destination RDS instance. The account must have the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. If a whitelist is configured for the user-created MySQL database, you must manually add the CIDR blocks of DTS servers to the whitelist of the database. To obtain the CIDR blocks of DTS servers, click **Copy to Clipboard** in the dialog box that appears. After you add the CIDR blocks of DTS servers to the whitelist of the database, click **Next**.

   > **Note** If you do not need to configure a whitelist for the user-created MySQL database, ignore the preceding settings and click **Next**.

6. Select the migration types and the objects to be migrated.

Setting	Description
Select the migration types	◦ To perform only full data migration, select **Schema Migration** and **Full Data Migration**. ◦ To ensure service continuity during data migration, select **Schema Migration**, **Full Data Migration**, and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.

Setting	Description
Select the objects to be migrated	Select objects from the **Available** section and click the icon to move the objects to the **Selected** section. **Note** ◦ You can select columns, tables, or databases as the objects to be migrated. ◦ By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. ◦ If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

7. In the lower-right corner of the page, click **Precheck**.

   Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

8. After the task passes the precheck, click **Next**.

   Note If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.2. Migrate data from a user-created MySQL database to a PolarDB-X instance

This topic describes how to migrate data from a user-created MySQL database to a PolarDB-X instance by using Data Transmission Service (DTS). PolarDB-X is formerly known as Distributed Relational Database Service (DRDS).

Precautions

- DTS cannot migrate schemas from a user-created MySQL database to a PolarDB-X instance.

  Note During schema migration, DTS migrates the schemas of the required objects, such as tables, from the source database to the destination database.

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the loads of the database servers. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- DTS uses the `ROUND(COLUMN,PRECISION)` function to retrieve values from columns of the FLOAT or DOUBLE data type. If you do not specify a precision, DTS sets the precision for the FLOAT data type to 38 digits and the precision for the DOUBLE data type to 308 digits. You must check whether the precision settings meet your business requirements.
- If you perform a primary/secondary switchover on the source database when the data migration task is running, the task fails.
- Migration latency is the difference between the timestamp of the latest migrated data in the destination database and the current timestamp in the source database. If no data manipulation language (DML) operations are performed on the source database for a long time, the migration latency displayed in the DTS console may be inaccurate. If the latency of the migration task is too high, you can perform a DML operation on the source database to update the latency.

> **Note** If you select an entire database as the object to be migrated, you can create a heartbeat table. The heartbeat table is updated or receives data every second.

SQL operations that can be synchronized during incremental data migration

INSERT, UPDATE, DELETE, and REPLACE

Permissions required for database accounts

Database	Full data migration	Incremental data migration
User-created MySQL database	The SELECT permission	The REPLICATION SLAVE, REPLICATION CLIENT, SHOW VIEW, and SELECT permissions
PolarDB-X	The read and write permissions	The read and write permissions

Procedure

1. Create databases and tables in the destination PolarDB-X instance based on the schemas of the source tables.
2. Create a data migration instance.
3. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
4. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
	Instance Type	Select **User-Created Database with Public IP Address**.

Section	Parameter	Description
Source Database	Instance Region	If the instance type is set to **User-Created Database with Public IP Address**, you do not need to specify the **instance region**.
	Database Type	Select **MySQL**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the user-created MySQL database.
	Port Number	Enter the service port number of the user-created MySQL database. The default port number is **3306**.
	Database Account	Enter the account of the user-created MySQL database. For more information about the permissions that are required for the account, see Permissions required for database accounts.
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select **DRDS Instance**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	DRDS Instance ID	Select the ID of the PolarDB-X instance.
	Database Name	Enter the name of the destination database.
	Database Account	Enter the database account of the PolarDB-X instance. For more information about the permissions that are required for the account, see Permissions required for database accounts.
	Database Password	Enter the password of the destination database account.

5. In the lower-right corner of the page, click **Set Whitelist and Next**.
6. If a whitelist is configured for the user-created MySQL database, you must manually add the CIDR blocks of DTS servers to the whitelist of the database. To obtain the CIDR blocks of DTS servers, click **Copy to Clipboard** in the dialog box that appears. After you add the CIDR blocks of DTS servers to the whitelist of the database, click **Next**.

   Note If you do not need to configure a whitelist for the user-created MySQL database, ignore the preceding settings and click **Next**.

7. Select the migration types and the objects to be migrated.

Setting	Description
Select the migration types	○ To perform only full data migration, select only **Full Data Migration**. ○ To ensure service continuity during data migration, select both **Full Data Migration** and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.

Setting	Description
Select the objects to be migrated	Select one or more objects from the **Available** section and click the icon to move the objects to the **Selected** section. **Note** • You can select columns, tables, or databases as the objects to be migrated. • By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. • If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

8. In the lower-right corner of the page, click **Precheck**.

   Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. After the task passes the precheck, click **Next**.

   Note If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.3. Migrate data from an ApsaraDB RDS for MySQL instance to a user-created Oracle database

This topic describes how to migrate data from an ApsaraDB RDS for MySQL instance to a user-created Oracle database by using Data Transmission Service (DTS). DTS supports full data migration and incremental data migration. You can select these migration types to ensure service continuity of the source ApsaraDB RDS for MySQL instance during data migration.

Prerequisites

The destination Oracle database is created. The schema of the Oracle database is the same as the schema of the source database in the ApsaraDB RDS for MySQL instance. This is because DTS does not support schema migration from an ApsaraDB RDS for MySQL instance to a user-created Oracle database.

Permissions required for database accounts

Database\Migration type	Full data migration	Incremental data migration
Source ApsaraDB RDS for MySQL instance	The read and write permissions	The read and write permissions
Destination Oracle database	The read and write permissions	The read and write permissions

Procedure

1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Optional. Enter a name for the task.

   DTS automatically generates a name for each task. Duplicate task names are allowed. You can edit the task name based on your needs. We recommend that you specify an informative name for easy identification.
4. Configure the source and destination databases. The following table describes the parameters.

Section	Parameter	Description
Source Database	Instance Type	Select **RDS Instance** as the type of the source instance.
	Instance Region	The region where the source instance resides.
	RDS Instance ID	Select the ID of the source database.
	Database Account	Enter an account that has the read and write permissions on the source database.
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select **User-Created Database with Public IP Address** as the type of the destination database.
	Instance Region	The region where the destination instance resides.
	Database Type	Select **Oracle**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the Oracle database.
	Port Number	The default port number is 1521.
	Instance Type	◦ **Non-RAC Instance**: If you select this option, you must specify the **SID**. ◦ **RAC or PDB Instance**: If you select this option, you must specify the **Service Name**.
	Database Account	Enter an account that has the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

5. Click **Test Connectivity** and confirm that the test results for both the source and destination databases are **Passed**.

6. In the lower-right corner of the page, click **Set Whitelist and Next**.
7. Select the migration types based on your needs. Select one or more objects from the Available section and click the › icon to move the objects to the **Selected** section.
   - To ensure service continuity during data migration, select **Full Data Migration** and **Incremental Data Migration**.
   - To perform only full data migration, select **Full Data Migration**.
8. Click **Precheck** and wait until the precheck is complete.

   > **Note** You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

9. Click **Next** to start the migration task.

   > **Note** If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.4. Migrate data from an ApsaraDB RDS for MySQL instance to a user-created Kafka cluster

Kafka is a distributed message queue service that features high throughput and high scalability. Kafka is widely used for big data analytics such as log collection, data aggregation, streaming processing, and online and offline analysis. It is important for the big data ecosystem. You can use Data Transmission Service (DTS) to migrate data from an ApsaraDB RDS for MySQL instance or a user-created MySQL database to a user-created Kafka cluster. The data migration feature allows you to extend message processing capabilities. This topic uses an ApsaraDB RDS for MySQL instance as an example.

Prerequisites

- If the source database is a user-created MySQL database, binary logging must be enabled for the database and the following requirements must be met:
  - The value of the `binlog_format` parameter is set to `row`.
  - The value of the `binlog_row_image` parameter is set to `full`.
- A Kafka cluster is created and the Kafka version is 0.10 to 2.0.

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the loads of the database servers. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- You can select only tables as the objects to be migrated.

Data format

The data that is migrated to the Kafka cluster is stored in the Avro format. You must parse the migrated data based on the Avro schema. For more information, see DTS Avro schema.

Procedure

1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Configure a task name.

   DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
4. Configure the source and destination databases.

Section	Parameter	Description
Source Database	Instance Type	Select **RDS Instance**.
	Instance Region	Select the region where the source database resides.
	RDS Instance ID	Select the ID of the source RDS instance.
	Database Account	Enter the database account of the source RDS instance. The account must have the SELECT permission on the objects to be migrated, the REPLICATION CLIENT permission, the REPLICATION SLAVE permission, and the SHOW VIEW permission.
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select **Kafka**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the Kafka cluster. In this example, enter the public IP address.
	Port Number	Enter the service port number of the Kafka cluster. The default port number is 9092.
	Database Account	Enter the username that is used to log on to the Kafka cluster. If no authentication is enabled for the Kafka cluster, you do not need to enter the username.
	Database Password	Enter the password of the username. If no authentication is enabled for the Kafka cluster, you do not need to enter the password.
	Topic	Click **Get Topic List**, and select a topic name from the drop-down list.
	Kafka Version	Select the version of the destination Kafka cluster. **Note** You cannot select Kafka 2.0 in the DTS console. If you are using Kafka 2.0, you must select Kafka 1.0.

Section	Parameter	Description
	Encryption	Select **Non-encrypted** or **SCRAM-SHA-256** based on your business and security requirements.

5. In the lower-right corner of the page, click **Set Whitelist and Next**.
6. Select the migration types and the objects to be migrated.

Setting	Description
Select the migration types	○ To perform only full data migration, select **Schema Migration** and **Full Data Migration**. ○ To ensure service continuity during data migration, select **Schema Migration**, **Full Data Migration**, and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.
Select the objects to be migrated	Select objects from the **Available** section and click the icon to move the objects to the **Selected** section. **Note** ○ You can select columns, tables, or databases as the objects to be migrated. ○ By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. ○ If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

7. In the lower-right corner of the page, click **Precheck**.

Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

8. After the task passes the precheck, click **Next**.

> **Note** If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.5. Migrate data from a user-created SQL Server database to an ApsaraDB RDS for SQL Server instance

This topic describes how to migrate incremental data from a user-created SQL Server database to an ApsaraDB RDS for SQL Server instance by using Data Transmission Service (DTS). DTS supports schema migration, full data migration, and incremental data migration. You can select all of the supported migration types to ensure service continuity.

Prerequisites

- The version of the user-created SQL Server database is 2005, 2008, 2008 R2, 2012, 2014, 2016, or 2017.

  > **Note**
  > - DTS does not support SQL Server clusters or SQL Server Always On availability groups (AOAGs).
  > - If the version of the source database is 2005, incremental data migration is not supported.
  > - If you migrate data between different versions of databases, make sure that the database versions are compatible.

- The tables to be migrated from the user-created SQL Server database have primary keys or UNIQUE NOT NULL indexes.

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the loads of the database servers. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- To ensure that the incremental data migration task runs as expected, do not frequently back up the source database. We recommend that you retain log files for more than three days. Otherwise, you cannot retrieve log files after they are truncated.
- To ensure that the delay time of incremental data migration is accurate, DTS adds a heartbeat table to the user-created SQL Server database. The name of the heartbeat table is `Source table name_dts_mysql_heartbeat`.
- DTS automatically creates a destination database in the ApsaraDB RDS for SQL Server instance. However, if the name of the source database is invalid, you must manually create a database in the ApsaraDB RDS for SQL Server instance before you configure the data migration task.
- If a data migration task fails, DTS automatically resumes the task. Before you switch your workloads to the destination instance, stop or release the data migration task. Otherwise, the data in the source database will overwrite the data in the destination instance after the task is resumed.
- If you perform a primary/secondary switchover on the source database when the data migration task is running, the task fails.
- Migration latency is the difference between the timestamp of the latest migrated data in the destination database and the current timestamp in the source database. If no data manipulation language (DML) operations are performed on the source database for a long time, the migration latency displayed in the DTS console may be inaccurate. If the latency of the migration task is too high, you can perform a DML operation on the source database to update the latency.

> **Note** If you select an entire database as the object to be migrated, you can create a heartbeat table. The heartbeat table is updated or receives data every second.

Limits

- A single data migration task can migrate incremental data from only one database. To migrate incremental data from multiple databases, you must create a data migration task for each database.
- DTS cannot migrate the schemas of assemblies, service brokers, full-text indexes, full-text catalogs, distributed schemas, distributed functions, CLR stored procedures, CLR scalar-valued functions, CLR table-valued functions, internal tables, systems, or aggregate functions.
- DTS cannot migrate data of the sql_variant type.
- DTS cannot migrate tables that contain computed columns.

Migration types

- Schema migration

  DTS migrates the schemas of the required objects to the destination instance. DTS supports schema migration for the following types of objects: table, view, trigger, synonym, SQL stored procedure, SQL function, plan guide, user-defined type, rule, and default.

- Full data migration

  DTS migrates historical data of the required objects from the user-created SQL Server database to the destination database.

- Incremental data migration

  After full data migration is complete, DTS migrates incremental data from the user-created SQL Server database to the destination database. Incremental data migration allows you to ensure service continuity when you migrate data from a user-created SQL Server database to Alibaba Cloud.

SQL operations that can be synchronized during incremental data migration

- INSERT, UPDATE, and DELETE

  > **Note** DTS does not synchronize the UPDATE operations that update only the large fields.

- CREATE TABLE

  > **Note** If a CREATE TABLE operation creates a partition table or a table that contains functions, DTS does not synchronize the operation.

- ALTER TABLE, including only ADD COLUMN, DROP COLUMN, and RENAME COLUMN
- DROP TABLE
- RENAME TABLE, TRUNCATE TABLE, and CREATE INDEX

Procedure

To prevent data migration failures caused by dependencies among objects, DTS migrates the schemas and data from the source SQL Server database in the following order:

1. Migrate the schemas of tables, views, synonyms, user-defined types, rules, defaults, and plan guides.
2. Perform full data migration.
3. Migrate the schemas of SQL stored procedures, SQL functions, triggers, and foreign keys.
4. Perform incremental data migration.

> **Note** During schema migration and full data migration, do not perform data definition language (DDL) operations on the required objects. Otherwise, the objects may fail to be migrated.

Before you begin

Before you configure a data migration task, configure log settings on the user-created SQL Server database.

> **Note** Skip this step if you do not need to perform incremental data migration.

Procedure

1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	If the instance type is set to **User-Created Database with Public IP Address**, you do not need to specify the **instance region**.
	Database Type	Select **SQL Server**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the user-created SQL Server database. In this example, enter the public IP address.
	Port Number	Enter the service port number of the user-created SQL Server database. The default port number is **1433**.
	Database Account	Enter the account that is used to log on to the user-created SQL Server database. **Note** To perform incremental data migration, the account must have the sysadmin permission. To perform schema migration or full data migration, the account must have the SELECT permission on the objects that you want to migrate.
	Database Password	Enter the password of the source database account.
	Instance Type	Select **RDS Instance**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.

Section	Parameter	Description
Destination Database	RDS Instance ID	Select the ID of the destination ApsaraDB RDS for SQL Server instance. **Note** In this scenario, the destination database can be only a SQL Server database.
	Database Account	Enter the database account of the destination ApsaraDB RDS for SQL Server instance. The account must have the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. If a whitelist is configured for the user-created SQL Server database, you must manually add the CIDR blocks of DTS servers to the whitelist of the database. To obtain the CIDR blocks of DTS servers, click **Copy to Clipboard** in the dialog box that appears. After you add the CIDR blocks of DTS servers to the whitelist of the database, click **Next**.

   Note If you do not need to configure a whitelist for the user-created SQL Server database, ignore the preceding settings and click **Next**.

6. Select the migration types and the objects to be migrated.

Setting	Description
Select the migration types	○ To perform only full data migration, select **Schema Migration** and **Full Data Migration**. ○ To ensure service continuity during data migration, select **Schema Migration**, **Full Data Migration**, and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.
Select the objects to be migrated	Select objects from the **Available** section and click the › icon to move the objects to the **Selected** section. **Note** ○ You can select columns, tables, or databases as the objects to be migrated. ○ By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. ○ If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.

Setting	Description
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

7. In the lower-right corner of the page, click **Precheck**.

   Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

8. After the task passes the precheck, click **Next**.

   Note If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.6. Migrate data between user-created Oracle databases

This topic describes how to migrate data between user-created Oracle databases by using Data Transmission Service (DTS). DTS supports schema migration, full data migration, and incremental data migration. You can select all of the supported migration types to ensure service continuity.

Prerequisites

- The version of the source Oracle database is 9i, 10g, 11g, 12c, 18c, or 19c.

  Note To ensure compatibility, make sure the versions of the source and destination databases are the same.

- Supplemental logging, including SUPPLEMENTAL_LOG_DATA_PK and SUPPLEMENTAL_LOG_DATA_UI, is enabled for the source Oracle database. For more information, see Supplemental Logging.
- The source Oracle database is running in ARCHIVELOG mode. Archived log files are accessible and a suitable retention period is set for archived log files. For more information, see Managing Archived Redo Log Files.
- The available storage space of the destination Oracle database is larger than the total size of the data in the source Oracle database.
- If you perform a primary/secondary switchover on the source database when the data migration task is running, the task fails.

Migration types

Migration type	Description
Schema migration	DTS migrates the schemas of the required objects to the destination Oracle database. DTS supports schema migration for the following types of objects: table, view, synonym, trigger, stored procedure, function, package, and user-defined type. **Note** If an object contains triggers, the data between the source and destination databases will become inconsistent.
Full data migration	DTS migrates historical data of the required objects from the source Oracle database to the destination Oracle database. **Note** During schema migration and full data migration, do not perform DDL operations on the objects to be migrated. Otherwise, the objects may fail to be migrated.
Incremental data migration	After full data migration, DTS retrieves redo log files from the source Oracle database. Then, DTS synchronizes incremental data from the source Oracle database to the destination Oracle database. Incremental data migration allows you to ensure service continuity when you migrate data between Oracle databases.

Permissions required for database accounts

Database	Schema migration	Full data migration	Incremental data migration
Source Oracle database	The owner permission on schemas	The owner permission on schemas	SYSDBA
Destination Oracle database	The owner permission on schemas	The owner permission on schemas	The owner permission on schemas

Note For more information about how to create and authorize an Oracle database account, see CREATE USER and GRANT.

Procedure

1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	If the instance type is set to **User-Created Database with Public IP Address**, you do not need to specify the **instance region**.

Section	Parameter	Description
Source Database	Database Type	Select **Oracle**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the source Oracle database.
	Port Number	Enter the port number of the source Oracle database. The default port number is 1521.
	Instance Type	Select **Non-RAC Instance** or **RAC or PDB Instance** based on the architecture of the source Oracle database.
	SID	Enter the system ID (SID) of the source Oracle database. **Note** This parameter is required if you select **Non-RAC Instance** as the instance type.
	Service Name	Enter the server name of the instance. **Note** This parameter is required if you select **RAC or PDB Instance** as the instance type.
	Database Account	Enter the account that is used to connect to the source Oracle database.
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select **User-Created Database with Public IP Address**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	Database Type	Select **Oracle**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the destination Oracle database.
	Port Number	Enter the port number of the destination Oracle database. The default port number is 1521.
	Instance Type	Select **Non-RAC Instance** or **RAC or PDB Instance** based on the architecture of the destination Oracle database.
	SID	Enter the SID of the destination Oracle database. **Note** This parameter is required if you select **Non-RAC Instance** as the instance type.

Section	Parameter	Description
	Service Name	Enter the server name of the instance. **Note** This parameter is required if you select **RAC or PDB Instance** as the instance type.
	Database Account	Enter the account that is used to connect to the destination Oracle database.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. If your Oracle databases have security settings, you must manually add the CIDR blocks of DTS servers to the whitelists of the databases. To obtain the CIDR blocks of DTS servers, click **Copy to Clipboard** in the dialog box that appears. After you add the CIDR blocks of DTS servers to the whitelist of the databases, click **Next**.

   Note If you do not need to configure whitelists for your Oracle databases, ignore the preceding settings and click **Next**.

6. Select the migration types and the objects to be migrated.

Setting	Description
Select the migration types	○ To perform only full data migration, select **Schema Migration** and **Full Data Migration**. ○ To ensure service continuity during data migration, select **Schema Migration**, **Full Data Migration**, and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.
Select the objects to be migrated	Select objects from the **Available** section and click the › icon to move the objects to the **Selected** section. **Note** ○ You can select columns, tables, or databases as the objects to be migrated. ○ By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. ○ If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.

Setting	Description
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

7. In the lower-right corner of the page, click **Precheck**.

   Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

8. After the task passes the precheck, click **Next**.

   Note If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.7. Migrate data from a user-created Oracle database to an ApsaraDB RDS for MySQL instance

This topic describes how to migrate data from a user-created Oracle database to an ApsaraDB RDS for MySQL instance by using Data Transmission Service (DTS). DTS supports schema migration, full data migration, and incremental data migration. When you migrate data from a user-created Oracle database, you can select all of the supported migration types to ensure service continuity.

Prerequisites

- The version of the user-created Oracle database is 9i, 10g, 11g, 12c, 18c, or 19c.
- Supplemental logging, including SUPPLEMENTAL_LOG_DATA_PK and SUPPLEMENTAL_LOG_DATA_UI, is enabled for the user-created Oracle database. For more information, see Supplemental Logging.
- The user-created Oracle database is running in ARCHIVELOG mode. Archived log files are accessible and a suitable retention period is set for archived log files. For more information, see Managing Archived Redo Log Files.

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the loads of the database servers. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- Table names in the ApsaraDB RDS for MySQL instance are case-insensitive. If a table name in the user-created Oracle database contains uppercase letters, ApsaraDB RDS for MySQL converts all uppercase letters to

lowercase letters before creating the table.

If the source Oracle database contains identical table names that differ only in capitalization, these table names are identified as duplicate. During schema migration, the following message is returned: "The object already exists". To prevent name conflicts in the destination database, you can change the names of the migrated objects by using the object name mapping feature. For more information, see Object name mapping.

- If you perform a primary/secondary switchover on the source database when the data migration task is running, the task fails.

Migration types

- Schema migration

  DTS supports schema migration for tables and indexes. DTS does not support schema migration for the following types of objects: view, synonym, trigger, stored procedure, function, package, and user-defined type. DTS has the following limits on schema migration for tables and indexes:

  - Schema migration of nested tables is not supported. Clustered tables and index-organized tables (IOTs) are converted into common tables in the destination database.
  - Schema migration of function-based indexes, domain indexes, bitmap indexes, and reverse indexes is not supported.

- Full data migration

  DTS migrates historical data of the required objects from the user-created Oracle database to the destination ApsaraDB RDS for MySQL instance.

- Incremental data migration

  DTS retrieves redo log files from the user-created Oracle database. Then, DTS synchronizes incremental data from the user-created Oracle database to the destination database in the ApsaraDB RDS for MySQL instance. Incremental data migration allows you to ensure service continuity when you migrate data from the user-created Oracle database to the destination database.

SQL operations that can be synchronized during incremental data migration

- INSERT, DELETE, and UPDATE
- CREATE TABLE

  > **Note** If a CREATE TABLE operation creates a table that contains functions, DTS does not synchronize the operation.

- ALTER TABLE, ADD COLUMN, DROP COLUMN, RENAME COLUMN, and ADD INDEX
- DROP TABLE
- RENAME TABLE, TRUNCATE TABLE, and CREATE INDEX

Data type mappings

For more information, see Data type mappings between heterogeneous databases.

Procedure

1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.
Source Database	Instance Type	Select an instance type based on the deployment of the source database. In this example, select **User-Created Database with Public IP Address**.
	Instance Region	If the instance type is set to **User-Created Database with Public IP Address**, you do not need to specify the **instance region**.
	Database Type	Select **Oracle**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the user-created Oracle database.
	Port Number	Enter the service port number of the user-created Oracle database. The default port number is **1521**.
	Instance Type	○ **Non-RAC Instance**: If you select this option, you must specify the **SID**. ○ **RAC or PDB Instance**: If you select this option, you must specify the **Service Name**.
	Database Account	Enter the account of the user-created Oracle database. To perform incremental data migration, the account must have the database administrator (DBA) permission. To perform schema migration or full data migration, the account must have the owner permission on schemas.
	Database Password	Enter the password of the source database account.
Destination Database	Instance Type	Select **RDS Instance**.
	Instance Region	The destination region that you selected when you created the data migration instance. You cannot change the value of this parameter.
	RDS Instance ID	Select the ID of the destination ApsaraDB RDS for MySQL instance.
	Database Account	Enter the database account of the destination ApsaraDB RDS for MySQL instance. The account must have the read and write permissions on the destination database.
	Database Password	Enter the password of the destination database account.

4. In the lower-right corner of the page, click **Set Whitelist and Next**.
5. If your Oracle databases have security settings, you must manually add the CIDR blocks of DTS servers to the whitelists of the databases. To obtain the CIDR blocks of DTS servers, click **Copy to Clipboard** in the dialog box that appears. After you add the CIDR blocks of DTS servers to the whitelist of the databases, click **Next**.

   Note If you do not need to configure whitelists for your Oracle databases, ignore the preceding settings and click **Next**.

6. Select the migration types and the objects to be migrated.

Setting	Description
Select the migration types	◦ To perform only full data migration, select **Schema Migration** and **Full Data Migration**. ◦ To ensure service continuity during data migration, select **Schema Migration**, **Full Data Migration**, and **Incremental Data Migration**. **Note** If **Incremental Data Migration** is not selected, do not write data to the source database during full data migration. This ensures data consistency between the source and destination databases.
Select the objects to be migrated	Select objects from the **Available** section and click the icon to move the objects to the **Selected** section. **Note** ◦ You can select columns, tables, or databases as the objects to be migrated. ◦ By default, after an object is migrated to the destination database, the name of the object remains unchanged. You can use the object name mapping feature to change the names of the objects that are migrated to the destination database. For more information, see Object name mapping. ◦ If you use the object name mapping feature on an object, other objects that are dependent on the object may fail to be migrated.
Specify the retry time for failed connection to the source or destination database	By default, if DTS fails to connect to the source or destination database, DTS retries within the next 12 hours. You can specify the retry time based on your needs. If DTS reconnects to the source and destination databases within the specified time, DTS resumes the data migration task. Otherwise, the data migration task fails. **Note** When DTS retries a connection, you are charged for the DTS instance. We recommend that you specify the retry time based on your business needs. You can also release the DTS instance at your earliest opportunity after the source and destination instances are released.

7. In the lower-right corner of the page, click **Precheck**.

   Note You can start the data migration task only after the task passes the precheck. If the task fails to pass the precheck, click the icon next to each failed item to view details. Troubleshoot the issues based on the causes and run a precheck again.

8. After the task passes the precheck, click **Next**.

   Note If Incremental Data Migration is not selected, wait until the migration task is completed. If Incremental Data Migration is selected, the migration task does not automatically stop. In this case, you must wait until **The migration task is not delayed** appears and manually stop the task.

18.1.3.3.8. Migrate data from a user-created Oracle database to a PolarDB cluster

This topic describes how to migrate data from a user-created Oracle database to a PolarDB cluster by using Data Transmission Service (DTS). DTS supports schema migration, full data migration, and incremental data migration. You can select all of the supported migration types to ensure service continuity.

Prerequisites

- The version of the user-created Oracle database is 9i, 10g, 11g, 12c, 18c, or 19c.
- Supplemental logging, including SUPPLEMENTAL_LOG_DATA_PK and SUPPLEMENTAL_LOG_DATA_UI, is enabled for the user-created Oracle database. For more information, see Supplemental Logging.
- The user-created Oracle database is running in ARCHIVELOG mode. Archived log files are accessible and a suitable retention period is set for archived log files. For more information, see Managing Archived Redo Log Files.

Precautions

- During full data migration, DTS uses read and write resources of the source and destination databases. This may increase the loads of the database servers. Before you migrate data, evaluate the impact of data migration on the performance of the source and destination databases. We recommend that you migrate data during off-peak hours.
- The source database must have PRIMARY KEY or UNIQUE constraints and all fields must be unique. Otherwise, the destination database may contain duplicate data records.
- DTS supports schema migration for the following types of objects: table, view, synonym, trigger, stored procedure, function, package, and user-defined type.
- If you perform a primary/secondary switchover on the source database when the data migration task is running, the task fails.

Limits

- During schema migration, the reverse indexes and bitmap indexes of the source database are stored as common indexes in the PolarDB cluster.
- During schema migration, partitioned indexes are converted into independent indexes on each partition in the PolarDB cluster.
- Incremental data migration supports only tables that have primary keys or UNIQUE NOT NULL indexes.
- Incremental data migration does not support the LONG data type.
- Data definition language (DDL) operations that are performed during incremental data migration cannot be synchronized to the destination database.
- Materialized views cannot be migrated.

Data type mappings

For more information, see Data type mappings between heterogeneous databases.

Procedure

1. Create a data migration instance.
2. Find the data migration instance that you created, and click **Configure Migration Task** in the Actions column.
3. Configure the source and destination databases.

Section	Parameter	Description
N/A	Task Name	DTS automatically generates a task name. We recommend that you specify an informative name for easy identification. You do not need to use a unique task name.

Section	Parameter	Description
Source Database	Instance Type	Select an instance type based on the deployment of the source database. In this example, select **User-Created Database with Public IP Address**.
	Instance Region	If the instance type is set to **User-Created Database with Public IP Address**, you do not need to specify the **instance region**.
	Database Type	Select **Oracle**.
	Hostname or IP Address	Enter the endpoint that is used to connect to the user-created Oracle database.
	Port Number	Enter the service port number of the user-created Oracle database. The default port number is **1521**.
	Instance Type	○ **Non-RAC Instance**: If you select this option, you must specify the **SID**. ○ **RAC or PDB Instance**: If you select this option, you must specify the **Service Name**.
