    SimpleDateFormat df = new SimpleDateFormat(ISO8601_DATE_FORMAT);
    df.setTimeZone(new SimpleTimeZone(0, "GMT"));
    return df.format(date);
}
```

3. Create a request string.

```
final String HTTP_METHOD = "GET";
Map parameters = new HashMap();
// Specify request parameters.
parameters.put("Product", "ascm");
parameters.put("Action", "GetOrganizationList");
parameters.put("Version", "2019-05-10");
parameters.put("AccessKeyId", "testid");
parameters.put("RegionId", "cn-region-test");
parameters.put("Timestamp", formatIso8601Date(new Date()));
parameters.put("SignatureMethod", "HMAC-SHA1");
parameters.put("SignatureVersion", "1.0");
parameters.put("SignatureNonce", UUID.randomUUID().toString());
parameters.put("Format", "JSON");
parameters.put("Id", "1");
// Arrange request parameters.
String[] sortedKeys = parameters.keySet().toArray(new String[]{});
Arrays.sort(sortedKeys);
final String SEPARATOR = "&";
// Create a string-to-sign.
StringBuilder stringToSign = new StringBuilder();
stringToSign.append(HTTP_METHOD).append(SEPARATOR);
stringToSign.append(percentEncode("/")).append(SEPARATOR);
StringBuilder canonicalizedQueryString = new StringBuilder();
for(String key : sortedKeys) {
    // Encode the key and the value.
    canonicalizedQueryString.append("&")
    .append(percentEncode(key)).append("=")
    .append(percentEncode(parameters.get(key)));
}
//Encode the canonicalized query string.
stringToSign.append(percentEncode(
canonicalizedQueryString.toString().substring(1)));
```

4. The signature. The key value used for calculation is `testsecret&` because `AccessKeySecret` is set to testsecret. The calculated signature is `OLeaidS1JvxuMvnyHOwuJ%2BuX5qY%3D` .

```
// The following sample code shows how to calculate the signature:
final String ALGORITHM = "HmacSHA1";
final String ENCODING = "UTF-8";
key = "testsecret&";
Mac mac = Mac.getInstance(ALGORITHM);
mac.init(new SecretKeySpec(key.getBytes(ENCODING), ALGORITHM));
byte[] signData = mac.doFinal(stringToSign.getBytes(ENCODING));
String signature = Base64.getEncoder().encodeToString(signData);
```

Encode the Signature parameter based on RFC 3986 and add it to the canonicalized query string. The following URL is obtained:

```
https://public.asapi.aliyuns.com/asapi/v3/?AccessKeyId=testid&Action=GetOrganizationLis
t&Format=JSON&Id=1&Product=ascm&RegionId=cn-region-test&SignatureMethod=HMAC-SHA1&Signa
tureNonce=43967c6e-e3ad-44fa-b06b-fcf3db5f39d2&SignatureVersion=1.0&Timestamp=2020-09-1
5T08%3A50%3A40Z&Version=2019-05-10
```

5. Use browsers or tools such as cURL and Wget to initiate an HTTP request.

4.1.1.1.5.4. Response

Responses are returned only in the JSON format. If a return code is greater than or equal to 200 and less than 300, a success response is returned. Otherwise, an error response is returned.

Sample success response

If a request is successful, the request ID and operation-specific parameter values are returned. For more information, see the developer guide of the corresponding Apsara Stack service.

```
 {
    "eagleEyeTraceId": "xxx-xxx-xxx-xxx", // The trace ID provided by EagleEye.
    "asapiSuccess": true,
    "RequestId": "xxxxxxxxxx",
    "Regions": { // The regions returned after you call the DescribeRegions operation.
        "Region": [
            {
                "RegionId": "",
                "RegionEndpoint": "",
                "LocalName": ""
            }
        ]
    }
}
```

Sample error response

If a request fails, the following information is returned. For more information, see the developer guide of the corresponding Apsara Stack service.

```
{
    "code": "asapi.server.api.notfound",// The error code.
    "eagleEyeTraceId": "xxx-xxx-xxx-xxx", // The trace ID provided by EagleEye.
    "asapiSuccess": false, // Indicates whether the request is successful.
    "hostId": "xxxx", // The ID of the host.
    "message": "Failed to ....", // The message returned.
    "asapiErrorMessage": "Failed to ....", // The error message provided by the ASAPI.
    "asapiErrorCode": "asapi.server.api.notfound" // The error code provided by the ASAPI.
}
```

4.1.2. API reference

4.1.2.1. Auto Scaling API

4.1.2.1.1. API usage instructions

Before you call Auto Scaling API operations, you must be granted the Auto Scaling API permissions in the Auto Scaling console.

The following table describes the errors that occur if you are not granted the permissions.

Description

HTTP status code	Error code	Error message	Description
403	Forbidden.Unsubscribed	Do not have permission to access this API.	The error message returned because Auto Scaling is not activated, and you are not authorized to call Auto Scaling API operations.
403	Forbidden.Unauthorized	A required authorization for the specified action is not supplied.	The error message returned because Auto Scaling is not authorized to call the specified operation.

4.1.2.1.2. Make API requests

Call an Auto Scaling API operation, send an HTTP GET request to the Auto Scaling API server, and then add corresponding parameters to the request based on the description of the corresponding API operation. After the request is processed, the system returns a result.

4.1.2.1.3. Request structure

This topic describes the structure of an API request.

- Endpoints

  For information about how to obtain an endpoint, see Generate the endpoint of ASAPI.

- Protocols

  You can send requests over HTTP or HTTPS. For a higher level of security, we recommend that you send requests over HTTPS.

- Methods

  You can use the HTTP GET method to send the request for calling an API operation. If you use this method, the request parameters must be included in the URL of the request.

- Parameters

  For each request, you must specify the operation that you want to perform, such as CreateScalingGroup. Additionally, each request must contain the common request parameters and operation-specific request parameters.

- Encoding

  All requests and responses are encoded in UTF-8.

4.1.2.1.4. Common parameters

4.1.2.1.4.1. Common request parameters

Common request parameters must be included in all Auto Scaling API requests.

Description

Parameter	Type	Required	Description
Format	String	No	The format in which to return the response. Valid values: JSON and XML. Default value: XML.
Version	String	Yes	The version number of the API. The format is YYYY-MM-DD. The version is 2014-08-28.
AccessKeyId	String	Yes	The AccessKey ID provided by Alibaba Cloud.
Signature	String	Yes	The signature string of the current request. For more information about how signatures are calculated, see Request signatures.
SignatureMethod	String	Yes	The encryption method of the signature string. Set the value to HMAC-SHA1.
Timestamp	String	Yes	The timestamp of the request. Specify the time in the ISO 8601 standard in the yyyy-MM-ddTHH:mm:ssZ format. The time must be in UTC. For example, 20:00:00, August 28, 2014, UTC+8 is written as 2014-08-28T12:00:00Z.
SignatureVersion	String	Yes	The version of the signature algorithm. Set the value to 1.0.
SignatureNonce	String	Yes	A unique random number used to prevent replay attacks. You must use different numbers for different requests.

XML format

```
https://ess.example.com/
?Format=xml
&Version=2014-08-28
&Signature=Pc5WB8gokVn0xfeu%2FZV%2BiNM1****
&SignatureMethod=HMAC-SHA1
&SignatureNonce=1521552885****
&SignatureVersion=1.0
&AccessKeyId=key-test
&Timestamp=2014-08-28T12:00:00Z
```

4.1.2.1.4.2. Common response parameters

Every response returns a unique RequestID regardless of whether the call is successful.

XML format

```
<?xml version="1.0" encoding="UTF-8"? >
<!--Root node of the response-->
<Operation name+Response>
    <! --Response tag-->
    <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
    <! --Responses-->
</Operation name+Response>
```

JSON format

```
{
    "RequestId": "4C467B38-3910-447D-87BC-AC049166F216",
    /*Responses*/
}
```

4.1.2.1.5. Responses

4.1.2.1.5.1. Successful response examples

API responses use the HTTP response format where a 2xx status code indicates a successful call and a 4xx or 5xx status code indicates a failed call. Responses can be returned in either the JSON or XML format. You can specify the response format in the request. The default response format is XML.

> **Note** Sample responses in our API documents are formatted in a way that is easier for you to read. The actual responses are not formatted with line breaks or indentation.

Responses in the XML format include information about whether the request succeeds and specific service data.

```
<?xml version="1.0" encoding="UTF-8"? >
<!--Result Root Node-->
<Operation Name+Response>
    <!--Return Request Tag-->
    <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
    <!--Return Result Data-->
</Operation Name+Response>
```

JSON format

```
{
    "RequestId": "4C467B38-3910-447D-87BC-AC049166F216",
    /* Return Result Data */
}
```

4.1.2.1.5.2. Sample error responses

When an error occurs during an API call, no result data is returned. You can locate the cause of an error based on the error codes defined by each API operation, the error code table in the appendix Client errors, and Server errors.

When an error occurs on an HTTP request for an API operation, a 4xx or 5xx HTTP status code is returned. The response body includes the error code and error message. The response body also contains a globally unique request ID (RequestId) and the ID of the site you accessed with this request (HostId).

XML format

```
<?xml version="1.0" encoding="UTF-8"? >
<Error>
   <RequestId>8906582E-6722-409A-A6C4-0E7863B733A5</RequestId>
   <HostId>ess.example.com</HostId>
   <Code>UnsupportedOperation</Code>
   <Message>The specified action is not supported. </Message>
</Error>
```

JSON format

```
{
    "RequestId": "8906582E-6722-409A-A6C4-0E7863B733A5",
    "HostId": "ess.example.com",
    "Code": "UnsupportedOperation",
    "Message": "The specified action is not supported."
}
```

4.1.2.1.6. Request signatures

This topic describes how to use the request signature to verify the identity of the API caller.

Auto Scaling authenticates each access request. Therefore, each request must contain signature information, regardless of whether the request is sent over HTTP or HTTPS. Auto Scaling implements symmetric encryption by using an AccessKey pair to verify the identity of the request sender. You can obtain the AccessKey ID and the AccessKey secret in the Apsara Uni-manager Management Console. For more information, see Obtain an AccessKey pair. The AccessKey ID is used to verify the identity of a user, while the AccessKey secret is used to encrypt and verify the signature string. You must keep your AccessKey secret confidential.

Perform the following operations to sign an access request:

1. Create a canonicalized query string by using request parameters.
   i. Arrange all request parameters in alphabetical order. These parameters include all common request parameters and operation-specific parameters except the Signature parameter in the common request parameters.

      If you use the GET method to make a request, the request parameters are included as a part of the request URL. The first parameter follows a question mark (`?`) in the URL, and the other parameters follow an ampersand (`&`).

   ii. Encode the name and value of each request parameter.

      The parameter names and values must be URL-encoded in UTF-8 based on the following encoding rules:

      - Uppercase letters, lowercase letters, digits, and some special characters such as ampersands (&), hyphens (-), underscores (_), periods (.), and tildes (~) do not need to be encoded.
      - Other characters must be percent encoded in the `%XY` format. `XY` represents the ASCII code of the characters in hexadecimal notation. For example, double quotation marks (") are encoded as `%22` .
      - Extended UTF-8 characters are encoded in the `%XY%ZA...` format.
      - Spaces must be encoded as `%20` . Do not encode spaces as plus signs `(+)` .

      > **Note** Most libraries that support URL encoding, such as java.net.URLEncoder, comply with the Multipurpose Internet Mail Extensions (MIME) encoding rules of `application/x-www-form-urlencoded` . If this encoding method is used, replace the plus signs (+) with `%20` , the asterisks (*) with `%2A` , and `%7E` with tildes (~) in the encoded strings to obtain the required strings.

   iii. Connect the encoded parameter names and values with equal signs (=).
   iv. Arrange the parameter name and value pairs connected by equal signs in alphabetical order, and connect them with ampersands (&) to obtain a canonicalized query string.
2. Create a string-to-sign from the encoded canonicalized query string based on the following rules:

```
StringToSign=
HTTPMethod + "&" +
percentEncode("/") + "&" +
percentEncode(CanonicalizedQueryString)
```

3. Use the signature string to calculate the HMAC value of the string-to-sign as defined in RFC 2104.

   The key used for signature calculation is the combination of your AccessKey secret and an ampersand (&) (ASCII 38). Secure Hash Algorithm 1 (SHA1) is used as the hash algorithm.

4. Encode the HMAC value in Base64 to obtain the signature string.
5. Add the signature string to the request as the Signature parameter to sign the request.

   When the signature string is submitted to the ECS instance as the final request parameter value, the string must be URL-encoded as other parameters based on the rules defined in RFC 3986.

DescribeScalingGroups is used in the example. The following section shows the request URL to be signed:

```
http://ess.example.com/?TimeStamp=2014-08-15T11%3A10%3A07Z&Format=xml&AccessKeyId=testid&Action=DescribeScalingGroups&SignatureMethod=HMAC-SHA1&RegionId=cn-qingdao&SignatureNonce=1324fd0e-e2bb-4bb1-917c-bd6e437f****&SignatureVersion=1.0&Version=2014-08-28
```

The following section shows the corresponding StringToSign:

```
GET&%2F&AccessKeyId%3Dtestid&Action%3DDescribeScalingGroups&Format%3Dxml&RegionId%3Dcn-qingdao&SignatureMethod%3DHMAC-SHA1&SignatureNonce%3D1324fd0e-e2bb-4bb1-917c-bd6e437f***&SignatureVersion%3D1.0&TimeStamp%3D2014-08-15T11%253A10%253A07Z&Version%3D2014-08-28
```

If the Access Key ID is testid and the AccessKey secret is testsecret, the key used for HMAC calculation is testsecret&. Then, the calculated signature value is SmhZuLUnXmqxSEZ%2FGqyiwGqmf%2BM=.

The following section shows the URL of the signed request:

```
http://ess.example.com/?TimeStamp=2014-08-15T11%3A10%3A07Z&Format=xml&AccessKeyId=testid&Action=DescribeScalingGroups&SignatureMethod=HMAC-SHA1&RegionId=cn-qingdao&SignatureNonce=1324fd0e-e2bb-4bb1-917c-bd6e437f****&SignatureVersion=1.0&Version=2014-08-28&Signature=SmhZuLUnXmqxSEZ%2FGqyiwGqmf%****
```

The signature string is used as the value of the Signature parameter, and the parameter is added to the request URL.

4.1.2.1.7. Scaling groups

4.1.2.1.7.1. CreateScalingGroup

You can call this operation to create a scaling group.

Description

You can call this operation to create a scaling group based on input parameters.

- MinSize specifies the minimum number of ECS instances in a scaling group. MaxSize specifies the maximum number of ECS instances in a scaling group.
  - If the number of ECS instances in a scaling group is less than the MinSize value, Auto Scaling automatically adds ECS instances to the scaling group to ensure that the number of instances is equal to the MinSize value.
  - If the number of ECS instances in a scaling group is greater than the MaxSize value, Auto Scaling automatically removes ECS instances from the scaling group to ensure that the number of instances is equal to the MaxSize value.
- DefaultCooldown specifies the default cooldown period of a scaling group.

  - During the cooldown period after a scale-in or scale-out event is executed in a scaling group, Auto Scaling cannot execute other scaling activities for the scaling group.
  - This parameter is valid only for scaling activities that are triggered by Cloud Monitor event-triggered tasks.
- RemovalPolicy is used to filter and remove ECS instances from a scaling group. This parameter allows you to remove instances based on multiple filter conditions.
  - If an SLB instance is associated with a scaling group, Auto Scaling automatically adds ECS instances that are added to the scaling group to the specified SLB instance.
  - The specified SLB instance must be in the Active state.
  - Health check must be enabled on all ports of listeners that are configured for the specified SLB instance. Otherwise, ECS instances fail to be created.
  - If ECS instances of the VPC type have been added to an SLB instance, the SLB instance cannot be associated with a scaling group.
  - The default weight of an ECS instance that is added to an SLB instance is 50.
- If an ApsaraDB RDS instance is specified for a scaling group, the scaling group automatically adds the internal IP addresses of its ECS instances to the whitelist of the specified ApsaraDB RDS instance.
  - The specified ApsaraDB RDS instance must be in the Running state.
  - The number of IP addresses that can be added to the whitelist of the specified ApsaraDB RDS instance cannot be greater than the upper limit.
- A scaling group does not immediately take effect after it is created. You must enable the scaling group to trigger scaling rules and execute scaling activities.
- The scaling group must be in the same region as the associated SLB instance and ApsaraDB RDS instance.
- You can create up to 20 scaling groups.

Request parameters

Description

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateScalingGroup.
RegionId	String	Yes	The ID of the region where the scaling group is located.
MaxSize	Integer	Yes	The maximum number of ECS instances in the scaling group. Valid values: 0 to 100.
MinSize	Integer	Yes	The minimum number of ECS instances in the scaling group. Valid values: 0 to 100.

Parameter	Type	Required	Description
ScalingGroupName	String	No	The name of the scaling group. The name must be 2 to 40 characters in length and can contain digits, letters, underscores (_), hyphens (-), and periods (.). It must start with a letter or digit. This name must be unique to an Apsara Stack account in a region. If you do not specify this parameter, the default value is ScalingGroupId.
DefaultCooldown	Integer	No	The default cooldown time of the scaling group. Valid values: 0 to 86400. Unit: seconds. Default value: 300.
RemovalPolicy.N	String	No	The policy for removing ECS instances from a scaling group. Valid values: • OldestInstance: removes the ECS instance that was added to the scaling group at the earliest point in time. • NewestInstance: removes the ECS instance that was most recently added to the scaling group. • OldestScalingConfiguration: removes the ECS instance that was created based on the earliest scaling configuration. Default values: OldestScalingConfiguration and OldestInstance. You can specify up to two values.
LoadBalancerIds	String	No	The IDs of SLB instances to be associated with the scaling group. The instance IDs are formatted as a JSON array. Example: [“lb-id0” , “lb-id1” , ... “lb-idz”]. You can specify a maximum of five SLB instances.
DBInstanceIds	String	No	The IDs of ApsaraDB RDS instances to be associated with the scaling group. The instance IDs are formatted as a JSON array. Example: [“rm-id0” , “rm-id1” , ... “rm-idz”]. You can specify a maximum of eight ApsaraDB RDS instances.
VSwitchId	String	No	The ID of the vSwitch. It must be specified when you create a scaling group of the VPC type.

Parameter	Type	Required	Description
VSwitchIds.N	String	No	• The ID of vSwitch N. If VSwitchIds.N is set, VSwitchId is ignored. • This parameter enables you to specify a maximum of five vSwitches of one VPC in multiple zones when you create a scaling group. Valid values of N: 1 to 5. • The vSwitch priority is indicated by an ascending set of numbers. 1 indicates the highest priority. • If an ECS instance cannot be created in the zone where the vSwitch with the highest priority resides, the system automatically uses the vSwitch with the next highest priority to create the ECS instance.

Response parameters

Description

Parameter	Type	Required
ScalingGroupId	String	The ID of the scaling group, which is generated by the system and globally unique.

Error codes

For more information about errors common to all operations, see Client errors or Server errors.

Description

Description	Error code	Error message	HTTP status code
The error message returned because the specified scaling group name already exists.	InvalidScalingGroupName.Duplicate	The specified value of parameter `<parameter name>` is duplicated.	400
The error message returned because the maximum number of scaling groups has been reached.	QuotaExceeded.ScalingGroup	Scaling group quota exceeded.	400
The error message returned because the specified region does not exist.	InvalidRegionId.NotFound	The specified region does not exist.	404

Description	Error code	Error message	HTTP status code
The error message returned because the specified MinSize value is greater than the MaxSize value.	InvalidParameter.Conflict	The value of parameter `<parameter name>` and parameter `<parameter name>` are conflict.	400
The error message returned because the specified SLB instance does not exist in this account.	InvalidLoadBalancerId.NotFound	The specified Load Balancer does not exist.	404
The error message returned because the specified SLB instance and scaling group are not in the same region.	InvalidLoadBalancerId.RegionMismatch	The specified Load Balancer and the specified scaling group are not in the same Region.	400
The error message returned because the specified SLB instance is not in the active state.	IncorrectLoadBalancerStatus	The current status of the specified load balancer does not support this action.	400
The error message returned because health check is not enabled for the specified SLB instance.	IncorrectLoadBalancerHealthCheck	The current health check type of specified load balancer does not support this action.	400
The error message returned because the network type of the specified SLB instance is VPC after you specify the vSwitch ID.	InvalidLoadBalancerId.IncorrectAddressType	The current address type of specified load balancer does not support this action.	400
The error message returned because the network type of the ECS instance that is added to the specified SLB instance is different from that of the scaling group.	InvalidLoadBalancerId.IncorrectInstanceNetworkType	The network type of the instance in specified Load Balancer does not support this action.	400
The error message returned because the ECS instance that is added to the specified SLB instance and the vSwitch are not in the same VPC.	InvalidLoadBalancerId.VPCMismatch	The specified virtual switch and the instance in specified Load Balancer are not in the same VPC.	400

Description	Error code	Error message	HTTP status code
The error message returned because the specified ApsaraDB RDS instance does not exist in this account.	InvalidDBInstanceId.NotFound	DB instance "XXX" does not exist.	404
The error message returned because the specified ApsaraDB RDS instance and scaling group are not in the same region.	InvalidDBInstanceId.RegionMismatch	DB instance "XXX" and the specified scaling group are not in the same Region.	400
The error message returned because the specified ApsaraDB RDS instance is not in the Running state.	IncorrectDBInstanceStatus	The current status of DB instance “XXX” does not support this action.	400
The error message returned because the maximum number of IP addresses that can be added to the whitelist of the specified ApsaraDB RDS instance has been reached.	QuotaExceeded.DBInstanceSecurityIP	Security IP quota exceeded in DB instance “XXX”.	400
The error message returned because the specified vSwitch does not exist.	InvalidVSwitchId.NotFound	The specified virtual switch does not exist.	404
The error message returned because the maximum number of private IP addresses of the vSwitch has been reached.	QuotaExceeded.PrivateIpAddress	Private IP address quota exceeded in the specified virtual switch.	400
The error message returned because the maximum number of instances in the VPC has been reached.	QuotaExceeded.VPCInstance	Instance quota exceeded in the specified VPC.	400
The error message returned because the vSwitch is unavailable, and instances cannot be created.	IncorrectVSwitchStatus	The current status of virtual switch does not support this operation.	400

Examples

Sample requests

```
http://ess.example.com/?Action=CreateScalingGroup
&RegionId=cn-qingdao
&MaxSize=20
&MinSize=2
&LoadBalancerId=147b46d767c-cn-qingdao-c****
&DBInstanceId.1=rdszzzyyuny****
&DBInstanceId.2=rdsia3u3yia****
&<Common request parameters>
```

Sample responses

XML format

```
<CreateScalingGroupResponse>
    <RequestId>536E9CAD-DB30-4647-AC87-AA5CC38C5382</RequestId>
    <ScalingGroupId>dP8VqSd9ENXPc0ciVmbc****</ScalingGroupId>
</CreateScalingGroupResponse>
```

JSON format

```
{
    "RequestId": "536E9CAD-DB30-4647-AC87-AA5CC38C5382",
    "ScalingGroupId": "dP8VqSd9ENXPc0ciVmbc****"
}
```

4.1.2.1.7.2. ModifyScalingGroup

You can modify a scaling group.

Description

- You can call this operation to modify the attributes of a scaling group. However, the following attributes cannot be modified:
  - RegionId
  - LoadBalancerId
  - DBInstanceId
- This operation can only be called when the scaling group is in active or inactive state.
- When the specified scaling configuration needs to be modified, the InstanceType of the modified scaling configuration must be the same as the active InstanceType of the scaling configuration.

  After a new scaling configuration is added to the scaling group, the running ECS instances that were created based on the previous scaling configuration will remain unchanged.
- If the number of ECS instances does not meet the requirements of the modified MaxSize and MinSize parameters, ECS instances will be added to or removed from the group, so that the number of instances is equal to the MaxSize or MinSize parameter.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyScalingGroup.
ScalingGroupId	String	Yes	The ID of a scaling group.
ScalingGroupName	String	No	The displayed name of the scaling group. The name must be 2 to 40 characters in length. It must start with a letter or number. It can contain numbers, uppercase letters, lowercase letters, underscores (_), hyphens (-), and periods (.). The name of the scheduled task must be unique to an Alibaba Cloud account in the region it is located.
ActiveScalingConfigurationId	String	No	The ID of the active scaling configuration in the scaling group.
MinSize	Integer	No	The minimum number of ECS instances in the scaling group. Valid values: [0, 100].
MaxSize	Integer	No	The maximum number of ECS instances in the scaling group. Valid values: [0, 100].
DefaultCooldown	Integer	No	The default cool-down time of the scaling group. Valid values: [0, 86400]. Unit: second.
RemovalPolicy.N	String	No	The ECS instance removal policy for the scaling group. Valid values: • OldestInstance: Remove the ECS instance that was added to the scaling group first. • NewestInstance: Remove the ECS instance that was added to the scaling group last. • OldestScalingConfiguration: Remove ECS instances that were created based on the earliest scaling configuration. A maximum of two values can be entered.

Response parameters

For more information, see Common response parameters.

Error code

For more information about common error codes, see Client errors or Server errors.

Description	Error code	Description	HTTP status code
The error message returned when the specified scaling group does not exist under this account.	InvalidScalingGroupId.NotFound	The specified scaling group does not exist.	404
The error message returned when the scaling group name already exists.	InvalidScalingGroupName.Duplicate	The specified value of parameter `<parameter name>` is duplicated.	400
The error message returned when the specified scaling configuration does not exist in the specified scaling group.	InvalidScalingConfigurationId.NotFound	The specified scaling configuration does not exist.	404
The error message returned when the instances types of the specified scaling configuration and the active scaling configuration are different.	InvalidScalingConfigurationId.InstanceTypeMismatch	The specified scaling configuration and existing active scaling configuration have different instance type.	400

Description	Error code	Description	HTTP status code
The error message returned when the specified MinSize is greater than MaxSize.	InvalidParameter.Conflict	The values of parameter `<Parameter name>` and parameter `<Parameter name>` are conflict.	400

Examples

Sample requests

```
http://ess.example.com/?Action=ModifyScalingGroup
&ScalingGroupId=cqS5QbbhmvGLcJbWoDbW****
&ScalingGroupName=ScalingGroup
&<Common request parameter>
```

Response examples

XML format

4.1.2.1.7.3. EnableScalingGroup

You can call this operation to enable a scaling group.

Description

- After a scaling group is enabled, the ECS instances specified by InstanceId.N are added to the scaling group. If the number of ECS instances in the scaling group is less than the MinSize value after the ECS instances are added, additional ECS instances are automatically created to achieve the MinSize value.

  For example, a scaling group is created with the MinSize parameter set to 5. Two existing ECS instances are specified in the InstanceId.N parameter when the scaling group is enabled. Then, three additional ECS instances are automatically created after the two ECS instances are added by Auto Scaling to the scaling group.
- You can call this operation only when the scaling group is inactive.
- If the scaling group has no active scaling configuration, you must specify a scaling configuration when you enable the scaling group.
  - A single scaling group can only have one active scaling configuration at a time.

- A single scaling group can only have one active scaling configuration at a time.
- If an active scaling configuration exists before the scaling group is enabled, this configuration will become inactive after you specify a new active scaling configuration when you call the operation.

- The limits on ECS instances to be added are as follows:
  - The ECS instances and the scaling group must be in the same region.
  - The ECS instances must have the same instance type as that of the active scaling configuration.
  - The ECS instances must be running.
  - The ECS instances have not been added to any scaling group.
  - If the VSwitchId parameter is specified for a scaling group, the ECS instances that reside in a classic network or in other VPCs cannot be added to the scaling group.
  - If the VSwitchId parameter is not specified for a scaling group, ECS instances that belong to a VPC cannot be added to the scaling group.
- If the sum of the number of instances to be added specified by this operation and the number of existing ECS instances in the scaling group is greater than the MaxSize value, the call fails.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to EnableScalingGroup.
ScalingGroupId	String	Yes	The ID of the scaling group.
ActiveScalingConfigurationId	String	No	The ID of the scaling configuration to be activated in the scaling group.
InstanceId.N	String	No	The IDs of ECS instances to be added to the enabled scaling group. Valid values of N: 1 to 20.

Response parameters

For more information, see Common response parameters.

Error codes

For more information about errors common to all operations, see Client errors or Server errors.

Description	Error code	Error message	HTTP status code
The error message returned because the specified scaling group does not exist under this account.	InvalidScalingGroupId.NotFound	The specified scaling group does not exist.	404

Description	Error code	Error message	HTTP status code
The error message returned because Auto Scaling is not authorized to call the specified operation.	Forbidden.Unauthorized	A required authorization for the specified action is not supplied.	403
The error message returned because the specified scaling group is currently being deleted.	IncorrectScalingGroupStatus	The current status of the specified scaling group does not support this action.	400
The error message returned because the specified scaling configuration does not exist in the specified scaling group.	InvalidScalingConfigurationId.NotFound	The specified scaling configuration does not exist.	404
The error message returned because the instance type of the specified scaling configuration is different from that of the active scaling configuration.	InvalidScalingConfigurationId.InstanceTypeMismatch	The specified scaling configuration and existing active scaling configuration have different instance type.	400
The error message returned because no active scaling configuration is specified for the scaling group.	MissingActiveScalingConfiguration	An active scaling configuration for the specified scaling group is not supplied.	400
The error message returned because the specified ECS instance does not exist in the current account.	InvalidInstanceId.NotFound	Instance "XXX" does not exist.	404

Description	Error code	Error message	HTTP status code
The error message returned because the specified ECS instance and the scaling group are not in the same region.	InvalidInstanceId. RegionMismatch	Instance "XXX" and the specified scaling group are not in the same Region.	400
The error message returned because the type of the specified ECS instance is different from that in the active scaling configuration.	InvalidInstanceId. InstanceTypeMismatch	Instance "XXX" and existing active scaling configuration have different instance type.	400
The error message returned because the specified ECS instance is not running.	IncorrectInstanceStatus	The current status of instance "XXX" does not support this action.	400
The error message returned because the network type of the specified ECS instance is different from that of the scaling group.	InvalidInstanceId. NetworkTypeMismatch	The network type of instance "XXX" does not support this action.	400
The error message returned because the added ECS instance and the specified scaling group are not in the same VPC.	InvalidInstanceId.VPCMismatch	Instance "XXX" and the specified scaling group are not in the same VPC.	400
The error message returned because the specified ECS instance is already added to another scaling group.	InvalidInstanceId.InUse	Instance "XXX" is already attached to another scaling group.	400

Description	Error code	Error message	HTTP status code
The error message returned because the specified SLB instance is not active.	IncorrectLoadBalancerStatus	The current status of the specified load balancer does not support this action.	400
The error message returned because health check is not enabled for the specified SLB instance.	IncorrectLoadBalancerHealthCheck	The current health check type of specified load balancer does not support this action.	400
The error message returned because the network type of the ECS instance attached to the specified SLB instance is different from that of the scaling group.	InvalidLoadBalancerId.IncorrectInstanceNetworkType	The network type of the instance in specified Load Balancer does not support this action.	400
The error message returned because the ECS instance attached to the specified SLB instance is not in the same VPC as the VSwitch specified by VSwitchID.	InvalidLoadBalancerId.VPCMismatch	The specified virtual switch and the instance in specified Load Balancer are not in the same VPC.	400
The error message returned because the specified RDS instance is not running.	IncorrectDBInstanceStatus	The current status of DB instance "XXX" does not support this action.	400

Description	Error code	Error message	HTTP status code
The error message returned because the total number of ECS instances (Total Capacity) exceeds the specified value of MaxSize after ECS instances are added to the specified scaling group.	IncorrectCapacity.MaxSize	To attach the instances, the total capacity will be greater than the max size.	400

Examples

Sample requests

```
http://ess.example.com/?Action=EnableScalingGroup
&ScalingGroupId=dmIDKNcyWfzncX9MWX1****
&InstanceId.1=i-283vv****
&<Common request parameters>
```

Sample responses

XML format

```

}
```

4.1.2.1.7.4. DisableScalingGroup

You can disable a specified scaling group.

Description

- The scaling activity that is being executed before this operation is called will be continued until it is completed. Scaling activity requests after this operation is called will be rejected.
- The operation can only be called when the scaling group is active.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DisableScalingGroup.
ScalingGroupId	String	Yes	The ID of the scaling group.

Response parameters

For more information about response parameters, see Common response parameters.

Error code

For more information about common error codes, see Client errors or Server errors.

Error message	Error code	Description	HTTP status code
The error message returned when the specified scaling group does not exist under this account.	InvalidScalingGroupId.NotFound	The specified scaling group does not exist.	404

Examples

Sample requests

```
http://ess.example.com/?Action=DisableScalingGroup
&ScalingGroupId=dmIDKNcyWfzncX9MWX1****
&<Common request parameter>
```

Response examples

XML format

```
< DisableScalingGroupResponse>
    <RequestId>6469DCD0-13AC-487E-85A0-CE4922908FDE</RequestId>
</ DisableScalingGroupResponse>
```

JSON format

```
{
    "RequestId": "6469DCD0-13AC-487E-85A0-CE4922908FDE"
}
```

4.1.2.1.7.5. DeleteScalingGroup

You can delete a specified scaling group.

Description

- ForceDelete indicates whether to forcibly delete a scaling group and remove and release its ECS instances when the scaling group contains ECS instances or is undergoing a scaling activity.
- When ForceDelete is set to false, the scaling group can only be deleted when the following conditions are met:
  - Condition 1: The scaling group is not currently undergoing a scaling activity.
  - Condition 2: The number of ECS instances currently in the scaling group (Total Capacity) is 0.
  - If these two conditions are met, the scaling group can be disabled and deleted.
- If ForceDelete is set to true, we recommend that you perform the following procedure:
  - Disable the scaling group to reject new scaling activity requests. Remove all ECS instances from the scaling group after the ongoing scaling activities are completed and then delete the scaling group. Manually added ECS instances are only removed from the scaling group, whereas automatically created instances are deleted.
- Note that deleting a scaling group also deletes its scaling configurations, rules, activities, and requests.
- The following tasks and instances are not deleted: scheduled tasks, CloudMonitor alarm tasks, Server Load Balancer instances, and ApsaraDB RDS instances.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteScalingGroup.
ScalingGroupId	String	Yes	The ID of the scaling group.
ForceDelete	Bool	No	Indicates whether to forcibly delete a scaling group and remove and release its ECS instances when the scaling group contains ECS instances or is undergoing scaling activity. The default value is false, indicating that the scaling group will not be forcibly deleted.

Response parameters

For more information about response parameters, see Common response parameters.

Error code

Error message	Error code	Description	HTTP status code
The error message returned when the specified scaling group does not exist under this account.	InvalidScalingGroupId.NotFound	The specified scaling group does not exist.	404

Error message	Error code	Description	HTTP status code
The error message returned when Auto Scaling does not have full authorization with Open API.	Forbidden.Unauthorized	A required authorization for the specified action is not supplied.	403
The error message returned when the specified scaling group still contains ECS instances.	InstanceInUse	You cannot delete a scaling configuration or scaling group while there is an instance associated with it.	400

Examples

Sample requests

```
http://ess.example.com/?Action=DeleteScalingGroup
&ScalingGroupId=dmIDKNcyWfzncX9MWX1****
&<Common request parameters>
```

Response examples

XML format

```
<DeleteScalingGroupResponse>
    <RequestId>6469DCD0-13AC-487E-85A0-CE4922908FDE</RequestId>
</DeleteScalingGroupResponse>
```

JSON format

```
{
   "RequestId": "6469DCD0-13AC-487E-85A0-CE4922908FDE"
}
```

4.1.2.1.7.6. DescribeScalingGroups

You can call this operation to query scaling groups.

Description

A scaling group can have the following lifecycle states:

- Active: The active scaling group can receive requests to execute scaling rules and trigger scaling activities.
- Inactive: The inactive scaling group cannot receive any requests to execute scaling rules.
- Deleting: The scaling group is being deleted and cannot receive any requests to execute scaling rules.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeScalingGroups.
RegionId	String	Yes	The ID of the region where the scaling group resides.
ScalingGroupId.N	String	No	The ID of the scaling group. Valid values of N: 1 to 20. The IDs of inactive scaling groups will not be displayed in the query result and no errors will be returned.
ScalingGroupName.N	String	No	The name of the scaling group. Valid values of N: 1 to 20. The names of inactive scaling groups will not be displayed in the query result and no errors will be returned.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 1 to 50. Default value: 10.

Response parameters

Parameter	Type	Description
TotalCount	Integer	The total number of scaling groups.
PageNumber	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
ScalingGroups	ScalingGroupSetType	A collection of details about the scaling groups you are querying.

ScalingGroupSetType is a collection of ScalingGroupItemType.

Parameter	Type	Description
ScalingGroup	ScalingGroupItemType	The details of the scaling group.

The following table describes the attributes of ScalingGroupItemType.

Parameter	Type	Description
ScalingGroupId	String	The ID of the scaling group.
ScalingGroupName	String	The display name of the scaling group.
ActiveScalingConfigurationId	String	The ID of the active scaling configuration in the scaling group.
RegionId	String	The ID of the region where the scaling group resides.
MinSize	Integer	The minimum number of ECS instances in the scaling group.
MaxSize	Integer	The maximum number of ECS instances in the scaling group.
DefaultCooldown	Integer	The default cooldown time of the scaling group.
RemovalPolicies	RemovalPolicySetType	The collection of policies for removing ECS instances from the scaling group.
LoadBalancerIds	List of LoadBalancerId	The IDs of the SLB instances.
DBInstanceIds	DBInstanceIdSetType	The IDs of the RDS instances.
VSwitchId	String	The ID of the VSwitch corresponding to the scaling group.

Parameter	Type	Description
LifecycleState	String	The lifecycle status of the scaling group. • Active: The active scaling group can receive requests to execute scaling rules and trigger scaling activities. • Inactive: The inactive scaling group cannot receive any requests to execute scaling rules. • Deleting: The scaling group is currently being deleted and cannot receive any requests to execute scaling rules.
TotalCapacity	Integer	The total number of ECS instances in the scaling group.
ActiveCapacity	Integer	The number of Elastic Compute Service (ECS) instances that have been added to the scaling group and are running properly.
PendingCapacity	Integer	The number of ECS instances that are being added to the scaling group, but are still being configured.
RemovingCapacity	Integer	The number of ECS instances that are being removed from the scaling group.
CreationTime	String	The time when the scaling group was created.

RemovalPolicySetType is a collection of strings.

Parameter	Type	Description
RemovalPolicy	String	The policy for removing ECS instances from the scaling group.

DBInstanceIdSetType is a collection of strings.

Parameter	Type	Description
DBInstanceId	String	The ID of the RDS instance.

Error codes

For more information about errors common to all operations, see Client errors or Server errors.

      }
    ]
  }
 }
```

4.1.2.1.7.7. DescribeScalingInstances

You can query ECS instances in a scaling group. You can query ECS instances by specifying the scaling group ID, scaling configuration ID, health status, lifecycle status, and creation type.

Description

- ECS instances in a scaling group can be either automatically created or manually added.
  - Automatically created ECS instances refer to those created by Auto Scaling during scaling based on user-defined scaling configurations and rules.
  - Manually added ECS instances refer to those added to a scaling group manually by you.

- An ECS instance in a scaling group will go through the following status during its lifecycle:
  - Pending: The ECS instance is currently being added to the scaling group. For example, the instance might currently be being created, added to a Server Load Balancer instance, or added to ApsaraDB RDS.
  - InService: The ECS instance has been successfully added to the scaling group and is providing service normally.
  - Removing: The ECS instance is being removed from the scaling group.
- An ECS instance in a scaling group can be in either of the following health status:
  - Healthy: If an ECS instance is running, it is considered as healthy.
  - Unhealthy: If an ECS instance is not in the **Running** status, it will be considered as unhealthy.
- Auto Scaling automatically removes unhealthy ECS instances from the scaling group.
  - Auto Scaling will stop and release automatically created ECS instances that are unhealthy.
  - Auto Scaling will not stop or release manually added ECS instances that are unhealthy.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value DescribeScalingInstances.
RegionId	String	Yes	The ID of the region where the scaling group is located.
ScalingGroupId	String	No	The ID of the scaling group.
ScalingConfigurationId	String	No	The ID of an associated scaling configuration.
InstanceId.N	String	No	The ID of ECS instance N. N ranges from 1 to 20. The IDs of inactive instances are ignored in the query results, and no error is reported.
HealthStatus	String	No	The health status of an ECS instance in the scaling group. Valid values: • Healthy: The ECS instances are in running status. • Unhealthy: The ECS instances are not in running status.

Parameter	Type	Required	Description
LifecycleState	String	No	The lifecycle status of an ECS instance in the scaling group. Valid values: • InService: the ECS instance has been added to the scaling group and runs properly. • Pending: the ECS instance is being added to the scaling group with relevant configurations not completed. • Removing: The ECS instance is being removed from the scaling group.
CreationType	String	No	The ECS instance type. Valid values: • AutoCreated: the ECS instance is automatically created by the Auto Scaling service in the scaling group. • Added: the ECS instance is created outside the Auto Scaling service and manually added to the scaling group.
PageNumber	Integer	No	The page number of the ECS instance list. The initial value and default value are both 1.
PageSize	Integer	No	When querying by page, this parameter indicates the number of lines per page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
TotalCount	Integer	The total number of the ECS instances.
PageNumber	Integer	The number of current page.
PageSize	Integer	The number of lines per page.
ScalingInstances	ScalingInstanceSetType	A collection of details about the ECS instances that you are querying.

ScalingInstanceSetType is a collection of ScalingInstanceItemTypes.

Parameter	Type	Description
ScalingInstance	ScalingInstanceItemType	The details of an ECS instance.

The following table describes the attributes of ScalingInstanceItemType.

Parameter	Type	Description
InstanceId	String	The ID of an ECS instance.
ScalingGroupId	String	The ID of the scaling group to which an ECS instance belongs.
ScalingConfigurationId	String	The ID of an associated scaling configuration.
HealthStatus	String	The health status of an ECS instance in the scaling group.
LifecycleState	String	The lifecycle status of an ECS instance in the scaling group.
CreationTime	String	The time at which an ECS instance was added to the scaling group.
CreationType	String	The ECS instance type.

Error code

For more information about common error codes, see Client errors or Server errors.

```

4.1.2.1.7.8. DescribeScalingActivities

You can call this operation to query the scaling activities of a scaling group.

Description

- You can specify a scaling group ID to query all scaling activities of the scaling group.
- You can filter query results based on the status of scaling activities.
- Only scaling activities during the last 30 days can be returned.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation you want to perform. Set the value to DescribeScalingActivities.
RegionId	String	Yes	The ID of the region where a scaling activity is located.
ScalingGroupId	String	No	The ID of the scaling group.
ScalingActivityId.N	String	No	The ID of the scaling activity. Valid values of N: 1 to 10. The IDs of inactive scaling activities will not be displayed in the query result and no errors will be returned.
StatusCode	String	No	The status of the scaling activity. Valid values: • Successful: The scaling activity was successful. • Warning: The scaling activity was partially successful. • Failed: The scaling activity failed. • InProgress: The scaling activity is in progress. • Rejected: The scaling activity request is rejected.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 1 to 50. Default value: 10.

Response parameters

Parameter	Type	Description
TotalCount	Integer	The total number of scaling activities.
PageNumber	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.

Parameter	Type	Description
ScalingActivities	ScalingActivitySetType	A collection of the scaling activity information.

ScalingActivitySetType is a collection of ScalingActivityItemType.

Parameter	Type	Description
ScalingActivity	ScalingActivityItemType	The details about the scaling activity.

The following table describes the attributes of ScalingActivityItemType.

Parameter	Type	Description
ScalingActivityId	String	The ID of the scaling activity.
ScalingGroupId	String	The ID of the scaling group.
Description	String	The description of the scaling activity.
Cause	String	The trigger for the scaling activity.
StartTime	String	The time when the scaling activity started.
EndTime	String	The time when the scaling activity ended.
Progress	Integer	The execution progress of the scaling activity.
StatusCode	String	The status of the scaling activity.
StatusMessage	String	Indicates whether the scaling activity is attaching or removing Elastic Compute Service (ECS) instances to or from the scaling group.

Error codes

For more information about errors common to all operations, see Client errors or Server errors.

4.1.2.1.8. Scaling configurations

4.1.2.1.8.1. CreateScalingConfiguration

You can call this operation to create a scaling configuration.

Description

- You can create up to 10 scaling configurations in a scaling group.
- The created scaling configuration cannot be modified. To use a different scaling configuration, you must create a new one and activate it in the scaling group by modifying the ActiveScalingConfigurationId parameter for the group.
- When creating a scaling configuration, you must select an image to determine the system disk configuration of the instances to be created. The image contains OS and application software configurations. The system disk of an instance created from an image is the clone of the image.
- A security group must be specified for an instance when it is created, so a scaling configuration must also have a security group specified for instances to be created. Instances in the same security group can access each other. By default, instances in different security groups are isolated by firewalls and cannot access each other. You can configure security group rules to allow instances in different groups to access each other.

  A security group can contain a maximum of 1,000 instances. If a security group already contains 1,000 instances, the group cannot be specified when you create an instance.
- When you create an instance, the system allocates a system disk of the appropriate size for the specified instance image. The system disk type can be specified as a cloud disk, or as an ephemeral disk if you have the permission to activate an ephemeral disk. New users do not have this permission.
- Windows operating systems are not supported on instances with memory of 512 MiB or less. 32-bit operating systems are not supported on instances with a memory greater than or equal to 4 GiB.
- The capacity of a cloud disk cannot exceed 2,000 GiB, and the capacity of an ephemeral disk cannot exceed 1 TiB (1,024 GiB).
- The Portable attribute of cloud disk that is created together with an instance is False. This indicates that the cloud disk cannot be added or removed. The DeleteWithInstance attribute of each created disk is True.
- A maximum of four data disks can be added to an instance. The total capacity of ephemeral disks added to an instance cannot exceed 2 TiB (2,048 GiB). This value does not include the capacity of the system disk.
- If the system disk is a cloud disk, you cannot add ephemeral disks as data disks. If the system disk is an ephemeral disk, you can add ephemeral or cloud disks as data disks.
- A security group with a specified VPCId cannot be specified for a scaling configuration unless the VSwitchId parameter has been specified for the scaling group.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateScalingConfiguration.
ScalingGroupId	String	Yes	The ID of the scaling group to which the scaling configuration belongs.
ImageId	String	Yes	The ID of the image file that you specified when you create the instance.

Parameter	Type	Required	Description
InstanceType	String	Yes	The ECS instance type.
SecurityGroupId	String	Yes	The ID of the security group to which the instance belongs. Instances that belong to the same security group have mutual access.
ScalingConfigurationName	String	No	The name of the scaling configuration. It must be 2 to 40 characters in length. It must start with a digit, uppercase letter, or lowercase letter. It can contain letters, digits, underscores (_), hyphens (-), and periods (.). This parameter must be unique in the scaling group. If this parameter is not specified, the default value is the value of ScalingConfigurationId.
InternetMaxBandwidthIn	Integer	No	Network ingress bandwidth (Mbit/s). Unit: Mbit/s. Valid values: 1 to 200. If this parameter is not specified, the default network ingress bandwidth is 200 Mbit/s.

IoOptimized	String	No	Specifies whether the instance is I/O optimized. Valid values:
			• Optimized: The instance is of I/O optimized type.
			• If this parameter is not specified:
			  ◦ Instance types of Generation I are non I/O-optimized by default.
			  ◦ Instance types other than Generation I are I/O-optimized by default.
			For non I/O-optimized instance types, this parameter cannot be specified.

SystemDisk.Category	String	No	The system disk type. Valid values: • cloud: basic disk • cloud_efficiency: ultra disk • cloud_ssd: standard SSD • ephemeral_ssd: local SSD The default value is cloud for I/O-optimized instances of Generation I types. The default value is cloud_efficiency for other types of instances.
SystemDisk.Size	Integer	No	The size of the system disk. Unit: GiB. Valid values: • cloud: 40 to 500 • cloud_efficiency: 40 to 500 • cloud_ssd: 40 to 500 • ephemeral_ssd: 40 to 500 Default value: 40 or the size of the image, depending on whichever is greater. If this parameter is specified, the size of the system disk must be greater than or equal to max{40, ImageSize}.

Parameter	Type	Required	Description
DataDisk.N.Category	String	No	The category of data disk N. Valid values: • cloud: basic disk • cloud_efficiency: ultra disk • cloud_ssd: standard SSD • ephemeral_ssd: local SSD Default value: cloud
DataDisk.N.Size	Integer	No	The size of data disk N. Unit: GiB. Valid values of N: 1 to 4. Valid values: • cloud: 5 to 2000 • cloud_efficiency: 20 to 32768 • cloud_ssd: 20 to 32768 • ephemeral_ssd: 5 to 800 The value of this parameter must be greater than or equal to the size specified by the SnapshotId parameter.
DataDisk.N.SnapshotId	String	No	The ID of the snapshot used to create data disk N. Valid values of N: 1 to 4. If this parameter is specified, the DataDisk.N.Size parameter is ignored. The size of the specified snapshot is equal to the size of the created data disk. If the snapshot was created on or before July 15, 2013, this operation cannot be performed and the InvalidSnapshot.TooOld error is returned in the response.
DataDisk.N.Device	String	No	The mount point of data disk N. Valid values of N: 1 to 4. When this parameter is not specified, a mount point is assigned automatically when an ECS instance is created. Valid values: /dev/xvdb, /dev/xvdc... /dev/xvdz. The parameter value is empty by default.
DataDisk.n.DeleteWithInstance	String	No	Specifies whether the data disk is released with the instance. Valid values: • true: The disk is released with the instance. • false: The disk is not released with the instance. Default value: true This parameter is valid only for disks that are created separately and whose DataDisk.N.Category parameter is set to cloud, cloud_efficiency, or cloud_ssd. If you set this parameter for other disks, an error is returned.
LoadBalancerWeight	Integer	No	The weight of the back-end server. Valid values: 0 to 100. Default value: 50.
UserData	String	No	The custom data of the instance. It must be encoded in Base64. The maximum size of the raw data is 16 KiB.

Parameter	Type	Required	Description
KeyPairName	String	No	The name of the key pair. • When you specify Windows-based ECS instances, ignore this parameter. Default value: null. The password is valid even if you have specified this parameter. • Linux instances forbid the use of passwords for log on during initialization.
RamRoleName	String	No	The RAM role name of the instance. It is provided and maintained by RAM. You can use ListRoles to query the role name. For more information about the RamRoleName parameter, see API CreateRole and ListRoles.
Tags	String	No	The tags of the instance. Tags must be specified as key-value pairs, such as {"key1":"value1","key2":"value2", ..."key5":"value5"}. A maximum of five tags can be specified for an instance. The following limits apply to a tag key: • It can be a maximum of 64 characters. • It cannot start with aliyun. • It cannot start with http:// or https://. • It cannot be a null string. The following limits apply to a tag value: • It can be a maximum of 128 characters. • It cannot start with aliyun. • It cannot start with http:// or https://. • It can be a null string.
InstanceTypes.N	String	No	• If you use the InstanceTypes.N parameter, ignore the InstanceType parameter. • Valid values of N: 1 to 10, which indicates that up to 10 instance types can be added to a scaling configuration. • In the InstanceTypes.N parameter, N indicates the priority of instance types in the current scaling configuration. The instance type with N set to 1 has the highest priority. A higher value of N indicates a lower priority. • If an instance type with the highest priority cannot be used to create an instance, the instance type with the next highest priority is automatically used.
InstanceName	String	No	The name of the ECS instance that is created based on the current scaling configuration.

Response parameters

Parameter	Type	Description
ScalingConfigurationId	String	The ID of the scaling configuration. It is generated by the system and must be globally unique.

Error codes

For more information about errors common to all operations, see Client errors or Server errors.

Description	Error code	Error message	HTTP status code
The error message returned because the specified scaling group does not exist under this account.	InvalidScalingGroupId.NotFound	The specified scaling group does not exist.	404
The error message returned because the specified scaling configuration name already exists.	InvalidScalingConfigurationName.Duplicate	The specified value of parameter `<parameter name>` is duplicated.	400
The error message returned because the number of scaling configurations in the specified scaling group reaches the upper limit.	QuotaExceeded.ScalingConfiguration	Scaling configuration quota exceeded in the specified scaling group.	400
The error message returned because the specified image does not exist under this account.	InvalidImageId.NotFound	The specified image does not exist.	404
The error message returned because the specified security group does not exist under this account.	InvalidSecurityGroupId.NotFound	The specified security group does not exist.	404
The error message returned because the specified instance type does not support the specified image.	InvalidImageId.InstanceTypeMismatch	The specified image does not support the specified instance type.	400

Description	Error code	Error message	HTTP status code
The error message returned because the network type of the specified security group is different from that of the specified scaling group.	InvalidSecurityGroupId.IncorrectNetworkType	The network type of specified Security Group does not support this action.	400
The error message returned because the specified security group and the specified VSwitch are not in the same VPC.	InvalidSecurityGroupId.VPCMismatch	The specified security group and the specified virtual switch are not in the same VPC.	400
The error message returned because the number of ECS instances in the specified security group reaches the upper limit.	QuotaExceeded.SecurityGroupInstance	Instance quota exceeded in the specified security group.	400
The error message returned because the instance type of the specified scaling configuration is different from that of the current scaling configuration.	InstanceType.Mismatch	The specified scaling configuration and existing active scaling configuration have different instance type.	400
The error message returned because the total capacity of mounted ephemeral disks exceeds 2 TiB (2,048 GiB).	QuotaExceeded.EphemeralDiskSize	Ephemeral disk size quota exceeded.	403
The error message returned because the type of the specified system disk conflicts with the data disk type.	InvalidParameter.Conflict	The value of parameter `<Parameter name>` and parameter `<Parameter name>` are conflict.	400
The error message returned because you do not have the permission to create an ephemeral disk.	InvalidSystemDiskCategory.ValueUnauthorized	The system disk category is not authorized.	403

Description	Error code	Error message	HTTP status code
The error message returned because the specified snapshot does not exist.	InvalidDataDiskSnapshotId.NotFound	Snapshot "XXX" does not exist.	404
The error message returned because the size of the specified snapshot exceeds the upper limit of the disk size.	InvalidDataDiskSnapshotId.SizeNotSupported	The capacity of snapshot "XXX" exceeds the size limit of the specified disk category.	400
The error message returned because the specified snapshot was created on or before July 15, 2013.	InvalidSnapshot.TooOld	This operation is denied because the specified snapshot is created before 2013-07-15.	403
The error message returned because the mount point of the data disk is already occupied.	InvalidDevice.InUse	Device "XXX" has been occupied.	403
The error message returned because the name of the specified key pair does not exist.	InvalidKeyPairName.NotFound	The specified KeyPairName does not exist in our records.	400
The error message returned because you specify the KeyPairName in Windows OS.	InvalidParameter	The specified value of parameter `KeyPairName` is not valid.	400
The error message returned because you specify the RAM role name for a classic network-type instance.	InvalidNetworkType.ForRAMRole	RAMRole can't be used For classic instance.	400
The error message returned when the specified RAM role name does not exist.	InvalidRamRole.NotFound	The specified RamRoleName does not exist.	400
The error message returned because the specified user data is not encoded in Base64 format.	InvalidUserData.Base64FormatInvalid	The specified parameter UserData must be base64 encoded.	400

Description	Error code	Error message	HTTP status code
The error message returned when the size of the raw user data exceeds 16 KiB.	InvalidUserData.SizeExceeded	The specified parameter UserData exceeds the size.	400

4.1.2.1.8.2. DescribeScalingConfigurations

You can call this operation to query scaling configurations.

Description

You can specify a scaling configuration ID or name to query a specific scaling configuration, or specify the scaling group ID to query all scaling configurations of the scaling group.

Scaling configuration status (LifecycleState) can be set to either of the following:

- Active: The scaling configuration is active in a scaling group. Scaling groups use scaling configurations in the active state to automatically create ECS instances.
- Inactive: The scaling configuration is inactive in a scaling group. The scaling group does not use scaling configurations in the inactive state to automatically create ECS instances.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeScalingConfigurations.
RegionId	String	Yes	The ID of the region where a scaling group to which a scaling configuration belongs is located.
ScalingGroupId	String	No	The ID of the scaling group.
ScalingConfigurationId.N	String	No	The ID of the scaling configuration. Valid values of N: 1 to 10. The IDs of inactive scaling configurations do not appear in the query result without any error reported.
ScalingConfigurationName.N	String	No	The name of the scaling configuration. Valid values of N: 1 to 10. The names of inactive scaling configurations do not appear in the query result and no errors are reported.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1. Default value: 1.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 1 to 50. Default value: 10.

Response parameters

Parameter	Type	Description
TotalCount	Integer	The total number of scaling configurations.
PageNumber	Integer	The page number of the returned page.
PageSize	Integer	The number of entries returned per page.
ScalingConfigurations	ScalingConfigurationSetType	A collection of scaling configuration information.

ScalingConfigurationSetType is a collection of ScalingConfigurationItemType.

Parameter	Type	Description
ScalingConfiguration	ScalingConfigurationItemType	The scaling configuration information.

The following table describes the attributes of ScalingConfigurationItemType.

Parameter	Type	Description
ScalingConfigurationId	String	The ID of the scaling configuration.
ScalingConfigurationName	String	The display name of the scaling configuration.
ScalingGroupId	String	The ID of the scaling group to which the scaling configuration belongs.
ImageId	String	The ID of the image file.
InstanceType	String	The ECS instance type.
SecurityGroupId	String	The ID of the security group.
InternetMaxBandwidthIn	Integer	The maximum inbound bandwidth from the Internet. Unit: Mbit/s.
InternetMaxBandwidthOut	Integer	The maximum outbound bandwidth to the Internet. Unit: Mbit/s.
SystemDisk.Category	Integer	The category of the system disk.
DataDisks	DataDiskSetType	A collection of data disk details.
LifecycleState	Integer	The lifecycle of the scaling configuration in the scaling group. Valid values: • Active: The scaling configuration is active in a scaling group. Scaling groups use scaling configurations in the active state to automatically create ECS instances. • Inactive: The scaling configuration is inactive in a scaling group. The scaling group does not use scaling configurations in the inactive state to automatically create ECS instances.
CreationTime	String	The time when the scaling configuration is created.

DataDiskSetType is a collection of DataDiskItemTypes.

Parameter	Type	Description
DataDisk	DataDiskItemType	The data disk information.

The following table describes the attributes of DataDiskItemType.

Parameter	Type	Description
Size	Integer	The size of the disk.
Category	Integer	The category of the disk.
SnapshotId	Integer	The ID of the snapshot used to create data disks.
Device	Integer	The data disk mounting point.

Error codes

For more information about errors common to all operations, see Client errors or Server errors.

```

4.1.2.1.8.3. DeleteScalingConfiguration

You can call this operation to delete a scaling configuration.

Description

- A scaling configuration that is active in a scaling group cannot be deleted.
- If any ECS instances that are created by a scaling configuration are still in a scaling group, the scaling configuration cannot be deleted.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteScalingConfiguration.

Parameter	Type	Required	Description
ScalingConfigurationId	String	Yes	The ID of the scaling configuration.

Response parameters

For more information, see Common response parameters.

Error codes

For more information about common error codes, see Client errors or Server errors.

Description	Error code	Error message	HTTP status code
The error message returned because the specified scaling configuration does not exist in the current account.	InvalidScalingConfigurationId.NotFound	The specified scaling configuration does not exist.	404
The error message returned because the specified scaling configuration is not in the Inactive state.	IncorrectScalingConfigurationLifecycleState	The current lifecycle state of specified scaling configuration does not support this action.	400
The error message returned because the specified scaling configuration still has associated ECS instances.	InstanceInUse	You cannot delete a scaling configuration or scaling group while there is an instance associated with it.	400

Examples

Sample requests

```
http://ess.example.com/?Action=DeleteScalingConfiguration

}
```

4.1.2.1.9. Scaling rules

4.1.2.1.9.1. CreateScalingRule

You can call this operation to create a scaling rule.

A scaling rule defines specific scaling actions, such as attaching or removing Elastic Compute Service (ECS) instances and determining the number of instances to be scaled.

If the number of ECS instances in a scaling group is smaller than MinSize or greater than MaxSize after the execution of a rule, Auto Scaling automatically adjusts the number of ECS instances to be added or removed by executing the "Adjust scaling group instance number to MinSize" or "Adjust scaling group instance number to MaxSize" rule.

- Example 1: A scaling group has a MaxSize of 3, a TotalCapacity of 2, and a scaling rule of adding three ECS instances. When executing this scaling rule, Auto Scaling adds only one instance to the group to prevent TotalCapacity from exceeding MaxSize. (The values in the scaling rule are not changed.)
- Example 2: A scaling group has a MinSize of 2, a TotalCapacity of 3, and a scaling rule of removing five ECS instances. When executing this scaling rule, Auto Scaling removes only one instance from the group to prevent TotalCapacity from becoming smaller than MinSize. (The values in the scaling rule are not changed.)

Description

You can create scaling rules based on input parameters.

- When the AdjustmentType value is TotalCapacity, the number of ECS instances currently in the scaling group is adjusted to the specified value. The corresponding AdjustmentValue value cannot be less than 0.
- When the AdjustmentType value is QuantityChangeInCapacity or PercentChangeInCapacity, a positive number of the AdjustmentValue value indicates adding ECS instances, and a negative number of the AdjustmentValue value indicates removing ECS instances.
- When AdjustmentType is set to PercentChangeInCapacity, Auto Scaling rounds the number of ECS instances to be scaled to the nearest integer based on the formula: Number of ECS instances to be scaled = Current number of instances × Value of AdjustmentValue/100.
- When the cool-down time (Cooldown) is specified in a scaling rule, the specified time is applied to the scaling group after this rule is executed. Otherwise, the DefaultCooldown is applied to the scaling group.
- A scaling group can have a maximum of 10 scaling rules.
- The following APIs use the unique identifier of a scaling rule (ScalingRuleAri) returned by this operation:
  - ExecuteScalingRule: You can call this operation to manually run a specified scaling rule by setting ScalingRuleAri to the identifier.
  - CreateScheduledTask: You can call this operation to create a periodically executed task for a specified scaling rule by setting ScheduledAction to the identifier.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateScalingRule.
ScalingGroupId	String	Yes	The ID of the scaling group to which the scaling rule belongs.
AdjustmentType	String	Yes	The adjustment mode of the scaling rule. Valid values: • QuantityChangeInCapacity: adds or removes a specified number of ECS instances. • PercentChangeInCapacity: adds or removes a specified proportion of ECS instances. • TotalCapacity: adds or removes ECS instances to ensure that the current scaling group has a specified number of ECS instances.
AdjustmentValue	Integer	Yes	The number of ECS instances that are added or released when scaling occurs. • QuantityChangeInCapacity: (0, 100] U (-100, 0] • PercentChangeInCapacity: [0, 10000] U [-10000, 0] • TotalCapacity: [0, 100]
ScalingRuleName	String	No	The display name of the scaling rule. The name must be 2 to 40 characters in length. It must start with a letter or digit. It can contain digits, uppercase letters, lowercase letters, underscores (_), hyphens (-), and periods (.). The name of a scaling rule must be unique within the scaling group that it belongs to. If you do not specify this parameter, the default value (ScalingRuleId) is used.
Cooldown	Integer	No	The cool-down time of the scaling rule. Valid values: 0 to 86,400. Unit: seconds. Default value: empty.

Response parameters

Parameter	Type	Description
ScalingRuleId	String	The globally unique scaling rule ID generated by the system.
ScalingRuleAri	String	The unique identifier of the scaling rule.

Error code

For more information about common error codes, see Client errors or Server errors.

Error message	Error code	Description	HTTP status code
The error message returned when the specified scaling group does not exist under this account.	InvalidScalingGroupId.NotFound	The specified scaling group does not exist.	404
The error message returned when the scaling rule name already exists.	InvalidScalingRuleName.Duplicate	The specified value of parameter `<parameter name>` is duplicated.	400
The error message returned when the number of scaling rules in the specified scaling group reaches the upper limit.	QuotaExceeded.ScalingRule	Scaling rule quota exceeded in the specified scaling group.	400

Examples

Sample requests

```
http://ess.example.com/?Action=CreateScalingRule

4.1.2.1.9.2. ModifyScalingRule

You can modify a scaling rule.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyScalingRule.
ScalingRuleId	String	Yes	The ID of the scaling rule.
AdjustmentType	String	No	The adjustment type of the scaling rule. Valid values: • QuantityChangeInCapacity: adds or removes the specified number of ECS instances. • PercentChangeInCapacity: adds or removes the specified proportion of ECS instances. • TotalCapacity: adds or removes ECS instances to ensure that the current scaling group has the specified number of ECS instances.
AdjustmentValue	Integer	No	The number of ECS instances that are added or released when scaling occurs. Valid values: • QuantityChangeInCapacity: (0, 100] U [-100, 0) • PercentChangeInCapacity: [0, 10000] U [-10000, 0] • TotalCapacity: [0, 100]

Parameter	Type	Required	Description
ScalingRuleName	String	No	The display name of the scaling rule. The name must be 2 to 40 characters in length. It must start with a letter or number. It can contain numbers, uppercase letters, lowercase letters, underscores (_), hyphens (-), and periods (.). The name of a scaling rule must be unique within the scaling group that it belongs to. If you do not specify this parameter, the default value (ScalingRuleId) is used.
Cooldown	Integer	No	The cool-down time of the scaling rule. Valid values: 0 to 86,400. Unit: second. Default value: empty.

Response parameters

parameter	Type	Description
ScalingRuleId	String	The globally unique scaling rule ID generated by the system.
ScalingRuleAri	String	The unique identifier of the scaling rule.

Error code

For more information about common error codes, see Client errors or Server errors.

Error message	Error code	Description	HTTP status code
The error message returned when the specified scaling group does not exist under this account.	InvalidScalingGroupId.NotFound	The specified scaling group does not exist.	404
The error message returned when the scaling rule name already exists.	InvalidScalingRuleName.Duplicate	The specified value of parameter `<parameter name>` is duplicated.	400

Error message	Error code	Description	HTTP status code
The error message returned when the number of scaling rules in the specified scaling group reach the upper limit.	QuotaExceeded.ScalingRule	Scaling rule quota exceeded in the specified scaling group.	400

Examples

Sample requests

```
http://ess.example.com/?Action=CreateScalingRule
&ScalingGroupId=AG6CQdPU8OKdwLjgZcJ****
&AdjustmentType=QuantityChangeInCapacity
&AdjustmentValue=-10
&<Common request parameter>
```

}
```

4.1.2.1.9.3. DescribeScalingRules

You can query information about scaling rules. You can query all scaling rules in a scaling group by specifying the scaling group ID.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeScalingRules.

Parameter	Type	Required	Description
RegionId	String	Yes	The ID of the region where the scaling group to which a scaling rule belongs is located.
ScalingGroupId	String	No	The ID of the scaling group to which a scaling rule belongs.
ScalingRuleId.N	String	No	The ID of scaling rule N. N ranges from 1 to 10. The IDs of inactive scaling rules are ignored in the query result and no error is reported.
ScalingRuleName.N	String	No	The name of scaling rule N. N ranges from 1 to 10. The names of inactive scaling rules are ignored in the query result and no error is reported.
ScalingRuleAri.N	String	No	The unique identifier of scaling rule N. N ranges from 1 to 10. The unique identifiers of inactive scaling rules are ignored in the query result and no error is reported.
PageNumber	Integer	No	The page number of the scaling rule list. The initial value and default value are both 1.
PageSize	Integer	No	The number of lines per page in paged query. Maximum value: 50. Default value: 10.

Response parameters

parameter	Type	Description
TotalCount	Integer	The total number of scaling rules.
PageNumber	Integer	The number of the current page.
PageSize	Integer	The number of lines per page.
ScalingRules	ScalingRuleSetType	A collection of details about the scaling rules you queried.

The ScalingRuleSetType is a collection of the ScalingRuleItemType.

Parameter	Type	Description
ScalingRule	ScalingRuleItemType	The details of a scaling rule.

The following table describes the attributes of ScalingRuleItemType.

Parameter	Type	Description
ScalingRuleId	String	The ID of the scaling rule.
ScalingGroupId	String	The ID of a scaling group.
ScalingRuleName	String	The name of a scaling rule.
Cooldown	Integer	The cool-down time of the scaling rule.
AdjustmentType	String	The adjustment method of the scaling rule.
AdjustmentValue	Integer	The adjustment value of the scaling rule.
ScalingRuleAri	String	The unique identifier of the scaling rule.

Error code

For more information about common error codes, see Client errors or Server errors.

}
```

4.1.2.1.9.4. DeleteScalingRule

You can delete the specified scaling rule.

Request parameters

Parameter	Type	Required	Description

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteScalingRule.
ScalingRuleId	String	Yes	The ID of the scaling rule.

Response parameters

For more information about response parameters, see Common response parameters.

Error code

For more information about common error codes, see Client errors or Server errors.

Error message	Error code	Description	HTTP status code
The error message returned when the specified scaling rule does not exist under this account.	InvalidScalingRuleId.NotFound	The specified scaling rule does not exist.	404

Examples

Sample requests

```
http://ess.example.com/?Action=DeleteScalingRule
&ScalingRuleId=eMKWG8SRNb9dBLAjweN****
&<Common request parameter>
```

Response examples

XML format

```
<DeleteScalingRuleResponse>
    <RequestId>F0595173-CA3A-4597-B0D3-97A07A042B9C</RequestId>
</DeleteScalingRuleResponse>
```

JSON format

```
{

}
```

4.1.2.1.10. Scaling tasks

4.1.2.1.10.1. ExecuteScalingRule

You can run a specified scaling rule.

Description

You can call this operation to run a scaling rule.

- You can only call this operation when the scaling group is active.
- You can only call this operation when the scaling group is not currently undergoing any scaling activities.
- If the scaling group does not have any scaling activities in progress, the operation can be immediately run without the need to wait for the cooldown period to expire.
- When you call this operation successfully, Auto Scaling receives the request and the scaling activity can be run. However, this operation may be unsuccessful. You can use the returned ScalingActivityId parameter to view the status of the scaling activity.
- If the number of ECS instances to be added would leave the number of instances in the scaling group greater than MaxSize, the rule Total Capacity = MaxSize is applied.
- If the number of ECS instances to be removed would leave the number of instances in the scaling group less than MinSize, the rule Total Capacity = MinSize is applied.
- A maximum of 100 ECS instances can be scaled automatically over all groups in all regions.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ExecuteScalingRule.
ScalingRuleAri	String	Yes	The unique identifier of the scaling rule.
ClientToken	String	No	This parameter is used to ensure the idempotence of the request. The value of this parameter is generated by the client and is unique among different requests. The maximum length is 64 ASCII characters. For more information about the ClientToken, see Ensure idempotence.

Response parameters

parameter	Type	Description
ScalingActivityId	String	The ID of the scaling activity.

Error code

For more information about common error codes, see Client errors or Server errors.

Error message	Error code	Description	HTTP status code
The error message returned when the specified scaling rule does not exist under this account.	InvalidScalingRuleAri.NotFound	The specified scaling rule Ari does not exist.	404
The error message returned when Auto Scaling does not have full authorization to Open API.	Forbidden.Unauthorized	A required authorization for the specified action is not supplied.	403
The error message returned when the scaling group to which the specified scaling rule belongs is inactive.	IncorrectScalingGroupStatus	The current status of the specified scaling group does not support this action.	400
The error message returned when the scaling group to which the specified scaling rule belongs has a scaling activity.	ScalingActivityInProgress	You cannot delete a scaling group or launch a new scaling activity while there is a scaling activity in progress for the specified scaling group.	400
The error message returned when the number of ECS instances under this account reach the upper limit.	QuotaExceed.Instance	Living instance quota exceeded.	400
The error message returned when the Server Load Balancer instance in the scaling group to which the specified scaling rule belongs is not active.	IncorrectLoadBalancerStatus	The current status of the specified load balancer does not support this action.	400
The error message returned when the health check is not enabled for the SLB instance in the scaling group to which the specified scaling rule belongs.	IncorrectLoadBalancerHealthCheck	The current health check type of the specified load balancer does not support this action.	400

Error message	Error code	Description	HTTP status code
The error message returned when the network type of the ECS instance connected to the specified SLB instance is different from that of the scaling group.	InvalidLoadBalancerId.IncorrectInstanceNetworkType	The network type of the instance in the specified load balancer does not support this action.	400
The error message returned when the ECS instance connected to the SLB instance of the specified scaling group and the VSwitch are not in the same VPC.	InvalidLoadBalancerId.VPCMismatch	The specified virtual switch and the instance in the specified load balancer are not in the same VPC.	400
The error message returned when the RDS instance in the scaling group to which the specified scaling rule belongs is not running.	IncorrectDBInstanceStatus	The current status of DB instance "XXX" does not support this action.	400
The error message returned when the number of IP addresses in the RDS instance whitelist in the scaling group to which the scaling rule belongs reach the upper limit.	QuotaExceeded.DBInstanceSecurityIP	Security IP quota exceeded in DB instance "XXX".	400
The error message returned when the number of ECS instances already added to the specified security group reach the upper limit.	QuotaExceeded.SecurityGroupInstance	Instance quota exceeded in the specified security group.	400
The error message returned when there is no change in the number of instances in the scaling group after the scaling rule is executed.	IncorrectCapacity.NoChange	To execute the specified scaling rule, the total capacity will not change.	400

Error message	Error code	Description	HTTP status code
The error message returned when the number of ECS instances of Auto Scaling reach the upper limit.	QuotaExceeded.ScalingInstance	Scaling instance quota exceeded.	400
The error message returned when the ECS instance or disk of the specified type cannot be created in the specified region.	ResourceNotAvailable.ECS	The specified region or zone does not offer the specified disk or instance category.	400

Examples

Sample requests

```
http://ess.example.com/?Action=ExecuteScalingRule
&ScalingRuleAri=ari:acs:ess:cn-qingdao:1344371:scalingRule/cCBpdYdQuBe2cUxOdu6****

   <ScalingActivityId>ebta5WbUzC8gcwUWvfch****</ScalingActivityId>
</ExecuteScalingRuleResponse>
```

JSON format

```
{
    "RequestId": "6469DCD0-13AC-487E-85A0-CE4922908FDE",
    "ScalingActivityId": "ebta5WbUzC8gcwUWvfch****"
}
```

4.1.2.1.10.2. AttachInstances

You can call this operation to add Elastic Compute Service (ECS) instances to a specified scaling group.

Description

- The restrictions on an added ECS instance are as follows:
  - The added ECS instance and the scaling group must be in the same region.
  - The added ECS instance must be running.
  - The added ECS instance cannot be added to another scaling group.

  - If the VSwitchId parameter is specified for a scaling group, Elastic Compute Service instances which reside in a classic network or in other VPCs cannot be added to the scaling group.
  - If the VSwitchId parameter is not specified for a scaling group, ECS instances of the VPC network type cannot be added to the scaling group.
- This operation can only be called when the scaling group is active.
- This operation can only be called when the scaling group is not currently undergoing any scaling activities.
- If the scaling group does not have any scaling activities in progress, the operation can be immediately run without the need to wait for the cooldown period to expire.
- When this operation is called, Auto Scaling receives the request. However, it is not guaranteed that the scaling activity can be run as intended. You can use the returned ScalingActivityId parameter to view the status of the scaling activity.
- When the sum of the number of ECS instances currently in the scaling group (Total Capacity) and the number of instances to be added specified by this operation is greater than MaxSize, calling the operation fails.
- Manually added ECS instances are not associated with the active scaling configuration of the scaling group.

Request parameters

Request parameter description

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to AttachInstances.
ScalingGroupId	String	Yes	The ID of the scaling group.
InstanceId.N	String	Yes	The ID of the ECS instance. N ranges from 1 to 20.

Response parameters

parameter	Type	Description
ScalingActivityId	String	The ID of the scaling activity.

Error code

For more information about common error codes, see Client errors or Server errors.

Error message	Error code	Description	HTTP status code
The error message returned when the specified scaling group does not exist under this account.	InvalidScalingGroupId.NotFound	The specified scaling group does not exist.	404
The error message returned when Auto Scaling does not have full authorization with Open API.	Forbidden.Unauthorized	A required authorization for the specified action is not supplied.	403
The error message returned when the specified scaling group is inactive.	IncorrectScalingGroupStatus	The current status of the specified scaling group does not support this action.	400
The error message returned when the specified ECS instance does not exist under this account.	InvalidInstanceId.NotFound	Instance "XXX" does not exist.	404
The error message returned when the specified Elastic Compute Service instance and the scaling group are not in the same region.	InvalidInstanceId. RegionMismatch	Instance "XXX" and the specified scaling group are not in the same Region.	400
The error message returned when the specified Elastic Compute Service instance type is different from that of the active scaling configuration.	InvalidInstanceId.InstanceTypeMismatch	Instance "XXX" and existing active scaling configurations have different instance types.	400
The error message returned when the specified Elastic Compute Service instance is not running.	IncorrectInstanceStatus	The current status of instance "XXX" does not support this action.	400

Error message	Error code	Description	HTTP status code
The error message returned when the network type of the specified ECS instance is different from that of the scaling group.	InvalidInstanceId.NetworkTypeMismatch	The network type of instance "XXX" does not support this action.	400
The error message returned when the added ECS instance and the specified scaling group are not in the same Virtual Private Cloud.	InvalidInstanceId.VPCMismatch	Instance "XXX" and the specified scaling group are not in the same Virtual Private Cloud.	400
The error message returned when the specified ECS instance is added to another scaling group.	InvalidInstanceId.InUse	Instance "XXX" is already added to another scaling group.	400
The error message returned when the specified scaling group has a scaling activity in progress.	ScalingActivityInProgress	You cannot delete a scaling group or launch a new scaling activity while there is a scaling activity in progress for the specified scaling group.	400
The error message returned when the SLB instance in the specified scaling group is inactive.	IncorrectLoadBalancerStatus	The current status of the specified load balancer does not support this action.	400
The error message returned when the health check is not enabled for the specified SLB instance.	IncorrectLoadBalancerHealthCheck	The current health check type of specified load balancer does not support this action.	400

Error message	Error code	Description	HTTP status code
The error message returned when the network type of the ECS instance connected to the specified SLB instance is different from that of the scaling group.	InvalidLoadBalancerId.IncorrectInstanceNetworkType	The network type of the instance in the specified load balancer does not support this action.	400
The error message returned when the Elastic Compute Service instance connected to the SLB instance of the specified scaling group and the VSwitch are not in the same VPC.	InvalidLoadBalancerId.VPCMismatch	The specified virtual switch and the instance in the specified load balancer are not in the same Virtual Private Cloud.	400
The error message returned when the RDS instance in the specified scaling group is not running.	IncorrectDBInstanceStatus	The current status of DB instance "XXX" does not support this action.	400
The error message returned when the number of IP addresses in the specified RDS instance whitelist reach the upper limit.	QuotaExceeded.DBInstanceSecurityIP	Security IP quota exceeded in DB instance "XXX".	400
The error message returned when the number of ECS instances in the specified security group reach the upper limit.	QuotaExceeded.SecurityGroupInstance	Instance quota exceeded in the specified security group.	400

Error message	Error code	Description	HTTP status code
The error message returned when the total number of ECS instances (Total Capacity) exceed MaxSize after an instance is added to the specified scaling group.	IncorrectCapacity.MaxSize	To add the instances, the total capacity will be greater than the MaxSize.	400

Examples

Sample requests

```
http://ess.example.com/?Action=AttachInstances
&ScalingGroupId=AG6CQdPU8OKdwLjgZcJ****
&InstanceId. 1=i-28wt4****
&<Common request parameter>
```

Response examples

XML format

```
<AttachInstancesResponse>
    <RequestId>DD0309B7-2613-4792-9B86-275906695253</RequestId>
    <ScalingActivityId>bybj9OcaOT4ucPMbFhcqHfA3</ScalingActivityId>
</AttachInstancesResponse>
```

JSON format

```
{
    "RequestId": "6469DCD0-13AC-487E-85A0-CE4922908FDE",
    "ScalingActivityId":"ebta5WbUzC8gcwUWvfch****"
}
```

4.1.2.1.10.3. RemoveInstances

You can remove ECS instances from a specified scaling group.

Description

- When an ECS instance automatically created by Auto Scaling is removed from a scaling group, the ECS instance is stopped and released.
- When a manually added ECS instance is removed from a scaling group, the ECS instance is neither stopped nor released.
- This operation can only be called when the scaling group is active.
- You can only call this operation when the scaling group does not currently have any scaling activities.
- If no scaling activity in the scaling group is in progress, the operation can be run immediately without

waiting for cooldown to expire.

- When this operation is called, Auto Scaling receives the request. However, it is not guaranteed that the scaling activity can be run as intended. You can use the returned ScalingActivityId parameter to check the status of the scaling activity.
- When the difference between the number of ECS instances currently in the scaling group (Total Capacity) and the number of ECS instances to be removed is smaller than MinSize, calling the operation fails.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to RemoveInstances.
ScalingGroupId	String	Yes	The ID of the scaling group.
InstanceId.N	String	Yes	The ID of the ECS instance. N ranges from 1 to 20.

Response parameters

Parameter	Type	Description
ScalingActivityId	String	The ID of the scaling activity.

Error code

For more information about common error codes, see Client errors or Server errors.

Error message	Error code	Description	HTTP status code
The error message returned when the specified scaling group does not exist under this account.	InvalidScalingGroupId.NotFound	The specified scaling group does not exist.	404
The error message returned when the specified ECS instance does not exist in the scaling group.	InvalidInstanceId.NotFound	Instance "XXX" does not exist.	404
The error message returned when Auto Scaling does not have full authorization to Open API.	Forbidden.Unauthorized	The required authorization for the specified action is not supplied.	403

Error message	Error code	Description	HTTP status code
The error message returned when the specified scaling group is not active.	IncorrectScalingGroupStatus	The current status of the specified scaling group does not support this action.	400
The error message returned when the specified scaling group is currently undergoing a scaling activity.	ScalingActivityInProgress	You cannot delete a scaling group or launch a new scaling activity while there is a scaling activity in progress for the specified scaling group.	400
The error message returned when the SLB instance in the scaling group to which the specified scaling rule belongs is inactive.	IncorrectLoadBalancerStatus	The current status of the specified load balancer does not support this action.	400
The error message returned when the RDS instance in the scaling group to which the specified scaling rule belongs is not running.	IncorrectDBInstanceStatus	The current status of DB instance "XXX" does not support this action.	400
The error message returned when the number of ECS instances to be removed will leave fewer total ECS instances than MinSize.	IncorrectCapacity.MinSize	To remove the instances, the total capacity will be lesser than the MinSize.	400

Examples

Sample requests

```
http://ess.example.com/?Action=RemoveInstances
&ScalingGroupId=AG6CQdPU8OKdwLjgZcJ****
&InstanceId. 1=i-28wt4****
&<Common request parameter>
```

Response examples

XML format

```
<RemoveInstancesResponse>
    <RequestId>DD0309B7-2613-4792-9B86-275906695253</RequestId>
    <ScalingActivityId>bybj9OcaOT4ucPMbFhcq****</ScalingActivityId>
</RemoveInstancesResponse>
```

JSON format

```
{
    "RequestId": "6469DCD0-13AC-487E-85A0-CE4922908FDE",
    "ScalingActivityId": "ebta5WbUzC8gcwUWvfch****"
}
```

4.1.2.1.10.4. DetachInstances

You can call this operation to remove one or more Elastic Compute Service (ECS) instances from a scaling group.

Description

After an ECS instance is removed, it can either exist independent of any scaling group or be added to another scaling group. For more information about AttachInstances, see AttachInstances. Removing an ECS instance does not stop or release it. You can manually stop or release an ECS instance as needed. When calling this operation, you must take note of the following points:

- The specified scaling group must be enabled.
- The specified scaling group must not have any scaling activities in progress.
- If there is no scaling activity currently in progress in the scaling group, the operation can be immediately run without waiting for the cooldown period to expire.
- When this operation is called successfully, Auto Scaling receives the request. The scaling activity can be triggered, but it is not guaranteed that the scaling activity can be successfully run. You can use the ScalingActivityId parameter returned in the response to query the status of the scaling activity.
- The difference between the number of ECS instances currently in the specified scaling group and the number of ECS instances to be removed must not be smaller than MinSize.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DetachInstances.
ScalingGroupId	String	Yes	The ID of the scaling group.
InstanceId.N	String	Yes	The ID of the ECS instance. N can be an integer from 1 to 20.

Response parameters

Parameter	Type	Description
RequestId	String	The request ID.
ScalingActivityId	String	The ID of the scaling activity.

Examples

Sample requests

```
http://ess.example.com/?Action=DetachInstances
&ScalingGroupId=AG6CQdPU8OKdwLj****
&InstanceId. 1=i-28wt4****
& <Common request parameters>
```

Response examples

XML format

```
<DetachInstancesResponse>
    <RequestId>04F0F334-1335-436C-A1D7-6C044FE73368</RequestId>
    <ScalingActivityId>asa-xxxxxxxxx</ScalingActivityId>
</DetachInstancesResponse>
```

JSON format

```
{
    "RequestId": "04F0F334-1335-436C-A1D7-6C044FE73368",
    "ScalingActivityId":"asa-****"
}
```

Error code

Error code	Error message	HTTP status code	Description
IncorrectScalingGroupStatus	The current status of the specified scaling group does not support this action.	400	The error message returned when the specified scaling group is not enabled.
ScalingActivityInProgress	You cannot delete a scaling group or launch a new scaling activity while there is a scaling activity in progress for the specified scaling group.	400	The error message returned when the specified scaling group currently has a scaling activity.
IncorrectLoadBalancerStatus	The current status of the specified load balancer does not support this action.	400	The error message returned when the SLB instance is not active in the specified scaling group.

Error code	Error message	HTTP status code	Description
IncorrectDBInstanceStatus	The current status of DB instance "XXX" does not support this action.	400	The error message returned when the RDS instance in the specified scaling group is not running.
IncorrectCapacity.MinSize	To remove the instances, the total capacity will be lesser than the MinSize.	400	The error message returned when removing a number of ECS instances from a scaling group, which will cause the group to contain fewer ECS instances than the MinSize value.
Forbidden.Unauthorized	A required authorization for the specified action is not supplied.	403	The error message returned when you are not authorized to call this operation.
InvalidScalingGroupId.NotFound	The specified scaling group does not exist.	404	The error message returned when the specified scaling group does not exist.
InvalidInstanceId.NotFound	Instance "XXX" does not exist.	404	The error message returned when the specified ECS instance does not exist.

4.1.2.1.11. Scheduled tasks

4.1.2.1.11.1. CreateScheduledTask

You can call this operation to create scheduled tasks based on specified input parameters.

Description

- You can create a maximum of 20 scheduled tasks.
- When a scheduled task fails to trigger due to an ongoing scaling activity in a scaling group or the scaling group is disabled, the scheduled task will be retried for the duration of the launch expiration time. After the duration of the launch expiration time, a scheduled task that has failed to be triggered will be abandoned.
- If multiple tasks are scheduled at similar times to run scaling rules in the same group, the earliest task will run its scaling activity first. Other tasks will make attempts to execute their rules during their launch expiration time, but only one scaling activity can be run in a scaling group at a time. If the previous scaling activity is completed while another scheduled task is making triggering attempts during its launch expiration time, the scaling rule is executed and the corresponding scaling activity is triggered.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateScheduledTask.
RegionId	String	Yes	The ID of the region where the scheduled task is located.
ScheduledAction	String	Yes	The operations to be performed when the scheduled task is triggered. When you set this parameter, you must also enter the unique identifier of the scaling rule.
LaunchTime	String	Yes	The time at which the scheduled task is triggered. Specify the time in the ISO 8601 standard in the YYYY-MM-DDThh:mmZ format. The time must be in UTC. If the RecurrenceType parameter is specified, the task will be executed repeatedly at the time specified by LaunchTime. If the RecurrenceType parameter is not specified, the task is only executed once at the date and time specified by LaunchTime. You cannot enter a time point later than 90 days from the scheduled task creation or modification.
ScheduledTaskName	String	No	The display name of the scheduled task. The name must be 2 to 40 characters in length and can contain digits, letters, underscores (_), hyphens (-), and periods (.). It must start with a letter or digit. The name of the scheduled task must be unique within the same region for the same Alibaba Cloud tenant account. If you do not specify this parameter, the default value is ScheduledScalingTaskId.

Parameter	Type	Required	Description
Description	String	No	The description of the scheduled task. The description must be 2 to 200 characters in length.
LaunchExpirationTime	Integer	No	The time period during which a failed scheduled task is retried. Default value: 600. Unit: seconds. Valid values: 0 to 21600.
RecurrenceType	String	No	The type of the scheduled task to be repeated. Valid values: • Daily: The scheduled task is executed once after the specified number of days. • Weekly: The scheduled task is executed on each specified day of a week. • Monthly: The scheduled task is executed on each specified day of a month. • If you set RecurrenceType, you must also set both RecurrenceEndTime and RecurrenceValue.
RecurrenceValue	String	No	The recurrence value of the scheduled task to be repeated. • Daily: You can enter a single value ranging from 1 to 31. • Weekly: You can enter multiple values corresponding to the days of the week. The values of Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, and Saturday are 0 to 6 in sequence. Separate multiple values with commas (,). • Monthly: You can enter two values ranging from 1 to 31. The format is A-B. B must be greater than or equal to A. If you set RecurrenceValue, you must also set both RecurrenceEndTime and RecurrenceType.

Parameter	Type	Required	Description
RecurrenceEndTime	String	No	The end time of the scheduled task to be repeated. Specify the time in the ISO 8601 standard in the YYYY-MM-DDThh:mmZ format. The time must be in UTC. You cannot enter a time point later than 90 days from the scheduled task creation or modification. If you set RecurrenceEndTime, you must also set both RecurrenceValue and RecurrenceType.
TaskEnabled	Bool	No	Specifies whether to start the scheduled task. • true: starts the scheduled task. • false: stops the scheduled task. Default value: true.

Response parameters

Parameter	Type	Description
ScheduledTaskId	String	The globally unique ID of the scheduled task generated by the system.

Error codes

For more information about errors common to all operations, see Client errors or Server errors.

Description	Error code	Error message	HTTP status code
The error message returned because the specified region does not exist.	InvalidRegionId.NotFound	The specified region does not exist.	404
The error message returned because the name of the scheduled task already exists.	InvalidScheduledTaskName.Duplicate	The specified value of parameter `<parameter name>` is duplicated.	400

Description	Error code	Error message	HTTP status code
The error message returned because the specified ScheduledAction parameter and the scheduled task are not in the same region.	ScheduledAction.RegionMismatch	The specified scheduled task and the specified scheduled action are not in the same Region.	400
The error message returned because the number of scheduled tasks created by you reaches the upper limit.	QuotaExceeded.ScheduledTask	Scheduled task quota exceeded.	400

Examples

Sample requests

```
http://ess.example.com/?Action=CreateScheduledTask
&RegionId=cn-qingdao
&LaunchTime=2014-08-17T16:52Z
&RecurrenceType=Daily
&RecurrenceValue=1
&RecurrenceEndTime=2014-08-17T16:55Z
&ScheduledAction=ari:acs:ess:cn-qingdao:1344371:scalingRule/cCBpdYdQuBe2cUxOdu6****
&<Common request parameters>
```

Sample responses

XML format

```
<CreateScheduledTaskResponse>
    <RequestId>0F02D931-2B12-44D7-A0E9-39925C13D15E</RequestId>
    <ScheduledTaskId>edRtShc57WGXdt8TlPbr****</ScheduledTaskId>
</CreateScheduledTaskResponse>
```

JSON format

```
{
    "RequestId": "04F0F334-1335-436C-A1D7-6C044FE73368",
    "ScheduledTaskId": "edRtShc57WGXdt8TlPbr****"
}
```

4.1.2.1.11.2. ModifyScheduledTask

You can modify a scheduled task.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyScheduledTask.
ScheduledTaskId	String	Yes	The ID of the scheduled task.
ScheduledTaskName	String	No	The display name of the scaling rule. The name must be 2 to 40 characters in length. It must start with a letter or number. It can contain numbers, uppercase letters, lowercase letters, underscores (_), hyphens (-), and periods (.). The name of the scheduled task must be unique within the same region for the same Alibaba Cloud account. If you do not specify this parameter, the default value (ScheduledScalingTaskId) is used.
Description	String	No	The description of the scheduled task. It must be 2 to 200 characters in length.
ScheduledAction	String	No	The operation performed when the scheduled task is triggered. Enter the unique identifier of the scaling rule.
LaunchTime	String	No	The time at which the scheduled task is triggered. UTC time is used and complies with the ISO 8601 standard. The format is YYYY-MM-DDThh:mm:ssZ. If the RecurrenceType parameter is specified, the task will be executed repeatedly at the time specified by LaunchTime. If the RecurrenceType parameter is not specified, the task is only executed once at the time specified by LaunchTime. You cannot enter a time point later than 90 days from the date of the scheduled task creation or modification.

Parameter	Type	Required	Description
LaunchExpirationTime	Integer	No	You can retry the task during this time period after the scheduled task fails. Unit: second. Default value: 600. Valid values: [0, 21600].
RecurrenceType	String	No	The type of the scheduled task to be repeated. Valid values: • Daily: The scheduled task is executed once after the specified number of days. • Weekly: The scheduled task is run on each specified day of the week. • Monthly: The scheduled task is run on each specified day of the month. After the scheduled task is modified, RecurrenceType, RecurrenceValue, and RecurrenceEndTime must be valid.

Parameter	Type	Required	Description
RecurrenceValue	String	No	The value determining how often a scheduled task recurs. • Daily: indicates the interval of days that a scheduled task is repeated on. You can enter a single value ranging from 1 to 31. • Weekly: indicates which days of the week that a scheduled task is repeated on. You can enter multiple values separated by commas (,). You can specify numbers from 0 to 6 for days from Sunday to Saturday in sequence. Multiple values must be separated by commas (,). • Monthly: You can enter two values ranging from 1 to 31. The format is A-B. B must be greater than or equal to A. After the scheduled task is modified, RecurrenceType, RecurrenceValue, and RecurrenceEndTime must be valid.
RecurrenceEndTime	String	No	The end time of the scheduled task to be repeated. UTC time is used and complies with the ISO 8601 standard. The format is YYYY-MM-DDThh:mmZ. You cannot enter a time point later than 90 days from the date of scheduled task creation or modification. After the scheduled task is modified, RecurrenceType, RecurrenceValue, and RecurrenceEndTime must be valid.

Parameter	Type	Required	Description
TaskEnabled	Bool	No	Indicates whether to start the scheduled task. • true: indicates the task is started. • false: indicates the task is stopped. Default value: true.

Response parameters

For more information about response parameters, see Common response parameters.

Error code

For more information about common error codes, see Client errors or Server errors.

Error message	Error code	Description	HTTP status code
The error message returned when the specified scheduled task does not exist under this account.	InvalidScheduledTaskId.NotFound	The specified scheduled task does not exist.	404
The error message returned when the name of the scheduled task already exists.	InvalidScheduledTaskName.Duplicate	The specified value of parameter `<parameter name>` is duplicated.	400
The error message returned when the specified ScheduledAction parameter and the scheduled task are not in the same region.	ScheduledAction.RegionMismatch	The specified scheduled task and the specified scheduled action are not in the same Region.	400

Examples

Sample requests

```
http://ess.example.com/?Action=ModifyScheduledTask
&ScheduledTaskId=edRtShc57WGXdt8TlPbr****
&LaunchTime=2014-08-18T10:52Z
&RecurrenceEndTime=2014-08-20T16:55Z
&<Common request parameter>
```

Response examples

XML format

```
<ModifyScheduledTaskResponse>
    <RequestId>F9372E8D-C163-471F-BEB4-3A02B3CE176E</RequestId>
</ModifyScheduledTaskResponse>
```

JSON format

```
{
    "RequestId": "04F0F334-1335-436C-A1D7-6C044FE73368"
}
```

4.1.2.1.11.3. DescribeScheduledTasks

You can query information about a scheduled task. You can query information about relevant scheduled tasks by specifying the ScheduledAction parameter.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeScheduledTasks.
RegionId	String	Yes	The ID of the region where a scheduled task is located.
ScheduledTaskId.N	String	No	The ID of scheduled task N. N ranges from 1 to 20. The IDs of inactive scheduled tasks are ignored in the query result and no error is reported.
ScheduledTaskName.N	String	No	The display name of scheduled task N. N ranges from 1 to 20. The names of inactive scheduled tasks are ignored in the query result and no error is reported.
ScheduledAction.N	String	No	The operation performed when scheduled task N is triggered. N ranges from 1 to 20. Inactive operations are ignored in the query result and no error is reported.
PageNumber	Integer	No	The page number of the scheduled task list. The initial value and default value are both 1.

Parameter	Type	Required	Description
PageSize	Integer	No	The number of lines per page in paged query. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Description
TotalCount	Integer	The total number of scheduled tasks.
PageNumber	Integer	The number of the current page.
PageSize	Integer	The number of lines per page.
ScheduledTasks	ScheduledTaskSetType	A collection of details about the scheduled tasks you queried.

ScheduledTaskSetType is a collection of ScheduledTaskItemType.

Parameter	Type	Description
ScheduledTask	ScheduledTaskItemType	The details of the scheduled task.

The following table describes the attributes of ScheduledTaskItemType.

Parameter	Type	Description
ScheduledTaskId	String	The ID of the scheduled task.
ScheduledTaskName	String	The name of the scheduled task.
Description	String	The description of the scheduled task.
ScheduledAction	String	The operation performed when a scheduled task is triggered.
LaunchTime	String	The time at which the scheduled task is triggered.
LaunchExpirationTime	Integer	You can retry the task during this time period after the scheduled task fails.
RecurrenceType	String	The type of the scheduled task to be repeated.
RecurrenceValue	String	The recurring value of the scheduled task to be repeated.
RecurrenceEndTime	String	The end of the task recurrence period.
TaskEnabled	Bool	Indicates whether to enable a scheduled task.

Error code

For more information about common error codes, see Client errors or Server errors.

Examples

Sample requests

```
http://ess.example.com/?Action=DescribeScheduledTasks
&RegionId=cn-qingdao
&ScheduledTaskId. 1=edRtShc57WGXdt8TlPbr****
&PageSize=50
&<Common request parameter>
```

Response examples

XML format

```
<DescribeScheduledTasksResponse>
    <RequestId>B9B498DA-E836-45FF-83C7-1930492FDD5A</RequestId>

        "ScheduledAction": "ari:acs:ess:cn-qingdao:1344371:scalingrule/qGx9feK1giadmp3XKer*
***"
      }
    ]
  }
}
```

4.1.2.1.11.4. DeleteScheduledTask

You can call this operation to delete the specified scheduled task.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteScheduledTask.
ScheduledTaskId	String	Yes	The ID of the scheduled task.

Response parameters

For more information about response parameters, see Common response parameters.

Error code

For more information about common error codes, see Client errors or Server errors.

Error message	Error code	Description	HTTP status code
The error message returned when the specified scheduled task does not exist under this account.	InvalidScheduledTaskId.NotFound	The specified scheduled task does not exist.	404

Examples

Sample requests

```
http://ess.example.com/?Action=DeleteScheduledTask
&ScheduledTaskId=edRtShc57WGXdt8TlPbr****
&<Common request parameter>
```

Response examples

XML format

```
<DeleteScheduledTaskResponse>
    <RequestId>7683D637-CF8A-41DC-85A8-E128061E65FC</RequestId>
</DeleteScheduledTaskResponse>
```

JSON format

```
{
    "RequestId": "04F0F334-1335-436C-A1D7-6C044FE73368"
}
```

4.1.2.1.12. Error codes

4.1.2.1.12.1. Client errors

This topic describes the details of errors caused by clients.

Description

HTTP	Error code	Error message	Description
400	MissingParameter	The input parameter `<parameter name>` that is mandatory for processing this request is not supplied.	The error message returned because a required parameter is not specified.
400	InvalidParameter	The specified value of parameter `<parameter name>` is not valid.	The error message returned because the specified parameter is invalid.

HTTP	Error code	Error message	Description
400	UnsupportedOperation	The specified action is not supported.	The error message returned because the specified API operation is invalid.
400	NoSuchVersion	The specified version does not exist.	The error message returned because the specified version is invalid.
400	Throttling	Request was denied due to request throttling.	The error message returned because the specified operation is denied by the throttling system.
400	InvalidAccessKeyId.NotFound	The Access Key ID provided does not exist in our records.	The error message returned because the specified AccessKey pair is invalid.
403	Forbidden	Users are not authorized to operate on the specified resource.	The error message returned because the specified operation is forbidden.
403	Forbidden.RiskControl	This operation is forbidden by Aliyun Risk Control system.	The error message returned because the specified operation is forbidden by the risk control system.
403	SignatureDoesNotMatch	The signature we calculated does not match the one you provided.	The error message returned because the specified signature is invalid.
403	Forbidden.Unsubscribed	Do not have permission to access this API.	The error message returned because you are not authorized to call Auto Scaling API operations.
403	Forbidden.UserVerification	Your user account is not verified by Aliyun.	The error message returned because the real-name verification is not complete.
400	ResourceNotAvailable	Resource you requested is not available in this region or zone.	The error message returned because Auto Scaling is unavailable in the specified region.

4.1.2.1.12.2. Server errors

This topic describes the details of errors caused by servers.

Description

HTTP status code	Error code	Error message	Description
500	InternalError	The request processing has failed due to some unknown error, exception or failure.	The error message returned because the server fails to process the request.
503	ServiceUnavailable	The request has failed due to a temporary failure of the server.	The error message returned because the server fails to process this request.

4.1.2.1.13. Ensure idempotence

This topic describes how to ensure that requests are idempotent by using ClientToken.

If a request times out or an internal server error occurs when the ExecuteScalingRule operation is called to create or release ECS instances, the client may attempt to resend the request. In this case, the client provides the ClientToken parameter to prevent the server from creating or releasing more instances than intended. The ClientToken parameter also ensures that requests are idempotent. The ClientToken value is a unique and case-sensitive string that is generated by the client. The token can only contain ASCII characters and cannot exceed 64 characters in length.

If the same ClientToken value is used to call the CreateInstance operation, the server returns identical request results with identical ScalingActivityId values. Therefore, when the request is resent due to an error, the same ClientToken value can ensure that only one scaling activity is created and the corresponding ScalingActivityId value is obtained.

If you provide a used ClientToken value and other request parameters are different, Auto Scaling returns the `IdempotentParameterMismatch` error code. Note: You must specify the SignatureNonce, Timestamp, and Signature parameters again before the request is resent because Auto Scaling uses SignatureNonce to prevent replay attacks and uses Timestamp to mark the time of each request. Therefore, you must provide different SignatureNonce and Timestamp values. This also produces a different Signature value.

Typically, you only need to configure the client to resend a request in the case of Error 503 (ServiceUnAvailable) or no response. If Error 200 is returned, a retry can obtain the same result as that of the previous request, but the server status is not affected. If Error 4xx or 500 is returned, the request cannot be retried unless the error message states `Try it later`.

5.Resource Orchestration Service (ROS)

5.1. Developer Guide

5.1.1. API Reference

5.1.1.1. List of operations by function

The following tables describe the API operations available for use in Resource Orchestration Service (ROS).

Stack operations

API	Description
CreateStack	Creates a stack.
ContinueCreateStack	Creates a stack based on the template of the previous stack that fails to be created.
UpdateStack	Updates a stack.
CancelUpdateStack	Cancels the update of a stack.
GetStack	Queries information of a stack.
DeleteStack	Deletes a stack.
ListStacks	Queries the list of stacks.
PreviewStack	Previews the stack to be created by using a specified template.
ListStackEvents	Queries stacks and their resource events.

Resource operations

API	Description
GetResourceTypeTemplate	Queries the template of a resource by resource type.
ListStackResources	Queries the resource list of a specific stack.
GetStackResource	Queries information of a resource in a specific stack.
GetResourceType	Queries detailed information of a resource type.
ListResourceTypes	Queries the list of supported resource types.

Template operations

API	Description
GetTemplateEstimateCost	Queries estimated prices of resources to be created based on a template.
ValidateTemplate	Validates a template that is used to create a stack.
GetTemplate	Queries detailed information of a template, including stacks and change sets associated with the template.
DeleteTemplate	Deletes a template.
ListTemplates	Queries the list of templates.
CreateTemplate	Creates a custom template.
UpdateTemplate	Updates a template.
GetTemplateSummary	Queries information of a new or existing template.

Stack policy operations

API	Description
SetStackPolicy	Configures a stack policy.
GetStackPolicy	Queries information of a stack policy.

Other operations

API	Description
DescribeRegions	Queries available regions.
SignalResource	Sends signals.
SetDeletionProtection	Configures deletion protection on a stack.
ListStackOperationRisks	Detects the resources that may face high risks caused by a stack deletion operation, and queries the reason for each risk.

5.1.1.2. Make API calls

To call the ROS API, you must send HTTP GET requests to the endpoint of the ROS API. You must add the request parameters that correspond to the API operation being called. After you call the API operation, the system returns a response. The request and response are both encoded in UTF-8.

Request syntax

ROS API operations use the RPC protocol. You can call ROS API operations by sending HTTP GET requests.

The following example describes the request syntax of a ROS API request:

```
http://Endpoint/?Action=xx&Parameters
```

The following table describes the parameters in the request syntax.

Parameter	Description
Endpoint	The endpoint of the ROS API. Set the value to *ros.aliyuncs.com*.
Action	The name of the operation being performed. For example, to query the list of stacks, set the value to ListStacks.
Parameters	The request parameters for the operation. Separate multiple parameters with ampersands (&). Request parameters include both common parameters and operation-specific parameters. Common parameters include information such as the API version number and authentication information. For more information, see Common parameters.

Sample requests

The following example demonstrates how to call the ListStacks operation to query the list of stacks:

> **Note** The sample requests in this topic are formatted for better readability.

```
http(s)://ros.aliyuncs.com/? Action=ListStacks
&RegionId=cn-hangzhou
&Format=JSON
&Version=2019-09-10
&Signature=xxxx%xxxx%3D
&SignatureMethod=HMAC-SHA1
&SignatureNonce=1521552885****
&SignatureVersion=1.0
&AccessKeyId=LTAI4GK3D6YtNkNZfjDV****
&TimeStamp=2020-05-01T12:00:00Z
...
```

5.1.1.3. Request signatures

You must sign all API requests to ensure security. Alibaba Cloud uses the request signature to verify the identity of the API caller. Each API request must contain the signature, regardless of whether the request is sent over HTTP or HTTPS.

Overview

You must add the signature to the ROS API request in the following format:

```
https://Endpoint/?SignatureVersion=1.0&SignatureMethod=HMAC-SHA1&Signature=CT9X0VtwR86fNWSnsc6v8YGOjuE%3D&SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf
```

A signature contains the following parameters:

- SignatureMethod: the encryption method of the signature string. Set the value to HMAC-SHA1.
- SignatureVersion: the version of the signature encryption algorithm. Set the value to 1.0.
- SignatureNonce: a unique, random number used to prevent replay attacks. You must use different random numbers for different requests. We recommend that you use universally unique identifiers (UUIDs).
- Signature: the signature generated after the request has been symmetrically encrypted by using the AccessKey secret.

The signature encryption algorithm complies with RFC 2104 HMAC-SHA1 specifications. The AccessKey secret is used to calculate the hash-based message authentication code (HMAC) value of the encoded and sorted query string, and the HMAC value is used as the signature string. Request signatures include operation-specific parameters. Therefore, the signature of a request varies based on the request parameters. To calculate a signature, follow the steps in this topic.

```
Signature = Base64( HMAC-SHA1( AccessKey Secret, UTF-8-Encoding-Of(StringToSign)) )
```

Step 1: Compose and encode a string-to-sign

1. Create a canonicalized query string by using the request parameters.
    i. Create a canonicalized query string by arranging the request parameters (including all common and operation-specific parameters except Signature) in alphabetical order.

    > **Note** If you use the GET method to submit the request, these parameters are the part located after the question mark (?) and connected by the ampersands (&) in the request uniform resource identifier (URI).

ii. Encode the names and values of the arranged request parameters in the request URL by using the unicode transformation format (UTF)-8 character set. The following table describes the encoding rules.

Character	Encoding rule
Uppercase letters, lowercase letters, digits, hyphens (-), underscores (_), periods (.), and tildes (~)	These characters do not need to be encoded.
Other characters	These characters must be percent encoded in `%XY` format. `XY` represents the ASCII code of the characters in hexadecimal notation. For example, double quotation marks (") are encoded as `%22`.
Extended ASCII characters (UTF-8)	These characters are encoded in `%XY%ZA...` format.

Spaces	Spaces must be encoded as `%20`. Do not encode spaces as plus signs (+).
	This encoding method is different from the `application/x-www-form-urlencoded` MIME encoding algorithm (such as the `java.net.URLEncoder` class provided by the Java standard library). However, you can apply the encoding algorithm and replace the plus sign (+) in the encoded string with `%20`, the asterisk (*) with `%2A`, and the tilde (~) with `%7E`. You can use the following `percentEncode` method to implement this algorithm:
	`private static final String ENCODING = "UTF-8";`
	`private static String percentEncode(String value)`
	`throws UnsupportedEncodingException`
	`{`
	`return value ! = null ? URLEncoder.encode(value,`
	`ENCODING).replace("+", "%20").replace("*",`
	`"%2A").replace("%7E", "~") : null;`
	`}`

iii. Connect the encoded parameter names and their values by using equal signs (=).

iv. Sort the connected parameter name and value pairs in the order specified in step i and connect the pairs by using ampersands (&) to obtain the canonicalized query string.

2. Create a string-to-sign from the encoded canonicalized query string in the following way:

```
StringToSign=
      HTTPMethod + "&" +
      percentEncode("/") + "&" +
       percentEncode(CanonicalizedQueryString)
```

A string-to-sign contains the following parameters:

- HTTPMethod: the HTTP method used to submit a request, such as GET.

- percentEncode("/"): specifies the encoded value (%2F) of a forward slash (/). The encoding follows the URL encoding rules.
- percentEncode(CanonicalizedQueryString): specifies the encoded canonicalized query string based on the URL encoding rules.

Step 2: Calculate the signature string

1. Calculate the HMAC value of the string-to-sign based on RFC 2104.

   > **Note** Use the SHA1 algorithm to calculate the HMAC value of the string-to-sign. The combination of your AccessKey secret and an ampersand (&) (ASCII code 38) that follows the secret is used as the key for the HMAC calculation.

2. Encode the HMAC value in Base64 to obtain the signature string.
3. Add the signature string to the request as the Signature parameter.

   > **Note** When the obtained signature value is submitted as the final request parameter value, the value must be URL-encoded that is similar to other parameters based on rules defined in RFC 3986.

Example

The `DescribeRegions` operation is used in this example. This example shows the signature process when `AccessKeyID` is set to testid and `AccessKeySecret` is set to testsecret:

1. Create a canonicalized query string.

   ```
   http://ros.aliyuncs.com/?Timestamp=2019-08-23T12%3A46%3A24Z&Format=XML&AccessKeyId=testid&Action=DescribeRegions&SignatureMethod=HMAC-SHA1&SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf&Version=2019-09-10&SignatureVersion=1.0
   ```

2. Create a string-to-sign.

   ```
   GET&%2F&AccessKeyId%3Dtestid%26Action%3DDescribeRegions%26Format%3DXML%26SignatureMethod%3DHMAC-SHA1%26SignatureNonce%3D3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf%26SignatureVersion%3D1.0%26Timestamp%3D2019-08-23T12%253A46%253A24Z%26Version%3D2019-09-10
   ```

3. Calculate the signature. Because `AccessKeySecret` is set to testsecret, the key value used for calculation is `testsecret&`. The calculated signature is `OLeaidS1JvxuMvnyHOwuJ+uX5qY=`. The Java Base64 encoding method is used in this example.

   ```
   Signature = Base64( HMAC-SHA1( AccessSecret, UTF-8-Encoding-Of(StringToSign) ) )
   ```

4. Add the `Signature=OLeaidS1JvxuMvnyHOwuJ%2BuX5qY%3D` string that has been encoded based on RFC 3986 to the URL in Step 1.

   ```
   http://ros.aliyuncs.com/?SignatureVersion=1.0&Action=DescribeRegions&Format=XML&SignatureNonce=3ee8c1b8-83d3-44af-a94f-4e0ad82fd6cf&Version=2019-09-10&AccessKeyId=testid&Signature=OLeaidS1JvxuMvnyHOwuJ%2BuX5qY%3D&SignatureMethod=HMAC-SHA1&Timestamp=2019-08-23T12%253A46%253A24Z
   ```

You can use browsers or tools such as cURL and Wget to initiate an HTTP request by using the new URL. The HTTP request calls the `DescribeRegions` operation to query the Alibaba Cloud region list.

5.1.1.4. Common parameters

This topic describes the common request and response parameters.

Common request parameters

Parameter	Type	Required	Description
Format	String	No	The format in which to return the response. Default value: JSON. Valid values: • JSON • XML
Version	String	Yes	The API version of the service. Specify the version number in the YYYY-MM-DD format. Set the value to 2019-09-10.
AccessKeyId	String	Yes	The AccessKey ID used to connect to the service. The AccessKey ID is provided by Alibaba Cloud for authentication.
Signature	String	Yes	The signature string of the request. For more information about how signatures are calculated, see Request signatures.
SignatureMethod	String	Yes	The encryption method of the signature string. Set the value to HMAC-SHA1.
Timestamp	String	Yes	The timestamp of the request. Specify the time in the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format. The time must be in UTC. Example: 2020-01-10T12:00:00Z.

Parameter	Type	Required	Description
SignatureVersion	String	Yes	The version of the signature encryption algorithm. Set the value to 1.0.
SignatureNonce	String	Yes	A unique, random number used to prevent replay attacks. You must use different numbers for different requests.

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=XXXXXX
&Format=xml
&Version=2019-09-10
&Signature=Pc5WB8gokVn0xfeu%2FZV%2BiNM1dgI%3D
&SignatureMethod=HMAC-SHA1
&SignatureNonce=1521552885****
&SignatureVersion=1.0
&AccessKeyId=LTAI4GK3D6YtNkNZfjDV****
&TimeStamp=2020-05-01T12:00:00Z
```

Common response parameters

Responses can be returned in the JSON or XML format. You can specify the response format in the request. The default response format is JSON. Every response returns a unique RequestId value regardless of whether the call is successful.

- A `2xx` HTTP status code indicates a successful call.
- A `4xx` or `5xx` HTTP status code indicates a failed call.

Sample responses

- XML format

```
<? xml version="1.0" encoding="utf-8"? >
    <!—Result Root Node-->
    <Interface Name+Response>
        <!—Return Request Tag-->
        <RequestId>4C467B38-3910-447D-87BC-AC049166F216</RequestId>
        <!—Return Result Data-->
    </Interface Name+Response>
```

- JSON format

```
{
    "RequestId":"4C467B38-3910-447D-87BC-AC049166F216"
    /*Return Result Data*/
}
```

5.1.1.5. RAM authorization

Before you use a RAM user account to call an Alibaba Cloud API, you must use an Alibaba Cloud account to create an authorization policy to assign permissions to the RAM user account.

Resource authorization

By default, a RAM user account is not authorized to call Alibaba Cloud APIs to create or modify cloud resources. Before you use a RAM user to call an API, you must grant the RAM user account the permission to call the API by creating an authorization policy and attaching the policy to the RAM user account.

When you create the authorization policy, you can specify the resource to authorize by its Alibaba Resource Name (ARN). An ARN is used to identify the resource to authorize. ARNs are in the following format:

```
acs:service-name:region:account-id:resource-relative-id
```

An ARN contains the following parameters:

- acs: the abbreviation for Alibaba Cloud Service.
- service-name: the name of an Alibaba Cloud service, such as ECS, OSS, and ROS.
- region: the region where the service resides. If this option is not supported, use the asterisk (`*`) instead.
- account-id: the ID of the user account, such as 123456789012****.
- resource-relative-id: the specific description of a resource. The description varies based on service. For more information, see the documentation of each service.

  For example, `acs:oss:123456789012****:sample_bucket/file1.txt` indicates a resource named *sample_bucket/file1.txt* in Object Storage Service (OSS) and `123456789012****` indicates the ID of the user to which the resource belongs.

Types of ROS resources that can be authorized

Resource type	ARN format in the authorization policy
Stack	acs:ros:$regionid:$accountid:stack/$stackid
	acs:ros:$regionid:$accountid:stack/*
Template	acs:ros:$regionid:$accountid:template/$templateid
	acs:ros:$regionid:$accountid:template/*
StackGroup	acs:ros:$regionid:$accountid:stack_group/*

ROS API operations that can be authorized

The following table lists ROS API operations that can be authorized and their corresponding ARN formats.

Operation	ARN
CreateStack	acs:ros:$regionid:$accountid:stack/*
UpdateStack	acs:ros:$regionid:$accountid:stack/$stackid
DeleteStack	acs:ros:$regionid:$accountid:stack/$stackid
GetStack	acs:ros:$regionid:$accountid:stack/$stackid
ListStacks	acs:ros:$regionid:$accountid:stack/*
PreviewStack	acs:ros:$regionid:$accountid:stack/*
GetTemplateEstimateCost	acs:ros:$regionid:$accountid:*
CancelUpdateStack	acs:ros:$regionid:$accountid:stack/$stackid
ContinueCreateStack	acs:ros:$regionid:$accountid:stack/$stackid
SetStackPolicy	acs:ros:$regionid:$accountid:stack/$stackid
GetStackPolicy	acs:ros:$regionid:$accountid:stack/$stackid
GetTemplate	acs:ros:$regionid:$accountid:stack/$stackid
	acs:ros:$regionid:$accountid:template/$templateid
CreateChangeSet	When ChangeSetType is set to CREATE: acs:ros:$regionid:$accountid:stack/*
	When ChangeSetType is set to UPDATE: acs:ros:$regionid:$accountid:stack/$stackid
GetChangeSet	acs:ros:$regionid:$accountid:stack/$stackid
ListChangeSets	acs:ros:$regionid:$accountid:stack/$stackid
ExecuteChangeSet	acs:ros:$regionid:$accountid:stack/$stackid
DeleteChangeSet	acs:ros:$regionid:$accountid:stack/$stackid
ListStackEvents	acs:ros:$regionid:$accountid:stack/$stackid
ListStackResources	acs:ros:$regionid:$accountid:stack/$stackid
GetStackResource	acs:ros:$regionid:$accountid:stack/$stackid
SignalResource	acs:ros:$regionid:$accountid:stack/$stackid
DetectStackDrift	acs:ros:$regionid:$accountid:stack/$stackid
DetectStackResourceDrift	acs:ros:$regionid:$accountid:stack/$stackid

Operation	ARN
GetStackDriftDetectionStatus	acs:ros:$regionid:$accountid:stack/$stackid
ListStackResourceDrifts	acs:ros:$regionid:$accountid:stack/$stackid
DetectStackGroupDrift	acs:ros:$regionid:$accountid:stack_group/*
UpdateStackTemplateByResources	acs:ros:$regionid:$accountid:stack/$stackid

5.1.1.6. Common error codes

This topic describes the common client and server error codes.

Client error codes

Error code	Error message	HTTP status code	Description
UnknownError	The request processing has failed due to some unknown error.	400	The error message returned because an unknown error that is not caused by a server-side issue has occurred on the client.
MissingParameter	The input parameter {name} should be specified.	400	The error message returned because the input parameter is missing. name indicates the parameter name.
	One of the input parameters {names} should be specified.	400	The error message returned because the input parameter is missing. You must specify one of the input parameters. names indicates the names of all the related parameters.
	The input parameter {name} should be specified, {reason}.	400	The error message returned because the input parameter is missing. name indicates the parameter name, and reason indicates the specific reason.
	The specified parameter {name} is invalid.	400	The error message returned because the specified parameter is invalid. name indicates the parameter name.

Error code	Error message	HTTP status code	Description
InvalidParameter	The specified parameter {name} is invalid, {reason}.	400	The error message returned because the specified parameter is invalid. name indicates the parameter name, and reason indicates the specific reason.
MultipleParameter	Only one of the input parameters {names} can be specified.	400	The error message returned because the number of specified parameters exceeds the limit. You can specify only one of the parameters. names indicates the names of all the related parameters.
InvalidIdempotenceParameter	The specified parameters are different from before.	400	The error message returned because the idempotent token is the same, but the specified parameters are different from before.
LastTokenProcessing	The last token request is processing.	400	The error message returned because the previous token request is being processed. Try again later.
Invalid	Data supplied was not valid: {reason}.	400	The error message returned because the value is invalid. reason indicates the specific reason.
InvalidValue	{reason}.	400	The error message returned because the value is invalid. reason indicates the specific reason.
RequestLimitExceeded	Request limit exceeded: {reason}.	400	The error message returned because the request contains content that exceeds the limit. reason indicates the specific reason. You can change the part of content that exceeds the limit by adjusting the quota.
NotSupported	{feature} is not supported.	400	The error message returned because a specified feature is not supported. feature indicates the specific feature or operation.

Error code	Error message	HTTP status code	Description
MismatchNextToken	{name} mismatches next token.	400	The error message returned because the specified parameter does not match the next token. name indicates the parameter name.
AssumeRoleFailure	Fail to assume role {name}: {reason}	400	The error message returned because ROS has failed to obtain a temporary identity to assume the specified RAM role. name indicates the RAM role name, and reason indicates the specific reason for the failure.
Forbidden	You are not authorized to complete this action.	403	The error message returned because you are not authorized to complete this action.
	A required authorization for the specified action {api} is not supplied. Code: {code} RequestId: {request_id}	403	The error message returned because you have not authorized ROS to call the operation. api indicates the name of the operation. code indicates the error code. request_id indicates the ID of the request.
AccountTypeNotSupported	Account type not supported.	403	The error message returned because the specified account type is not supported.
NotFound	{reason}.	404	The error message returned because the request contains content that does not exist. reason indicates the specific reason.

Server error codes

Error code	Error message	HTTP status code	Description
InternalError	Server error.	500	The error message returned because an internal error has occurred.

Error code	Error message	HTTP status code	Description
ServiceUnavailable	The request has failed due to a temporary failure of the server.	503	The error message returned because a server error has occurred. Try again later. If the problem persists, submit a ticket.

5.1.1.7. Stack operations

5.1.1.7.1. CreateStack

You can call this operation to create a stack.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	CreateStack	The operation that you want to perform. Set the value to CreateStack.
Parameters.N.ParameterKey	String	Yes	InstanceId	The key of parameter N. If the key and value of the parameter are not specified, the key and value in the template are used. Maximum value of N: 200. **Note** • Parameters is an optional parameter. • If you need to specify Parameters, you must specify both Parameters.N.ParameterKey and Parameters.N.ParameterValue.

Parameter	Type	Required	Example	Description
Parameters.N.ParameterValue	String	Yes	i-xxxxxx	The value of parameter N. Maximum value of N: 200. **Note** • Parameters is an optional parameter. • If you need to specify Parameters, you must specify both Parameters.N.ParameterKey and Parameters.N.ParameterValue.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackName	String	Yes	MyStack	The name of the stack. The name can be up to 255 characters in length and can contain digits, letters, hyphens (-), and underscores (_). It must start with a digit or letter.
DisableRollback	Boolean	No	false	Specifies whether to disable rollback on stack creation failure. Default value: false. Valid values: • true: disables rollback on stack creation failure. • false: enables rollback on stack creation failure.

Parameter	Type	Required	Example	Description
TemplateBody	String	No	{ "ROSTemplateFormatVersion": "2015-09-01" }	The structure that contains the template body. The template body must be 1 to 524,288 bytes in length. If the length of the template body is longer than required, we recommend that you add parameters to the HTTP POST request body to avoid request failures due to excessive length of URLs. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.
StackPolicyURL	String	No	oss://ros-stack-policy/demo	The URL of the file that contains the stack policy. The URL must point to a policy located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/stack-policy/demo and oss://ros/stack-policy/demo?RegionId=cn-hangzhou. The policy can be up to 16,384 bytes in length and the URL can be up to 1,350 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You must specify one of the StackPolicyBody and StackPolicyURL parameters, but you cannot specify both of them.
TimeoutInMinutes	Long	No	10	The timeout period that is specified for the stack creation request. • Default value: 60. • Unit: minutes.

Parameter	Type	Required	Example	Description
StackPolicyBody	String	No	{"Statement": [{"Action": "Update:*", "Resource": "*", "Effect": "Allow", "Principal": "*"}]}	The structure that contains the stack policy body. The stack policy body must be 1 to 16,384 bytes in length. **Note** You must specify one of the StackPolicyBody and StackPolicyURL parameters, but you cannot specify both of them.
ClientToken	String	No	123e4567-e89b-12d3-a456-42665544****	The client token that is used to ensure the idempotence of the request. You can use the client to generate the value, but you must make sure that it is unique among different requests. The token can be up to 64 characters in length and can contain letters, digits, hyphens (-), and underscores (_).
TemplateURL	String	No	oss://ros-template/demo	The URL of the file that contains the template body. The URL must point to a template located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/template/demo and oss://ros/template/demo?RegionId=cn-hangzhou. The template must be 1 to 524,288 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.

Parameter	Type	Required	Example	Description
NotificationURLs.N	RepeatList	No	http://my-site.com/ros-event	The callback URL for receiving stack event N. Only HTTP POST is supported. • Maximum value of N: 5. • Each URL can be up to 1,024 bytes in length. ROS sends a notification to the specified URL when the stack state changes. If rollback is enabled on the stack, notifications are sent if the stack is in the CREATE_ROLLBACK or ROLLBACK state, but are not sent when the stack is in the CREATE_FAILED or UPDATE_FAILED state. **Note** ROS does not send notifications when the stack is in the IN_PROGRESS state. Notifications are sent regardless of whether the Outputs parameter is specified. The following code is an example of a notification: `{ "Outputs": [ { "Description": "No description given", "OutputKey": "InstanceId", "OutputValue": "i-xxx" } ], "StackId": "80bd6b6c-e888-4573-ae3b-93d29113****", "StackName": "test-notification-url", "Status": "CREATE_COMPLETE" }`

Parameter	Type	Required	Example	Description
RamRoleName	String	No	test-role	The name of the RAM role. ROS assumes the specified RAM role to create the stack and call API operations by using the credentials of the role. All operations are performed under this role. If a RAM user is authorized to perform operations on the stack but does not have the permission to use the role, ROS still uses the role and grants the role the least privilege. If you do not specify this parameter, ROS uses the role previously associated with the stack. If no roles are available, ROS uses the temporary credentials generated from the credentials of your account. The RAM role name can be up to 64 characters in length.
DeletionProtection	String	No	Enabled	Specifies whether to enable deletion protection on the stack. Default value: Disabled. Valid values: • Enabled: enables deletion protection on the stack. • Disabled: disables deletion protection on the stack. You can release the stack by using the ROS console or by calling the DeleteStack operation. **Note** The deletion protection property of a nested stack is the same as that of its root stack.

Parameter	Type	Required	Example	Description
CreateOption	String	No	KeepStackOnCreationComplete	Specifies whether to delete the stack after it is created. Default value: KeepStackOnCreationComplete. Valid values: • KeepStackOnCreationComplete: retains the stack and all its resources after the stack is created. • AbandonStackOnCreationComplete: deletes the stack but retains all its resources after the stack is created. This helps you ensure that the maximum number of stacks allowed to be created is not reached. If the stack fails to be created, the stack is retained.

Response parameters

Parameter	Type	Example	Description
StackId	String	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6F	The ID of the request.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=CreateStack
&RegionId=cn-hangzhou
&StackName=MyStack
&Parameters.1.ParameterKey=InstanceId
&Parameters.1.ParameterValue=i-xxxxxx
&TimeoutInMinutes=10
&<Common request parameters>
```

Sample success responses

`XML` format

```
<CreateStackResponse>
          <StackId>4a6c9851-3b0f-4f5f-b4ca-a14bf691****</StackId>
          <RequestId>B288A0BE-D927-4888-B0F7-B35EF84B6E6F</RequestId>
</CreateStackResponse>
```

`JSON` format

```
{
    "StackId": "4a6c9851-3b0f-4f5f-b4ca-a14bf691****",
    "RequestId": "B288A0BE-D927-4888-B0F7-B35EF84B6E6F"
}
```

Error code	Error message	HTTP status code	Description
CircularDependency	Circular Dependency Found: {reason}.	400	The error message returned because the template contains a circular reference. reason indicates the specific reason.
InvalidSchema	{reason}.	400	The error message returned because the specified template format is incorrect. reason indicates the specific reason.
InvalidTemplateAttribute	The Referenced Attribute ({resource} {name}) is incorrect.	400	The error message returned because the resource attribute referenced in the template is incorrect. resource indicates the resource name, and name indicates the attribute name.
InvalidTemplatePropertyType	The specified value type of ({resource} {section}) is incorrect.	400	The error message returned because the type of the specified resource section defined in the template is invalid. resource indicates the resource name, and section indicates the section name.

Error code	Error message	HTTP status code	Description
InvalidTemplateReference	The specified reference "{name}" (in {referencer}) is incorrect.	400	The error message returned because the template contains an invalid reference. name indicates the reference name, and referencer indicates the referencer name.
InvalidTemplateSection	The template section is invalid: {section}.	400	The error message returned because the template contains an invalid section. section indicates the section name.
InvalidTemplateVersion	The template version is invalid: {reason}.	400	The error message returned because the template version is incorrect. reason indicates the specific reason.
StackValidationFailed	{reason}.	400	The error message returned because the stack validation failed. reason indicates the specific reason.
UnknownUserParameter	The Parameter ({name}) was not defined in template.	400	The error message returned because the specified parameter is not defined in the template. name indicates the parameter key.
UserParameterMissing	The Parameter {name} was not provided.	400	The error message returned because no value is passed into the specified parameter defined in the template. name indicates the parameter key.

Error code	Error message	HTTP status code	Description
ActionInProgress	Stack {name} already has an action ({action}) in progress.	409	The error message returned because the specified stack has a change operation in progress. name indicates the name or ID of the stack, and action indicates the change operation.
StackExists	The Stack ({name}) already exists.	409	The error message returned because a stack with the same name already exists. name indicates the stack name.

5.1.1.7.2. ContinueCreateStack

Creates a stack based on the template of the previous stack that fails to be created.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ContinueCreateStack	The operation that you want to perform. Set the value to ContinueCreateStack.
Parameters.N.ParameterKey	String	Yes	Amount	The key of template parameter N to be overridden. If the key and value of the parameter are not specified, the key and value are set to those in the template of the stack that fails to be created. Maximum value of N: 200. **Note** This parameter takes effect only when the Mode parameter is set to Recreate.

Parameter	Type	Required	Example	Description
Parameters.N.ParameterValue	String	Yes	12	The value of template parameter N to be overridden. Maximum value of N: 200. This parameter takes effect only when the Mode parameter is set to Recreate. Take note of the following limits on the template parameter to be overridden: • This parameter cannot change values in the Conditions section of the template from true to false or from false to true. • This parameter can be referenced only by resources that are recreated.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.
RecreatingResources.N	RepeatList	No	WebServer	The resource N to be recreated upon creation failure. ROS recreates the resources you list in this parameter and all resources that depend on the resources.
RamRoleName	String	No	test-role	The name of the Resource Access Management (RAM) role. Resource Orchestration Service (ROS) assumes the specified RAM role to create the stack and call API operations by using the credentials of the role. All operations are performed under this role. If a RAM user is authorized to perform operations on the stack but does not have the permissions to use the role, ROS still uses the role and grants the role the least privilege. If you do not specify this parameter, ROS uses the role previously associated with the stack. If no roles are available, ROS uses the temporary credentials generated from the credentials of your account. The RAM role name can be up to 64 characters in length.

Parameter	Type	Required	Example	Description

Parameter	Type	Required	Example	Description

Mode	String	No	Recreate	The stack recreation mode. Default value: Recreate. Valid values:
				• Recreate
				  ◦ Only the following types of resources are recreated:
				  ▪ Resources that fail to be created
				  ▪ Resources specified in the RecreatingResources.N parameter
				  ▪ Resources that depend on the resources specified in the RecreatingResources.N parameter
				  ▪ Resources for which creation operations are not initiated
				  ◦ The RecreatingResources.N, TemplateBody, TemplateURL, and Parameters parameters take effect only when the Mode parameter is set to Recreate.
				• Ignore:
				  ◦ ROS ignores and discards all resources that fail to be recreated and the resources for which creation operations are not initiated. Then, the stack creation operation is marked as successful.
				  ◦ Content of the template is changed.

Parameter	Type	Required	Example	Description

TemplateBody	String	No	{ "ROSTemplateFormatVersion": "2015-09-01" }	The structure that contains the template body. The template body must be 1 to 524,288 bytes in length.
				If the length of the template body is longer than required, we recommend that you add parameters to the HTTP POST request body to avoid request failures due to excessive length of URLs.
				Note You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.
				This parameter takes effect only when the Mode parameter is set to Recreate. Take note of the following limits on the template:
				• Only the Description, Metadata, Resources, and Outputs sections in the template can be modified.
				• No sections can be added to or removed from the outermost layer of the template.
				• Take note of the following limits on the Resources section of the template:
				  ◦ The resources not to be recreated cannot be deleted, and their template content cannot be modified.
				  ◦ The resources to be recreated can be deleted, and their template content can be modified.
				  ◦ New resources can be added.

Parameter	Type	Required	Example	Description
TemplateURL	String	No	oss://ros-template/demo	The URL of the file that contains the template body. The URL must point to a template located in an HTTP or HTTPS web server or an Object Storage Service (OSS) bucket. Examples: oss://ros/template/demo and oss://ros/template/demo?RegionId=cn-hangzhou.The template can be up to 524,288 bytes in length. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them. This parameter takes effect only when the Mode parameter is set to Recreate. For information about the limits on the template specified in this parameter, see the description of the TemplateBody parameter.
DryRun	Boolean	No	false	Specifies whether to check the validity of the request without actually making the request. Default value: false. Valid values: • true: checks the validity of the request without actually making the request. • false: makes the request to recreate the stack.

Response parameters

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6	The ID of the request.
StackId	String	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/?Action=ContinueCreateStack
&RegionId=cn-hangzhou
&StackId=4a6c9851-3b0f-4f5f-b4ca-a14bf691****
&<Common request parameters>
```

Sample success responses

`XML` format

```
<ContinueCreateStackResponse>
       <RequestId type="string">B288A0BE-D927-4888-B0F7-B35EF84B6E6F</RequestId>

HTTP status code	Error code	Error message	Description
400	CircularDependency	Circular Dependency Found: {reason}.	The error message returned because the template contains a circular reference. reason indicates the specific reason.
400	InvalidSchema	{reason}.	The error message returned because the specified template format is invalid. reason indicates the specific reason.
400	InvalidTemplateAttribute	The Referenced Attribute ({resource} {name}) is incorrect.	The error message returned because the resource attribute referenced in the template is invalid. resource indicates the resource name, and name indicates the attribute name.

HTTP status code	Error code	Error message	Description
400	InvalidTemplatePropertyType	The specified value type of ({resource} {section}) is incorrect.	The error message returned because the type of the specified resource section defined in the template is invalid. resource indicates the resource name, and section indicates the section name.
400	InvalidTemplateReference	The specified reference "{name}" (in {referencer}) is incorrect.	The error message returned because the template contains an invalid reference. name indicates the reference name, and referencer indicates the referencer name.
400	InvalidTemplateSection	The template section is invalid: {section}.	The error message returned because the template contains an invalid section. section indicates the section name.
400	InvalidTemplateVersion	The template version is invalid: {reason}.	The error message returned because the template version is invalid. reason indicates the specific reason.

HTTP status code	Error code	Error message	Description
400	StackValidationFailed	{reason}.	The error message returned because the stack validation failed. reason indicates the specific reason.
400	UnknownUserParameter	The Parameter ({name}) was not defined in template.	The error message returned because the specified parameter is not defined in the template. name indicates the parameter key.
400	UserParameterMissing	The Parameter {name} was not provided.	The error message returned because no value is passed into the specified parameter defined in the template. name indicates the parameter key.
400	ContinueCreateStackValidationFailed	{reason}.	The error message returned because the stack validation failed. reason indicates the specific reason.
404	ResourceNotFound	The Resource ({name}) could not be found in Stack {stack}.	The error message returned because the specified resource does not exist in the specified stack. name indicates the resource name, and stack indicates the stack name or ID.

HTTP status code	Error code	Error message	Description
404	StackNotFound	The Stack ({name}) could not be found.	The error message returned because the stack does not exist. name indicates the name or ID of the stack.
409	ActionInProgress	Stack {name} already has an action ({action}) in progress.	The error message returned because the specified stack has a change operation in progress. name indicates the name or ID of the stack, and action indicates the change operation.

5.1.1.7.3. UpdateStack

You can call this operation to update a stack.

The values of Parameters and UsePreviousParameters in the request are related. If parameters defined in the template are not specified by Parameters, take note of the following items:

- When UsePreviousParameters is set to false, if the parameter has a default value in the template, the default value is used. If the parameter does not have a default value in the template, you must specify the parameter in the Parameters section.
- When UsePreviousParameters is set to true, if the parameter is specified when the stack is created, the specified value is used. If the parameter is not specified and it has a default value in the template, the default value is used.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	UpdateStack	The operation that you want to perform. Set the value to UpdateStack.

Parameter	Type	Required	Example	Description
Parameters.N.ParameterKey	String	Yes	Amount	The key of parameter N. If the key and value of the parameter are not specified, the key and value in the template are used. Maximum value of N: 200. **Note** • Parameters is an optional parameter. • If you need to specify Parameters, you must specify both Parameters.N.ParameterKey and Parameters.N.ParameterValue.
Parameters.N.ParameterValue	String	Yes	12	The value of parameter N. Maximum value of N: 200. **Note** • Parameters is an optional parameter. • If you need to specify Parameters, you must specify both Parameters.N.ParameterKey and Parameters.N.ParameterValue.
RegionId	String	Yes	cn-beijing	The region ID of the stack.
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.

Parameter	Type	Required	Example	Description
ClientToken	String	No	123e4567-e89b-12d3-a456-42665544****	The client token that is used to ensure the idempotence of the request. You can use the client to generate the value, but you must make sure that it is unique among different requests. The token can be up to 64 characters in length and can contain letters, digits, hyphens (-), and underscores (_).
StackPolicyDuringUpdateBody	String	No	{"Statement": [{"Effect": "Allow", "Action": "Update:*", "Principal": "*", "Resource": "*"}]}	The structure that contains the body of the temporary overriding stack policy. The stack policy body must be 1 to 16,384 bytes in length. To update protected resources, specify a temporary overriding stack policy during the update. If you do not specify a stack policy, the current policy that is associated with the stack is used. This parameter takes effect only when the ChangeSetType parameter is set to UPDATE. You can specify only one of the following parameters: • StackPolicyBody • StackPolicyURL • StackPolicyDuringUpdateBody • StackPolicyDuringUpdateURL
TimeoutInMinutes	Long	No	10	The timeout period that is specified for the stack update request. • Default value: 60. • Unit: minutes.

Parameter	Type	Required	Example	Description
TemplateBody	String	No	{"ROSTemplateFormatVersion": "2015-09-01"}	The structure that contains the template body. The template body must be 1 to 524,288 bytes in length. If the length of the template body is longer than required, we recommend that you add parameters to the HTTP POST request body to avoid request failures due to excessive length of URLs. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.
StackPolicyURL	String	No	oss://ros-stack-policy/demo	The URL of the file that contains the stack policy. The URL must point to a policy located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/stack-policy/demo and oss://ros/stack-policy/demo?RegionId=cn-hangzhou. The policy can be up to 16,384 bytes in length and the URL can be up to 1,350 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You must specify one of the StackPolicyBody and StackPolicyURL parameters, but you cannot specify both of them.

Parameter	Type	Required	Example	Description
StackPolicyDuringUpdateURL	String	No	oss://ros-stack-policy/demo	The URL of the file that contains the temporary overriding stack policy. The URL must point to a policy located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/stack-policy/demo and oss://ros/stack-policy/demo?RegionId=cn-hangzhou. The policy can be up to 16,384 bytes in length and the URL can be up to 1,350 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You must specify one of the StackPolicyBody and StackPolicyURL parameters, but you cannot specify both of them. To update protected resources, specify a temporary overriding stack policy during the update. If you do not specify a stack policy, the current policy that is associated with the stack is used. This parameter takes effect only when the ChangeSetType parameter is set to UPDATE. You can specify only one of the following parameters: • StackPolicyBody • StackPolicyURL • StackPolicyDuringUpdateBody • StackPolicyDuringUpdateURL
StackPolicyBody	String	No	{"Statement": [{"Action": "Update:*", "Resource": "*", "Effect": "Allow", "Principal": "*"}]}	The structure that contains the stack policy body. The stack policy body must be 1 to 16,384 bytes in length. **Note** You must specify one of the StackPolicyBody and StackPolicyURL parameters, but you cannot specify both of them.

Parameter	Type	Required	Example	Description
UsePreviousParameters	Boolean	No	true	Specifies whether to use the values that were passed last time for the parameters that you do not specify in the current request. Valid values: • true • false
DisableRollback	Boolean	No	false	This parameter cannot take effect when the stack is being updated. If the update fails, a rollback is performed regardless of the value of this parameter.
TemplateURL	String	No	oss://ros-template/demo	The URL of the file that contains the template body. The URL must point to a template located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/template/demo and oss://ros/template/demo?RegionId=cn-hangzhou. The template must be 1 to 524,288 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.

Parameter	Type	Required	Example	Description
RamRoleName	String	No	test-role	The name of the RAM role. ROS assumes the specified RAM role to create the stack and call API operations by using the credentials of the role. All operations are performed under this role. If a RAM user is authorized to perform operations on the stack but does not have the permission to use the role, ROS still uses the role and grants the role the least privilege. If you do not specify this parameter, ROS uses the role previously associated with the stack. If no roles are available, ROS uses the temporary credentials generated from the credentials of your account. The RAM role name can be up to 64 characters in length.
ReplacementOption	String	No	Disabled	Specifies whether to enable replacement update after a resource attribute that does not support modification update is changed. Modification update keeps the physical ID of the resource unchanged. However, the resource is deleted and then recreated, and its physical ID is changed if replacement update is enabled. Default value: Disabled. Valid values: • Enable: enables replacement update. • Disabled: disables replacement update. Note Modification update takes precedence over replacement update.

Response parameters

Parameter	Type	Example	Description
StackId	String	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6F	The ID of the request.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=UpdateStack
&RegionId=cn-beijing
&StackId=4a6c9851-3b0f-4f5f-b4ca-a14bf691****
&Parameters.1.ParameterKey=Amount
&Parameters.1.ParameterValue=12
&<Common request parameters>
```

Sample success responses

`XML` format

```

</UpdateStackResponse>
```

`JSON` format

```
{
    "StackId": "4a6c9851-3b0f-4f5f-b4ca-a14bf691****",
    "RequestId": "B288A0BE-D927-4888-B0F7-B35EF84B6E6F"
}
```

HTTP status code	Error code	Error message	Description
400	CircularDependency	Circular Dependency Found: {reason}.	The error message returned because the template contains a circular dependency. reason indicates the specific reason.

HTTP status code	Error code	Error message	Description
400	InvalidSchema	{reason}.	The error message returned because the specified template format is incorrect. reason indicates the specific reason.
400	InvalidTemplateAttribute	The Referenced Attribute ({resource} {name}) is incorrect.	The error message returned because the resource attribute referenced in the template is incorrect. resource indicates the resource name, and name indicates the attribute name.
400	InvalidTemplatePropertyType	The specified value type of ({resource} {section}) is incorrect.	The error message returned because the type of the specified resource section defined in the template is incorrect. resource indicates the resource name, and section indicates the section name.
400	InvalidTemplateReference	The specified reference "{name}" (in {referencer}) is incorrect.	The error message returned because the template contains an invalid reference. name indicates the reference name, and referencer indicates the referencer name.
400	InvalidTemplateSection	The template section is invalid: {section}.	The error message returned because the template contains an invalid section. section indicates the section name.

HTTP status code	Error code	Error message	Description
400	InvalidTemplateVersion	The template version is invalid: {reason}.	The error message returned because the template version is incorrect. reason indicates the specific reason.
400	StackPolicyValidationFailed	Action denied by stack policy: {reason}.	The error message returned because the stack policy validation failed. reason indicates the specific reason.
400	StackValidationFailed	{reason}.	The error message returned because the stack validation failed. reason indicates the specific reason.
400	UnknownUserParameter	The Parameter ({name}) was not defined in template.	The error message returned because the specified parameter is not defined in the template. name indicates the parameter key.
400	UserParameterMissing	The Parameter {name} was not provided.	The error message returned because no value is passed into the specified parameter defined in the template. name indicates the parameter key.
404	StackNotFound	The Stack ({name}) could not be found.	The error message returned because the specified stack does not exist. name indicates the name or ID of the stack.

HTTP status code	Error code	Error message	Description
409	ActionInProgress	Stack {name} already has an action ({action}) in progress.	The error message returned because the specified stack has a change operation in progress. name indicates the name or ID of the stack, and action indicates the change operation.

5.1.1.7.4. CancelUpdateStack

Cancels the update of a stack.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	CancelUpdateStack	The operation that you want to perform. Set the value to CancelUpdateStack.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.
CancelType	String	No	Safe	The method to cancel the update operation. Valid values: • Quick: cancels the update of a stack as soon as possible. • Safe: cancels the update of a stack as safely as possible.

Response parameters

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6F	The ID of the request.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/?Action=CancelUpdateStack
&RegionId=cn-hangzhou
&StackId=4a6c9851-3b0f-4f5f-b4ca-a14bf691****
&<Common request parameters>
```

Sample success responses

`XML` format

```
<CancelUpdateStackResponse>
         <RequestId>B288A0BE-D927-4888-B0F7-B35EF84B6E6F</RequestId>
         <StackId>4a6c9851-3b0f-4f5f-b4ca-a14bf691****</StackId>
</CancelUpdateStackResponse>
```

`JSON` format

```
{
   "RequestId": "B288A0BE-D927-4888-B0F7-B35EF84B6E6F",
   "StackId": "4a6c9851-3b0f-4f5f-b4ca-a14bf691****"
}
```

HTTP status code	Error code	Error message	Description
404	StackNotFound	The Stack ({name}) could not be found.	The error message returned because the stack does not exist. name indicates the name or ID of the stack.
409	ActionInProgress	Stack {name} already has an action ({action}) in progress.	The error message returned because the specified stack has a change operation in progress. name indicates the name or ID of the stack, and action indicates the change operation.

5.1.1.7.5. GetStack

You can call this operation to query information about a stack.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	GetStack	The operation that you want to perform. Set the value to GetStack.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.
ClientToken	String	No	123e4567-e89b-12d3-a456-42665544****	The client token that is used to ensure the idempotence of the request. You can use the client to generate the value, but you must make sure that it is unique among different requests. The token can be up to 64 characters in length and can contain letters, digits, hyphens (-), and underscores (_).

Response parameters

Parameter	Type	Example	Description
CreateTime	String	2019-08-01T04:07:39	The time when the stack was created. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ss format. The time is displayed in UTC.
Description	String	my stack description	The description of the stack.
DisableRollback	Boolean	false	Indicates whether rollback is disabled on stack creation failure. Default value: false. Valid values: • true: The rollback on stack creation failure is disabled. • false: The rollback on stack creation failure is enabled.
NotificationURLs	List	["http://127.XX.XX.1:8080/x", "http://127.0.XX.XX:8080/y"]	The callback URLs for receiving stack events.

Parameter	Type	Example	Description
Outputs	List	[{"Description": "Instance ID","OutputKey": "InstanceId","OutputValue": "i-a****"}]	The output parameters of the stack.
Parameters	Array of Parameter		The list of input parameters of the stack.
ParameterKey	String	InstanceType	The key of the parameter.
ParameterValue	String	ecs.cm4.6xlarge	The value of the parameter.
ParentStackId	String	4a6c9851-3b0f-4f5f-b4ca-a14bf692****	The ID of the parent stack.
RegionId	String	cn-beijing	The region ID of the stack.

Parameter	Type	Example	Description
Status	String	CREATE_COMPLETE	The state of the stack. Valid values: • CREATE_IN_PROGRESS • CREATE_FAILED • CREATE_COMPLETE • UPDATE_IN_PROGRESS • UPDATE_FAILED • UPDATE_COMPLETE • DELETE_IN_PROGRESS • DELETE_FAILED • DELETE_COMPLETE • CREATE_ROLLBACK_IN_PROGRESS • CREATE_ROLLBACK_FAILED • CREATE_ROLLBACK_COMPLETE • ROLLBACK_IN_PROGRESS • ROLLBACK_FAILED • ROLLBACK_COMPLETE • CHECK_IN_PROGRESS • CHECK_FAILED • CHECK_COMPLETE • REVIEW_IN_PROGRESS • IMPORT_CREATE_IN_PROGRESS • IMPORT_CREATE_FAILED • IMPORT_CREATE_COMPLETE • IMPORT_CREATE_ROLLBACK_IN_PROGRESS • IMPORT_CREATE_ROLLBACK_FAILED • IMPORT_CREATE_ROLLBACK_COMPLETE • IMPORT_UPDATE_IN_PROGRESS • IMPORT_UPDATE_FAILED • IMPORT_UPDATE_COMPLETE • IMPORT_UPDATE_ROLLBACK_IN_PROGRESS • IMPORT_UPDATE_ROLLBACK_FAILED • IMPORT_UPDATE_ROLLBACK_COMPLETE
StackId	String	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.

Parameter	Type	Example	Description
StackName	String	MyStack	The name of the stack. The name can be up to 255 characters in length and can contain digits, letters, hyphens (-), and underscores (_). It must start with a digit or letter.
UpdateTime	String	2019-08-01T04:07:39	The time when the stack was last updated. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ss format. The time is displayed in UTC.
StatusReason	String	Stack successfully created	The reason why the stack is in its current state.
TemplateDescription	String	Some description	The description of the stack.
TimeoutInMinutes	Integer	10	The timeout period that is specified for the stack creation request. Unit: minutes.
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6F	The ID of the request.
DeletionProtection	String	Enabled	Indicates whether deletion protection is enabled on the stack. Valid values: • Enabled: Deletion protection is enabled on the stack. • Disabled: Deletion protection is disabled on the stack. You can release the stack by using the ROS console or by calling the DeleteStack operation. **Note** The deletion protection property of a nested stack is the same as that of its root stack.

Parameter	Type	Example	Description
DriftDetectionTime	String	2020-02-27T07:47:47	The time when the last successful drift detection operation was initiated.
RamRoleName	String	test-role	The name of the RAM role. ROS assumes the specified RAM role to create the stack and call API operations by using the credentials of the role. All operations are performed under this role. If a RAM user is authorized to perform operations on the stack but does not have the permission to use the role, ROS still uses the role and grants the role the least privilege. If you do not specify this parameter, ROS uses the role previously associated with the stack. If no roles are available, ROS uses the temporary credentials generated from the credentials of your account. The RAM role name can be up to 64 characters in length.
RootStackId	String	4a6c9851-3b0f-4f5f-b4ca-a14bf692****	The ID of the root stack. This parameter is returned if the specified stack is a nested stack.
StackDriftStatus	String	IN_SYNC	The drift state of the stack in the last successful drift detection. Valid values: • DRIFTED: The stack has drifted. • NOT_CHECKED: No drift detection has been successful on the stack group. • IN_SYNC: The stack is being synchronized.
StackType	String	ROS	The type of the stack. Valid values: • ROS: The stack was created based on an ROS template. • Terraform: The stack was created based on a Terraform template.

Examples

HTTP status code	Error code	Error message	Description
404	StackNotFound	The Stack ({name}) could not be found.	The error message returned because the specified stack does not exist. name indicates the name or ID of the stack.

5.1.1.7.6. DeleteStack

You can call this operation to delete a stack and all of its resources.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	DeleteStack	The operation that you want to perform. Set the value to DeleteStack.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.
RetainAllResources	Boolean	No	false	Specifies whether to retain the resources in the stack.
RetainResources.N	RepeatList	No	WebServer	The list of resources to retain.
RamRoleName	String	No	test-role	The name of the RAM role. ROS assumes the specified RAM role to create the stack and call API operations by using the credentials of the role. All operations are performed under this role. If a RAM user is authorized to perform operations on the stack but does not have the permission to use the role, ROS still uses the role and grants the role the least privilege. If you do not specify this parameter, ROS does not use the role previously associated with the stack. If you want to use a role, you must specify it in this parameter. If no roles are available, ROS uses the temporary credentials generated from the credentials of your account. The RAM role name can be up to 64 characters in length.

Response parameters

Parameter	Type	Example	Description

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6F	The ID of the request.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=DeleteStack
&RegionId=cn-hangzhou
&StackId=4a6c9851-3b0f-4f5f-b4ca-a14bf691****
&<Common request parameters>
```

Sample success responses

`XML` format

```
<DeleteStackResponse>
      <RequestId>B288A0BE-D927-4888-B0F7-B35EF84B6E6F</RequestId>
</DeleteStackResponse>
```

`JSON` format

```
{
  "RequestId": "B288A0BE-D927-4888-B0F7-B35EF84B6E6F"
}
```

HTTP status code	Error code	Error message	Description
400	InvalidOperation.DeletionProtection	Fail to delete stack {ID}, as deletion protection is enabled.	The error message returned because deletion protection prevented the stack from being deleted. ID indicates the stack ID.
404	StackNotFound	The Stack ({name}) could not be found.	The error message returned because the specified stack does not exist. name indicates the name or ID of the stack.

HTTP status code	Error code	Error message	Description
409	ActionInProgress	Stack {name} already has an action ({action}) in progress.	The error message returned because the specified stack has a change operation in progress. name indicates the name or ID of the stack, and action indicates the change operation.

5.1.1.7.7. ListStacks

Queries the list of stacks.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ListStacks	The operation that you want to perform. Set the value to ListStacks.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.

Parameter	Type	Required	Example	Description
Status.N	RepeatList	No	CREATE_COMPLETE	The status of stack N. Valid values: • CREATE_IN_PROGRESS • CREATE_FAILED • CREATE_COMPLETE • UPDATE_IN_PROGRESS • UPDATE_FAILED • UPDATE_COMPLETE • DELETE_IN_PROGRESS • DELETE_FAILED • DELETE_COMPLETE • CREATE_ROLLBACK_IN_PROGRESS • CREATE_ROLLBACK_FAILED • CREATE_ROLLBACK_COMPLETE • ROLLBACK_IN_PROGRESS • ROLLBACK_FAILED • ROLLBACK_COMPLETE • CHECK_IN_PROGRESS • CHECK_FAILED • CHECK_COMPLETE • REVIEW_IN_PROGRESS • IMPORT_CREATE_IN_PROGRESS • IMPORT_CREATE_FAILED • IMPORT_CREATE_COMPLETE • IMPORT_CREATE_ROLLBACK_IN_PROGRESS • IMPORT_CREATE_ROLLBACK_FAILED • IMPORT_CREATE_ROLLBACK_COMPLETE • IMPORT_UPDATE_IN_PROGRESS • IMPORT_UPDATE_FAILED • IMPORT_UPDATE_COMPLETE • IMPORT_UPDATE_ROLLBACK_IN_PROGRESS • IMPORT_UPDATE_ROLLBACK_FAILED • IMPORT_UPDATE_ROLLBACK_COMPLETE Valid values of N: 1 to 5.

Parameter	Type	Required	Example	Description
PageSize	Long	No	10	The number of entries to return on each page. Maximum value: 50. Default value: 10.
ParentStackId	String	No	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the parent stack.
StackName.N	RepeatList	No	MyStack	The name of stack N. The name can be up to 255 characters in length and can contain digits, letters, hyphens (-), and underscores (_). It must start with a digit or letter. Fuzzy search with an asterisk (*) is supported. Valid values of N: 1 to 5.
PageNumber	Long	No	1	The number of the page to return. Pages start from page 1. Default value: 1.
ShowNestedStack	Boolean	No	true	Specifies whether to display nested stacks. Default value: false. Valid values: • true • false Note This parameter is set to true if the ParentStackId parameter is specified.
Tag.N.Key	String	No	usage	The key of tag N of the stack. Valid values of N: 1 to 20.
Tag.N.Value	String	No	test	The value of tag N of the stack. Valid values of N: 1 to 20.

Parameter	Type	Required	Example	Description
StackId	String	No	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack. If detailed information about the stack is not required, you can use this parameter to replace the GetStack operation.

Response parameters

Parameter	Type	Example	Description
Stacks	Array of Stack		The list of stacks.
CreateTime	String	2019-08-01T04:07:39	The time when the stack was created. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ss format. The time is displayed in UTC.
DisableRollback	Boolean	false	Indicates whether rollback is disabled when the stack fails to be created. Default value: false. Valid values: • true: Rollback is disabled when the stack fails to be created. • false: Rollback is enabled when the stack fails to be created.
DriftDetectionTime	String	2020-02-27T07:47:47	The time when the latest successful drift detection operation was initiated.
ParentStackId	String	4a6c9851-3b0f-4f5f-b4ca-a14bf692****	The ID of the parent stack.
RegionId	String	cn-hangzhou	The region ID of the stack.
StackDriftStatus	String	IN_SYNC	The drift status of the stack in the latest successful drift detection. Valid values: • DRIFTED: The stack has drifted. • NOT_CHECKED: No drift detection has been performed on the stack. • IN_SYNC: The stack is being synchronized.
StackId	String	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.

Parameter	Type	Example	Description
StackName	String	MyStack	The name of the stack.
StackType	String	ROS	The type of the stack. Set the value to ROS, which indicates that the stack was created based on an ROS template.
Status	String	CREATE_COMPLETE	The status of the stack. Valid values: • CREATE_IN_PROGRESS • CREATE_FAILED • CREATE_COMPLETE • UPDATE_IN_PROGRESS • UPDATE_FAILED • UPDATE_COMPLETE • DELETE_IN_PROGRESS • DELETE_FAILED • DELETE_COMPLETE • CREATE_ROLLBACK_IN_PROGRESS • CREATE_ROLLBACK_FAILED • CREATE_ROLLBACK_COMPLETE • ROLLBACK_IN_PROGRESS • ROLLBACK_FAILED • ROLLBACK_COMPLETE • CHECK_IN_PROGRESS • CHECK_FAILED • CHECK_COMPLETE • REVIEW_IN_PROGRESS • IMPORT_CREATE_IN_PROGRESS • IMPORT_CREATE_FAILED • IMPORT_CREATE_COMPLETE • IMPORT_CREATE_ROLLBACK_IN_PROGRESS • IMPORT_CREATE_ROLLBACK_FAILED • IMPORT_CREATE_ROLLBACK_COMPLETE • IMPORT_UPDATE_IN_PROGRESS • IMPORT_UPDATE_FAILED • IMPORT_UPDATE_COMPLETE • IMPORT_UPDATE_ROLLBACK_IN_PROGRESS • IMPORT_UPDATE_ROLLBACK_FAILED • IMPORT_UPDATE_ROLLBACK_COMPLETE

Parameter	Type	Example	Description
StatusReason	String	Stack successfully created	The reason why the stack is in its current state.
TimeoutInMinutes	Integer	10	The timeout period that is specified for the stack creation request. Unit: minutes.
UpdateTime	String	2019-08-01T04:07:39	The time when the stack was last updated. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ss format. The time is displayed in UTC.
PageSize	Integer	10	The number of entries returned per page. Maximum value: 50. Default value: 10.
PageNumber	Integer	1	The page number of the returned page.
TotalCount	Integer	1	The total number of stacks.
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6F	The ID of the request.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/?Action=ListStacks
&RegionId=cn-hangzhou
&<Common request parameters>
```

Sample success responses

`XML` format

```
<ListStacksResponse>
    <Stacks>
        <Stack>
            <StackId>4a6c9851-3b0f-4f5f-b4ca-a14bf691****</StackId>
            <ParentStackId>4a6c9851-3b0f-4f5f-b4ca-a14bf692****</ParentStackId>

```

5.1.1.7.8. PreviewStack

You can call this operation to preview the stack to be created by using a specified template.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	PreviewStack	The operation that you want to perform. Set the value to PreviewStack.
Parameters.N.ParameterKey	String	Yes	InstanceType	The key of parameter N. If the key and value of the parameter are not specified, the key and value in the template are used. Maximum value of N: 200. **Note** • Parameters is an optional parameter. • If you need to specify Parameters, you must specify both Parameters.N.ParameterKey and Parameters.N.ParameterValue.
Parameters.N.ParameterValue	String	Yes	ecs.cm4.6xlarge	The value of parameter N. Maximum value of N: 200. **Note** • Parameters is an optional parameter. • If you need to specify Parameters, you must specify both Parameters.N.ParameterKey and Parameters.N.ParameterValue.
RegionId	String	Yes	cn-beijing	The region ID of the stack.

Parameter	Type	Required	Example	Description
StackName	String	Yes	MyStack	The name of the stack. The name can be up to 255 characters in length and can contain digits, letters, hyphens (-), and underscores (_). It must start with a digit or letter.
DisableRollback	Boolean	No	false	Specifies whether to disable rollback on stack creation failure. Default value: false. Valid values: • true: disables rollback on stack creation failure. • false: enables rollback on stack creation failure.
TimeoutInMinutes	Long	No	10	The timeout period that is specified for the stack creation request. Unit: minutes. Default value: 60.
TemplateBody	String	No	{"ROSTemplateFormatVersion": "2015-09-01" }	The structure that contains the template body. The template body must be 1 to 524,288 bytes in length. If the length of the template body is longer than required, we recommend that you add parameters to the HTTP POST request body to avoid request failures due to excessive length of URLs. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.

Parameter	Type	Required	Example	Description
StackPolicyURL	String	No	oss://ros-stack-policy/demo	The URL of the file that contains the stack policy. The URL must point to a policy located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/stack-policy/demo and oss://ros/stack-policy/demo?RegionId=cn-hangzhou. The policy can be up to 16,384 bytes in length and the URL can be up to 1,350 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You must specify one of the StackPolicyBody and StackPolicyURL parameters, but you cannot specify both of them.
StackPolicyBody	String	No	{"Statement": [{"Action": "Update:*", "Resource": "*", "Effect": "Allow", "Principal": "*"}]}	The structure that contains the stack policy body. The stack policy body must be 1 to 16,384 bytes in length. **Note** You must specify one of the StackPolicyBody and StackPolicyURL parameters, but you cannot specify both of them.
ClientToken	String	No	123e4567-e89b-12d3-a456-42665544****	The client token that is used to ensure the idempotence of the request. You can use the client to generate the value, but you must make sure that it is unique among different requests. The token can be up to 64 characters in length and can contain letters, digits, hyphens (-), and underscores (_).

Parameter	Type	Required	Example	Description
TemplateURL	String	No	oss://ros-template/demo	The URL of the file that contains the template body. The URL must point to a template located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/template/demo and oss://ros/template/demo?RegionId=cn-hangzhou. The template must be 1 to 524,288 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.

Response parameters

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6F	The ID of the request.
Stack	Struct		Details about the stack.
Description	String	One ECS instance.	The description of the stack.
DisableRollback	Boolean	false	Indicates whether rollback is disabled.
Parameters	Array of Parameter		The parameters of the stack.
ParameterKey	String	SystemDiskCategory	The key of the parameter.
ParameterValue	String	cloud_ssd	The value of the parameter.
RegionId	String	cn-beijing	The region ID of the stack.
Resources	Array of Resource		The list of resources in the stack.

Parameter	Type	Example	Description
Description	String	ECS instance.	The description of the resource.
LogicalResourceId	String	WebServer	The logical resource ID.
Properties	Map	{ "DiskMappings": [{ "Category": "cloud_ssd", "Size": "20" }], "SystemDisk_Category": "cloud_ssd", "InstanceChargeType": "PostPaid", "AutoRenew": "False", "WillReplace": true, "ImageId": "centos_7", "InstanceType": "ecs.g6.large", "AllocatePublicIP": true, "AutoRenewPeriod": 1, "IoOptimized": "optimized", "ZoneId": "cn-beijing-g", "VSwitchId": "", "SecurityGroupId": "", "Period": 1, "InternetChargeType": "PayByTraffic", "SystemDiskCategory": "cloud_efficiency", "InternetMaxBandwidthOut": 1, "VpcId": "", "InternetMaxBandwidthIn": 200, "PeriodUnit": "Month" }	The properties of the resource.
RequiredBy	List	["Resource1", "Resource2"]	The list of one or more resources that are dependent on the stack.
ResourceType	String	ALIYUN::ECS::Instance	The type of the resource.

Parameter	Type	Example	Description
Stack	Map	{}	Details about the nested stacks. The data structure of this parameter is the same as that of the entire responses.
StackName	String	MyStack	The name of the stack.
StackPolicyBody	Map	{ "Statement": [{ "Action": "Update:*", "Resource": "*", "Effect": "Allow", "Principal": "*" }, { "Action": "Update:*", "Resource": "LogicalResourceId/apple1", "Effect": "Deny", "Principal": "*" }] }	The stack policy.
TemplateDescription	String	One ECS instance.	The description of the template.
TimeoutInMinutes	Integer	10	The timeout period. Unit: minutes.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=PreviewStack
&RegionId=cn-beijing
&Parameters.1.ParameterValue=ecs.cm4.6xlarge
&Parameters.1.ParameterKey=InstanceType
&StackName=MyStack
&TimeoutInMinutes=10
&<Common request parameters>
```

Sample success responses

`XML` format

```
<PreviewStackResponse>
          <Stack>
                <Description>No description</Description>
                <DisableRollback>true</DisableRollback>
                <Parameters>
                      <ParameterKey>UpdateVersion</ParameterKey>
                      <ParameterValue>1</ParameterValue>
```

```
                </Parameters>
                <RegionId>cn-beijing</RegionId>
                <Resources>

HTTP status code	Error code	Error message	Description
400	CircularDependency	Circular Dependency Found: {reason}.	The error message returned because the template contains a circular dependency. reason indicates the specific reason.
400	InvalidSchema	{reason}.	The error message returned because the specified template format is invalid. reason indicates the specific reason.
400	InvalidTemplateAttribute	The Referenced Attribute ({resource} {name}) is incorrect.	The error message returned because the resource attribute referenced in the template is incorrect. resource indicates the resource name, and name indicates the attribute name.
400	InvalidTemplatePropertyType	The specified value type of ({resource} {section}) is incorrect.	The error message returned because the type of the specified resource section defined in the template is incorrect. resource indicates the resource name, and section indicates the section name.

HTTP status code	Error code	Error message	Description
400	InvalidTemplateReference	The specified reference "{name}" (in {referencer}) is incorrect.	The error message returned because the template contains an invalid reference. name indicates the reference name, and referencer indicates the referencer name.
400	InvalidTemplateSection	The template section is invalid: {section}.	The error message returned because the template contains an invalid property. section indicates the section name.
400	InvalidTemplateVersion	The template version is invalid: {reason}.	The error message returned because the template version is incorrect. reason indicates the specific reason.
400	StackValidationFailed	{reason}.	The error message returned because the stack validation failed. reason indicates the specific reason.
400	UnknownUserParameter	The Parameter ({name}) was not defined in template.	The error message returned because the specified parameter is not defined in the template. name indicates the parameter key.

HTTP status code	Error code	Error message	Description
400	UserParameterMissing	The Parameter {name} was not provided.	The error message returned because no value is passed into the specified parameter defined in the template. name indicates the parameter key.
409	StackExists	The Stack ({name}) already exists.	The error message returned because a stack with the same name already exists. name indicates the stack name.

5.1.1.7.9. ListStackEvents

You can call this operation to query stacks and their resource events.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ListStackEvents	The operation that you want to perform. Set the value to ListStackEvents.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.

Parameter	Type	Required	Example	Description
Status.N	RepeatList	No	CREATE_IN_PROGRESS	The state of resource N. Valid values: • CREATE_COMPLETE • CREATE_FAILED • CREATE_IN_PROGRESS • UPDATE_IN_PROGRESS • UPDATE_FAILED • UPDATE_COMPLETE • UPDATE_SKIPPED • DELETE_IN_PROGRESS • DELETE_FAILED • CHECK_IN_PROGRESS • CHECK_FAILED • CHECK_COMPLETE • IMPORT_IN_PROGRESS • IMPORT_FAILED • IMPORT_COMPLETE
ResourceType.N	RepeatList	No	ALIYUN::ECS::Instance	The type of resource N. Maximum value of N: 200.
LogicalResourceId.N	RepeatList	No	WebServer	The logical ID of the resource as defined in the template.
PageNumber	Long	No	1	The number of the page to return. Pages start from page 1. Default value: 1.
PageSize	Long	No	10	The number of entries to return on each page. Maximum value: 50. Default value: 10.

Response parameters

Parameter	Type	Example	Description
Events	Array of Event		The list of events.

Parameter	Type	Example	Description
CreateTime	String	2019-08-01T04:07:39	The time when the task was created. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ss format. The time is displayed in UTC.
EventId	String	0086612d-77cf-4056-b0b5-ff8e94ad****	The ID of the event.
LogicalResourceId	String	WebServer	The logical ID of the resource as defined in the template.
PhysicalResourceId	String	i-m5e3tfdbinchnexh****	The physical ID of the resource.
ResourceType	String	ALIYUN::ECS::Instance	The type of the resource.
StackId	String	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.
StackName	String	StackName	The name of the stack.
Status	String	CREATE_COMPLETE	The state of the resource.
StatusReason	String	state changed	The reason why the resource is in its current state.
PageNumber	Integer	1	The page number of the returned page. Pages start from page 1. Default value: 1.
PageSize	Integer	10	The number of entries returned per page. Maximum value: 50. Default value: 10.
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6	The ID of the request.
TotalCount	Integer	20	The total number of returned events.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=ListStackEvents
&RegionId=cn-hangzhou
&StackId=4a6c9851-3b0f-4f5f-b4ca-a14bf691****
&<Common request parameters>
```

Sample success responses

HTTP status code	Error code	Error message	Description
404	StackNotFound	The Stack ({name}) could not be found.	The error message returned because the specified stack does not exist. name indicates the name or ID of the stack.

5.1.1.8. Resource operations

5.1.1.8.1. GetResourceTypeTemplate

You can call this operation to query the template of a resource by resource type.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	GetResourceTypeTemplate	The operation that you want to perform. Set the value to GetResourceTypeTemplate.
ResourceType	String	Yes	ALIYUN::ECS::VPC	The type of the resource.

Response parameters

Parameter	Type	Example	Description
RequestId	String	87F54B2B-AEF0-4C33-A72A-3F8856A575E9	The ID of the request.
TemplateBody	Map	{"ROSTemplateFormatVersion": "2015-09-01"}	The structure that contains the template body. The template body must be 1 to 51,200 bytes in length.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=GetResourceTypeTemplate
&ResourceType=ALIYUN::ECS::VPC
&<Common request parameters>
```

Sample success responses

`XML` format

```
<GetResourceTypeTemplateResponse>
	<RequestId type="string">87F54B2B-AEF0-4C33-A72A-3F8856A575E9</RequestId>
	<TemplateBody class="object">
		<Parameters class="object">
			<CidrBlock class="object">
				<Type type="string">String</Type>
			</CidrBlock>

        },
        "Type": "ALIYUN::ECS::VPC"
      }
    }
  }
}
```

HTTP status code	Error code	Error message	Description
404	ResourceTypeNotFound	The Resource Type ({name}) could not be found.	The error message returned because the specified resource type does not exist. name indicates the name of the resource type.

5.1.1.8.2. ListStackResources

You can call this operation to query the resource list of a specific stack.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ListStackResources	The operation that you want to perform. Set the value to ListStackResources.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.

Response parameters

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6	The ID of the request.
Resources	Array of Resource		The list of resources.
CreateTime	String	2019-08-01T06:01:23	The time when the resource was created. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format. The time is displayed in UTC.
DriftDetectionTime	String	2020-02-27T07:47:47	The time when the last successful drift detection operation was initiated.
LogicalResourceId	String	dummy	The logical resource ID defined in the template.
PhysicalResourceId	String	d04af923-e6b7-4272-aeaa-47ec9777****	The physical ID of the resource.

Parameter	Type	Example	Description
ResourceDriftStatus	String	IN_SYNC	The drift state of the resource in the last successful drift detection. Valid values: • DELETED: The actual configuration of the resource differs from its expected template configuration because the resource has been deleted. • MODIFIED: The actual configuration of the resource differs from its expected template configuration. • NOT_CHECKED: ROS has not checked whether the actual configuration of the resource differs from its expected template configuration. • IN_SYNC: The actual configuration of the resource matches its expected template configuration.
ResourceType	String	ALIYUN::ROS::Stack	The type of the resource.
StackId	String	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.
StackName	String	test-describe-resource	The name of the stack. The name can be up to 255 characters in length and can contain digits, letters, hyphens (-), and underscores (_). It must start with a digit or letter.

Parameter	Type	Example	Description
Status	String	UPDATE_COMPLETE	The state of the resource. Valid values: • CREATE_COMPLETE • CREATE_FAILED • CREATE_IN_PROGRESS • UPDATE_IN_PROGRESS • UPDATE_FAILED • UPDATE_COMPLETE • DELETE_IN_PROGRESS • DELETE_FAILED • DELETE_COMPLETE • CHECK_IN_PROGRESS • CHECK_FAILED • CHECK_COMPLETE • IMPORT_IN_PROGRESS • IMPORT_FAILED • IMPORT_COMPLETE
StatusReason	String	state changed	The reason why the resource is in its current state.
UpdateTime	String	2019-08-01T06:01:29	The time when the resource was last updated. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format. The time is displayed in UTC.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=ListStackResources
&RegionId=cn-hangzhou
&StackId=4a6c9851-3b0f-4f5f-b4ca-a14bf691****
&<Common request parameters>
```

Sample success responses

`XML` format

```
<ListStackResourcesResponse>

Error code	Error message	HTTP status code	Description
StackNotFound	The Stack ({name}) could not be found.	404	The error message returned because the specified stack does not exist. name indicates the name or ID of the stack.

5.1.1.8.3. GetStackResource

You can call this operation to query information about a resource in a specific stack.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	GetStackResource	The operation that you want to perform. Set the value to GetStackResource.
LogicalResourceId	String	Yes	WebServer	The logical ID of the resource as defined in the template.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.
ClientToken	String	No	123e4567-e89b-12d3-a456-42665544****	The client token that is used to ensure the idempotence of the request. You can use the client to generate the value, but you must make sure that it is unique among different requests. The token can be up to 64 characters in length and can contain letters, digits, hyphens (-), and underscores (_).

Parameter	Type	Required	Example	Description
ShowResourceAttributes	Boolean	No	true	Specifies whether to query resource attributes. Valid values: • true • false

Response parameters

Parameter	Type	Example	Description
Status	String	CREATE_COMPLETE	The state of the resource. Valid values: • CREATE_COMPLETE • CREATE_FAILED • CREATE_IN_PROGRESS • UPDATE_IN_PROGRESS • UPDATE_FAILED • UPDATE_COMPLETE • DELETE_IN_PROGRESS • DELETE_FAILED • CHECK_IN_PROGRESS • CHECK_FAILED • CHECK_COMPLETE • IMPORT_IN_PROGRESS • IMPORT_FAILED • IMPORT_COMPLETE
Description	String	no description	The description of the resource.
LogicalResourceId	String	WebServer	The logical ID of the resource as defined in the template.
StackId	String	efdf5c10-96a5-4fd7-ab89-68e7baa2****	The ID of the stack.
StackName	String	test-describe-resource	The name of the stack. The name can be up to 255 characters in length and can contain digits, letters, hyphens (-), and underscores (_). It must start with a digit or letter.

Parameter	Type	Example	Description
StatusReason	String	state changed	The reason why the resource is in its current state.
PhysicalResourceId	String	d04af923-e6b7-4272-aeaa-47ec9777****	The physical ID of the resource.
ResourceType	String	ALIYUN::ROS::WaitConditionHandle	The type of the resource.
CreateTime	String	2019-08-01T06:01:23	The time when the stack was created. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ss format. The time is displayed in UTC.
Metadata	Map	{"key": "value"}	The metadata.
UpdateTime	String	2019-08-01T06:01:29	The time when the stack was last updated. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ss format. The time is displayed in UTC.

Parameter	Type	Example	Description
ResourceAttributes	List	[{ "ResourceAttributeValue":"curl -Uri \"http://100.100.XX.XX/waitcondition?stackname=test-describe-resource&stackid=efdf5c10-96a5-4fd7-ab89-68e7baa2****&resource=WaitConditionHandle&expire=156468****&signature=991d910a901a89db6580d74233119960c004****\" -Method Post -Headers @{\"Content-Type\"=\"application/json\"; \"Accept\"=\"application/json\"; \"x-acs-region-id\"=\"cn-beijing\"}", "ResourceAttributeKey":"PowerShellCurlCli" }]	The list of resource attributes.
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6	The ID of the request.
DriftDetectionTime	String	2020-02-27T07:47:47	The time when the last successful drift detection operation was initiated.

Parameter	Type	Example	Description
ResourceDriftStatus	String	IN_SYNC	The drift state of the resource in the last successful drift detection. Valid values: • DELETED: The actual configuration of the resource differs from its expected template configuration because the resource had been deleted. • MODIFIED: The actual configuration of the resource differs from its expected template configuration. • NOT_CHECKED: ROS has not checked whether the actual configuration of the resource differs from its expected template configuration. • IN_SYNC: The actual configuration of the resource matches its expected template configuration.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=GetStackResource

HTTP status code	Error code	Error message	Description

HTTP status code	Error code	Error message	Description
404	ResourceNotFound	The Resource ({name}) could not be found in Stack {stack}.	The error message returned because the specified resource does not exist in the stack. name indicates the resource name, and stack indicates the name or ID of the stack.
404	StackNotFound	The Stack ({name}) could not be found.	The error message returned because the specified stack does not exist. name indicates the name or ID of the stack.

5.1.1.8.4. GetResourceType

You can call this operation to query details about resource types.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	GetResourceType	The operation that you want to perform. Set the value to GetResourceType.
ResourceType	String	Yes	ALIYUN::ROS::WaitConditionHandle	The type of the resource.

Response parameters

Parameter	Type	Example	Description
Attributes	Map	{"CurlCli": {},"PowerShellCurlCli": {},"WindowsCurlCli": {}}	The attributes of the resource.
Properties	Map	{"Count": {},"Mode": {"Constraints": []}}	The properties of the resource.

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6	The ID of the request.
ResourceType	String	ALIYUN::ROS::WaitConditionHandle	The type of the resource.
SupportDriftDetection	Boolean	false	Indicates whether the resource supports drift detection. Valid values: • true: The resource supports drift detection. • false: The resource does not support drift detection.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=GetResourceType
&ResourceType=ALIYUN::SLB::LoadBalancer
&<Common request parameters>
```

Sample success responses

`XML` format

```
<GetResourceTypeResponse>
       <Attributes class="object">
              <CurlCli class="object">
                     <Description type="string">Convenience attribute, provides curl CLI command prefix, which can be used for signalling handle completion or failure. HTTP status code	Error code	Error message	Description
404	ResourceTypeNotFound	The Resource Type ({name}) could not be found.	The error message returned because the specified resource type does not exist. name indicates the name of the resource type.

5.1.1.8.5. ListResourceTypes

Queries the list of supported resource types.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ListResourceTypes	The operation that you want to perform. Set the value to ListResourceTypes.

Response parameters

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6	The ID of the request.
ResourceTypes	List	["ALIYUN::ECS::Instance","ALIYUN::RDS::Instance"]	The array of resource types.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/?Action=ListResourceTypes
&<Common request parameters>
```

Sample success responses

`XML` format

```

5.1.1.9. Template operations

5.1.1.9.1. GetTemplateEstimateCost

You can call this operation to query estimated prices of resources to be created based on a template.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	GetTemplateEstimateCost	The operation that you want to perform. Set the value to GetTemplateEstimateCost.
Parameters.N.ParameterKey	String	Yes	InstanceId	The key of parameter N. If the key and value of the parameter are not specified, the key and value specified in the template are used. Maximum value of N: 200. **Note** • Parameters is an optional parameter. • If you need to specify Parameters, you must specify both Parameters.N.ParameterKey and Parameters.N.ParameterValue.
Parameters.N.ParameterValue	String	Yes	i-m5e3tfdbinchnexh****	The value of parameter N. Maximum value of N: 200. **Note** • Parameters is an optional parameter. • If you need to specify Parameters, you must specify both Parameters.N.ParameterKey and Parameters.N.ParameterValue.
RegionId	String	Yes	cn-beijing	The region ID of the stack.

Parameter	Type	Required	Example	Description
TemplateURL	String	No	oss://ros-template/demo	The URL of the file that contains the template body. The URL must point to a template located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/template/demo and oss://ros/template/demo?RegionId=cn-hangzhou. The template can be up to 524,288 bytes in length, and the URL can be up to 1,024 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.
TemplateBody	String	No	{"ROSTemplateFormatVersion": "2015-09-01"}	The structure that contains the template body. The template body must be 1 to 524,288 bytes in length. If the length of the template body is longer than required, we recommend that you add parameters to the HTTP POST request body to avoid request failures due to excessive length of URLs. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.
ClientToken	String	No	123e4567-e89b-12d3-a456-42665544****	The client token that is used to ensure the idempotence of the request. You can use the client to generate the value, but you must make sure that it is unique among different requests. The token can be up to 64 characters in length and can contain letters, digits, hyphens (-), and underscores (_).

Response parameters

Parameter	Type	Example	Description
Resources	Map	The parameters in the Resources section	The details about resources.
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6F	The ID of the request.

The following table describes the parameters in the Resources section.

Parameter	Type	Example	Description
Order			Details about the order.
Currency	String	CNY	The currency unit.
DiscountAmount	Long	100	The discount.
HandlingFeeAmount	Long	0	The service fee.
OptionalMixPromotions	Array	[]	The available mixed discounts.
OptionalPromotions	Array	[]	The available discounts.
OrderLines	String		The order information.
OriginalAmount	Long	200	The original price of the service.
RiCycleAmount	Long	0	The deducted amount of money.
RuleIds	Array	[100000****]	The list of one or more IDs of the discount rules.
TaxAmount	Long	0	The amount of tax.

Parameter	Type	Example	Description
TradeAmount	Long	100	The final price after the discount.
Rules			Details about the discount rules.
Name	String	Get 15% off a 1-year subscription	The name of the discount rule.
RuleDescId	Long	100000****	The ID of the discount rule.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=GetTemplateEstimateCost
&RegionId=cn-beijing
&Parameters.1.ParameterKey=InstanceId
&Parameters.1.ParameterValue=i-m5e3tfdbinchnexh****
&<Common request parameters>
```

Sample success responses

`XML` format

```
<Resources>
    <NewEip>
        <Result>
            <Order>
                <Currency>CNY</Currency>
                <DiscountAmount>2.4</DiscountAmount>
                <HandlingFeeAmount>0</HandlingFeeAmount>
                <OrderLines/>
                <OriginalAmount>2.4</OriginalAmount>
                <RiCycleAmount>0</RiCycleAmount>
                <RuleIds>100000****</RuleIds>
                <TaxAmount>0</TaxAmount>
                <TradeAmount>0</TradeAmount>
            </Order>
            <Rules>
                <Rule>
                    <Name>Get 15% off a 1-year subscription</Name>

}
```

HTTP status code	Error code	Error message	Description
400	CircularDependency	Circular Dependency Found: {reason}.	The error message returned because the template contains a circular dependency. reason indicates the specific reason.

HTTP status code	Error code	Error message	Description
400	InvalidSchema	{reason}.	The error message returned because the specified template format is invalid. reason indicates the specific reason.
400	InvalidTemplateAttribute	The Referenced Attribute ({resource} {name}) is incorrect.	The error message returned because the resource attribute referenced in the template is invalid. resource indicates the resource name, and name indicates the attribute name.
400	InvalidTemplatePropertyType	The specified value type of ({resource} {section}) is incorrect.	The error message returned because the type of the specified resource section defined in the template is invalid. resource indicates the resource name, and section indicates the section name.
400	InvalidTemplateReference	The specified reference "{name}" (in {referencer}) is incorrect.	The error message returned because the template contains an invalid reference. name indicates the reference name, and referencer indicates the referencer name.
400	InvalidTemplateSection	The template section is invalid: {section}.	The error message returned because the template contains an invalid property. section indicates the section name.

HTTP status code	Error code	Error message	Description
400	InvalidTemplateVersion	The template version is invalid: {reason}.	The error message returned because the template version is invalid. reason indicates the specific reason.
400	StackValidationFailed	{reason}.	The error message returned because the stack validation failed. reason indicates the specific reason.
400	UnknownUserParameter	The Parameter ({name}) was not defined in template.	The error message returned because the specified parameter is not defined in the template. name indicates the parameter key.
400	UserParameterMissing	The Parameter {name} was not provided.	The error message returned because no value is passed into the specified parameter defined in the template. name indicates the parameter key.

5.1.1.9.2. ValidateTemplate

You can call this operation to validate the template that is used to create stacks.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ValidateTemplate	The operation that you want to perform. Set the value to ValidateTemplate.

Parameter	Type	Required	Example	Description
TemplateURL	String	No	oss://ros/template/demo	The URL of the file that contains the template body. The URL must point to a template located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/template/demo and oss://ros/template/demo?RegionId=cn-hangzhou. The template can be up to 524,288 bytes in length, and the URL can be up to 1,024 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.
RegionId	String	No	cn-hangzhou	The region ID of the stack template.
TemplateBody	String	No	{"ROSTemplateFormatVersion":"2015-09-01"}	The structure that contains the template body. The template body must be 1 to 524,288 bytes in length. If the length of the template body is longer than required, we recommend that you add parameters to the HTTP POST request body to avoid request failures due to excessive length of URLs. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.

Response parameters

Parameter	Type	Example	Description
Description	String	No description	The description of the stack template.

Parameter	Type	Example	Description
Parameters	List	[{"Description": "", "Label": "param_integer", "NoEcho": "false", "ParameterKey": "param_integer", "Type": "Number"},{ "Description": "", "Label": "param_float", "NoEcho": "false", "ParameterKey": "param_float", "Type": "Number"}]	The input parameters of the stack template. The input parameters define the parameters that you must specify to create stacks based on the template. These parameters specify information about a stack, such as the username, password, and environment-related ECS instance type.
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6	The ID of the request.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=ValidateTemplate
&TemplateURL=oss://ros/template/demo
&<Common request parameters>
```

Sample success responses

`XML` format

```
<ValidateTemplateResponse>
       <Description type="string">No description</Description>

```

Error code	Error message	HTTP status code	Description
InvalidTemplate	{reason}.	400	The error message returned because the specified template is invalid. reason indicates the specific reason.

5.1.1.9.3. GetTemplate

You can call this operation to query details about a template.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	GetTemplate	The operation that you want to perform. Set the value to GetTemplate.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackId	String	No	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.
ChangeSetId	String	No	1f6521a4-05af-4975-afe9-bc4b45ad****	The ID of the change set.

Parameter	Type	Required	Example	Description
TemplateId	String	No	5ecd1e10-b0e9-4389-a565-e4c15efc****	The ID of the template.

Response parameters

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6	The ID of the request.
TemplateBody	String	{\"ROSTemplateFormatVersion\": \"2015-09-01\"}	The structure that contains the template body.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=GetTemplate
&RegionId=cn-hangzhou
&<Common request parameters>
```

Sample success responses

`XML` format

```

}
```

HTTP status code	Error code	Error message	Description
404	StackNotFound	The Stack ({name}) could not be found.	The error message returned because the specified stack does not exist. name indicates the name or ID of the stack.
404	TemplateNotFound	The Tempalte ({ ID }) could not be found.	The error message returned because the specified template does not exist. ID indicates the template ID.

5.1.1.9.4. DeleteTemplate

You can call this operation to delete a stack and all of its resources.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	DeleteTemplate	The operation that you want to perform. Set the value to DeleteTemplate.
TemplateId	String	Yes	5ecd1e10-b0e9-4389-a565-e4c15efc****	The ID of the stack.

Response parameters

Parameter	Type	Example	Description
RequestId	String	8C5D90E1-66B6-496C-9371-3807F8DA80A8	The ID of the request.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=DeleteTemplate
&TemplateId=5ecd1e10-b0e9-4389-a565-e4c15efc****
&<Common request parameters>
```

Sample success responses

`XML` format

```
<DeleteTemplateResponse>
          <RequestId>8C5D90E1-66B6-496C-9371-3807F8DA80A8</RequestId>
</DeleteTemplateResponse>
```

`JSON` format

```
{
    "RequestId": "8C5D90E1-66B6-496C-9371-3807F8DA80A8"
}
```

HTTP status code	Error code	Error message	Description
404	TemplateNotFound	The Tempalte ({ ID }) could not be found.	The error message returned because the specified stack does not exist.

5.1.1.9.5. ListTemplates

You can call this operation to query the list of one or more templates.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ListTemplates	The operation that you want to perform. Set the value to ListTemplates.
TemplateName	String	No	MyTemplate	The name of the template. The name can be up to 255 characters in length and can contain digits, letters, hyphens (-), and underscores (_). It must start with a digit or letter.
PageNumber	Long	No	10	The number of the page to return. Pages start from page 1. Default value: 1.
PageSize	Long	No	1	The number of entries to return on each page. Valid values: 1 to 50. Default value: 10.
Tag.N.Key	String	No	TestKey	The key of tag N. Valid values of N: 1 to 20. The tag key cannot be an empty string. The tag key can be up to 128 characters in length and cannot contain http:// or https://. It cannot start with acs: or aliyun.
Tag.N.Value	String	No	TestValue	The value of tag N. Valid values of N: 1 to 20. The tag value can be an empty string. The tag value can be up to 128 characters in length and cannot contain http:// or https://. It cannot start with acs: or aliyun.

Response parameters

Parameter	Type	Example	Description
RequestId	String	C3A8413B-1F16-4DED-AC3E-61A00718DE8A	The ID of the request.
PageSize	Integer	10	The number of entries returned per page.
PageNumber	Integer	1	The page number of the returned page. Pages start from page 1.
TotalCount	Integer	3	The total number of templates.
Templates	Array of Template		Details about the templates.
CreateTime	String	2019-10-15T08:17:14.000000	The time when the template was created.
Description	String	test-description	The description of the template.
TemplateId	String	4d4f5aa2-3260-4e47-863b-763fbb12****	The ID of the template.
TemplateName	String	test-list-templates	The name of the template.
UpdateTime	String	2019-10-15T08:17:14.000000	The time when the template was created.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=ListTemplates
&<Common request parameters>
```

Sample success responses

`XML` format

```
<ListTemplatesResponse>
    <PageNumber>1</PageNumber>
    <PageSize>10</PageSize>
    <RequestId>C3A8413B-1F16-4DED-AC3E-61A00718DE8A</RequestId>

5.1.1.9.6. CreateTemplate

You can call this operation to create a template.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	CreateTemplate	The operation that you want to perform. Set the value to CreateTemplate.
TemplateName	String	Yes	MyTemplate	The name of the template. The name can be up to 255 characters in length and can contain digits, letters, hyphens (-), and underscores (_). It must start with a digit or letter.

Parameter	Type	Required	Example	Description
TemplateURL	String	No	oss://ros/template/demo	The URL of the file that contains the template body. The URL must point to a template located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/template/demo and oss://ros/template/demo?RegionId=cn-hangzhou. The template can be up to 524,288 bytes in length, and the URL can be up to 1,024 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You can specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.
Description	String	No	It is a demo.	The description of the template. The description can be up to 256 characters in length.
TemplateBody	String	No	{"ROSTemplateFormatVersion":"2015-09-01"}	The structure that contains the template body. The template body must be 1 to 524,288 bytes in length. If the length of the template body is longer than required, we recommend that you add parameters to the HTTP POST request body to avoid request failures due to excessive length of URLs. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.

Response parameters

Parameter	Type	Example	Description
RequestId	String	8C5D90E1-66B6-496C-9371-3807F8DA80A8	The ID of the request.
TemplateId	String	5ecd1e10-b0e9-4389-a565-e4c15efc****	The ID of the template.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=CreateTemplate
&TemplateName=MyTemplate
&TemplateURL=oss://ros/template/demo
&<Common request parameters>
```

Sample success responses

`XML` format

```
<CreateTemplateResponse>
          <RequestId>8C5D90E1-66B6-496C-9371-3807F8DA80A8</RequestId>
          <TemplateId>5ecd1e10-b0e9-4389-a565-e4c15efc****</TemplateId>
</CreateTemplateResponse>
```

`JSON` format

```
{
    "RequestId": "8C5D90E1-66B6-496C-9371-3807F8DA80A8",
    "TemplateId": "5ecd1e10-b0e9-4389-a565-e4c15efc****"
}
```

HTTP status code	Error code	Error message	Description
400	InvalidSchema	{reason}.	The error message returned because the specified template format is invalid. reason indicates the specific reason.

HTTP status code	Error code	Error message	Description
400	InvalidTemplateAttribute	The Referenced Attribute ({resource} {name}) is incorrect.	The error message returned because the resource attribute referenced in the template is incorrect. resource indicates the resource name, and name indicates the attribute name.
400	InvalidTemplatePropertyType	The specified value type of ({resource} {section}) is incorrect.	The error message returned because the type of the specified resource section defined in the template is incorrect. resource indicates the resource name, and section indicates the section name.
400	InvalidTemplateReference	The specified reference "{name}" (in {referencer}) is incorrect.	The error message returned because the template contains an invalid reference. name indicates the reference name, and referencer indicates the referencer name.
400	InvalidTemplateSection	The template section is invalid: {section}.	The error message returned because the template contains an invalid property. section indicates the section name.
400	InvalidTemplateVersion	The template version is invalid: {reason}.	The error message returned because the template version is incorrect. reason indicates the specific reason.

5.1.1.9.7. UpdateTemplate

You can call this operation to update a template.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	UpdateTemplate	The operation that you want to perform. Set the value to UpdateTemplate.
TemplateId	String	Yes	5ecd1e10-b0e9-4389-a565-e4c15efc****	The ID of the template.
TemplateURL	String	No	oss://ros/template/demo	The URL of the file that contains the template body. The URL must point to a template located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/template/demo and oss://ros/template/demo?RegionId=cn-hangzhou. The template can be up to 524,288 bytes in length, and the URL can be up to 1,024 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.
TemplateName	String	No	MyTemplate	The name of the template. The name can be up to 255 characters in length and can contain digits, letters, hyphens (-), and underscores (_). It must start with a digit or letter.
Description	String	No	It is a demo.	The description of the template. The description can be up to 256 characters in length.

Parameter	Type	Required	Example	Description
TemplateBody	String	No	{"ROSTemplateFormatVersion":"2015-09-01"}	The structure that contains the template body. The template body must be 1 to 524,288 bytes in length. If the length of the template body is longer than required, we recommend that you add parameters to the HTTP POST request body to avoid request failures due to excessive length of URLs. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.

Response parameters

Parameter	Type	Example	Description
RequestId	String	8C5D90E1-66B6-496C-9371-3807F8DA80A8	The ID of the request.
TemplateId	String	5ecd1e10-b0e9-4389-a565-e4c15efc****	The ID of the template.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=UpdateTemplate
&TemplateId=5ecd1e10-b0e9-4389-a565-e4c15efc****
&TemplateURL=oss://ros/template/demo
&<Common request parameters>
```

Sample success responses

`XML` format

```
<UpdateTemplateResponse>
          <RequestId>8C5D90E1-66B6-496C-9371-3807F8DA80A8</RequestId>
          <TemplateId>5ecd1e10-b0e9-4389-a565-e4c15efc****</TemplateId>
</UpdateTemplateResponse>
```

`JSON` format

```
{
    "RequestId": "8C5D90E1-66B6-496C-9371-3807F8DA80A8",
    "TemplateId": "5ecd1e10-b0e9-4389-a565-e4c15efc****"
}
```

HTTP status code	Error code	Error message	Description
404	TemplateNotFound	The Tempalte ({ ID }) could not be found.	The error message returned because the specified template does not exist.
400	InvalidSchema	{reason}.	The error message returned because the specified template format is invalid. reason indicates the specific reason.
400	InvalidTemplateAttribute	The Referenced Attribute ({resource} {name}) is incorrect.	The error message returned because the resource attribute referenced in the template is invalid. resource indicates the resource name, and name indicates the attribute name.
400	InvalidTemplatePropertyType	The specified value type of ({resource} {section}) is incorrect.	The error message returned because the type of the specified resource section defined in the template is invalid. resource indicates the resource name, and section indicates the section name.

HTTP status code	Error code	Error message	Description
400	InvalidTemplateReference	The specified reference "{name}" (in {referencer}) is incorrect.	The error message returned because the template contains an invalid reference. name indicates the reference name, and referencer indicates the referencer name.
400	InvalidTemplateSection	The template section is invalid: {section}.	The error message returned because the template contains an invalid property. section indicates the section name.
400	InvalidTemplateVersion	The template version is invalid: {reason}.	The error message returned because the template version is invalid. reason indicates the specific reason.

5.1.1.9.8. GetTemplateSummary

You can call this operation to query information about a new or existing template.

To specify the query object, you must specify one of the StackId, ChangeSetId, TemplateId, TemplateBody, and TemplateURL parameters.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	GetTemplateSummary	The operation that you want to perform. Set the value to GetTemplateSummary.
StackId	String	No	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.

Parameter	Type	Required	Example	Description
TemplateBody	String	No	{"ROSTemplateFormatVersion":"2015-09-01"}	The structure that contains the template body. The template body must be 1 to 524,288 bytes in length. If the length of the template body is longer than required, we recommend that you add parameters to the HTTP POST request body to avoid request failures due to excessive length of URLs. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.
RegionId	String	No	cn-hangzhou	The region ID of the stack.
TemplateId	String	No	5ecd1e10-b0e9-4389-a565-e4c15efc****	The ID of the template.

Parameter	Type	Required	Example	Description
TemplateURL	String	No	oss://ros/template/demo	The URL of the file that contains the template body. The URL must point to a template located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/template/demo and oss://ros/template/demo?RegionId=cn-hangzhou. The template can be up to 524,288 bytes in length, and the URL can be up to 1,024 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You must specify one of the TemplateBody and TemplateURL parameters, but you cannot specify both of them.
ChangeSetId	String	No	1f6521a4-05af-4975-afe9-bc4b45ad****	The ID of the change set.

Response parameters

Parameter	Type	Example	Description
Description	String	No description	The description of the stack template.
Metadata	Map	{"key": "value"}	The metadata that is specified in the template.
Parameters	List	[{"Description":"", "Label":"Name", "NoEcho":"false", "ParameterKey":"Name", "Type":"String"}]	Details about the parameter declarations that describe the attributes of parameters.

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6	The ID of the request.
ResourceIdentifierSummaries	Array of ResourceIdentifierSummary		Details about the resource identifier summaries. A summary describes the resource into which you want to import other resources and the attributes that can be used to identify the resource. For example, VpcId is the identifier of the ALIYUN::ECS::VPC resource.
LogicalResourceIds	List	["Vpc"]	The logical IDs of all resources that are of the type that is specified by the ResourceType parameter.
ResourceIdentifiers	List	["VpcId"]	The attributes of the resource. The attributes are used to identify the resource into which you want to import other resources. For example, VpcId is the identifier of the ALIYUN::ECS::VPC resource.
ResourceType	String	ALIYUN::ECS::VPC	The type of the resource. **Note** You can import resources into the ALIYUN::ECS::VPC resource type.
ResourceTypes	List	["ALIYUN::ECS::VPC"]	All the resource types that are used in the template.
Version	String	2015-09-01	The version of the template.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=GetTemplateSummary
&StackId=4a6c9851-3b0f-4f5f-b4ca-a14bf691****
&RegionId=cn-hangzhou
&TemplateURL=oss://ros/template/demo
&<Common request parameters>
```

Sample success responses

`XML` format

```
<GetTemplateSummary>
          <Description>No description</Description>
          <Metadata></Metadata>
          <Parameters>
                <Description>Description of the vpc, [2, 256] characters. Do not fill or em
pty, the default is empty. </Description>
                <Label>Description</Label>
                <NoEcho>false</NoEcho>
                <ParameterKey>Description</ParameterKey>
                <Type>String</Type>
          </Parameters>
          <Parameters>
                <Description>Tags to attach to vpc. Max support 20 tags to add during creat
e vpc. Each tag with two properties Key and Value, and Key is required. </Description>
                <Label>Tags</Label>
                <MaxLength>20</MaxLength>
                <NoEcho>false</NoEcho>
                <ParameterKey>Tags</ParameterKey>
                <Type>Json</Type>

HTTP status code	Error code	Error message	Description
400	StackValidationFailed	{reason}.	The error message returned because the stack validation failed. reason indicates the specific reason.
404	StackNotFound	The Stack ({name}) could not be found.	The error message returned because the specified stack does not exist. name indicates the name or ID of the stack.
404	TemplateNotFound	The Tempalte ({ ID }) could not be found.	The error message returned because the specified template does not exist. ID indicates the template ID.

5.1.1.10. Stack policy operations

5.1.1.10.1. SetStackPolicy

You can call this operation to set a stack policy.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	SetStackPolicy	The operation that you want to perform. Set the value to SetStackPolicy.

Parameter	Type	Required	Example	Description
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.
StackPolicyBody	String	No	{"Statement":[{"Effect":"Allow","Action":"Update:*","Principal":"*","Resource":"*"}]}	The structure that contains the stack policy body. The stack policy body must be 1 to 16,384 bytes in length. **Note** You must specify one of the StackPolicyBody and StackPolicyURL parameters, but you cannot specify both of them.
StackPolicyURL	String	No	oss://ros/stack-policy/demo	The URL of the file that contains the stack policy. The URL must point to a policy located in an HTTP or HTTPS web server or an Alibaba Cloud OSS bucket. Examples: oss://ros/stack-policy/demo and oss://ros/stack-policy/demo?RegionId=cn-hangzhou. The policy can be up to 16,384 bytes in length and the URL can be up to 1,350 bytes in length. If the region of the OSS bucket is not specified, the RegionId value is used. **Note** You must specify one of the StackPolicyBody and StackPolicyURL parameters, but you cannot specify both of them.

Response parameters

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6F	The ID of the request.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=SetStackPolicy
&StackId=4a6c9851-3b0f-4f5f-b4ca-a14bf691****
&StackPolicyURL=oss://ros/stack-policy/demo
&RegionId=cn-hangzhou
&<Common request parameters>
```

Sample success responses

`XML` format

```
<SetStackPolicyResponse>
      <RequestId>B288A0BE-D927-4888-B0F7-B35EF84B6E6F</RequestId>
</SetStackPolicyResponse>
```

`JSON` format

```
{
   "RequestId": "B288A0BE-D927-4888-B0F7-B35EF84B6E6F"
}
```

Error code	Error message	HTTP status code	Description
StackValidationFailed	{reason}.	400	The error message returned because the stack validation failed. reason indicates the specific reason.
StackNotFound	The Stack ({name}) could not be found.	404	The error message returned because the specified stack does not exist. name indicates the name or ID of the stack.

5.1.1.10.2. GetStackPolicy

You can call this operation to query information about a stack policy.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	GetStackPolicy	The operation that you want to perform. Set the value to GetStackPolicy.

Parameter	Type	Required	Example	Description
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.

Response parameters

Parameter	Type	Example	Description
StackPolicyBody	Map	{"Statement": [{"Action": "Update:*", "Effect": "Allow","Principal": "*","Resource": "*"}]}	The structure that contains the stack policy body. The policy body must be 1 to 16,384 bytes in length.
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6F	The ID of the request.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=GetStackPolicy
&StackId=4a6c9851-3b0f-4f5f-b4ca-a14bf691****
&RegionId=cn-hangzhou
&<Common request parameters>
```

Sample success responses

`XML` format

```
<GetStackPolicyResponse>
    <StackPolicyBody>
        <Statement>
            <Statement>
                <Resource>*</Resource>
                <Principal>*</Principal>
                <Action>Update:*</Action>
                <Effect>Allow</Effect>
            </Statement>
            <Statement>
                <Resource>LogicalResourceId/WebServer</Resource>
                <Principal>*</Principal>
                <Action>Update:*</Action>
                <Effect>Deny</Effect>
            </Statement>
        </Statement>
    </StackPolicyBody>
    <RequestId>B288A0BE-D927-4888-B0F7-B35EF84B6E6F</RequestId>
</GetStackPolicyResponse>
```

`JSON` format

```
{
  "StackPolicyBody": {
    "Statement": [
      {
        "Action": "Update:*",
        "Effect": "Allow",
        "Principal": "*",
        "Resource": "*"
      },
      {
        "Action": "Update:*",
        "Effect": "Deny",
        "Principal": "*",
        "Resource": "LogicalResourceId/WebServer"
      }
    ]
  },
  "RequestId": "B288A0BE-D927-4888-B0F7-B35EF84B6E6F"
}
```

Error code	Error message	HTTP status code	Description
StackNotFound	The Stack ({name}) could not be found.	404	The error message returned because the specified stack could not be found. name indicates the name or ID of the stack.

5.1.1.11. Other operations

5.1.1.11.1. DescribeRegions

You can call this operation to query available regions.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	DescribeRegions	The operation that you want to perform. Set the value to DescribeRegions.
AcceptLanguage	String	No	zh-CN	The natural language that is used to filter responses. Default value: zh-CN. Valid values: • zh-CN • en-US • ja

Response parameters

Parameter	Type	Example	Description
Regions	Array of Region		Details about the regions.
LocalName	String	China (Hangzhou)	The name of the region in the local language.
RegionEndpoint	String	ros.aliyuncs.com	The endpoint of the region.
RegionId	String	cn-hangzhou	The ID of the region.
RequestId	String	59F0F0A0-A637-4292-9B91-251EF5010913	The ID of the request.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=DescribeRegions
&<Common request parameters>
```

Sample success responses

`XML` format

```
<DescribeRegionsResponse>
    <Regions>
        <Region>
            <RegionId>cn-qingdao</RegionId>

            "RegionEndpoint": "ros.aliyuncs.com",
            "RegionId": "ap-northeast-1"
        },
        {
            "localName": "Singapore (Singapore)",
            "RegionEndpoint": "ros.aliyuncs.com",
            "RegionId": "ap-southeast-1"
        },
        {
            "localName": "Australia (Sydney)",
            "RegionEndpoint": "ros.aliyuncs.com",
            "RegionId": "ap-southeast-2"
```

```
            "RegionId": "ap-southeast-2"
        },
        {
            "localName": "Malaysia (Kuala Lumpur)",
            "RegionEndpoint": "ros.aliyuncs.com",
            "RegionId": "ap-southeast-3"
        },
        {
            "localName": "Indonesia (Jakarta)",
            "RegionEndpoint": "ros.aliyuncs.com",
            "RegionId": "ap-southeast-5"
        },
        {
            "localName": "India (Mumbai)",
            "RegionEndpoint": "ros.aliyuncs.com",
            "RegionId": "ap-south-1"
        },
        {
            "localName": "US (Virginia)",
            "RegionEndpoint": "ros.aliyuncs.com",
            "RegionId": "us-east-1"
        },
        {
            "localName": "US (Silicon Valley)",
            "RegionEndpoint": "ros.aliyuncs.com",
            "RegionId": "us-west-1"
        },
        {
            "localName": "UK (London)",
            "RegionEndpoint": "ros.aliyuncs.com",
            "RegionId": "eu-west-1"
        },
        {
            "localName": "UAE (Dubai)",
            "RegionEndpoint": "ros.aliyuncs.com",
            "RegionId": "me-east-1"
        },
        {
            "LocalName": "Germany (Frankfurt)"
            "RegionEndpoint": "ros.aliyuncs.com",
            "RegionId": "eu-central-1"
        }
    ],
    "RequestId": "59F0F0A0-A637-4292-9B91-251EF5010913"
}
```

5.1.1.11.2. SignalResource

You can call this operation to send signals.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	SignalResource	The operation that you want to perform. Set the value to SignalResource.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.
LogicalResourceId	String	Yes	WebServer	The logical ID of the resource as defined in the template.
Status	String	Yes	SUCCESS	The state of the signal. Failure signals can cause stack creation or update to fail. If all signals are warnings, the stack cannot be created or updated. Valid values: • SUCCESS • FAILURE • WARNING
UniqueId	String	Yes	27c7347b-352a-4377-accf-63d361c1****	The unique ID of the signal. The ID must be 1 to 64 characters in length. If multiple signals are sent to a single resource, each signal must have a unique ID.
ClientToken	String	No	123e4567-e89b-12d3-a456-42665544****	The client token that is used to ensure the idempotence of the request. You can use the client to generate the value, but you must make sure that it is unique among different requests. The token can be up to 64 characters in length and can contain letters, digits, hyphens (-) and underscores (_).

Response parameters

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6	The ID of the request.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=SignalResource
&RegionId=cn-hangzhou
&StackId=4a6c9851-3b0f-4f5f-b4ca-a14bf691****
&LogicalResourceId=WebServer
&Status=SUCCESS
&UniqueId=27c7347b-352a-4377-accf-63d361c1****
&<Common request parameters>
```

Sample success responses

`XML` format

```
<SignalResourceResponse>
      <RequestId>B288A0BE-D927-4888-B0F7-B35EF84B6E6F</RequestId>
</SignalResourceResponse>
```

`JSON` format

```
{
   "RequestId": "B288A0BE-D927-4888-B0F7-B35EF84B6E6F"
}
```

HTTP status code	Error code	Error message	Description
404	ResourceNotAvailable	The Resource ({name}) is not available.	The error message returned because the specified resource is unavailable. name indicates the resource name.
404	ResourceNotFound	The Resource ({name}) could not be found in Stack {stack}.	The error message returned because the specified resource does not exist in the specified stack. name indicates the resource name, and stack indicates the stack name or ID.

HTTP status code	Error code	Error message	Description
404	StackNotFound	The Stack ({name}) could not be found.	The error message returned because the specified stack does not exist. The name parameter indicates the name or ID of the stack.

5.1.1.11.3. SetDeletionProtection

You can call this operation to configure deletion protection on a stack.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	SetDeletionProtection	The operation that you want to perform. Set the value to SetDeletionProtection.
DeletionProtection	String	Yes	Enabled	Specifies whether to enable deletion protection on the stack. Default value: Disabled. Valid values: • Enabled: enables deletion protection on the stack. • Disabled: disables deletion protection on the stack. You can release the stack by using the ROS console or by calling the DeleteStack operation. Note The deletion protection property of a nested stack is the same as that of its root stack.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack. The deletion protection property of a nested stack is the same as that of its parent stack and cannot be changed.

Response parameters

Parameter	Type	Example	Description
RequestId	String	B288A0BE-D927-4888-B0F7-B35EF84B6E6F	The ID of the request.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=SetDeletionProtection
&DeletionProtection=Enabled
&RegionId=cn-hangzhou
&StackId=4a6c9851-3b0f-4f5f-b4ca-a14bf691****
&<Common request parameters>
```

Sample success responses

`XML` format

```
<SetDeletionProtectionResponse>
    <RequestId>B288A0BE-D927-4888-B0F7-B35EF84B6E6F</RequestId>
</SetDeletionProtectionResponse>
```

`JSON` format

```
{
    "RequestId": "B288A0BE-D927-4888-B0F7-B35EF84B6E6F"
}
```

HTTP status code	Error code	Error message	Description

HTTP status code	Error code	Error message	Description
400	InvalidOperation.SetDeletionProtection	Fail to set deletion protection for {type} {ID}, {reason}.	The error message returned because deletion protection failed to be enabled for a stack. type indicates the type of the object on which to perform the operation. ID indicates the ID of the object on which to perform the operation. reason indicates the specific reason.
404	StackNotFound	The Stack ({name}) could not be found.	The error message returned because the specified stack does not exist. name indicates the name or ID of the stack.

5.1.1.11.4. ListStackOperationRisks

You can call this operation to detect the resources that may face high risks caused by a stack deletion operation, and query the reason for each risk.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ListStackOperationRisks	The operation that you want to perform. Set the value to ListStackOperationRisks.
OperationType	String	Yes	DeleteStack	The operation type to be detected. The DeleteStack value specifies to detect resources that may face high risks caused by a stack deletion operation.
RegionId	String	Yes	cn-hangzhou	The region ID of the stack.

Parameter	Type	Required	Example	Description
StackId	String	Yes	4a6c9851-3b0f-4f5f-b4ca-a14bf691****	The ID of the stack.
ClientToken	String	No	123e4567-e89b-12d3-a456-42665544****	The client token that is used to ensure the idempotence of the request. You can use the client to generate the value, but you must make sure that it is unique among different requests. The token can be up to 64 characters in length and can contain letters, digits, hyphens (-), and underscores (_).
RamRoleName	String	No	test-role	The name of the RAM role. • If you specify a RAM role, ROS creates stacks based on the permissions granted to the RAM role and uses the credentials of the RAM role to call API operations. • If you do not specify a RAM role, ROS creates stacks based on the permissions of the current account. The RAM role name can be up to 64 characters in length.
RetainAllResources	Boolean	No	false	Specifies whether to retain all resources in the stack. Default value: false. Valid values: • true: The resources in the stack are retained. • false: The resources in the stack are not retained. Note This parameter is valid only when the OperationType parameter is set to DeleteStack.
RetainResources.N	RepeatList	No	WebServer	The list of resources to retain. Note This parameter is valid only when the OperationType parameter is set to DeleteStack.

Response parameters

Parameter	Type	Example	Description
RequestId	String	72108E7A-E874-4A5E-B22C-A61E94AD12CD	The ID of the request.
RiskResources	Array of Resource		The resources that face high risks caused by the stack deletion operation.
Code	String	NoPermission	The error code that is returned when the risk detection fails. This parameter is not returned when the risk detection succeeds.
LogicalResourceId	String	MySG	The logical ID of the resource. It is the resource name defined in the template.
Message	String	You are not authorized to complete this action.	The error message that is returned when the risk detection fails. This parameter is not returned when the risk detection succeeds.
PhysicalResourceId	String	sg-bp1dpioafqphedg9****	The physical ID of the resource.
Reason	String	There are some ECS instances (i-bp18el96s4wq635e****) depending on the security group.	The reason for the risk.
RequestId	String	DF4296CF-F45F-4845-A72B-BE617601DB25	The request ID that is returned when the risk detection fails. This parameter is not returned when the risk detection succeeds.
ResourceType	String	ALIYUN::ECS::SecurityGroup	The type of the resource.
RiskType	String	Referenced	The type of the risk. Valid values: • Referenced: The current resource is referenced by other resources. • MaybeReferenced: The current resource may be referenced by other resources. • AdditionalRiskCheckRequired: An additional risk detection is required for nested stacks.

Examples

Sample requests

```
http(s)://ros.aliyuncs.com/? Action=ListStackOperationRisks
&OperationType=DeleteStack
&RegionId=cn-hangzhou
&StackId=4a6c9851-3b0f-4f5f-b4ca-a14bf691****
&<Common request parameters>
```

Sample success responses

`XML` format

```
<ListStackOperationRisks>
    <RequestId>72108E7A-E874-4A5E-B22C-A61E94AD12CD</RequestId>
    <RiskResources>
       <LogicalResourceId>MySG</LogicalResourceId>
       <PhysicalResourceId>sg-bp1dpioafqphedg9****</PhysicalResourceId>
       <ResourceType>ALIYUN::ECS::SecurityGroup</ResourceType>
       <Reason>There are some ECS instances (i-bp18el96s4wq635e****) depending on the secur
ity group. </Reason>
       <RiskType>Referenced</RiskType>
    </RiskResources>
</ListStackOperationRisks>
```

`JSON` format

```
{
  "RequestId": "772108E7A-E874-4A5E-B22C-A61E94AD12CD",
  "RiskResources": [
    {
      "LogicalResourceId": "MySG",
      "PhysicalResourceId": "sg-bp1dpioafqphedg9****",
      "ResourceType": "ALIYUN::ECS::SecurityGroup",
      "Reason": "There are some ECS instances (i-bp18el96s4wq635e****) depending on the sec
urity group.",
      "RiskType": "Referenced"
    }
  ]
}
```

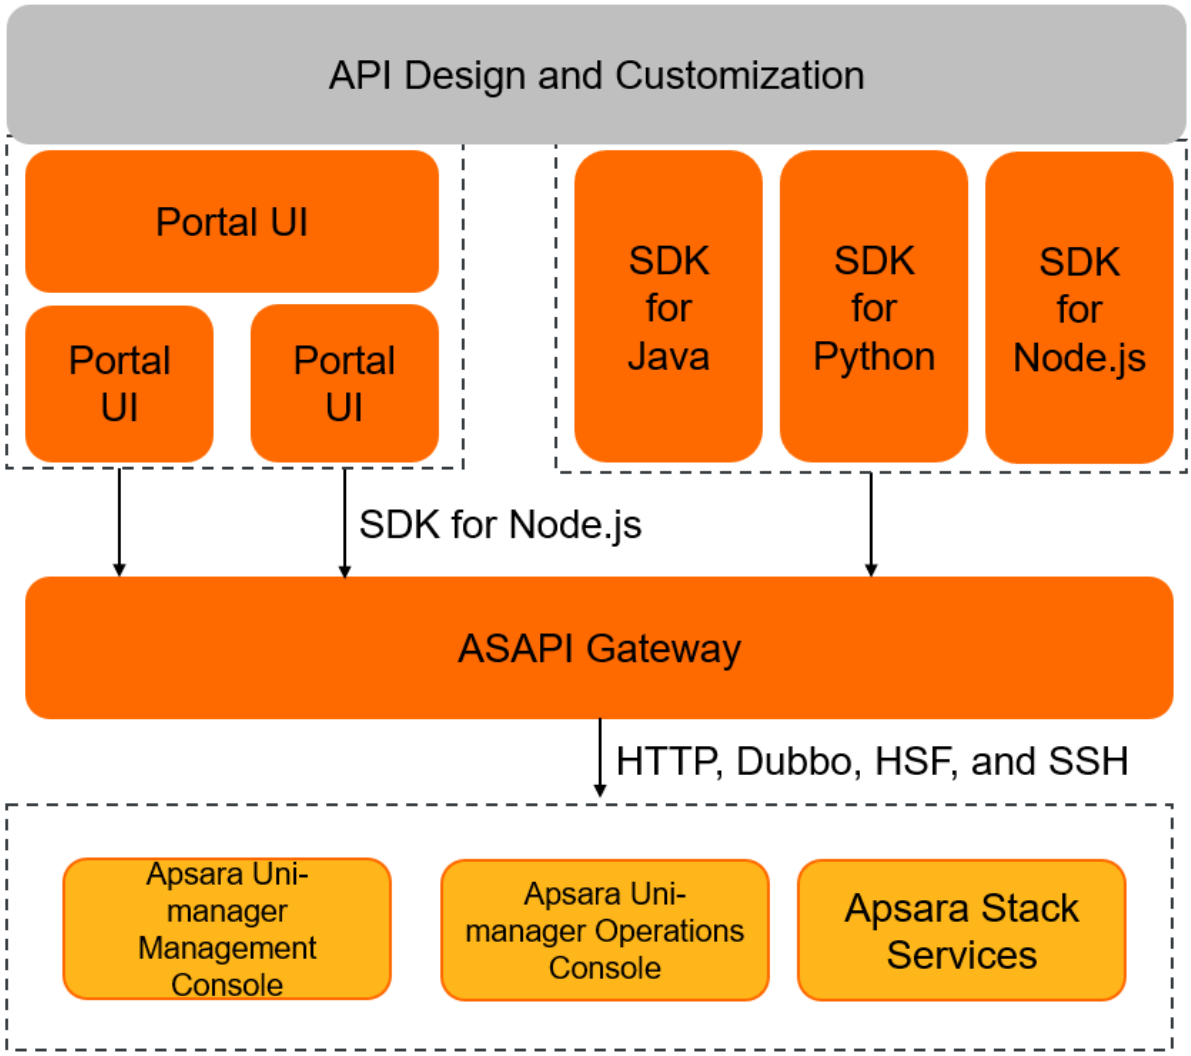
5.1.2. Use ASAPI to call Apsara Stack SDKs

5.1.2.1. 文档标题缺失，请补全后重新导出

5.1.2.1.1. ASAPI overview

This topic describes the architecture and features of the Apsara Stack API (ASAPI).

The ASAPI is a unified ingress gateway for Apsara Stack services and a main component of the Apsara Uni-manager Management Console. The ASAPI provides a unified method for you to manage and make API calls. You can use Apsara Stack SDK to centrally make API calls to Apsara Stack services, including Elastic Compute Service (ECS) and Virtual Private Cloud (VPC).



The ASAPI allows you to make API calls to manage and maintain Apsara Stack services.

- Make API calls to implement enterprise-grade management. For example, you can manage organizations, users, roles, resource sets, and logon policies. These operations are provided by the Apsara Uni-manager Management Console.
- Make API calls to manage operations. For example, you can manage quotas, usage statistics, specifications, and password policies. These operations are provided by the Apsara Uni-manager Management Console.
- Make API calls to manage resources. For example, you can create, delete, query, or modify cloud resources. These operations are provided by Apsara Stack services. If you call an API operation to create an ECS instance or a VPC, the API operation is provided by ECS or VPC.
- Make API calls to query monitoring metrics of Apsara Stack services. These operations are provided by the Apsara Uni-manager Management Console.
- Make API calls to perform O&M. For example, you can manage monitoring and alerting, inventories, tasks, and physical servers. These operations are provided by the Apsara Uni-manager Operations

Console.

For more information, see the developer guide of the corresponding Apsara Stack service. For information about API operations used to manage organization users, see *Apsara Uni-manager Management Console Developer Guide*. For information about the API operation used to create an ECS instance, see *ECS Developer Guide*.

> **Note** If the "Use Apsara Stack SDK to make API calls" section is included in the developer guide of an Apsara Stack service, the ASAPI is supported by the Apsara Stack service. In this case, you can make API calls based on the developer guide.

5.1.2.1.2. Preparations

5.1.2.1.2.1. Log on to the API Tool console

You can log on to the API Tool console from the Apsara Uni-manager Management Console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 10 to 32 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Log On**.
4. In the top navigation bar, choose **Products > Others > API Tool**.

5.1.2.1.2.2. View information about API operations

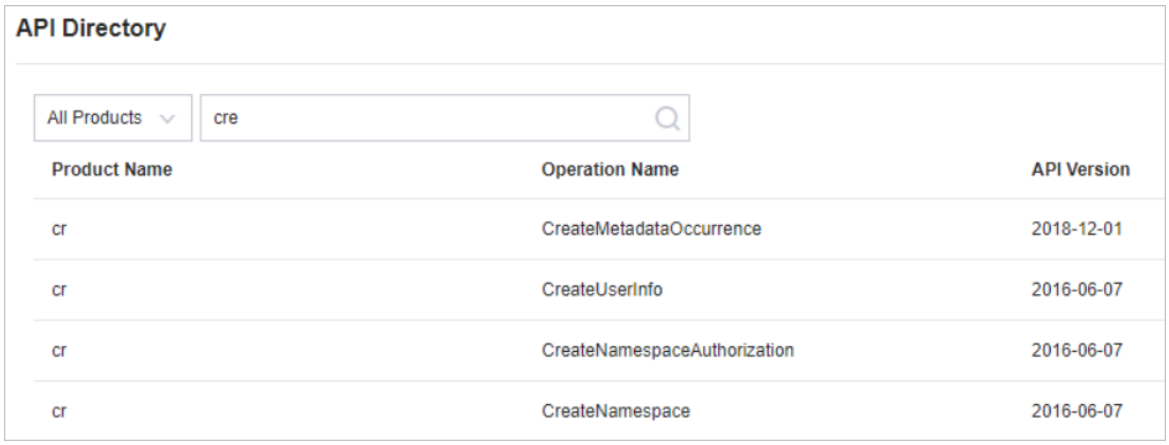
This topic describes how to view information about API operations. Before you use SDKs, obtain service names, API operation names, and API operation versions.

Context

The API operations on the API Directory page are only for reference. For information about how to call API operations, see developer guides of the corresponding cloud services. If the information on the API Directory page is inconsistent with that in the developer guide of the corresponding cloud service, the information in the developer guide prevails.

Procedure

1. Go to the API Tool console. For more information, see Log on to the API Tool console.
2. In the left-side navigation pane, click **API Directory**.
3. On the **API Directory** page, select the desired service from the drop-down list, enter a keyword of an API operation name in the search box, and then click the search icon.



4. Then, you can view the service name, API operation name, and API operation version.

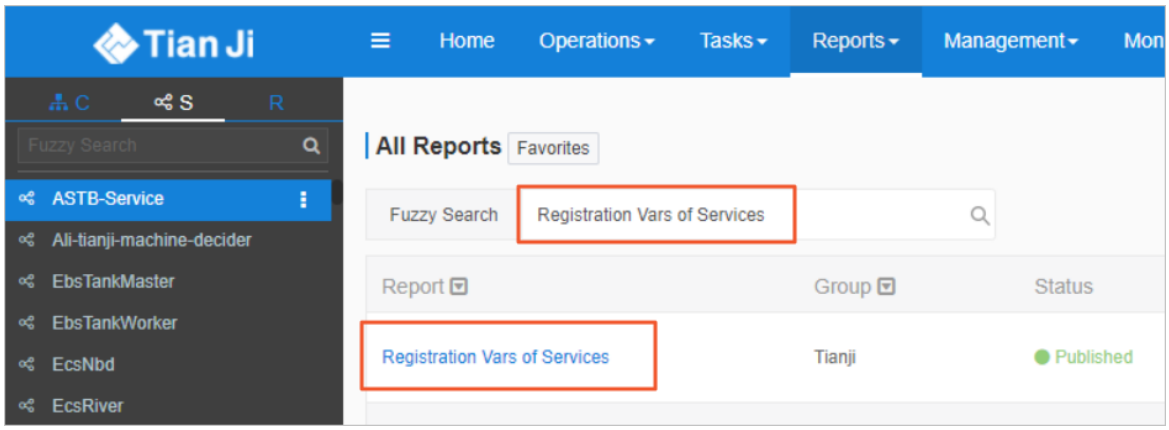
5.1.2.1.2.3. Generate an endpoint for the ASAPI

This topic describes three methods used to generate an endpoint for the Apsara Stack API (ASAPI).

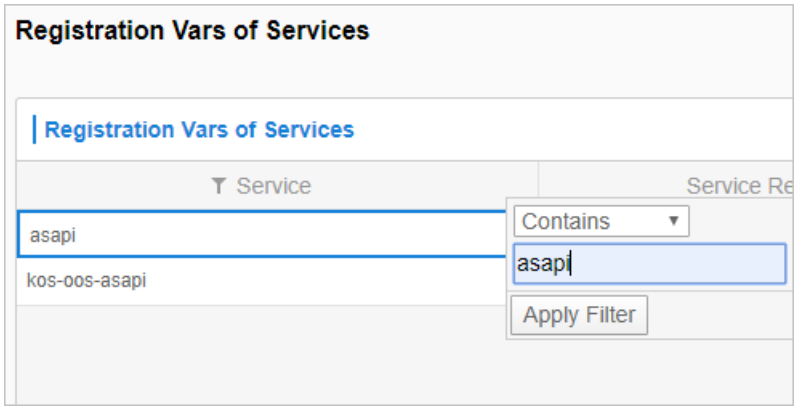
Method 1: Use Registration Vars of Services to generate an endpoint

1. Log on to Apsara Infrastructure Management Framework.
   i. Log on to the Apsara Uni-manager Operations Console.
   ii. In the top navigation bar, click **O&M**.
   iii. In the left-side navigation pane, choose **Product Management** > **Products**.
   iv. In the Apsara Stack O&M section, click **Apsara Infrastructure Management Framework**.
2. In the left-side navigation pane, click **Reports**.

3. On the **All Reports** page, search for `Registration Vars of Services` and click the report name.



4. On the **Registration Vars of Services** page, click the icon next to **Service** and search for `asapi`.



5. Find the asapi service, right-click in the **Service Registration** column, and then select **Show More** from the shortcut menu.

   In the **Details** dialog box, obtain the value of **asapi.public.endpoint**.

6. Generate an endpoint for the ASAPI based on the following format:

```
https://<asapi.public.endpoint>/asapi/v3
```

Method 2: Use cluster resources to generate an endpoint

1. Log on to Apsara Infrastructure Management Framework.
   i. Log on to the Apsara Uni-manager Operations Console.
   ii. In the top navigation bar, click **O&M**.
   iii. In the left-side navigation pane, choose **Product Management** > **Products**.
   iv. In the Apsara Stack O&M section, click **Apsara Infrastructure Management Framework**.
2. Go to the cluster operations page.
   i. In the left-side navigation pane, choose Operations > Cluster Operations.
   ii. In the **Cluster** search box, enter `ascm`.

iii. Find the cluster that you want to manage and click **Operations** in the **Actions** column.

3. Obtain the value of the domain parameter.
   i. Click the Cluster Resources tab.
   ii. In the **Name** field, search for `asapi_dns_public`.
   iii. Click **Details** in the **Application Parameter** column.
   In the **Application Parameter** message, obtain the value of the **domain** parameter.

4. Generate an endpoint for the ASAPI based on the following format:

```
https://<domain>/asapi/v3
```

Method 3: Concatenate strings to generate an endpoint

You can also concatenate strings to generate an endpoint based on the following format:

```
https://public.asapi.<region>.<internet-domain>/asapi/v3
```

> **Note**
>
> 1. Replace <region> with your actual region ID. For information about how to query a region ID, see Query a region ID.
> 2. Replace <internet-domain> with the root domain of your Apsara Stack service. To obtain the root domain, contact Apsara Stack O&M personnel. Take note of this point: Use the internet-domain parameter instead of the intranet-domain parameter.

If the **region** value is `cn-****-****-d01` and the **internet-domain** value is `inter.****.****.com`, the following endpoint can be generated:

```
https://public.asapi.cn-****-****-d01.inter.****.****.com/asapi/v3
```

5.1.2.1.2.4. Obtain Apsara Stack SDKs

The Apsara Stack API (ASAPI) is a unified portal provided by Apsara Stack. You can use the ASAPI to connect to all Apsara Stack services. Apsara Stack provides SDKs for API calls.

For more information about how to obtain Apsara Stack SDKs, see Apsara Stack documentation.

5.1.2.1.2.5. Obtain an AccessKey pair

An AccessKey pair that consists of an AccessKey ID and an AccessKey secret is used to implement symmetric encryption. This helps you verify the identity of a requester. The AccessKey ID is used to identify a user. The AccessKey secret is used to encrypt the signature string. This topic describes how to obtain an AccessKey pair.

Prerequisites

An account of the operations administrator or the level-1 organization administrator is obtained. Only an operations administrator or a level-1 organization administrator can obtain an AccessKey pair.

Context

If you need to make API calls to the Apsara Uni-manager Management Console or other Apsara Stack services, we recommend that you use the AccessKey pair of a personal account. If you use the AccessKey pair of a personal account, configure the request headers that are described in the following table for access control. Otherwise, an error that indicates insufficient permissions can occur.

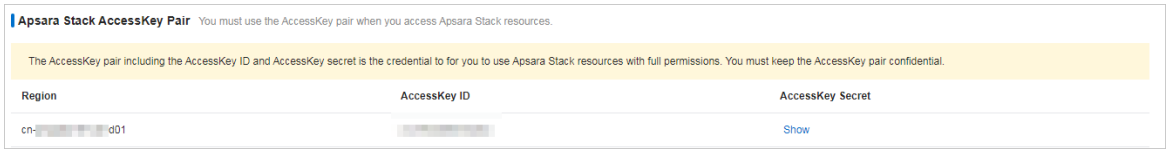
Parameter	Description
x-acs-regionid	The ID of the region, for example, cn-hangzhou-*.
x-acs-organizationid	The ID of the organization in the Apsara Uni-manager Management Console. For information about how to obtain an organization ID, see the "GetOrganizationList" section in Apsara Uni-manager Management Console Developer Guide.
x-acs-resourcegroupid	The ID of the resource set in the Apsara Uni-manager Management Console. For information about how to obtain a resource set ID, see the "ListResourceGroup" section in Apsara Uni-manager Management Console Developer Guide.
x-acs-instanceid	The ID of the instance to which you make API calls. If you need to make API calls to an Elastic Compute Service (ECS) instance, obtain the ID of the ECS instance on the Instances page.

Warning The AccessKey pair of a personal account is managed and controlled by the permission system of the Apsara Uni-manage Management Console. If you need to obtain the AccessKey pair of an account that has permissions on an organization, make sure that your operation is allowed by an administrator. This ensures security. The account that has permissions on an organization is a privileged account.

Obtain the AccessKey pair of a personal account

To obtain the AccessKey pair of a personal account, perform the following operations:

1. Log on to the Apsara Uni-manager Management Console.
2. In the upper-right corner of the homepage, move the pointer over the profile picture and click **User Information**.
3. In the **Apsara Stack AccessKey Pair** section, obtain the AccessKey pair.



> **Note** The AccessKey pair that consists of an AccessKey ID and an AccessKey secret is the credential for you to have full permissions on Apsara Stack resources. Keep your AccessKey pair confidential.

Obtain the AccessKey pair of an account that has permissions on an organization

To obtain the AccessKey pair of an account that has permissions on an organization, perform the following operations:

1. Log on to the Apsara Uni-manager Management Console as an administrator.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Organizations**.
4. In the Organizations navigation tree, click the name of the organization that you want to manage.
5. On the right side of the page, click **Obtain AccessKey Pair**.
6. In the message that appears, obtain the AccessKey pair of the account that has permissions on the organization.

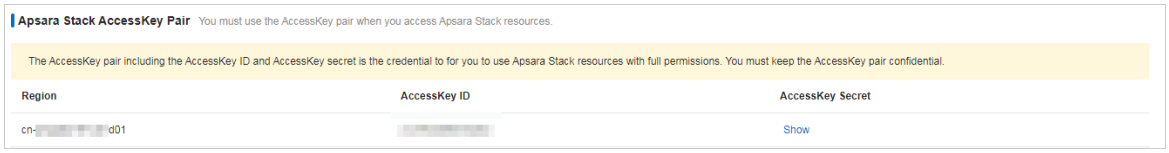
> **Note** The system automatically allocates an AccessKey pair to the account that has permissions on the level-1 organization. The same AccessKey pair is used by the accounts that have permissions on the subordinate organizations.

5.1.2.1.2.6. Query a region ID

When you use Apsara Stack SDK for Node.js to make API calls, specify a region ID. You can obtain a region ID in the Apsara Uni-manager Management Console.

Procedure

1. Log on to the Apsara Uni-manager Management Console as an administrator.
2. In the upper-right corner of the homepage, move the pointer over the profile picture and click **User Information**.
3. In the **Apsara Stack AccessKey Pair** section, view the region ID.



5.1.2.1.3. Common parameters

Common request parameters must be included in all API requests.

Sample common parameters

. .

The following table describes the common parameters that are used when you call API operations supported by the Apsara Stack API (ASAPI).

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. For more information, see View information about API operations.
Product	String	Yes	The name of the service.
Version	String	Yes	The version of the API operation. For more information, see View information about API operations.
RegionId	String	Yes	The ID of the region. For more information, see Query a region ID.
AccessKeyId	String	Yes	The AccessKey ID used to connect to the service. For more information, see Obtain an AccessKey pair.
Signature	String	Yes	The signature string of the current request. For more information about how signatures are calculated, see Request signatures.
SignatureMethod	String	Yes	The encryption method of the signature string. Valid values: HMAC-SHA1 and HMAC-SHA256.

Parameter	Type	Required	Description
SignatureVersion	String	Yes	The version of the signature encryption algorithm. Valid values: 1.0 and 2.0.
SignatureNonce	String	Yes	A unique, random number used to prevent replay attacks. You must use different numbers for different requests.
Timestamp	String	Yes	The timestamp of the request. Specify the time in the ISO 8601 standard in the yyyy-MM-ddTHH:mm:ssZ format. The time must be in UTC. Sample value: 2018-01-01T12:00:00Z.
Format	String	Yes	The format in which to return the response. Set the value to JSON.

Note

The `Signature`, `SignatureMethod`, `SignatureVersion`, `SignatureNonce`, `Timestamp`, and `Format` parameters are encapsulated into Apsara Stack SDK. You do not need to configure these parameters.

5.1.2.1.4. SDK description

5.1.2.1.4.1. Use Apsara Stack SDK for Java to call API operations

This topic describes how to obtain and use Apsara Stack SDK for Java to call API operations.

Prerequisites

- An authorized account and an AccessKey pair are obtained. The AccessKey pair consists of an

AccessKey ID and an AccessKey secret. For more information about how to obtain an AccessKey pair in the Apsara Uni-manager Management Console, see Obtain an AccessKey pair.

- The endpoint of the Apsara Stack API (ASAPI) is obtained. For more information, see Generate an endpoint for the ASAPI.
- Apsara Stack SDK for Java 1.8 or later is installed.

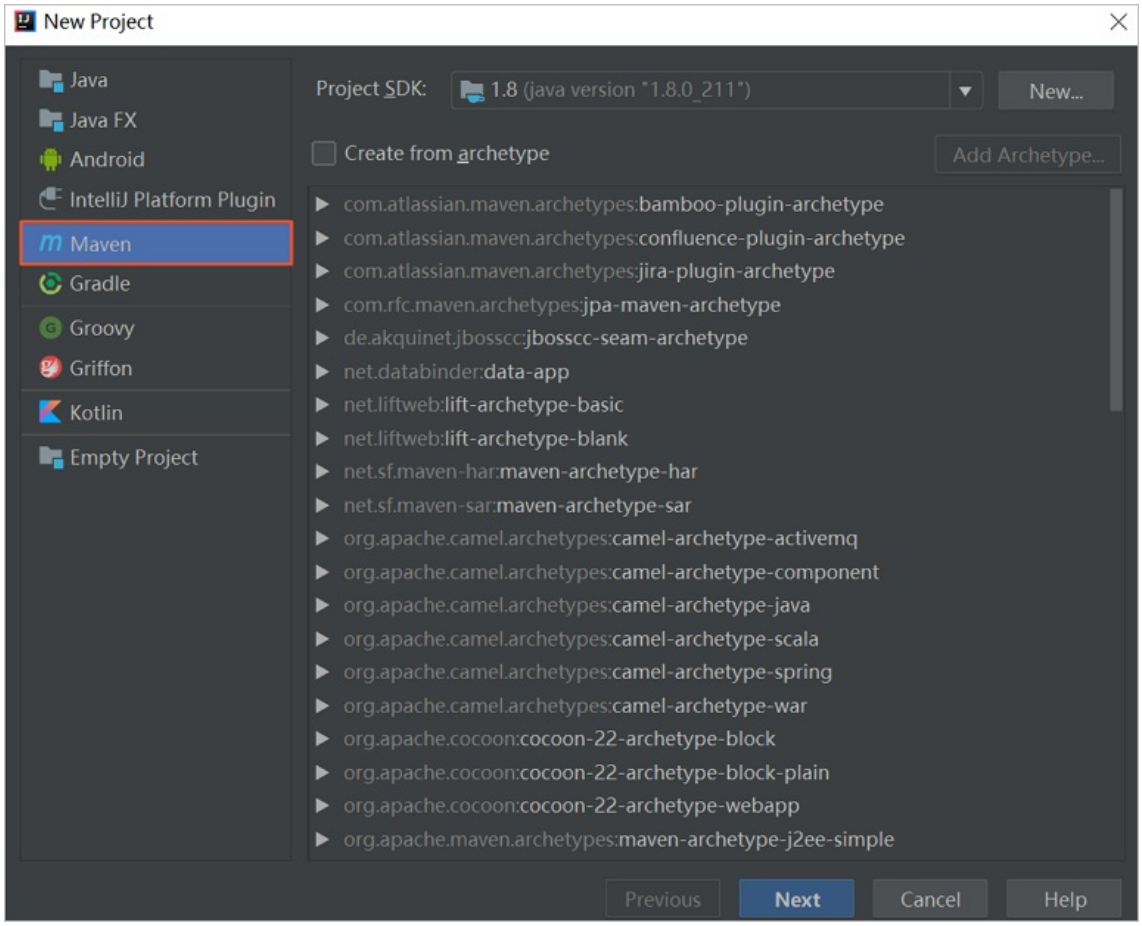
Background information

The help center of Apsara Stack provides Maven dependencies and JAR files for Apsara Stack SDK for Java. You can write code to use Apsara Stack SDK for Java to call API operations.

In this example, the Windows 10 64-bit OS and IntelliJ IDEA are used.

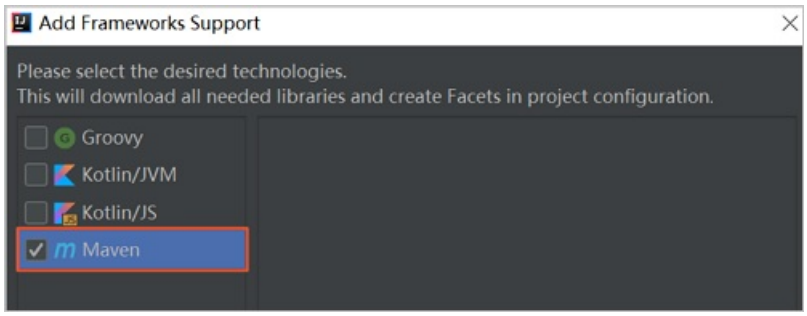
Procedure

1. Use one of the following methods to configure Maven in IntelliJ IDEA. Maven is a tool used for project management.
   - Use Maven that is integrated in IntelliJ IDEA.
   - Download Maven based on the OS that you are using from the official website and configure Maven. For more information, see Download Maven.
2. Obtain the Maven dependencies for Apsara Stack SDK for Java from the official website. For more information about how to obtain the dependencies, see Obtain the core package for ASAPI.
3. Use one of the following methods to create a Maven project:
   - Method 1: Create a Maven project in IntelliJ IDEA.

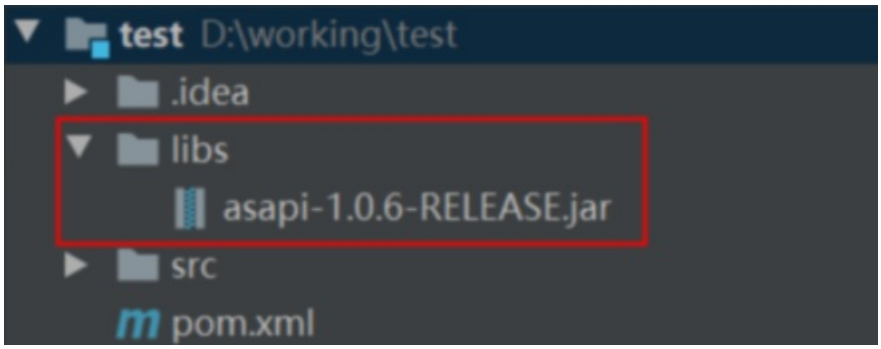


- Method 2: Convert an existing project to a Maven project.
  a. Right-click the project that you want to convert and select **Add Framework Support...**.

  b. Select **Maven** and click **OK**.



4. Create a folder named libs in the root directory of the project. Then, add the JAR file of Apsara Stack SDK for Java to the libs folder, as shown in the following figure.



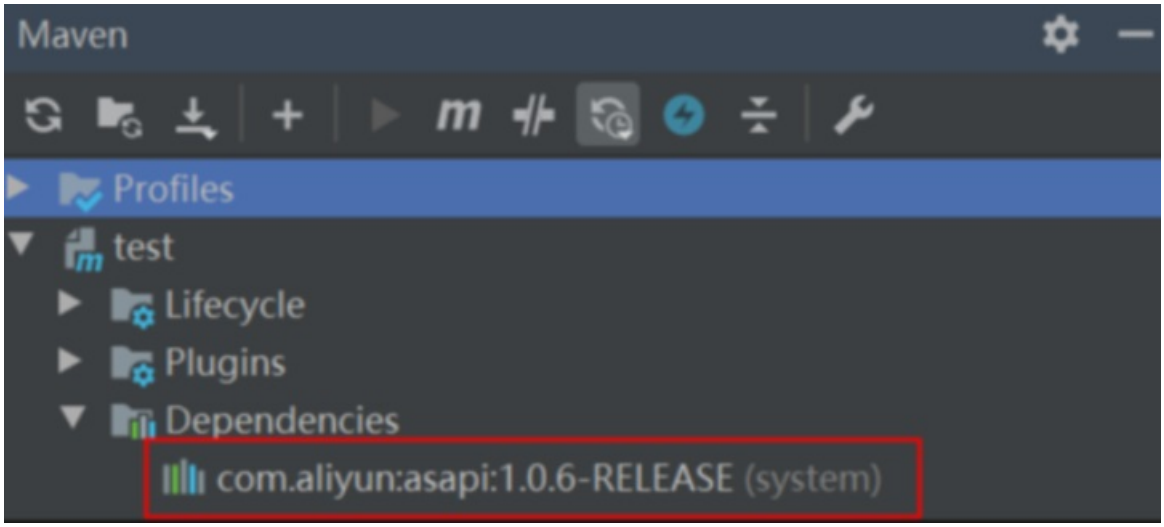
5. Add the dependencies of Apsara Stack SDK for Java to the pom.xml file in the project directory.

```
<dependencies>
    <dependency>
        <groupId>com.aliyun</groupId>
        <artifactId>asapi</artifactId>
        <version>1.0.6-RELEASE</version>
        <scope>system</scope>
        <systemPath>${project.basedir}/libs/asapi-1.0.6-RELEASE.jar</systemPath>
    </dependency>
  <dependency>
        <groupId>com.alibaba</groupId>
        <artifactId>alicrypto-java-aliyun</artifactId>
    <version>1.0.4</version>
    <systemPath>${project.basedir}/libs/alicrypto-java-aliyun-1.0.4.jar</systemPath>
  </dependency>
  <dependency>
    <groupId>com.aliyun</groupId>
    <artifactId>gmsse</artifactId>
    <version>1.1.0</version>
    <systemPath>${project.basedir}/libs/gmsse-1.1.0.jar</systemPath>
  </dependency>
</dependencies>
```

Note Replace `1.0.6-RELEASE` with the actual version of Apsara Stack SDK for Java.

6. On the right side of IntelliJ IDEA, view information in the Maven section.

   If the information in the following figure appears, the dependencies are added.



Use Apsara Stack SDK for Java

You can use the GET or POST method to call API operations provided by the ASAPI. The following sample code shows how to call API operations:

```
// 1. Create a connection to an ASClient object.
ASClient client = new ASClient();
// 2. Configure the identifier of the requester. This parameter is required and used only for identification. You can set this parameter to a random value.
client.setSdkSource("<The identifier of the requester>");
Map<String, Object> parameters = new HashMap<String, Object>();
// 3. Configure the parameters for authorization. The parameter values vary based on your environment.
// The AccessKey ID of your Apsara Stack tenant account.
parameters.put("AccessKeyId","<AccessKey ID>");
// The AccessKey secret of your Apsara Stack tenant account.
parameters.put("AccessKeySecret", "<AccessKey Secret>");
// The ID of the region.
parameters.put("RegionId", "<your RegionID>");
// 4. Configure parameters for an API call. In this example, the Product, Action, and Version parameters are configured.
parameters.put("Product", "<The name of the service>");
parameters.put("Action", "<The name of the API operation>");
parameters.put("Version", "<The version of the API operation>");
// 5. Configure operation-specific parameters.
parameters.put("<The name of the operation-specific parameter>", "<The value of the operation-specific parameter>");
// 6. Configure request headers and the encryption method for the signature string. Valid values of the SignatureMethod parameter: HMAC-SHA1 and HMAC-SHA256. By default, HMAC-SHA256 is used.
Map<String, String> headers = new HashMap<String, String>();
//headers.put("SignatureMethod", "HMAC-SHA1");
headers.put("x-acs-regionid", "<your-regionid>");
headers.put("x-acs-resourcegroupid", "<your-resourcegroupid>");
headers.put("x-acs-organizationid", "<your-organizationid>");
headers.put("x-acs-instanceid", "<your-instanceid>");
// 7. Make an API call. We recommend that you use the doPost() method.
// Configure the time-out period for a connection.
//client.setConnectTimeout(10000);
// Configure the time-out period for a request.
// client.setSocketTimeout(10000);
String result = client.doPost(endpoint, headers, parameters);
System.out.println(result);
```

Configure a proxy

If you need to use a proxy to make API calls, use the following sample code to configure the proxy:

```
Cloud cloud = new Cloud();
// Configure the IP address of the proxy.
cloud.setConfig("proxy_host", "<IP>");
// Configure the port used by the proxy.
cloud.setConfig("proxy_port", "<Port>");
// 1. Create a connection to an ASClient object.
ASClient client = new ASClient(cloud);
```

Request headers

Parameter	Description
x-acs-regionid	The ID of the region. For more information about how to obtain a region ID, see Query the region ID.
x-acs-organizationid	The ID of the organization in the Apsara Uni-manager Management Console.
x-acs-resourcegroupid	The ID of the resource set in the Apsara Uni-manager Management Console.
x-acs-instanceid	The ID of the instance to which you make API calls.

5.1.2.1.4.2. Use Apsara Stack SDK for Python to call API operations

This topic describes how to use Apsara Stack SDK for Python to call API operations provided by the Apsara Stack API (ASAPI).

Preparations

- An authorized account and an AccessKey pair are obtained. The AccessKey pair consists of an AccessKey ID and an AccessKey secret. For more information about how to obtain an AccessKey pair in the Apsara Uni-manager Management Console, see Obtain an AccessKey pair.
- The endpoint of the ASAPI is obtained. For more information, see Generate an endpoint for the ASAPI.

Install Apsara Stack SDK for Python

1. Download the required version of Apsara Stack SDK for Python. For more information, see Obtain Apsara Stack SDKs.
2. Upload the compressed file of Apsara Stack SDK for Python to the host from which you want to send API requests and extract the file. Then, run the following code in the directory of the extracted files to install Apsara Stack SDK for Python:

```
# Install Apsara Stack SDK for Python 2.x.
pip install aliyun-python2-sdk-asapi-2.4.7.tar.gz
# Install Apsara Stack SDK for Python 3.x.
pip3 install aliyun-python3-sdk-asapi-2.4.7.tar.gz
```

> **Note**
>
> Replace `2.4.7` with the actual version of Apsara Stack SDK for Python.

Sample requests

You can use the GET or POST method to call API operations provided by the ASAPI.

```
    # 1. Import dependencies.
    from aliyunsdkasapi.ASClient import ASClient
    from aliyunsdkasapi.AsapiRequest import AsapiRequest

    if __name__ == '__main__':
     # 2. Create a request. The Product parameter specifies the name of the service. The Ver
sion parameter specifies the version of the API operation. The Action parameter specifies t
he operation that you want to perform. The asapi-endpoint parameter specifies the endpoint
of the ASAPI.
     req = AsapiRequest("<Product>", "<Version>", "<Action>", "<asapi-endpoint>")
     # 3. Configure operation-specific parameters.
     req.add_body_params("<key>", "<value>")
     # 4. Configure request headers.
     req.add_header("x-acs-resourcegroupid", "<your-resourcegroupid>");
     req.add_header("x-acs-organizationid", "<your-organizationid>");
     req.add_header("x-acs-regionid", "<your-regionid>");
     req.add_header("x-acs-instanceid", "<your-instanceid>");
     # 5. Configure a request method.
     req.set_method("POST")
     # 6. Configure initialization parameters for an ASClient object. The parameter values v
ary based on your environment. The timeout parameter specifies the time-out period for a re
quest. The cert_file parameter specifies the certificate. The verify parameter specifies wh
ether to verify the certificate.
     as_client = ASClient("<accesskeyid>", "<accesskeysecret>", "<regionid>",timeout=1000,
             cert_file=None,
             verify=False)
     # Configure the identifier of the requester. This parameter is required and used only f
or identification. You can set this parameter to a random value.
     as_client.setSdkSource("<The identifier of the requester>")
     response = as_client.do_request(req)
     print(response)
```

Request headers

Parameter	Description
x-acs-resourcegroupid	The ID of the resource set in the Apsara Uni-manager Management Console.
x-acs-organizationid	The ID of the organization in the Apsara Uni-manager Management Console.
x-acs-regionid	The ID of the region. For more information about how to obtain a region ID, see Query a region ID.
x-acs-instanceid	The ID of the instance to which you make API calls.

Configure a proxy

Perform the following steps to configure a proxy:

1. Import OS dependencies.

```
import os
```

2. Configure one or more proxies.

```
# Before you make an API call, configure one or more proxies.
os.environ['http_proxy'] = "http://x.x.x.x:xxxx"
os.environ['https_proxy'] = "https://x.x.x.x:xxxx"
```

5.1.2.1.4.3. Use Apsara Stack SDK for Node.js to call API operations

This topic describes how to obtain and use Apsara Stack SDK for Node.js to call API operations.

Preparations

- An authorized account and an AccessKey pair are obtained. The AccessKey pair consists of an AccessKey ID and an AccessKey secret. For more information about how to obtain an AccessKey pair in the Apsara Uni-manager Management Console, see Obtain an AccessKey pair.
- The endpoint of the Apsara Stack API (ASAPI) is obtained. For more information, see Generate an endpoint for the ASAPI.
- A region ID is obtained. For more information about how to obtain a region ID, see Query the region ID.

Add dependencies

Run the following command to install Apsara Stack SDK for Node.js:

```
tnpm install --save @ali/asapi-nodejs-sdk
```

Use Apsara Stack SDK for Node.js

The following sample code shows how to use Apsara Stack SDK for Node.js to make API calls:

```
// 1. Import the dependencies of Apsara Stack SDK for Node.js.
const Controller = require('egg').Controller;
const ASAPIClient = require('@ali/asapi-nodejs-sdk');
// 2. Configure the parameters.
const cnofig = {
    API_GATEWAY: '<The endpoint of the ASAPI>',
    regionId: '<The ID of the region in which the Apsara Stack service is deployed>',
    accessKeyId: '<The AccessKey ID of your Apsara Stack tenant account>',
    accessKeySecret: '<The AccessKey secret of your Apsara Stack tenant account>'
};
// 3. Initialize a client for API calls.
const AsapiClient = new ASAPIClient(cnofig, this.ctx);
// 4. Configure request parameters.
const params = {
    "Action": "<The name of the API operation>",
    "Product": "<The name of the service that provides the API operation>",
    "Version": "<The version of the API operation>",
    "regionId": '<The ID of the region in which the Apsara Stack service is deployed>',
      "<The name of the operation-specific parameter required by the API operation>": "<The
value of the operation-specific parameter>"
}
// 5. Configure request headers.
AsapiClient.addHeader('x-acs-caller-sdk-source', '<The identifier of the requester>')
AsapiClient.addHeader('x-acs-roleid', '<The ID of the role>')
AsapiClient.addHeader('x-acs-userid', '<The ID of the user>')
AsapiClient.addHeader('x-acs-organizationid', '<your-organizationid>')
AsapiClient.addHeadert("x-acs-regionid", "<your-regionid>");
AsapiClient.addHeader("x-acs-resourcegroupid", "<your-resourcegroupid>");
AsapiClient.addHeader("x-acs-instanceid", "<your-instanceid>");
// 6. Make an API call and obtain the response.
try {
  const res = await AsapiClient.doRequest(cnofig.API_GATEWAY, params, {
    method: 'POST', // The request method.
    formatParams: false, // Specifies whether to format parameters and capitalize the first
letter of each parameter.
    enableProxy: true, // Specifies whether to configure a proxy.
    proxy: 'http://x.x.x.x:xxxx',
    timeout: 10000, // The time-out period.
  // ca: , // The certificate issued by a certificate authority (CA). For more information,
visit https://nodejs.org/api/https.html#https_https_request_options_callback.
  })
  console.log(res)
} catch (e) {
  console.log(e)
}
```

Disable certificate validation

The following sample code shows how to disable certificate validation:

```
Configure the environment variable.
NODE_TLS_REJECT_UNAUTHORIZED=0
```

Request headers

Parameter	Description
x-acs-regionid	The ID of the region. For more information about how to obtain a region ID, see Query the region ID.
x-acs-organizationid	The ID of the organization in the Apsara Uni-manager Management Console.
x-acs-resourcegroupid	The ID of the resource set in the Apsara Uni-manager Management Console.
x-acs-instanceid	The ID of the instance to which you make API calls.
x-acs-caller-sdk-source	The custom name of the requester or the system. This parameter is used to identify the source of the API request.
x-acs-roleid	The ID of the role.
x-acs-userid	The ID of the user.

5.1.2.1.4.4. SDK for POP

SDK for Java

Before you use Apsara Stack API (ASAPI) SDK for POP for Java to access ASAPI, you must know the remote procedure call (RPC) and resource-oriented architecture (ROA) styles that are supported for API calls. ASAPI is compatible with both styles. Their difference lies in the ASAPI endpoints that are used for API calls.

Prerequisites

- An Alibaba Cloud SDK package is downloaded for the service that you want to access. The required dependencies are installed.
- SSL certificate validation is ignored for requests over HTTPS.

Background information

ASAPI supports only the HTTPS request protocol.

Difference between two styles

When you use the RPC or ROA style to make API calls, take note that the two styles use different ASAPI endpoints.

```
# ASAPI endpoint for the RPC style:
public.asapi.<global:region>.<global:internet-domain>/asapi/v3
# ASAPI endpoint for the ROA style:
public.asapi.<global:region>.<global:internet-domain>/asapi/v3/roa
```

Call examples

The following sample code provides an example on how to use the RPC style to make an API call. In this example, the DescribeInstances operation of Elastic Compute Service (ECS) is called, and the API version is 2014-05-26.

Sample code:

```
package com.aliyuns.client.pop.ecs;

import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.ecs.model.v20140526.DescribeInstancesRequest;
import com.aliyuncs.ecs.model.v20140526.DescribeInstancesResponse;
import com.aliyuncs.http.HttpClientConfig;
import com.aliyuncs.http.ProtocolType;
import com.aliyuncs.profile.DefaultProfile;

import java.util.List;

public class DescribeInstancesTest {
    public static void main(String[] args) {
        // Specify the endpoint of ASAPI.
        String endpoint = "public.asapi.<global:region>.<global:internet-domain>/asapi/v3";
        // Specify the region where the ECS service resides.
        String region = "<global:region>";
        // Specify the name of the service that you want to access.
        String product = "ECS";
        // Specify your AccessKey pair.
        String ak = "<accessKeyId>";
        String sk = "<accessKeySecret>";
        try {
            DefaultProfile clientProfile = DefaultProfile.getProfile(region, ak, sk);
            // Ignore SSL certificate validation.
            HttpClientConfig clientConfig = HttpClientConfig.getDefault();
            clientConfig.setIgnoreSSLCerts(true);
            // Set the connection timeout period.
            clientConfig.setConnectionTimeoutMillis(3000L);
            // Set the read timeout period.
            clientConfig.setReadTimeoutMillis(10000L);
            clientProfile.setHttpClientConfig(clientConfig);
            // Create a connection.
            DefaultAcsClient acsClient = new DefaultAcsClient(clientProfile);
            // Create a request.
            DescribeInstancesRequest request = new DescribeInstancesRequest();
            // Specify the endpoint of ASAPI.
            request.setSysEndpoint(endpoint);
            // Specify the name of the service that you want to access and the region where
the service resides.
            request.setSysLocationProduct(product);
            request.setSysRegionId(region);
            // Set the request protocol to HTTPS.
            request.setSysProtocol(ProtocolType.HTTPS);
            DescribeInstancesResponse result =  acsClient.getAcsResponse(request);
            List<DescribeInstancesResponse.Instance> instances = result.getInstances();
            for (DescribeInstancesResponse.Instance instance: instances) {
                System.out.println(instance.getInstanceId());
                System.out.println(instance.getInstanceName());
```

```
            }

        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

The following sample code provides an example on how to use the ROA style to make an API call. In this example, the GetNamespaceList operation of Container Registry is called, and the API version is 2016-06-07.

Sample code:

```
package com.aliyuns.client.pop.cr;

import com.aliyuncs.CommonRequest;
import com.aliyuncs.CommonResponse;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.http.FormatType;
import com.aliyuncs.http.HttpClientConfig;
import com.aliyuncs.http.MethodType;
import com.aliyuncs.http.ProtocolType;
import com.aliyuncs.profile.DefaultProfile;

public class GetNamespaceListTest {
    public static void main(String[] args) {
        // Specify the endpoint of ASAPI.
        String endpoint = "public.asapi.<global:region>.<global:internet-domain>/asapi/v3/roa";
        // Specify the region where the Container Registry service resides.
        String region = "<global:region>";
        // Specify the name of the service that you want to access.
        String product = "cr";
        // Specify your AccessKey pair.
        String ak = "<accessKeyId>";
        String sk = "<accessKeySecret>";
        DefaultProfile profile = DefaultProfile.getProfile(region, ak, sk);
        // Ignore SSL certificate validation.
        HttpClientConfig clientConfig = HttpClientConfig.getDefault();
        clientConfig.setIgnoreSSLCerts(true);
        // Set the connection timeout period.
        clientConfig.setConnectionTimeoutMillis(3000L);
        // Set the read timeout period.
        clientConfig.setReadTimeoutMillis(10000L);
        profile.setHttpClientConfig(clientConfig);
        // Create a connection for the client.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create a request.
        CommonRequest request = new CommonRequest();
        // Set the request protocol to HTTPS.
```

```
        request.setSysProtocol(ProtocolType.HTTPS);
        // Specify the request method.
        request.setSysMethod(MethodType.GET);
        // Specify the endpoint of ASAPI.
        request.setSysDomain(endpoint);
        // Specify the version of the API.
        request.setSysVersion("2016-06-07");
        // Specify the pattern of the uniform resource identifier (URI).
        request.setSysUriPattern("/namespace");
        // Specify the name of the service that you want to access and the region where the
service resides.
        request.setSysLocationProduct(product);

        request.putHeadParameter("Content-Type", "application/json");
        String requestBody = "" +
                "{}";
        request.setHttpContent(requestBody.getBytes(), "utf-8", FormatType.JSON);
        try {
            CommonResponse response = client.getCommonResponse(request);
            System.out.println(response.getData());
        } catch (ServerException e) {
            e.printStackTrace();
        } catch (ClientException e) {
            e.printStackTrace();
        }
    }
}
```

> **Notice**
>
> If you send a request over HTTPS, you must enable the request to ignore SSL certificate validation.

SDK for Go

This topic describes how to use Apsara Stack API (ASAPI) SDK for POP for Go.

Prerequisites

An Alibaba Cloud SDK package is downloaded for the service that you want to access. The required dependencies are installed.

Background information

Only the remote procedure call (RPC) style is supported for API calls.

Call examples

The following sample code provides an example on how to make an API call. In this example, the DescribeInstances operation of Elastic Compute Service (ECS) is called, and the API version is 2014-05-26.

Sample code:

```
package main
```

```
import (
 "fmt"
 "time"

 "github.com/aliyun/alibaba-cloud-sdk-go/sdk"
 "github.com/aliyun/alibaba-cloud-sdk-go/sdk/auth/credentials"
 "github.com/aliyun/alibaba-cloud-sdk-go/sdk/requests"
 "github.com/aliyun/alibaba-cloud-sdk-go/sdk/responses"
)

func getSdkConfig() *sdk.Config {
 return sdk.NewConfig().
  WithTimeout(time.Duration(30) * time.Second).
  WithEnableAsync(true).
  WithGoRoutinePoolSize(100).
  WithMaxTaskQueueSize(10000).
  WithDebug(false).
  WithScheme("HTTP")
}

func main(){
 ak := "<The AccessKey ID of your Apsara Stack tenant account.>"
 sk := "<The AccessKey secret of your Apsara Stack tenant account.>"
 regionId := "<The region where the ECS service resides.>"
 endpoint := "<The endpoint of ASAPI.>" // No network protocol.
 request := requests.NewCommonRequest()
  request.SetReadTimeout(10 * time.Second) // Set the read timeout period of the request to
10 seconds.
  request.SetConnectTimeout(5 * time.Second)  // Set the connection timeout period of the r
equest to 5 seconds.
 request.Method = requests.GET
 request.Domain = endpoint         // Location Service will not be enabled if the host is s
pecified. For example, the service with a certification type-bearer token must be specified
.
 request.Version = "2014-05-26"            // Specify the version of the API.
 request.Scheme = "https"                // Specify the request protocol. Default value: ht
tp.
 request.ApiName = "DescribeInstances"
 request.QueryParams["Product"] = "Ecs"  // Specify the name of the service that you want t
o access.
 request.TransToAcsRequest()
 client, err := sdk.NewClientWithOptions(regionId,getSdkConfig(),credentials.NewAccessKeyCr
edential(ak,sk))
 // If relevant parameters are not set for the request, the client settings are used.
  //client.SetReadTimeout(10 * time.Second)              // Set the read timeout period of
the client to 10 seconds.
 //client.SetConnectTimeout(5 * time.Second)            // Set the connection timeout perio
d of the client to 5 seconds.
  resp := responses.BaseResponse{}
  err = client.DoAction(request, &resp)
    if err != nil {
        panic(err)
    }
 fmt.Print(endpoint)
```

```
}
```

Configure proxies

You can configure proxies in one of the following ways:

- Configure proxies by using environment variables.

  Set the HTTP_PROXY and HTTPS_PROXY environment variables, or set the NO_PROXY environment variable.

  Sample code:

```
import (
    "os"
)
func main(){
 os.Setenv("HTTP_PROXY", "http://x.x.x.x:xxxx") // Set the HTTP_PROXY environment variable.
 os.Setenv("HTTPS_PROXY", "https://x.x.x.x:xxxx") // Set the HTTPS_PROXY environment variable.
}
```

- Configure proxies on the client.

  Sample code:

```
// The proxies that are configured on the client take precedence over those that are configured by using environment variables.
client.SetHttpProxy("http://x.x.x.x:xxxx")    // Configure the HTTP proxy.
client.GetHttpProxy()                           // Query the HTTP proxy.

client.SetHttpsProxy("https://x.x.x.x:xxxx")    // Configure the HTTPS proxy.
client.GetHttpsProxy()                            // Query the HTTPS proxy.

client.SetNoProxy("127.0.0.1,localhost")      // Configure the proxy whitelist.
client.GetNoProxy()                           // Query the proxy whitelist.
```

SDK for Python

This topic describes how to use Apsara Stack API (ASAPI) SDK for POP for Python.

Prerequisites

An Alibaba Cloud SDK package is downloaded for the service that you want to access. The required dependencies are installed.

Background information

Only the remote procedure call (RPC) style is supported for API calls.

Call examples

The following sample code provides an example on how to make an API call. In this example, the DescribeInstances operation of Elastic Compute Service (ECS) is called, and the API version is 2014-05-26.

Sample code:

```
from aliyunsdkcore.client import AcsClient
from aliyunsdkcore.acs_exception.exceptions import ClientException
from aliyunsdkcore.acs_exception.exceptions import ServerException
from aliyunsdkecs.request.v20140526 import DescribeInstancesRequest
import os

# Create an AcsClient instance.
client = AcsClient(
   "<your-access-key-id>",
   "<your-access-key-secret>",
   "<your-region-id>",

   timeout=1000,  # Set the timeout period.
    verify=False, # Ignore certificate validation. or verify='<The location where the certi
ficate is stored.>'
);
# Set the following parameters for the HTTPS request protocol:
# client.set_verify(False)
# os.environ["HTTPS_PROXY"] = "http://127.0.0.1:8080"

# os.environ["HTTP_PROXY"] = "http://127.0.0.1:8080"
def hello_ecs_instance():
    # Create a request and set the parameters.
    request = DescribeInstancesRequest.DescribeInstancesRequest()

    params = {"PageNumber":"1", "Product":"Ecs","Version": "2014-05-26","Action": "Describe
Instances"};
    request.set_body_params(params)
    # The endpoint that contains no network protocol is in the following format: ASAPI doma
in name/asapi/v3.
    request.set_endpoint('<The endpoint of ASAPI.>')
    # Set the following parameter if the endpoint contains no network protocol:
    request.set_protocol_type("https")

    request.set_PageSize(10)
    # Initiate the API request and obtain the response.
    response = client.do_action_with_exception(request)
    print(response)

if __name__ == '__main__':
    print("Hello Aliyun OpenApi!")
    hello_ecs_instance()
```

Configure proxies

Set the HTTP_PROXY and HTTPS_PROXY environment variables.

Sample code:

```
# Configure the HTTPS proxy.
os.environ["HTTPS_PROXY"] = "http://x.x.x.x:xxxx"

# Configure the HTTP proxy.
os.environ["HTTP_PROXY"] = "https://x.x.x.x:xxxx"
```

5.1.2.1.5. HTTP requests

5.1.2.1.5.1. Overview

This topic describes how to make API requests and is intended for users who use API URLs to initiate HTTP GET requests.

If you are using an SDK to initiate requests, you can skip this topic.

The request URL consists of different parameters and has a fixed syntax. The URL contains common request parameters, your signature, and operation-specific parameters. Sample request URLs are provided for each API operation. These URLs are not encoded to make them easy to read. Before you make a request, you must encode the request URL. After the authentication process is complete based on your signature, the results are returned to you. Response parameters are returned if the call is successful, whereas an error message is returned if the call fails. You can troubleshoot issues based on the error message.

5.1.2.1.5.2. Request syntax

The Apsara Stack API (ASAPI) allows you to call API operations by sending HTTP GET requests based on URLs. Each URL must include request parameters. This topic describes the syntax of HTTP GET requests and provides the endpoint of the ASAPI.

Sample request

GetOrganizationList is used in the following unencoded URL request:

```
https://public.asapi.aliyuns.com/asapi/v3?Action=GetOrganizationList&Product=ascm&Version=2019-05-10&Id=<Organization ID>&<Common parameters>
```

- `https`: the protocol used to transmit the request.
- `public.asapi.aliyuns.com/asapi/v3`: the endpoint of the ASAPI.
- `Action=GetOrganizationList Product=ascm Version=2019-05-10`: the API operation to call.
- `Id`: the ID of the organization.
- `<Common parameters>`: the common parameters specified in the system.

Protocol

The ASAPI supports only HTTPS.

Endpoint

For more information about how to obtain an endpoint, see Generate an endpoint for the ASAPI.

Parameter

To specify an API operation, use the `Action, Product, and Version` parameters. For example, set `Action` to GetOrganizationList, Product to ascm, and Version to 2019-05-10. You must also specify other operation-specific parameters and common parameters. For more information, see Common parameters.

5.1.2.1.5.3. Request signatures

This topic describes how to sign HTTP API requests. ASAPI uses the request signature to verify the identity of the request sender. ASAPI implements symmetric encryption by using an AccessKey pair to verify the identity of the request sender.

> **Note**
>
> - An AccessKey pair consists of an AccessKey ID and an AccessKey secret, which are issued to each user or organization in the Apsara Uni-manager Management Console.
> - The AccessKey ID is used to verify identities of users, and the AccessKey secret is used to encrypt and verify signature strings. You must keep your AccessKey secret confidential.
> - ASAPI provides SDKs for Node.js, Python, and Java to facilitate complex signature calculation. For more information, see Obtain the core package for ASAPI.

Step 1: Create a canonicalized query string

1. Arrange the request parameters in alphabetical order, including all common and operation-specific parameters except the `Signature` parameter.

   > **Note**
   >
   > If you use the GET method to send a request,these parameters are connected by ampersands (&) and included in the request URL. The first request parameter follows a question mark (?).

2. Encode the request parameters and their values in UTF-8 based on RFC 3986. The following rules apply in the encoding process:
   - Letters, digits, and special characters such as hyphens (`-`), underscores (`_`), and periods (`.`) do not need to be encoded.
   - Other characters must be percent encoded in the `%XY` format. `XY` represents the ASCII code of the characters in hexadecimal notation. For example, double quotation marks (`"`) are encoded as `%22` .

- Extended UTF-8 characters are encoded in the `%XY%ZA...` format.
- Spaces must be encoded as `%20`. Do not encode spaces as plus signs (`+`).

  This encoding method is similar to but different from the `application/x-www-form-urlencoded` MIME encoding algorithm.

  If you use `java.net.URLEncoder` from the Java standard library, use `percentEncode` to encode request parameters and their values. In the encoded query string, replace the plus signs (`+`) with `%20` , asterisks (`*`) with `%2A` , and `%7E` with tildes (`~`). This way, you can obtain an encoded string that matches the preceding encoding rules.

```
private static final String ENCODING = "UTF-8";
private static String percentEncode(String value) throws UnsupportedEncodingException
{
    return value != null ? URLEncoder.encode(value, ENCODING).replace("+", "%20").rep
lace("*", "%2A").replace("%7E", "~") : null;
}
```

3. Use equal signs (`=`) to connect the encoded request parameters and their values.
4. Use ampersands (`&`) to connect the encoded request parameters. These parameters must be arranged in the same order as those in Step 1.

Then, a canonicalized query string that follows the request structure is obtained. For more information, see Request structure.

Step 2: Create a string-to-sign

1. Create a `string-to-sign` . You can also use `percentEncode` to encode the canonicalized query string created in Step 1 based on the following rules:

```
StringToSign=
    HTTPMethod + "&" + //HTTPMethod: the HTTP method that is used to send a request, su
ch as GET.
    percentEncode("/") + "&" + //percentEncode("/"): Encode the forward slash (/) in UT
F-8 as %2F.
    percentEncode(CanonicalizedQueryString) // Encode the canonicalized query string cr
eated in Step 1.
```

2. Calculate the RFC 2104-compliant HMAC-SHA1 or HMAC-256 value of `StringToSign` . In the following example, Java Base64 is used:

```
String signature = Base64.getEncoder().encodeToString(signData);
```

> **Note**
>
> When you calculate the signature, the key value specified by RFC 2104 is your `AccessKey secret` plus an ampersand (&), which has an ASCII value of 38. For more information, see Obtain an AccessKey pair.

3. Encode the `Signature` parameter based on RFC 3986 and add it to the canonicalized query string.

Example 1: Concatenate parameters

`GetOrganizationList` is used in this example to query regions. For example, `AccessKeyID` is set to testid and `AccessKeySecret` is set to testsecret. Perform the following operations:

1. Construct a canonicalized query string.

```
https://public.asapi.aliyuns.com/asapi/v3/?AccessKeyId=testid&Action=GetOrganizationList&Format=JSON&Id=1&Product=ascm&RegionId=cn-region-test&SignatureMethod=HMAC-SHA1&SignatureNonce=43967c6e-e3ad-44fa-b06b-fcf3db5f39d2&SignatureVersion=1.0&Timestamp=2020-09-15T08%3A50%3A40Z&Version=2019-05-10
```

2. Create a `string-to-sign` .

```
GET&%2F&AccessKeyId%3Dtestid%26Action%3DGetOrganizationList%26Format%3DJSON%26Id%3D1%26Product%3Dascm%26RegionId%3Dcn-region-test%26SignatureMethod%3DHMAC-SHA1%26SignatureNonce%3D43967c6e-e3ad-44fa-b06b-fcf3db5f39d2%26SignatureVersion%3D1.0%26Timestamp%3D2020-09-15T08%253A50%253A40Z%26Version%3D2019-05-10
```

3. Calculate the signature.

   Calculate the signature. The key value used for calculation is `testsecret&` because `AccessKeySecret` is set to testsecret. The calculated signature is `OLeaidS1JvxuMvnyHOwuJ+uX5qY=` . Java Base64 is used in the following sample code:

   `String signature = Base64.getEncoder().encodeToString(signData);` Encode `Signature=hvqv9Ll5RE6kQ4YsQXFAf9VuRIY=` based on RFC 3986 and add it to the canonicalized query string.

```
https://public.asapi.aliyuns.com/asapi/v3/?AccessKeyId=testid&Action=GetOrganizationList&Format=JSON&Id=1&Product=ascm&RegionId=cn-region-test&SignatureMethod=HMAC-SHA1&SignatureNonce=43967c6e-e3ad-44fa-b06b-fcf3db5f39d2&SignatureVersion=1.0&Timestamp=2020-09-15T08%3A50%3A40Z&Version=2019-05-10
```

You can use browsers or tools such as cURL and Wget to initiate an HTTP request for calling the `DescribeRegions` operation to query the Alibaba Cloud region list.

Example 2: Use the standard library of the programming language

`GetOrganizationList` is used in this example to query regions. For example, `AccessKeyID` is set to testid, `AccessKeySecret` is set to testsecret, and all request parameters are stored in a Java `Map<String, String>` object.

1. Predefine an encoding method.

```
private static final String ENCODING = "UTF-8";
private static String percentEncode(String value) throws UnsupportedEncodingException {
        return value != null ? URLEncoder.encode(value, ENCODING).replace("+", "%20").r
eplace("*", "%2A").replace("%7E", "~") : null;
}
```

2. Predefine the time format for the `Timestamp` parameter. Specify the `Timestamp` parameter in the ISO 8601 format. The time must be in UTC+0.

```
private static final String ISO8601_DATE_FORMAT = "yyyy-MM-dd'T'HH:mm:ss'Z'";
private static String formatIso8601Date(Date date) {
    SimpleDateFormat df = new SimpleDateFormat(ISO8601_DATE_FORMAT);
    df.setTimeZone(new SimpleTimeZone(0, "GMT"));
    return df.format(date);
}
```

3. Create a request string.

```
final String HTTP_METHOD = "GET";
Map parameters = new HashMap();
// Specify request parameters.
parameters.put("Product", "ascm");
parameters.put("Action", "GetOrganizationList");
parameters.put("Version", "2019-05-10");
parameters.put("AccessKeyId", "testid");
parameters.put("RegionId", "cn-region-test");
parameters.put("Timestamp", formatIso8601Date(new Date()));
parameters.put("SignatureMethod", "HMAC-SHA1");
parameters.put("SignatureVersion", "1.0");
parameters.put("SignatureNonce", UUID.randomUUID().toString());
parameters.put("Format", "JSON");
parameters.put("Id", "1");
// Arrange request parameters.
String[] sortedKeys = parameters.keySet().toArray(new String[]{});
Arrays.sort(sortedKeys);
final String SEPARATOR = "&";
// Create a string-to-sign.
StringBuilder stringToSign = new StringBuilder();
stringToSign.append(HTTP_METHOD).append(SEPARATOR);
stringToSign.append(percentEncode("/")).append(SEPARATOR);
StringBuilder canonicalizedQueryString = new StringBuilder();
for(String key : sortedKeys) {
    // Encode the key and the value.
    canonicalizedQueryString.append("&")
    .append(percentEncode(key)).append("=")
    .append(percentEncode(parameters.get(key)));
}
//Encode the canonicalized query string.
stringToSign.append(percentEncode(
canonicalizedQueryString.toString().substring(1)));
```

4. The signature. The key value used for calculation is `testsecret&` because `AccessKeySecret` is set to testsecret. The calculated signature is `OLeaidS1JvxuMvnyHOwuJ%2BuX5qY%3D`.

```
// The following sample code shows how to calculate the signature:
final String ALGORITHM = "HmacSHA1";
final String ENCODING = "UTF-8";
key = "testsecret&";
Mac mac = Mac.getInstance(ALGORITHM);
mac.init(new SecretKeySpec(key.getBytes(ENCODING), ALGORITHM));
byte[] signData = mac.doFinal(stringToSign.getBytes(ENCODING));
String signature = Base64.getEncoder().encodeToString(signData);
```

Encode the Signature parameter based on RFC 3986 and add it to the canonicalized query string. The following URL is obtained:

```
https://public.asapi.aliyuns.com/asapi/v3/?AccessKeyId=testid&Action=GetOrganizationLis
t&Format=JSON&Id=1&Product=ascm&RegionId=cn-region-test&SignatureMethod=HMAC-SHA1&Signa
tureNonce=43967c6e-e3ad-44fa-b06b-fcf3db5f39d2&SignatureVersion=1.0&Timestamp=2020-09-1
5T08%3A50%3A40Z&Version=2019-05-10
```

5. Use browsers or tools such as cURL and Wget to initiate an HTTP request.

5.1.2.1.5.4. Response

Responses are returned only in the JSON format. If a return code is greater than or equal to 200 and less than 300, a success response is returned. Otherwise, an error response is returned.

Sample success response

If a request is successful, the request ID and operation-specific parameter values are returned. For more information, see the developer guide of the corresponding Apsara Stack service.

```
 {
    "eagleEyeTraceId": "xxx-xxx-xxx-xxx", // The trace ID provided by EagleEye.
    "asapiSuccess": true,
    "RequestId": "xxxxxxxxxx",
    "Regions": { // The regions returned after you call the DescribeRegions operation.
        "Region": [
            {
                "RegionId": "",
                "RegionEndpoint": "",
                "LocalName": ""
            }
        ]
    }
}
```

Sample error response

If a request fails, the following information is returned. For more information, see the developer guide of the corresponding Apsara Stack service.

```
{
    "code": "asapi.server.api.notfound",// The error code.
    "eagleEyeTraceId": "xxx-xxx-xxx-xxx", // The trace ID provided by EagleEye.
    "asapiSuccess": false, // Indicates whether the request is successful.
    "hostId": "xxxx", // The ID of the host.
    "message": "Failed to ....", // The message returned.
    "asapiErrorMessage": "Failed to ....", // The error message provided by the ASAPI.
    "asapiErrorCode": "asapi.server.api.notfound" // The error code provided by the ASAPI.
}
```

6.Object Storage Service (OSS)

6.1. Developer Guide

6.1.1. OSS API

6.1.1.1. Overview

Apsara Stack Object Storage Service (OSS) is a secure, cost-effective, and highly reliable cloud storage service. It enables you to store a large amount of data in the cloud. You can upload data to and download data from OSS anytime, anywhere, and on any Internet device by calling the simple RESTful APIs. OSS enables you to develop a variety of services that are capable of processing large amounts of data. These services include multimedia sharing websites, online storage, and personal and corporate data backups.

> **Note** Before you call these operations, ensure that you understand the OSS service instructions and usage agreements.

Instructions

OSS API reference provides request syntax, parameters, sample requests, and sample responses for operations. To implement secondary development, use SDK packages. For more information about how to install and use SDK, see OSS SDK reference.

Terms

Term	Description
bucket	The container used to store objects in OSS. Every object is contained in a bucket.
object	Objects are the basic unit for data operations in OSS. Objects are also known as files. Each object has metadata, data, and a key. A key can uniquely identify an object in a bucket.
endpoint	The domain name used to access OSS. OSS uses HTTP RESTful APIs to provide services. Different regions are accessed by using different endpoints. A region has different endpoints for access over the internal network and for access over the Internet. For more information, see Obtain an endpoint.
AccessKey	The access credential that is used to identify the requester. An AccessKey pair consists of an AccessKey ID and an AccessKey secret. The AccessKey ID is used to verify the identity of the user, while the AccessKey secret is used to encrypt and verify the signature string. You must keep your AccessKey secret confidential. For more information, see Obtain an AccessKey pair.

6.1.1.2. Access control

6.1.1.2.1. Authenticate users by using signatures

OSS uses an AccessKey pair, which includes an AccessKey ID and an AccessKey secret to implement symmetric encryption and verify the identity of a requester. The AccessKey ID is used to verify the identity of the user, while the AccessKey secret is used to encrypt and verify the signature string. You must keep your AccessKey secret confidential.

> **Note** For more information about how to obtain an AccessKey pair, see Obtain an AccessKey pair.

AccessKey pairs can be categorized based on the account types.

- AccessKey pair of an Alibaba Cloud account: The AccessKey pair of an Alibaba Cloud account has full permissions on its resources.
- AccessKey pair of a RAM user: A RAM user is created and authorized by an Alibaba Cloud account. The AccessKey pair of a RAM user has limited permissions on specified resources.
- AccessKey pair of an STS temporary access credential: A temporary access credential is generated by an Alibaba Cloud account or a RAM user. The AccessKey pair of a temporary credential has limited permissions on specified resources within the validity period of the credential. An STS temporary access credential becomes invalid after its validity period is exceeded.

Before you send a request to OSS as an individual user, you must generate a signature string in the specified format for the request and use your AccessKey secret to encrypt the signature string and generate a verification code. After OSS receives the request, OSS finds the AccessKey secret based on your AccessKey ID, and uses the AccessKey secret to decrypt the signature string and verification code. Then, OSS calculates a verification code and compares it against the decrypted verification code. If the two verification codes are the same, OSS determines that the request is valid. Otherwise, OSS rejects the request and returns HTTP status code 403.

6.1.1.2.2. Add signatures to the Authorization header

You can include the Authorization header in the HTTP request to carry signature information and indicate that the requester has been authorized.

Calculation of the Authorization header

```
Authorization = "OSS " + AccessKeyId + ":" + Signature
Signature = base64(hmac-sha1(AccessKeySecret,
 VERB + "\n"
 + Content-MD5 + "\n"
 + Content-Type + "\n"
 + Date + "\n"
 + CanonicalizedOSSHeaders
 + CanonicalizedResource))
```

- `AccessKeySecret`: the key required for a signature.
- `VERB`: the HTTP request method such as PUT, GET, POST, HEAD, or DELETE.

- `\n`: the line break.
- `Content-MD5`: optional. This parameter specifies the Content-MD5 value of the message content (excluding headers). The value is obtained by calculating the 128-bit hash value and then encoding the value in Base64. This request header can be used for the message validity check. The message content is valid if the received message content is the same as the content that is sent. Example: eB5eJF1ptWaXm4bijSPyxw==. For more information, visit RFC 2616 Content-MD5.
- `Content-Type`: optional. This parameter specifies the type of the requested content. Example: application/octet-stream.
- `Date`: the time when the request is sent. The time must be in GMT. Example: Sun, 22 Nov 2015 08:16:38 GMT.
- `CanonicalizedOSSHeaders`: the HTTP headers in alphabetical order. The prefix of the HTTP headers is x-oss-.
- `CanonicalizedResource`: the OSS resource you want to access.

Specifically, the values of Date and CanonicalizedResource are required. If the difference between the time on the client when the request is sent and the time on the server when the request is received is greater than 15 minutes, the OSS server rejects the request and returns HTTP status code 403.

Create CanonicalizedOSSHeaders

All HTTP headers whose prefixes are x-oss- are called canonicalized OSS headers. Process of creating canonicalized OSS headers:

1. The names of all HTTP request headers whose prefixes are x-oss- must be in lowercase letters. For example, `X-OSS-Meta-Name: TaoBao` is converted to `x-oss-meta-name: TaoBao`.
2. If the request is sent by using the AccessKey ID and AccessKey secret obtained by using STS, you must add the obtained security-token value to the signature string in the `x-oss-security-token:security-token` format.
3. Sort all obtained HTTP request headers in alphabetical order.
4. Delete any space on either side of a delimiter between the request header and content. For example, `x-oss-meta-name: TaoBao` is converted to `x-oss-meta-name:TaoBao`.
5. Separate all content and headers with the (`\n`) delimiter to form the final canonicalized OSS headers.

> **Note**
> - CanonicalizedOSSHeaders is optional. The (`\n`) delimiter at the end can be removed.
> - To create only one canonicalized OSS header, add the (`\n`) delimiter to the end of the header. Example: `x-oss-meta-a\n`.
> - To create multiple canonicalized OSS headers, add the (`\n`) delimiter to the end of each header. Example: `x-oss-meta-a:a\nx-oss-meta-b:b\nx-oss-meta-c:c\n`.

Create CanonicalizedResource

Destination OSS resources specified in the request sent by the user is called canonicalized resources. Process of creating canonicalized resources:

1. Set CanonicalizedResource to empty character string ("").

2. Specify the OSS resource you want to access in the following format: `/BucketName/ObjectName`. Set CanonicalizedResource to `/BucketName/` to access a bucket or to the forward slash (`/`) delimiter to access OSS.
3. If the requested resource contains subresources, sort all subresources in alphabetical order and separate them with the ampersand (`&`) delimiter. The question mark (`?`) and subresource string are added to the end of the CanonicalizedResource string. In this case, CanonicalizedResource is in the format of `/BucketName/ObjectName? acl&uploadId=UploadId`
4. If query strings (also called HTTP request parameters) are specified in the request, sort these query strings and request values in alphabetical order. Separate each pair of parameters and values with the ampersand (`&`) delimiter. Add the concatenated content to CanonicalizedResource as parameters. In this case, CanonicalizedResource is in the format of `/BucketName/ObjectName? acl&response-content-type=ContentType&uploadId=UploadId`.

> **Note**
>
> - Subresources supported by OSS include but are not limited to: acl, uploads, location, cors, logging, website, referer, lifecycle, delete, append, tagging, objectMeta, uploadId, partNumber, security-token, position, img, style, styleName, replication, replicationProgress, replicationLocation, cname, bucketInfo, comp, qos, live, status, vod, startTime, endTime, symlink, x-oss-process, response-content-type, response-content-language, response-expires, response-cache-control, response-content-disposition, and response-content-encoding.
> - Three types of subresources are available:
>   - Resource identifiers such as acl, append, uploadId, and symlink subresources
>   - Subresources that specify the response header fields. Example: `response-***`.
>   - Methods to process objects. Example: `x-oss-process`.

Rules to calculate signatures for the Authorization header

1. A signature string must be in the UTF-8 format. A signature string that contains Chinese characters must be encoded in UTF-8. The encoded signature string is used together with AccessKeySecret to calculate the final signature.
2. The HMAC-SHA1 method defined in RFC 2104 is used to calculate the final signature. In this method, the Key is `AccessKeySecret`.
3. Content-Type and Content-MD5 are optional in a request. If the request requires signature verification, the null value must be replaced with a line break (`\n`).
4. Among all non-standard HTTP headers, only headers that start with `x-oss-` require signature strings. Other non-standard HTTP headers are ignored by OSS. For example, the x-oss-magic header in the preceding example requires a signature string.
5. Headers that start with `x-oss-` must comply with the following conventions before signature verification:
   - The header names must be in lowercase.
   - The headers are sorted in alphabetical order.
   - No spaces exist on either side of a colon (:) between the header name and value.
   - Each header is followed by a line break (`\n`). If no headers are used, `CanonicalizedOSSHeader`

`s` is set to null.

Examples

Assume that the AccessKey ID is `4***7`, and the AccessKey secret is `O***V`.

Signature examples

Request	Signature string calculation formula	Signature string
`PUT /nelson HTTP/1.0 Content-MD5: eB5eJF1ptWaXm4bijSPyxw== Content-Type: text/html Date: Thu, 17 Nov 2005 18:49:58 GMT Host: oss-example.regionid.example.com X-OSS-Meta-Author: ***@bar.com X-OSS-Magic: a***a`	`Signature = base64(hmac-sha1(AccessKeySecret,VERB + "\n" + Content-MD5 + "\n"+ Content-Type + "\n" + Date + "\n" + CanonicalizedOSSHeaders+ CanonicalizedResource))`	`"PUT\n ***w==\n text/html\n Thu, 17 Nov 2005 18:49:58 GMT\n x-oss-magic:a***a\nx-oss-meta-author:***@bar.com\n/oss-example/nelson"`

An example of the signature calculation method:

```
import base64
import hmac
import sha
h = hmac.new("O***V",
 "PUT\n***M=\ntext/html\nThu, 17 Nov 2005 18:49:58 GMT\nx-oss-magic:abracadabra\nx-oss-meta
-author:***@bar.com\n/oss-example/nelson", sha)
Signature = base64.b64encode(h.digest())
print("Signature: %s" % Signature)
```

The signature calculation result must be 2***A= based on Authorization = "OSS" + AccessKeyId + ":" + Signature. Authorization that consists of OSS 4***7:2***A= and the Authorization header is sent:

```
PUT /nelson HTTP/1.0
Authorization:OSS 4***7:2***A=
Content-Md5: e***w==
Content-Type: text/html
Date: Thu, 17 Nov 2005 18:49:58 GMT
Host: oss-example.regionid.example.com
X-OSS-Meta-Author: ***@bar.com
X-OSS-Magic: a***a
```

Detail analysis

- If the imported AccessKey ID does not exist or is inactive, 403 Forbidden is returned. Error code: InvalidAccessKeyId.
- If the Authorization value format in the request header is incorrect, 400 Bad Request is returned. Error code: InvalidArgument.
- All OSS requests must use GMT stipulated in HTTP/1.1. The date format is `date1 = 2DIGIT SP month`

`SP 4DIGIT; day month year`. Example. 02 Jun 1982. In this format, day uses two digits. Therefore, Jun 2, 2 Jun 1982, and 2-Jun-1982 are all invalid formats.

- If no date is entered or the date is in the invalid format during signature verification, 403 Forbidden is returned. Error code: AccessDenied.
- The difference between the time on the client when the request is sent and the time on the server when the request is received must be within 15 minutes. Otherwise, 403 Forbidden is returned. Error code: RequestTimeTooSkewed.
- If the AccessKey ID is active but OSS determines that the signature of the request is invalid, 403 Forbidden is returned. The correct signature string for verification and encryption is returned in the response. You can check whether the signature string is valid based on the response of OSS. Sample response:

```
<? xml version="1.0" ? >
<Error>
 <Code>
 SignatureDoesNotMatch
 </Code>
 <Message>
 The request signature we calculated does not match the signature you provided. Check your
key and signing method.
 </Message>
 <StringToSignBytes>

Wed, 11 May 2011 07:59:25 GMT
/oss-example? acl
 </StringToSign>
 <OSSAccessKeyId>
 A***Q
 </OSSAccessKeyId>
</Error>
```

OSS SDK automatically implements signatures in your requests. You do not need to manually calculate your signature when you use OSS SDK. For more information about the signature implementation for specific programming languages, see the OSS SDK code. The following table describes the sample code used to implement signatures in various SDKs. Sample code used to implement signatures in various SDKs

SDK	Signature implementation
Java SDK	OSSRequestSigner.java
Python SDK	auth.py
.Net SDK	OssRequestSigner.cs
PHP SDK	OssClient.php
C SDK	oss_auth.c
JavaScript SDK	client.js
Go SDK	auth.go
Ruby SDK	util.rb
iOS SDK	OSSModel.m
Android SDK	OSSUtils.java

FAQ

Example: Calculate the Content-MD5 value of message content "123456789". Correct method:

1. Calculate the 128-bit MD5 hash.
2. Encode the 128-bit MD5 hash (but not the 32-bit string) in Base64.

Python is used in this example. Correct calculation code:

```
>>> import base64,hashlib
>>> hash = hashlib.md5()
>>> hash.update("0123456789")
>>> base64.b64encode(hash.digest())
'eB5eJF1ptWaXm4bijSPyxw=='
```

Note that you must use hash.digest() to calculate the 128-bit MD5 hash.

```
>>> hash.digest()
'x\x1e^$]i\xb5f\x97\x9b\x86\xe2\x8d#\xf2\xc7'
```

A common incorrect method is to directly encode the 32-bit string in Base64. Example: Call the hash.hexdigest() function to obtain a printable 32-bit string.

```
>>> hash.hexdigest()
'781e5e245d69b566979b86e28d23f2c7'
```

Result of encoding the incorrect MD5 value in Base64:

```
>>> base64.b64encode(hash.hexdigest())
'NzgxZTVlMjQ1ZDY5YjU2Njk3OWI4NmUyOGQyM2YyYzc='
```

6.1.1.2.3. Generate a signed URL

In addition to using an Authorization field in the header, you can also add signature information to a URL so that you can forward the URL to a third party for authorized access.

Implementation

- The following code provides an example on how to generate a signed URL:

```
http://oss-example.regionid.example.com/oss-api.pdf?
AccessKeyId=AccessKeyId&Expires=1141889120&Signature=vjb***%3D
```

- A signed URL must include at least the following parameters: Signature, Expires, and AccessKeyId.
  - `Expires` specifies the timeout time of the URL. The value of this parameter follows the UNIX time format and must be in UTC. The value is the number of seconds that have elapsed since 00:00:00 Thursday, 1 January 1970. If the time OSS receives the URL request is later than the value of Expires that is included in the signature, a request timeout error code is returned. For example, the current time is 1141889060. To create a URL that is scheduled to expire in 60 seconds, you can set the value of Expires to 1141889120.
  - `AccessKeyId` specifies the AccessKey ID in the AccessKey pair.
  - `Signature` specifies the signature information. For all requests and header fields that OSS supports, the algorithm of signing the string for a URL is basically the same as that of signing the string for a header.

    ```
    Signature = urlencode(base64(hmac-sha1(AccessKeySecret,
     VERB + "\n"
     + CONTENT-MD5 + "\n"
     + CONTENT-TYPE + "\n"
     + EXPIRES + "\n"
     + CanonicalizedOSSHeaders
     + CanonicalizedResource)))
    ```

    The following differences are listed:

    - When a signed URL is generated, the Expires parameter replaces the Date parameter.
    - Signatures cannot be included in a URL and a header at the same time.
    - If more than one Signature, Expires, or AccessKeyId value is imported, the first imported value is used.
    - Before OSS authenticates a request by using a signature, OSS checks the request time to determine whether it is later than the time specified in Expires.
    - When you add a signature string to a URL, you must encode the URL.
  - When you add a signature to a URL for temporary access, you must include `security-token`. Format:

    ```
    http://oss-example.regionid.example.com/oss-api.pdf?
    AccessKeyId=AccessKeyId&Expires=1141889120&Signature=vjb***%3D&security-token=SecurityToken
    ```

Sample code

The following code provides an example on how to add a signature to a URL in Python:

```
import base64
import hmac
import sha
import urllib
h = hmac.new("O***V",
 "GET\n\n\n1141889120\n/oss-example/oss-api.pdf",
 sha)
urllib.quote (base64.encodestring(h.digest()).strip())
```

OSS SDK provides methods for adding a signature to a URL. For more information, see the "Authorized access" topic in SDK documents. The following table describes the implementation of a signed URL for OSS SDK.

URL signature implementation files for OSS SDK

SDK	URL signature method	Implementation file
Java SDK	OSSClient.generatePresignedUrl	OSSClient.java
Python SDK	Bucket.sign_url	api.py
.Net SDK	OssClient.GeneratePresignedUri	OssClient.cs
PHP SDK	OssClient.signUrl	OssClient.php
JavaScript SDK	signatureUrl	object.js
C SDK	oss_gen_signed_url	oss_object.c

Detail analysis

- If you adopt the approach of generating a signed URL, the authorized data is exposed on the Internet before the authorization period is exceeded. We recommend that you assess the use risks in advance.
- You can add a signature to a URL in PUT and GET requests.
- When a signature is added to a URL, the sequence of the Signature, Expires, and AccessKeyId parameters can be swapped. If one or more of the Signature, Expires, and AccessKeyId parameters are missing, 403 Forbidden is returned. Error code: AccessDenied.
- If the current access time is later than the Expires value that is set in the request or the time format is invalid, 403 Forbidden is returned. Error code: AccessDenied.
- If a URL includes one or more of the Signature, Expires, and AccessKeyId parameters and the header includes signature information, 400 Bad Request is returned. Error code: InvalidArgument.
- When the signature string is generated, Date is replaced by Expires, but the headers such as content-type and content-md5 defined in the preceding section are still included. (Although Date still exists in the request header, you do not need to add Date to the signature string.)

6.1.1.2.4. Authorize temporary access

OSS allows you to use STS to authorize temporary access. You can use STS to grant a third-party application or your RAM user an access credential that specifies the custom validity period and permissions.

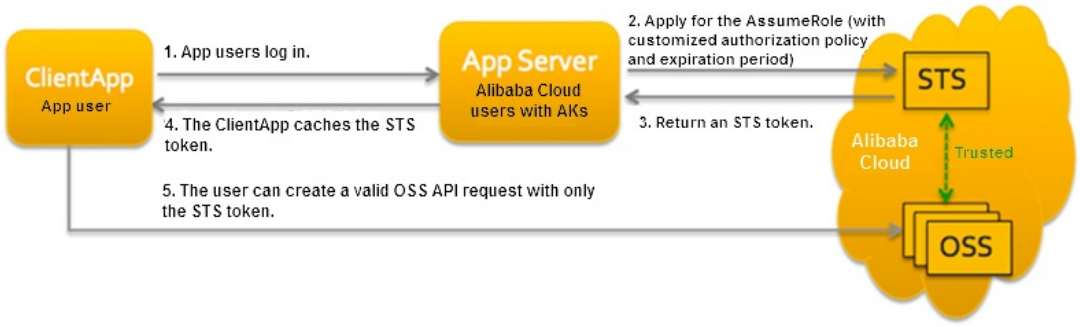
Introduction to STS

STS is a web service that provides temporary access tokens for cloud computing users. You can use STS to grant a third-party application or federated user (whose user ID is managed by yourself) an access credential with a custom validity period and permissions. The third-party application or federated user can use the access credential to directly call the operations provided by Alibaba Cloud services or use the Alibaba Cloud service SDKs to access the operations.

- You do not need to expose your long-term AccessKey pair to a third-party application. You need only to generate an access token and send it to the third-party application. You can customize the permissions and validity period of this token.
- The access token automatically becomes invalid when it expires.

The following figure uses an application as an example to show the authorization process.

Authorization process



Detailed solution description:

1. Log on as an application user. You can manage your application user ID. You can customize the ID management system or use an external web account or open ID. AppServer can define the principle of least privilege (POLP) of each valid application user.
2. AppServer requests a security token from STS. Before you call STS API operations, AppServer determines the POLP (described in policy syntax) of the app user and the validity period of the temporary security token. Then, AppServer calls the AssumeRole API operation of STS to obtain the security token. For more information about how to manage and use roles, see "Role management" in RAM User Guide.
3. STS returns a valid access credential to AppServer, including a security token, a temporary AccessKey pair (AccessKey ID and AccessKey secret), and the expiration time.
4. AppServer returns the access credential to ClientApp. ClientApp caches this credential. When the credential becomes invalid, ClientApp must request a new valid access credential from AppServer. For example, if the access credential is valid for one hour, ClientApp can request AppServer to update the access credential every 30 minutes.
5. ClientApp uses the cached access credential to call API operations provided by Alibaba Cloud services. Cloud services detect the STS access credential, verify the credential based on the STS service, and respond to the user request.

For more information about STS security tokens, see "Role management" in RAM User Guide. The key of the process is to call the AssumeRole operation of STS to obtain a valid access credential. You can also use STS SDK to call this API operation.

Use an STS credential to create a request that includes a signature

After the client of the user obtains an STS temporary credential, the client of the user uses the security token and temporary AccessKey pair (AccessKey ID and AccessKey secret) in the credential to create a signature. The method to create a signature for authorized access is the same as using the AccessKey pair of a root account to add a signature to the Authorization header. Take note of the following items:

- The signature key used by the user is the temporary AccessKey pair (AccessKey ID and AccessKey secret) that STS provides.
- The user needs to add the security token to the request header or in the URI as a request parameter. Only one of these two methods can be used. If both methods are selected, OSS returns InvalidArgument.
  - `x-oss-security-token:SecurityToken` is included in the request header. When CanonicalizedOSSHeaders of the signature is calculated, x-oss-security-token is taken into consideration.
  - security-token=SecurityToken is included in the URL. When CanonicalizedResource of the signature is calculated, security-token is taken into consideration as a subresource.

6.1.1.2.5. Bucket ACL

You can set the access control list (ACL) when you create a bucket, or modify the ACL for a created bucket. Only bucket owners can set or modify the ACL for buckets.

The following list describes the ACLs for buckets:

- Public read/write: Any users, including anonymous users can perform the PutObject, GetObject, and DeleteObject operations on the objects in the bucket. The bucket owner is charged for these operations. Exercise caution when you specify this ACL.
- Public read: Only the bucket owner can perform the PutObject and DeleteObject operations on the objects in the bucket. Other users, including anonymous users can perform only the GetObject operation on the objects in the bucket.
- Private: Only the bucket owner can perform the PutObject, GetObject, and DeleteObject operations on the objects in the bucket.

When you create a bucket, OSS sets the bucket ACL to private if you do not specify the bucket ACL. Only the bucket owner can call the PutBucketACL operation to modify the ACL of an existing bucket.

6.1.1.3. Common HTTP headers

This topic describes common request and response headers that are used for RESTful APIs.

Common request headers

In OSS, common HTTP request headers are used for RESTful APIs. These request headers can be used in all OSS requests. The following table lists the specific definitions of the request headers.

Common request headers

Header	Description

Header	Description
Authorization	The authentication information used to authenticate a request. Type: string Default value: null Scenario: non-anonymous requests
Content-Length	The content length of an HTTP request that is defined in RFC 2616. For more information, visit RFC 2616. Type: string Default value: null Scenario: requests that need to submit data to OSS
Content-Type	The content type of an HTTP request that is defined in RFC 2616. For more information, visit RFC 2616. Type: string Default value: null Scenario: requests that need to submit data to OSS
Date	The time in GMT stipulated in HTTP/ 1.1. Example: Wed, 05 Sep. 2012 23:00:00 GMT. Type: string Default value: null
Host	The value of the host to access. Format: `<bucketname>.regionid.example.com`. Type: string Default value: null

Common response headers

In OSS, common HTTP response headers are used for RESTful APIs. These response headers can be used in all the OSS requests. The following table lists the specific definitions of the response headers.

Common response headers

Header	Description
Content-Length	The content length of an HTTP request that is defined in RFC 2616. For more information, visit RFC 2616. Type: string Default value: null Scenario: requests that need to submit data to OSS

Header	Description
Connection	The connection status between the client and the OSS server. Type: enumeration Valid values: open and close Default value: null
Date	The time in GMT stipulated in HTTP/ 1.1. Example: Wed, 05 Sep. 2012 23:00:00 GMT. Type: string Default value: null
ETag	The entity tag (ETag) that is created to identify the content of the object when the object is created. If an object is created by using the PutObject request, the ETag value of the object is the MD5 hash of the object content. If an object is created by using another method, the ETag value of the content is the universally unique identifier (UUID) of the object content. The ETag value of the object can be used to check whether the object content is modified. Type: string Default value: null
Server	The server that generates a response. Type: string Default value: AliyunOSS
x-oss-request-id	The UUID that is created by the OSS server to identify the response. If you encounter any problems when you use OSS, you can contact OSS support personnel and provide this field to help them locate the problems. Type: string Default value: null

6.1.1.4. Service-relevant operations

6.1.1.4.1. GetService (ListBuckets)

You can call this operation to obtain all buckets that you own. The forward slash (/) in the request structure represents the root directory.

Usage notes

- The GetService operation is valid only for users who are authenticated.
- If no information for user authentication is provided in a request (anonymous access), OSS returns 403 Forbidden and error code AccessDenied.
- When all buckets are returned, the returned XML does not contain the Prefix, Marker, MaxKeys,

IsTruncated, and NextMarker nodes. If not all results are returned, the preceding nodes are added, in which NextMarker is used to assign the marker for the subsequent query.

Request structure

```
GET / HTTP/1.1
Host: oss.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request parameters

When you call GetService (ListBucket), you can set the parameters described in the following table to limit the list of buckets returned so that only specified results are returned.

Parameter	Type	Required	Example	Description
prefix	String	No	example	The prefix that the names of returned buckets must contain. If this parameter is not specified, prefix information is not used to filter the returned buckets.
marker	String	No	examplebucket	The name of the object after which the list begins. If this parameter is not specified, all results are returned.
max-keys	String	No	100	The maximum number of buckets that can be returned this time. Valid values: 1 to 1000 Default value: 100

Response parameters

Parameter	Type	Example	Description
ListAllMyBucketsResult	Container	N/A	The container that stores the result of the GetService (ListBucket) request.
Prefix	String	example	The prefix that the names of returned buckets contain. This node is available only when not all buckets are returned.

Parameter	Type	Example	Description
Marker	String	examplebucket	The name of the bucket after which the list begins. This node is available only when not all buckets are returned.
MaxKeys	String	1	The maximum number of returned buckets in the response. This node is available only when not all buckets are returned.
IsTruncated	Enumerated string	true	Indicates whether all results are returned. Valid values: • `true`: indicates that not all of the results are returned this time. • `false`: indicates that all of the results are returned this time. This node is available only when not all buckets are returned.
NextMarker	String	xz02tphky6fjfiuc0	The marker for the next GetService (ListBucket) request to return the remaining results. This node is available only when not all buckets are returned.
Owner	Container	N/A	The container that stores the information about the bucket owner.
ID	String	17464******02745	The user ID of the bucket owner.
DisplayName	String	17464******02745	The name of the bucket owner, which is the same as the user ID.
Buckets	Container	N/A	The container that stores the information about multiple buckets.
Bucket	Container	N/A	The container that stores the bucket information.
Name	String	examplebucket	The name of the bucket.
CreateDate	Date	2011-12-01T12:27:13.000Z	The time when the bucket was created. Format: `yyyy-mm-ddThh:mm:ss.timezone`.
Location	String	oss-cn-shenzhen	The data center in which the bucket is located.

Parameter	Type	Example	Description
ExtranetEndpoint	String	oss-cn-shenzhen.aliyuncs.com	The public endpoint of the bucket.
IntranetEndpoint	String	oss-cn-shenzhen-internal.aliyuncs.com	The internal endpoint of the bucket.

Examples

- Sample Request 1

```
GET / HTTP/1.1
Date: Thu, 15 May 2014 11:18:32 GMT
Host: regionid.example.com
Authorization: OSS n***i:C***I=
```

- Sample Response 1

```
HTTP/1.1 200 OK
Date: Thu, 15 May 2014 11:18:32 GMT
Content-Type: application/xml
Content-Length: 556
Connection: keep-alive
Server: AliyunOSS
x-oss-request-id: 5***4
<? xml version="1.0" encoding="UTF-8"? >
<ListAllMyBucketsResult>
 <Owner>
 <ID>17464******02745</ID>
 <DisplayName>17464******02745</DisplayName>
 </Owner>
 <Buckets>
 <Bucket>
 <CreationDate>2015-12-17T18:12:43.000Z</CreationDate>
 <ExtranetEndpoint>regionid.example.com</ExtranetEndpoint>
 <IntranetEndpoint>regionid-internal.example.com</IntranetEndpoint>
 <Location>oss-cn-shanghai</Location>
 <Name>app-base-oss</Name>
 </Bucket>
 <Bucket>
 <CreationDate>2014-12-25T11:21:04.000Z</CreationDate>
 <ExtranetEndpoint>regionid.example.com</ExtranetEndpoint>
 <IntranetEndpoint>regionid-internal.example.com</IntranetEndpoint>
 <Location>regionid</Location>
 <Name>examplebucket</Name>
 </Bucket>
 </Buckets>
</ListAllMyBucketsResult>
```

- Sample Request 2

```
GET /? prefix=xz02tphky6fjfiuc&max-keys=1 HTTP/1.1
Date: Thu, 15 May 2014 11:18:32 GMT
Host:  regionid.example.com
Authorization: OSS n***i:C***I=
```

- Sample Response 2

```
HTTP/1.1 200 OK
Date: Thu, 15 May 2014 11:18:32 GMT
Content-Type: application/xml
Content-Length: 545
Connection: keep-alive
Server: AliyunOSS
x-oss-request-id: 5***5
<? xml version="1.0" encoding="UTF-8"? >
<ListAllMyBucketsResult>
 <Prefix>xz02tphky6fjfiuc</Prefix>
 <Marker></Marker>
 <MaxKeys>1</MaxKeys>
 <IsTruncated>true</IsTruncated>
 <NextMarker>xz02tphky6fjfiuc0</NextMarker>
 <Owner>
 <ID>17464******02745</ID>
 <DisplayName>17464******02745</DisplayName>
 </Owner>
 <Buckets>
 <Bucket>
 <CreationDate>2014-05-15T11:18:32.000Z</CreationDate>
 <ExtranetEndpoint>regionid.example.com</ExtranetEndpoint>
 <IntranetEndpoint>oss-cn-hangzhou-internal.example.com</IntranetEndpoint>
 <Location>oss-cn-hangzhou</Location>
 <Name>examplebucket</Name>
 </Bucket>
 </Buckets>
</ListAllMyBucketsResult>
```

6.1.1.5. Bucket-relevant operations

6.1.1.5.1. PutBucket

You can call this operation to create a bucket. The region where the new bucket is located is consistent with the region in the endpoint that is contained in a request. After the data center of the bucket is determined, all objects in this bucket are stored in the corresponding region.

Request structure

```
PUT / HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
x-oss-acl: Permission
Authorization: SignatureValue
```

Usage notes

When you call the PutBucket operation, take note of the following items:

- Anonymous access is not supported.
- You can create up to 100 buckets in the same region by using an Alibaba Cloud account.

Request headers

Header	Type	Required	Example	Description
x-oss-acl	String	No	private	The access control list (ACL) for a bucket. Default value: private. Valid values: • *public-read-write* • *public-read* • *private*

For more information about other common request headers included in PutBucket requests, see Common request headers.

Request elements

Element	Type	Required	Example	Description
StorageClass	String	No	Standard	The storage class of the bucket. Default value: Standard. Valid storage: *Standard*

Response headers

The response headers involved in the PutBucket operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
PUT / HTTP/1.1
Host: BucketName.regionid.example.com
Date: Fri, 24 Feb 2012 03:15:40 GMT
x-oss-acl: private
Authorization: OSS qn6qrrqxo2oawuk53otfjbyc:77Dvh5wQgIjWjwO/KyRt8dOP****
<? xml version="1.0" encoding="UTF-8"? >
<CreateBucketConfiguration>
    <StorageClass>Standard</StorageClass>
</CreateBucketConfiguration>
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***B
Date: Fri, 24 Feb 2012 03:15:40 GMT
Location: /***
Content-Length: 0
Connection: keep-alive
Server: AliyunOSS
```

6.1.1.5.2. PutBucketACL

You can call this operation to modify the access control list (ACL) of a bucket.

Request structure

```
PUT /? acl HTTP/1.1
x-oss-acl: Permission
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Usage notes

When you call the PutBucketAcl operation, take note of the following items:

- To call this operation, you must have write permissions on the bucket.
- PutBucketAcl uses the overwriting semantics. A new ACL overwrites the existing one.
- If the specified bucket for which you want to set ACL does not exist when you call this operation, a new bucket is created.

Request headers

Header	Type	Required	Example	Description

Header	Type	Required	Example	Description
x-oss-acl	String	Yes	private	The ACL that you want to set for the bucket. This header is included in PutBucketAcl requests to set the ACL of the bucket. If this header is not included, the ACL settings do not take effect. Valid values: public-read-write, public-read, and private • public-read-write: Any users, including anonymous users can read and write objects in the bucket. Exercise caution when you set the ACL of a bucket to public-read-write. • public-read: Only the owner or authorized users of this bucket can write objects in the bucket. Other users, including anonymous users can only read objects in the bucket. Exercise caution when you set the ACL of a bucket to public-read. • private: Only the owner or authorized users of this bucket can read and write objects in the bucket. Other users, including anonymous users cannot access the objects in the bucket without authorization.

For more information about other common request headers involved in the PutBucketAcl operation, see Common request headers.

Response headers

For more information about other common response headers involved in the PutBucketAcl operation, see Common response headers.

Examples

Sample requests

```
PUT /? acl HTTP/1.1
x-oss-acl: public-read
Host: BucketName.regionid.example.com
Date: Fri, 24 Feb 2012 03:21:12 GMT
Authorization: OSS q***c:K***=
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***B
Date: Fri, 24 Feb 2012 03:21:12 GMT
Content-Length: 0
Connection: keep-alive
Server: AliyunOSS
```

If the specified ACL does not exist, OSS returns HTTP status code 400.

Sample error responses

```
HTTP/1.1 400 Bad Request
x-oss-request-id: 5***9
Date: Fri, 24 Feb 2012 03:55:00 GMT
Content-Length: 309
Content-Type: text/xml; charset=UTF-8
Connection: keep-alive
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<Error>
  <Code>InvalidArgument</Code>
  <Message>no such bucket access control exists</Message>
  <RequestId>5***9</RequestId>
  <HostId>***-test.example.com</HostId>
  <ArgumentName>x-oss-acl</ArgumentName>
  <ArgumentValue>error-acl</ArgumentValue>
</Error>
```

6.1.1.5.3. PutBucketLogging

Bucket owners can enable logging for their buckets. When this feature is enabled, OSS automatically records detailed information about the requests to this bucket, and follows the user-specified rules to write access logs as an object to the user-specified bucket on an hourly basis.

Notice OSS provides logging for bucket owners to understand and analyze access to buckets. OSS does not guarantee that the bucket access logs contain all access records.

Usage notes

- The source bucket to which an object belongs and the destination bucket where the processed object is stored must belong to the same user.
- To disable logging for a bucket, you need only to send a request that contains an empty BucketLoggingStatus element. For more information about the specific method, see the following sample request.
- All PutBucketLogging requests must include signatures. Anonymous access is not supported.
- When the source bucket is deleted, the corresponding logging rules are also deleted.
- OSS generates bucket access log objects on an hourly basis. However, requests in the previous hour may be recorded in the log object generated for the subsequent hour.
- In the naming conventions for log objects generated by the OSS, UniqueString is just a UUID that OSS

generates to uniquely identify the object.

- Each time OSS generates a bucket access log object, OSS performs a PUT operation and records the storage space that the object uses. However, OSS does not record the traffic generated by the PUT operation. After log objects are generated, you can perform operations on these objects as common objects.
- OSS ignores all query string parameters whose values contain the x- prefix. However, these parameters are recorded in access log objects. To identify a special request from a large number of access logs, you can add a query string parameter whose value contains the x- prefix to the URL of the request. Example
  - `http://oss-example.regionid.example.com/aliyun-logo.png`
  - `http://oss-example.regionid.example.com/aliyun-logo.png?x-user=admin`

  When OSS processes the preceding two requests, the results are the same. However, you can search for access logs by x-user=admin to locate the marked request.
- A hyphen (`-`) may be contained in any field in OSS logs. The hyphen (-) indicates that data is unknown or the field is invalid for the current request.
- More fields will be added to OSS logs. We recommend that developers consider potential compatibility issues when you develop log processing tools.

Request structure

```
PUT /? logging HTTP/1.1
Date: GMT Date
Content-Length: ContentLength
Content-Type: application/xml
Authorization: SignatureValue
Host: BucketName.regionid.example.com
<? xml version="1.0" encoding="UTF-8"? >
<BucketLoggingStatus>
 <LoggingEnabled>
 <TargetBucket>TargetBucket</TargetBucket>
 <TargetPrefix>TargetPrefix</TargetPrefix>
 </LoggingEnabled>
</BucketLoggingStatus>
```

Request elements

Element	Type	Required	Example	Description
BucketLoggingStatus	Container	Yes	N/A	The container that stores the logging status information.
LoggingEnabled	Container	No	N/A	The container that stores the access log information. This element is required only when logging is enabled.

Element	Type	Required	Example	Description
TargetBucket	String	This element is required when logging is enabled.	doc-log	The bucket that stores access logs.
TargetPrefix	String	No	MyLog-	The prefix of the access log object.

Response headers

Response headers involved in the PUTBucketLogging operation contain only common response headers. For more information, see Common response headers.

The name format of the object that stores access logs

```
<TargetPrefix><SourceBucket>-YYYY-mm-DD-HH-MM-SS-UniqueString
```

TargetPrefix is specified by the user. YYYY-mm-DD-HH-MM-SS indicates the time when an access log object is created. YYYY indicates the year (four-digit). mm indicates the month (two-digit). DD indicates the day (two-digit). HH indicates the hour (two-digit). MM indicates the minute (two-digit). SS indicates the second (two-digit). UniqueString indicates the string generated by OSS. An example for the name of an access log object:

```
MyLog-oss-example-2012-09-10-04-00-00-0000
```

In the preceding example, MyLog- is the object name prefix specified by the user. oss-example is the name of the source bucket. 2012-09-10-04-00-00 is the object creation time (UTC+8). 0000 is the string generated by OSS.

Log object format

Element	Example	Description
Remote IP	119.140.142.11	The IP address from which a request originates. The proxy or your firewall may block this field.
Reserved	N/A	A reserved field.
Reserved	N/A	A reserved field.
Time	[02/May/2012:00:00:04 +0800]	The time when OSS received a request.
Request-URI	"GET /aliyun-logo.png HTTP/1.1"	The requested URI, including query string parameters.
HTTP Status	200	The HTTP status code that OSS returned.

Element	Example	Description
SentBytes	5576	The traffic consumed when a user downloads logs from OSS.
RequestTime (ms)	71	The length of time in milliseconds used to complete the request.
Referer	http://www.aliyun.com/product/oss	The HTTP header that identifies the address of the web page which is linked to the resource being requested.
User-Agent	curl/7.15.5	The user-agent header in an HTTP request.
HostName	oss-example.regionid.example.com	The domain name that is requested.
Request ID	505B01695037C2AF032593A4	The UUID used to uniquely identify this request.
LoggingFlag	true	Indicates whether the access logging feature is enabled.
Requester Aliyun ID	1657136103983691	The Alibaba Cloud ID of the requester. The value of this field is a hyphen (`-`) for anonymous access.
Operation	GetObject	The type of a request.
Bucket	oss-example	The name of the bucket that you requested.
Key	/aliyun-logo.png	The key of the object that is requested.
ObjectSize	5576	The size of an object.
Server Cost Time (ms)	17	The length of time for the OSS server to process this request. Unit: milliseconds.
Error Code	NoSuchBucket	The error code that OSS returned.
Request Length	302	The length of the request. Unit: bytes.
UserID	1657136103983691	The ID of a bucket owner.
Delta DataSize	280	The variation of the size of a bucket. The value of this field is a hyphen (`-`) if the bucket size does not change.
Sync Request	-	Indicates whether the request is forwarded to the origin by using Content Delivery Network (CDN). The value of this field is a hyphen (`-`) if this is not a CDN back-to-origin request.
Reserved	-	A reserved field.

Examples

Sample requests where bucket logging is enabled:

```
PUT /? logging HTTP/1.1
Host: ***.regionid.example.com
Content-Length: 186
Date: Fri, 04 May 2012 03:21:12 GMT
Authorization: OSS q***c:K***=
<? xml version="1.0" encoding="UTF-8"? >
<BucketLoggingStatus>
<LoggingEnabled>
<TargetBucket>doc-log</TargetBucket>
<TargetPrefix>MyLog-</TargetPrefix>
</LoggingEnabled>
</BucketLoggingStatus>
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***B
Date: Fri, 04 May 2012 03:21:12 GMT
Content-Length: 0
Connection: keep-alive
Server: AliyunOSS
```

Sample requests where bucket logging is disabled:

```
PUT /? logging HTTP/1.1
Host: ***.regionid.example.com
Content-Type: application/xml
Content-Length: 86
Date: Fri, 04 May 2012 04:21:12 GMT
Authorization: OSS q***c:K***=
<? xml version="1.0" encoding="UTF-8"? >
<BucketLoggingStatus>
</BucketLoggingStatus>
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***B
Date: Fri, 04 May 2012 04:21:12 GMT
Content-Length: 0
Connection: keep-alive
Server: AliyunOSS
```

6.1.1.5.4. PutBucketWebsite

You can call this operation to set the static website hosting mode for a bucket.

Usage notes

- Static websites are the websites where all web pages consist of static content, such as scripts in JavaScript run on the client. OSS does not support content that needs to be processed by the server, such as PHP, JSP, and APS.NET content.
- After a bucket is set to the static website hosting mode, OSS returns the index page for anonymous access to the root domain name of the static website, and returns the result of GetBucket for signed access to the root domain name of the static website.

Request structure

```
PUT /? website HTTP/1.1
Date: GMT Date
Content-Length: ContentLength
Content-Type: application/xml
Host: BucketName.regionid.example.com
Authorization: SignatureValue
<? xml version="1.0" encoding="UTF-8"? >
<WebsiteConfiguration>
    <IndexDocument>
        <Suffix>index.html</Suffix>
    </IndexDocument>
    <ErrorDocument>
        <Key>errorDocument.html</Key>
    </ErrorDocument>
</WebsiteConfiguration>
```

Request parameters

- The following table describes the parameters that you can configure in the WebsiteConfiguration field in a request.

Parameter	Type	Required	Description
WebsiteConfiguration	Container	Yes	The root node. Parent nodes: none

- The following table describes the parameters that you can configure in the IndexDocument field in a request.

Element	Type	Required	Example	Description

Element	Type	Required	Example	Description
IndexDocument	Container	Conditional. You must specify at least one of the following containers: IndexDocument, ErrorDocument, and RoutingRules.	N/A	The container for the default homepage. Parent nodes: WebsiteConfiguration
Suffix	String	Conditional. This parameter must be specified if IndexDocument is specified.	index.html	The default homepage. If this parameter is set, the default homepage is returned for access to objects whose names end with a forward slash (/). Parent nodes: IndexDocument
SupportSubDir	String	No	false	Specifies whether a request sent to access a subfolder is redirected to the default homepage of the subfolder. Valid values: ◦ A value of true indicates that the request is redirected to the default homepage of the subfolder. ◦ A value of false indicates that the request is redirected to the default homepage of the root folder instead of that of the subfolder. If the default homepage for access to bucket.oss-cn-hangzhou.aliyuncs.com/subdir/ is set to index.html. A value of false indicates that the request is redirected to bucket.oss-cn-hangzhou.aliyuncs.com/index.html, and a value of true indicates that the request is redirected to bucket.oss-cn-hangzhou.aliyuncs.com/subdir/index.html. Default value: false Parent nodes: IndexDocument

Element	Type	Required	Example	Description
Type	Enumeration	No	0	Specifies the operation to perform when the default homepage is set, the name of the accessed object does not end with a forward slash (/), and the object does not exist. **Note** This parameter takes effect only when SupportSubDir is set to true. It takes effect after RoutingRule and before ErrorFile. If the default homepage for access to bucket.oss-cn-hangzhou.aliyuncs.com/abc is set to index.html and the abc object does not exist. The following content describes the operations that correspond to the valid values of Type: ◦ *0*: OSS checks whether the object named abc/index.html, which is in the `Object + Forward slash (/) + Homepage` format exists. If the object exists, OSS returns 302 and the Location header `/abc/`, which is in the `Forward slash (/) + Object + Forward slash (/)` format, in the response is URL-encoded. If the object does not exist, OSS returns 404 and continues to check ErrorFile. ◦ *1*: OSS returns 404 and NoSuchKey and continues to check ErrorFile. ◦ *2*: OSS checks whether abc/index.html exists. If abc/index.html exists, the content of the object is returned. If abc/index.html does not exist, OSS returns 404 and continues to check ErrorFile. Default value: 0 Parent nodes: IndexDocument

- The following table describes the parameters that you can configure in the ErrorDocument field in a request.

Parameter	Type	Required	Description
ErrorDocument	Container	Conditional. You must specify at least one of the following containers: IndexDocument, ErrorDocument, and RoutingRules.	The container used to store the default 404 page. Parent nodes: WebsiteConfiguration
Key	Container	Conditional. This parameter must be specified if ErrorDocument is specified.	The default 404 page. If this parameter is specified, the 404 page is returned when the target object does not exist. Parent nodes: ErrorDocument

- The following table describes RoutingRules, RoutingRule, and RuleNumber you can configure in a request.

Parameter	Type	Required	Example	Description
RoutingRules	Container	Conditional. You must specify at least one of the following containers: IndexDocument, ErrorDocument, and RoutingRules.	N/A	The container used to store RoutingRule. Parent nodes: WebsiteConfiguration
RoutingRule	Container	No	N/A	Specifies redirection-based back-to-origin rules or mirroring-based back-to-origin rules. You can specify a maximum of 20 rules. Parent nodes: RoutingRules
RuleNumber	String	Conditional. This parameter must be specified if RoutingRule is specified.	1	The sequence number used to match and execute redirection rules. Redirection rules are matched based on this parameter. If a match succeeds, the rule is executed and the subsequent rules are not executed. Parent nodes: RoutingRule

- The following table describes RoutingRules, RoutingRule, and Condition in a request.

Parameter	Type	Required	Example	Description
Condition	Container	Conditional. This parameter must be specified if RoutingRule is specified.	N/A	The matching conditions. If all of the specified conditions are met, the rule is executed. A rule is determined as matched only when the rule meets the conditions specified by all nodes in Condition. Parent nodes: RoutingRule
KeyPrefixEquals	String	No	abc/	Specifies that only objects whose names contain the specified prefix match the rule. Parent nodes: Condition
HttpErrorCodeReturnedEquals	HTTP status code	No	404	Specifies that the rule is matched only when the specified object is accessed and the specified status code is returned. If the redirection rule is a mirroring-based back-to-origin rule, the parameter value must be 404. Parent nodes: Condition
IncludeHeader	Container	No	N/A	Specifies that the rule is matched only when the specified header is included in the request and the header value is equal to the specified value. You can specify up to five headers. Parent nodes: Condition
Key	String	Conditional. This parameter must be specified if IncludeHeader is specified.	host	Specifies that the rule is matched only when the specified header is included in the request and the header value is equal to the value specified by Equals. Parent nodes: IncludeHeader
Equals	String	Conditional. This parameter must be specified if IncludeHeader is specified.	test.oss-cn-beijing-internal.aliyuncs.com	Specifies that the rule is matched only when the header specified by Key is included in the request and the header value is equal to the specified value. Parent nodes: IncludeHeader

Parameter	Type	Required	Example	Description
KeySuffixEquals	String	No	zip	Specifies that only objects whose names contain the specified suffix match the rule. The default value is null, which indicates that no suffix is specified. Parent nodes: Condition

- The following table describes RoutingRules, RoutingRule, and Redirect you can configure in a request.

Parameter	Type	Required	Example	Description
Redirect	Container	Conditional. This parameter must be specified if RoutingRule is specified.	N/A	The operation to perform after the rule is matched. Parent nodes: RoutingRule
RedirectType	String	Conditional. This parameter must be specified if Redirect is specified.	Mirror	The redirection type. Valid values: ◦ Mirror: mirroring-based back-to-origin ◦ External: external redirection. OSS returns the 3xx HTTP redirect code and the Location header for your to redirect the request to another IP address. ◦ Internal: internal redirection. OSS redirects the access from Object1 to Object2 based on the rule. In this case, the user accesses Object2 instead of Object1. ◦ AliCDN: redirection based on Alibaba Cloud CDN. OSS adds an additional header to the request, which is different from the External type. After CDN identifies the header, CDN redirects the access to the specified IP address and returns the obtained data instead of the redirect request to the user. Parent nodes: Redirect

Parameter	Type	Required	Example	Description
PassQueryString	Boolean	No	true	Specifies whether parameters in the original request are contained in the redirect request when redirection-based or mirroring-based back-to-origin is performed. For example, if the PassQueryString parameter is set to true and the `? a=b&c=d` parameter is contained in the request sent to OSS, this parameter is added to the Location header in the redirect request when the HTTP redirect code is 302. For example, if the request is `Location :www.test.com? a=b&c=d` and the redirecting type is mirroring-based back-to-origin, the ?a=b&c=d parameter is also contained in the back-to-origin request. Valid values: true and false Default value: false Parent nodes: Redirect
MirrorURL	String	Conditional. This parameter must be specified if RedirectType is set to Mirror.	http://www.example.com/	Specifies the IP address of the origin in mirroring-based back-to-origin. This parameter takes effect only when the value of RedirectType is Mirror. URLs that start with http:// or https:// must end with a forward slash (/). OSS adds the object name to the string to form the back-to-origin URL. For example, the object to access is myobject. If the specified URL is `http://www.example.com/`, the back-to-origin URL is `http://www.test.com/myobject`. If the specified URL is `http://www.test.com/dir1/`, the back-to-origin URL is `http://www.test.com/dir1/myobject`. Parent nodes: Redirect

Parameter	Type	Required	Example	Description
MirrorPassQueryString	Boolean	No	true	This parameter plays the same role as PassQueryString and has a higher priority than PassQueryString. This parameter takes effect only when the value of RedirectType is Mirror. Default value: false Parent nodes: Redirect
MirrorFollowRedirect	Boolean	No	true	Specifies whether the access is redirected to the specified Location if the origin returns a 3XX HTTP status code and when the origin receives a mirroring-based back-to-origin request. For example, when a mirroring-based back-to-origin request is initiated, the origin returns 302, and Location is specified. ◦ In this case, if the value of MirrorFollowRedirect is true, OSS continues to send requests to the IP address specified by Location. A request can be redirected for a maximum of 10 times. If a request is redirected for more than 10 times, a mirroring-based back-to-origin failure is returned. ◦ If the value of MirrorFollowRedirect is false, OSS returns 302 and passes through the Location. This parameter takes effect only when the value of RedirectType is Mirror. Default value: true Parent node: Redirect

Parameter	Type	Required	Example	Description
MirrorCheckMd5	Boolean	No	false	Specifies whether OSS checks the MD5 hash of the body of the response returned by the origin. When the value of this parameter is true and the response returned by the origin includes the Content-Md5 header, OSS checks whether the MD5 hash of the obtained data matches the header value. If the MD5 hash of the obtained data does not match the header value, OSS does not store the data. This parameter takes effect only when the value of RedirectType is Mirror. Default value: false Parent nodes: Redirect
MirrorHeaders	Container	No	N/A	Specifies the headers contained in the response that is returned when you use mirroring-based back-to-origin. This parameter takes effect only when the value of RedirectType is Mirror. Parent nodes: Redirect
PassAll	Boolean	No	true	Specifies whether OSS passes through all request headers ○ except for reserved headers and headers that start with oss-, x-oss-, and x-drs-, such as content-length, authorization2, authorization, range, and date ○ to the origin. This parameter takes effect only when the value of RedirectType is Mirror. Default value: false Parent nodes: MirrorHeaders

Parameter	Type	Required	Example	Description
Pass	String	No	myheader-key1	Specifies the headers to pass through to the origin. The header can be up to 1,024 bytes in length and can contain only letters, digits, and hyphens (-). This parameter takes effect only when the value of RedirectType is Mirror. You can specify up to 10 headers. Parent nodes: MirrorHeaders
Remove	String	No	myheader-key3	Specifies the headers that are not allowed to be passed through to the origin. The header can be up to 1,024 bytes in length. The character set of this parameter is the same as that of Pass. This parameter takes effect only when the value of RedirectType is Mirror. You can specify up to 10 headers. This parameter is used together with PassAll. Parent nodes: MirrorHeaders
Set	Container	No	N/A	Specifies the headers that are sent to the origin. The specified headers are configured in the data returned by the origin regardless of whether the headers are contained in the request. You can specify up to 10 header sets. This parameter takes effect only when the value of RedirectType is Mirror. Parent nodes: MirrorHeaders
Key	String	Conditional. This parameter must be specified if Set is specified.	myheader-key5	Specifies the key of the header. The key can be up to 1,024 bytes in length. The character set of this parameter is the same as that of Pass. This parameter takes effect only when the value of RedirectType is Mirror. Parent nodes: Set

Parameter	Type	Required	Example	Description
Value	String	Conditional. This parameter must be specified if Set is specified.	myheader-value5	Specifies the value of the header. The value can be up to 1,024 bytes in length and cannot contain `\r\n`. This parameter takes effect only when the value of RedirectType is Mirror. Parent nodes: Set
Protocol	String	Conditional. This parameter must be specified if the value of RedirectType is External or AliCDN.	http	The protocol used for redirection. For example, if you access the object named test, Protocol is set to https, and Hostname is set to `www.example.com`, the Location header is `https://www.example.com/test`. This parameter takes effect only when the value of RedirectType is External or AliCDN. Valid values: *http* and *https*. Parent nodes: Redirect
HostName	String	Conditional. This parameter must be specified if the value of RedirectType is External or AliCDN.	www.example.com	The domain name used for redirection, which must comply with the naming conventions for domain names. For example, if you access the object named test, Protocol is set to https, and Hostname is set to `www.example.com`, the Location header is `https://www.example.com/test`. Parent nodes: Redirect

Parameter	Type	Required	Example	Description
ReplaceKeyPrefixWith	String	No	abc/	Specifies the string that is used to replace the prefix of the object name in the redirect request. If the prefix of the object is empty, this string is added before the object name. **Note** You can specify only one of the ReplaceKeyWith and ReplaceKeyPrefixWith nodes in a rule. If KeyPrefixEquals is set to abc/ and ReplaceKeyPrefixWith is set to def/, when you access the abc/test.txt object, the Location header is `http://www.example.com/def/test.txt`. Parent nodes: Redirect
EnableReplacePrefix	Boolean	No	true	If this parameter is set to true, the prefix of object names is replaced with the value specified by ReplaceKeyPrefixWith. If this parameter is not specified or empty, the prefix of object names is truncated. **Note** When the ReplaceKeyWith parameter is not empty, this parameter cannot be set to true. Default value: false Parent nodes: Redirect
ReplaceKeyWith	String	No	prefix/${key}.suffix	Specifies the string that is used to replace the requested object name when the request is redirected. This parameter can be a variable. The ${key} variable that indicates the object name in the request is supported. If ReplaceKeyWith is set to `prefix/${key}.suffix`, when you access the object named test, the Location header is `http://www.example.com/prefix/test.suffix`. Parent nodes: Redirect

Parameter	Type	Required	Example	Description
HttpRedirectCode	HTTP status code	Conditional. This parameter must be specified if the value of RedirectType is External or AliCDN.	301	The HTTP redirect code in the response. This parameter takes effect only when the value of RedirectType is External or AliCDN. Valid values: 301, 302, and 307 Parent nodes: Redirect

For more information about other common request elements of PutBucketWebsite, see Common request headers.

Response elements

For more information about the response elements of PutBucketWebsite, see Common response headers.

Examples

- Sample requests

```
PUT /? website HTTP/1.1
Host: oss-example.oss-cn-hangzhou.aliyuncs.com
Content-Length: 209
Date: Fri, 04 May 2012 03:21:12 GMT
Authorization: OSS qn6qrrqx******k53otfjbyc:KU5h8YM******0dXqf3JxrTZHiA=
<? xml version="1.0" encoding="UTF-8"? >
<WebsiteConfiguration>
  <IndexDocument>
    <Suffix>index.html</Suffix>
      <SupportSubDir>true</SupportSubDir>
      <Type>0</Type>
  </IndexDocument>

x-oss-server-time: 47
```

6.1.1.5.5. PutBucketReferer

You can call this operation to configure a Referer whitelist and specify whether to allow a request whose Refer field is empty.

Usage notes

PutBucketReferer replaces the existing configured whitelist with the whitelist specified by RefererList. When empty RefererList that contains no Referer request elements is uploaded, this operation overwrites the configured whitelist. The existing RefererList is deleted.

Request structure

```
PUT /? referer HTTP/1.1
Date: GMT Date
Content-Length: ContentLength
Content-Type: application/xml
Host: BucketName.oss.example.com
Authorization: SignatureValue
<? xml version="1.0" encoding="UTF-8"? >
<RefererConfiguration>
<AllowEmptyReferer>true</AllowEmptyReferer >
    <RefererList>
        <Referer> http://www.aliyun.com</Referer>
        <Referer> https://www.aliyun.com</Referer>
        <Referer> http://www. *.com</Referer>
        <Referer> https://www.?.aliyuncs.com</Referer>
    </RefererList>
</RefererConfiguration>
```

Request elements

Element	Type	Required	Example	Description
RefererConfiguration	Container	Yes	N/A	The container that contains the Referer configurations. Type: container Child nodes: AllowEmptyReferer and RefererList Parent node: none
AllowEmptyReferer	Boolean	Yes	true	Specifies whether to allow a request whose Refer field is empty. Default value: true
RefererList	Container	Yes	N/A	The container that contains the Referer whitelist.
Referer	String	No	http://www.aliyun.com	The Referer whitelist.

Response headers

The response headers involved in the PutBucketReferer operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests that exclude the Referer element

```
PUT /? referer HTTP/1.1
Host: BucketName.oss.example.com
Content-Length: 247
Date: Fri, 04 May 2012 03:21:12 GMT
Authorization: OSS q***c:K***=
<? xml version="1.0" encoding="UTF-8"? >
<RefererConfiguration>
<AllowEmptyReferer>true</AllowEmptyReferer >
< RefererList />
</RefererConfiguration>
```

Sample requests that include the Referer element

```
PUT /? referer HTTP/1.1
Host: BucketName.oss.example.com
Content-Length: 247
Date: Fri, 04 May 2012 03:21:12 GMT
Authorization: OSS q***c:K***=
<? xml version="1.0" encoding="UTF-8"? >
<RefererConfiguration>
<AllowEmptyReferer>true</AllowEmptyReferer >
< RefererList>
<Referer> http://www.aliyun.com</Referer>
<Referer> https://www.aliyun.com</Referer>
<Referer> http://www. *.com</Referer>
<Referer> https://www.?.aliyuncs.com</Referer>
</ RefererList>
</RefererConfiguration>
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***B
Date: Fri, 04 May 2012 03:21:12 GMT
Content-Length: 0
Connection: keep-alive
Server: AliyunOSS
```

6.1.1.5.6. PutBucketLifecycle

A bucket owner has permissions to call PutBucketLifecycle to configure lifecycle for a bucket. After a lifecycle rule is enabled, OSS automatically deletes objects that match the rule or converts the storage class for the objects based on the rule on a regular basis.

Usage notes

When you call the PutBucketLifecycle operation, take note of the following items:

- Only bucket owners or RAM users who have the PutBucketLifecycle permission can initiate a PutBucketLifecycle request.
- If no lifecycle rules are configured for a bucket, a lifecycle rule is created after you call PutBucketLifecycle. If a lifecycle rule is configured for the bucket, a lifecycle rule is created and the existing lifecycle rule is overwritten.
- PutBucketLifecycle uses the overwriting semantics. New lifecycle rules overwrite the existing rules. To add lifecycle rules for a bucket, call GetBucketLifecycle to obtain the existing lifecycle configurations of the bucket, add new lifecycle configurations, and then call PutBucketLifecycle to update the lifecycle configurations for the bucket.
- When you call the PutBucketLifecycle operation, you can set a validity period or expiration date for objects or parts that are generated in incomplete multipart upload tasks.

Request structure

```
PUT /? lifecycle HTTP/1.1
Date: GMT Date
Content-Length: ContentLength
Content-Type: application/xml
Authorization: SignatureValue
Host: BucketName.oss.example.com
<? xml version="1.0" encoding="UTF-8"? >
<LifecycleConfiguration>
 <Rule>
 <ID>RuleID</ID>
 <Prefix>Prefix</Prefix>
 <Status>Status</Status>
 <Expiration>
 <Days>Days</Days>
 </Expiration>
 <AbortMultipartUpload>
 <Days>Days</Days> </AbortMultipartUpload>
 </Rule>
</LifecycleConfiguration>
```

Request headers

Request headers involved in the PutBucketLifecycle operation contain only common request headers. For more information, see Common request headers.

Request elements

Element	Type	Required	Example	Description
CreatedBeforeDate	String	Either Days or CreatedBeforeDate required	2002-10-11T00:00:00.000Z	The date based on which to run lifecycle rules. OSS performs the specified operation on data whose last modified date is before this date. Specify the time in the ISO 8601 standard. The time must be at UTC 00:00:00. For example, 2002-10-11T00:00:00.000Z indicates that objects last updated before 2002-10-11T00: 00: 00.000Z are deleted or the storage classes of these objects are converted to another storage class. Objects last updated at or after this time are not deleted or their storage classes are not converted to another storage class.
Days	Positive integer	Either Days or CreatedBeforeDate required	1	The number of days within which objects can be retained after they are last modified.
Expiration	Container	No	N/A	The delete operation on the objects for the lifecycle rule.

Element	Type	Required	Example	Description
AbortMultipartUpload	Container	No	N/A	The delete operation on the multipart upload tasks that are incomplete.
ID	String	No	rule1	The unique ID of a lifecycle rule. The ID can be a maximum of 255 bytes in length. If the value of this parameter is null or not specified, OSS automatically generates a unique ID for the lifecycle rule.
LifecycleConfiguration	Container	Yes	N/A	The container that stores lifecycle configurations. The container can contain up to 1,000 rules.
Prefix	String	Yes	data	The prefix of the names of objects to which the rule applies. The prefixes specified by different rules cannot overlap. • If Prefix is specified, this rule applies only to objects whose names contain the specified prefix in the bucket. • If Prefix is not specified, this rule applies to all objects in the bucket.
Rule	Container	Yes	N/A	Identifies the rule.
Status	String	Yes	Enabled	Specifies whether to run the rule. A value of Enabled indicates that OSS runs the rule. A value of Disabled indicates that OSS ignores the rule.

Response headers

The response headers involved in the PutBucketLifecycle operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
PUT /? lifecycle HTTP/1.1
Host: BucketName.oss.example.com
Content-Length: 443
Date: Mon, 14 Apr 2014 01:08:38 GMT
Authorization: OSS q***c:K***=
<? xml version="1.0" encoding="UTF-8"? >
</LifecycleConfiguration>
 <Rule>
 <ID>rule1</ID>
 <Prefix>logs/</Prefix>
 <Status>Enabled</Status>
 <Expiration>
 <Days>1</Days>
 </Expiration>
 <AbortMultipartUpload>
 <Days>1</Days>
 </AbortMultipartUpload>
 </Rule>
 <Rule>
 <ID>rule2</ID>
 <Prefix>backup/</Prefix>
 <Status>Enabled</Status>
 <Expiration>
 <CreatedBeforeDate>2014-10-11T00:00:00.000Z</CreatedBeforeDate>
 </Expiration>
 <AbortMultipartUpload>
 <CreatedBeforeDate>2014-10-11T00:00:00.000Z</CreatedBeforeDate>
 </AbortMultipartUpload>
 </Rule>
</LifecycleConfiguration>
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***B
Date: Mon, 14 Apr 2014 01:17:10 GMT
Content-Length: 0
Connection: keep-alive
Server: AliyunOSS
```

6.1.1.5.7. GetBucket (ListObjects)

You can call this operation to list the information about all objects in a bucket.

Detail analysis

- User metadata of objects is not returned for the GetBucket request.
- If listing cannot be complete at a time because of the max-keys setting, `<NextMarker>` is added to the returned result, which indicates that the subsequent listing can start from this marker. The value of NextMarker is still in the list result.
- During a conditional query, even if the marker does not exist in the list, items after the marker are

returned in alphabetical order. If the value of max-keys is smaller than 0 or greater than 1000, OSS returns 400 Bad Request and error code InvalidArgument.

- The prefix and marker parameters are used to list the returned objects by page. The parameter value must be smaller than 1,024 bytes in length.
- If prefix is set to a folder name in the request, the objects whose names contain this prefix are listed, including all objects and subfolders in the folder. If prefix is set to a folder name and delimiter is set to a forward slash (/) in the request, the names of the objects and subfolders in the folder are listed in the CommonPrefixes element. Objects and subfolders are not listed. For example, a bucket contains the following objects: fun/test.jpg, fun/movie/001.avi, and fun/movie/007.avi. If prefix is set to fun/, the three objects are returned. If prefix is set to fun/ and delimiter is set to a forward slash (/), fun/test.jpg and fun/movie/are returned.

Request structure

```
GET / HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request parameters

Parameter	Type	Required	Example	Description
delimiter	String	No	/	The character used to group objects by name. If you specify the Delimiter parameter in the request, the response contains the CommonPrefixes element. Objects whose names contain the same string from the prefix to the next occurrence of the delimiter are grouped as a single result element in CommonPrefixes. Default value: null
marker	String	No	test1.txt	The name of the object after which the list begins. If this parameter is specified, objects whose names are alphabetically greater than the marker parameter value are returned. The marker parameter is used to list the returned objects by page, and this parameter value must be smaller than 1,024 bytes in length. Even if the specified marker does not exist in the list during a conditional query, the list starts from the object whose name is alphabetically greater than the marker parameter value. Default value: null

Parameter	Type	Required	Example	Description
max-keys	String	No	200	The maximum number of objects to return. If the listing cannot be complete at a time because max-keys is specified, the NextMarker element is included in the response as the marker for next listing. Valid values: 1 to 1000 Default value: 100
prefix	String	No	fun	The prefix that the returned object names must contain. • The value of prefix must be smaller than 1,024 bytes in length. • If you specify a prefix to query objects, the names of the returned objects still contain the prefix. If prefix is set to a folder name in the request, the objects whose names contain this prefix are listed, including all objects and subfolders in the folder. If prefix is specified and delimiter is set to a forward slash (/), only the objects in the folder are listed. The subfolders are grouped together as a single result in CommonPrefixes. Objects and folders in the subfolders are not listed. For example, a bucket contains the following objects: fun/test.jpg, fun/movie/001.avi, and fun/movie/007.avi. If prefix is set to fun/, the three objects are returned. If prefix is set to fun/ and delimiter is set to a forward slash (/), fun/test.jpg and fun/movie/ are returned. Default value: null
encoding-type	String	No	URL	The encoding type of the object name in the response. Default value: null Valid value: URL **Notice** The delimiter, marker, prefix, NextMarker, and Key values are UTF-8 encoded. If delimiter, marker, prefix, NextMarker, and Key contain control characters that are not supported by the XML 1.0 standard, you can specify encoding-type to encode Delimiter, Marker, Prefix, NextMarker, and Key in the response.

Response elements

Element	Type	Example	Description
Contents	Container	N/A	The container that stores the returned object metadata. Parent nodes: ListBucketResult
CommonPrefixes	String	N/A	If the Delimiter parameter is specified in the request, the response contains the CommonPrefixes element. Objects whose names contain the same string from the prefix to the next occurrence of the delimiter are grouped as a single result element in CommonPrefixes. Parent nodes: ListBucketResult
Delimiter	String	/	The character used to group objects by name. If you specify the Delimiter parameter in the request, the response contains the CommonPrefixes element. Objects whose names contain the same string from the prefix to the next occurrence of the delimiter are grouped as a single result element in CommonPrefixes. Parent nodes: ListBucketResult
EncodingType	String	N/A	The encoding type of the object name in the response. In addition, you can use the encoding-type parameter to encode the following elements in the response: Delimiter, Marker, Prefix, NextMarker, and Key. Parent nodes: ListBucketResult
DisplayName	String	user_example	The name of the object owner. Parent nodes: ListBucketResult, Contents, and Owner
ETag	String	5B3C1A2E053D763E1B002CC607C5A0FE1****	The entity tag (ETag). An ETag is created when the object is created to identify the content of an object. • If an object is created using a PutObject request, the ETag value is the MD5 hash of the object content. • If an object is created using other methods, the ETag value is the UUID of the object content. • The ETag value of an object can be used to check whether the object content is changed. However, we recommend that you do not use the ETag of an object as the MD5 hash of the object to verify data integrity. Parent nodes: ListBucketResult and Contents
ID	String	0022012****	The user ID of the bucket owner. Parent nodes: ListBucketResult, Contents, and Owner

Element	Type	Example	Description
IsTruncated	Enumerated string	false	Indicates whether the returned results are truncated. Valid values: *true* and *false* • true indicates that not all of the results are returned this time. • false indicates that all of the results are returned this time. Parent nodes: ListBucketResult
Key	String	fun/test.jpg	The key of the object. Parent nodes: ListBucketResult and Contents
LastModified	Date	2012-02-24T08:42:32.000Z	The last modified time of the object. Parent nodes: ListBucketResult and Contents
ListBucketResult	Container	N/A	The container that stores the result of the GetBucket request. Child nodes: Name, Prefix, Marker, MaxKeys, Delimiter, IsTruncated, NextMarker, and Contents Parent node: none
Marker	String	test1.txt	The name of the object after which the listing begins. Parent nodes: ListBucketResult
MaxKeys	String	100	The maximum number of returned objects in the response. Parent nodes: ListBucketResult
Name	String	oss-example	The name of the bucket. Parent nodes: ListBucketResult
Owner	Container	N/A	The container that stores the information about the bucket owner. Child nodes: DisplayName and ID Parent nodes: ListBucketResult
Prefix	String	fun/	The prefix that the names of returned objects contain. Parent nodes: ListBucketResult
Size	String	344606	The size of the returned object. Unit: byte. Parent nodes: ListBucketResult and Contents

Element	Type	Example	Description
StorageClass	String	Standard	The storage class of the object. Parent nodes: ListBucketResult and Contents

For more information about other common response headers involved in the GetBucket operation, such as `x-oss-request-id` and `Content-Type`, see Common response headers.

Examples

- Sample requests for the simple GetBucket operation

```
GET / HTTP/1.1
Host: oss-example.oss-cn-hangzhou.aliyuncs.com
Date: Fri, 24 Feb 2012 08:43:27 GMT
Authorization: OSS qn6qrrqxo2oawuk53otfjbyc:BC+oQIXVR2/ZghT7cGa0ykbo****
```

Sample responses

```

```

6.1.1.5.8. GetBucketAcl

You can call this operation to obtain the access control list (ACL) of a bucket.

Request structure

```
GET /? acl HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

For more information about the common request headers involved in the GetBucketACL operation, see Common request headers.

Response elements

Element	Type	Example	Description
AccessControlPolicy	Container	N/A	The container that contains the result of the GetBucketACL request.
Owner	Container	N/A	The container that stores the information about the bucket owner.
ID	String	0022012****	The user ID of the bucket owner.
DisplayName	String	0022012****	The name of the bucket owner, which is the same as the user ID.
AccessControlList	Container	N/A	The container that contains the ACL information.
Grant	Enumerated string	public-read	The ACL for the bucket. Valid values: private, public-read, and public-read-write

Examples

Sample requests

```
GET /? acl HTTP/1.1
Host: ***.regionid.example.com
Date: Fri, 24 Feb 2012 04:11:23 GMT
Authorization: OSS q***c:C***=
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***B
Date: Fri, 24 Feb 2012 04:11:23 GMT
Content-Length: 253
Content-Tupe: application/xml
Connection: keep-alive
Server: AliyunOSS
<? xml version="1.0" ? >
<AccessControlPolicy>
    <Owner>
        <ID>0022012****</ID>
        <DisplayName>0022012****</DisplayName>
    </Owner>
    <AccessControlList>
        <Grant>public-read</Grant>
    </AccessControlList>
</AccessControlPolicy>
```

6.1.1.5.9. GetBucketLocation

You can call this operation to view the location information about the data center to which a bucket belongs.

Request structure

```
GET /? location HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

For more information about the common request headers involved in the GetBucketLocation operation, see Common request headers.

Response elements

Element	Type	Example	Description
LocationConstraint	String	oss-cn-hangzhou	The region to which the bucket belongs.

Examples

Sample requests

```
Get /? location HTTP/1.1
Host: ***.regionid.example.com
Date: Fri, 04 May 2012 05:31:04 GMT
Authorization: OSS q***c:c***=
```

Sample responses

```
HTTP/1.1 200
x-oss-request-id: 5***B
Date: Fri, 15 Mar 2013 05:31:04 GMT
Connection: keep-alive
Content-Length: 90
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<LocationConstraint xmlns="http://doc.oss-cn-hangzhou.aliyuncs.com">oss-cn-hangzhou</Locati
onConstraint >
```

6.1.1.5.10. GetBucketInfo

You can call this operation to view the information about a bucket.

You can view the following information when you call GetBucketInfo:

- The time when the bucket was created
- The public endpoint
- The internal endpoint
- The bucket owner information
- The bucket access control list (ACL)

Request structure

```
GET /? bucketInfo HTTP/1.1
Host: BucketName.oss.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

For more information about the common request headers involved in the GetBucketInfo operation, see Common request headers.

Response elements

Element	Type	Example	Description
BucketInfo	Container	N/A	The container that stores the bucket information content.
Bucket	Container		The container that stores the specific information about the bucket.
CreationDate	Date	2013-07-31T10:56:21.000Z	The time when the bucket was created.

Element	Type	Example	Description
ExtranetEndpoint	String	oss-cn-hangzhou.aliyuncs.com	The public endpoint.
IntranetEndpoint	String	oss-cn-hangzhou-internal.aliyuncs.com	The internal endpoint.
Location	String	cn-hangzhou	The region of the data center to which the bucket belongs.
Name	String	oss-example	The name of the bucket.
Owner	Container	N/A	The container that stores the information about the bucket owner.
ID	String	2***3	The user ID of the bucket owner.
DisplayName	String	2***3	The name of the bucket owner, which is the same as the user ID.
AccessControlList	Container	N/A	The container that contains the ACL information.
Grant	Enumeration	private	The ACL for the bucket. Valid values: private, public-read, and public-read-write

Examples

Sample requests

```
Get /? bucketInfo HTTP/1.1
Host: BucketName.oss.example.com
Date: Sat, 12 Sep 2015 07:51:28 GMT
Authorization: OSS q***c: B***=
```

Sample success responses when the information about a bucket is obtained

```
HTTP/1.1 200
x-oss-request-id: 5***B
Date: Sat, 12 Sep 2015 07:51:28 GMT
Connection: keep-alive

  <HostId>BucketName.oss.example.com</HostId>
</Error>
```

6.1.1.5.11. GetBucketLogging

You can call this operation to view the logging configurations of a bucket.

Request structure

```
GET /? logging HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

For more information about the common request headers involved in the GetBucketLogging operation, see Common request headers.

Response elements

Element	Type	Example	Description
BucketLoggingStatus	Container	N/A	The container that stores the logging status information.
LoggingEnabled	Container	N/A	The container that stores the access log information. This element is required only when logging is enabled.
TargetBucket	String	mybucketlogs	The bucket that stores access logs.
TargetPrefix	String	mybucket-access_log/	The prefix of the access log object.

Examples

Sample requests

```
Get /? logging HTTP/1.1
Host: ***.regionid.example.com
Date: Fri, 04 May 2012 05:31:04 GMT
Authorization: OSS q***c:c***=
```

Sample responses for buckets that have logging rules configured

```
HTTP/1.1 200
x-oss-request-id: 5***B
Date: Fri, 04 May 2012 05:31:04 GMT
Connection: keep-alive
Content-Length: 210
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<BucketLoggingStatus xmlns="http://doc.oss-cn-hangzhou.aliyuncs.com">
    <LoggingEnabled>
        <TargetBucket>mybucketlogs</TargetBucket>
        <TargetPrefix>mybucket-access_log/</TargetPrefix>
    </LoggingEnabled>
</BucketLoggingStatus>
```

Sample responses for buckets that have no logging rules configured

```
HTTP/1.1 200
x-oss-request-id: 5***B
Date: Fri, 04 May 2012 05:31:04 GMT
Connection: keep-alive
Content-Length: 110
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<BucketLoggingStatus xmlns="http://doc.oss-cn-hangzhou.aliyuncs.com">
</BucketLoggingStatus>
```

6.1.1.5.12. GetBucketWebsite

You can call this operation to view the static website hosting status of a bucket.

Request structure

```
GET /? website HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

For more information about the common request headers involved in the GetBucketWebsite operation, see Common request headers.

Response elements

Element	Type	Example	Description
ErrorDocument	Container	N/A	The parent element of the Key child element.
IndexDocument	Container	N/A	The parent element of the Suffix child element.
Key	String	error.html	The file name used when the 404 HTTP status code is returned.
Suffix	String	index.html	The index file name added when a folder URL is returned. This element cannot be empty or contain a slash (/). For example, if the index file is set to index.html, regionid.example.com/mybucket/mydir/ included in a request is converted into regionid.example.com/mybucket/index.html by default.
WebsiteConfiguration	Container	N/A	The container for the request.

Examples

Sample requests

```
Get /? website HTTP/1.1
Host: BucketName.regionid.example.com
Date: Thu, 13 Sep 2012 07:51:28 GMT
Authorization: OSS q***c:B***=
```

Sample success responses

```
HTTP/1.1 200
x-oss-request-id: 5***B
Date: Thu, 13 Sep 2012 07:51:28 GMT
Connection: keep-alive
Content-Length: 218
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<WebsiteConfiguration xmlns="http://doc.oss-cn-hangzhou.aliyuncs.com">
<IndexDocument>
<Suffix>index.html</Suffix>
    </IndexDocument>
    <ErrorDocument>
        <Key>error.html</Key>
    </ErrorDocument>
</WebsiteConfiguration>
```

Sample error responses

```
HTTP/1.1 404
x-oss-request-id: 5***B
Date: Thu, 13 Sep 2012 07:56:46 GMT
Connection: keep-alive
Content-Length: 308
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<Error xmlns="http://doc.oss-cn-hangzhou.aliyuncs.com">
    <Code>NoSuchWebsiteConfiguration</Code>
    <Message>The specified bucket does not have a website configuration. </Message>
    <BucketName>oss-example</BucketName>
    <RequestId>5***F</RequestId>
    <HostId>BucketName.regionid.example.com</HostId>
</Error>
```

6.1.1.5.13. GetBucketReferer

You can call this operation to view the Referer configurations of a bucket.

Request structure

```
GET /? referer HTTP/1.1
Host: BucketName.oss.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

For more information about the common request headers involved in the GetBucketReferer operation, see Common request headers.

Response elements

Element	Type	Example	Description
RefererConfiguration	Container	N/A	The container that contains the Referer configurations.
AllowEmptyReferer	Enumerated string	true	Specifies whether to allow a request whose Refer field is empty. Valid values: true and false Default value: true
RefererList	Container	N/A	The container that contains the Referer whitelist.
Referer	String	http://www.aliyun.com	The Referer whitelist.

Examples

Sample requests

```
Get /? referer HTTP/1.1
Host: BucketName.oss.example.com
Date: Thu, 13 Sep 2012 07:51:28 GMT
Authorization: OSS q***: B***=
```

Sample responses to requests that include the Referer element

```
HTTP/1.1 200
x-oss-request-id: 5***B
Date: Thu, 13 Sep 2012 07:51:28 GMT
Connection: keep-alive
Content-Length: 218
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<RefererConfiguration>
<AllowEmptyReferer>true</AllowEmptyReferer >
    <RefererList>
        <Referer>http://www.aliyun.com</Referer>
        <Referer>https://www.aliyun.com</Referer>
        <Referer>http://www. *.com</Referer>
        <Referer>https://www.?.aliyuncs.com</Referer>
    </RefererList>
</RefererConfiguration>
```

Sample responses to requests that exclude the Referer element

```
HTTP/1.1 200
x-oss-request-id: 5***B
Date: Thu, 13 Sep 2012 07:56:46 GMT
Connection: keep-alive
Content-Length: 308
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<RefererConfiguration>
<AllowEmptyReferer>true</AllowEmptyReferer >
< RefererList />
</RefererConfiguration>
```

6.1.1.5.14. GetBucketLifecycle

You can call this operation to view the lifecycle configurations of a bucket.

```
GET /? lifecycle HTTP/1.1
Host: BucketName.oss.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

For more information about the common request headers involved in the GetBucketLifecycle operation, see Common request headers.

Response elements

Element	Type	Example	Description
CreatedBeforeDate	String	2002-10-11T00:00:00.000Z	The date based on which to run lifecycle rules. OSS performs the specified operation on data whose last modified date is before this date. Specify the time in the ISO 8601 standard. The time must be at UTC 00:00:00. For example, 2002-10-11T00:00:00.000Z indicates that objects last updated before 2002-10-11T00:00: 00.000Z are deleted or the storage classes of these objects are converted to another storage class. Objects last updated at or after this time are not deleted or their storage classes are not converted to another storage class.
Days	Positive integer	1	The number of days within which objects can be retained after the objects are last modified.
Expiration	Container	N/A	The delete operation on the objects based on the lifecycle rule.
AbortMultipartUpload	Container	N/A	The delete operation on the multipart upload tasks that are incomplete.
ID	String	rule1	The unique ID of a lifecycle rule. The ID can be a maximum of 255 bytes in length. If the value of this parameter is null or not specified, OSS generates a unique ID for the lifecycle rule.
LifecycleConfiguration	Container	N/A	The container that stores lifecycle configurations. The container can contain up to 1,000 rules.
Prefix	String	logs/	The prefix of names of objects to which the rule applies. • If Prefix is specified, this rule applies only to objects whose names contain the specified prefix in the bucket. • If Prefix is not specified, this rule applies to all objects in the bucket.
Rule	Container	N/A	Identifies the rule.
Status	String	Enabled	Specifies whether to run the rule. A value of Enabled indicates that OSS runs the rule. A value of Disabled indicates that OSS ignores the rule.

Examples

Sample requests

```
Get /? lifecycle HTTP/1.1
Host: BucketName.oss.example.com
Date: Mon, 14 Apr 2014 01:17:29 GMT
Authorization: OSS q***:c***=
```

Sample responses for buckets that have lifecycle rules configured

```
HTTP/1.1 200
x-oss-request-id: 5***B
Date: Mon, 14 Apr 2014 01:17:29 GMT
Connection: keep-alive
Content-Length: 255
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<LifecycleConfiguration>
<Rule>
 <ID>rule1</ID>
 <Prefix>logs/</Prefix>
 <Status>Enabled</Status>
 <Expiration>
 <Days>1</Days>
 </Expiration>
 <AbortMultipartUpload>
 <Days>1</Days>
 </AbortMultipartUpload>
 </Rule>
 <Rule>
 <ID>rule2</ID>
 <Prefix>backup/</Prefix>
 <Status>Enabled</Status>
 <Expiration>
 <CreatedBeforeDate>2014-10-11T00:00:00.000Z</CreatedBeforeDate>
 </Expiration>
 <AbortMultipartUpload>
 <CreatedBeforeDate>2014-10-11T00:00:00.000Z</CreatedBeforeDate>
 </AbortMultipartUpload>
 </Rule>
</LifecycleConfiguration>
```

Sample responses for buckets that have no lifecycle rules configured

```
HTTP/1.1 404
x-oss-request-id: 5***B
Date: Mon, 14 Apr 2014 01:17:29 GMT
Connection: keep-alive
Content-Length: 278
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<Error>
  <BucketName>oss-example</BucketName>
  <Code>NoSuchLifecycle</Code>
  <Message>No Row found in Lifecycle Table. </Message>
  <RequestId>5***9</RequestId>
  <HostId> BucketName.oss.example.com</HostId>
</Error>
```

6.1.1.5.15. DeleteBucket

You can call this operation to delete a bucket.

Request structure

```
DELETE / HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Usage notes

- To prevent unexpected data loss, OSS does not allow users to delete non-empty buckets.
- If you delete a non-empty bucket, OSS returns 409 Conflict and error code BucketNotEmpty.
- Only the bucket owner can delete the bucket. If you delete a bucket when you are not authorized, OSS returns 403 Forbidden and error code AccessDenied.

Request headers

The request headers involved in the DeleteBucket operation contain only common request headers. For more information, see Common request headers.

Response headers

The response headers involved in the DeleteBucket operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
DELETE / HTTP/1.1
Host: ***.regionid.example.com
Date: Fri, 24 Feb 2012 05:31:04 GMT
Authorization: OSS q***:c***=
```

Sample responses

```
HTTP/1.1 204 No Content
x-oss-request-id: 534B371674E88A4D8906008B
Date: Fri, 24 Feb 2012 05:31:04 GMT
Connection: keep-alive
Content-Length: 0
Server: AliyunOSS
```

6.1.1.5.16. DeleteBucketLogging

You can call this operation to disable logging for a bucket.

Request structure

```
DELETE /? logging HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

The request headers involved in the DeleteBucketLogging operation contain only common request headers. For more information, see Common request headers.

Response headers

The response headers involved in the DeleteBucketLogging operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
DELETE /? logging HTTP/1.1
Host: ***.regionid.example.com
Date: Fri, 24 Feb 2012 05:35:24 GMT
Authorization: OSS q***c:6***=
```

Sample responses

```
HTTP/1.1 204 No Content
x-oss-request-id: 5***B
Date: Fri, 24 Feb 2012 05:35:24 GMT
Connection: keep-alive
Content-Length: 0
Server: AliyunOSS
```

6.1.1.5.17. DeleteBucketWebsite

You can call this operation to disable static website hosting for a bucket.

Request structure

```
DELETE /? website HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

Request headers involved in the DeleteBucketWebsite operation contain only common request headers. For more information, see Common request headers.

Response headers

Response headers involved in the DeleteBucketWebsite operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
DELETE /? website HTTP/1.1
Host: ***.regionid.example.com
Date: Fri, 24 Feb 2012 05:45:34 GMT
Authorization: OSS q***:L***=
```

Sample responses

```
HTTP/1.1 204 No Content
x-oss-request-id: 5***B
Date: Fri, 24 Feb 2012 05:45:34 GMT
Connection: keep-alive
Content-Length: 0
Server: AliyunOSS
```

6.1.1.5.18. DeleteBucketLifecycle

You can call this operation to delete the lifecycle configurations for a specific bucket.

Request structure

```
DELETE /? lifecycle HTTP/1.1
Host: BucketName.oss.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

Request headers involved in the DeleteBucketLifecycle operation contain only common request headers. For more information, see Common request headers.

Response headers

Response headers involved in the DeleteBucketLifecycle operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
DELETE /? lifecycle HTTP/1.1
Host: BucketName.oss.example.com
Date: Mon, 14 Apr 2014 01:17:35 GMT
Authorization: OSS q***:6***=
```

Sample responses

```
HTTP/1.1 204 No Content
x-oss-request-id: 5***B
Date: Mon, 14 Apr 2014 01:17:35 GMT
Connection: keep-alive
Content-Length: 0
Server: AliyunOSS
```

6.1.1.6. Object-relevant operations

6.1.1.6.1. PutObject

You can call this operation to upload objects.

Request structure

```
PUT /ObjectName HTTP/1.1
Content-Length: ContentLength
Content-Type: ContentType
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Usage notes

When you call the PutObject operation, take note of the following items:

- PutObject cannot be used to upload objects larger than 5 GB.
- By default, if you upload an object that has the same name as that of an accessible existing object, the existing object is overwritten by the uploaded object and 200 OK is returned.
- OSS does not use folders. All elements are stored as objects. You can create a simulated folder by

creating an object whose name ends with a forward slash (/) and that is 0 KB in size.

- To ensure data integrity, OSS provides multiple methods for you to check the MD5 hashes of the data. To perform MD5 verification based on the Content-MD5 header, add the header to the request. When the Content-MD5 header value is specified in a request, OSS calculates the MD5 hash of the sent data and compares the calculated MD5 hash with the Content-MD5 value specified in the request. If the two values do not match, the operation fails and 400 (Bad Request) is returned.

Request headers

Header	Type	Required	Example	Description
Cache-Control	String	No	no-cache	The web page caching behavior that is specified when the object is downloaded. For more information, visit RFC 2616.
Content-Disposition	String	No	attachment;filename=oss_download.jpg	The presentational information of the object when the object is downloaded. For more information, visit RFC 2616.
Content-Encoding	String	No	utf-8	The content encoding type of the object during the download. For more information, visit RFC 2616. Type: string Default value: null
Content-MD5	String	No	uk8Os/oShU2MMhcajpeAVA==	The Content-MD5 value of the message content (excluding headers). The value is obtained by calculating the 128-bit hash value and then encoding the value in Base64 based on RFC 1864. This request header can be used to check the message validity. The message content is valid if the received message content is the same as the content that is sent. Although this request header is optional, we recommend that you use it for end-to-end checks.
Expires	String	No	Fri, 28 Feb 2012 05:38:42 GMT	The time period after which the response is considered expired. For more information, visit RFC 2616. **Note** OSS does not limit or verify this value.

Header	Type	Required	Example	Description
x-oss-server-side-encryption	String	No	KMS	The server-side encryption algorithm that is used when OSS creates the object. Valid values: *AES256* and *KMS* If you specify this parameter, this parameter is returned in the response header and the uploaded object is encrypted and stored. When you download the encrypted object, the x-oss-server-side-encryption header is included in the response and the header value is set to the algorithm used to encrypt the object.
x-oss-server-side-data-encryption	String	No	SM4	The algorithm used to encrypt objects. If this element is not specified, objects are encrypted by using AES-256. This parameter is valid only when x-oss-server-side-encryption is set to KMS. Valid values: SM4
x-oss-server-side-encryption-key-id	String	No	3dea0cae-5fd6-4bf8-8574-87c557******	The ID of the customer master key (CMK) hosted in KMS. This parameter is valid only when x-oss-server-side-encryption is set to KMS.
x-oss-object-acl	String	No	private	The ACL of the object when the object is created. Valid values: public-read, private, and public-read-write

Response headers

Response headers involved in the PutObject operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
PUT /oss.jpg HTTP/1.1
Host: ***.regionid.example.com
Cache-control: no-cache
Expires: Fri, 28 Feb 2012 05:38:42 GMT
Content-Encoding: utf-8
Content-Disposition: attachment;filename=oss_download.jpg
Date: Fri, 24 Feb 2012 06:03:28 GMT
Content-Type: image/jpg
Content-Length: 344606
Authorization: OSS q***:k***=
[344606 bytes of object data]
```

Sample responses

```
HTTP/1.1 200 OK
Server: AliyunOSS
Date: Sat, 21 Nov 2015 18:52:34 GMT
Content-Length: 0
Connection: keep-alive
x-oss-request-id: 5***A
x-oss-bucket-version: 1***9
ETag: "A***2"
```

6.1.1.6.2. GetObject

You can call this operation to query an object. Before you call this operation, you must have read permissions on the object.

Detail analysis

- You can set the Range parameter in the GetObject request to implement resumable data transfer. We recommend that you use this parameter when you upload large objects.
- If you set Range in the request, the response contains the length of the entire object and the range of bytes copied for this operation. For example, Content-Range: bytes 0-9/44 indicates that the length of the entire object is 44 bytes. The range of copied bytes is from byte 0 to byte 9. If the value of Range is invalid, the entire object is returned and the response returned by OSS does not include Content-Range.
- Parameters in the GetObject request cannot be customized for OSS to return corresponding headers in the response if the access is anonymous.
- If this object is encrypted by using a server-side encryption algorithm based on entropy encoding, OSS automatically returns the decrypted object and x-oss-server-side-encryption in the response when OSS receives the GetObject request. The value of x-oss-server-side-encryption indicates the server-side encryption algorithm of the object.
- To obtain an object compressed in the GZIP format, add Accept-Encoding:gzip to the display mode in the request. OSS determines whether to return data compressed in the GZIP format based on the Content-Type value and size of the object. If the object is compressed in the GZIP format, the response returned by OSS does not include the ETag value of the object. OSS supports GZIP for objects whose Content-Type header is set to one of the following values: HTML, JavaScript, CSS, XML, RSS, and JSON. The object must be at least 1 KB in size.

Request structure

```
GET /ObjectName HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
Range: bytes=ByteRange (optional)
```

Request parameters

OSS allows you to customize parameters in the GET request for OSS to return corresponding headers in the response if the GET request includes a signature. The following table describes the headers.

Header	Type	Required	Example	Description
response-content-type	String	No	text	Specifies the content-type header of the response.
response-content-language	String	No	Chinese characters	Specifies the content-language header of the response.
response-expires	String	No	Fri, 24 Feb 2012 17:00:00 GMT	Specifies the expires header of the response.
response-cache-control	String	No	No-cache	Specifies the cache-control header of the response. Type: string Default value: null
response-content-disposition	String	No	attachment; filename:testing.txt	Specifies the content-disposition header of the response. Type: string Default value: null
response-content-encoding	String	No	utf-8	Specifies the content-encoding header of the response. Type: string Default value: null

Request headers

Header	Type	Required	Example	Description

Header	Type	Required	Example	Description
Range	String	No	bytes=100-900	The range of data you want to return. For example, if you specify bytes=0-9, OSS transfers byte 0 to byte 9, a total of 10 bytes.
If-Modified-Since	String	No	Fri, 13 Nov 2015 14:47:53 GMT	The object transfer condition. If the specified time is earlier than the actual modified time of the object, the system transfers the object and returns 200 OK. Otherwise, the system returns 304 Not Modified. The time must be in GMT.
If-Unmodified-Since	String	No	Fri, 13 Nov 2015 14:47:53 GMT	The object copy condition. If the specified time is later than or equal to the actual modified time of the object, OSS transfers the object and returns 200 OK. Otherwise, OSS returns 412 Precondition Failed. The time must be in GMT.
If-Match	String	No	5B3C1A2E0563E1B002CC607C*****	The object transfer condition. If the specified ETag value of the object matches the actual ETag value, OSS transfers the object and returns 200 OK. Otherwise, OSS returns 412 Precondition Failed.
If-None-Match	String	No	5B3C1A2E0563E1B002CC607C*****	The object transfer condition. If the specified ETag value does not match the actual ETag value, OSS transfers the object and returns 200 OK. Otherwise, OSS returns 304 Not Modified. Type: string Default value: null

Response headers

If the requested object is a symbolic link, the content of the object is returned. Response headers `Content-Length`, `ETag`, and `Content-Md5` indicate the metadata of the requested object. The `Last-Modified` header indicates the later one of the time points when the requested object and the symbolic link are last modified. All other headers indicate the metadata of the symbolic link.

Header	Type	Example	Description
x-oss-server-side-encryption	String	x-oss-server-side-encryption	If the requested object is encrypted by using a server-side encryption algorithm based on entropy encoding, OSS automatically decrypts and returns the object after OSS receives the GetObject request. OSS includes x-oss-server-side-encryption in the response to indicate the encryption algorithm that is used to encrypt the object on the server.

Examples

Sample requests

```
GET /oss.jpg HTTP/1.1
Host: ***.regionid.example.com
Date: Fri, 24 Feb 2012 06:38:30 GMT
Authorization: OSS q***:U***=
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 3***1
x-oss-object-type: Normal
Date: Fri, 24 Feb 2012 06:38:30 GMT
Last-Modified: Fri, 24 Feb 2012 06:07:48 GMT
ETag: "5***E "
Content-Type: image/jpg
Content-Length: 344606
Server: AliyunOSS
[344606 bytes of object data]
```

Sample requests that include the Range parameter

```
GET //oss.jpg HTTP/1.1
Host:***. regionid.example.com
Date: Fri, 28 Feb 2012 05:38:42 GMT
Range: bytes=100-900
Authorization: OSS q***:q***=
```

Sample responses

```
HTTP/1.1 206 Partial Content
x-oss-request-id: 2***9
x-oss-object-type: Normal
Date: Fri, 28 Feb 2012 05:38:42 GMT
Last-Modified: Fri, 24 Feb 2012 06:07:48 GMT
ETag: "5***E "
Accept-Ranges: bytes
Content-Range: bytes 100-900/344606
Content-Type: image/jpg
Content-Length: 801
Server: AliyunOSS
[801 bytes of object data]
```

Sample requests that include custom headers to return in responses

```
GET /oss.jpg? response-expires=Thu%2C%2001%20Feb%202012%2017%3A00%3A00%20GMT& response-cont
ent-type=text&response-cache-control=No-cache&response-content-disposition=attachment%253B%
2520filename%253Dtesting.txt&response-content-encoding=utf-8&response-content-language=%E4%
B8%AD%E6%96%87 HTTP/1.1
Host: ***.regionid.example.com:
Date: Fri, 24 Feb 2012 06:09:48 GMT

Server: AliyunOSS
[344606 bytes of object data]
```

6.1.1.6.3. CopyObject

You can call this operation to copy objects within a bucket or between different buckets in the same region.

To create a copy for an existing object in OSS, you can send a PUT request to OSS, and add x-oss-copy-source to the PUT request to specify the source object you want to copy. OSS determines that this is a copy operation and performs the copy operation on the server side. If the copy operation is successful, OSS returns the information of the new object to you. You can call this operation to copy objects smaller than 1 GB. To copy an object larger than 1 GB, you must use multipart upload. For more information, see UploadPartCopy.

Usage notes

- If the source object URL is the same as the destination object URL during the CopyObject operation, the system replaces the metadata of the source object regardless of the value of x-oss-metadata-directive.
- Request headers for the CopyObject operation start with x-oss- and must be added to a string-to-sign.
- If the x-oss-server-side-encryption header is specified in the CopyObject request, the destination object is encrypted on the server after the CopyObject operation is performed regardless of whether the source object is encrypted on the server. In addition, the CopyObject response header contains the x-oss-server-side-encryption header, the value of which is set to the encryption algorithm of the destination object. When this destination object is downloaded, the response also contains the x-oss-server-side-encryption header, the value of which is set to the encryption algorithm of this destination object. If the x-oss-server-side-encryption request header is not specified for the CopyObject operation, the destination object is the data that is not encrypted on the server even if the source object is encrypted on the server.
- Objects created by using the AppendObject operation cannot be copied.

Request structure

```
PUT /DestObjectName HTTP/1.1
Host: DestBucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
x-oss-copy-source: /SourceBucketName/SourceObjectName
```

Request headers

Header	Type	Required	Example	Description
x-oss-copy-source	String	Yes	/oss-example/oss.jpg	The address of the source object. Default value: null
x-oss-copy-source-if-match	String	No	5B3C1A2E053D763E1B002CC607C5****	If the ETag value of the source object is the same as the ETag value specified in the request, OSS copies the object and returns 200 OK. Otherwise, OSS returns 412 Precondition Failed, which indicates that the preprocessing has failed. Default value: null

Header	Type	Required	Example	Description
x-oss-copy-source-if-none-match	String	Failed	5B3C1A2E053D763E1B002CC607C5****	If the ETag value of the source object is different from the ETag value specified in the request, OSS copies the object and returns 200 OK. Otherwise, OSS returns 304 Not Modified, which indicates that the preprocessing has failed. Default value: null
x-oss-copy-source-if-unmodified-since	String	No	2019-04-09T07:01:56.000Z	If the specified time is the same as or later than the modified time of the object, OSS copies the object and returns 200 OK. Otherwise, OSS returns 412 Precondition Failed, which indicates that the preprocessing has failed. Default value: null
x-oss-copy-source-if-modified-since	String	No	2019-04-09T07:01:56.000Z	If the source object is modified after the specified time, OSS copies the object. Otherwise, OSS returns 304 Not Modified, which indicates that the preprocessing has failed. Default value: null
x-oss-metadata-directive	String	No	COPY	The method used to set the metadata of the destination object. Default value: COPY. Valid values: • *COPY*: The tag of the source object is copied to the destination object. x-oss-server-side-encryption of the source object is not copied to the destination object. The method to encrypt the destination object depends on whether x-oss-server-side-encryption is specified in the CopyObject request. • *REPLACE*: The metadata specified in the request is used, instead of the metadata of the source object.

Header	Type	Required	Example	Description
x-oss-server-side-encryption	String	No	AES256	The entropy coding-based encryption algorithm that OSS uses to encrypt an object when you create the object. Valid values: *AES256* and *KMS*. • If the x-oss-server-side-encryption header is not specified in the CopyObject request, the destination object is not encrypted on the server regardless of whether the source object has been encrypted on the server. • If the x-oss-server-side-encryption header is specified in the CopyObject request, the destination object is encrypted on the server after the CopyObject operation is performed regardless of whether the source object has been encrypted on the server. In addition, the CopyObject response header contains x-oss-server-side-encryption, the value of which is set to the encryption algorithm of the destination object. When the destination object is downloaded, the x-oss-server-side-encryption header is included in the response header and its value is set to the algorithm used to encrypt the object.
x-oss-server-side-encryption-key-id	String	No	9468da86-3509-4f8d-a61e-6eab1eac****	The ID of the customer master key (CMK) hosted in KMS. This parameter is valid only when x-oss-server-side-encryption is set to KMS.
x-oss-object-acl	String	No	private	The ACL configured when OSS creates the destination object. Valid values: *public-read*, *private*, *public-read-write*, and *default*.

Examples of common request headers involved in the CopyObject operation: Host and Date. For more information, see Common request headers.

Response headers

Examples of common response headers involved in the CopyObject operation: Content-Length and Connection. For more information, see Common response headers.

Response elements

Element	Type	Example	Description
CopyObjectResult	Container	N/A	The result of the CopyObject operation. Default value: null
ETag	String	5B3C1A2E053D763E1B002CC607C5***	The ETag value of the destination object. Parent nodes: CopyObjectResult
LastModified	String	Fri, 24 Feb 2012 07:18:48 GMT	The time when the destination object was last modified. Parent nodes: CopyObjectResult

Examples

Sample requests

```
PUT /copy_oss.jpg HTTP/1.1
Host: ***.regionid.example.com
Date: Fri, 24 Feb 2012 07:18:48 GMT
x-oss-copy-source: /oss-example/oss.jpg
Authorization: OSS q***:g***=
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***1
Content-Type: application/xml
Content-Length: 193
Connection: keep-alive
Date: Fri, 24 Feb 2012 07:18:48 GMT
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<CopyObjectResult xmlns="http://doc.oss-cn-hangzhou.aliyuncs.com">
 <LastModified>Fri, 24 Feb 2012 07:18:48 GMT</LastModified>
 <ETag>"5***E"</ETag>
</CopyObjectResult>
```

6.1.1.6.4. AppendObject

You can call this operation to upload an object by appending the object to an existing object. Objects created by using the AppendObject operation are append objects, whereas objects uploaded by using the PutObject operation are normal objects.

Usage notes

- You can perform AppendObject only for an append object. For example, if a normal object that shares the same name already exists and AppendObject is called, OSS returns HTTP status code 409 and error code ObjectNotAppendable.
- If you perform a PutObject operation on an existing append object, the append object is overwritten

by a new normal object.

- After HeadObject is performed, OSS returns x-oss-object-type to indicate the type of the object. If HeadObject is performed on an append object, the object type is Appendable. If HeadObject is performed on an append object, OSS also returns x-oss-next-append-position and x-oss-hash-crc64ecma.
- In the response in XML to the GetBucket (ListObjects) request, the type of an append object is set to Appendable.
- You can neither use CopyObject to copy an append object nor change the server-side encryption attribute of this object. You can use CopyObject to modify the user metadata of this object.
- The append and position parameters belong to CanonicalizedResource that must be included in signatures.

Request structure

```
POST /ObjectName? append&position=Position HTTP/1.1
Content-Length: ContentLength
Content-Type: ContentType
Host: BucketName.oss.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

Header	Type	Required	Example	Description
append	String	Yes	N/A	The request that is sent to perform an AppendObject operation. Each time an AppendObject operation is performed, the last modified time of this object is updated.

Header	Type	Required	Example	Description
position	String	Yes	0	The position from which the AppendObject operation starts. Each time an AppendObject operation succeeds, x-oss-next-append-position in the response header specifies the position of the next AppendObject request. The value of position in the first AppendObject operation must be 0. The value of position in the subsequent operation is the current object length. For example, if the value of position specified in the first AppendObject request is 0, and the value of content-length is 65536, the value of position specified in the second AppendObject request must be set to 65536. • If the value of position is 0 and an object with the same name does not exist, you can set headers, such as x-oss-server-side-encryption in the AppendObject request in the same way as you set in a PutObject request. If you add a correct x-oss-server-side-encryption header in an AppendObject request in which the value of position is 0, the x-oss-server-side-encryption header is also included in the response header. You can initiate a CopyObject request to modify the metadata of the object in subsequent operations. • If the position value is correct and the content with a length of 0 is appended to an existing append object, the status of the object does not change.
Cache-control	String	No	no-cache	The web page caching behavior for the object. For more information, see RFC 2616. Default value: null
Content-Disposition	String	No	attachment;filename=oss_download.jpg	The name of the object when the object is downloaded. For more information, see RFC 2616. Default value: null
Content-Encoding	String	No	utf-8	The object encoding format of the object. For more information, see RFC 2616. Default value: null

Header	Type	Required	Example	Description
Content-MD5	String	No	ohhnqLBJFiKkPSBO1eNaUA==	The Content-MD5 header value is a string calculated by using the MD5 algorithm. This header is used to check whether the content of the received message is the same as that of the sent message. To obtain the value of the Content-MD5 header, calculate a 128-bit byte array based on the message content, rather than the header, and then encode the byte array in Base64. Default value: null Limits: none
Expires	GMT	No	Wed, 08 Jul 2015 16:57:01 GMT	The time period after which the response is considered expired. For more information, see RFC 2616. Default value: null
x-oss-server-side-encryption	String	No	AES256	The method used to encrypt objects on the OSS server. Valid values: • *AES256*: uses keys managed by OSS for encryption and decryption (SSE-OSS). • *KMS*: uses CMKs managed by KMS for encryption and decryption. • *SM4*: uses the SM4 block cipher algorithm for encryption and decryption.
x-oss-object-acl	String	No	private	The ACL for the object. Valid values: • *public-read*: Only the bucket owner can perform write operations on objects in the bucket. Other users, including anonymous users, can perform only read operations on the objects in the bucket. • *private*: Only the bucket owner or authorized users can read from and write to the objects in the bucket. Other users, including anonymous users, cannot access objects in the bucket. • *public-read-write*: All users, including anonymous users, can perform read and write operations on objects in the bucket. Fees incurred by these operations are paid by the bucket owner. Use this ACL policy only when necessary.

Header	Type	Required	Example	Description
x-oss-meta-*	String	No	x-oss-meta-location	You can add parameters prefixed with x-oss-meta-* when you create an append object by calling the AppendObject operation. However, you cannot add these parameters when you append objects to an existing append object. Parameters prefixed with x-oss-meta-* are considered metadata. You can configure multiple parameters prefixed with x-oss-meta-* for an object. However, the total size of metadata cannot exceed 8 KB. The name of parameters prefixed with x-oss-meta-* can contain hyphens (-), digits, and letters. Uppercase letters are converted to lowercase letters. Other characters such as underscores (_) are not supported.

For more information about the common request headers included in AppendObject requests, see Common request headers.

Response headers

Header	Type	Example	Description
x-oss-next-append-position	64-bit integer	1717	The position that must be provided in the next request, which is the current object length. This header is returned when a successful message is returned for an AppendObject request, or when the 409 HTTP status code is returned because the position and the object length do not match.
x-oss-hash-crc64ecma	64-bit integer	3231342946509354535	The 64-bit CRC value of the object. This value is calculated based on the ECMA-182 standard.

For more information about other common response headers involved in the AppendObject operation, see Common response headers.

Method for calculating the 64-bit CRC value

The CRC-64 value of an append object is calculated based on the ECMA-182 standard. You can calculate the CRC-64 by using the following methods:

- Use the Boost CRC module

```
typedef boost::crc_optimal<64, 0x42F0E1EBA9EA3693ULL, 0xffffffffffffffffULL, 0xffffffffffffffffULL, true, true> boost_ecma;
uint64_t do_boost_crc(const char* buffer, int length)
{
    boost_ecma crc;
    crc.process_bytes(buffer, length);
    return crc.checksum();
}
```

- Use the crcmod function in Python

```
do_crc64 = crcmod.mkCrcFun(0x142F0E1EBA9EA3693L, initCrc=0L, xorOut=0xffffffffffffffffL,
rev=True)
print do_crc64("123456789")
```

Examples

Sample requests

```
POST /oss.jpg? append&position=0 HTTP/1.1
Host: BucketName.oss.example.com
Cache-control: no-cache
Expires: Wed, 08 Jul 2015 16:57:01 GMT
Content-Encoding: utf-8
Content-Disposition: attachment;filename=oss_download.jpg
Date: Wed, 08 Jul 2015 06:57:01 GMT
Content-Type: image/jpg
Content-Length: 1717
Authorization: OSS q***:k***=
[1717 bytes of object data]
```

Sample responses

```
HTTP/1.1 200 OK
Date: Wed, 08 Jul 2015 06:57:01 GMT
ETag: "0***0"
Connection: keep-alive
Content-Length: 0
Server: AliyunOSS
x-oss-hash-crc64ecma: 14741617095266562575
x-oss-next-append-position: 1717
x-oss-request-id: 5***1
```

6.1.1.6.5. DeleteObject

You can call this operation to delete an object.

Usage notes

When you call the DeleteObject operation, take note of the following items:

- You must have write permissions on the object that you want to delete.
- HTTP status code 204 is returned when the DeleteObject operation succeeds, regardless of whether the object exists.
- If the object you want to delete is a symbolic link, the DeleteObject operation deletes only the symbolic link but not the content that the link points to.

Request structure

```
DELETE /ObjectName HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

The request headers involved in the DeleteObject operation contain only common request headers. For more information, see Common request headers.

Response headers

The response headers involved in the DeleteObject operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
DELETE /copy_oss.jpg HTTP/1.1
Host: ***.regionid.example.com
Date: Fri, 24 Feb 2012 07:45:28 GMT
Authorization: OSS q***:z***=
```

Sample responses

```
HTTP/1.1 204 NoContent
x-oss-request-id: 5***1
Date: Fri, 24 Feb 2012 07:45:28 GMT
Content-Length: 0
Connection: keep-alive
Server: AliyunOSS
```

6.1.1.6.6. DeleteMultipleObjects

You can call this operation to delete multiple objects in the same bucket by using one HTTP request.

A maximum of 1,000 objects can be deleted when you call the DeleteMultipleObjects operation. This operation supports the following return modes:

- Verbose mode: The message body returned by OSS contains the result of each deleted object.
- Quiet mode: The message body returned by OSS contains only the results for objects that fail to be deleted. If all objects are deleted, no message body is returned.

Detail analysis

- You must specify Content-Length and Content-MD5 for the DeleteMultipleObjects request. OSS verifies that the received message body is correct based on the two header values before the delete operation is performed.
- The Content-MD5 value of the message content (excluding headers) is obtained by calculating the 128-bit hash value and then encoding the value in Base64 based on RFC 1864.
- If DeleteMultipleObjects is used to delete an object that does not exist, the operation is considered

to be successful.

- The message body for DeleteMultipleObjects can be up to 2 MB. If the size of the message body exceeds 2 MB, OSS returns the MalformedXML error code.
- A maximum of 1,000 objects can be deleted when you call the DeleteMultipleObjects operation. If more than 1,000 objects are requested, OSS returns the MalformedXML error code.
- If the Content-MD5 request header is specified, OSS calculates the MD5 hash of the received content and compares the calculated MD5 hash with the Content-MD5 header value in the request. If the two MD5 hashes are different, OSS returns InvalidDigest.

Request structure

```
POST /? delete HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Content-Length: ContentLength
Content-MD5: MD5Value
Authorization: SignatureValue
<? xml version="1.0" encoding="UTF-8"? >
<Delete>
  <Quiet>true</Quiet>
  <Object>
    <Key>key</Key>
  </Object>
...
</Delete>
```

Request headers

When you call the DeleteMultipleObjects operation, you can use the encoding-type parameter to encode the object names in the response.

Header	Type	Required	Example	Description
Encoding-type	String	No	url	The Key parameter is UTF-8 encoded. If the Key parameter includes control characters that are not supported by the XML 1.0 standard, you can specify this header to encode the Key parameter value in the response. Valid values: *url*
Content-Length	String	Yes	151	The length of the HTTP message body. OSS verifies the received message body based on this header, and deletes the object only when the length of the message body is the same as this header.

Header	Type	Required	Example	Description
Content-MD5	String	Yes	lVaXz0QX0UTCXraY9Z61mQ==	The Content-MD5 header value is a string calculated by using the MD5 algorithm. This header is used to check whether the content of the received message is same as that of the sent message. After the Content-MD5 request header is uploaded, OSS calculates the MD5 hash of the received object and checks whether the calculated MD5 hash is the same as the MD5 hash provided in the request. **Note** To obtain the value of the Content-MD5 header, encrypt the message body of the DeleteMultipleObjects request by using the MD5 algorithm to obtain a 128-bit byte array, and then encode the byte array in Base64.

Request elements

Element	Type	Required	Example	Description
Delete	Container	Yes	N/A	The container that stores the DeleteMultipleObjects request.
Object	Container	Yes	N/A	The container that stores the information about the object.
Key	String	Yes	test.jpg	The name of the object to be deleted.
Quiet	Boolean	Yes	true	Enables the Quiet response mode. DeleteMultipleObjects provides the following two response modes: • Quiet: The message body of the response returned by OSS includes only objects that fail to be deleted. If all objects are deleted, the response does not include a message body. • Verbose: The message body of the response returned by OSS includes the results of all deleted objects. By default, this mode is used. Valid values: *true* (enables the Quiet mode) and *false* (enables the Verbose mode) Default value: *false*

Response headers

Response headers involved in the DeleteMultipleObjects operation contain only common response headers. For more information, see Common response headers.

Examples

Sample Request 1

```
POST /? delete HTTP/1.1
Host: ***.regionid.example.com
Date: Wed, 29 Feb 2012 12:26:16 GMT
Content-Length:151
Content-MD5: o***==
Authorization: OSS q***:+z***=
<? xml version="1.0" encoding="UTF-8"? >
<Delete>
  <Quiet>false</Quiet>
  <Object>
    <Key>multipart.data</Key>
  </Object>
  <Object>
    <Key>test.jpg</Key>
  </Object>
  <Object>
    <Key>demo.jpg</Key>
  </Object>
</Delete>
```

Sample response

```
HTTP/1.1 200 OK
x-oss-request-id: 7***7
Date: Wed, 29 Feb 2012 12:26:16 GMT
Content-Length: 244
Content-Type: application/xml
Connection: keep-alive
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<DeleteResult xmlns="http://doc.oss-cn-hangzhou.aliyuncs.com">
    <Deleted>
       <Key>multipart.data</Key>
    </Deleted>
    <Deleted>
       <Key>test.jpg</Key>
    </Deleted>
    <Deleted>
       <Key>demo.jpg</Key>
    </Deleted>
</DeleteResult>
```

Sample Request 2

```
POST /? delete HTTP/1.1
Host: ***.regionid.example.com
Date: Wed, 29 Feb 2012 12:33:45 GMT
Content-Length:151
Content-MD5: o***A==
Authorization: OSS q***c:W***=
<? xml version="1.0" encoding="UTF-8"? >
<Delete>
  <Quiet>true</Quiet>
  <Object>
    <Key>multipart.data</Key>
  </Object>
  <Object>
    <Key>test.jpg</Key>
  </Object>
  <Object>
    <Key>demo.jpg</Key>
  </Object>
</Delete>
```

Sample response

```
HTTP/1.1 200 OK
x-oss-request-id: 5***1
Date: Wed, 29 Feb 2012 12:33:45 GMT
Content-Length: 0
Connection: keep-alive
Server: AliyunOSS
```

6.1.1.6.7. HeadObject

You can call this operation to return only the metadata of a specified object without returning the object content.

Detail analysis

- After the HeadObject request is sent, no message body is returned even if the system returns the 200 OK message or an error message.
- If you specify user metadata prefixed with x-oss-meta- when you send a PutObject request, such as x-oss-meta-location, the user metadata is returned.
- If the object does not exist, the system returns 404 Not Found.
- If server-side encryption is configured for the object, OSS returns the x-oss-server-side-encryption header in the response. The value of the x-oss-server-side-encryption header indicates the server-side encryption algorithm of the object.

Request structure

```
HEAD /ObjectName HTTP/1.1
Host: BucketName/regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

Header	Type	Required	Example	Description
If-Modified-Since	String	No	Fri, 24 Feb 2012 07:32:52 GMT	The information return condition. If the specified time is earlier than the last modified time of the object, OSS returns the metadata of the object and 200 OK. If the specified time is equal to or later than the last modified time of the object, OSS returns 304 Not Modified. Default value: null
If-Unmodified-Since	String	No	Fri, 24 Feb 2012 07:32:52 GMT	The information return condition. If the specified time is equal to or later than the last modified time of the object, OSS returns the metadata of the object and 200 OK. If the specified time is earlier than the last modified time of the object, OSS returns 412 Precondition Failed. Default value: null
If-Match	String	No	215697CF4417D144C25EB698F5******	The information return condition. If the input ETag value matches the ETag value of the object, OSS returns the metadata of the object and 200 OK. If the input ETag value does not match the ETag value of the object, OSS returns 412 Precondition Failed. Default value: null
If-None-Match	String	No	215697CF4417D144C25EB698F5******	The information return condition. If the input ETag value does not match the ETag value of the object, OSS returns the metadata of the object and 200 OK. If the input ETag value matches the ETag value of the object, OSS returns 304 Not Modified. Default value: null

Response headers

If the requested object is a symbolic link, the following headers are included in the response:

- The Content-Length, ETag, and Content-Md5 header are the metadata of the object to which the symbolic link points.
- The Last-Modified header is the later one of the last modified time of the symbolic link and the object to which the symbolic link points.
- Other response headers are the metadata of the symbolic link.

Header	Type	Example	Description
x-oss-meta-*	String	x-oss-meta-test	The user metadata prefixed with x-oss-meta-. If you specify headers prefixed with x-oss-meta- in the PutObject request, the user metadata of the object is included in the response.
Custom headers that are not prefixed with x-oss-meta-	String	x-oss-persistent-headers	If you specify headers that are not prefixed with x-oss-meta- in the PutObject request to configure the user metadata of the object, the headers are included in the response. Example: x-oss-persistent-headers: *key1:base64_encode(value1),key2:base64_encode(value2)...* ..
x-oss-server-side-encryption	String	KMS	This header is included in the response if the object is encrypted by using the server-side encryption algorithm based on entropy encoding. The value of this header is the algorithm used to encrypt the object at the server side.
x-oss-server-side-encryption-key-id	String	3dea0cae-5fd6-4bf8-8574-87c557******	This header is included in the response if the object is encrypted by using KMS at the server side. The value of this header is the CMK ID used to encrypt the object.
x-oss-object-type	String	Normal	The type of the object. Valid values: • Normal: The object is uploaded by using PutObject. • Appendable: The object is uploaded by using AppendObject. • Multipart: The object is uploaded by using MultipartUpload.
x-oss-next-append-position	String	100	The position for the next append operation. This header is included in the response only when the type of the object is Appendable.
x-oss-hash-crc64ecma	String	15429415218160274758	The 64-bit CRC value of the object. This value is calculated based on the ECMA-182 standard. If an object is created before OSS supports CRC-64, this header may not be included in the response when you call HeadObject to query the metadata of the object.
Content-Md5	String	IVaXz0QX0UTCXraY9Z61mQ==	• This header is included in the response only when the object type is Normal. The value of this header is calculated based on the following process:1. Calculate the MD5 hash of the message content except for the headers based on RFC 1864 to obtain a 128-bit digit.2. Encode the digit by using Base64. • This header is not included in the response if the object type is Multipart or Appendable.

Header	Type	Example	Description
Last-Modified	String	Fri, 24 Feb 2012 06:07:48 GMT	The last time when the object is modified. The time is in GMT specified in HTTP/1.1.

Examples

Sample requests

```
HEAD /oss.jpg HTTP/1.1
Host: ***.regionid.example.com
Date: Fri, 24 Feb 2012 07:32:52 GMT
Authorization: OSS q***:J***=
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***1
x-oss-object-type: Normal
Date: Fri, 24 Feb 2012 07:32:52 GMT
Last-Modified: Fri, 24 Feb 2012 06:07:48 GMT
ETag: "f***8"
Content-Length: 344606
Content-Type: image/jpg
Connection: keep-alive
Server: AliyunOSS
```

6.1.1.6.8. GetObjectMeta

You can call this operation to query the basic metadata of an object in a bucket. The basic metadata includes the ETag, Size (object size), and LastModified. The object content is not returned.

Usage notes

- After the GetObjectMeta request is sent, no message body is contained in the response.
- You must include the Object meta parameter in the request when you call the GetObjectMeta operation. Otherwise, the request is used for GetObject.
- If the object does not exist, OSS returns 404 Not Found.
- GetObjectMeta is more lightweight than HeadObject. Only some basic metadata of an object in a bucket is returned for GetObjectMeta. The basic metadata includes the ETag, Size (object size), and LastModified. The value of the Content-Length response header indicates the object size.

Request structure

```
GET /ObjectName? objectMeta HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

Request headers involved in the GetObjectMeta operation contain only common request headers. For more information, see Common request headers.

Response headers

Header	Type	Example	Description
Content-Length	String	344606	The size of the object.
ETag	String	215697CF4417D144C25EB698F59EB599	The ETag that is created to identify the content of the object when the object is created. If an object created by using a PutObject request, the ETag of the object is the MD5 hash of the object content. If an object is created by using other methods, the ETag value is the UUID of the object content. The ETag value of the object can be used to check whether the object content is modified. However, we recommend that you do not use the ETag of an object as the MD5 hash of the object to check data integrity. Default value: null
Last-Modified	String	Fri, 24 Feb 2012 06:07:48 GMT	The last time when the object is modified. The time is in GMT specified in HTTP/1.1.

Examples

Sample requests

```
GET /oss.jpg? objectMeta HTTP/1.1
Host: ***.regionid.example.com
Date: Wed, 29 Apr 2015 05:21:12 GMT
Authorization: OSS q***c:C***=
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***1
Date: Wed, 29 Apr 2015 05:21:12 GMT
ETag: "5***E"
Last-Modified: Fri, 24 Feb 2012 06:07:48 GMT
Content-Length: 344606
Connection: keep-alive
Server: AliyunOSS
```

6.1.1.6.9. PutObjectACL

You can call this operation to modify the ACL of an object.

When you call PutObjectACL, you can set the x-oss-object-acl header in the PUT request to configure ACL for an object. Only bucket owners have permissions to configure object ACL. If the operation succeeds, 200 is returned. Otherwise, the corresponding error code and message are returned. The following object ACLs are available: private, public-read, public-read-write, and default.

Usage notes

- You can call PutObjectACL to configure ACL for an object. In addition, when you write an object, you can also include the x-oss-object-acl header in the request to configure ACL for the object. For example, you can include the x-oss-object-acl header in the request to configure the ACL for an object when you call PutObject.
- The object ACL takes precedence over its bucket ACL. For example, the bucket ACL is private, but the object ACL is public read/write. When the object is accessed, the object ACL takes precedence over the bucket ACL. If an object has no ACL configured, its bucket ACL applies.

Request structure

```
PUT /ObjectName? acl HTTP/1.1
x-oss-object-acl: Permission
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

Header	Type	Required	Example	Description
x-oss-object-acl	String	Yes	private	The ACL of the object when the object was created. Valid values: • private: Only the owner or authorized users of the bucket can read and write the object. • public-read: Only the owner or authorized users of this bucket can write the object. Other users, including anonymous users can only read the object. • public-read-write: All users, including anonymous users, can read and write the object. • default: The ACL of an object is the same as that of the bucket in which the object is stored.

For more information about the other common request headers involved in the PutObjectACL operation, see Common request headers.

Response headers

The response headers involved in the PutObjectACL operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
PUT /test-object? acl HTTP/1.1
x-oss-object-acl: public-read
Host: ***.regionid.example.com
Date: Wed, 29 Apr 2015 05:21:12 GMT
Authorization: OSS q***c:K***=
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***1
Date: Wed, 29 Apr 2015 05:21:12 GMT
Content-Length: 0
Connection: keep-alive
Server: AliyunOSS
```

6.1.1.6.10. GetObjectACL

You can call this operation to query the ACL of an object.

Request structure

```
GET /ObjectName? acl HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

The request headers involved in the GetObjectACL operation contain only common request headers. For more information, see Common request headers.

Response elements

Element	Type	Example	Description
AccessControlList	Container	N/A	The container that contains the ACL information.
AccessControlPolicy	Container	N/A	The container used to store results of the GetObjectACL request.
DisplayName	String	1746495857******	The name of the bucket owner, which is the same as the user ID.

Element	Type	Example	Description
Grant	Enumerated string	private	The ACL of the object. Valid values: private, public-read, and public-read-write
ID	String	1746495857******	The user ID of the bucket owner.
Owner	Container	N/A	The container that stores the information about the bucket owner.

Examples

Sample requests

```
GET /test-object? acl HTTP/1.1
Host: ***.regionid.example.com
Date: Wed, 29 Apr 2015 05:21:12 GMT
Authorization: OSS q***c:C***=
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***1
Date: Wed, 29 Apr 2015 05:21:12 GMT
Content-Length: 253
Content-Type: application/xml
Connection: keep-alive
Server: AliyunOSS
<? xml version="1.0" ? >
<AccessControlPolicy>
    <Owner>
        <ID>0***2</ID>
        <DisplayName>0***2</DisplayName>
    </Owner>
    <AccessControlList>
        <Grant>public-read </Grant>
    </AccessControlList>
</AccessControlPolicy>
```

6.1.1.6.11. PostObject

You can call this operation to upload an object to a specific bucket by using HTML forms.

Usage notes

When you call the PostObject operation, take note of the following items:

- To perform the PostObject operation on a bucket, you must have write permissions on the bucket. If the ACL of the bucket is public read/write, you do not need to upload the signature information. If

the ACL of the bucket is not public read/write, signature verification is required for this operation.

- Unlike PutObject, PostObject uses an AccessKey secret to calculate the signature for a policy. The calculated signature string is used as the value of the Signature form field. OSS checks this value to verify the validity of the signature.
- The URL of the submitted form can be the domain name of the bucket. You do not need to specify the object in the URL. In other words, the request line is in the format of `POST / HTTP/1.1` instead of `POST /ObjectName HTTP/1.1`.
- OSS does not check the signature included in headers or URLs in PostObject requests.

Request structure

```
POST / HTTP/1.1
Host: BucketName.regionid.example.com
User-Agent: browser_data
Content-Length: ContentLength
Content-Type: multipart/form-data; boundary=9431149156168
--9431149156168
Content-Disposition: form-data; name="key"
key
--9431149156168
Content-Disposition: form-data; name="success_action_redirect"
success_redirect
--9431149156168
Content-Disposition: form-data; name="Content-Disposition"
attachment;filename=oss_download.jpg
--9431149156168
Content-Disposition: form-data; name="x-oss-meta-uuid"
myuuid
--9431149156168
Content-Disposition: form-data; name="x-oss-meta-tag"
mytag
--9431149156168
Content-Disposition: form-data; name="OSSAccessKeyId"
access-key-id
--9431149156168
Content-Disposition: form-data; name="policy"
encoded_policy
--9431149156168
Content-Disposition: form-data; name="Signature"
signature
--9431149156168
Content-Disposition: form-data; name="file"; filename="MyFilename.jpg"
Content-Type: image/jpeg
file_content
--9431149156168
Content-Disposition: form-data; name="submit"
Upload to OSS
--9431149156168--
```

Request headers

> **Note** The message body of a PostObject request is encoded in the multipart/form-data format. In PostObject operations, parameters are passed as form fields in the request message body, whereas parameters are passed as HTTP request headers in PutObject operations.

Header	Type	Required	Example	Description
OSSAccessKeyId	String	Conditional	LTAI4Fw2NbDUCV8zYU******	The AccessKey ID of the bucket owner. Default value: null Constraint: This form field is required when the bucket ACL is not public read/write or when the policy or Signature form field is provided.
policy	String	Conditional	`{ "expiration": "2014-12-01T12:00:00.000Z", "conditions": [ {"bucket": "johnsmith" }, ["starts-with", "$key", "user/eric/"] ] }`	Specifies the validity of the form fields in the request. A request that does not contain the policy form field is considered to be an anonymous request, and can be used only to access buckets whose ACLs are public read/write. For more information about the policy example, see Post policy. Default value: null Constraint: This form field is required when the bucket ACL is not public read/write or when the OSSAccessKeyId or Signature form field is provided. **Note** The form and the policy form field must be encoded in UTF-8.
Signature	String	Conditional	None	Specifies the signature information that is calculated based on the AccessKey secret and the policy form field. OSS checks the signature information to verify the validity of the PostObject request. Default value: null Constraint: This form field is required when the bucket ACL is not public read/write or when the OSSAccessKeyId or policy form field is provided. **Note** Form fields are case-insensitive, but their values are case-sensitive.

Header	Type	Required	Example	Description
Cache-Control, Content-Type, Content-Disposition, Content-Encoding, and Expires	String	No	None	The HTTP request headers. For more information, see PutObject. Default value: null The form submitted by the PostObject operation must be encoded in the `multipart/form-data` format. For example, the Content-Type header must be in the `multipart/form-data;boundary=xxxxxx` format, where boundary is a boundary string.
x-oss-content-type	String	No	text/h323	You can add the x-oss-content-type header in the message body of a PostObject request to specify the Content-Type of the object to upload. The Content-Type value specified by the x-oss-content-type header has the highest priority. The content type of the object is determined by three headers in the following priority in descending order: x-oss-content-type > Content-Type in the form field > Content-Type. Default value: null
key	String	Yes	/user/a/objectName.txt	The name of the object to upload. If the object name includes a path such as a/b/c/b.jpg, OSS automatically creates corresponding folders. Default value: null
success_action_redirect	String	No	None	The URL to which the client is redirected after the object is uploaded. If this form field is not specified, the returned result is specified by success_action_status. If the upload fails, OSS returns an error code, and the client is not redirected to a URL. Default value: null

Header	Type	Required	Example	Description
success_action_status	String	No	200	The status code returned to the client when the success_action_redirect form field is not specified and the object is uploaded. Default value: 204 Valid values: 200, 201, and 204. • If the value of this form field is set to 200 or 204, OSS returns an empty file and the 200 or 204 status code. • If the value of this form field is set to 201, OSS returns an XML file and the 201 status code. • If the value of this form field is not specified or set to an invalid value, OSS returns an empty file and the 204 status code.
x-oss-meta-*	String	No	x-oss-meta-location	The metadata customized by the user. Default value: null If the request contains a form field prefixed with x-oss-meta-, the form field is considered to be the user metadata. Example: x-oss-meta-location. **Note** An object may have multiple similar parameters prefixed with x-oss-meta-, but the total size of the user metadata cannot exceed 8 KB.
x-oss-server-side-encryption	String	No	KMS	The server-side encryption algorithm that is used when OSS creates the object. Valid values: *AES256* and *KMS* If you specify this parameter, it is returned in the response header and the uploaded object is encrypted and stored. When you download the encrypted object, the x-oss-server-side-encryption field is included in the response header and the field value is set to the algorithm used to encrypt the object.

Header	Type	Required	Example	Description
x-oss-server-side-encryption-key-id	String	No	3dea0cae-5fd6-4bf8-8574-87c557******	The ID of the customer master key (CMK) hosted in KMS. This parameter is valid only when the value of x-oss-server-side-encryption is set to KMS.
x-oss-object-acl	String	No	private	The ACL of the object when the object is created. Valid values: *public-read*, *private*, and *public-read-write*
x-oss-security-token	String	No	None	The security token for temporary authorization. If an STS temporary security credential is used for this access, you must set this field to the SecurityToken value and set OSSAccessKeyId to the value of the paired temporary AccessKey ID. The method to calculate a signature based on a temporary AccessKey ID is the same as that based on a typical AccessKey ID. Default value: null
file	String	Yes	MyFilename.txt	The file or text content. Browsers automatically set the Content-Type header based on the file type and overwrite the user setting. Only one file can be uploaded to OSS at a time. Default value: null **Notice** This header must be the last field in the form.

Response headers

Header	Type	Example	Description
x-oss-server-side-encryption	String	KMS	If x-oss-server-side-encryption is specified in the request, the response contains this header to indicate the encryption algorithm used to encrypt the object at the server side.

Response elements

Element	Type	Example	Description
PostResponse	Container	N/A	The container that stores the result of the Post request.
Bucket	String	examplebucket	The bucket name.
ETag	String	E64478CDF7F0BFAF602F8D676D5B04E1	The entity tag (ETag) that is created when an object is generated. If an object is created by calling the PostObject operation, the ETag value is the object UUID, which can be used to check whether the object content is changed.
Location	String	https://examplebucket.endpoint/user/a/objectName.txt	The URL of the new object that is created.

Examples

Sample requests

```
POST / HTTP/1.1
Host: ***.regionid.example.com
Content-Length: 344606
Content-Type: multipart/form-data; boundary=9431149156168

```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 6***e
Date: Fri, 24 Feb 2014 06:03:28 GMT
ETag: 5***E
Connection: keep-alive
Content-Length: 0
Server: AliyunOSS
```

Post policy

The policy form field in a PostObject request is used to verify the validity of the request. The policy value is a JSON text encoded in UTF-8 and Base64. This value declares the conditions that a PostObject request must meet. The policy form field is optional for uploading objects to a bucket whose ACL is public read/write. However, to limit PostObject requests, we recommend that you use this field.

- Policy example

```
{ "expiration": "2014-12-01T12:00:00.000Z",
 "conditions": [
 {"bucket": "johnsmith" },
 ["starts-with", "$key", "user/eric/"]
 ]
}
```

In the PostObject request, the policy must contain the expiration and conditions attributes.

- Expiration

Expiration specifies the expiration time of the policy, which is expressed in ISO 8601 GMT. For example, "2014-12-01T12:00:00.000Z" indicates that the PostObject request must be sent before 12:00:00 on December 1, 2014.

- Conditions

Conditions is a list that specifies the valid values of form fields in the PostObject request. The value of a form field is extended after OSS checks the policy. Therefore, the valid value of the form field set in policy is equivalent to the value of the form field before extension. For example, if the key form field is set to user/user1/${filename} and the object name before the upload is a.txt, the key form field in policy of the PostObject request must be set to ["eq", "$key", "user/user1/\${filename}"] instead of ["eq", "$key","$key", "user/user1/a.txt"]. The following table lists the conditions supported by the policy.

Conditions

Condition	Description
content-length-range	The acceptable maximum and minimum sizes of the uploaded file. This condition supports the content-length-range match mode.
Cache-Control, Content-Type, Content-Disposition, Content-Encoding, Expires	HTTP request headers. This condition supports the exact match and starts-with match modes.
key	The name of the object after the upload. This condition supports the exact match and starts-with match modes.
success_action_redirect	The URL to which the client is redirected after the object is uploaded. This condition supports the exact match and starts-with match modes.
success_action_status	The status code returned after the object is uploaded if success_action_redirect is not specified. This condition supports the exact match and starts-with match modes.
x-oss-meta-*	The metadata customized by the user. This condition supports the exact match and starts-with match modes.

If the PostObject request contains other form fields, these extra form fields can be added to conditions of the policy. OSS does not check validity of the form fields that are not included in conditions.

- Condition match modes

Match mode	Description
Exact match	The value of a form field must be exactly the same as the value that is declared in conditions. For example, if the value of the key form field must be a, the condition can be {"key": "a"} or ["eq", "$key", "a"].
Starts With	The value of a form field must start with the specified value. For example, if the value of the key form field must start with /user/user1, the condition is ["starts-with", "$key", "/user/user1"].
Specified object size	The maximum and minimum sizes of the object that can be uploaded. For example, if the acceptable object size is 1 to 10 bytes, the condition is ["content-length-range", 1, 10].

- Escape characters

  In the policy of a PostObject request, a dollar sign ($) is used to indicate a variable. Therefore, to describe the dollar sign ($), you must use escape characters (\$). In addition, some characters in JSON are escaped. The following table describes escape characters for the JSON string of the policy in the PostObject request.

  Escape characters

Escape character	Description
\/	Slash
\	Backslash
\"	Double quotation marks
\$	Dollar sign
\b	Backspace
\f	Form feed
\n	Line feed
\r	Carriage return
\t	Horizontal tab
\uxxxx	Unicode character

Post Signature

For signature authentication, the HTML form must contain policy and Signature. policy specifies the values that are valid in the request. The procedure to calculate the Signature field value:

1. Create a UTF-8 encoded policy.
2. Encode the policy in Base64. The encoding result is the value of the policy form field, and this value is used as the string-to-sign.
3. Use the AccessKey secret to sign the string. The signing method is the same as the method to calculate the signature in the header, which replaces the string-to-sign with the policy form field value.

6.1.1.6.12. Callback

To enable OSS to return callback information of an object to an application server after the object is uploaded to OSS, you need only to include a callback parameter in the upload request that is sent to OSS. This topic describes how to implement upload callback in detail.

> **Note** Operations that support callbacks include PutObject, PostObject, and CompleteMultipartUpload.

Step 1: Create parameters

- Callback parameter

  A callback parameter is a Base64-encoded string (field) in the JSON format. To create a callback parameter, you must specify the URL (callbackUrl) of the server to which the callback information is sent and the content (callbackBody) of the callback information.

  The following table describes the JSON fields that are included in a callback parameter.

Field	Description	Required
callbackUrl	Field descriptions and usage notes: ○ After an object is uploaded, OSS sends a callback request by using the POST method to this URL. The body of the request is the content specified in callbackBody. In most cases, the URL returns an `HTTP/1.1 200 OK` response. The response body must be in the JSON format, and the Content-Length response header value is smaller than 3 MB. ○ You can configure up to five URLs that are separated with semicolons (;) for a request. OSS sends requests to each URL until the first success response is returned. ○ If no URLs are configured or the value of this field is null, OSS determines that the callback feature is not configured. ○ HTTPS-based URLs are supported. ○ To ensure that Chinese characters can be correctly processed, the callback URL must be encoded.	Yes

Field	Description	Required
callbackHost	Field descriptions and usage notes: ○ The value of the Host header in the callback request. This field is valid only when callbackUrl is specified. ○ If callbackHost is not specified, the host values are resolved from the URLs of the callbackUrl field and are specified as the value of callbackHost.	No
callbackBody	Field descriptions and usage notes: ○ The value of the callback request body. Example: key=$(key)&etag=$(etag)&my_var=$(x:my_var). ○ OSS system variables as well as custom variables and constants are supported. The following table lists supported system variables. Custom variables are passed in by using the callback-var parameter in the PutObject and CompleteMultipart operations and by using form fields in the PostObject operation.	Yes
callbackBodyType	Field descriptions and usage notes: ○ The Content-Type header in the callback request. Valid values: application/x-www-form-urlencoded and application/json. Default value: application/x-www-form-urlencoded. ○ If callbackBodyType is set to application/x-www-form-urlencoded, the variables in callbackBodyType are replaced with URL-encoded values. If callbackBodyType is set to application/json, the variables in callbackBodyType are replaced with JSON-formatted values.	No

Examples of the JSON fields:

```
{
"callbackUrl":"121.101.166.30/test.php",
"callbackHost":"oss-cn-hangzhou.aliyuncs.com",
"callbackBody":"{\"mimeType\":${mimeType},\"size\":${size}}",
"callbackBodyType":"application/json"
}
```

```
{
"callbackUrl":"121.43.113.8:23456/index.html",
"callbackBody":"bucket=${bucket}&object=${object}&etag=${etag}&size=${size}&mimeType=${mimeType}&imageInfo.height=${imageInfo.height}&imageInfo.width=${imageInfo.width}&imageInfo.format=${imageInfo.format}&my_var=${x:my_var}"
}
```

The following table lists the system parameters you can configure for callbackBody.

System parameter	Description
bucket	The name of the bucket.
object	The name of the object.
etag	The ETag field configured for the object and returned to the requester.
size	The size of the object to request, which is the total size of the entire object in CompleteMultipartUpload operations.
mimeType	The type of the resource. For example, the resource type of JPEG images is image/jpeg.
imageInfo.height	The height of the image.
imageInfo.width	The width of the image.
imageInfo.format	The format of the image. Examples: JPG and PNG.

> **Note** This parameter applies only to image objects. If the object is not an image, the values of imageInfo.height, imageInfo.width, and imageInfo.format are null.

- Create custom parameters by using callback-var

  You can configure custom parameters by using the callback-var parameter. Custom parameters are key-value pairs in map. You can add the required parameters to the map. When a POST callback request is initiated, OSS adds these custom parameters and the system parameters described in the preceding section to the body of the POST request. This method allows these parameters to be obtained by the requester.

  You can create a custom parameter the way you create a callback parameter, which must be passed in the JSON format. The JSON string is a map that consists of key-value pairs of all custom parameters.

  > **Note** The key of a custom parameter must start with x: and be lowercase letters. Otherwise, OSS returns an error.

  Assume that you must configure two custom parameters x:var1 and x:var2. The value of x:var1 is value1. The value of x:var2 is value2. Created JSON string:

```
{
"x:var1":"value1",
"x:var2":"value2"
}
```

Note If the input callback parameter or callback-var parameter is invalid, HTTP status code 400 and error code InvalidArgument are returned. This error occurs in the following scenarios:

- URLs and headers are passed in at the same time to the callback parameter (x-oss-callback) or the callback-var parameter (x-oss-callback-var) in PutObject and CompleteMultipartUpload operations.
- The size of the callback or callback-var parameter exceeds 5 KB. This does not occur in PostObject operations because the callback-var parameter is unavailable in PostObject operations.
- The callback or callback-var parameter is not Base64-encoded or is not in a valid JSON format after the callback or callback-var parameter is decoded.
- The callbackUrl field that is decoded from the callback parameter includes more than five URLs, or the port in the URL is invalid. Example:

```
{"callbackUrl":"10.101.166.30:test",
    "callbackBody":"test"}
```

- The callbackBody field that is decoded from the callback parameter is null.
- The value of the callbackBodyType field decoded from the callback parameter is not `application/x-www-form-urlencoded` or `application/json`.
- The variables in the callbackBody field decoded from the callback parameter are not in the format of ${var}.
- The variables in the callbackBody field decoded from the callback-var parameter are not in the expected JSON format of `{"x:var1":"value1","x:var2":"value2"...}`.

Step 2: Create a callback request

After you create the callback and callback-var parameters, you must add the parameters to the callback request that is sent to OSS.

You can use the following methods to add parameters:

- Add the parameters to a URL.
- Add the parameters to the header.
- Add the parameters to the form fields in the body of a POST request.

Note You can use only this method to specify callback parameters when you upload objects by using POST requests.

You can use only one of the preceding three methods. If you use more than one method, OSS returns the InvalidArgument error code.

To add the parameters to a request that is sent to OSS, you must use Base64 to encode the JSON string created in the preceding section, and then add the parameters:

- To add the parameters to a URL, add `callback=[CallBack]` or `callback-var=[CallBackVar]` to the request as a URL parameter. When the signature for the CanonicalizedResource field is calculated, callback or callback-var is used as a subresource.
- To add the parameters to the header, add `x-oss-callback=[CallBack]` or `x-oss-callback-var=[CallBackVar]` to the request as a header. When the signature for the CanonicalizedOSSHeaders

field is calculated, include x-oss-callback-var and x-oss-callback. Examples:

```
PUT /test.txt HTTP/1.1
Host: callback-test.oss-test.aliyun-inc.com
Accept-Encoding: identity
Content-Length: 5
x-oss-callback-var: eyJ4Om15X3ZhciI6ImZvci1jYWxsYmFjay10ZXN0In0=
User-Agent: aliyun-sdk-python/0.4.0 (Linux/2.6.32-220.23.2.ali1089.el5.x86_64/x86_64;2.5.
4)
x-oss-callback: eyJjYWxsYmFja1VybCI6IjEyMS40My4xMTMuODoyMzQ1Ni9pbmRleC5odG1sIiwgICJjYWxsY
mFja0JvZHkiOiJidWNrZXQ9JHtidWNrZXR9Jm9iamVjdD0ke29iamVjdH0mZXRhZz0ke2V0YWd9JnNpemU9JHtzaX
plfSZtaW1lVHlwZT0ke21pbWVUeXBlfSZpbWFnZUluZm8uaGVpZ2h0PSR7aW1hZ2VJbmZvLmhlaWdodH0maW1hZ2V
JbmZvLndpZHRoPSR7aW1hZ2VJbmZvLndpZHRofSZpbWFnZUluZm8uZm9ybWF0PSR7aW1hZ2VJbmZvLmZvcmlhdH0m
bXlfdmFyPSR7eDpteV92YXJ9In0=
Host: callback-test.oss-test.aliyun-inc.com
Expect: 100-Continue
Date: Mon, 14 Sep 2015 12:37:27 GMT
Content-Type: text/plain
Authorization: OSS mlepou3zr4u7b14:5a74vhd4UXpmyuudV14Kaen5****
Test
```

- Add the parameters to the form fields in the body of a POST request.
  - It is complex to add the callback parameter when the POST method is used to upload an object because the callback parameter must be added by using a separate form field. Example:

```
--9431149156168
Content-Disposition: form-data; name="callback"
eyJjYWxsYmFja1VybCI6IjEwLjEwMS4xNjYuMzA6ODA4My9jYWxsYmFjay5waHAiLCJjYWxsYmFja0hvc3QiOiI
xMC4xMDEuMTY2LjMwIiwiY2FsbGJhY2tCb2R5IjoiZmlsZW5hbWU9JChmaWxlbmFtZSkmdGFibGU9JHt4OnRhYm
xlfSIsImNhbGxiYWNrQm9keVR5cGUiOiJhcHBsaWNhdGlvbi94LXd3dy1mb3JtLXVybGVuY29kZWQifQ==
```

- Each custom parameter uses a separate form field. You cannot add the callback-var parameter to existing fields. Examples of JSON fields for customer parameters:

```
{
"x:var1":"value1",
"x:var2":"value2"
}
```

The form fields in the POST request:

```
--9431149156168
Content-Disposition: form-data; name="callback"
eyJjYWxsYmFja1VybCI6IjEwLjEwMS4xNjYuMzA6ODA4My9jYWxsYmFjay5waHAiLCJjYWxsYmFja0hvc3QiOiI
xMC4xMDEuMTY2LjMwIiwiY2FsbGJhY2tCb2R5IjoiZmlsZW5hbWU9JChmaWxlbmFtZSkmdGFibGU9JHt4OnRhYm
xlfSIsImNhbGxiYWNrQm9keVR5cGUiOiJhcHBsaWNhdGlvbi94LXd3dy1mb3JtLXVybGVuY29kZWQifQ==
--9431149156168
Content-Disposition: form-data; name="x:var1"
value1
--9431149156168
Content-Disposition: form-data; name="x:var2"
value2
```

You can also add callback conditions to the policy (if callback parameters are not added, upload verification is not performed on the policy). Example:

```
{ "expiration": "2014-12-01T12:00:00.000Z",
  "conditions": [
    {"bucket": "johnsmith" },
    {"callback": "eyJjYWxsYmFja1VybCI6IjEwLjEwMS4xNjYuMzA6ODA4My9jYWxsYmFjay5waHAiLCJjY
WxsYmFja0hvc3QiOiIxMC4xMDEuMTY2LjMwIiwiY2FsbGJhY2tCb2R5IjoiZmlsZW5hbWU9JChmaWxlbmFtZSki
LCJjYWxsYmFja0JvZHlUeXBlIjoiYXBwbGljYXRpb24veC13d3ctZm9ybS11cmxlbmNvZGVkIn0="},
    ["starts-with", "$key", "user/eric/"],
  ]
}
```

Step 3: Initiate a callback request

If an object is uploaded, OSS sends the content specified by the callback and callback-var parameters in the request to the application server by using the POST method. Example:

```
POST /index.html HTTP/1.0
Host: 121.43.113.8
Connection: close
Content-Length: 181
Content-Type: application/x-www-form-urlencoded
User-Agent: http-client/0.0.1
bucket=callback-test&object=test.txt&etag=D8E8FCA2DC0F896FD7CB4CB0031BA249&size=5&mimeType=
text%2Fplain&imageInfo.height=&imageInfo.width=&imageInfo.format=&x:var1=for-callback-test
```

Step 4: (Optional) Sign the callback request

If the callback parameter is configured in the request, OSS uses POST to send a callback request to the application server based on the specified callback URL. To verify whether the callback request received by the application server is initiated by OSS, you can sign the callback request.

- Generate a signature

  A callback request is signed by OSS by using the RSA asymmetric algorithm.

  To generate a signature, encrypt the callback string by using a private key. Example:

  ```
  authorization = base64_encode(rsa_sign(private_key, url_decode(path) + query_string + '\n
  ' + body, md5))
  ```

  > **Note** In the preceding code, private_key is a private key known only by OSS, path is the resource path included in the callback request, query_string is the query string, and body is the message body specified in the callback request.

  A callback request is signed in the following steps:

  i. Obtain the callback string to sign, which consists of the resource path that is obtained by decoding the URL, the original query string, a carriage return, and the callback message body.

  ii. Sign the callback string by using the RSA encryption algorithm. Use the private key to encrypt the signature string. The hash function used for the signature is MD5.

  iii. Use Base64 to encode the signed result to obtain the final signature and add the signature to the Authorization header in the callback request.

  Examples:

  ```
  POST /index.php? id=1&index=2 HTTP/1.0
  Host: 121.43.113.8
  Connection: close
  Content-Length: 18
  authorization: kKQeGTRccDKyHB3H9vF+xYMSrmhMZjzzl2/kdD1ktNVgbWEfYTQG0G2SU/RaHBovRCE8OkQDjC
  3uG33esH2t****
  Content-Type: application/x-www-form-urlencoded
  User-Agent: http-client/0.0.1
  x-oss-pub-key-url: aHR0cDovL2dvc3NwdWJsaWMuYWxpY2RuLmNvbS9jYWxsYmFja19wdWJfa2V5X3YxLnBlbQ
  ==
  bucket=yonghu-test
  ```

  In the preceding code, path is set to `/index.php`, and query_string is set to `? id=1&index=2`, and the body is set to `bucket=yonghu-test`. The final signature is `kKQeGTRccDKyHB3H9vF+xYMSrmhMZjzzl2/kdD1ktNVgbWEfYTQG0G2SU/RaHBovRCE8OkQDjC3uG33esH2txA==`.

- Verify the signature

  Signature verification is an inverse process of signing a request. The signature is verified by the application server. Process:

  ```
  Result = rsa_verify(public_key, md5(url_decode(path) + query_string + '\n' + body), base6
  4_decode(authorization))
  ```

  The fields in the preceding code and the fields that are used to sign the request have the same meanings. public_key specifies the public key and authorization specifies the signature in the callback request header. Process of verifying the signature:

  i. The x-oss-pub-key-url header in the callback request stores the Base64-encoded URL of the public key. Therefore, you must decode the Base64-encoded URL to obtain the public key.

```
public_key = urlopen(base64_decode(x-oss-pub-key-url header value))
```

> **Note** To ensure that the public key is issued by OSS, you must verify whether the value of the `x-oss-pub-key-url` header starts with `http://gosspublic.alicdn.com/` or `https://gosspublic.alicdn.com/`.

ii. Obtain the signature decoded in Base64.

```
signature = base64_decode(authorization header value)
```

iii. Obtain the string to sign the way described in the process of signing the callback request.

```
sign_str = url_decode(path) + query_string + '\n' + body
```

iv. Verify the signature.

```
result = rsa_verify(public_key, md5(sign_str), signature)
```

Complete process of verifying the signature:

i. Obtain the URL of the public key by decoding `aHR0cDovL2dvc3NwdWJsaWMuYWxpY2RuLmNvbS9jYWxsYmFja19wdWJfa2V5X3YxLnBlbQ==` in Base64. The decoded URL is `http://gosspublic.alicdn.com/callback_pub_key_v1.pem`.

ii. Decode `kKQeGTRccDKyHB3H9vF+xYMSrmhMZjzzl2/kdD1ktNVgbWEfYTQG0G2SU/RaHBovRCE8OkQDjC3uG33esH2txA==` in Base64. The decoded result cannot be displayed because it is a nonprintable string.

iii. Obtain the string to sign, which is url_decode("index.php") + "? id=1&index=2" + "\n" + "bucket=yonghu-test", and perform MD5 verification on the string.

iv. Verify the signature.

- Example for an application server to verify a signature:

  The following Python code provides an example of how an application server verifies a signature. Before you run the code, the M2Crypto library must be installed.

```
import httplib
import base64
import md5
import urllib2
from BaseHTTPServer import BaseHTTPRequestHandler, HTTPServer
from M2Crypto import RSA
from M2Crypto import BIO
def get_local_ip():
    try:
        csock = socket.socket(socket.AF_INET, socket.SOCK_DGRAM)
        csock.connect(('8.8.8.8', 80))
        (addr, port) = csock.getsockname()
        csock.close()
        return addr
    except socket.error:
        return ""
class MyHTTPRequestHandler(BaseHTTPRequestHandler):
    '''
    def log_message(self, format, *args):
```

```
    def log_message(self, format, *args):
        return
    '''
    def do_POST(self):
        #get public key
        pub_key_url = ''
        try:
            pub_key_url_base64 = self.headers['x-oss-pub-key-url']
            pub_key_url = pub_key_url_base64.decode('base64')
            if not pub_key_url.startswith("http://gosspublic.alicdn.com/") and not pub_ke
y_url.startswith("https://gosspublic.alicdn.com/"):
                self.send_response(400)
                self.end_headers()
                return
            url_reader = urllib2.urlopen(pub_key_url)
            #you can cache it
            pub_key = url_reader.read()
        except:
            print 'pub_key_url : ' + pub_key_url
            print 'Get pub key failed!'
            self.send_response(400)
            self.end_headers()
            return
        #get authorization
        authorization_base64 = self.headers['authorization']
        authorization = authorization_base64.decode('base64')
        #get callback body
        content_length = self.headers['content-length']
        callback_body = self.rfile.read(int(content_length))
        #compose authorization string
        auth_str = ''
        pos = self.path.find('?')
        if -1 == pos:
            auth_str = urllib2.unquote(self.path) + '\n' + callback_body
        else:
            auth_str = urllib2.unquote(self.path[0:pos]) + self.path[pos:] + '\n' + callb
ack_body
        print auth_str
        #verify authorization
        auth_md5 = md5.new(auth_str).digest()
        bio = BIO.MemoryBuffer(pub_key)
        rsa_pub = RSA.load_pub_key_bio(bio)
        try:
            result = rsa_pub.verify(auth_md5, authorization, 'md5')
        except:
            result = False
        if not result:
            print 'Authorization verify failed!'
            print 'Public key : %s' % (pub_key)
            print 'Auth string : %s' % (auth_str)
            self.send_response(400)
            self.end_headers()
            return
        #do something according to callback_body
        #response to OSS
```

```
        resp_body = '{"Status":"OK"}'
        self.send_response(200)
        self.send_header('Content-Type', 'application/json')
        self.send_header('Content-Length', str(len(resp_body)))
        self.end_headers()
        self.wfile.write(resp_body)
class MyHTTPServer(HTTPServer):
    def __init__(self, host, port):
        HTTPServer.__init__(self, (host, port), MyHTTPRequestHandler)
if '__main__' == __name__:
    server_ip = get_local_ip()
server_port = 23451
server = MyHTTPServer(server_ip, server_port)
server.serve_forever()
```

The code for the server in other programming languages:

Java:

- Download link: Java
- Running method: Decompress the package, and run `java -jar oss-callback-server-demo.jar 9000`. 9000 is the port number and can be customized.

PHP:

- Download link: PHP
- Running method: Deploy the code to an Apache environment because some headers in the PHP code depend on the environment. You can modify the example code based on the environment.

Python:

- Download link: Python
- Running method: Decompress the package, and run `python callback_app_server.py`. Before you run the code, RSA dependencies must be installed.

.NET:

- Download link: .NET
- Running method: Decompress the package, and follow `README.md`.

Go:

- Download link: Go
- Running method: Decompress the package, and follow `README.md`.

Ruby:

- Download link: Ruby
- Running method: Run the ruby aliyun_oss_callback_server.rb command.

Step 5: Return the callback result

The application server returns the response to OSS.

The response to the callback request:

```
HTTP/1.0 200 OK
Server: BaseHTTP/0.3 Python/2.7.6
Date: Mon, 14 Sep 2015 12:37:27 GMT
Content-Type: application/json
Content-Length: 9
{"a":"b"}
```

Note The response returned by the application server to OSS must contain the Content-Length header. The size of the response body cannot exceed 1 MB.

Step 6: Return the upload result

OSS returns the information that is returned by the application server to the user.

An example of the returned response:

```
HTTP/1.1 200 OK
Date: Mon, 14 Sep 2015 12:37:27 GMT
Content-Type: application/json
Content-Length: 9
Connection: keep-alive
ETag: "D8E8FCA2DC0F896FD7CB4CB0031BA249"
Server: AliyunOSS
x-oss-bucket-version: 1442231779
x-oss-request-id: 55F6BF87207FB30F2640C548
{"a":"b"}
```

Note

- The body of responses to some requests such as CompleteMultipartUpload contains content such as information in the XML format. If you use the upload callback feature, the original body content such as `{"a":"b"}` is overwritten. Exercise caution when you implement upload callback.
- If the upload callback fails, HTTP status code 203 and error code CallbackFailed are returned. This response indicates that the object is uploaded to OSS, but the callback fails. A callback failure only indicates that OSS does not receive the expected callback response. It does not indicate that the application server does not receive a callback request. For example, a callback failure occurs if the response returned by the application server is not in the JSON format.

6.1.1.7. Multipart upload-relevant operations

6.1.1.7.1. Overview

OSS provides multipart upload in addition to operations such as PutObject and PostObject.

Multipart upload can be used in the following scenarios but is not limited to:

- Resumable upload of the object is required.

- The size of the object you want to upload is larger than 5 GB.
- The OSS server is frequently disconnected due to poor network conditions.
- The size of the object you want to upload is unknown.

6.1.1.7.2. InitiateMultipartUpload

Before you use multipart upload to upload data, you must call the InitiateMultipartUpload operation to notify OSS to initiate a multipart upload task.

The OSS server returns a globally unique upload ID for the InitiateMultipartUpload operation. The upload ID uniquely identifies the multipart upload task. You can initiate operations such as stopping or querying the multipart upload task based on this upload ID.

Usage notes

- When you perform this operation to calculate the signature for authentication, you must add `?uploads` to CanonicalizedResource.
- If you set the x-oss-server-side-encryption header in the InitiateMultipartUpload request, the response contains this header. When each part is uploaded, the server encrypts and stores them. OSS server-side encryption supports the AES-256 and SM4 algorithms. If other algorithms are specified, OSS returns HTTP status code 400 and InvalidEncryptionAlgorithmError. When you upload each part, you do not need to add the x-oss-server-side-encryption request header. If this header is specified, OSS returns HTTP status code 400 and InvalidArgument.

Request structure

```
POST /ObjectName?uploads HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT date
Authorization: SignatureValue
```

Request parameters

The encoding-type parameter can be specified in the InitiateMultipartUpload request. OSS uses the specified encoding type to encode the object name in the response.

Parameter	Type	Required	Example	Description
encoding-type	String	No	url	The encoding type of the object names in the response. The object name can contain characters that are encoded in UTF-8. However, the XML 1.0 standard cannot be used to parse certain control characters such as characters with an ASCII value from 0 to 10. You can set the encoding-type parameter to encode the object names in the response. Set the value to url. Default value: null Valid value: url

Request headers

Header	Type	Required	Example	Description
Cache-Control	String	No	no-cache	The web page caching behavior that is specified when the object is downloaded. For more information, visit RFC 2616. Type: string. Default value: null
Content-Disposition	String	No	attachment; filename=oss_download.jpg	The presentational information of the object during the download. For more information, visit RFC 2616. Type: string. Default value: null
Content-Encoding	String	No	utf-8	The content encoding type of the object during the download. For more information, visit RFC 2616. Type: string. Default value: null
Expires	Integer	No	None	The expiration time in milliseconds. For more information, visit RFC 2616. Default value: null
x-oss-server-side-encryption	String	No	AES256	The encryption algorithm that OSS uses to encrypt each uploaded part of an object before storage. Valid values: AES256 and SM4

Response elements

Element	Type	Example	Description
Bucket	String	multipart_upload	The name of the bucket to which the object is uploaded by the multipart upload task.
InitiateMultipartUploadResult	Container	N/A	The container that is used to store the result of the InitiateMultipartUpload request.
Key	String	multipart.data	The name of the object that is uploaded by the multipart upload task.
UploadId	String	0***D	The unique ID of the multipart upload task.

Element	Type	Example	Description
EncodingType	String	url	The encoding type of the object name in the response. If the encoding-type parameter is specified in the request, the object name in the response is encoded.

Examples

Sample requests

```
POST /multipart.data? uploads HTTP/1.1
Host: ***.regionid.example.com
Date: Wed, 22 Feb 2012 08:32:21 GMT
Authorization: OSS q***4=
```

Sample responses

```
HTTP/1.1 200 OK
Content-Length: 230
Server: AliyunOSS
Connection: keep-alive
x-oss-request-id: 4***8
Date: Wed, 22 Feb 2012 08:32:21 GMT
Content-Type: application/xml
<? xml version="1.0" encoding="UTF-8"? >
<InitiateMultipartUploadResult xmlns="http://doc.oss-cn-hangzhou.aliyuncs.com">
    <Bucket>multipart_upload</Bucket>
    <Key>multipart.data</Key>
    <UploadId>0***D</UploadId>
</InitiateMultipartUploadResult>
```

6.1.1.7.3. UploadPart

After initializing a MultipartUpload task, you can call this operation to upload data in parts based on the specified object name and upload ID.

Usage notes

- Before you call UploadPart to upload parts, you must call InitiateMultipartUpload to obtain an upload ID issued by the OSS server.
- The part number ranges from 1 to 10000. If a part number is not within this range, OSS returns the InvalidArgument error code.
- In the multipart upload mode, the minimum size of each part except the last part is 100 KB. The UploadPart operation does not immediately verify the sizes of the uploaded parts because this operation cannot immediately determine which part is the last part. The size of the uploaded part is verified only when multipart upload is complete.
- OSS includes the MD5 hash for each part received by the server in the ETag header and returns the ETag header to the user.

- If the x-oss-server-side-encryption request header is specified when you call InitiateMultipartUpload, the uploaded parts are encoded. The x-oss-server-side-encryption header is included in the response to the UploadPart request, which indicates the server-side encryption method of the parts. For more information, see InitiateMultipartUpload.

Request structure

```
PUT /ObjectName? partNumber=PartNumber&uploadId=UploadId HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Content-Length: Size
Authorization: SignatureValue
```

Request headers

The request headers involved in the UploadPart operation contain only common request headers. For more information, see Common request headers.

Response headers

The response headers involved in the UploadPart operation contains only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
PUT /multipart.data? partNumber=1&uploadId=0***6 HTTP/1.1
Host: ***.regionid.example.com
Content-Length:6291456
Date: Wed, 22 Feb 2012 08:32:21 GMT
Authorization: OSS q***I=
[6291456 bytes data]
```

Sample responses

```
HTTP/1.1 200 OK
Server: AliyunOSS
Connection: keep-alive
ETag: 7***9
x-oss-request-id: 3***a
Date: Wed, 22 Feb 2012 08:32:21 GMT
```

6.1.1.7.4. UploadPartCopy

You can call this operation to copy data from an existing object to upload a part.

Usage notes

To copy an object larger than 1 GB, use UploadPartCopy. For more information about how to upload an object smaller than 1 GB, see CopyObject.

When you call UploadPartCopy, take note of the following items:

- You cannot call AppendObject to copy data from append objects.
- When you call UploadPartCopy, the source and destination buckets must be located within the same region.
- Before you call UploadPart to upload a part, you must call InitiateMultipartUpload to obtain an upload ID issued by the OSS server.
- If the x-oss-server-side-encryption request header is specified when you call InitiateMultipartUpload, the uploaded part is encoded. The x-oss-server-side-encryption header is included in the response header of UploadPart, which indicates the server-side encryption method of the part.
- In multipart upload mode, each part except the last part must be larger than 100 KB in size. The size of each part is not verified when you call UploadPart because not all parts are uploaded and the system does not know which part is the last part. The size of each part is verified only when you call CompleteMultipartUpload.

Request structure

```
PUT /ObjectName? partNumber=PartNumber&uploadId=UploadId HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Content-Length: Size
Authorization: SignatureValue
x-oss-copy-source: /SourceBucketName/SourceObjectName
x-oss-copy-source-range:bytes=first-last
```

Request headers

The following table describes the x-oss-copy-source and x-oss-copy-source-range request headers except for common request headers in the UploadPartCopy request.

Header	Type	Required	Example	Description
x-oss-copy-source	String	Yes	oss-example/src-object	The source object address. You must have permissions to read the source object. Default value: null

Header	Type	Required	Example	Description
x-oss-copy-source-range	Integer	No	bytes=100-6291756	The range of bytes to copy data from the source object. For example, if you set bytes to 0 to 9, the system transfers byte 0 to byte 9, a total of 10 bytes. Default value: null • If the x-oss-copy-source-range request header is not specified, the entire source object is copied. • If the x-oss-copy-source-range request header is specified, the response contains the length of the entire object and the range of bytes to be copied for this operation. For example, Content-Range: bytes 0~9/44 indicates that the length of the entire object is 44 bytes. The range of bytes to be copied is byte 0 to byte 9. • If the specified range does not conform to the range conventions, OSS copies the entire object and does not include Content-Range in the response.

The following table describes request headers that are used for x-oss-copy-source to specify the source object.

Header	Type	Required	Example	Description
x-oss-copy-source-if-match	String	No	5B3C1A2E053D763E1B002CC607C5****	The copy operation condition. If the ETag value of the source object is the same as the ETag value provided by the user, OSS copies data. Otherwise, OSS returns 412 Precondition Failed. Type: string Default value: null
x-oss-copy-source-if-none-match	String	No	2019-04-09T07:01:56.000Z	The object copy condition. If the ETag value of the source object is different from the ETag value specified in the request, OSS copies the object. Otherwise, OSS returns 412 Precondition Failed. Type: string Default value: null

Header	Type	Required	Example	Description
x-oss-copy-source-if-unmodified-since	String	No	2019-04-09T07:01:56.000Z	The object copy condition. If the specified time is later than or equal to the actual modified time of the object, OSS transfers the object and returns 200 OK. Otherwise, OSS returns 412 Precondition Failed. Type: string Default value: null
x-oss-copy-source-if-modified-since	String	No	2019-04-09T07:01:56.000Z	The object copy condition. If the source object is modified after the time specified in the request, OSS copies the object. Otherwise, OSS returns 412 Precondition Failed. Type: string Default value: null

Response elements

Element	Type	Example	Description
CopyObjectResult	Container	N/A	The result of the CopyObject operation.
LastModified	String	2019-04-09T07:01:56.000Z	The time when the destination object was last modified.
ETag	String	5B3C1A2E053D763E1B002CC607C5****	The ETag value of the destination object.

Examples

Sample requests

```
PUT /multipart.data? partNumber=1&uploadId=0***6 HTTP/1.1
Host: ***.regionid.example.com
Content-Length: 6291456
Date: Wed, 22 Feb 2012 08:32:21 GMT
Authorization: OSS q***I=
x-oss-copy-source: /oss-example/ src-object
x-oss-copy-source-range:bytes=100-6291756
```

Sample responses

```
HTTP/1.1 200 OK
Server: AliyunOSS
Connection: keep-alive
x-oss-request-id: 3***a
Date: Thu, 17 Jul 2014 06:27:54 GMT'
<? xml version="1.0" encoding="UTF-8"? >
<CopyPartResult xmlns="http://doc.oss-cn-hangzhou.aliyuncs.com">
 <LastModified>2014-07-17T06:27:54.000Z</LastModified>
 <ETag>"5***E"</ETag>
</CopyPartResult>
```

6.1.1.7.5. CompleteMultipartUpload

You can call this operation to complete multipart upload of an object after all parts are uploaded.

Usage notes

When you call the CompleteMultipartUpload operation, you must provide a complete list of all valid parts, which includes the part number and ETag of each part. After OSS receives the list of parts, OSS verifies the validity of each part one by one. After all these parts are validated, OSS combines these parts into a complete object.

- Confirm the size of each part

  When you perform the CompleteMultipartUpload operation, OSS checks whether each part except the last part is larger than or equal to 100 KB in size and verifies the part number and ETag of each part that are provided in the part list. Therefore, when a part is uploaded, the client must record not only the part number of the part but also the ETag value of the part returned from the server.

- Handle requests

  It may take a while for OSS to process the CompleteMultipartUpload request. If the client is disconnected from OSS during this period, OSS continues to process the request.

- PartNumber

  OSS verifies the value of PartNumber when you call the CompleteMultipartUpload operation.

  The value of PartNumber ranges from 1 to 10000. The part numbers listed in the request do not have to be consecutive but must be sorted in ascending order. For example, if the part number of the first part is 1, the part number of the second part can be 5.

- UploadId

  An object can be uploaded by multiple upload tasks that have independent upload IDs. When one upload task is complete, the corresponding upload ID becomes invalid and the upload IDs of other upload tasks are not affected.

- x-oss-server-side-encryption request header

  If the x-oss-server-side-encryption header is specified in an InitiateMultipartUpload request, this header is returned in the response to the request. The value of the x-oss-server-side-encryption header in the response indicates the method used to encrypt the object on the OSS server.

Request structure

```
POST /ObjectName? uploadId=UploadId HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Content-Length: Size
Authorization: Signature
<CompleteMultipartUpload>
<Part>
<PartNumber>PartNumber</PartNumber>
<ETag>ETag</ETag>
</Part>
...
</CompleteMultipartUpload>
```

Request headers

Header	Type	Required	Description
x-oss-complete-all:yes	String	No	Specifies whether to list all parts uploaded by using the current upload ID. • If x-oss-complete-all:yes is specified in the request, OSS lists all parts that are uploaded by using the current upload ID, sorts the parts by their part numbers, and then performs the CompleteMultipartUpload operation. OSS cannot detect parts that are not uploaded or being uploaded in the CompleteMultipartUpload operation. Therefore, you must ensure that all parts are uploaded before you perform the CompleteMultipartUpload operation. • If x-oss-complete-all:yes is specified in the request, the request body cannot be specified. Otherwise, an error occurs. • The format of the response remains unchanged if x-oss-complete-all:yes is specified in the request.

For more information about other common request headers such as Host and Date, see Common request headers.

Request elements

Element	Type	Required	Example	Description
CompleteMultipartUpload	Container	Yes	N/A	The container that stores the content of the CompleteMultipartUpload request.
ETag	String	No	3***9	The ETag values that are returned by OSS after parts are uploaded.

Element	Type	Required	Example	Description
Part	Container	Yes	N/A	The container that stores the uploaded parts.
PartNumber	Integer	Yes	1	The number of parts.

Response elements

Element	Type	Example	Description
Bucket	String	oss-example	The name of the bucket.
CompleteMultipartUploadResult	Container	N/A	The container that stores the response to the CompleteMultipartUpload request.
ETag	String	B***D-3	The UUID of the object content. The ETag is created to identify the content of an object when the object is created by using the CompleteMultipartUpload request. The ETag value of an object can be used to check whether the object content is changed.
Location	String	http://oss-example.endpoint/multipart.data	The URL of the new object that is created.
Key	String	multipart.data	The name of the created object.
EncodingType	String	utf-8	The encoding type of the object name in the response. If the encoding-type parameter is specified in the request, the object name in the response is encoded.

Examples

Sample requests

```
POST /multipart.data? uploadId=0***4  HTTP/1.1
Host: ***.regionid.example.com
Content-Length: 1056
Date: Fri, 24 Feb 2012 10:19:18 GMT
Authorization: OSS q***0=
<CompleteMultipartUpload>
    <Part>
        <PartNumber>1</PartNumber>
        <ETag>"3***9"</ETag>
    </Part>
    <Part>
        <PartNumber>5</PartNumber>
        <ETag>"8***A"</ETag>
    </Part>
    <Part>
        <PartNumber>8</PartNumber>
        <ETag>"8***2"</ETag>
    </Part>
</CompleteMultipartUpload>
```

Sample responses

```
HTTP/1.1 200 OK
Server: AliyunOSS
Content-Length: 329
Content-Type: Application/xml
Connection: keep-alive
x-oss-request-id: 5***e
Date: Fri, 24 Feb 2012 10:19:18 GMT
<? xml version="1.0" encoding="UTF-8"? >
<CompleteMultipartUploadResult xmlns="http://doc.oss-cn-hangzhou.aliyuncs.com">
    <Location>http://oss-example.endpoint /multipart.data</Location>
    <Bucket>oss-example</Bucket>
    <Key>multipart.data</Key>
    <ETag>B***D-3</ETag>
</CompleteMultipartUploadResult>
```

6.1.1.7.6. AbortMultipartUpload

You can call this operation to cancel a multipart upload task based on the specified upload ID.

Usage notes

When you call AbortMultipartUpload, take note of the following items:

- You must provide the upload ID of the multipart upload task that you want to cancel.
- When you cancel a multipart upload task, parts that are being uploaded cannot be deleted.
- After a multipart upload task is canceled, the upload ID of the task cannot be used to perform any operations and the parts uploaded by the task are deleted.
- We recommend that you complete or cancel multipart upload tasks that are not complete in a timely

manner because parts generated by these tasks consume storage space and incur storage fees.

Request structure

```
DELETE /ObjectName? uploadId=UploadId HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: Signature
```

Request elements

Element	Type	Required	Example	Description
uploadId	String	Yes	F18A92392DFD4B3FA897C26782*****	The ID of the multipart upload task.

For more information about other common request headers such as Host and Date, see Common request headers.

Response headers

Response headers involved in the AbortMultipartUpload operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
Delete /multipart.data? &uploadId=0***E  HTTP/1.1
Host: ***.regionid.example.com
Date: Wed, 22 Feb 2012 08:32:21 GMT
Authorization: OSS q***I=
```

Sample responses

```
HTTP/1.1 204
Server: AliyunOSS
Connection: keep-alive
x-oss-request-id: 0***d
Date: Wed, 22 Feb 2012 08:32:21 GMT
```

6.1.1.7.7. ListMultipartUploads

You can call this operation to list all ongoing multipart upload tasks that have been initiated but not complete or canceled.

The list returned by OSS contains a maximum of 1,000 multipart upload tasks. To specify the number of tasks that are returned in the response from OSS, you can add the max-uploads parameter to the request. In the response returned by OSS, the IsTruncated element indicates whether the response contains all the ongoing multipart upload tasks.

Request structure

```
Get /? uploads HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: Signature
```

Request parameters

Parameter	Type	Required	Example	Description
delimiter	String	No	None	The delimiter used to group objects by name. If you specify the Delimiter parameter in the request, the response contains the CommonPrefixes element. Objects whose names contain the same string from the prefix to the next occurrence of the delimiter are grouped as a single result element in CommonPrefixes.
max-uploads	String	No	1000	The maximum number of multipart upload tasks to return for one request. If this parameter is not specified, default value 1000 applies. The max-uploads value cannot exceed 1000. Type: string
key-marker	String	No	None	The name of the object after which the list begins. This parameter is used together with the upload-id-marker parameter. • If the upload-id-marker parameter is not set, OSS returns multipart upload tasks in which object names are listed after the key-marker value. Multipart upload tasks are listed in alphabetical order of their object names. • If the upload-id-marker parameter is set, OSS returns the following tasks:Multipart upload tasks in which object names are listed after the key-marker value. Multipart upload tasks are listed in alphabetical order of their object names.Multipart upload tasks in which object names are the key-marker value but upload IDs are greater than the upload-id-marker value.

Parameter	Type	Required	Example	Description
prefix	String	No	None	The prefix that the returned object names must contain. Note that if you use a prefix to make a query, the returned object names still contain the prefix.
upload-id-marker	String	No	None	The upload ID of the multipart upload task after which the list begins. This parameter is used together with the key-marker parameter. • If the key-marker parameter is not set, OSS ignores the upload-id-marker parameter. • If the key-marker is set, the response includes the following tasks:Multipart upload tasks in which object names are listed after the key-marker value. Multipart upload tasks are listed in alphabetical order of their object names.Multipart upload tasks in which object names are equal to the key-marker parameter value but upload IDs are greater than the upload-id-marker parameter value.
encoding-type	String	No	utf-8	The encoding type of the object names in the response. Values of Delimiter, KeyMarker, Prefix, NextKeyMarker, and Key can be encoded in UTF-8. However, the XML 1.0 standard cannot be used to parse control characters such as characters with an ASCII value 0 to 10. You can set the encoding-type parameter to encode values of Delimiter, KeyMarker, Prefix, NextKeyMarker, and Key in the response. Default value: null

Response elements

Element	Type	Example	Description
ListMultipartUploadsResult	Container	N/A	The container that stores the response of the ListMultipartUpload request.
Bucket	String	oss-example	The name of the bucket.

Element	Type	Example	Description
EncodingType	String	UTF-8	The encoding type of the object name in the response. If encoding-type is specified in the request, values of those elements including Delimiter, KeyMarker, Prefix, NextKeyMarker, and Key are encoded in the returned result.
KeyMarker	String	5	The name of the object after which the list begins.
UploadIdMarker	String	None	The upload ID of the multipart upload task after which the list begins.
NextKeyMarker	String	oss.avi	The object name marker in the response for the next request to return the remaining results.
NextUploadMarker	String	0004B99B8E707874FC2D692FA5D77D3F	The NextUploadMarker value that is used for the UploadMarker value in a subsequent request when the response does not contain all required results.
MaxUploads	Integer	1000	The maximum number of upload tasks returned by OSS.
IsTruncated	Enumerated string	false	Indicates whether the multipart upload task list returned in this response is truncated. A value of true indicates that the response does not contain all required results. A value of false indicates that the response contains all required results. Valid values: false and true Default value: false
Upload	Container	N/A	The container that stores the information about multipart upload tasks.
Key	String	multipart.data	The object name in an initiated multipart upload task.
UploadId	String	0004B999EF518A1FE585B0C9360DC4C8	The ID of the multipart upload task.
Initiated	Release date	2012-02-23T04:18:23.000Z	The time when the multipart upload task was initiated.

Detail analysis

- The maximum value of the max-uploads parameter is 1000.
- The results returned by OSS are listed based on the alphabetical order of object names. If multipart upload tasks involve the same object, the results are listed in ascending order of time.
- You can use prefixes to group and manage objects in a bucket in the same way you manage a folder in a file system.

- ListMultipartUploads supports the following request parameters: prefix, marker, delimiter, upload-id-marker, and max-uploads. You can use one or more of the preceding parameters to configure rules to query multipart upload tasks so that results that meet conditions are returned.

Examples

Sample requests

```
Get /? uploads  HTTP/1.1
Host:***.regionid.example.com
Date: Thu, 23 Feb 2012 06:14:27 GMT
Authorization: OSS q***Y=
```

Sample responses

```
HTTP/1.1 200
Server: AliyunOSS
Connection: keep-alive
Content-length: 1839
Content-type: application/xml
x-oss-request-id: 5***a
Date: Thu, 23 Feb 2012 06:14:27 GMT
<? xml version="1.0" encoding="UTF-8"? >
<ListMultipartUploadsResult xmlns="http://doc.oss-cn-hangzhou.aliyuncs.com">
    <Bucket>oss-example</Bucket>
    <KeyMarker></KeyMarker>
    <UploadIdMarker></UploadIdMarker>
    <NextKeyMarker>oss.avi</NextKeyMarker>
    <NextUploadIdMarker>0***F</NextUploadIdMarker>
    <Delimiter></Delimiter>
    <Prefix></Prefix>
    <MaxUploads>1000</MaxUploads>
    <IsTruncated>false</IsTruncated>
    <Upload>
        <Key>multipart.data</Key>
        <UploadId>0***8</UploadId>
        <Initiated>2012-02-23T04:18:23.000Z</Initiated>
    </Upload>
    <Upload>
        <Key>multipart.data</Key>
        <UploadId>0***5</UploadId>
        <Initiated>2012-02-23T04:18:23.000Z</Initiated>
    </Upload>
    <Upload>
        <Key>oss.avi</Key>
        <UploadId>0***F</UploadId>
        <Initiated>2012-02-23T06:14:27.000Z</Initiated>
    </Upload>
</ListMultipartUploadsResult>
```

6.1.1.7.8. ListParts

You can call this operation to list all uploaded parts that are mapped to a specific upload ID.

Usage notes

- ListParts supports two request parameters: max-parts and part-number-marker.
- The maximum value of the max-parts parameter is 1000. The default value is 1000.
- The results returned by OSS are listed based on the ascending order of part numbers.
- Errors may occur during network transmission. We recommend that you do not use the results (part numbers and ETag values) of ListParts to generate the final part list of CompleteMultipart.

Request structure

```
Get  /ObjectName? uploadId=UploadId HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: Signature
```

Request parameters

Parameter	Type	Required	Example	Description
uploadId	String	No	0004B999EF5A239BB9138C6227D69F95	The ID of the multipart upload task. Default value: null
max-parts	Integer	No	1000	The maximum number of parts that can be returned by OSS. Type: integer Default value: 1000
part-number-marker	Integer	No	5	The number of the part after which the list begins. All parts whose part numbers are greater than this parameter value are listed. Type: integer Default value: null
encoding-type	String	No	url	The encoding type of the object name in the response. The object name can contain any characters that are encoded in UTF-8. However, the XML 1.0 standard cannot be used to parse control characters such as characters with an ASCII value from 0 to 10. You can set the encoding-type parameter to encode the object names in the response. Set the value to url.

Response elements

Element	Type	Example	Description
ListPartsResult	Container	N/A	The container that stores the response to the ListParts request.
Bucket	String	multipart_upload	The name of the bucket.
EncodingType	String	url	The encoding type of the object name in the response. If the encoding-type parameter is specified in the request, the object name in the response is encoded.
Key	String	multipart.data	The name of the object.
UploadId	String	0004B999EF5A239BB9138C6227D69F95	The ID of an upload task.
PartNumberMarker	Integer	5	The number of the part after which the list begins. All parts whose part numbers are greater than this parameter value are listed.
NextPartNumberMarker	Integer	5	The NextPartNumberMarker value that is used for the PartNumberMarker value in a subsequent request when the response does not contain all required results.
MaxParts	Integer	1000	The maximum number of parts in this response.
IsTruncated	Enumerated string	false	Indicates whether the part list returned in this response is truncated. A value of true indicates that the response does not contain all required results. A value of false indicates that the response contains all required results. Valid values: true and false
Part	Container	N/A	The container that stores part information.
PartNumber	Integer	1	The number that identifies a part.
LastModified	Release date	2012-02-23T07:01:34.000Z	The time when the part was uploaded.
ETag	String	3349DC700140D7F86A0784842780****	The ETag value of the content of the uploaded part. Type: Parent nodes: ListPartsResult and Part
Size	Integer	6291456	The size of the uploaded part.

Examples

Sample requests

```
Get  /multipart.data? uploadId=0***5  HTTP/1.1
Host: ***.regionid.example.com
Date: Thu, 23 Feb 2012 07:13:28 GMT
Authorization: OSS q***8=
```

Sample responses

```

    </Part>
</ListPartsResult>
```

6.1.1.8. CORS

6.1.1.8.1. Overview

Cross-origin resource sharing (CORS) allows web applications to access resources across origins. OSS allows you to use CORS to develop more flexible web applications. OSS provides CORS-related API operations for developers to control cross-origin access.

6.1.1.8.2. PutBucketcors

You can call this operation to configure a cross-origin resource sharing (CORS) rule for a specific bucket. If a CORS rule is configured for the bucket, PutBucketCORS overwrites the existing rule. By default, CORS is disabled for buckets. All cross-origin requests are not allowed.

Usage notes

When you call PutBucketCors, take note of the following items:

- Disabled-by-default design

  By default, CORS is disabled for buckets. All cross-origin requests are not allowed.

- Overwriting mechanism

  When you call PutBucketCors to configure a new CORS rule for a bucket for which a CORS rule is already configured, the existing rule is overwritten.

- Usage in applications

  When you use CORS in applications, you must call PutBucketCors to configure a CORS rule to enable CORS.

  For example, if you want to use the `XMLHttpRequest` feature of your browser to access OSS from the domain name `www.a.com`, you must call PutBucketCORS to configure a CORS rule that is described by an XML message body.

- CORS rule matching

  When OSS receives a cross-origin request or an OPTIONS request sent for a bucket, OSS reads the CORS rules configured for the bucket and checks the permission of the request. OSS matches the request with the rules one by one. When OSS finds the first match, OSS returns a corresponding header in the response. If no match is found, OSS does not include any CORS header in the response.

  The following conditions must be met before OSS determines that a CORS rule matches the request:

  - The origin from which the request is initiated must match the value of one `AllowedOrigin` element in the CORS rule.
  - The method of the request such as GET or PUT or the method corresponding to the `Access-Control-Request-Method` header in an OPTIONS request must match the value of one `AllowedMethod` element in the CORS rule.
  - Each header included in `Access-Control-Request-Headers` in an OPTIONS request must match the value of one `AllowedHeader` element in the CORS rule.

Request structure

```
PUT /? cors HTTP/1.1
Date: GMT Date
Content-Length: ContentLength
Content-Type: application/xml
Host: BucketName.regionid.example.com
Authorization: SignatureValue
<? xml version="1.0" encoding="UTF-8"? >
<CORSConfiguration>
    <CORSRule>
      <AllowedOrigin>the origin you want allow CORS request from</AllowedOrigin>
      <AllowedOrigin>… </AllowedOrigin>
      <AllowedMethod>HTTP method</AllowedMethod>
      <AllowedMethod>… </AllowedMethod>
        <AllowedHeader> headers that allowed browser to send</AllowedHeader>
          <AllowedHeader>… </AllowedHeader>
          <ExposeHeader> headers in response that can access from client app</ExposeHeader>
          <ExposeHeader>… </ExposeHeader>
          <MaxAgeSeconds>time to cache pre-fight response</MaxAgeSeconds>
    </CORSRule>
    <CORSRule>
      …
    </CORSRule>
…
</CORSConfiguration >
```

Request elements

Element	Type	Required	Example	Description
CORSRule	Container	Yes	N/A	The container for CORS rules. A maximum of 10 rules can be configured for each bucket.
AllowedOrigin	String	Yes	*	The origin from which a request is allowed. You can use multiple elements to specify multiple origins. Each rule can contain only one asterisk (*) as the wildcard. If AllowedOrigin is set to an asterisk (*), all cross-origin requests are allowed.
AllowedMethod	Enumerated string	Yes	GET	The cross-origin request methods that are allowed. Valid values: GET, PUT, DELETE, POST, and HEAD

Element	Type	Required	Example	Description
AllowedHeader	String	No	Authorization	Specifies whether the headers specified by Access-Control-Request-Headers in the preflight (OPTIONS) request are allowed. Each header specified by Access-Control-Reqluest-Headers must match the value of an AllowedHeader element. Each rule can contain only one asterisk (*) as the wildcard.
ExposeHeader	String	No	x-oss-test	The list of headers that can be exposed to the browser. The headers are the response headers that allow access from an application such as XMLHttpRequest in JavaScript. Asterisks (*) cannot be included as wildcards in the value of this parameter.
CORSConfiguration	Container	Yes	N/A	The container that stores the CORS rules configured for a bucket.
MaxAgeSeconds	Integer	No	100	The time the browser can cache the response to a preflight (OPTIONS) request to a specific resource. Unit: seconds. Only one MaxAgeSeconds element can be configured for each CORS rule.

Response headers

The response headers involved in the PutBucketcors operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
PUT /? cors HTTP/1.1
Host: ***.regionid.example.com
Content-Length: 186
Date: Fri, 04 May 2012 03:21:12 GMT
Authorization: OSS q***A=
<? xml version="1.0" encoding="UTF-8"? >
<CORSConfiguration>
    <CORSRule>
      <AllowedOrigin>*</AllowedOrigin>
      <AllowedMethod>PUT</AllowedMethod>
      <AllowedMethod>GET</AllowedMethod>
      <AllowedHeader>Authorization</AllowedHeader>
    </CORSRule>
    <CORSRule>
      <AllowedOrigin>http://www.a.com</AllowedOrigin>
      <AllowedOrigin>http://www.b.com</AllowedOrigin>
      <AllowedMethod>GET</AllowedMethod>
      <AllowedHeader> Authorization</AllowedHeader>
      <ExposeHeader>x-oss-test</ExposeHeader>
      <ExposeHeader>x-oss-test1</ExposeHeader>
      <MaxAgeSeconds>100</MaxAgeSeconds>
    </CORSRule>
</CORSConfiguration >
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***F
Date: Fri, 04 May 2012 03:21:12 GMT
Content-Length: 0
Connection: keep-alive
Server: AliyunOSS
```

6.1.1.8.3. GetBucketcors

You can call this operation to query the existing CORS rules of a specified bucket.

Request structure

```
GET /? cors HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

The request headers involved in the GetBucketcors operation contain only common request headers. For more information, see Common request headers.

Response elements

Element	Type	Example	Description
CORSRule	Container	N/A	The container that stores CORS rules. Up to 10 rules can be configured for a bucket.
AllowedOrigin	String	*	The sources from which cross-origin requests are allowed. If AllowedOrigin is set to an asterisk (*), cross-origin requests from all sources are allowed.
AllowedMethod	Enumerated string	GET	The cross-origin request methods that are allowed. Valid values: GET, PUT, DELETE, POST, and HEAD
AllowedHeader	String	*	Indicates whether the headers specified by Access-Control-Request-Headers in the OPTIONS preflight request are allowed. Each header specified by Access-Control-Request-Headers must match the value of an AllowedHeader element.
ExposeHeader	String	x-oss-test	The response headers for allowed access requests from applications, such as an XMLHttpRequest object in JavaScript.
MaxAgeSeconds	Integer	100	The period of time within which the browser can cache the response for an OPTIONS preflight request to specific resources. A CORS rule can contain only one MaxAgeSeconds parameter.
CORSConfiguration	Container	N/A	The container that stores the CORS rules configured for a bucket.

Examples

Sample requests

```
Get /? cors HTTP/1.1
Host: ***.regionid.example.com
Date: Thu, 13 Sep 2012 07:51:28 GMT
Authorization: OSS q***w=
```

Sample responses if CORS rules exist

```
HTTP/1.1 200
x-oss-request-id: 5***F
Date: Thu, 13 Sep 2012 07:51:28 GMT
Connection: keep-alive
Content-Length: 218
Server: AliyunOSS
<? xml version="1.0" encoding="UTF-8"? >
<CORSConfiguration>
    <CORSRule>
      <AllowedOrigin>*</AllowedOrigin>
      <AllowedMethod>GET</AllowedMethod>
      <AllowedHeader>*</AllowedHeader>
      <ExposeHeader>x-oss-test</ExposeHeader>
      <MaxAgeSeconds>100</MaxAgeSeconds>
    </CORSRule>
</CORSConfiguration>
```

6.1.1.8.4. DeleteBucketcors

You can call this operation to delete CORS rules.

Request structure

```
DELETE /? cors HTTP/1.1
Host: BucketName.regionid.example.com
Date: GMT Date
Authorization: SignatureValue
```

Request headers

Request headers involved in the DeleteBucketcors operation contain only common request headers. For more information, see Common request headers.

Response headers

Response headers involved in the DeleteBucketcors operation contain only common response headers. For more information, see Common response headers.

Examples

Sample requests

```
DELETE /? cors HTTP/1.1
Host: ***.regionid.example.com
Date: Fri, 24 Feb 2012 05:45:34 GMT
Authorization: OSS q***g=
```

Sample responses

```
HTTP/1.1 204 No Content
x-oss-request-id: 5***C
Date: Fri, 24 Feb 2012 05:45:34 GMT
Connection: keep-alive
Content-Length: 0
Server: AliyunOSS
```

6.1.1.8.5. OptionObject

Before a cross-origin request is sent, the browser sends a preflight (OPTIONS) request that includes a specific origin, HTTP method, and header information to OSS to determine whether to send the cross-origin request.

OSS allows you to call the PutBucketcors operation to enable CORS for buckets. OSS determines whether to allow the preflight request of the browser based on the specified rules after CORS is enabled. If OSS rejects this request or CORS is disabled, 403 Forbidden is returned.

Request structure

```
OPTIONS /ObjectName HTTP/1.1
Host: BucketName.regionid.example.com
Origin:Origin
Access-Control-Request-Method:HTTP method
Access-Control-Request-Headers:Request Headers
```

Request headers

Header	Type	Required	Example	Description
Origin	String	Yes	http://www.example.com	The origin of the request, used to identify a cross-origin request. Default value: null
Access-Control-Request-Method	String	Yes	PUT	The method to use in the cross-origin request. Default value: null
Access-Control-Request-Headers	String	Yes	x-oss-test	The request headers, except for standard headers, to use in the cross-origin request. Default value: null

Response headers

Header	Type	Example	Description
Access-Control-Allow-Origin	String	http://www.example.com	The origin that is included in the request. If the request is denied, the response does not contain the header.

Header	Type	Example	Description
Access-Control-Allow-Methods	String	PUT	The HTTP method of the request. If the request is denied, the response does not contain the header.
Access-Control-Allow-Headers	String	x-oss-test	The list of headers included in the request. If the request includes headers that are not allowed, the response does not contain the headers and the request is denied.
Access-Control-Expose-Headers	String	Content-Length	The list of headers that are accessible to JavaScript applications on a client.
Access-Control-Max-Age	Integer	100	The maximum duration for the browser to cache preflight results. Unit: seconds.

Examples

Sample requests

```
OPTIONS /testobject HTTP/1.1
Host: ***.regionid.example.com
Date: Fri, 24 Feb 2012 05:45:34 GMT
Origin:http://www.example.com
Access-Control-Request-Method:PUT
Access-Control-Request-Headers:x-oss-test
```

Sample responses

```
HTTP/1.1 200 OK
x-oss-request-id: 5***C
Date: Fri, 24 Feb 2012 05:45:34 GMT
Access-Control-Allow-Origin: http://www.example.com
Access-Control-Allow-Methods: PUT
Access-Control-Expose-Headers: x-oss-test
Connection: keep-alive
Content-Length: 0
Server: AliyunOSS
```

6.1.1.9. Error responses

If an error occurs when you access OSS, OSS returns the error code and error message so that you can locate and rectify the error.

OSS error response format

If an error occurs when you access OSS, OSS returns HTTP status code 3xx, 4xx, or 5xx and a message body in the application/xml format.

Example of an error response body:

```
<? xml version="1.0" ? >
<Error xmlns="http://doc.oss-cn-hangzhou.aliyuncs.com">
 <Code>
 AccessDenied
 </Code>
 <Message>
 Query-string authentication requires the Signature, Expires and OSSAccessKeyId parameters
 </Message>
 <RequestId>
 1D842BC5425544BB
 </RequestId>
 <HostId>
 regionid.example.com
 </HostId>
</Error>
```

All error message bodies include the following elements:

- Code: the error code that OSS returns to the user.
- Message: the detailed error message provided by OSS.
- RequestId: the UUID that uniquely identifies a request. If a problem persists, submit the request ID to OSS technical support personnel to seek help.
- HostId: the ID of the host in the accessed OSS cluster, which is the same as the host ID specified in the request.

For more information about the elements in error messages, see specific request descriptions.

Error codes

The following table lists the OSS error codes.

Error codes

Error code	Description	HTTP status code
AccessDenied	The error message returned because the access is denied.	403
BucketAlreadyExists	The error message returned because the bucket already exists.	409
BucketNotEmpty	The error message returned because the bucket is not empty.	409
EntityTooLarge	The error message returned because the entity is too large.	400

Error code	Description	HTTP status code
EntityTooSmall	The error message returned because the entity is too small.	400
FieldItemTooLong	The error message returned because the total length of the form fields in the POST request exceeds the limit.	400
FilePartInterity	The error message returned because the part has changed.	400
FilePartNotExist	The error message returned because the part does not exist.	400
FilePartStale	The error message returned because the part has expired.	400
IncorrectNumberOfFilesInPOSTRequest	The error message returned because the number of objects in the POST request is invalid.	400
InvalidArgument	The error message returned because the parameter format is invalid.	400
InvalidAccessKeyId	The error message returned because the AccessKey ID does not exist.	403
InvalidBucketName	The error message returned because the bucket name is invalid.	400
InvalidDigest	The error message returned because Content-MD5 you specified is invalid.	400
InvalidEncryptionAlgorithmError	The error message returned because the specified encryption algorithm based on entropy encoding is invalid.	400
InvalidObjectName	The error message returned because the object name is invalid.	400
InvalidPart	The error message returned because the part is invalid.	400
InvalidPartOrder	The error message returned because the part sequence is invalid.	400

Error code	Description	HTTP status code
InvalidPolicyDocument	The error message returned because the content of the form does not meet the conditions specified in the policy document.	400
InvalidTargetBucketForLogging	The error message returned because the destination bucket specified for logging is invalid.	400
InternalError	The error message returned because an internal OSS error occurs.	500
MalformedXML	The error message returned because the XML format is invalid.	400
MalformedPOSTRequest	The error message returned because the format of the POST request body is invalid.	400
MaxPOSTPreDataLengthExceededError	The error message returned because the POST request body, excluding the object content to upload, is too large.	400
MethodNotAllowed	The error message returned because the method is not supported.	405
MissingArgument	The error message returned because the required parameters are not set.	411
MissingContentLength	The error message returned because the content length is not specified.	411
NoSuchBucket	The error message returned because the specified bucket does not exist.	404
NoSuchKey	The error message returned because the specified object does not exist.	404
NoSuchUpload	The error message returned because the specified multipart upload ID does not exist.	404
NotImplemented	The error message returned because the method cannot be implemented.	400

Error code	Description	HTTP status code
PreconditionFailed	The error message returned because the precondition you specified does not hold.	412
RequestTimeTooSkewed	The error message returned because the difference between the time on the client when the request is sent and the time on the server when the request is received is greater than 15 minutes.	403
RequestTimeout	The error message returned because the request times out.	400
RequestIsNotMultiPartContent	The error message returned because the content-type value specified in the POST request is invalid.	400
SignatureDoesNotMatch	The error message returned because the request signature provided does not match the signature calculated by OSS.	403
TooManyBuckets	The error message returned because the number of the buckets in your account has exceeded the limit.	400

Operations not supported by OSS

If an operation not supported by OSS is performed to access a resource, OSS returns HTTP status code 405 and error code MethodNotAllowed.

Sample error requests

```
ABC /1.txt HTTP/1.1
Host: bucketname.regionid.example.com
Date: Thu, 11 Aug 2016 03:53:40 GMT
Authorization: signatureValue
```

Sample responses

```
HTTP/1.1 405 Method Not Allowed
Server: AliyunOSS
Date: Thu, 11 Aug 2016 03:53:44 GMT
Content-Type: application/xml
Content-Length: 338
Connection: keep-alive
x-oss-request-id: 57ABF6C8BC4D25D86CBA5ADE
Allow: GET DELETE HEAD PUT POST OPTIONS
<? xml version="1.0" encoding="UTF-8"? >
<Error>
 <Code>MethodNotAllowed</Code>
 <Message>The specified method is not allowed against this resource. </Message>
 <RequestId>57ABF6C8BC4D25D86CBA5ADE</RequestId>
 <HostId>bucketname.regionid.example.com</HostId>
 <Method>abc</Method>
 <ResourceType>Bucket</ResourceType>
</Error>
```

Note If the accessed resource is /bucket/, ResourceType must be set to Bucket. If the accessed resource is /bucket/object, ResourceType must be set to Object.

Operations supported by OSS but not supported by parameters

If parameters not supported by OSS are added to the request for the object supported by OSS (for example, the If-Modified-Since parameter is added to the PUT operation request), OSS returns 400 Bad Request.

Sample error requests

```
PUT /abc.zip HTTP/1.1
Host: bucketname.regionid.example.com
Accept: */*
Date: Thu, 11 Aug 2016 01:44:50 GMT
If-Modified-Since: Thu, 11 Aug 2016 01:43:51 GMT
Content-Length: 363
```

Sample responses

```
HTTP/1.1 400 Bad Request
Server: AliyunOSS
Date: Thu, 11 Aug 2016 01:44:54 GMT
Content-Type: application/xml
Content-Length: 322
Connection: keep-alive
x-oss-request-id: 57ABD896CCB80C366955187E
x-oss-server-time: 0
<? xml version="1.0" encoding="UTF-8"? >
<Error>
 <Code>NotImplemented</Code>
 <Message>A header you provided implies functionality that is not implemented. </Message>
 <RequestId>57ABD896CCB80C366955187E</RequestId>
 <HostId>bucketname.regionid.example.com</HostId>
 <Header>If-Modified-Since</Header>
</Error>
```

6.1.2. SDK reference

6.1.2.1. Java SDK

6.1.2.1.1. Preface

This topic is written for OSS SDK for Java version 3.8.0.

Compatibility

- For SDKs version 3.×.×:
  - API operation: compatible
  - Namespace: compatible
- For SDKs version 2.×.×:
  - API operation: compatible
  - Namespace: compatible
- For SDKs version 1.0.×:
  - API operation: compatible
  - Namespace: incompatible. The Tablestore code in version 1.0.x is removed from version 2.0.0. Package names `com.aliyun.openservices.*` and `com.aliyun.openservices.oss.*` are replaced with `com.aliyun.oss.*`.

SDK source code and API documents

For the SDK source code, visit GitHub. For more information, visit Aliyun OSS SDK for Java V3.8.0 API.

Sample code

OSS SDK for Java provides a variety of sample code for you to reference or use. The following table describes the sample code.

Sample file	Description
GetStartedSample.java	Shows you how to perform basic upload and download operations.
SimpleGetObjectSample.java	Shows you how to download objects.
ListObjectsSample.java	Shows you how to list objects.
DeleteObjectsSample.java	Shows you how to delete multiple objects at a time.
AppendObjectSample.java	Shows you how to use append upload.
ObjectMetaSample.java	Shows you how to use object metadata.
CreateFolderSample.java	Shows you how to create a folder. For more information about OSS folders, see the topic about folders.
UploadSample.java	Shows you how to use resumable upload.
DownloadSample.java	Shows you how to use resumable download.
ImageSample.java	Shows you how to use IMG.
PostObjectSample.java	Shows you how to use PostObject. The implementation is independent of OSS SDK for Java.
GetProgressSample.java	Shows you how to use progress bars in object upload and download.
CallbackSample.java	Shows you how to perform upload callback.
CRCSample.java	Shows you how to perform CRC for object upload and download.
BucketOperationsSample.java	Shows you how to configure a bucket, including configuring ACL, lifecycle, logging, hotlink protection, and CORS.
MultipartUploadSample.java	We recommend that you use the uploadFile operation to perform resumable upload for concurrent uploads implemented by the multipart upload API operation.
ConcurrentGetObjectSample.java	We recommend that you use the downloadFile operation to perform resumable download for concurrent downloads implemented by range download.
UploadPartCopySample.java	Shows you how to perform multipart copy for large objects.

6.1.2.1.2. Installation

This topic describes how to install OSS SDK for Java.

Prerequisites

- Environment

  Use Java 1.7 or later.

- Compatibility

  Run the `java -version` command to check the Java version.

Download the SDK

- Download directly
- Download from GitHub
- Download previous versions

Install the SDK

- Method 1: (Recommended) Add dependencies to your Maven project

  To use OSS SDK for Java in Maven, you need only to add the corresponding dependencies to the pom.xml file. For example, when you use OSS SDK for Java version 3.8.0, add the following content to <dependencies>:

  ```
  <dependency>
      <groupId>com.aliyun.oss</groupId>
      <artifactId>aliyun-sdk-oss</artifactId>
      <version>3.8.0</version>
  </dependency>
  ```

- Method 2: Import the JAR package to your Eclipse project

  For example, when you use OSS SDK for Java version 3.8.0, take the following steps to install the SDK:

  i. Download the OSS SDK for Java package.
  ii. Decompress the package.
  iii. Copy the *aliyun-sdk-oss-3.8.0.jar* file and all files in the lib directory to your project.
  iv. Right-click your project name in Eclipse. Choose **Properties > Java Build Path > Add JARs**.
  v. Select all JAR files that you have copied in Step 3 and import them to Libraries.

- Method 3: Import the JAR package to your IntelliJ IDEA project

  For example, when you use OSS SDK for Java version 3.8.0, take the following steps to install the SDK:

  i. Download the OSS SDK for Java package.
  ii. Decompress the package.
  iii. Copy the *aliyun-sdk-oss-3.8.0.jar* file and all JAR files in the lib directory to your project.
  iv. In IntelliJ IDEA, select your project and choose **File > Project Structure > Modules > Dependencies > + > JARs or directories**.
  v. Select all JAR files that you have copied in Step 3 and import them to External Libraries.

6.1.2.1.3. Initialization

OSSClient serves as the Java client to manage OSS resources such as buckets and objects. To use OSS SDK for Java to initiate a request, you must initialize an OSSClient instance and modify the default configuration items of ClientConfiguration.

Create an OSSClient instance

To create an OSSClient instance, you must specify an endpoint. For more information about endpoints, see Obtain an endpoint.

To create an OSSClient instance, you must specify an AccessKey pair. For more information about how to obtain an AccessKey pair, see Obtain an AccessKey pair.

- Create an OSSClient instance based on an OSS endpoint

  The following code provides an example on how to create an OSSClient instance based on an OSS endpoint:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "https://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

  You can use one or more OSSClient instances for your project. In other words, you can use multiple OSSClient instances simultaneously.

- Create an OSSClient instance based on Apsara Stack or a private region

  The following code provides an example on how to create an OSSClient instance based on Apsara Stack or a private region:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "https://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create a ClientConfiguration instance and modify the default parameters based on your
requirements.
ClientBuilderConfiguration conf = new ClientBuilderConfiguration();
// Disable CNAME.
conf.setSupportCname(false);
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret, conf
);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- Create an OSSClient instance based on an IP address

  The following code provides an example on how to create an OSSClient instance based on an IP address:

```
// In some special cases such as a private region, the IP address is used as the endpoint
. In such cases, specify the actual IP address based on your requirements.
String endpoint = "http://10.10.10.10";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create a ClientConfiguration instance.
ClientBuilderConfiguration conf = new ClientBuilderConfiguration();
// By default, access from a second-level domain is disabled. Enable OSS access from a se
cond-level domain. You must configure this parameter for OSS SDK for Java version 2.1.2 o
r earlier. The versions later than OSS SDK for Java version 2.1.2 automatically detect IP
addresses.
conf.setSLDEnabled(true);
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret, conf
);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- Create an OSSClient instance based on STS

  The following code provides an example on how to create an OSSClient instance based on Security Token Service (STS):

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "https://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String securityToken = "<yourSecurityToken>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret, secu
rityToken);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Configure an OSSClient instance

ClientConfiguration is a configuration class of OSSClient. You can use ClientConfiguration to configure parameters such as host proxies, connection timeouts, and the maximum number of connections. The following table describes the parameters of this operation.

Parameter	Description	Configuration method
MaxConnections	The maximum number of HTTP connections that are allowed. Default value: 1024.	ClientConfiguration.setMaxConnections
SocketTimeout	The timeout period for data transmission at the socket layer. Unit: milliseconds. Default value: 50000.	ClientConfiguration.setSocketTimeout

Parameter	Description	Configuration method
ConnectionTimeout	The timeout period for establishing a connection. Unit: milliseconds. Default value: 50000.	ClientConfiguration.setConnectionTimeout
ConnectionRequestTimeout	The timeout period to obtain a connection from the connection pool. Unit: milliseconds. By default, this parameter is not configured.	ClientConfiguration.setConnectionRequestTimeout
IdleConnectionTime	The idle connection timeout period to close the connection. Unit: milliseconds. Default value: 60000.	ClientConfiguration.setIdleConnectionTime
MaxErrorRetry	The maximum number of allowed retry attempts in the case of a request error. Default value: 3.	ClientConfiguration.setMaxErrorRetry
SupportCname	Specifies whether CNAME can be used as an endpoint. By default, CNAME can be used as an endpoint.	ClientConfiguration.setSupportCname
SLDEnabled	Specifies whether access over second-level domains is enabled. By default, access over second-level domains is disabled.	ClientConfiguration.setSLDEnabled
Protocol	The protocol used to connect to OSS. Default value: HTTP. Valid values: HTTP and HTTPS.	ClientConfiguration.setProtocol
UserAgent	The user agent in the HTTP header. Default value: aliyun-sdk-java.	ClientConfiguration.setUserAgent
ProxyHost	The IP address to access the proxy host.	ClientConfiguration.setProxyHost
ProxyPort	The port for the proxy host.	ClientConfiguration.setProxyPort
ProxyUsername	The username verified by the proxy host.	ClientConfiguration.setProxyUsername
ProxyPassword	The password verified by the proxy host.	ClientConfiguration.setProxyPassword

The following code provides an example on how to configure parameters for an OSSClient instance with ClientConfiguration:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "https://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create a ClientConfiguration instance. ClientConfiguration is a configuration class of OSSClient. You can use ClientConfiguration to configure parameters such as host proxies, connection timeouts, and the maximum number of connections.
ClientBuilderConfiguration conf = new ClientBuilderConfiguration();
// Configure the maximum number of HTTP connections allowed by an OSSClient instance. Default value: 1024.
conf.setMaxConnections(200);
// Configure the timeout period for data transmission at the socket layer. Unit: milliseconds. Default value: 50000.
conf.setSocketTimeout(10000);
// Configure the timeout period for establishing a connection. Unit: milliseconds. Default value: 50000.
conf.setConnectionTimeout(10000);
// Configure the timeout period for obtaining a connection from the connections pool. Unit: milliseconds. By default, this parameter is not configured.
conf.setConnectionRequestTimeout(1000);
// Configure the timeout period for idle connections. The connection is closed when the timeout period expires. Unit: milliseconds. Default value: 60000.
conf.setIdleConnectionTime(10000);
// Configure the maximum number of allowed retry attempts in the case of a request error. Default value: 3.
conf.setMaxErrorRetry(5);
// Configure whether CNAME can be used as an endpoint. By default, CNAME can be used as an endpoint.
conf.setSupportCname(true);
// Configure whether access from second-level domains is enabled. By default, access from second-level domains is disabled.
conf.setSLDEnabled(true);
// Configure the protocol used to connect to OSS. Default value: HTTP. Valid values: HTTP and HTTPS.
conf.setProtocol(Protocol.HTTP);
// Configure the user agent in the HTTP header. Default value: aliyun-sdk-java.
conf.setUserAgent("aliyun-sdk-java");
// Configure the port for the proxy host.
conf.setProxyHost("<yourProxyHost>");
// Configure the username verified by the proxy host.
conf.setProxyUsername("<yourProxyUserName>");
// Configure the password verified by the proxy host.
conf.setProxyPassword("<yourProxyPassword>");
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret, conf);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.4. Quick start

This topic describes how to use OSS SDK for Java to complete routine operations such as create buckets, upload objects, and download objects.

Sample projects

OSS SDK for Java provides Maven- and Ant-based sample projects. You can compile and run the sample projects on local devices or develop your own applications based on the sample projects. For more information about how to compile and run a project, see README.md in the project directory.

- Maven-based sample project: aliyun-oss-java-sdk-demo-mvn.zip
- Ant-based sample project: aliyun-oss-java-sdk-demo-ant.zip

Create a bucket

A bucket is a global namespace in OSS. A bucket is a container for objects stored in OSS. The following code provides an example on how to create a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Create a bucket.
ossClient.createBucket(bucketName);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

For more information about how to obtain an AccessKey ID and AccessKey secret, see Obtain an AccessKey pair.

For more information about how to obtain an endpoint, see Obtain an endpoint.

Upload objects

The following code provides an example on how to upload an object to OSS:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
// Upload content to a specified bucket and save it by using the specified object name.
String content = "Hello OSS";
ossClient.putObject(bucketName, objectName, new ByteArrayInputStream(content.getBytes()));
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Download an object

The following code provides an example on how to query the content of an object:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
// Call ossClient.getObject to query an OSSObject instance. The OSSObject instance contains the content and metadata of the object.
OSSObject ossObject = ossClient.getObject(bucketName, objectName);
// Call ossObject.getObjectContent to query an input stream of the object. Read the input stream to query the content of the object.
InputStream content = ossObject.getObjectContent();
if (content ! = null) {
    BufferedReader reader = new BufferedReader(new InputStreamReader(content));
    while (true) {
        String line = reader.readLine();
        if (line == null) break;
        System.out.println("\n" + line);
    }
    // You must close the connection after each use to prevent connection leaks. Otherwise, requests may be unable to establish connections and the program cannot run properly.
    content.close();
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

List objects

The following code provides an example on how to list objects in a specified bucket. By default, a maximum of 100 objects are listed.

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
// Call ossClient.listObjects to obtain an ObjectListing instance. The ObjectListing instance contains the response to the listObject request.
ObjectListing objectListing = ossClient.listObjects(bucketName);
// Call objectListing.getObjectSummaries to query the descriptions of all objects.
for (OSSObjectSummary objectSummary : objectListing.getObjectSummaries()) {
    System.out.println(" - " + objectSummary.getKey() + "  " +
            "(size = " + objectSummary.getSize() + ")");
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Delete objects

For the complete code used to delete objects, visit GitHub.

The following code provides an example on how to delete an object:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
// Delete the object.
ossClient.deleteObject(bucketName, objectName);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.5. Buckets

6.1.2.1.5.1. Create buckets

A bucket is a container for objects stored in OSS. Every object is contained in a bucket. This topic describes how to create a bucket.

The following code provides an example on how to create a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Create a bucket.
ossClient.createBucket(bucketName);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.5.2. List buckets

A bucket is a container for objects stored in OSS. Every object is contained in a bucket. This topic describes how to list buckets.

Buckets are listed in alphabetical order. You can list all buckets or only buckets that meet specified conditions. To list buckets of the IA or Archive storage class, use OSS SDK for Java version 2.6.0 or later.

List all buckets

The following code provides an example on how to list all buckets:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// List all buckets.
List<Bucket> buckets = ossClient.listBuckets();
for (Bucket bucket : buckets) {
    System.out.println(" - " + bucket.getName());
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

List buckets whose names contain a specified prefix

The following code provides an example on how to list buckets whose names contain a specified prefix:

```
ListBucketsRequest listBucketsRequest = new ListBucketsRequest();
// List buckets whose names contain a specified prefix.
listBucketsRequest.setPrefix("<yourBucketPrefix>");
BucketList bucketList = ossClient.listBuckets(listBucketsRequest);
for (Bucket bucket : bucketList.getBucketList()) {
    System.out.println(" - " + bucket.getName());
}
```

List buckets whose names come after a specified marker

The marker parameter specifies the name of the bucket after which the list begins. The following code provides an example on how to list buckets whose names come after a specified marker:

```
ListBucketsRequest listBucketsRequest = new ListBucketsRequest();
// List buckets whose names come after the specified marker.
listBucketsRequest.setMarker("<yourBucketMarker>");
BucketList bucketList = ossClient.listBuckets(listBucketsRequest);
for (Bucket bucket : bucketList.getBucketList()) {
    System.out.println(" - " + bucket.getName());
}
```

List a specified number of buckets

The following code provides an example on how to specify the maxKeys parameter to list a specified number of buckets:

```
ListBucketsRequest listBucketsRequest = new ListBucketsRequest();
// Set the maximum number of buckets to list each time to 500. The default value is 100. Th
e maximum value is 1000.
listBucketsRequest.setMaxKeys(500);
BucketList bucketList = ossClient.listBuckets(listBucketsRequest);
for (Bucket bucket : bucketList.getBucketList()) {
    System.out.println(" - " + bucket.getName());
}
```

6.1.2.1.5.3. Determine whether buckets exist

A bucket is a container for objects stored in OSS. Every object is contained in a bucket. This topic describes how to determine whether a bucket exists.

The following code provides an example on how to determine whether a specific bucket exists:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Security risks may arise if you use the AccessKey pair of an Alibaba Cloud account to log on to OSS because the account has permissions on all API operations. We recommend that you use a RAM user to call API operations or perform routine operations and maintenance. To create a RAM user, log on to https://ram.console.aliyun.com.
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
boolean exists = ossClient.doesBucketExist("<yourBucketName>");
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.5.4. Manage bucket ACLs

A bucket is a container for objects stored in OSS. Every object is contained in a bucket. This topic describes how to configure and obtain the access control list (ACL) of a bucket.

Configure ACL for a bucket

The following table describes the ACLs for buckets.

ACL	Description	Value
Private	Only the owner or authorized users of the bucket can read and write the object.	CannedAccessControlList.Private
Public read	Only the owner or authorized users of this bucket can write the object. Other users, including anonymous users can only read the object. Exercise caution when you use this ACL.	CannedAccessControlList.PublicRead
Public read/write	Any users, including anonymous users can read and write the object. Exercise caution when you use this ACL.	CannedAccessControlList.PublicReadWrite

The following code provides an example on how to configure ACL for a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Set the ACL of the bucket to private.
ossClient.setBucketAcl("<yourBucketName>", CannedAccessControlList.Private);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Query the ACL of a bucket

The following code provides an example on how to query the ACL of a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Query the ACL of the bucket.
AccessControlList acl = ossClient.getBucketAcl("<yourBucketName>");
System.out.println(acl.toString());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.5.5. Delete buckets

A bucket is a container for objects stored in OSS. Every object is contained in a bucket. This topic describes how to delete a bucket.

> **Note** Before you delete a bucket, you must delete all objects and parts generated by multipart upload in the bucket.

The following code provides an example on how to delete a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Delete the bucket.
ossClient.deleteBucket("<yourBucketName>");
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.5.6. Manage lifecycle rules

You can configure lifecycle rules for an OSS bucket to automatically delete expired objects to save storage space. This topic describes how to manage lifecycle rules.

Background

Each lifecycle rule contains the following information:

- Policy: specifies the mode to match objects and parts.
  - Match by prefix: matches objects and parts by prefix. You can create multiple rules to configure different prefixes. Each prefix must be unique.
  - Match by bucket: matches all objects and parts contained in the bucket. You can create only one rule if you select this method.
- Object lifecycle policy: specifies the validity period or expiration data and the operation to perform on these objects after they expire.
  - Validity period: specifies the number of days within which parts can be retained after they are last modified. After the validity period, expired objects are deleted.
  - Expiration date: specifies a date. Objects that are last modified before this date expire and are deleted.
- Part lifecycle policy: specifies the validity period or expiration time and the delete operation to perform on these objects after they expire.
  - Validity period: specifies the number of days within which parts can be retained after they are last modified. After the validity period, expired parts are deleted.
  - Expiration date: specifies a date. Parts that are last modified before this date expire and are deleted.

Lifecycle rules also apply to the parts uploaded by using uploadPart. In this case, the last modified time of an object is the time the multipart upload task is initiated.

Configure lifecycle rules

The following code provides an example on how to configure lifecycle rules:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
SetBucketLifecycleRequest request = new SetBucketLifecycleRequest(bucketName);
// Set the rule ID and the prefix of object names to match the rule.
String ruleId0 = "rule0";
String matchPrefix0 = "A0/";
String ruleId1 = "rule1";
String matchPrefix1 = "A1/";
String ruleId2 = "rule2";
String matchPrefix2 = "A2/";
String ruleId3 = "rule3";
String matchPrefix3 = "A3/";
// Specify that objects expire three days after they are last modified.
request.AddLifecycleRule(new LifecycleRule(ruleId0, matchPrefix0, RuleStatus.Enabled, 3));
// Specify that the objects that are last modified before the specified date expire.
LifecycleRule rule = new LifecycleRule(ruleId1, matchPrefix1, RuleStatus.Enabled);
rule.setCreatedBeforeDate(DateUtil.parseISO8601Date("2022-10-12T00:00:00.000Z"));
request.AddLifecycleRule(rule);
// Specify that parts expire three days after they are last modified.
rule = new LifecycleRule(ruleId2, matchPrefix2, RuleStatus.Enabled);
LifecycleRule.AbortMultipartUpload abortMultipartUpload = new LifecycleRule.AbortMultipartUpload();
abortMultipartUpload.setExpirationDays(3);
rule.setAbortMultipartUpload(abortMultipartUpload);
request.AddLifecycleRule(rule);
// Specify that the parts that are last modified before the specified date expire.
rule = new LifecycleRule(ruleId3, matchPrefix3, RuleStatus.Enabled);
abortMultipartUpload = new LifecycleRule.AbortMultipartUpload();
abortMultipartUpload.setCreatedBeforeDate(DateUtil.parseISO8601Date("2022-10-12T00:00:00.000Z"));
rule.setAbortMultipartUpload(abortMultipartUpload);
request.AddLifecycleRule(rule);
ossClient.setBucketLifecycle(request);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

View lifecycle rules

The following code provides an example on how to view lifecycle rules:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
List<LifecycleRule> rules = ossClient.getBucketLifecycle(bucketName);
for (LifecycleRule rule : rules) {
    System.out.println(rule.getId());
    System.out.println(rule.getPrefix());
    System.out.println(rule.getExpirationDays());
    System.out.println(rule.getCreatedBeforeDate());
    if(rule.hasAbortMultipartUpload()) {
        System.out.println(rule.getAbortMultipartUpload().getExpirationDays());
        System.out.println(rule.getAbortMultipartUpload().getCreatedBeforeDate());
    }
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Delete lifecycle rules

The following code provides an example on how to delete the lifecycle rules configured for a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
ossClient.deleteBucketLifecycle(bucketName);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.5.7. Configure hotlink protection

OSS provides hotlink protection to prevent unauthorized domain names from accessing your OSS data. You can configure the Referer field in the HTTP header.

To configure hotlink protection, you must configure the following parameters:

- Referer Whitelist: Only specified domain names are allowed to access OSS resources.
- Allow Empty Referer: If you do not allow empty Refer fields, a request is allowed to access OSS resources only if the request includes the Referer field configured in the HTTP or HTTPS header.

Configure a Referer whitelist

The following code provides an example on how to configure the Referer whitelist for a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
List<String> refererList = new ArrayList<String>();
// Add Referer values to the whitelist. You can use an asterisk (*) or a question mark (?) as a wildcard to set the Referer parameter.
refererList.add("http://www.aliyun.com");
refererList.add("http://www. *.com");
refererList.add("http://www.?.aliyuncs.com");
// Configure BucketReferer. A value of true indicates that an empty Referer field is allowed.
BucketReferer br = new BucketReferer(true, refererList);
ossClient.setBucketReferer(bucketName, br);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Query the hotlink configurations of a bucket

The following code provides an example on how to query the hotlink configurations of a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Query the Referer whitelist of the bucket.
BucketReferer br = ossClient.getBucketReferer(bucketName);
List<String> refererList = br.getRefererList();
for (String referer : refererList) {
    System.out.println(referer);
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Delete the hotlink configurations of a bucket

The following code provides an example on how to delete the hotlink configurations of a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// You cannot delete a Referer whitelist directly. To delete a Referer whitelist, you must create a rule that allows an empty Referer field to replace the existing rule.
BucketReferer br = new BucketReferer();
ossClient.setBucketReferer(bucketName, br);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.5.8. Configure CORS

Cross-origin resource sharing (CORS) allows web applications to access resources that belong to different regions. OSS provides CORS operations to facilitate cross-origin access control.

Configure CORS rules

The following code provides an example on how to configure CORS rules for a specific bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
SetBucketCORSRequest request = new SetBucketCORSRequest(bucketName);
// Create a container for the CORS rules. A maximum of 10 CORS rules can be configured for each bucket.
ArrayList<CORSRule> putCorsRules = new ArrayList<CORSRule>();
CORSRule corRule = new CORSRule();
ArrayList<String> allowedOrigin = new ArrayList<String>();
// Specify the allowed origins from which CORS requests are sent.
allowedOrigin.add( "http://www.b.com");
ArrayList<String> allowedMethod = new ArrayList<String>();
// Specify the HTTP methods that CORS requests are allowed to use, including GET, PUT, DELETE, POST, and HEAD.
allowedMethod.add("GET");
ArrayList<String> allowedHeader = new ArrayList<String>();
// Determine whether to allow the header specified in Access-Control-Request-Headers of the preflight (OPTIONS) request.
allowedHeader.add("x-oss-test");
ArrayList<String> exposedHeader = new ArrayList<String>();
// Specify the response headers that you are allowed to access from applications.
exposedHeader.add("x-oss-test1");
// You can use only one asterisk (*) as the wildcard for AllowedOrigins and AllowedMethods in a CORS rule. Asterisks (*) indicate to allow all origins or operations.
corRule.setAllowedMethods(allowedMethod);
corRule.setAllowedOrigins(allowedOrigin);
// AllowedHeaders and ExposeHeaders do not support wildcards.
corRule.setAllowedHeaders(allowedHeader);
corRule.setExposeHeaders(exposedHeader);
// Specifies the time the browser can cache the response to a preflight (OPTIONS) request to a specific resource. Unit: seconds.
corRule.setMaxAgeSeconds(10);
// You can configure up to 10 CORS rules for the bucket.
putCorsRules.add(corRule);
// The existing rules are replaced.
request.setCorsRules(putCorsRules);
ossClient.setBucketCORS(request);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Query CORS rules

The following code provides an example on how to query CORS rules configured for a specific bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
ArrayList<CORSRule> corsRules;
// Query the CORS rule list.
corsRules =  (ArrayList<CORSRule>) ossClient.getBucketCORSRules(bucketName);
for (CORSRule rule : corsRules) {
    for (String allowedOrigin1 : rule.getAllowedOrigins()) {
        // Query the allowed origins from which CORS requests are sent.
        System.out.println(allowedOrigin1);
    }
    for (String allowedMethod1 : rule.getAllowedMethods()) {
        // Query the allowed cross-origin request methods.
        System.out.println(allowedMethod1);
    }
    if (rule.getAllowedHeaders().size() > 0){
        for (String allowedHeader1 : rule.getAllowedHeaders()) {
            // Query the list of headers allowed in cross-origin requests.
            System.out.println(allowedHeader1);
        }
    }
    if (rule.getExposeHeaders().size() > 0) {
        for (String exposeHeader : rule.getExposeHeaders()) {
            // Query the list of response headers that can be accessed from an application.
            System.out.println(exposeHeader);
        }
    }
    if ( null ! = rule.getMaxAgeSeconds()) {
        System.out.println(rule.getMaxAgeSeconds());
    }
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Delete CORS rules

The following code provides an example on how to delete the CORS rules configured for a specific bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Delete the CORS rules configured for the bucket.
ossClient.deleteBucketCORSRules(bucketName);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.5.9. Configure logging

You can enable logging to record access to a bucket in log objects, which are stored in a specified bucket.

The log objects are in the following format: `<TargetPrefix><SourceBucket>-YYYY-mm-DD-HH-MM-SS-UniqueString`.

Enable logging

The following code provides an example on how to enable logging for a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
SetBucketLoggingRequest request = new SetBucketLoggingRequest("<yourSourceBucketName>");
// Specify the bucket used to store log objects.
request.setTargetBucket("<yourTargetBucketName>");
// Specify the folder where log objects are stored.
request.setTargetPrefix("<yourTargetPrefix>");
ossClient.setBucketLogging(request);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

View logging configurations

The following code provides an example on how to view the logging configurations of a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
BucketLoggingResult result = ossClient.getBucketLogging("<yourSourceBucketName>");
System.out.println(result.getTargetBucket());
System.out.println(result.getTargetPrefix());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Disable logging

The following code provides an example on how to disable logging for a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
SetBucketLoggingRequest request = new SetBucketLoggingRequest("<yourSourceBucketName>");
request.setTargetBucket(null);
request.setTargetPrefix(null);
ossClient.setBucketLogging(request);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.5.10. Configure static website hosting

This topic describes how to set your bucket to the static website hosting mode. After the configurations take effect, you can use the bucket domain name to access this static website and be redirected to a specified index page or error page.

Configure static website hosting

The following code provides an example on how to configure static website hosting:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
SetBucketWebsiteRequest request = new SetBucketWebsiteRequest("<yourBucketName>");
request.setIndexDocument("index.html");
request.setErrorDocument("error.html");
ossClient.setBucketWebsite(request);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

View static website hosting configurations

The following code provides an example on how to view static website hosting configurations:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
BucketWebsiteResult result = ossClient.getBucketWebsite("<yourBucketName>");
System.out.println(result.getIndexDocument());
System.out.println(result.getErrorDocument());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Delete static website hosting configurations

The following code provides an example on how to delete static website hosting configurations:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
ossClient.deleteBucketWebsite("<yourBucketName>");
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.6. Upload objects

6.1.2.1.6.1. Overview

This topic describes a variety of methods OSS SDK for Java provides to upload objects.

Objects are the basic unit for data operations in OSS. OSS SDK for Java provides the following object upload methods:

- Simple upload: includes streaming upload and local file upload. You can use this method to upload an object up to 5 GB in size.
- Form upload: uploads an object up to 5 GB in size.
- Append upload: uploads an object up to 5 GB in size.
- Resumable upload: supports concurrent upload and resumable upload in which you can define the size of each part. This method is suitable for the upload of large objects. You can use this method to upload an object up to 48.8 TB in size.
- Multipart upload: supports the upload of an object up to 48.8 TB in size. This method is suitable for the upload of large objects.

During object upload, you can configure object metadata and view upload progress by using a progress bar. After the object is uploaded, you can perform upload callback.

6.1.2.1.6.2. Simple upload

Simple upload allows you to use the PutObject operation to upload a single object to OSS. This topic describes how to perform simple upload by using OSS SDK for Java.

Simple upload includes stream upload and file upload. Stream upload uses InputStream as the source object. File upload uses a local file as the source object.

> **Note** For the complete code used to perform simple upload, visit GitHub.

Stream upload

Use ossClient.putObject to upload a data stream to OSS.

- Upload a string

  The following code provides an example on how to upload a string:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Create a PutObjectRequest object.
String content = "Hello OSS";
// <yourObjectName> indicates the complete path of the object you want to upload to OSS. The path must include the extension of the object name. Example: abc/efg/123.jpg.
PutObjectRequest putObjectRequest = new PutObjectRequest("<yourBucketName>", "<yourObjectName>", new ByteArrayInputStream(content.getBytes()));
// Upload the string.
ossClient.putObject(putObjectRequest);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- Upload a byte array

  The following code provides an example on how to upload a byte array:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId,accessKeySecret);
// Upload the byte array.
byte[] content = "Hello OSS".getBytes();
ossClient.putObject("<yourBucketName>", "<yourObjectName>", new ByteArrayInputStream(content));
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- Upload a network stream

  The following code provides an example on how to upload a network stream:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Upload the network stream.
InputStream inputStream = new URL("https://www.aliyun.com/").openStream();
ossClient.putObject("<yourBucketName>", "<yourObjectName>", inputStream);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- Upload a file stream

  The following code provides an example on how to upload a file stream:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Upload the file stream.
InputStream inputStream = new FileInputStream("<yourlocalFile>");
ossClient.putObject("<yourBucketName>", "<yourObjectName>", inputStream);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Local file upload

The following code provides an example on how to upload a local file to OSS:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Create a PutObjectRequest object.
PutObjectRequest putObjectRequest = new PutObjectRequest("<yourBucketName>", "<yourObjectNa
me>", new File("<yourLocalFile>"));
// Upload the local file.
ossClient.putObject(putObjectRequest);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.6.3. Form upload

Form upload uses an HTML form to upload an object to a specified bucket. The maximum size of an object to upload is 5 GB.

The following code provides an example on how to implement form upload:

```
public class PostObjectSample {
    // Upload an object.
    private String localFilePath = "<yourLocalFile>";
    // The endpoint of the China (Hangzhou) region is used in this example. Specify the act
ual endpoint.
    private String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
    // Security risks may arise if you log on with the AccessKey pair of an Alibaba Cloud a
ccount because the account has permissions on all API operations. We recommend that you use
a RAM user's credentials to call API operations or perform routine operations and maintenan
ce. To create a RAM user, log on to https://ram.console.aliyun.com.
    private String accessKeyId = "<yourAccessKeyId>";
    private String accessKeySecret = "<yourAccessKeySecret>";
    // Specify the bucket name.
    private String bucketName = "<yourBucketName>";
```

```
    // Specify the object name.
    private String objectName = "<yourObjectName>";
    /**
     // Start form upload.
     * @throws Exception
     */
    private void PostObject() throws Exception {
        // Add the bucket name to the URL. The URL format is http://yourBucketName.oss-cn-h
angzhou.aliyuncs.com.
        String urlStr = endpoint.replace("http://", "http://" + bucketName+ ".") ;
        // Create a map for the form.
        Map<String, String> formFields = new LinkedHashMap<String, String>();
        // Specify the object name.
        formFields.put("key", this.objectName);
        // Configure Content-Disposition.
        formFields.put("Content-Disposition", "attachment;filename="
                + localFilePath);
        // Configure callback parameters.
        Callback callback = new Callback();
        // Configure the URL of the server to which you want to send the callback request.
Example: http://oss-demo.aliyuncs.com:23450 or http://127.0.0.1:9090.
        callback.setCallbackUrl("<yourCallbackServerUrl>");
        // Configure the Host header in the callback request. Example: oss-cn-hangzhou.aliy
uncs.com.
        callback.setCallbackHost("<yourCallbackServerHost>");
        // Configure the body field for the callback request.
        callback.setCallbackBody("{\\\"mimeType\\\":${mimeType},\\\"size\\\":${size}}");
        // Configure Content-Type for the callback request.
        callback.setCalbackBodyType(CalbackBodyType.JSON);
        // Configure the custom parameters used to send the callback request. Each custom p
arameter consists of a key-value pair. The key must start with x: and be in lower case.
        callback.addCallbackVar("x:var1", "value1");
        callback.addCallbackVar("x:var2", "value2");
        // Configure the callback parameter in Map for the form.
        setCallBack(formFields, callback);
        // Set OSSAccessKeyId.
        formFields.put("OSSAccessKeyId", accessKeyId);
        String policy = "{\"expiration\": \"2120-01-01T12:00:00.000Z\",\"conditions\": [[\"
content-length-range\", 0, 104857600]]}";
        String encodePolicy = new String(Base64.encodeBase64(policy.getBytes()));
        // Set the policy.
        formFields.put("policy", encodePolicy);
        // Set a signature.
        String signaturecom = com.aliyun.oss.common.auth.ServiceSignature.create().computeS
ignature(accessKeySecret, encodePolicy);
        // Set the signature.
        formFields.put("Signature", signaturecom);
        String ret = formUpload(urlStr, formFields, localFilePath);
        System.out.println("Post Object [" + this.objectName + "] to bucket [" + bucketName
+ "]");
        System.out.println("post reponse:" + ret);
    }
    private static String formUpload(String urlStr, Map<String, String> formFields, String
localFile)
```

```
            throws Exception {
        String res = "";
        HttpURLConnection conn = null;
        String boundary = "9431149156168";
        try {
            URL url = new URL(urlStr);
            conn = (HttpURLConnection) url.openConnection();
            conn.setConnectTimeout(5000);
            conn.setReadTimeout(30000);
            conn.setDoOutput(true);
            conn.setDoInput(true);
            conn.setRequestMethod("POST");
            conn.setRequestProperty("User-Agent",
                    "Mozilla/5.0 (Windows; U; Windows NT 6.1; zh-CN; rv:1.9.2.6)");
            // Set the MD5 hash. The MD5 hash is calculated based on the entire body.
            conn.setRequestProperty("Content-MD5", "<yourContentMD5>");
            conn.setRequestProperty("Content-Type",
                    "multipart/form-data; boundary=" + boundary);
            OutputStream out = new DataOutputStream(conn.getOutputStream());
            // Recursively read all Map data in the form and write the data to the output s
tream.
            if (formFields ! = null) {
                StringBuffer strBuf = new StringBuffer();
                Iterator<Entry<String, String>> iter = formFields.entrySet().iterator();
                int i = 0;
                while (iter.hasNext()) {
                    Entry<String, String> entry = iter.next();
                    String inputName = entry.getKey();
                    String inputValue = entry.getValue();
                    if (inputValue == null) {
                        continue;
                    }
                    if (i == 0) {
                        strBuf.append("--").append(boundary).append("\r\n");
                        strBuf.append("Content-Disposition: form-data; name=\""
                                + inputName + "\"\r\n\r\n");
                        strBuf.append(inputValue);
                    } else {
                        strBuf.append("\r\n").append("--").append(boundary).append("\r\n");
                        strBuf.append("Content-Disposition: form-data; name=\""
                                + inputName + "\"\r\n\r\n");
                        strBuf.append(inputValue);
                    }
                    i++;
                }
                out.write(strBuf.toString().getBytes());
            }
            // Read the object and write it to the output stream.
            File file = new File(localFile);
            String filename = file.getName();
            String contentType = new MimetypesFileTypeMap().getContentType(file);
            if (contentType == null || contentType.equals("")) {
                contentType = "application/octet-stream";
            }
            StringBuffer strBuf = new StringBuffer();
```

```
            StringBuffer strBuf = new StringBuffer();
            strBuf.append("\r\n").append("--").append(boundary)
                    .append("\r\n");
            strBuf.append("Content-Disposition: form-data; name=\"file\"; "
                    + "filename=\"" + filename + "\"\r\n");
            strBuf.append("Content-Type: " + contentType + "\r\n\r\n");
            out.write(strBuf.toString().getBytes());
            DataInputStream in = new DataInputStream(new FileInputStream(file));
            int bytes = 0;
            byte[] bufferOut = new byte[1024];
            while ((bytes = in.read(bufferOut)) ! = -1) {
                out.write(bufferOut, 0, bytes);
            }
            in.close();
            byte[] endData = ("\r\n--" + boundary + "--\r\n").getBytes();
            out.write(endData);
            out.flush();
            out.close();
            // Read the returned data.
            strBuf = new StringBuffer();
            BufferedReader reader = new BufferedReader(new InputStreamReader(conn.getInputS
tream()));
            String line = null;
            while ((line = reader.readLine()) ! = null) {
                strBuf.append(line).append("\n");
            }
            res = strBuf.toString();
            reader.close();
            reader = null;
        } catch (Exception e) {
            System.err.println("Send post request exception: " + e);
            throw e;
        } finally {
            if (conn ! = null) {
                conn.disconnect();
                conn = null;
            }
        }
        return res;
    }
     private static void setCallBack(Map<String, String> formFields, Callback callback) {
        if (callback ! = null) {
            String jsonCb = OSSUtils.jsonizeCallback(callback);
            String base64Cb = BinaryUtil.toBase64String(jsonCb.getBytes());
            formFields.put("callback", base64Cb);
            if (callback.hasCallbackVar()) {
                Map<String, String> varMap = callback.getCallbackVar();
                for (Entry<String, String> entry : varMap.entrySet()) {
                    formFields.put(entry.getKey(), entry.getValue());
                }
            }
        }
    }
    public static void main(String[] args) throws Exception {
        PostObjectSample ossPostObject = new PostObjectSample();
```

```
        ossPostObject.PostObject();
    }
}
```

6.1.2.1.6.4. Append upload

OSS allows you to use append object to append content directly to the end of an object. This method applies to append objects.

You cannot perform copyObject for append objects.

The following code provides an example on how to perform append upload:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Security risks may arise if you log on with the AccessKey pair of an Alibaba Cloud account because the account has permissions on all API operations. We recommend that you use a RAM user's credentials to call API operations or perform routine operations and maintenance. To create a RAM user, log on to https://ram.console.aliyun.com.
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String content1 = "Hello OSS A \n";
String content2 = "Hello OSS B \n";
String content3 = "Hello OSS C \n";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
ObjectMetadata meta = new ObjectMetadata();
// Specify the type of content you want to upload.
meta.setContentType("text/plain");
// Configure parameters by using AppendObjectRequest.
AppendObjectRequest appendObjectRequest = new AppendObjectRequest("<yourBucketName>", "<yourObjectName>", new ByteArrayInputStream(content1.getBytes()),meta);
// Configure a single parameter by using AppendObjectRequest.
// Specify the bucket name.
//appendObjectRequest.setBucketName("<yourBucketName>");
// Specify the object name.
//appendObjectRequest.setKey("<yourObjectName>");
// Specify the content you want to append. Two types of content are available: InputStream and File. Select InputStream.
//appendObjectRequest.setInputStream(new ByteArrayInputStream(content1.getBytes()));
// Specify the content you want to append. Two types of content are available: InputStream and File. Select File.
//appendObjectRequest.setFile(new File("<yourLocalFile>"));
// Specify object metadata. The specified object metadata takes effect from the first append.
//appendObjectRequest.setMetadata(meta);
// Start the first append.
// Configure the position where the object is appended based on the previous object length.
appendObjectRequest.setPosition(0L);
AppendObjectResult appendObjectResult = ossClient.appendObject(appendObjectRequest);
// Calculate the 64-bit CRC value. The value is calculated based on the ECMA-182 standard.
System.out.println(appendObjectResult.getObjectCRC());
// Start the second append.
// nextPosition indicates the position included in the next request, which is equal to the length of the current object.
appendObjectRequest.setPosition(appendObjectResult.getNextPosition());
appendObjectRequest.setInputStream(new ByteArrayInputStream(content2.getBytes()));
appendObjectResult = ossClient.appendObject(appendObjectRequest);
// Start the third append.
appendObjectRequest.setPosition(appendObjectResult.getNextPosition());
appendObjectRequest.setInputStream(new ByteArrayInputStream(content3.getBytes()));
appendObjectResult = ossClient.appendObject(appendObjectRequest);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.6.5. Resumable upload

If the system stops responding during multipart upload, you can resume the upload by using the ListMultipartUploads and ListParts operations to retrieve all multipart upload tasks on an object and list the uploaded parts in each task. This method allows an upload task to be resumed from the last uploaded part.

The following code provides an example on how to perform resumable upload:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
ObjectMetadata meta = new ObjectMetadata();
// Specify the type of content you want to upload.
meta.setContentType("text/plain");
// Configure parameters by using UploadFileRequest.
UploadFileRequest uploadFileRequest = new UploadFileRequest("<yourBucketName>","<yourObject
Name>");
// Configure a single parameter by using UploadFileRequest.
// Specify the bucket name.
//uploadFileRequest.setBucketName("<yourBucketName>");
// Specify the object name.
//uploadFileRequest.setKey("<yourObjectName>");
// Specify the local file to upload.
uploadFileRequest.setUploadFile("<yourLocalFile>");
// Specify the number of threads for simultaneous upload. Default value: 1.
uploadFileRequest.setTaskNum(5);
// Specify the size of a part you want to upload. Valid values: 100 KB to 5 GB. The default
size of each part is calculated based on the formula: Default size of each part = Object si
ze/10000.
uploadFileRequest.setPartSize(1 * 1024 * 1024);
// Enable resumable upload. By default, resumable upload is disabled.
uploadFileRequest.setEnableCheckpoint(true);
// Specify the checkpoint file that records the upload results of each part. You need to co
nfigure this parameter when you enable resumable upload. This file stores progress informat
ion. If a part fails to be uploaded, you can continue the upload based on the progress info
rmation recorded in the checkpoint file. After the object is uploaded, the checkpoint file
is deleted. By default, this file is stored in uploadFile.ucp, which is the same directory
as that of the local file you want to upload.
uploadFileRequest.setCheckpointFile("<yourCheckpointFile>");
// Configure object metadata.
uploadFileRequest.setObjectMetadata(meta);
// Configure upload callback. The parameter type is Callback.
uploadFileRequest.setCallback("<yourCallbackEvent>");
// Start resumable upload.
ossClient.uploadFile(uploadFileRequest);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.6.6. Multipart upload

OSS allows you to use multipart upload to split an object into several parts and upload them separately. After all parts are uploaded, you can combine the uploaded parts into a complete object to finish the upload.

To implement multipart upload, perform the following operations:

1. Initiate a multipart upload task.

   Call the ossClient.initiateMultipartUpload method to obtain a unique upload ID in OSS.

2. Upload the parts.

   Call the ossClient.uploadPart method to upload the parts.

   > **Note**
   > - Part numbers identify the relative positions of parts in an object that share the same upload ID. If you have uploaded a part and used its part number again to upload another part, the latter part overwrites the former part.
   > - OSS includes the MD5 hash of part data in the ETag header and returns the MD5 hash to the user.
   > - OSS calculates the MD5 hash of uploaded data and compares it with the MD5 hash calculated by the SDK. If the two hashes are different, the InvalidDigest error code is returned.

3. Complete the multipart upload task.

   After all parts are uploaded, call the ossClient.completeMultipartUpload method to combine these parts into a complete object.

The following code provides an example on how to perform multipart upload:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// <yourObjectName> indicates the complete path of the object you want to upload to OSS. Th
e path must include the extension of the object name. Example: abc/efg/123.jpg.
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Create an InitiateMultipartUploadRequest object.
InitiateMultipartUploadRequest request = new InitiateMultipartUploadRequest("<yourBucketNam
e>", "<yourObjectName>");
// Optional. Specify the storage class.
// ObjectMetadata metadata = new ObjectMetadata();
// metadata.setHeader(OSSHeaders.OSS_STORAGE_CLASS, StorageClass.Standard.toString());
// request.setObjectMetadata(metadata);
// Initiate a multipart upload task.
InitiateMultipartUploadResult upresult = ossClient.initiateMultipartUpload(request);
// Obtain an upload ID. The upload ID is the unique identification of a multipart upload ta
```

```
sk. You can initiate related requests based on the upload ID, such as canceling a multipart upload and querying a multipart upload.
String uploadId = upresult.getUploadId();
// partETags is a set of PartETags. A PartETag consists of an ETag and a part number.
List<PartETag> partETags =  new ArrayList<PartETag>();
// Calculate the total number of parts to upload.
final long partSize = 1 * 1024 * 1024L;   // 1MB
final File sampleFile = new File("<localFile>");
long fileLength = sampleFile.length();
int partCount = (int) (fileLength / partSize);
if (fileLength % partSize ! = 0) {
    partCount++;
 }
// Upload each part sequentially until all parts are uploaded.
for (int i = 0; i < partCount; i++) {
    long startPos = i * partSize;
    long curPartSize = (i + 1 == partCount) ? (fileLength - startPos) : partSize;
    InputStream instream = new FileInputStream(sampleFile);
    // Skip the uploaded parts.
    instream.skip(startPos);
    UploadPartRequest uploadPartRequest = new UploadPartRequest();
    uploadPartRequest.setBucketName(bucketName);
    uploadPartRequest.setKey(objectName);
    uploadPartRequest.setUploadId(uploadId);
    uploadPartRequest.setInputStream(instream);
    // Configure the size of each part. Each part except for the last part must be larger than 100 KB.
    uploadPartRequest.setPartSize(curPartSize);
    // Configure part numbers. Each part is configured with a part number. The number ranges from 1 to 10000. If you configure a number beyond the range, OSS returns an InvalidArgument error code.
    uploadPartRequest.setPartNumber( i + 1);
    // Parts are not necessarily uploaded in order. They may be uploaded from different OSS clients. OSS sorts the parts based on their part numbers and combines them to obtain a complete object.
    UploadPartResult uploadPartResult = ossClient.uploadPart(uploadPartRequest);
    // After you upload a part, OSS returns a result that contains a PartETag. The PartETag is stored in partETags.
    partETags.add(uploadPartResult.getPartETag());
}
// Create a CompleteMultipartUploadRequest object.
// When the multipart upload task is complete, you must provide all valid partETags. After OSS receives the partETags, OSS verifies the validity of all parts one by one. After all parts are validated, OSS combines these parts into a complete object.
CompleteMultipartUploadRequest completeMultipartUploadRequest =
        new CompleteMultipartUploadRequest(bucketName, objectName, uploadId, partETags);
// Optional. Set the ACL.
// completeMultipartUploadRequest.setObjectACL(CannedAccessControlList.PublicRead);
// Complete the multipart upload task.
CompleteMultipartUploadResult completeMultipartUploadResult = ossClient.completeMultipartUpload(completeMultipartUploadRequest);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Cancel a multipart upload task

You can call the ossClient.abortMultipartUpload method to cancel a multipart upload task. If a multipart upload task is canceled, the upload ID can no longer be used to upload any parts. The parts uploaded by using that upload ID are also deleted.

The following code provides an example on how to cancel a multipart upload task:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Cancel the multipart upload task. The upload ID is returned by InitiateMultipartUpload.
AbortMultipartUploadRequest abortMultipartUploadRequest =
        new AbortMultipartUploadRequest("<yourBucketName>", "<yourObjectName>", "<uploadId>
");
ossClient.abortMultipartUpload(abortMultipartUploadRequest);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

List uploaded parts

You can call the ossClient.listParts method to list all parts that are uploaded by using the specified upload ID.

- Simple list

  The following code provides an example for simple list:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// List uploaded parts. The upload ID is returned by InitiateMultipartUpload.
ListPartsRequest listPartsRequest = new ListPartsRequest("<yourBucketName>", "<yourObject
Name>", "<uploadId>");
 // Configure an upload ID.
 //listPartsRequest.setUploadId(uploadId);
 // Set the maximum number of parts to list on each page to 100. By default, a maximum of
1,000 parts can be listed.
 listPartsRequest.setMaxParts(100);
 // Specify the start point of the list. Only the parts whose part numbers are greater th
an the value of this parameter are listed.
 listPartsRequest.setPartNumberMarker(2);
PartListing partListing = ossClient.listParts(listPartsRequest);
for (PartSummary part : partListing.getParts()) {
    // Query part numbers.
    part.getPartNumber();
    // Query the part size.
    part.getSize();
    // Query the ETag.
    part.getETag();
    // Query the last modified time.
    part.getLastModified();
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- List all uploaded parts

  By default, listParts can list up to 1,000 parts at a time. The following code provides an example on how to list more than 1,000 parts:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// List all uploaded parts.
PartListing partListing;
ListPartsRequest listPartsRequest = new ListPartsRequest("<yourBucketName>", "<yourObject
Name>", "<uploadId>");
do {
    partListing = ossClient.listParts(listPartsRequest);
    for (PartSummary part : partListing.getParts()) {
        // Query part numbers.
        part.getPartNumber();
        // Query the part size.
        part.getSize();
        // Query the ETag.
        part.getETag();
        // Query the last modified time.
        part.getLastModified();
    }
// Specify the start point of the list. Only the parts whose part numbers are greater tha
n the value of this parameter are listed.
listPartsRequest.setPartNumberMarker(partListing.getNextPartNumberMarker());
} while (partListing.isTruncated());
// Shut down the OSSClient instance.
ossClient.shutdown()
```

- List all uploaded parts by page

  The following code provides an example on how to specify the maximum number of parts to list on each page and list all uploaded parts by page:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// List all uploaded parts by page.
PartListing partListing;
ListPartsRequest listPartsRequest = new ListPartsRequest("<yourBucketName>", "<yourObject
Name>", "<uploadId>");
// Set the maximum number of parts to list on each page to 100.
listPartsRequest.setMaxParts(100);
do {
    partListing = ossClient.listParts(listPartsRequest);
    for (PartSummary part : partListing.getParts()) {
        // Query part numbers.
        part.getPartNumber();
        // Query the part size.
        part.getSize();
        // Query the ETag.
        part.getETag();
        // Query the last modified time.
        part.getLastModified();
    }
    listPartsRequest.setPartNumberMarker(partListing.getNextPartNumberMarker());
} while (partListing.isTruncated());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

List multipart upload tasks

You can call the ossClient.listMultipartUploads method to list all ongoing multipart upload tasks. Ongoing multipart upload tasks are tasks that are initiated but incomplete or tasks that are canceled. The following table describes the parameters.

Parameter	Description	Configuration method
prefix	Specifies that the returned object names must contain a specified prefix. Note that if you use a prefix for a query, the returned object names contain the prefix.	ListMultipartUploadsRequest.setPrefix(String prefix)
delimiter	Groups objects by name. Objects whose names contain the same string from the prefix and the next occurrence of the delimiter are grouped as a single result element in CommonPrefixes.	ListMultipartUploadsRequest.setDelimiter(String delimiter)

Parameter	Description	Configuration method
maxUploads	Specifies the maximum number of multipart upload tasks to return. The default value is the same as the maximum value, which is 1000.	ListMultipartUploadsRequest.setMaxUploads(Integer maxUploads)
keyMarker	Specifies the key-marker value from which to start the list. Multipart upload tasks are listed in alphabetical order of their object names. You can use this parameter with the uploadIdMarker parameter to specify the start point to list the returned results.	ListMultipartUploadsRequest.setKeyMarker(String keyMarker)
uploadIdMarker	UploadIdMarker is used with the keyMarker parameter to specify the start point to list the returned results. If the keyMarker parameter is not configured, the uploadIdMarker parameter is invalid. If the keyMarker parameter is configured, the query result includes: • All objects whose names come after the value of keyMarker. • All multipart upload tasks in which the object names come after the keyMarker value and the upload IDs are greater than the uploadIdMarker value.	ListMultipartUploadsRequest.setUploadIdMarker(String uploadIdMarker)

- Simple list

  The following code provides an example for simple list:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// List multipart upload tasks. By default, a maximum of 1,000 parts can be listed.
ListMultipartUploadsRequest listMultipartUploadsRequest = new ListMultipartUploadsRequest
(bucketName);
MultipartUploadListing multipartUploadListing = ossClient.listMultipartUploads(listMultip
artUploadsRequest);
for (MultipartUpload multipartUpload : multipartUploadListing.getMultipartUploads()) {
    // Query upload IDs.
    multipartUpload.getUploadId();
    // Query object names.
    multipartUpload.getKey();
    // Query the time the multipart upload tasks are initiated.
    multipartUpload.getInitiated();
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

If the value of the isTruncated field in the returned result is false, values of nextKeyMarker and nextUploadIdMarker are returned and used as the start point for the next object reading. If all multipart upload tasks cannot be returned at a time, list them by page.

- List all multipart upload tasks

  By default, listMultipartUploads can list up to 1,000 multipart upload tasks at a time. The following code provides an example on how to list more than 1,000 multipart upload tasks:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// List multipart upload tasks.
MultipartUploadListing multipartUploadListing;
ListMultipartUploadsRequest listMultipartUploadsRequest = new ListMultipartUploadsRequest
(bucketName);
do {
    multipartUploadListing = ossClient.listMultipartUploads(listMultipartUploadsRequest);
    for (MultipartUpload multipartUpload : multipartUploadListing.getMultipartUploads())
{
        // Query upload IDs.
        multipartUpload.getUploadId();
        // Query object names.
        multipartUpload.getKey();
        // Query the time the multipart upload tasks are initiated.
        multipartUpload.getInitiated();
    }
    listMultipartUploadsRequest.setKeyMarker(multipartUploadListing.getNextKeyMarker());
    listMultipartUploadsRequest.setUploadIdMarker(multipartUploadListing.getNextUploadIdM
arker());
} while (multipartUploadListing.isTruncated());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- List all multipart upload tasks by page

  The following code provides an example on how to list all multipart upload tasks by page:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// List multipart upload tasks.
MultipartUploadListing multipartUploadListing;
ListMultipartUploadsRequest listMultipartUploadsRequest = new ListMultipartUploadsRequest
(bucketName);
// Specify the number of multipart upload tasks to list on each page.
listMultipartUploadsRequest.setMaxUploads(50);
do {
    multipartUploadListing = ossClient.listMultipartUploads(listMultipartUploadsRequest);
    for (MultipartUpload multipartUpload : multipartUploadListing.getMultipartUploads())
{
        // Query upload IDs.
        multipartUpload.getUploadId();
        // Query object names.
        multipartUpload.getKey();
        // Query the time the multipart upload tasks are initiated.
        multipartUpload.getInitiated();
    }
    listMultipartUploadsRequest.setKeyMarker(multipartUploadListing.getNextKeyMarker());
    listMultipartUploadsRequest.setUploadIdMarker(multipartUploadListing.getNextUploadIdM
arker());
} while (multipartUploadListing.isTruncated());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.6.7. Use a progress bar

Progress bars are used to indicate the progress of an upload or download.

The following code provides an example on how to use upload progress bars by using the ossClient.putObject method:

```
public class PutObjectProgressListener implements ProgressListener {
    private long bytesWritten = 0;
    private long totalBytes = -1;
    private boolean succeed = false;
    @Override
    public void progressChanged(ProgressEvent progressEvent) {
        long bytes = progressEvent.getBytes();
        ProgressEventType eventType = progressEvent.getEventType();
        switch (eventType) {
        case TRANSFER_STARTED_EVENT:
            System.out.println("Start to upload......");
            break;
        case REQUEST_CONTENT_LENGTH_EVENT:
            this.totalBytes = bytes;
```

```
            System.out.println(this.totalBytes + " bytes in total will be uploaded to OSS")
;
            break;
        case REQUEST_BYTE_TRANSFER_EVENT:
            this.bytesWritten += bytes;
            if (this.totalBytes ! = -1) {
                int percent = (int)(this.bytesWritten * 100.0 / this.totalBytes);
                System.out.println(bytes + " bytes have been written at this time, upload p
rogress: " + percent + "%(" + this.bytesWritten + "/" + this.totalBytes + ")");
            } else {
                System.out.println(bytes + " bytes have been written at this time, upload r
atio: unknown" + "(" + this.bytesWritten + "/...)");
            }
            break;
        case TRANSFER_COMPLETED_EVENT:
            this.succeed = true;
            System.out.println("Succeed to upload, " + this.bytesWritten + " bytes have bee
n transferred in total");
            break;
        case TRANSFER_FAILED_EVENT:
            System.out.println("Failed to upload, " + this.bytesWritten + " bytes have been
transferred");
            break;
        default:
            break;
        }
    }
    public boolean isSucceed() {
        return succeed;
    }
    public static void main(String[] args) {
        // The endpoint of the China (Hangzhou) region is used in this example. Specify the
actual endpoint.
        String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
        // Security risks may arise if you use the AccessKey pair of an Alibaba Cloud accou
nt to log on to OSS because the account has permissions on all API operations. We recommend
that you use a RAM user to call API operations or perform routine operations and maintenanc
e. To create a RAM user, log on to https://ram.console.aliyun.com.
        String accessKeyId = "<yourAccessKeyId>";
        String accessKeySecret = "<yourAccessKeySecret>";
        String bucketName = "<yourBucketName>";
        String objectName = "<yourObjectName>";
        // Create an OSSClient instance.
        OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret
);
        try {
            // View the upload progress information while you upload an object.
            ossClient.putObject(new PutObjectRequest(bucketName, objectName, new File("<you
rLocalFile>")).
                    <PutObjectRequest>withProgressListener(new PutObjectProgressListener())
);
        } catch (Exception e) {
            e.printStackTrace();
        }
```

```
        // Shut down the OSSClient instance.
        ossClient.shutdown();
    }
}
```

You can view progress information when you use ossClient.putObject, ossClient.getObject, or ossClient.uploadPart. However, you cannot view progress information when you use ossClient.uploadFile or ossClient.downloadFile.

6.1.2.1.6.8. Upload callback

This topic describes how to use upload callback.

The following code provides an example on how to use upload callback:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// Specify the IP address of the server to which you want send the callback request. Example: http://oss-demo.aliyuncs.com:23450 or http://127.0.0.1:9090.
String callbackUrl = "<yourCallbackServerUrl>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
String content = "Hello OSS";
PutObjectRequest putObjectRequest = new PutObjectRequest(bucketName, objectName,new ByteArrayInputStream(content.getBytes()));
// Configure upload callback parameters.
Callback callback = new Callback();
callback.setCallbackUrl(callbackUrl);
// Optional. Configure the value of the host field included in the callback request header. This value is the same as the value of the host field specified for your server.
// callback.setCallbackHost("yourCallbackHost");
// Configure the value of the body field included in the callback request.
callback.setCallbackBody("{\\\"mimeType\\\":${mimeType},\\\"size\\\":${size}}");
// Configure Content-Type for the callback request.
callback.setCalbackBodyType(CalbackBodyType.JSON);
// Configure custom parameters for the callback request. Each custom parameter consists of a key and a value. The key must start with x:.
callback.addCallbackVar("x:var1", "value1");
callback.addCallbackVar("x:var2", "value2");
putObjectRequest.setCallback(callback);
PutObjectResult putObjectResult = ossClient.putObject(putObjectRequest);
// Read the response for the upload callback request.
byte[] buffer = new byte[1024];
putObjectResult.getResponse().getContent().read(buffer);
// You must close the stream after the object is read. Otherwise, connection leaks may occur. Consequently, no connections are available and an exception occurs.
putObjectResult.getResponse().getContent().close();
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.7. Download objects

6.1.2.1.7.1. Overview

OSS provides a variety of methods for you to download objects from OSS.

OSS SDK for Java provides the following object download methods:

- Streaming download
- Download to local files
- Range download

- Resumable download
- Conditional download

You can view the download progress by using a progress bar. For more information, see Use a progress bar.

6.1.2.1.7.2. Streaming download

If you have a large object to download or it is time-consuming to download the entire object at a time, you can use streaming download. Streaming download enables you to download part of the object content each time until you download the entire object.

If you do not close the ossObject object after it is used, connection leaks may occur. As a result, no connection is available and an exception occurs. The following code provides an example on how to close an ossObject object:

```
OSSObject ossObject = ossClient.getObject(bucketName, objectName);
ossObject.close();
```

The following code provides an example on how to download an object by using streaming download:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// <yourObjectName> indicates the complete path of the object you want to download from OSS
. The path must include the file extension of the object. For example, set <yourObjectName>
to abc/efg/123.jpg.
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// ossObject includes the bucket name, object name, object metadata, and an input stream.
OSSObject ossObject = ossClient.getObject(bucketName, objectName);
// Read the object content.
System.out.println("Object content:");
BufferedReader reader = new BufferedReader(new InputStreamReader(ossObject.getObjectContent
()));
while (true) {
    String line = reader.readLine();
    if (line == null) break;
    System.out.println("\n" + line);
}
// You must close the stream that is obtained by using ossClient.getObject after the object
is read. Otherwise, connection leaks may occur. As a result, no connections are available a
nd an exception occurs.
reader.close();
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.7.3. Download to local files

This topic describes how to download an object to a local file.

The following code provides an example on how to download a specified object to a local file:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Download the object to a local file. If the name of the object is the same as that of the local file, the object replaces the local file. If the name of the object is different from that of the local file, the object is downloaded.
ossClient.getObject(new GetObjectRequest(bucketName, objectName), new File("<yourLocalFile>"));
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.7.4. Range download

If you need only part of the data in an object, you can use range download to download data within the specified range.

Specify a valid range

The following code provides an example on how to specify a valid range to download an object:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// <yourObjectName> indicates the complete path of the object you want to download from OSS. The path must include the file extension of the object. Example: abc/efg/123.jpg.
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
GetObjectRequest getObjectRequest = new GetObjectRequest(bucketName, objectName);
// The valid range for an object whose size is 1,000 bytes is from byte 0 to byte 999.
// Query the data that is within the range from byte 0 to byte 999, which includes a total of 1,000 bytes. If the specified range is invalid, for example, the specified range includes a negative number, or the specified value is larger than the object size, the entire object is downloaded.
getObjectRequest.setRange(0, 999);
// Start range download.
OSSObject ossObject = ossClient.getObject(getObjectRequest);
// Read the data.
byte[] buf = new byte[1024];
InputStream in = ossObject.getObjectContent();
for (int n = 0; n ! = -1; ) {
    n = in.read(buf, 0, buf.length);
}
// You must close the stream that is obtained by using ossClient.getObject after the object is read. Otherwise, connection leaks may occur. As a result, no connections are available and an exception occurs.
in.close();
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Streaming download may not read all data at a time. To read 64 KB of data from OSS in streaming mode, you can use the following method to read the data multiple times until 64 KB of data or the entire object is read. For more information, see InputStream.read.

```
byte[] buf = new byte[1024];
InputStream in = ossObject.getObjectContent();
for (int n = 0; n ! = -1; ) {
    n = in.read(buf, 0, buf.length);
}
in.close();
```

Specify an invalid range

The valid range for an object whose size is 1,000 bytes is from byte 0 to byte 999. If the specified range is not within the range, the range does not take effect. Then, OSS returns the 200 HTTP status code and the data of the entire object. The following list provides examples of invalid requests and the returned results:

- If you set Range: bytes to 500-2000, the value at the end of the range is invalid. Then, OSS returns the 200 HTTP status code and the data of the entire object.

- If you set Range: bytes to 1000-2000, the value at the start of the range is invalid. Then, OSS returns the 200 HTTP status code and the data of the entire object.

Compatible download

If you add x-oss-range-behavior:standard to the request header, the download behavior is modified when the specified range is not within the valid range. Example: Use range download to download an object whose size is 1,000 bytes.

- If you set Range: bytes to 500-2000, the value at the end of the range is invalid. Then, OSS returns the 206 HTTP status code and the data that is within the range from byte 500 to byte 999.
- If you set Range: bytes to 1000-2000, the value at the start of the range is invalid. Then, OSS returns the 416 HTTP status code and the error code InvalidRange.

The following code provides an example on how to perform compatible download:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Specify an object whose size is 1,000 bytes.
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Specify the compatible behavior.
// When the value at the end of the range is invalid, OSS returns the data that is within t
he range from byte 500 to byte 999. The 206 HTTP status code is also returned.
getObjectRequest = new GetObjectRequest(bucketName, objectName);
getObjectRequest.setRange(500, 2000);
getObjectRequest.addHeader("x-oss-range-behavior", "standard");
OSSObject ossObject = ossClient.getObject(getObjectRequest);
ossObject.close();
System.out.println("standard get " + "500~2000 "+ "statusCode:"  + ossObject.getResponse().
getStatusCode());
System.out.println("standard get " + "500~2000 " + "contentLength:" + ossObject.getResponse
().getContentLength());
try {
    // When the value at the start of the range is invalid, exceptions are returned for the
following code. The returned HTTP status code is 416 and the returned error code is Invalid
Range.
    getObjectRequest = new GetObjectRequest(bucketName, objectName);
    getObjectRequest.setRange(1000, 2000);
    getObjectRequest.addHeader("x-oss-range-behavior", "standard");
    ossClient.getObject(getObjectRequest);
} catch (OSSException e) {
    System.out.println("standard get " + "1000~2000:" + "error code:" + e.getErrorCode());
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.7.5. Resumable download

You may fail to download a large object if the network is unstable or if the program stops responding. In some cases, you may still fail to download the object even after multiple attempts. To solve this problem, OSS SDK for Java provides the resumable download feature.

To enable resumable download, you need to split the object you want to download into multiple parts and download them separately. After all parts are downloaded, these parts are combined into a complete object.

You can use ossClient.downloadFile to enable resumable download. The following table describes the parameters you can configure for DownloadFileRequest.

Parameter	Description	Required	Default value	Configuration method
bucket	The name of the bucket.	Yes	None	Constructor
key	The name of the object.	Yes	None	Constructor
downloadFile	The path to the local file. The OSS object is downloaded to this file.	No	Name of the object	Constructor or setUploadFile
partSize	The size of each part. Valid values: 1 byte to 5 GB.	No	Object size/10000	setPartSize
taskNum	The number of parts you need to download simultaneously.	No	1	setTaskNum
enableCheckpoint	Specifies whether to enable resumable upload.	No	false	setEnableCheckpoint

Parameter	Description	Required	Default value	Configuration method
checkpointFile	The file that records the results of multipart download. This parameter must be configured to enable resumable upload. This file stores information about download progress. If you fail to download a part, the next download continues based on the recorded progress. After the object is downloaded, the checkpoint file is deleted.	No	downloadFile.ucp (share the same directory with DownloadFile)	setCheckpointFile

The following code provides an example on how to perform resumable download:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Send a request to download 10 tasks simultaneously and start resumable download.
DownloadFileRequest downloadFileRequest = new DownloadFileRequest(bucketName, objectName);
downloadFileRequest.setDownloadFile("<yourDownloadFile>");
downloadFileRequest.setPartSize(1 * 1024 * 1024);
downloadFileRequest.setTaskNum(10);
downloadFileRequest.setEnableCheckpoint(true);
downloadFileRequest.setCheckpointFile("<yourCheckpointFile>");
// Download the object.
DownloadFileResult downloadRes = ossClient.downloadFile(downloadFileRequest);
// After the object is downloaded, the object metadata is returned.
downloadRes.getObjectMetadata();
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.7.6. Conditional download

This topic describes how to download objects that meet the specified conditions.

OSS allows you to configure one or more conditions for object downloads. If the specified conditions are met, the object can be downloaded. If the specified conditions are not met, an error code is returned and the object cannot be downloaded. The following table describes the download conditions.

Parameter	Description
If-Modified-Since	If the specified time is earlier than the time the object is modified, the object can be downloaded. Otherwise, 304 Not modified is returned.
If-Unmodified-Since	If the specified time is later than or equal to the time the object is modified, the object can be downloaded. Otherwise, 412 Precondition failed is returned.
If-Match	If the specified ETag matches that of an object, the object can be downloaded. Otherwise, 412 Precondition failed is returned.
If-None-Match	If the specified ETag does not match that of an object, the object can be downloaded. Otherwise, 304 Not modified is returned.

You can use If-Modified-Since and If-Unmodified-Since as object download conditions at the same time. You can also configure both If-Match and If-None-Match for object downloads.

You can obtain the ETag by using ossClient.getObjectMeta.

The following code provides an example on how to perform conditional download:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
GetObjectRequest request = new GetObjectRequest(bucketName, objectName);
// Configure the download conditions.
request.setModifiedSinceConstraint(new Date());
// Download the object to a local file.
ossClient.getObject(request, new File("<yourLocalFile>"));
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Conditional download supports ossClient.getObject and ossClient.downloadFile.

6.1.2.1.7.7. Use a progress bar

Progress bars are used to indicate the progress of an upload or download.

For the complete code of download progress bars, visit GitHub.

The following code provides an example on how to use upload progress bars in ossClient.getObject:

```
static class GetObjectProgressListener implements ProgressListener {
        private long bytesRead = 0;
        private long totalBytes = -1;
        private boolean succeed = false;
        @Override
        public void progressChanged(ProgressEvent progressEvent) {
            long bytes = progressEvent.getBytes();
            ProgressEventType eventType = progressEvent.getEventType();
            switch (eventType) {
            case TRANSFER_STARTED_EVENT:
                System.out.println("Start to download......");
                break;
            case RESPONSE_CONTENT_LENGTH_EVENT:
                this.totalBytes = bytes;
                System.out.println(this.totalBytes + " bytes in total will be downloaded to
a local file");
                break;
            case RESPONSE_BYTE_TRANSFER_EVENT:
                this.bytesRead += bytes;
                if (this.totalBytes ! = -1) {
                    int percent = (int)(this.bytesRead * 100.0 / this.totalBytes);
                    System.out.println(bytes + " bytes have been read at this time, downloa
d progress: " +
                            percent + "%(" + this.bytesRead + "/" + this.totalBytes + ")");
                } else {
                    System.out.println(bytes + " bytes have been read at this time, downloa
d ratio: unknown" +
                            "(" + this.bytesRead + "/...)");
                }
                break;
            case TRANSFER_COMPLETED_EVENT:
                this.succeed = true;
                System.out.println("Succeed to download, " + this.bytesRead + " bytes have
been transferred in total");
                break;
            case TRANSFER_FAILED_EVENT:
                System.out.println("Failed to download, " + this.bytesRead + " bytes have b
een transferred");
                break;
            default:
                break;
            }
        }
        public boolean isSucceed() {
            return succeed;
        }
```

```
    }
public static void main(String[] args) {
    // The endpoint of the China (Hangzhou) region is used in this example. Specify the act
ual endpoint.
    String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
    String accessKeyId = "<yourAccessKeyId>";
    String accessKeySecret = "<yourAccessKeySecret>";
    String bucketName = "<yourBucketName>";
    String objectName = "<yourObjectName>";
    OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
    try {
            // View the download progress while you download an object.
            ossClient.getObject(new GetObjectRequest(bucketName, objectName).
                    <GetObjectRequest>withProgressListener(new GetObjectProgressListener())
,
                    new File("<yourLocalFile>"));
    } catch (Exception e) {
        e.printStackTrace();
    }
    // Shut down the OSSClient instance.
    ossClient.shutdown();
}
```

You can view progress information when you use ossClient.putObject, ossClient.getObject, or ossClient.uploadPart. However, you cannot view progress information when you use ossClient.uploadFile or ossClient.downloadFile.

6.1.2.1.8. Manage objects

6.1.2.1.8.1. Overview

You can manage objects in a bucket by using a series of API operations such as SetObjectAcl, GetObjectAcl, ListObjects, DeleteObject, CopyObject, and DoesObjectExist.

By using the preceding operations, you can perform the following operations:

- Determine whether an object exists
- Manage object ACLs
- Manage object metadata
- List objects
- Query objects
- Delete objects
- Copy objects

6.1.2.1.8.2. Determine whether an object exists

This topic describes how to determine whether an object exists.

The following code provides an example on how to determine whether an object exists:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Determine whether the object exists. doesObjectExist includes the isOnlyInOSS parameter.
If the value of isOnlyInOSS is true, OSS does not perform redirection back-to-origin or mirroring back-to-origin when the object does not exist.
If the value of isOnlyInOSS is false, OSS performs redirection back-to-origin or mirroring back-to-origin when the object does not exist.
boolean found = ossClient.doesObjectExist("<yourBucketName>", "<yourObjectName>");
System.out.println(found);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.8.3. Manage object ACLs

This topic describes how to manage the access control list (ACL) of an object.

The following table describes the ACLs that can be configured for objects.

ACL	Description	Value
Inherited from bucket	The ACL of an object is the same as that of the bucket in which the object is stored.	CannedAccessControlList.Default
Private	Only the owner or authorized users of the bucket can read and write the object.	CannedAccessControlList.Private
Public read	Only the owner or authorized users of this bucket can write the object. Other users, including anonymous users can only read the object. Exercise caution when you use this ACL.	CannedAccessControlList.PublicRead
Public read/write	Any users, including anonymous users can read and write the object. Exercise caution when you use this ACL.	CannedAccessControlList.PublicReadWrite

The ACL of an object takes precedence over the ACL of the bucket in which the object is stored. For example, the ACL of a bucket is private, while the ACL of the object that is stored in this bucket is public. All users can read and write the object. If an object does not have a configured ACL, the object will inherit the ACL of the bucket in which the object is stored.

Configure ACL for an object

The following code provides an example on how to configure ACL for an object:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Configure the ACL of the specified object to public read.
ossClient.setObjectAcl("<yourBucketName>", "<yourObjectName>", CannedAccessControlList.PublicRead);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Query the ACL of an object

The following code provides an example on how to query the ACL of a specified object:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
// Query the ACL of an object.
ObjectAcl objectAcl = ossClient.getObjectAcl("<yourBucketName>", "<yourObjectName>");
System.out.println(objectAcl.getPermission().toString());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.8.4. Manage object metadata

Object metadata contains HTTP headers and user metadata.

Configure object metadata

- Configure HTTP headers

  The following code provides an example on how to configure HTTP headers:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String content = "Hello OSS";
// Create object metadata. You can configure HTTP headers by using object metadata.
ObjectMetadata meta = new ObjectMetadata();
String md5 = BinaryUtil.toBase64String(BinaryUtil.calculateMd5(content.getBytes()));
// Enable MD5 verification. After MD5 verification is enabled, OSS calculates the actual
MD5 hash and compares this MD5 hash wih that provided in the request. If the two values a
re different, an error occurs.
meta.setContentMD5(md5);
// Specify the type of content you want to upload. The browser determines the format and
encoding type used to read the object based on the content type of the object. If the con
tent type is not specified, a content type is generated based on the object name extensio
n. If no extension is available, default value application/octet-stream is used as the co
ntent type.
meta.setContentType("text/plain");
// Specify the name for the object when the content is downloaded.
meta.setContentDisposition("attachment; filename=\"DownloadFilename\"");
// Specify the length of the object content to upload. If the actual object length is gre
ater than the specified length, the object is uploaded based on the specified length. If
the object is smaller than the specified length, the object is uploaded based on the actu
al length.
meta.setContentLength(content.length());
// Specify the caching behavior of the website when the content is downloaded.
meta.setCacheControl("Download Action");
// Specify the expiration time of the cache in the GMT.
meta.setExpirationTime(DateUtil.parseIso8601Date("2022-10-12T00:00:00.000Z"));
// Specify the content encoding format when the content is downloaded.
meta.setContentEncoding("utf-8");
// Configure the header.
meta.setHeader("<yourHeader>", "<yourHeaderValue>");
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Upload the object.
ossClient.putObject("<yourBucketName>", "<yourObjectName>", new ByteArrayInputStream(cont
ent.getBytes()), meta);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

For more information about HTTP headers, visit RFC 2616.

- Configure user metadata

  You can configure the user metadata of an object to describe the object.

  The following code provides an example on how to configure the user metadata of an object:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Security risks may arise if you use the AccessKey pair of an Alibaba Cloud account to
log on to OSS because the account has permissions on all API operations. We recommend tha
t you use a RAM user to call API operations or perform routine operations and maintenance
. To create a RAM user, log on to https://ram.console.aliyun.com.
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String content = "Hello OSS";
// Create an OSSClient instance.
OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
// Create object metadata.
ObjectMetadata meta = new ObjectMetadata();
// Set the value of the property parameter for the user metadata to property-value. We re
commend that you use the Base64 encoding method.
meta.addUserMetadata("property", "property-value");
// Upload the object.
ossClient.putObject("<yourBucketName>", "<yourObjectName>", new ByteArrayInputStream(cont
ent.getBytes()), meta);
// Query the object metadata.
ossClient.getObjectMetadata("<yourBucketName>", "<yourObjectName>");
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Object metadata is downloaded with the object. An object may contain multiple pieces of object metadata. The total size of the object metadata cannot exceed 8 KB.

Modify object metadata

The following code provides an example on how to modify object metadata:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String sourceBucketName = "<yourSourceBucketName>";
String sourceObjectName = "<yourSourceObjectName>";
String destinationBucketName = "<yourDestinationBucketName>";
String destinationObjectName = "<yourDestinationObjectName>";
// Create an OSSClient instance.
OSSClient ossClient = new OSSClient(endpoint, accessKeyId,accessKeySecret);
// Replace the source object with the target object. Call ossClient.copyObject to modify object metadata.
CopyObjectRequest request = new CopyObjectRequest(sourceBucketName, sourceObjectName, destinationBucketName, destinationObjectName);
ObjectMetadata meta = new ObjectMetadata();
// Specify the type of content you want to upload. The browser determines the format and encoding type used to read the object based on the content type of the object. If the content type is not specified, a content type is generated based on the object name extension. If no extension is available, the default value application/octet-stream is used as the content type.
meta.setContentType("text/plain");
// Specify the name for the object when the content is downloaded.
meta.setContentDisposition("Download File Name");
// Specify the caching behavior of the website when the content is downloaded.
meta.setCacheControl("Download Action");
// Specify the expiration time of the cache in the GMT.
meta.setExpirationTime(DateUtil.parseIso8601Date("2022-10-12T00:00:00.000Z"));
// Specify the content encoding format when the content is downloaded.
meta.setContentEncoding("utf-8");
// Configure the header.
meta.setHeader("<yourHeader>", "<yourHeaderValue>");
// Set the value of the property parameter for the user metadata to property-value.
meta.addUserMetadata("property", "property-value");
request.setNewObjectMetadata(meta);
// Modified the object metadata.
ossClient.copyObject(request);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Query object metadata

The following table lists the methods you can use to query object metadata.

Configuration method	Description	Benefits
ossClient.getSimplifiedObjectMeta	Queries part of object metadata such as the ETag, Size, and LastModified (the last modified time) values of the object.	More lightweight and faster
ossClient.getObjectMetadata	Queries all object metadata	None

The following code provides an example on how to query the object metadata:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
// Create an OSSClient instance.
OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
// Query parts of the object metadata.
SimplifiedObjectMeta objectMeta = ossClient.getSimplifiedObjectMeta("<yourBucketName>", "<yourObjectName>");
System.out.println(objectMeta.getSize());
System.out.println(objectMeta.getETag());
System.out.println(objectMeta.getLastModified());
// Query all object metadata.
ObjectMetadata metadata = ossClient.getObjectMetadata("<yourBucketName>", "<yourObjectName>");
System.out.println(metadata.getContentType());
System.out.println(metadata.getLastModified());
System.out.println(metadata.getExpirationTime());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.8.5. List objects

Objects in a bucket are sorted alphabetically. You can use ossClient.listObjects to list objects in a bucket.

listObjects supports the following types of parameter formats:

- ObjectListing listObjects(String bucketName): lists objects in a bucket. A maximum of 100 objects can be listed.
- ObjectListing listObjects(String bucketName, String prefix): lists objects whose names contain a specified prefix in a bucket. A maximum of 100 objects can be listed.
- ObjectListing listObjects(ListObjectsRequest listObjectsRequest): provides multiple filtering features to implement flexible queries.

The following table describes parameters you can configure for ObjectListing.

Parameter	Description	Configuration method
objectSummaries	Specifies the object metadata you want to return.	List<OSSObjectSummary> getObjectSummaries()
prefix	Specifies the prefix that the returned object names must contain.	String getPrefix()
delimiter	Specifies the character used to group objects by name.	String getDelimiter()

Parameter	Description	Configuration method
marker	Specifies the name of the object after which the list begins.	String getMarker()
maxKeys	Specifies the maximum number of objects that can be listed each time.	int getMaxKeys()
nextMarker	Specifies the name of the object after which the next list begins.	String getNextMarker()
isTruncated	Indicates whether the objects list is truncated. • If all objects are listed, the returned value of this parameter is false. • If only part of objects are listed, the returned value of this parameter is true.	boolean isTruncated()
commonPrefixes	Specifies a set of substrings of object names. Objects whose names contain the same string from the prefix and the next occurrence of the delimiter are grouped as a single result element in commonPrefixes.	List<String> getCommonPrefixes()
encodingType	Specifies the encoding type of the object names in the response.	String getEncodingType()

Simple list

The following code provides an example on how to list objects in a specified bucket. By default, a maximum of 100 objects can be listed.

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String KeyPrefix = "<yourKeyPrefix>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// List objects. If you do not set KeyPrifex, all objects in the bucket are listed. If you set KeyPrifex, objects whose names contain the specified prefix in the bucket are listed.
ObjectListing objectListing = ossClient.listObjects(bucketName, KeyPrefix);
List<OSSObjectSummary> sums = objectListing.getObjectSummaries();
for (OSSObjectSummary s : sums) {
    System.out.println("\t" + s.getKey());
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

List objects by using ListObjectsRequest

You can configure parameters of ListObjectsRequest to implement flexible queries. The following table describes the parameters you can configure for ListObjectsRequest.

Parameter	Description	Configuration method
prefix	Specifies the prefix that returned object names must contain.	setPrefix(String prefix)
delimiter	Specifies the character used to group objects by name. Objects whose names contain the same string from the prefix and the next occurrence of the delimiter are grouped as a single result element in commonPrefixes.	setDelimiter(String delimiter)
marker	Specifies the name of the object after which the list begins.	setMarker(String marker)
maxKeys	Specifies the maximum number of objects that can be listed each time. The default value is 100. The maximum value is 1000.	setMaxKeys(Integer maxKeys)
encodingType	Specifies the encoding type of the object names in the response. Only URL encoding is supported.	setEncodingType(String encodingType)

- List a specified number of objects

  The following code provides an example on how to list a specified number of objects:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Specifies the maximum number of objects that can be listed each time.
final int maxKeys = 200;
// List objects.
ObjectListing objectListing = ossClient.listObjects(new ListObjectsRequest(bucketName).wi
thMaxKeys(maxKeys));
List<OSSObjectSummary> sums = objectListing.getObjectSummaries();
for (OSSObjectSummary s : sums) {
    System.out.println("\t" + s.getKey());
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- List objects whose names contain a specified prefix

  The following code provides an example on how to list objects whose names contain a specified prefix:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Specify a prefix.
final String keyPrefix = "<yourkeyPrefix>";
// List the objects whose names contain the specified prefix. By default, a maximum of 10
0 objects can be listed.
ObjectListing objectListing = ossClient.listObjects(new ListObjectsRequest(bucketName).wi
thPrefix(keyPrefix));
List<OSSObjectSummary> sums = objectListing.getObjectSummaries();
for (OSSObjectSummary s : sums) {
    System.out.println("\t" + s.getKey());
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- List objects whose names come after a specified marker

  The marker parameter specifies the name of the object after which the list begins. The following code provides an example on how to list objects whose names come after a specified marker:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
final String marker = "<yourMarker>";
// List the objects whose names come after the specified marker. By default, a maximum of
100 objects can be listed.
ObjectListing objectListing = ossClient.listObjects(new ListObjectsRequest(bucketName).wi
thMarker(marker));
List<OSSObjectSummary> sums = objectListing.getObjectSummaries();
for (OSSObjectSummary s : sums) {
    System.out.println("\t" + s.getKey());
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- List all objects by page

  The following code provides an example on how to list all objects in a specified bucket by page. The maximum number of objects that can be listed on each page is specified by maxKeys.

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
final int maxKeys = 200;
String nextMarker = null;
ObjectListing objectListing;
do {
    objectListing = ossClient.listObjects(new ListObjectsRequest(bucketName).withMarker(n
extMarker).withMaxKeys(maxKeys));
    List<OSSObjectSummary> sums = objectListing.getObjectSummaries();
    for (OSSObjectSummary s : sums) {
        System.out.println("\t" + s.getKey());
    }
    nextMarker = objectListing.getNextMarker();
} while (objectListing.isTruncated());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- List objects whose names contain a specified prefix by page

  The following code provides an example on how to list objects whose names contain a specified prefix by page:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Specify that the maximum number of objects that can be listed on each page is 200.
final int maxKeys = 200;
final String keyPrefix = "<yourkeyPrefix>";
String nextMarker = "<yourNextMarker>";
ObjectListing objectListing;
do {
    objectListing = ossClient.listObjects(new ListObjectsRequest(bucketName).
            withPrefix(keyPrefix).withMarker(nextMarker).withMaxKeys(maxKeys));
    List<OSSObjectSummary> sums = objectListing.getObjectSummaries();
    for (OSSObjectSummary s : sums) {
        System.out.println("\t" + s.getKey());
    }
    nextMarker = objectListing.getNextMarker();
} while (objectListing.isTruncated());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- List objects and specify the encoding type of the object names in the response

  An object name that contains any of the following special characters needs to be encoded before it is transmitted. Only URL encoding is supported.

  - Single quotation mark (')
  - Double quotation mark (")
  - Ampersands (&)
  - Angle brackets (<>)
  - Pause marker (、)
  - Chinese characters

  The following code provides an example on how to list objects and specify the encoding type of the object names in the response:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
final int maxKeys = 200;
final String keyPrefix = "<yourkeyPrefix>";
String nextMarker = "<yourNextMarker>";
ObjectListing objectListing;
do {
    ListObjectsRequest listObjectsRequest = new ListObjectsRequest(bucketName);
    listObjectsRequest.setPrefix(keyPrefix);
    listObjectsRequest.setMaxKeys(maxKeys);
    listObjectsRequest.setMarker(nextMarker);
    // Specify the encoding type of the object names in the response.
    listObjectsRequest.setEncodingType("url");
    objectListing = ossClient.listObjects(listObjectsRequest);
    // Decode the object names.
    for (OSSObjectSummary objectSummary: objectListing.getObjectSummaries()) {
        System.out.println("Key:" + URLDecoder.decode(objectSummary.getKey(), "UTF-8"));
    }
    // Decode the value of commonPrefixes.
    for (String commonPrefixes: objectListing.getCommonPrefixes()) {
        System.out.println("CommonPrefixes:" + URLDecoder.decode(commonPrefixes, "UTF-8")
);
    }
    // Decode the value of nextMarker.
    if (objectListing.getNextMarker() ! = null) {
        nextMarker = URLDecoder.decode(objectListing.getNextMarker(), "UTF-8");
    }
} while (objectListing.isTruncated());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

List objects by folder

OSS does not use a hierarchical structure for objects, but instead uses a flat structure. All elements are stored as objects in buckets. A folder is an object whose size is 0 and whose name ends with a forward slash. You can upload and download this object. By default, the OSS console displays objects whose names end with a forward slash (/) as a folder.

You can use the delimiter and prefix parameters to list objects by folder.

- If prefix is set to the name of a folder, objects and subfolders whose names contain the prefix are listed.
- If you also set delimiter to a forward slash (/) in the request, the objects and subfolders whose names start with the specified prefix in the folder are listed. Each subfolder is listed as a single result element in commonPrefixes. The objects and folders in these subfolders are not listed.

For the complete code used to create a folder, visit GitHub.

Example: A bucket contains the following objects: oss.jpg, fun/test.jpg, fun/movie/001.avi, and fun/movie/007.avi. The forward slash (/) is used as the folder delimiter. The following examples show you how to list objects by folder in a bucket.

- List all objects in a bucket

  The following code provides an example on how to list all objects in a bucket:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Create ListObjectsRequest.
ListObjectsRequest listObjectsRequest = new ListObjectsRequest(bucketName);
// List all objects in the bucket.
ObjectListing listing = ossClient.listObjects(listObjectsRequest);
// Traverse all the objects to display them.
System.out.println("Objects:");
for (OSSObjectSummary objectSummary : listing.getObjectSummaries()) {
    System.out.println(objectSummary.getKey());
}
// Traverse all the commonPrefix elements to display them.
System.out.println("CommonPrefixes:");
for (String commonPrefix : listing.getCommonPrefixes()) {
    System.out.println(commonPrefix);
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

  Example output:

```
Objects:
fun/movie/001.avi
fun/movie/007.avi
fun/test.jpg
oss.jpg
CommonPrefixes:
```

- List all objects in a specified folder

  The following code provides an example on how to list all objects whose names contain a specified prefix:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Create ListObjectsRequest.
ListObjectsRequest listObjectsRequest = new ListObjectsRequest(bucketName);
// Set prefix to fun/ to list all objects in the fun/ folder.
listObjectsRequest.setPrefix("fun/");
// Lists all objects in the fun/ folder.
ObjectListing listing = ossClient.listObjects(listObjectsRequest);
// Traverse the listed objects to display them.
System.out.println("Objects:");
for (OSSObjectSummary objectSummary : listing.getObjectSummaries()) {
    System.out.println(objectSummary.getKey());
}
// Traverse the listed commonPrefix elements to display them.
System.out.println("\nCommonPrefixes:");
for (String commonPrefix : listing.getCommonPrefixes()) {
    System.out.println(commonPrefix);
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Example output:

```
Objects:
fun/movie/001.avi
fun/movie/007.avi
fun/test.jpg
CommonPrefixes:
```

- List the objects and subfolders in a folder

  The following code provides an example on how to list the objects and subfolders in a specified directory:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Create ListObjectsRequest.
ListObjectsRequest listObjectsRequest = new ListObjectsRequest(bucketName);
// Set the delimiter to a forward slash (/).
listObjectsRequest.setDelimiter("/");
// List all objects and subfolders in the fun folder.
listObjectsRequest.setPrefix("fun/");
ObjectListing listing = ossClient.listObjects(listObjectsRequest);
// Traverse all objects to display them.
System.out.println("Objects:");
// In the response, objectSummaries lists the objects in the fun folder.
for (OSSObjectSummary objectSummary : listing.getObjectSummaries()) {
    System.out.println(objectSummary.getKey());
}
// Traverse all commonPrefix elements to display them.
System.out.println("\nCommonPrefixes:");
// commonPrefixs lists the subfolders in the fun folder. The fun/movie/001.avi and fun/mo
vie/007.avi objects are not listed because they are in the movie subfolder of the fun fol
der.
for (String commonPrefix : listing.getCommonPrefixes()) {
    System.out.println(commonPrefix);
}
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Example output:

```
Objects:
fun/test.jpg
CommonPrefixes:
fun/movie/
```

- Query the sizes of objects in a specified folder

  The following code provides an example on how to query the sizes of objects in a specified folder:

```
// Query the total size of objects in the specified folder.
    private static long calculateFolderLength(OSS ossClient, String bucketName, String fo
lder) {
        long size = 0L;
        ObjectListing objectListing = null;
        do {
              // The default value of MaxKeys is 100. The maximum value of MaxKeys is 100
0.
            ListObjectsRequest request = new ListObjectsRequest(bucketName).withPrefix(fo
lder).withMaxKeys(1000);
```

```
            if (objectListing ! = null) {
                request.setMarker(objectListing.getNextMarker());
            }
            objectListing = ossClient.listObjects(request);
            List<OSSObjectSummary> sums = objectListing.getObjectSummaries();
            for (OSSObjectSummary s : sums) {
                size += s.getSize();
            }
        } while (objectListing.isTruncated());
        return size;
    }
    public void Calculate() {
        // The endpoint of the China (Hangzhou) region is used in this example. Specify t
he actual endpoint.
        String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
        String accessKeyId = "<yourAccessKeyId>";
        String accessKeySecret = "<yourAccessKeySecret>";
        String bucketName = "<yourBucketName>";
        // Create an OSSClient instance.
        OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecr
et);
        // Specify the prefix. If you want to traverse the sizes of objects in the root f
older, leave this parameter empty.
        final String keyPrefix = "<YourPrefix>";
        ObjectListing objectListing = null;
        do {
            // By default, a maximum of 100 objects can be listed each time.
            ListObjectsRequest request = new ListObjectsRequest(bucketName).withDelimiter
("/").withPrefix(keyPrefix);
            if (objectListing ! = null) {
                request.setMarker(objectListing.getNextMarker());
            }
            objectListing = ossClient.listObjects(request);
            List<String> folders = objectListing.getCommonPrefixes();
            for (String folder : folders) {
                System.out.println(folder + " : " + (calculateFolderLength(ossClient, buc
ketName, folder) / 1024) + "KB");
            }
            List<OSSObjectSummary> sums = objectListing.getObjectSummaries();
            for (OSSObjectSummary s : sums) {
                System.out.println(s.getKey() + " : " + (s.getSize() / 1024) + "KB");
            }
        } while (objectListing.isTruncated());
        ossClient.shutdown();
    }
```

6.1.2.1.8.6. Query objects

This topic describes how to call SelectObject to query CSV and JSON objects by using OSS SDK for Java.

The following code provides an example on how to query CSV and JSON objects:

```
package samples;
import com.aliyun.oss.model.*;
```

```
import com.aliyun.oss.OSS;
import com.aliyun.oss.OSSClientBuilder;
import java.io.BufferedReader;
import java.io.ByteArrayInputStream;
import java.io.InputStreamReader;
/**
 * Examples of create select object metadata and select object.
 *
 */
public class SelectObjectSample {
    private static String endpoint = "<endpoint, http://oss-cn-hangzhou.aliyuncs.com>";
    private static String accessKeyId = "<yourAccessKeyId>";
    private static String accessKeySecret = "<yourAccessKeySecret>";
    private static String bucketName = "<yourBucketName>";
    public static void main(String[] args) throws Exception {
        OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret
);
        selectCsvSample("test.csv", ossClient);
        selectJsonSample("test.json", ossClient);
        ossClient.shutdown();
    }
    private static void selectCsvSample(String key, OSS ossClient) throws Exception {
        String content = "name,school,company,age\r\n" +
                "Lora Francis,School A,Staples Inc,27\r\n" +
                "Eleanor Little,School B,\"Conectiv, Inc\",43\r\n" +
                "Rosie Hughes,School C,Western Gas Resources Inc,44\r\n" +
                "Lawrence Ross,School D,MetLife Inc.,24";
        ossClient.putObject(bucketName, key, new ByteArrayInputStream(content.getBytes()));
        SelectObjectMetadata selectObjectMetadata = ossClient.createSelectObjectMetadata(
                new CreateSelectObjectMetadataRequest(bucketName, key)
                        .withInputSerialization(
                                new InputSerialization().withCsvInputFormat(
                                        new CSVFormat().withHeaderInfo(CSVFormat.Header.Use
).withRecordDelimiter("\r\n"))));
        System.out.println(selectObjectMetadata.getCsvObjectMetadata().getTotalLines());
        System.out.println(selectObjectMetadata.getCsvObjectMetadata().getSplits());
        SelectObjectRequest selectObjectRequest =
                new SelectObjectRequest(bucketName, key)
                        .withInputSerialization(
                                new InputSerialization().withCsvInputFormat(
                                        new CSVFormat().withHeaderInfo(CSVFormat.Header.Use
).withRecordDelimiter("\r\n")))
                        .withOutputSerialization(new OutputSerialization().withCsvOutputFor
mat(new CSVFormat()));
        selectObjectRequest.setExpression("select * from ossobject where _4 > 40");
        OSSObject ossObject = ossClient.selectObject(selectObjectRequest);
        // read object content from ossObject
        BufferedReader reader = new BufferedReader(new InputStreamReader(ossObject.getObjec
tContent()));
        while (true) {
            String line = reader.readLine();
            if (line == null) {
                break;
            }
```

```
            System.out.println(line);
        }
        reader.close();
        ossClient.deleteObject(bucketName, key);
    }
    private static void selectJsonSample(String key, OSS ossClient) throws Exception {
        final String content = "{\n" +
                "\t\"name\": \"Lora Francis\",\n" +
                "\t\"age\": 27,\n" +
                "\t\"company\": \"Staples Inc\"\n" +
                "}\n" +
                "{\n" +
                "\t\"name\": \"Eleanor Little\",\n" +
                "\t\"age\": 43,\n" +
                "\t\"company\": \"Conectiv, Inc\"\n" +
                "}\n" +
                "{\n" +
                "\t\"name\": \"Rosie Hughes\",\n" +
                "\t\"age\": 44,\n" +
                "\t\"company\": \"Western Gas Resources Inc\"\n" +
                "}\n" +
                "{\n" +
                "\t\"name\": \"Lawrence Ross\",\n" +
                "\t\"age\": 24,\n" +
                "\t\"company\": \"MetLife Inc.\"\n" +
                "}";
        ossClient.putObject(bucketName, key, new ByteArrayInputStream(content.getBytes()));
        SelectObjectRequest selectObjectRequest =
                new SelectObjectRequest(bucketName, key)
                        .withInputSerialization(new InputSerialization()
                                .withCompressionType(CompressionType.NONE)
                                .withJsonInputFormat(new JsonFormat().withJsonType(JsonType
.LINES)))
                        .withOutputSerialization(new OutputSerialization()
                                .withCrcEnabled(true)
                                .withJsonOutputFormat(new JsonFormat()))
                        .withExpression("select * from ossobject as s where s.age > 40");
        OSSObject ossObject = ossClient.selectObject(selectObjectRequest);
        // read object content from ossObject
        BufferedReader reader = new BufferedReader(new InputStreamReader(ossObject.getObjec
tContent()));
        while (true) {
            String line = reader.readLine();
            if (line == null) {
                break;
            }
            System.out.println(line);
        }
        reader.close();
        ossClient.deleteObject(bucketName, key);
    }
}
```

6.1.2.1.8.7. Delete objects

This topic describes how to delete objects.

Warning Deleted objects cannot be recovered. Exercise caution when you delete objects.

Delete a single object

The following code provides an example on how to delete a single object:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Delete the object. To delete a folder, set ObjectName to the folder name. If the folder is not empty, you must delete all objects in the folder before you can delete the folder.
ossClient.deleteObject(bucketName, objectName);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Delete multiple objects

A maximum of 1,000 objects can be deleted each time. The deletion results can be returned in the following two modes:

- Verbose: returns a list of deleted objects. The default mode is Verbose.
- quiet: returns a list of objects you failed to delete.

The following table describes the parameters for DeleteObjectsRequest.

Parameter	Description	Configuration method
Keys	Specifies the objects you want to delete.	setKeys(List<String>)
quiet	Specifies the return mode. true indicates quiet. false indicates Verbose. Default value: false.	setQuiet(boolean)
encodingType	Specifies the encoding type of the object name in the response. Only URL encoding is supported.	setEncodingType(String)

The following table describes the parameters you can configure for DeleteObjectsResult.

Parameter	Description	Configuration method
deletedObjects	Indicates the results of the operation. The list of deleted objects is returned when the Verbose mode is used. The list of objects that fail to be deleted is returned when the quiet mode is used.	List<String> getDeletedObjects()
encodingType	Indicates the method for encoding the objects names listed in deletedObjects. When the parameter is empty, the object names are not encoded.	getEncodingType()

The following code provides an example on how to delete multiple objects at a time:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Delete the objects. key is equivalent to ObjectName, which indicates the complete path of the object you want to delete from OSS, and must include the extension of the object name. Example: abc/efg/123.jpg.
List<String> keys = new ArrayList<String>();
keys.add("key0");
keys.add("key1");
keys.add("key2");
DeleteObjectsResult deleteObjectsResult = ossClient.deleteObjects(new DeleteObjectsRequest(bucketName).withKeys(keys));
List<String> deletedObjects = deleteObjectsResult.getDeletedObjects();
// Shut down the OSSClient instance.
ossClient.shutdown();
```

For the complete code used to delete multiple objects, visit GitHub.

Delete objects whose names contain a specified prefix

The following code provides an example on how to delete objects whose names contain a specified prefix:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
// Specify the prefix.
final String prefix = "<yourkeyPrefix>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// List all objects whose names contain the specified prefix and delete the objects.
String nextMarker = null;
ObjectListing objectListing = null;
do {
    ListObjectsRequest listObjectsRequest = new ListObjectsRequest(bucketName)
            .withPrefix(prefix)
            .withMarker(nextMarker);
    objectListing = ossClient.listObjects(listObjectsRequest);
    if (objectListing.getObjectSummaries().size() > 0) {
        List<String> keys = new ArrayList<String>();
        for (OSSObjectSummary s : objectListing.getObjectSummaries()) {
            System.out.println("key name: " + s.getKey());
            keys.add(s.getKey());
        }
        DeleteObjectsRequest deleteObjectsRequest = new DeleteObjectsRequest(bucketName).wi
thKeys(keys);
        ossClient.deleteObjects(deleteObjectsRequest);
    }
    nextMarker = objectListing.getNextMarker();
} while (objectListing.isTruncated());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.8.8. Copy objects

This topic describes how to copy a small object and a large object.

Copy a small object

You can use ossClient.copyObject to copy an object that is up to 1 GB in size from a source bucket to another destination bucket within the same region. The following table describes the configuration methods of ossClient.copyObject.

Configuration method	Description
CopyObjectResult copyObject(String sourceBucketName, String sourceKey, String destinationBucketName, String destinationKey)	Allows you to specify the source bucket, source object, destination bucket, and destination object. After an object is copied, the content and metadata of the destination object are the same as that of the source object. This method is called simple copy.

Configuration method	Description
CopyObjectResult copyObject(CopyObjectRequest copyObjectRequest)	Allows you to specify metadata of the destination object and copy conditions. If the URLs of the source object and destination object for the copy operation are the same, the metadata of the source object replaces the metadata of the destination object.

The following table describes the parameters you can configure for CopyObjectRequest.

Parameter	Description	Configuration method
sourceBucketName	The name of the source bucket.	setSourceBucketName(String sourceBucketName)
sourceKey	The name of the source object.	setSourceKey(String sourceKey)
destinationBucketName	The name of the destination bucket.	setDestinationBucketName(String destinationBucketName)
destinationKey	The name of the destination object.	setDestinationKey(String destinationKey)
newObjectMetadata	The metadata of the destination object.	setNewObjectMetadata(ObjectMetadata newObjectMetadata)
matchingETagConstraints	The condition for the copy operation. If the ETag value of the source object is the same as the ETag value provided by the user, the copy operation is performed. Otherwise, an error is returned.	setMatchingETagConstraints(List<String> matchingETagConstraints)
nonmatchingEtagConstraints	The condition for the copy operation. If the ETag value of the source object is different from the ETag value provided by the user, the copy operation is performed. Otherwise, an error is returned.	setNonmatchingETagConstraints(List<String> nonmatchingEtagConstraints)
unmodifiedSinceConstraint	The condition for the copy operation. If the specified time is equal to or later than the actual modified time of the source object, the copy operation is performed. Otherwise, an error is returned.	setUnmodifiedSinceConstraint(Date unmodifiedSinceConstraint)

Parameter	Description	Configuration method
modifiedSinceConstraint	The condition for the copy operation. If the source object is modified after the specified time, the copy operation is performed. Otherwise, an error is returned.	setModifiedSinceConstraint(Date modifiedSinceConstraint)

The following table describes the parameters for CopyObjectRequest.

Parameter	Description	Configuration method
etag	The unique tag of the object.	String getETag()
lastModified	The last modified time of the object.	Date getLastModified()

Note This operation has the following limits:

- You must have read and write permissions on the source object.
- You cannot copy an object from a region to another region.
- The size of the object you want to copy cannot exceed 1 GB.

The following methods can be used to copy small objects.

- Simple copy

  The following code provides an example on how to perform simple copy:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String sourceBucketName = "<yourSourceBucketName>";
String sourceObjectName = "<yourSourceObjectName>";
String destinationBucketName = "<yourDestinationBucketName>";
String destinationObjectName = "<yourDestinationObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Copy the object.
CopyObjectResult result = ossClient.copyObject(sourceBucketName, sourceObjectName, destin
ationBucketName, destinationObjectName);
System.out.println("ETag: " + result.getETag() + " LastModified: " + result.getLastModifi
ed());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- Use CopyObjectRequest to copy an object

  The following code provides an example on how to copy an object by using CopyObjectRequest:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String sourceBucketName = "<yourSourceBucketName>";
String sourceObjectName = "<yourSourceObjectName>";
String destinationBucketName = "<yourDestinationBucketName>";
String destinationObjectName = "<yourDestinationObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Create a CopyObjectRequest object.
CopyObjectRequest copyObjectRequest = new CopyObjectRequest(sourceBucketName, sourceObjec
tName, destinationBucketName, destinationObjectName);
// Configure new object metadata.
ObjectMetadata meta = new ObjectMetadata();
meta.setContentType("text/html");
copyObjectRequest.setNewObjectMetadata(meta);
// Copy the object.
CopyObjectResult result = ossClient.copyObject(copyObjectRequest);
System.out.println("ETag: " + result.getETag() + " LastModified: " + result.getLastModifi
ed());
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Copy a large object

To copy an object larger than 1 GB, you must use multipart copy. To implement multipart copy, perform the following operations:

1. Use ossClient.initiateMultipartUpload to initiate a multipart copy task.
2. Use ossClient.uploadPartCopy to perform the multipart copy task. All parts except for the last part must be larger than 100 KB.
3. Use ossClient.completeMultipartUpload to complete the multipart copy task.

For the complete code that is used to perform multipart copy, visit GitHub.

The following code provides an example on how to perform multipart copy:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String sourceBucketName = "<yourSourceBucketName>";
String sourceObjectName = "<yourSourceObjectName>";
String destinationBucketName = "<yourDestinationBucketName>";
String destinationObjectName = "<yourDestinationObjectName>";
ObjectMetadata objectMetadata = ossClient.getObjectMetadata(sourceBucketName, sourceObjectN
ame);
// Query the size of the object to copy.
long contentLength = objectMetadata.getContentLength();
// Set the size of each part to 10 MB.
long partSize = 1024 * 1024 * 10;
```

```
long partSize = 1024 * 1024 * 10;
// Calculate the total number of parts.
int partCount = (int) (contentLength / partSize);
if (contentLength % partSize ! = 0) {
    partCount++;
}
System.out.println("total part count:" + partCount);
// Initiate a multipart copy task. You can call the InitiateMultipartUploadRequest operation to specify the metadata of the target object.
InitiateMultipartUploadRequest initiateMultipartUploadRequest = new InitiateMultipartUploadRequest(destinationBucketName, destinationObjectName);
InitiateMultipartUploadResult initiateMultipartUploadResult = ossClient.initiateMultipartUpload(initiateMultipartUploadRequest);
String uploadId = initiateMultipartUploadResult.getUploadId();
// Start the multipart copy task.
List<PartETag> partETags = new ArrayList<PartETag>();
for (int i = 0; i < partCount; i++) {
     // Calculate the size of each part.
    long skipBytes = partSize * i;
    long size = partSize < contentLength - skipBytes ? partSize : contentLength - skipBytes;
    // Create an UploadPartCopyRequest object. You can call the UploadPartCopyRequest operation to specify conditions.
    UploadPartCopyRequest uploadPartCopyRequest =
        new UploadPartCopyRequest(sourceBucketName, sourceObjectName, destinationBucketName, destinationObjectName);
    uploadPartCopyRequest.setUploadId(uploadId);
    uploadPartCopyRequest.setPartSize(size);
    uploadPartCopyRequest.setBeginIndex(skipBytes);
    uploadPartCopyRequest.setPartNumber(i + 1);
    UploadPartCopyResult uploadPartCopyResult = ossClient.uploadPartCopy(uploadPartCopyRequest);
    // Store the returned part ETag in partETags.
    partETags.add(uploadPartCopyResult.getPartETag());
}
// Complete the multipart copy task.
CompleteMultipartUploadRequest completeMultipartUploadRequest = new CompleteMultipartUploadRequest(
                    destinationBucketName, destinationObjectName, uploadId, partETags);
ossClient.completeMultipartUpload(completeMultipartUploadRequest);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.9. Authorized access

This topic describes how to use Security Token Service (STS) and a signed URL to authorize access.

Use STS to authorize temporary access

Alibaba Cloud Security Token Service (STS) is a web service that provides a temporary access token to a cloud computing user. You can use STS to grant a third-party application or your RAM user an access credential with a customized validity period and permissions.

STS has the following benefits:

- You need only to generate an access token and send the access token to a third-party application, instead of exposing your long-term AccessKey pair to the third-party application. You can customize the access permissions and validity period of this token.
- The access token automatically expires when the validity period ends.

The following code provides an example on how to create a signature request by using STS:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String securityToken = "<yourSecurityToken>";
// After you obtain a temporary STS credential for your OSSClient, an OSSClient instance is created based on the security token and temporary AccessKey pair (AccessKey ID and AccessKey secret) contained in the credential.
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret, securityToken);
// Perform an operation in OSS. For example, you can upload or download an object.
// Upload an object to OSS.
// ossClient.putObject(putObjectRequest);
// Download an object to a local file. If the name of the object is the same as that of the local file, the object replaces the local file. If the name of the object is different from that of the local file, the object is downloaded.
// ossClient.getObject(new GetObjectRequest(bucketName, objectName), new File("<yourLocalFile>"));
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Use a signed URL to authorize temporary access

- Generate a signed URL

  You can generate a signed URL and provide it to a visitor to grant temporary access. When you generate a signed URL, you can specify the validity period of the URL to restrict the period of access from visitors.

- Generate a signed URL to allow HTTP GET requests

  The following code provides an example on how to generate a signed URL to allow HTTP GET requests:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Set the validity period of the URL to one hour.
Date expiration = new Date(new Date().getTime() + 3600 * 1000);
// Generate a signed URL to allow HTTP GET requests. Visitors can use a browser for acces
s.
URL url = ossClient.generatePresignedUrl(bucketName, objectName, expiration);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- Generate a signed URL to allow other HTTP methods

  If you want to allow visitors to temporarily perform other operations such as uploading or deleting objects, you must generate a corresponding signed URL. The following code provides an example on how to upload an object by using a signed URL to allow HTTP PUT requests:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String securityToken = "<yourSecurityToken>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// After you obtain a temporary STS credential for your OSSClient, an OSSClient instance
is created based on the security token and temporary AccessKey pair (AccessKey ID and Acc
essKey secret) contained in the credential.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret, secu
rityToken);
GeneratePresignedUrlRequest request = new GeneratePresignedUrlRequest(bucketName, objectN
ame, HttpMethod.PUT);
// Set the validity period of the URL to one hour.
Date expiration = new Date(new Date().getTime() + 3600 * 1000);
request.setExpiration(expiration);
// Set ContentType.
request.setContentType(DEFAULT_OBJECT_CONTENT_TYPE);
// Set user metadata.
request.addUserMetadata("author", "aliy");
// Generate a signed URL to allow HTTP PUT requests.
URL signedUrl = ossClient.generatePresignedUrl(request);
Map<String, String> requestHeaders = new HashMap<String, String>();
requestHeaders.put(HttpHeaders.CONTENT_TYPE, DEFAULT_OBJECT_CONTENT_TYPE);
requestHeaders.put(OSS_USER_METADATA_PREFIX + "author", "aliy");
// Use the signed URL to upload an object.
ossClient.putObject(signedUrl, new ByteArrayInputStream("Hello OSS".getBytes()), -1, requ
estHeaders, true);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

Visitors can specify the HttpMethod.PUT parameter and use the signed URL to upload objects.

- Generate a signed URL with specified parameters

  The following code provides an example on how to generate a signed URL with specified parameters:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Create a request.
GeneratePresignedUrlRequest generatePresignedUrlRequest = new GeneratePresignedUrlRequest
(bucketName, objectName);
// Set HttpMethod to PUT.
generatePresignedUrlRequest.setMethod(HttpMethod.PUT);
// Add user metadata.
generatePresignedUrlRequest.addUserMetadata("author", "baymax");
// Set Content-Type.
generatePresignedUrlRequest.setContentType("application/octet-stream");
// Set the validity period of the URL to one hour.
Date expiration = new Date(new Date().getTime() + 3600 * 1000);
generatePresignedUrlRequest.setExpiration(expiration);
// Generate a signed URL.
URL url = ossClient.generatePresignedUrl(generatePresignedUrlRequest);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- Use a signed URL to upload or download an object

- Use a signed URL to download an object

  The following code provides an example on how to download a specified object by using a signed URL:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the act
ual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
Date expiration = DateUtil.parseRfc822Date("Wed, 18 Mar 2022 14:20:00 GMT");
GeneratePresignedUrlRequest request = new GeneratePresignedUrlRequest(bucketName, objec
tName, HttpMethod.GET);
// Set the validity period.
request.setExpiration(expiration);
// Generate a signed URL to allow HTTP GET requests.
URL signedUrl = ossClient .generatePresignedUrl(request);
System.out.println("signed url for getObject: " + signedUrl);
// Use the signed URL to send a request.
Map<String, String> customHeaders = new HashMap<String, String>();
// Specify the request headers of GetObject.
customHeaders.put("Range", "bytes=100-1000");
OSSObject object = ossClient.getObject(signedUrl,customHeaders);
// Shut down the OSSClient instance.
ossClient.shutdown();
```

- Use a signed URL to upload an object

  The following code provides an example on how to upload an object by using a signed URL:

```
// The endpoint of the China (Hangzhou) region is used in this example. Specify the act
ual endpoint.
String endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
String accessKeyId = "<yourAccessKeyId>";
String accessKeySecret = "<yourAccessKeySecret>";
String bucketName = "<yourBucketName>";
String objectName = "<yourObjectName>";
// Create an OSSClient instance.
OSS ossClient = new OSSClientBuilder().build(endpoint, accessKeyId, accessKeySecret);
// Generate a signed URL.
Date expiration = DateUtil.parseRfc822Date("Thu, 19 Mar 2019 18:00:00 GMT");
GeneratePresignedUrlRequest request = new GeneratePresignedUrlRequest(bucketName, objec
tName, HttpMethod.PUT);
// Set the validity period.
request.setExpiration(expiration);
// Set Content-Type.
request.setContentType("application/octet-stream");
// Add user metadata.
request.addUserMetadata("author", "aliy");
// Generate a signed URL to allow HTTP PUT requests.
URL signedUrl = ossClient.generatePresignedUrl(request);
System.out.println("signed url for putObject: " + signedUrl);
// Use the signed URL to send a request.
File f = new File("<yourLocalFile>");
FileInputStream fin = new FileInputStream(f);
// Specify the request headers of PutObject.
Map<String, String> customHeaders = new HashMap<String, String>();
customHeaders.put("Content-Type", "application/octet-stream");
customHeaders.put("x-oss-meta-author", "aliy");
PutObjectResult result = ossClient.putObject(signedUrl, fin, f.length(), customHeaders)
;
// Shut down the OSSClient instance.
ossClient.shutdown();
```

6.1.2.1.10. IMG

OSS Image Processing (IMG) is a secure, cost-effective, and highly reliable image processing service that can process large amounts of data. After you upload source images to OSS, you can call RESTful API operations to process the images anytime, anywhere, and on any Internet device. You can use OSS IMG to build your own image processing service.

Basic features

OSS IMG provides the following features:

- Query image information.
- Convert image formats.
- Resize, crop, and rotate images.
- Apply image effect.
- Add image, text, and text-and-image watermarks to images.

- Customize image processing styles. Log on to the OSS console. Click a bucket name to go to the bucket details page. Click the **Image Processing (IMG)** tab and click **Create Rule** to customize an image processing style.
- Use cascade processing to call multiple IMG features.

Usage

You can use standard `HTTP GET` requests to access IMG. All processing parameters are encoded in the query string of a URL.

- Anonymous access

  If the ACL of an image object is public-read, as described in the following table, anonymous users can access the image object.

Bucket ACL	Object ACL
public-read or public-read-write	default
Any ACL	public-read or public-read-write

  You can anonymously access IMG by using a third-level domain in the following format:

```
http://bucket.<endpoint>/object?x-oss-process=image/action,parame_value
```

Parameter	Description
bucket	The name of the bucket.
endpoint	The domain name used to access the region.
object	The name of the image object.
image	The identifier reserved by IMG.
action	The operations performed on images, such as scaling, cropping, and rotating.
param	The parameters corresponding to the operations performed on the images.

  - Basic operations

    For example, you can scale an image to a width of 100 and adjust the height based on the ratio:

```
http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100
```

- Customize image styles

  You can anonymously access IMG by using a third-level domain in the following format:

  ```
  http://<yourBucketName>.<yourEndpoint>/<yourObjectName>?x-oss-process=style/<yourStyleName>
  ```

  - style: the identifier reserved by IMG for the custom style.
  - yourStyleName: the name of the custom style. The name is specified by the Rule Name parameter when you create the custom style in the console.

  Example:

  ```
  http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=style/oss-pic-style-w-100
  ```

- Cascade processing

  You can use cascade processing to perform multiple operations in sequence on an image by using a URL in the following format:

  ```
  http://<yourBucketName>.<yourEndpoint>/<yourObjectName>?x-oss-process=image/<yourAction1>,<yourParamValue1>/<yourAction2>,<yourParamValue2>/...
  ```

  Example:

  ```
  http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100/rotate,90
  ```

- Access by using HTTPS

  IMG supports access by using HTTPS. Example:

  ```
  https://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100
  ```

- Authorized access

  If the ACL of an image object is private, you must have permissions on the image object before you can perform operations on it.

Bucket ACL	Object ACL
private	default
Any ACL	private

  The following code provides an example on how to generate a signed URL to access IMG:

```
    String endpoint = "<Your OSS endpoint. Example: http://oss-cn-hangzhou.aliyuncs.com>"
;
    String accessKeyId = "<accessKeyId>";
    String accessKeySecret = "<accessKeySecret>";
    String bucketName = "<bucketName>";
    private static String key = "example.jpg";
    OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
    // Configure the IMG style.
    String style = "image/resize,m_fixed,w_100,h_100/rotate,90";
    // Set the validity period to 10 minutes.
    Date expiration = new Date(new Date().getTime() + 1000 * 60 * 10 );
    GeneratePresignedUrlRequest req = new GeneratePresignedUrlRequest(bucketName, key, Ht
tpMethod.GET);
    req.setExpiration(expiration);
    req.setProcess(style);
    URL signedUrl = ossClient.generatePresignedUrl(req);
    System.out.println(signedUrl);
```

> **Note**
> - You can set Create Style, HTTPS, and Cascading Processing for authorized access.
> - Use code in the following format to specify the expiration time: `Date expiration = DateUtil.parseRfc822Date("Wed, 21 Dec 2022 14:20:00 GMT");` .

- Access by using SDKs

  You can use OSS SDKs to access and process image objects of any ACLs.

  > **Note**
  > - For the complete IMG code, visit GitHub.
  > - You can use OSS SDKs to process image objects by configuring Create Style, HTTPS, and Cascading Processing.

  - Basic operations

    The following code provides an example on how to perform basic IMG operations including obtaining image information, converting image formats, resizing, cropping, rotating, watermarking, and applying effects:

```
    String endpoint = "<Your OSS endpoint. Example: http://oss-cn-hangzhou.aliyuncs.com
>";
    String accessKeyId = "<accessKeyId>";
    String accessKeySecret = "<accessKeySecret>";
    String bucketName = "<bucketName>";
    String key = "example.jpg";
    OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
    // Resize the image.
    String style = "image/resize,m_fixed,w_100,h_100";
    GetObjectRequest request = new GetObjectRequest(bucketName, key);
    request.setProcess(style);
    ossClient.getObject(request, new File("example-resize.jpg"));
    // Crop the image.
    style = "image/crop,w_100,h_100,x_100,y_100,r_1";
    request = new GetObjectRequest(bucketName, key);
    request.setProcess(style);
    ossClient.getObject(request, new File("example-crop.jpg"));
    // Rotate the image.
    style = "image/rotate,90";
    request = new GetObjectRequest(bucketName, key);
    request.setProcess(style);
    ossClient.getObject(request, new File("example-rotate.jpg"));
    // Sharpen the image.
    style = "image/sharpen,100";
    request = new GetObjectRequest(bucketName, key);
    request.setProcess(style);
    ossClient.getObject(request, new File("example-sharpen.jpg"));
    // Add watermarks to the image.
    style = "image/watermark,text_SGVsbG8g5Zu-54mH5pyN5YqhIQ";
    request = new GetObjectRequest(bucketName, key);
    request.setProcess(style);
    ossClient.getObject(request, new File("example-watermark.jpg"));
    // Convert the image format.
    style = "image/format,png";
    request = new GetObjectRequest(bucketName, key);
    request.setProcess(style);
    ossClient.getObject(request, new File("example-format.png"));
    // Obtain the image information.
    style = "image/info";
    request = new GetObjectRequest(bucketName, key);
    request.setProcess(style);
    ossClient.getObject(request, new File("example-info.txt"));
    ossClient.shutdown();
```

- Custom image styles

```
    String endpoint = "<Your OSS endpoint. Example: http://oss-cn-hangzhou.aliyuncs.com
>";
    String accessKeyId = "<accessKeyId>";
    String accessKeySecret = "<accessKeySecret>";
    String bucketName = "<bucketName>";
    String key = "example.jpg";
    OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
    // Customize the image style.
    String style = "style/oss-pic-style-w-100";
    GetObjectRequest request = new GetObjectRequest(bucketName, key);
    request.setProcess(style);
    ossClient.getObject(request, new File("example-new.jpg"));
    ossClient.shutdown();
```

- Cascade processing

```
    String endpoint = "<Your OSS endpoint. Example: http://oss-cn-hangzhou.aliyuncs.com
>";
    String accessKeyId = "<accessKeyId>";
    String accessKeySecret = "<accessKeySecret>";
    String bucketName = "<bucketName>";
    private static String key = "example.jpg";
    OSSClient ossClient = new OSSClient(endpoint, accessKeyId, accessKeySecret);
    // Perform cascade processing.
    String style = "image/resize,m_fixed,w_100,h_100/rotate,90";
    GetObjectRequest request = new GetObjectRequest(bucketName, key);
    request.setProcess(style);
    ossClient.getObject(request, new File("example-new.jpg"));
    ossClient.shutdown();
```

6.1.2.1.11. Handle exceptions

If an exception occurs when you call the OSSClient class-related API operation, the related operation fails. Otherwise, the related operation succeeds. If an exception occurs, the data returned by the operation is invalid. OSS SDK for Java exceptions are classified into two types: OSSException and ClientException. Both are subclasses of RuntimeException.

Examples

```
try {
    // Do some operations with the instance here, such as put object...
    client.putObject(...);
} catch (OSSException oe) {
    System.out.println("Caught an OSSException, which means your request made it to OSS, "
            + "but was rejected with an error response for some reason.") ;
    System.out.println("Error Message: " + oe.getErrorCode());
    System.out.println("Error Code:       " + oe.getErrorCode());
    System.out.println("Request ID:      " + oe.getRequestId());
    System.out.println("Host ID:           " + oe.getHostId());
} catch (ClientException ce) {
    System.out.println("Caught an ClientException, which means the client encountered "
            + "a serious internal problem while trying to communicate with OSS, "
            + "such as not being able to access the network.") ;
    System.out.println("Error Message: " + ce.getMessage());
} finally {
    if (client ! = null) {
        client.shutdown();
    }
}
```

ClientException

ClientException indicates the exception that occurs when a client sends a request or transmit data to OSS. For example, ClientException is returned when a request is sent under poor network conditions. ClientException is also returned when an I/O exception occurs during object upload.

OSSException

OSSException indicates an error response from OSS. The error code and error message are returned so that you can find the problem and handle it properly.

OSSException involves the following error information:

- Code: the error code that OSS returns to the user.
- Message: the detailed error message provided by OSS.
- RequestId: the UUID of a request. If the problem persists, you can seek help from OSS development engineers and provide them with the request ID.
- HostId: the ID of a host to identify the accessed OSS cluster, which is the same as the host ID specified in the request.

Error codes

Error code	Error message	HTTP status code
AccessDenied	The error message returned because the access is denied.	403
BucketAlreadyExists	The error message returned because the bucket already exists.	409
BucketNotEmpty	The error message returned because the bucket is not empty.	409

Error code	Error message	HTTP status code
EntityTooLarge	The error message returned because the entity exceeds the maximum allowed size.	400
EntityTooSmall	The error message returned because the entity is smaller than the minimum allowed size.	400
FileGroupTooLarge	The error message returned because the object group exceeds the maximum allowed size.	400
FilePartNotExist	The error message returned because the specified part does not exist.	400
FilePartStale	The error message returned because the part has expired.	400
InvalidArgument	The error message returned because the parameter format is invalid.	400
InvalidAccessKeyId	The error message returned because the specified Accesskey ID does not exist.	403
InvalidBucketName	The error message returned because the bucket name is invalid.	400
InvalidDigest	The error message returned because the digest is invalid.	400
InvalidObjectName	The error message returned because the object name is invalid.	400
InvalidPart	The error message returned because the part is invalid.	400
InvalidPartOrder	The error message returned because the part sequence is invalid.	400
InvalidTargetBucketForLogging	The error message returned because the destination bucket specified for logging is invalid.	400
InternalError	The error message returned because an internal OSS error occurs.	500
MalformedXML	The error message returned because the XML format is invalid.	400
MethodNotAllowed	The error message returned because the method is not supported.	405

Error code	Error message	HTTP status code
MissingArgument	The error message returned because the required parameters are not set.	411
MissingContentLength	The error message returned because the content length is not specified.	411
NoSuchBucket	The error message returned because the specified bucket does not exist.	404
NoSuchKey	The error message returned because the specified object does not exist.	404
NoSuchUpload	The error message returned because the specified multipart upload ID does not exist.	404
NotImplemented	The error message returned because the method cannot be implemented.	501
PreconditionFailed	The error message returned because a precondition error occurs.	412
RequestTimeTooSkewed	The error message returned because the difference between the time on the client when the request is sent and the time on the server when the request is received is greater than 15 minutes.	403
RequestTimeout	The error message returned because the request times out.	400
SignatureDoesNotMatch	The error message returned because the signature is invalid.	403
InvalidEncryptionAlgorithmError	The error message returned because the specified encryption algorithm based on entropy encoding is invalid.	400

6.1.2.1.12. FAQ

This topic lists the causes and solutions for common errors you may encounter when you use OSS SDK for Java.

JAR conflicts

If an error similar to the following is displayed when you use OSS SDK for Java, a JAR conflict is in your project:

```
Exception in thread "main" java.lang.NoClassDefFoundError: org/apache/http/ssl/TrustStrateg
y
    at com.aliyun.oss.OSSClient.<init>(OSSClient.java:268)
    at com.aliyun.oss.OSSClient.<init>(OSSClient.java:193)
    at com.aliyun.oss.demo.HelloOSS.main(HelloOSS.java:77)
Caused by: java.lang.ClassNotFoundException: org.apache.http.ssl.TrustStrategy
    at java.net.URLClassLoader$1.run(URLClassLoader.java:366)
    at java.net.URLClassLoader$1.run(URLClassLoader.java:355)
    at java.security.AccessController.doPrivileged(Native Method)
    at java.net.URLClassLoader.findClass(URLClassLoader.java:354)
    at java.lang.ClassLoader.loadClass(ClassLoader.java:425)
    at sun.misc.Launcher$AppClassLoader.loadClass(Launcher.java:308)
    at java.lang.ClassLoader.loadClass(ClassLoader.java:358)
    ... 3 more
```

Or

```
Exception in thread "main" java.lang.NoSuchFieldError: INSTANCE
 at org.apache.http.impl.io.DefaultHttpRequestWriterFactory.<init>(DefaultHttpRequestWriter
Factory.java:52)
 at org.apache.http.impl.io.DefaultHttpRequestWriterFactory.<init>(DefaultHttpRequestWriter

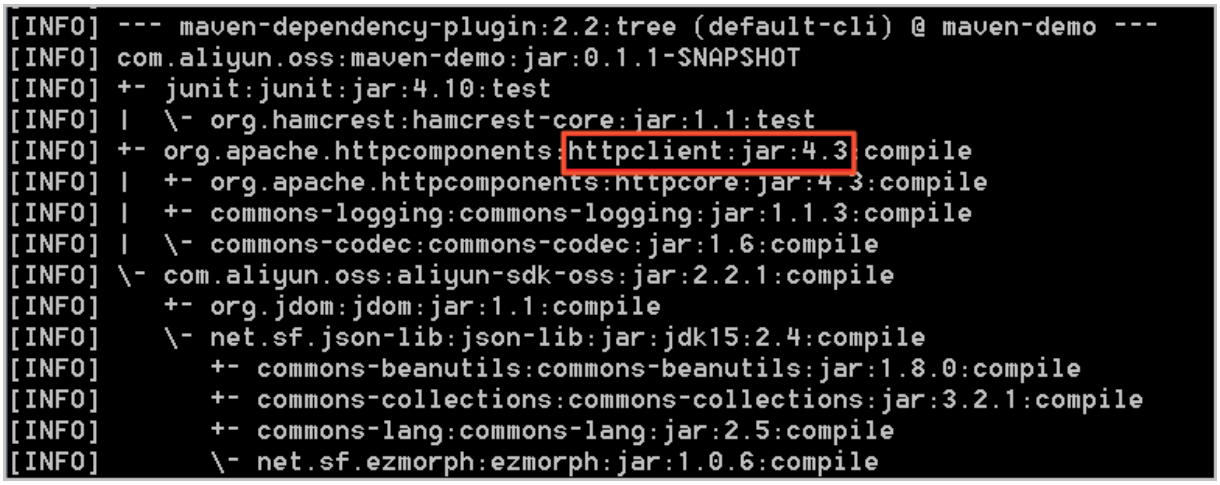
 at OSSManagerImpl.main(OSSManagerImpl.java:63)
```

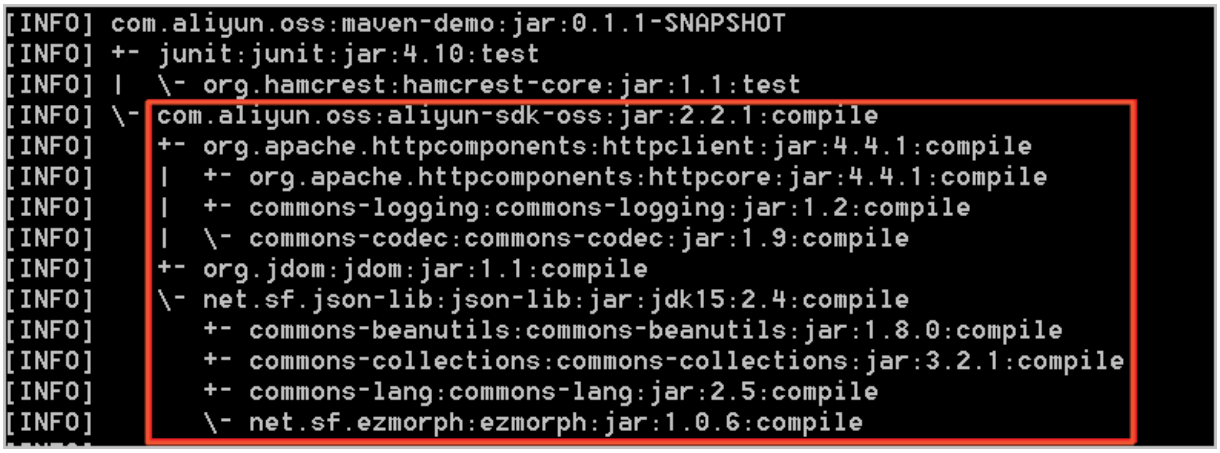
Cause: A possible cause is that the OSS Java SDK uses Apache httpclient 4.4.1, whereas your project uses a version of Apache httpclient or commons-httpclient that conflicts with Apache httpclient 4.4.1. To view the JAR package and its version that is used in your project, run the `mvn dependency:tree` command in the directory of the project. The following figure shows that the project uses Apache HttpClient 4.3.



Solution: Use one of the following methods to resolve JAR conflicts:

- Use consistent versions of Apache HttpClient. If your project uses a version of Apache HttpClient that conflicts with Apache HttpClient 4.4.1, use Apache HttpClient 4.4.1 and delete all other Apache HttpClient version dependencies in the pom.xml file. If your project uses Commons HttpClient, conflicts may also occur. To resolve these conflicts, delete Commons HttpClient.
- Resolve dependency conflicts. If your project is dependent on multiple third-party packages and the third-party packages are dependent on different versions of Apache HttpClient, your project may contain dependency conflicts. Use exclusions to resolve these conflicts. For more information, visit Maven Guides.

OSS SDK for Java is dependent on the following package versions. The solution to conflicts is similar to that for HttpClient.



Missing packages

An error similar to the following is displayed when you use OSS SDK for Java:

```
Exception in thread "main" java.lang.NoClassDefFoundError: org/apache/http/auth/Credentials
        at com.aliyun.oss.OSSClient.<init>(OSSClient.java:268)
        at com.aliyun.oss.OSSClient.<init>(OSSClient.java:193)
        at com.aliyun.oss.demo.HelloOSS.main(HelloOSS.java:76)
Caused by: java.lang.ClassNotFoundException: org.apache.http.auth.Credentials
        at java.net.URLClassLoader$1.run(URLClassLoader.java:366)
        at java.net.URLClassLoader$1.run(URLClassLoader.java:355)
        at java.security.AccessController.doPrivileged(Native Method)
        at java.net.URLClassLoader.findClass(URLClassLoader.java:354)
        at java.lang.ClassLoader.loadClass(ClassLoader.java:425)
        at sun.misc.Launcher$AppClassLoader.loadClass(Launcher.java:308)
        at java.lang.ClassLoader.loadClass(ClassLoader.java:358)
        ... 3 more
```

Or

```

        at sun.misc.Launcher$AppClassLoader.loadClass(Launcher.java:308)
        at java.lang.ClassLoader.loadClass(ClassLoader.java:358)
        ... 11 more
```

Cause: The JAR package used to compile or run OSS SDK for Java may be missing in your project. OSS SDK for Java depends on the following JAR packages:

- aliyun-sdk-oss-2.2.1.jar
- hamcrest-core-1.1.jar
- jdom-1.1.jar
- commons-codec-1.9.jar
- httpclient-4.4.1.jar
- commons-logging-1.2.jar
- httpcore-4.4.1.jar
- log4j-1.2.15.jar

All packages except the log4j-1.2.15.jar package are required for OSS Java SDK. However, if you want to enable logging, you must also include the log4j-1.2.15.jar package.

Solution: Add packages on which OSS SDK for Java is dependent to your projects by using the following methods:

- If you run your project in Eclipse, import dependencies to Eclipse, as instructed in the "Method 2: Import a JAR package" section of Installation.
- If you run your project in Ant, add the packages on which OSS SDK for Java is dependent to the lib directory of the project.
- If you use the .javac or .java file, use the -classpath or -cp option to specify the path in which OSS Java SDK dependent packages are added, or save the Java SDK dependencies to classpath.

Connection timeout

If a similar exception is displayed when you run OSS SDK for Java:

```
com.aliyun.oss.ClientException: SocketException
    at com.aliyun.oss.common.utils.ExceptionFactory.createNetworkException(ExceptionFactory
.java:71)
    at com.aliyun.oss.common.comm.DefaultServiceClient.sendRequestCore(DefaultServiceClient
.java:116)
    at com.aliyun.oss.common.comm.ServiceClient.sendRequestImpl(ServiceClient.java:121)
    at com.aliyun.oss.common.comm.ServiceClient.sendRequest(ServiceClient.java:67)
    at com.aliyun.oss.internal.OSSOperation.send(OSSOperation.java:92)
    at com.aliyun.oss.internal.OSSOperation.doOperation(OSSOperation.java:140)
    at com.aliyun.oss.internal.OSSOperation.doOperation(OSSOperation.java:111)
    at com.aliyun.oss.internal.OSSBucketOperation.getBucketInfo(OSSBucketOperation.java:115
2)
    at com.aliyun.oss.OSSClient.getBucketInfo(OSSClient.java:1220)
    at com.aliyun.oss.OSSClient.getBucketInfo(OSSClient.java:1214)
    at com.aliyun.oss.demo.HelloOSS.main(HelloOSS.java:94)
Caused by: org.apache.http.conn.HttpHostConnectException: Connect to oss-test.oss-cn-hangzh
ou-internal.aliyuncs.com:80 [oss-test.oss-cn-hangzhou-internal.aliyuncs.com/10.84.135.99] f
ailed: Connection timed out: connect
    at org.apache.http.impl.conn.DefaultHttpClientConnectionOperator.connect(DefaultHttpCli
entConnectionOperator.java:151)
    at org.apache.http.impl.conn.PoolingHttpClientConnectionManager.connect(PoolingHttpClie
ntConnectionManager.java:353)
    at org.apache.http.impl.execchain.MainClientExec.establishRoute(MainClientExec.java:380
)
    at org.apache.http.impl.execchain.MainClientExec.execute(MainClientExec.java:236)
    at org.apache.http.impl.execchain.ProtocolExec.execute(ProtocolExec.java:184)
    at org.apache.http.impl.execchain.RedirectExec.execute(RedirectExec.java:110)
    at org.apache.http.impl.client.InternalHttpClient.doExecute(InternalHttpClient.java:184
)
    at org.apache.http.impl.client.CloseableHttpClient.execute(CloseableHttpClient.java:82)
    at com.aliyun.oss.common.comm.DefaultServiceClient.sendRequestCore(DefaultServiceClient
.java:113)
    ... 9 more
```

Cause: The endpoint is incorrect or the network is disconnected.

Solution: Solve the network problem and try again.

org.apache.http.NoHttpResponseException: The target server failed to respond

If a similar exception is displayed when you run OSS SDK for Java:

```
com.aliyun.oss.ClientException: Unknown
        at com.aliyun.oss.common.utils.ExceptionFactory.createNetworkException(ExceptionFactory.java:68) ~[aliyun-sdk-oss-2.1.0.jar:na]

        at java.util.concurrent.ThreadPoolExecutor$Worker.run(ThreadPoolExecutor.java:615) [na:1.7.0_51]
        at java.lang.Thread.run(Thread.java:744) [na:1.7.0_51]
Caused by: org.apache.http.NoHttpResponseException: The target server failed to respond
        at org.apache.http.impl.conn.DefaultHttpResponseParser.parseHead(DefaultHttpResponseParser.java:143) ~[httpclient-4.4.jar:4.4]
        at org.apache.http.impl.conn.DefaultHttpResponseParser.parseHead(DefaultHttpResponseParser.java:57) ~[httpclient-4.4.jar:4.4]
        at org.apache.http.impl.io.AbstractMessageParser.parse(AbstractMessageParser.java:261) ~[httpcore-4.4.jar:4.4]
        at org.apache.http.impl.DefaultBHttpClientConnection.receiveResponseHeader(DefaultBHttpClientConnection.java:165) ~[httpcore-4.4.jar:4.4]
        at org.apache.http.impl.conn.CPoolProxy.receiveResponseHeader(CPoolProxy.java:167) ~[httpclient-4.4.jar:4.4]
        at org.apache.http.protocol.HttpRequestExecutor.doReceiveResponse(HttpRequestExecutor.java:272) ~[httpcore-4.4.jar:4.4]
```

Cause: The preceding error may occur if expired connections are used. This error occurs only when a Java SDK version earlier than 2.1.2 is used.

Solution: Upgrade OSS SDK for Java to V2.1.2 or later.

OSS SDK for Java stops responding when OSS SDK for Java is called

If OSS SDK for Java stops responding when you call OSS SDK for Java, call `jstack -l <pid>` to view the stack. The similar error is displayed at the following positions:

```
"main" prio=6 tid=0x000000000291e000 nid=0xc40 waiting on condition [0x0000000002dae000]
java.lang.Thread.State: WAITING (parking)
    at sun.misc.Unsafe.park(Native Method)
    - parking to wait for  <0x00000007d85697f8> (a java.util.concurrent.locks.AbstractQueue
dSynchronizer$ConditionObject)
    at java.util.concurrent.locks.LockSupport.park(LockSupport.java:186)
    at java.util.concurrent.locks.AbstractQueuedSynchronizer$ConditionObject.await(Abstract
QueuedSynchronizer.java:2043)
    at org.apache.http.pool.PoolEntryFuture.await(PoolEntryFuture.java:138)
    at org.apache.http.pool.AbstractConnPool.getPoolEntryBlocking(AbstractConnPool.java:306
)
    at org.apache.http.pool.AbstractConnPool.access$000(AbstractConnPool.java:64)
    at org.apache.http.pool.AbstractConnPool$2.getPoolEntry(AbstractConnPool.java:192)
    at org.apache.http.pool.AbstractConnPool$2.getPoolEntry(AbstractConnPool.java:185)
    at org.apache.http.pool.PoolEntryFuture.get(PoolEntryFuture.java:107)
    at org.apache.http.impl.conn.PoolingHttpClientConnectionManager.leaseConnection(Pooling
HttpClientConnectionManager.java:276)
    at org.apache.http.impl.conn.PoolingHttpClientConnectionManager$1.get(PoolingHttpClient
ConnectionManager.java:263)
    at org.apache.http.impl.execchain.MainClientExec.execute(MainClientExec.java:190)
    at org.apache.http.impl.execchain.ProtocolExec.execute(ProtocolExec.java:184)
    at org.apache.http.impl.execchain.RedirectExec.execute(RedirectExec.java:110)
    at org.apache.http.impl.client.InternalHttpClient.doExecute(InternalHttpClient.java:184
)
    at org.apache.http.impl.client.CloseableHttpClient.execute(CloseableHttpClient.java:82)
    at com.aliyun.oss.common.comm.DefaultServiceClient.sendRequestCore(DefaultServiceClient
.java:113)
    at com.aliyun.oss.common.comm.ServiceClient.sendRequestImpl(ServiceClient.java:123)
    at com.aliyun.oss.common.comm.ServiceClient.sendRequest(ServiceClient.java:68)
    at com.aliyun.oss.internal.OSSOperation.send(OSSOperation.java:94)
    at com.aliyun.oss.internal.OSSOperation.doOperation(OSSOperation.java:146)
    at com.aliyun.oss.internal.OSSOperation.doOperation(OSSOperation.java:113)
    at com.aliyun.oss.internal.OSSObjectOperation.getObject(OSSObjectOperation.java:229)
    at com.aliyun.oss.OSSClient.getObject(OSSClient.java:629)
    at com.aliyun.oss.OSSClient.getObject(OSSClient.java:617)
    at samples.HelloOSS.main(HelloOSS.java:49)
```

Cause: Connection leaks occur in the connection pool. It may be because `OSSClient.getObject` is not closed after use.

Solution: Check your program and ensure that no connection leaks occur. The following code provides an example on how to close ossObject:

```
// Read an object.
OSSObject ossObject = ossClient.getObject(bucketName, objectName);
// Perform operations in OSS.
// Close your ossObject.
ossObject.close();
```

Connection closure

An error similar to the following is displayed when you use ossClient.getObject:

```
Exception in thread "main" org.apache.http.ConnectionClosedException: Premature end of Cont
ent-Length delimited message body (expected: 11990526; received: 202880
    at org.apache.http.impl.io.ContentLengthInputStream.read(ContentLengthInputStream.java:
180)
    at org.apache.http.impl.io.ContentLengthInputStream.read(ContentLengthInputStream.java:
200)
    at org.apache.http.impl.io.ContentLengthInputStream.close(ContentLengthInputStream.java
:103)
    at org.apache.http.impl.execchain.ResponseEntityProxy.streamClosed(ResponseEntityProxy.
java:128)
    at org.apache.http.conn.EofSensorInputStream.checkClose(EofSensorInputStream.java:228)
    at org.apache.http.conn.EofSensorInputStream.close(EofSensorInputStream.java:174)
    at java.io.FilterInputStream.close(FilterInputStream.java:181)
    at java.io.FilterInputStream.close(FilterInputStream.java:181)
    at com.aliyun.oss.event.ProgressInputStream.close(ProgressInputStream.java:147)
    at java.io.FilterInputStream.close(FilterInputStream.java:181)
    at samples.HelloOSS.main(HelloOSS.java:39)
```

Cause: The interval between the two data reading attempts exceeded one minute. OSS closes the connection if no data is sent or received after more than one minute. This error occurs when your application functions as follows and the time for the application to process data varies: Read part of the data, process the data, read the data, and then process the data.

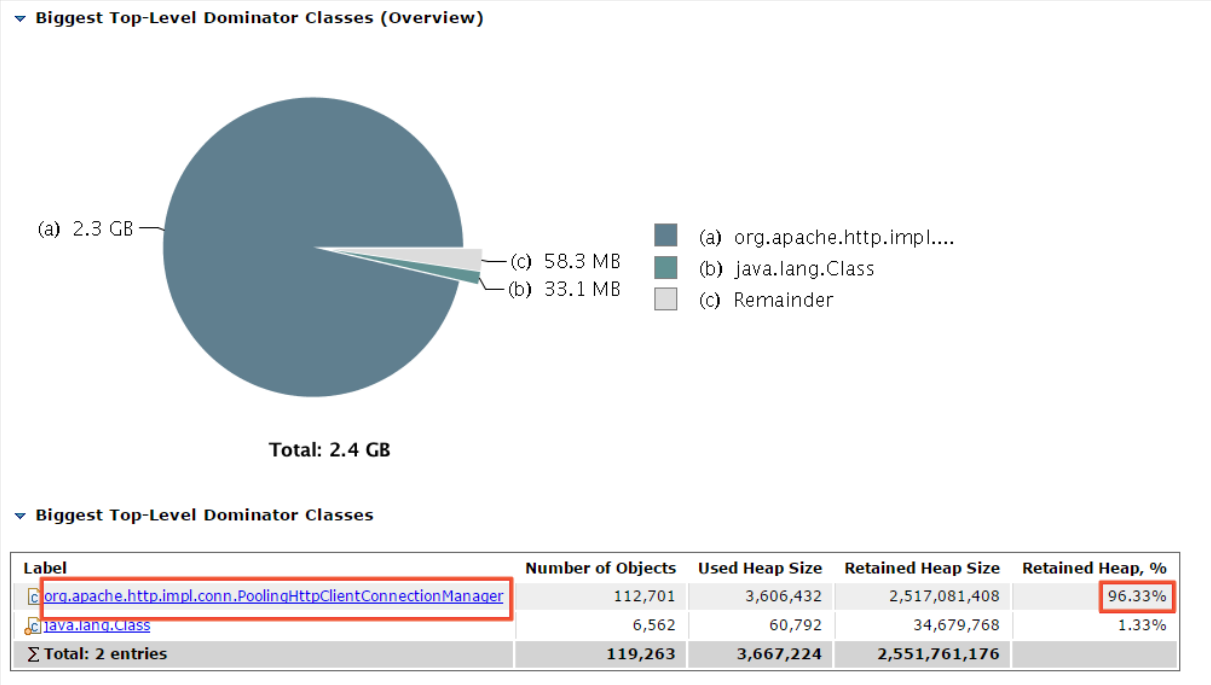
Solution: If you need to read part of the data during unspecified time periods, you can use range download to avoid connection closure during data reading.

Memory leaks

Memory leaks occur when OSS SDK for Java program runs for an extended period of time. This period ranges from several hours to several days based on the amount of access traffic.

Cause: Use the memory analysis tool to analyze the memory usage. We recommend that you use Eclipse Memory Analyzer (MAT) to analyze memory usage. For more information, visit Use MAT for Heap Dump File Analysis.

If the analysis result is similar to that shown in the following figure, PoolingHttpClientConnectionManager takes up 96% of memory. The cause is that the new OSSClient command is run multiple times while ossClient.shutdown is not called. As a result, memory leaks occur.



Solution: You must ensure that ossClient.shutdown is called after you run the new OSSClient command.

InterruptedException occurs when OSSClient.shutdown is called

A similar exception is displayed when OSSClient.shutdown is called:

```
java.lang.InterruptedException: sleep interrupted
        at java.lang.Thread.sleep(Native Method)
        at com.aliyun.oss.common.comm.IdleConnectionReaper.run(IdleConnectionReaper:76)
```

Cause: A background thread IdleConnectionReaper from OSSClient shuts down idle connections in a timely manner. If the shutdown method is called when the IdleConnectionReaper thread is asleep, the preceding exception is displayed.

Solution:

- Upgrade OSS SDK for Java to version 2.3.0 or later because this problem is fixed in OSS SDK for Java V2.3.0.
- For versions earlier than OSS Java SDK version 2.3.0, use the following code to ignore the exception:

```
try {
serviceClient.shutdown();
} catch(Exception e) {
}
```

6.1.2.2. Python-SDK

6.1.2.2.1. Preface

This topic describes the sample code of OSS SDK for Python in various use cases.

Source code

For the source code of OSS SDK for Python, visit GitHub.

Sample programs

The sample code of OSS SDK for Python is in the examples directory. For more information, visit GitHub. The following table describes the sample files in the sample programs.

Sample file	Description
object_basic.py	Shows you how to perform basic object-related operations such as object upload, download, list, and deletion.
object_extra.py	Shows you how to perform advanced object-related operations such as configure the language and user metadata, copy objects, and append objects.
upload.py	Shows you how to perform advanced object upload operations such as resumable upload and multipart upload.
download.py	Shows you how to perform object download operations such as object download, range download, and resumable download.
object_check.py	Shows you how to verify data during upload and download, including MD5 verification and CRC.
object_progress.py	Shows you how to use a progress bar during upload and download.
object_callback.py	Shows you how to perform upload callback.
object_post.py	Shows you how to use PostObject. The PostObject implementation is independent of the SDK for Python.
sts.py	Shows you how to use STS, including obtain the temporary AccessKey pair by assuming a role and use the temporary AccessKey pair to access OSS.
live_channel.py	Shows you how to use LiveChannel.
image.py	Shows you how to use Image Processing (IMG).
bucket.py	Shows you how to manage buckets such as bucket creation, deletion, and listing.

6.1.2.2.2. Installation

This topic describes how to install OSS SDK for Python.

Preparation

The version of OSS SDK for Python in this topic is compatible with Python 2.6, 2.7, 3.3, 3.4, 3.5, and 3.6.

- Install the environment

  For more information about how to install an appropriate version of Python, visit python.

- Check the Python version

  Run the `python -V` command to check Python version.

  In Windows, if a message is displayed, indicating that it is not an internal or external command, edit the environment variable `Path`. Add the installation path of Python and pip. The installation path of pip is the Scripts directory under the installation path of Python.

  > **Note** You may need to restart your computer to ensure that the environment variables take effect.

Download OSS SDK for Python

- Download from GitHub
- Download previous versions

For more information, see API Reference.

Install python-devel

OSS SDK for Python uses the crcmod library to calculate the value of CRC. The crcmod library depends on the Python.h file. If the Python.h file is missing, SDK installation is not affected but the installation of crcmod extensions in C fails. Therefore, the efficiency of operations such as object upload and download is low. Install python-devel if it does not exist.

- When you install Python in Windows or Mac OS X systems, the Python.h file is installed together with Python. Therefore, you do not need to install python-devel.
- When you install Python in CentOS, RHEL, or Fedora systems, run the following command to install python-devel:

  ```
  yum install python-devel
  ```

- When you install Python in Debian or Ubuntu systems, run the following command to install python-devel:

  ```
  apt-get install python-dev
  ```

Install OSS SDK for Python

- Use pip

  Run the following command:

  ```
  pip install oss2
  ```

  > **Note** If pip is not installed in your environment, visit the official pip website to install pip.

- Use the source code

  Click here to visit GitHub and download the OSS SDK for Python package of an appropriate version. Decompress the package. Check whether the setup.py file exists in the directory and then run the following command:

```
python setup.py install
```

Verification

- Verify the version of OSS SDK for Python
  i. Enter `python` in the command line and press Enter to go to the Python environment.
  ii. Run the following command to verify the version of OSS SDK for Python:

  ```
  >>> import oss2
  >>> oss2.__version__
  '2.0.0'
  ```

  If an output similar to the preceding example is displayed, OSS SDK for Python version 2.0.0 is installed.

- Verify crcmod

  OSS SDK for Python uses the following methods to calculate the value of CRC: the C extension mode, which uses the crcmod dependent library to call the _crcfunext.so extension library to calculate the CRC value, and the Python-only mode. The performance of the C extension mode is superior than the Python-only mode. The crcmod library is automatically installed together with oss2. For more information about crcmod, visit crcmod introduction.

  When you use OSS SDK for Python, if the object upload and download efficiency remains much lower than that of other tools or other SDKs, the installation of crcmod extensions in C may fail. In this case, the Python-only mode is used to calculate the value of CRC for object upload and download.

  You can use the following methods to determine whether the C extension mode of the crcmod library is installed:

  i. Enter `python` in the command line and press the Enter key to go the Python environment.
  ii. Enter `import crcmod._crcfunext` and press Enter.
    - If no error message is displayed, the crcmod extensions in C are installed.

- If the following error message is displayed, the installation of crcmod extensions in C failed:

```
>>> import crcmod._crcfunext
Traceback (most recent call last):
File "<stdin>", line 1, in <module>
ImportError: No module named _crcfunext
```

When you compile the crcmod library, the _crcfunext.so file depends on the Python.h file. The error occurs because the Python.h file does not exist in the system, which causes the _crcfunext.so file failed to be generated. Therefore, the Python-only mode is used to calculate the value of CRC. OSS SDK for Python is installed, but the efficiency of operations such as object upload and download is low.

If the error occurs, perform the following operations:

a. Run the following command to uninstall the crcmod library:

```
pip uninstall crcmod
```

b. Install python-devel.

c. Run the following command to re-install the crcmod library:

```
pip install crcmod
```

If the crcmod library fails to be installed after you perform the preceding operations, uninstall the crcmod library. Run the following command to view the detailed causes of the installation failures.

```
pip install crcmod -v
```

Uninstall OSS SDK for Python

If OSS SDK for Python fails to be installed, uninstall OSS SDK for Python by using pip and reinstall OSS SDK for Python. Run the following code to uninstall OSS SDK for Python:

```
pip uninstall oss2
```

6.1.2.2.3. Quick start

This topic describes how to use OSS SDK for Python to perform routine operations such as create buckets, upload objects, and download objects.

Create a bucket

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Set the ACL of the bucket to private.
bucket.create_bucket(oss2.models.BUCKET_ACL_PRIVATE)
```

For more information about how to obtain an AccessKey ID and AccessKey secret, see Obtain an AccessKey pair.

For more information about how to obtain an endpoint, see Obtain an endpoint.

Upload objects

The following code provides an example on how to upload objects to OSS by using stream upload:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# <yourObjectName> indicates the complete path of the object you want to upload to OSS, and
must include the extension of the object name. Example: abc/efg/123.jpg.
# <yourLocalFile> consists of a local file path and an object name with extension. Example:
/users/local/myfile.txt.
bucket.put_object_from_file('<yourObjectName>', '<yourLocalFile>')
```

Download objects

The following code provides an example on how to download a specified object to a local directory:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# <yourObjectName> indicates the complete path of the object you want to download from OSS,
and must include the extension of the object name. Example: abc/efg/123.jpg.
# <yourLocalFile> consists of a local file path and an object name with extension. Example:
/users/local/myfile.txt.
bucket.get_object_to_file('<yourObjectName>', '<yourLocalFile>')
```

List objects

The following code provides an example on how to list 10 objects in a specified bucket:

```
# -*- coding: utf-8 -*-
import oss2
from itertools import islice
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# oss2.ObjectIteratorr is used to traverse objects.
for b in islice(oss2.ObjectIterator(bucket), 10):
    print(b.key)
```

Delete objects

The following code provides an example on how to delete an object:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# <yourObjectName> indicates the complete path of the object you want to delete from OSS, a
nd must include the extension of the object name. Example: abc/efg/123.jpg.
bucket.delete_object('<yourObjectName>')
```

6.1.2.2.4. Initialization

This topic describes how to initialize OSS SDK for Python.

Most operations of OSS SDK for Python are performed based on oss2.Service and oss2.Bucket.

- oss2.Service is used to list buckets.
- oss2.Bucket is used to upload, download, and delete objects as well as configure buckets.

You need to specify the endpoint when you initialize the two classes. oss2.Service does not support access from custom domain names. For more information about endpoints, see Obtain an endpoint.

Initialize oss2.Service

For more information, see List buckets.

Initialize oss2.Bucket

- Use OSS domain names to initialize oss2.Bucket

  The following code provides an example on how to initialize oss2.Bucket by uisng an OSS domain name:

  ```
  # -*- coding: utf-8 -*-
  import oss2
  auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
  # The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
  endpoint.
  endpoint = 'https://oss-cn-hangzhou.aliyuncs.com'
  bucket = oss2.Bucket(auth, endpoint, '<yourBucketName>')
  ```

- Configure the connection timeout period

  The following code provides an example on how to configure the connection timeout period:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
endpoint = 'https://oss-cn-hangzhou.aliyuncs.com'
# Set the timeout period to 30 seconds.
bucket = oss2.Bucket(auth, endpoint, '<yourBucketName>', connect_timeout=30)
```

- Disable CRC

  By default, CRC is enabled to ensure data integrity when you upload or download objects. The following code provides an example on how to disable CRC:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
endpoint = 'https://oss-cn-hangzhou.aliyuncs.com'
bucket = oss2.Bucket(auth, endpoint, '<yourBucketName>', enable_crc=False)
```

  Warning We recommend that you do not disable CRC. If you disable CRC, data integrity during upload and download may be affected.

6.1.2.2.5. Buckets

6.1.2.2.5.1. Create buckets

A bucket is a container used to store objects in Object Storage Service (OSS). Each object is contained in a bucket. This topic describes how to create a bucket.

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# After you specify the endpoint and bucket name, you can create a bucket in the specified
region. The endpoint of the China (Hangzhou) region is used in this example. Specify the ac
tual endpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Create the bucket. By default, the ACL of the created bucket is private.
bucket.create_bucket()
```

6.1.2.2.5.2. List buckets

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
service = oss2.Service(auth, 'http://oss-cn-hangzhou.aliyuncs.com')
print([b.name for b in oss2.BucketIterator(service)])
```

6.1.2.2.5.3. Determine whether buckets exist

A bucket is a container used to store objects in Object Storage Service (OSS). Every object is contained in a bucket. This topic describes how to determine whether a bucket exists.

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
def does_bucket_exist(bucket):
    try:
        bucket.get_bucket_info()
    except oss2.exceptions.NoSuchBucket:
        return False
    except:
        raise
    return True
exist = does_bucket_exist(bucket)
# If the returned value is true, a bucket with the specified name exists. If the returned v
alue is false, a bucket with the specified name does not exist.
if exist:
    print('bucket exist')
else:
    print('bucket not exist')
```

6.1.2.2.5.4. Manage bucket ACLs

A bucket is a container used to store objects in Object Storage Service (OSS). Every object is contained in a bucket. This topic describes how to configure and query the access control list (ACL) of a bucket.

Configure ACL for a bucket

The following table describes the bucket ACLs.

ACL	Description	Value
Private	Only the owner or authorized users of the bucket can read and write the object.	oss2.BUCKET_ACL_PRIVATE

ACL	Description	Value
Public read	Only the owner or authorized users of this bucket can write the object. Other users, including anonymous users can only read the object. Exercise caution when you use this ACL.	oss2.BUCKET_ACL_PUBLIC_READ
Public read/write	Any users, including anonymous users can read and write the object. Exercise caution when you use this ACL.	oss2.BUCKET_ACL_PUBLIC_READ_WRITE

The following code provides an example on how to configure the ACL of a bucket:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Set the ACL of the bucket to private.
bucket.put_bucket_acl(oss2.BUCKET_ACL_PRIVATE)
```

Query the ACL of a bucket

The following code provides an example on how to query the ACL of a bucket:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
print(bucket.get_bucket_acl().acl)
```

6.1.2.2.5.5. Delete buckets

Before you delete a bucket, ensure that all objects, LiveChannels, and parts that are generated during multipart upload in the bucket are deleted. The following code provides an example on how to delete buckets:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
try:
    # Delete the bucket.
    bucket.delete_bucket()
except oss2.exceptions.BucketNotEmpty:
    print('bucket is not empty.')
except oss2.exceptions.NoSuchBucket:
    print('bucket does not exist')
```

To delete a bucket that is not empty, you must clear the bucket by listing and deleting objects in the bucket. If a multipart upload task is ongoing, you must terminate the task before you can delete the bucket.

6.1.2.2.5.6. Manage lifecycle rules

Object Storage Service (OSS) allows you to configure lifecycle rules to delete expired objects and parts or convert the storage class of expired objects to Infrequent Access (IA) or Archive to reduce your storage costs. This topic describes how to manage lifecycle rules for buckets.

Background

Each lifecycle rule contains the following information:

- Policy: specifies the mode to match objects and parts.
  - Match by prefix: matches objects and parts by prefix. You can create multiple rules to configure different prefixes. Each prefix must be unique.
  - Match by bucket: matches all objects and parts contained in the bucket. You can create only one rule if you select this method.
- Object lifecycle policy: specifies the validity period or expiration data and the operation to perform on these objects after they expire.
  - Validity period: specifies the number of days within which parts can be retained after they are last modified. After the validity period, expired objects are deleted.
  - Expiration date: specifies a date. Objects that are last modified before this date expire and are deleted.
- Part lifecycle policy: specifies the validity period or expiration time and the delete operation to perform on these objects after they expire.
  - Validity period: specifies the number of days within which parts can be retained after they are last modified. After the validity period, expired parts are deleted.
  - Expiration date: specifies a date. Parts that are last modified before this date expire and are deleted.

Lifecycle rules also apply to the parts uploaded by using uploadPart. In this case, the last modified time of an object is the time the multipart upload task is initiated.

Configure lifecycle rules

```
# -*- coding: utf-8 -*-
import oss2
from oss2.models import LifecycleExpiration, LifecycleRule, BucketLifecycle,AbortMultipartU
pload
import datetime
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Specify that objects expire three days after they are last modified.
rule1 = LifecycleRule('rule1', 'tests/',
                      status=LifecycleRule.ENABLED,
                      expiration=LifecycleExpiration(days=3))
# Specify an expiration date. Objects that are last modified before this date expired.
rule2 = LifecycleRule('rule2', 'logging-',
                      status=LifecycleRule.DISABLED,
expiration=LifecycleExpiration(created_before_date=datetime.date(2018, 12, 12)))
# Specify that parts expire three days after they are last modified.
rule3 = LifecycleRule('rule3', 'tests1/',
                      status=LifecycleRule.ENABLED,
            abort_multipart_upload=AbortMultipartUpload(days=3))
# Specify an expiration data. Parts that are last modified before this date expired.
rule4 = LifecycleRule('rule4', 'logging1-',
                      status=LifecycleRule.DISABLED,
                      abort_multipart_upload = AbortMultipartUpload(created_before_date=dat
etime.date(2018, 12, 12)))
lifecycle = BucketLifecycle([rule1, rule2,rule3,rule4])
bucket.put_bucket_lifecycle(lifecycle)
```

View lifecycle rules

The following code provides an example on how to query the lifecycle rules configured for the bucket named examplebucket:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
lifecycle = bucket.get_bucket_lifecycle()
for rule in lifecycle.rules:
    if rule.abort_multipart_upload is None:
        print('id={0}, prefix={1}, status={2}, days={3}, created_before_date={4}'
              .format(rule.id, rule.prefix, rule.status,
                      rule.expiration.days,
                      rule.expiration.created_before_date))
    else:
        print('id={0}, prefix={1}, status={2}, days={3}, created_before_date={4}'
              .format(rule.id, rule.prefix, rule.status,
                      rule.abort_multipart_upload.days,
                      rule.abort_multipart_upload.created_before_date))
```

Delete lifecycle rules

The following code provides an example on how to delete lifecycle rules configured for the bucket named examplebucket:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
bucket.delete_bucket_lifecycle()
# An exception occurs when you view lifecycle rules again.
try:
    lifecycle = bucket.get_bucket_lifecycle()
except oss2.exceptions.NoSuchLifecycle:
    print('lifecycle is not configured')
```

6.1.2.2.5.7. Static website hosting

This topic describes how to set the static website hosting mode for your bucket. After the configurations take effect, you can use the bucket domain name to access this static website and be redirected to a specified index page or error page.

Configure static website hosting

Run the following code to configure static website hosting:

```
# -*- coding: utf-8 -*-
import oss2
from oss2.models import BucketWebsite
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Enable static website hosting for the bucket. Set the index page to index.html and the er
ror page to error.html.
bucket.put_bucket_website(BucketWebsite('index.html', 'error.html'))
```

View static website hosting configurations

Run the following code to view static website hosting configurations:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
try:
    # If static website hosting is disabled, the system returns NoSuchWebsite when get_buck
et_website is used.
    website = bucket.get_bucket_website()
    print('Index file is {0}, error file is {1}'.format(website.index_file, website.error_f
ile))
except oss2.exceptions.NoSuchWebsite as e:
    print('Website is not configured, request_id={0}'.format(e.request_id))
```

Delete static website hosting configurations

Run the following code to delete static website hosting configurations:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
bucket.delete_bucket_website()
```

6.1.2.2.5.8. Configure CORS

Cross-origin resource sharing (CORS) allows web applications to access resources that belong to different regions. OSS provides CORS operations to facilitate cross-origin access control.

Configure CORS rules

Run the following code to configure CORS rules for the specified bucket:

```
# -*- coding: utf-8 -*-
import oss2
from oss2.models import BucketCors, CorsRule
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
rule = CorsRule(allowed_origins=['*'],
                allowed_methods=['GET', 'HEAD'],
                allowed_headers=['*'],
                max_age_seconds=1000)
# The existing rules are replaced.
bucket.put_bucket_cors(BucketCors([rule]))
```

Query CORS rules

Run the following code to obtain CORS rules:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
try:
    cors = bucket.get_bucket_cors()
except oss2.exceptions.NoSuchCors:
    print('cors is not set')
else:
    for rule in cors.rules:
        print('AllowedOrigins={0}'.format(rule.allowed_origins))
        print('AllowedMethods={0}'.format(rule.allowed_methods))
        print('AllowedHeaders={0}'.format(rule.allowed_headers))
        print('ExposeHeaders={0}'.format(rule.expose_headers))
        print('MaxAgeSeconds={0}'.format(rule.max_age_seconds))
```

Delete CORS rules

Run the following code to delete all CORS rules for the specified bucket:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
bucket.delete_bucket_cors()
```

6.1.2.2.5.9. Configure hotlink protection

OSS provides hotlink protection to prevent unauthorized domain names from accessing your OSS data. You can configure the Referer field in the HTTP header.

To configure hotlink protection, you must configure the following parameters:

- Referer Whitelist: Only specified domain names are allowed to access OSS resources.
- Allow Empty Referer: If you do not allow empty Refer fields, a request is allowed to access OSS resources only if the request includes the Referer field configured in the HTTP or HTTPS header.

Configure hotlink protection

Run the following code to configure the referer whitelist:

```
# -*- coding: utf-8 -*-
import oss2
from oss2.models import BucketReferer
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Set Allow Empty Referer to True. True indicates that an empty Referer field is allowed an
d False indicates that an empty Referer field is not allowed. Configure the Referer whiteli
st.
bucket.put_bucket_referer(BucketReferer(True, ['http://aliyun.com', 'http://*.aliyuncs.com'
]))
```

Query hotlink protection configurations

Run the following code to obtain a referer whiltelist:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
config = bucket.get_bucket_referer()
print('allow empty referer={0}, referers={1}'.format(config.allow_empty_referer, config.ref
erers))
```

Delete hotlink protection configurations

The following code provides an example on how to delete hotlink protection configurations of a bucket:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# You cannot delete a Referer whitelist directly. To delete a Referer whitelist, you must c
reate a rule that allows an empty Referer field to replace the existing rule.
bucket.put_bucket_referer(BucketReferer(True, []))
```

6.1.2.2.5.10. Configure logging

You can enable logging to record access to a bucket in log objects, which are stored in a specified bucket.

The log objects are in the following format: `<TargetPrefix><SourceBucket>-YYYY-mm-DD-HH-MM-SS-UniqueString`.

Enable logging

Run the following code to enable bucket access logging:

```
# -*- coding: utf-8 -*-
import oss2
from oss2.models import BucketLogging
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Enable logging. Save the log objects to the current bucket. Set the folder that stores th
e log files to `logging/`.
logging = bucket.put_bucket_logging(BucketLogging(bucket.bucket_name, 'logging/'))
if logging.status == 200:
    print("Enable access logging")
else:
    print("request_id : ", logging.request_id)
    print("resp : ", logging.resp.response)
```

View logging configurations

Run the following code to view the access logging configurations for a bucket:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
logging = bucket.get_bucket_logging()
print('TargetBucket={0}, TargetPrefix={1}'.format(logging.target_bucket, logging.target_pre
fix))
```

Disable logging

Run the following code to disable access logging for a bucket:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
logging = bucket.delete_bucket_logging()
if logging.status == 204:
    print("Disable access logging")
else:
    print("request_id : ", logging.request_id)
    print("resp : ", logging.resp.response)
```

6.1.2.2.6. Upload objects

6.1.2.2.6.1. Overview

Objects are the basic unit for data operations in OSS. OSS SDK for Python provides a variety of methods to upload objects.

OSS SDK for Python supports the following object upload methods:

- Simple upload: uploads an object up to 5 GB in size.
- Append upload: uploads an object up to 5 GB in size.
- Resumable upload: supports concurrent upload and resumable upload in which you can define the size of each part. This method is suitable for the upload of large objects. You can use this method to upload an object up to 48.8 TB in size.
- Multipart upload: uploads an object up to 48.8 TB in size. This method is suitable for the upload of large objects.

During object upload, you can configure object metadata and view upload progress by using a progress bar. For more information, see Use progress bars. After the object is uploaded, you can perform upload callback. For more information, see Upload callback.

6.1.2.2.6.2. Simple upload

You can use simple upload to upload objects of the following types: strings, bytes, Unicode, network streams, and local files.

You can use the bucket.put_object method to upload an object. The following table describes the types of inputs supported by this method.

Type	Upload method
Strings	Upload directly.
Bytes	Upload directly.
Unicode	Convert to bytes encoded in UTF-8 to upload.
Local files	File object. The file object must be opened in binary mode such as the rb mode.
Network streams	Iterable object. The iterable object is uploaded by using chunked encoding.

Note If you upload an object with the same name as that of an accessible existing object, the existing object is overwritten by the uploaded object and a 200 OK is returned.

Upload strings

The following code provides an example on how to upload a string to the exampleobject.txt object in the exampledir directory of the examplebucket bucket:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Obtain the return result.
result = bucket.put_object('<yourObjectName>', 'content of object')
# Obtain the returned HTTP status code.
print('http status: {0}'.format(result.status))
# Obtain the unique request ID. We recommend that you add this parameter to the program log
s.
print('request_id: {0}'.format(result.request_id))
# Obtain the ETag value returned by the put_object method.
print('ETag: {0}'.format(result.etag))
# Obtain the HTTP response headers.
print('date: {0}'.format(result.headers['date']))
```

Upload bytes

The following code provides an example on how to upload bytes:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
bucket.put_object('<yourObjectName>', b'content of object')
```

Upload Unicode characters

The following code provides an example on how to upload Unicode:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
bucket.put_object('<yourObjectName>', u'content of object')
```

Upload local files

The following code provides an example on how to upload a local file to OSS:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# The object must be opened in binary mode because the number of bytes in the object must b
e available before the upload.
with open('<yourLocalFile>', 'rb') as fileobj:
    # Use the seek method to read data from the specified position of the 1000th byte. The
data is uploaded from the specified 1000th byte until the entire object is uploaded.
    fileobj.seek(1000, os.SEEK_SET)
    # Use the tell method to obtain the current position.
    current = fileobj.tell()
    bucket.put_object('<yourObjectName>', fileobj)
```

OSS SDK for Python also provides a more convenient method to upload local files:

```
bucket.put_object_from_file('<yourObjectName>', '<yourLocalFile>')
```

Upload network streams

The following code provides an example on how to upload a network stream:

```
# -*- coding: utf-8 -*-
import oss2
import requests
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# The requests.get method returns an iterable object. In this case, OSS SDK for Python uplo
ads the object by using chunked encoding.
input = requests.get('http://www.aliyun.com')
bucket.put_object('<yourObjectName>', input)
```

6.1.2.2.6.3. Append upload

OSS allows you to use append upload to append content directly to the end of an object. You can apply this method only to append objects.

Run the following code for append upload:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Set the position for the first upload (the Position parameter) to 0.
result = bucket.append_object('<yourObjectName>', 0, 'content of first append')
# If you have appended content to the object, you can obtain the position from which the op
eration starts this time from the next_position field in the response returned by the last
operation or by using the bucket.head_object method.
bucket.append_object('<yourObjectName>', result.next_position, 'content of second append')
```

If the object already exists, exceptions occur in the following two cases:

- If the object is not appendable, ObjectNotAppendable is returned.
- If the object is appendable but the append position does not match the current object size, PositionNotEqualToLength is returned.

6.1.2.2.6.4. Resumable upload

If the system stops responding during multipart upload, you can resume the upload by using the ListMultipartUploads and ListParts operations to retrieve all multipart upload tasks on an object and list the uploaded parts in each task. This method allows an upload task to be resumed from the last uploaded part.

You can use the oss2.resumable_upload method to perform resumable upload for a specified object. The following table describes the parameters you can configure for the oss2.resumable_upload method.

Parameter	Description	Required	Default value
bucket	The name of the bucket.	Yes	None
key	The name of the object.	Yes	None
filename	The local file path from which to upload the object.	Yes	None
store	The directory where the checkpoint information is stored.	No	The *.py-oss-upload* directory created in the HOME directory.
headers	The HTTP headers.	No	None
multipart_threshold	The object length threshold for multipart upload. If the object length exceeds the threshold, multipart upload is used.	No	10 MB
part_size	The size of the part.	No	Automatically calculated
progress_callback	The callback function to return upload progress.	No	None
num_threads	The number of concurrent upload threads.	No	1

The following code provides an example on how to perform resumable upload:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Use multipart upload when the object length is greater than or equal to the multipart_thr
eshold value. The multipart_threshold parameter is optional, and the default value of multi
part_threshold is 10 MB. If you do not specify a directory by using the store parameter, th
e .py-oss-upload directory is created in the HOME directory to store the checkpoint informa
tion.
oss2.resumable_upload(bucket, '<yourObjectName>', '<yourLocalFile>')
```

OSS SDK for Python version 2.1.0 and later support resumable upload by using optional parameters. The following code provides an example on how to use optional parameter in resumable upload:

```
# If you specify a directory by using the store parameter, the checkpoint information is st
ored in the specified directory. If you use num_threads to specify the number of concurrent
upload threads, ensure that oss2.defaults.connection_pool_size is set to a value greater th
an the number of concurrent upload threads. The default number of concurrent upload threads
is 1.
oss2.resumable_upload(bucket, '<yourObjectName>', '<yourLocalFile>',
    store=oss2.ResumableStore(root='/tmp'),
    multipart_threshold=100*1024,
    part_size=100*1024,
    num_threads=4)
```

Note

- Multiple threads are used in resumable upload. Therefore, you do not need to encapsulate multiple upload threads when you call the resumable upload method. Otherwise, data may be transferred repeatedly.
- We recommend that you increase the part size when network conditions are good, and decrease the part size when network conditions are poor.

6.1.2.2.6.5. Multipart upload

OSS allows you to use multipart upload to split an object into several parts and upload them separately. After all parts are uploaded, you can combine the uploaded parts into a complete object to complete the upload.

To implement multipart upload, perform the following operations:

1. Initiate a multipart upload task.

   Call the ossClient.initiateMultipartUpload method to obtain a unique upload ID in OSS.

2. Upload the parts.

   Call the ossClient.uploadPart method to upload the parts.

   Note

   - Part numbers identify the relative positions of parts in an object that share the same upload ID. If you have uploaded a part and used its part number again to upload another part, the latter part overwrites the former part.
   - OSS includes the MD5 hash of part data in the ETag header and returns the MD5 hash to the user.
   - OSS calculates the MD5 hash of uploaded data and compares it with the MD5 hash calculated by the SDK. If the two hashes are different, the InvalidDigest error code is returned.

3. Complete the multipart upload task.

   After all parts are uploaded, call the ossClient.completeMultipartUpload method to combine these parts into a complete object.

The following code provides an example on how to perform multipart upload:

```
# -*- coding: utf-8 -*-
import os
from oss2 import SizedFileAdapter, determine_part_size
from oss2.models import PartInfo
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
key = '<yourObjectName>'
filename = '<yourLocalFile>'
total_size = os.path.getsize(filename)
# Use the determine_part_size method to determine the part size.
part_size = determine_part_size(total_size, preferred_size=100 * 1024)
# Initiate a multipart upload task.
# To set the storage class for the object when you initiate the multipart upload task, set
the headers parameter in the init_multipart_upload function.
# headers = dict()
# headers["x-oss-storage-class"] = "Standard"
# upload_id = bucket.init_multipart_upload(key, headers=headers).upload_id
upload_id = bucket.init_multipart_upload(key).upload_id
parts = []
# Upload the parts one by one.
with open(filename, 'rb') as fileobj:
    part_number = 1
    offset = 0
    while offset < total_size:
        num_to_upload = min(part_size, total_size - offset)
        # The SizedFileAdapter(fileobj, size) method generates a new object, and resets the
append position.
        result = bucket.upload_part(key, upload_id, part_number,
                                    SizedFileAdapter(fileobj, num_to_upload))
        parts.append(PartInfo(part_number, result.etag))
        offset += num_to_upload
        part_number += 1
# Complete the multipart upload task.
# To configure ACL for the object when you complete the multipart upload task, set the head
ers parameter in the complete_multipart_upload function.
# headers = dict()
# headers["x-oss-object-acl"] = oss2.OBJECT_ACL_PRIVATE
# bucket.complete_multipart_upload(key, upload_id, parts, headers=headers)
bucket.complete_multipart_upload(key, upload_id, parts)
# Verify multipart upload.
with open(filename, 'rb') as fileobj:
    assert bucket.get_object(key).read() == fileobj.read()
```

Cancel a multipart upload task

You can call bucket.abort_multipart_upload to cancel a multipart upload task. If you cancel a multipart upload task, you cannot use the upload ID to perform any operations on the parts. The uploaded parts are deleted.

The following code provides an example on how to cancel a multipart upload task:

```
# -*- coding: utf-8 -*-
import os
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
key = '<yourObjectName>'
# Obtain the upload ID returned by the init_multipart_upload operation.
upload_id = '<yourUploadId>'
# When you cancel the multipart upload task by using the specified upload ID, the uploaded
parts are deleted.
bucket.abort_multipart_upload(key, upload_id)
```

List uploaded parts

The following code provides an example on how to list uploaded parts:

```
# -*- coding: utf-8 -*-
import os
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
key = '<yourObjectName>'
# Obtain the upload ID returned by the init_multipart_upload operation.
upload_id = '<yourUploadId>'
# List uploaded parts by using the specified upload ID.
for part_info in oss2.PartIterator(bucket, key, upload_id):
    print('part_number:', part_info.part_number)
    print('etag:', part_info.etag)
    print('size:', part_info.size)
```

List multipart upload tasks

- List multipart upload tasks of a specified object

  The following code provides an example on how to list multipart upload tasks of a specified object:

```
# -*- coding: utf-8 -*-
import os
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
key = '<yourObjectName>'
# List all multipart upload tasks of the object. Each time init_multipart_upload is calle
d for the same object, different upload_id values are returned.
# One upload ID corresponds to one multipart upload task.
for upload_info in oss2.ObjectUploadIterator(bucket, key):
    print('key:', upload_info.key)
    print('upload_id:', upload_info.upload_id)
```

- List all multipart upload tasks in a bucket

  The following code provides an example on how to list all multipart upload tasks in a bucket:

```
# -*- coding: utf-8 -*-
import os
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# List all multipart upload tasks in the bucket.
for upload_info in oss2.MultipartUploadIterator(bucket):
    print('key:', upload_info.key)
    print('upload_id:', upload_info.upload_id)
```

- List all multipart upload tasks for objects whose names contain a specified prefix in a bucket

  The following code provides an example on how to list multipart upload tasks for objects whose names contain a specified prefix in a bucket:

```
# -*- coding: utf-8 -*-
import os
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# List multipart upload tasks for objects whose names contain the prefix test in the buck
et.
for upload_info in oss2.MultipartUploadIterator(bucket, prefix='test'):
    print('key:', upload_info.key)
    print('upload_id:', upload_info.upload_id)
```

6.1.2.2.6.6. Use progress bars

Progress bars are used to indicate the progress of an upload or download.

For the complete code of progress bar, visit GitHub.

The following code uses bucket.put_object as an example to describe how to use a progress bars:

```
# -*- coding: utf-8 -*-
from __future__ import print_function
import os, sys
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# If the length of the data to upload cannot be determined, the value of total_bytes is Non
e.
def percentage(consumed_bytes, total_bytes):
    if total_bytes:
        rate = int(100 * (float(consumed_bytes) / float(total_bytes)))
        print('\r{0}% '.format(rate), end='')
        sys.stdout.flush()
# progress_callback is an optional parameter used to return progress information.
bucket.put_object('<yourObjectName>', 'a'*1024*1024, progress_callback=percentage)
```

6.1.2.2.6.7. Upload callback

This topic describes how to use upload callback.

For the complete code used to implement upload callback, visit GitHub.

You can use upload callback when you use put_object, put_object_from_file, and complete_multipart_upload.

```
# -*- coding: utf-8 -*-
import json
import base64
import os
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Configure the upload callback parameter.
callback_dict = {}
# Configure the IP address of the server to which you want to send the callback request. Ex
ample: http://oss-demo.aliyuncs.com:23450 or http://127.0.0.1:9090.
callback_dict['callbackUrl'] = 'http://oss-demo.aliyuncs.com:23450'
# Optional. Configure the value of the host field carried in the callback request header.
# callback_dict['callbackHost'] = 'yourCallbackHost'
# Configure the value of the body field included in the callback request.
callback_dict['callbackBody'] = 'filename=${object}&size=${size}&mimeType=${mimeType}'
# Configure Content-Type for the callback request.
callback_dict['callbackBodyType'] = 'application/x-www-form-urlencoded'
# The callback parameter is in the JSON format and encoded in Base64.
callback_param = json.dumps(callback_dict).strip()
base64_callback_body = base64.b64encode(callback_param)
# Configure the header with the encoded parameter and send the header to OSS.
headers = {'x-oss-callback': base64_callback_body}
# Upload the object and perform upload callback.
result = bucket.put_object('<yourObjectName>', 'a'*1024*1024, headers)
```

6.1.2.2.7. Download objects

6.1.2.2.7.1. Overview

Objects are the basic unit for data operations in OSS. OSS SDK for Python provides the following object download methods:

You can use one of the following methods to download an object:

- Streaming download
- Download to local files
- Range download
- Resumable download

You can view the download progress by using a progress bar. For more information, see Use progress bars.

6.1.2.2.7.2. Streaming download

If you need to download a large object or it takes a long time to download an object at a time, you can use streaming download to download the object incrementally until the entire object is downloaded.

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# The return value of bucket.get_object is a file-like and iterable object.
object_stream = bucket.get_object('<yourObjectName>')
print(object_stream.read())
# You must call read() to read the object from the stream returned by get_object before you
can calculate the CRC-64 checksum of the object.
if object_stream.client_crc ! = object_stream.server_crc:
    print "The CRC checksum between client and server is inconsistent!"
```

The following code provides an example on how to download data to a local file in streaming mode:

```
import shutil
# object_stream is a file-like object. You can use the shutil.copyfileobj method to downloa
d the data to your local file.
object_stream = bucket.get_object('<yourObjectName>')
with open('<yourLocalFile>', 'wb') as local_fileobj:
    shutil.copyfileobj(object_stream, local_fileobj)
```

The following code provides an example on how to copy data to another object in streaming mode:

```
# object_stream is a iterable object. You can copy object_stream to another object in strea
ming mode.
object_stream = bucket.get_object('<yourObjectName>')
bucket.put_object('<yourBackupObjectName>', object_stream)
```

6.1.2.2.7.3. Download to local files

This topic describes how to download an object to a local file.

The following code provides an example on how to download a specified object to a local file:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Download the object to a local file. If the specified local file already exists, the down
loaded object replaces the local file. If the specified local file does not exist, it is cr
eated.
# <yourLocalFile> consists of a local file path and an object name with an extension. Examp
le: /users/local/myfile.txt.
bucket.get_object_to_file('<yourObjectName>', '<yourLocalFile>')
```

6.1.2.2.7.4. Range download

If you need only part of the data in an object, you can use range download to download data within the specified range.

Specify a valid range

The following code provides an example on how to specify a valid range to download data:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# If an object is 1,000 bytes in size, the valid range is from byte 0 to byte 999.
# Query the data that is within the range from byte 0 to byte 999, which includes a total o
f 1,000 bytes. If the specified range is invalid, for example, the specified range includes
a negative number, or the specified value is larger than the object size, the entire object
is downloaded.
object_stream = bucket.get_object('<yourObjectName>', byte_range=(0, 999))
```

Specify an invalid range

The valid range for an object whose size is 1,000 bytes is from byte 0 to byte 999. If the specified range is not within the range, the range does not take effect. Then, OSS returns the 200 HTTP status code and the data of the entire object. The following list provides examples of invalid requests and the returned results:

- If you set Range: bytes to 500-2000, the value at the end of the range is invalid. Then, OSS returns the 200 HTTP status code and the data of the entire object.
- If you set Range: bytes to 1000-2000, the value at the start of the range is invalid. Then, OSS returns the 200 HTTP status code and the data of the entire object.

Compatible download

If you add x-oss-range-behavior:standard to the request header, the download behavior is modified when the specified range is not within the valid range. Example: Use range download to download an object whose size is 1,000 bytes.

- If you set Range: bytes to 500-2000, the value at the end of the range is invalid. Then, OSS returns HTTP status code 206 and the data that is within the range from byte 500 to byte 999.
- If you set Range: bytes to 1000-2000, the value at the start of the range is invalid. Then, OSS returns HTTP status code 416 and error code InvalidRange.

The following code provides an example on how to specify compatible behaviors to download data by range:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Create an object whose size is 1,000 bytes.
object_name = 'rangeTest.txt'
content = 'a' * 1000
bucket.put_object(object_name, content)
headers = {'x-oss-range-behavior':'standard'}
# Specify the compatible behavior.
# When the value at the end of the range is invalid, OSS returns the data that is within th
e range from byte 500 to byte 999. The 206 HTTP status code is also returned.
object_stream = bucket.get_object(object_name, byte_range=(500, 2000), headers=headers)
print('standard get 500~2000 http status code:', object_stream.status)
print('standard get 500~2000 contnet_length:', object_stream.content_length)
try:
    # When the value at the start of the range is invalid, exceptions are returned for the
following code. The returned HTTP status code is 416 and the returned error code is Invalid
Range.
    object_stream = bucket.get_object(object_name, byte_range=(1000, 2000), headers=headers
)
except oss2.exceptions.ServerError as e:
    print('standard get 1000~2000 http status code:', e.status)
    print('standard get 1000~2000 error code:', e.code)
```

6.1.2.2.7.5. Resumable download

You may fail to download a large object if the network is unstable or if the program stops responding. In some cases, you may still fail to download the object even after multiple attempts. To solve this problem, OSS SDK for Java provides the resumable download feature.

You can perform the following steps to perform resumable download:

1. Create a temporary local file with a name that consists of the original object name and a random suffix.
2. Read the object based on the range specified in the Range header in the HTTP request and write the read content to the corresponding position of the temporary local file.
3. After the download is complete, rename the temporary file as the destination file. If the destination file already exists, the downloaded data overwrites the data in the existing file.

Otherwise, a new file is created.

You can use the oss2.resumable_download method to perform resumable download. The following table describes the parameters used in this method.

Parameter	Description	Required	Default value
bucket	The name of the bucket.	Yes	None
key	The name of the object.	Yes	None
filename	The path to the local file. The local file to which the object is downloaded.	Yes	None
store	The file that records the results of multipart download. This file stores information about download progress. If you fail to download a part, the download continues based on the recorded progress.	No	The *.py-oss-upload* directory created in the HOME directory.
multipart_threshold	The threshold for the object size. If the object size exceeds the threshold, resumable download is enabled.	No	10 MB
part_size	The size of the part.	No	Automatically calculated.
progress_callback	The callback function used to return download progress information.	No	None
num_threads	The number of threads for simultaneous downloads.	No	1

Run the following code for resumable download:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
oss2.resumable_download(bucket, '<yourObjectName>', '<yourLocalFile>')
```

You can configure optional parameters for resumable upload when you use OSS SDK for Python V2.1.0 or later version. The following code provides you an example:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Set oss2.defaults.connection_pool_size to a value greater than or equal to the number of
threads. Then set part_size to a value greater than or equal to the oss2.defaults.multiget_
part_size value.
oss2.resumable_download(bucket, '<yourObjectName>', '<yourLocalFile>',
  store=oss2.ResumableDownloadStore(root='/tmp'),
  multiget_threshold=20*1024*1024,
  part_size=10*1024*1024,
  num_threads=3)
```

Note Do not use multiple programs or threads to call the method simultaneously to download the same object to a same destination file. This is because one piece of checkpoint information overwrites another on the local disk, or one temporary file name conflicts with another.

6.1.2.2.7.6. Use progress bars

Progress bars are used to indicate the progress of an upload or download.

For the complete code of progress bar, visit GitHub.

The following code provides an example on how to use a progress bar in object download performed by using the bucket.get_object_to_file method:

```
# -*- coding: utf-8 -*-
from __future__ import print_function
import os, sys
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# If Content-Length is not configured in the HTTP response header, the value of total_bytes
is None.
def percentage(consumed_bytes, total_bytes):
    if total_bytes:
        rate = int(100 * (float(consumed_bytes) / float(total_bytes)))
        print('\r{0}% '.format(rate), end='')
        sys.stdout.flush()
# progress_callback is an optional parameter used to implement a progress bar.
bucket.get_object_to_file('<yourObjectName>', '<yourLocalFile>', progress_callback=percenta
ge)
```

6.1.2.2.8. Manage objects

6.1.2.2.8.1. Overview

You can manage objects in a bucket by using a variety of operations such as SetObjectAcl, GetObjectAcl, ListObjects, DeleteObject, and CopyObject.

By using the preceding operations, you can perform the following operations:

- Determine whether an object exists
- Manage object ACLs
- Manage object metadata
- List objects
- Query objects
- Delete objects
- Copy an object

6.1.2.2.8.2. Determine whether an object exists

This topic describes how to determine whether an object exists.

Run the following code to determine whether a specified object exists:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
exist = bucket.object_exists('<yourObjectName>')
# If the returned value is true, the specified object exists. If the returned value is fals
e, the specified object does not exist.
if exist:
    print('object exist')
else:
    print('object not exist')
```

6.1.2.2.8.3. Manage object ACLs

This topic describes how to manage the access control list (ACL) of an object.

The following table describes the ACLs that can be configured for an object.

ACL	Description	Value
Inherited from the bucket	The ACL of an object is the same as that of the bucket to which the object belongs.	oss2.OBJECT_ACL_DEFAULT
Private	Only the bucket owner and authorized users have the read and write permissions on the object.	oss2.OBJECT_ACL_PRIVATE
Public Read	Only the bucket owner and authorized users have read and write permissions on the object. Other users have only read permissions on the object. Exercise caution when you use this ACL.	oss2.OBJECT_ACL_PUBLIC_READ
Public	All users have read and write permissions on the object. Exercise caution when you use this ACL.	oss2.OBJECT_ACL_PUBLIC_READ_WRITE

The ACL of objects take precedence over that of buckets. For example, if the ACL of a bucket is private, while the object ACL is public read-write, all users can read and write the object. If an object is not configured with an ACL, its ACL is the same as that of its bucket by default.

Configure ACL for an object

You can run the following code to configure an ACL for an object:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Configure ACL for the object.
bucket.put_object_acl('<yourObjectName>', oss2.OBJECT_ACL_PUBLIC_READ)
```

Query the ACL of an object

You can run the following code to obtain the ACL for an object:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
print(bucket.get_object_acl('<yourObjectName>').acl)
```

6.1.2.2.8.4. Manage object metadata

Object metadata includes HTTP headers and user metadata.

Configure HTTP headers

Run the following code to configure HTTP headers:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
bucket.put_object('<yourObjectName>', '{"age": 1}', headers={'Content-Type': 'application/j
son; charset=utf-8'})
```

For more information about HTTP headers, see RFC2616.

Configure user metadata

You can define user-defined Object Meta for object descriptions.

Run the following code to configure user-defined Object Meta:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
bucket.put_object('<yourObjectName>', 'a novel', headers={'x-oss-meta-author': 'O. Henry',
'Content-Type': 'application/json; charset=utf-8'})
```

Modify object metadata

Run the following code to modify Object Meta:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
bucket.update_object_meta('<yourObjectName>', {'x-oss-meta-author': 'O. Henry'})
# Each time you call bucket.update_object_meta, the existing user metadata is updated.
bucket.update_object_meta('<yourObjectName>', {'x-oss-meta-price': '100 dollar'})
```

The following code provides an example on how to modify object metadata such as Content-Type:

```
bucket.update_object_meta('<yourObjectName>', {'x-oss-meta-author': 'O. Henry'})
# Each time you call bucket.update_object_meta, the existing user metadata is updated.
bucket.update_object_meta('<yourObjectName>', {'Content-Type': 'text/plain'})
```

Query object metadata

You can use the operations provided by OSS SDK for Python to query object metadata.

Configuration method	Description	Benefits
get_object_meta	Queries parts of the object metadata including the ETag, size, and last modified time of the object.	More lightweight and faster
head_object	Queries all object metadata.	None

Run the following code to obtain Object Meta:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
// Query parts of the object metadata.
simplifiedmeta = bucket.get_object_meta("<yourObjectName>")
print(simplifiedmeta.headers['Last-Modified'])
print(simplifiedmeta.headers['Content-Length'])
print(simplifiedmeta.headers['ETag'])
// Query all object metadata.
objectmeta = bucket.head_object("<yourObjectName>")
print(objectmeta.headers['Content-Type'])
print(objectmeta.headers['Last-Modified'])
print(objectmeta.headers['x-oss-object-type'])
```

6.1.2.2.8.5. List objects

Objects in a bucket are sorted alphabetically. OSS SDK for Python provides a series of object listing methods.

Simple list

The following code provides an example on how to list 10 objects in a specified bucket:

```
# -*- coding: utf-8 -*-
import oss2
from itertools import islice
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
for b in islice(oss2.ObjectIterator(bucket), 10):
    print(b.key)
```

List all objects in a bucket

The following code provides an example on how to list all objects in a bucket:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# List all objects in the bucket.
for obj in oss2.ObjectIterator(bucket):
    print(obj.key)
```

List objects whose names contain a specified prefix

Example: A bucket contains the following objects: oss.jpg, fun/test.jpg, fun/movie/001.avi, and fun/movie/007.avi. The forward slash (/) is used as the folder delimiter.

The following code provides an example on how to list all objects whose names contain a specified prefix:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# List all objects in the fun folder, including objects from the subfolders.
for obj in oss2.ObjectIterator(bucket, prefix='fun/'):
    print(obj.key)
```

Example output:

```
fun/movie/001.avi
fun/movie/007.avi
fun/test.jpg
```

List objects and subfolders in a specified folder

OSS does not use folders. All elements are stored as objects. To simulate a folder on the OSS console, you actually create a 0 MB object whose name ends with a forward slash (/). This object can be uploaded and downloaded. By default, the OSS console displays an object whose name ends with a forward slash (/) as a folder.

The delimiter and prefix parameters can be used to simulate folder functions.

- If prefix is set to the name of a folder, objects and subfolders whose names contain the prefix are listed.
- If delimiter is set to a forward slash (/), only the objects and subfolders in the folder are listed. The objects and folders in subfolders are not listed.

Run the following code to list all objects in a specified folder:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# List objects and subfolders in the fun folder. Objects in the subfolders are not listed.
for obj in oss2.ObjectIterator(bucket, prefix = 'fun/', delimiter = '/'):
    # Use is_prefix to determine whether obj is a folder.
    if obj.is_prefix():  # folder
        print('directory: ' + obj.key)
    else:                # object
        print('file: ' + obj.key)
```

Example output:

```
directory: fun/movie/
file: fun/test.jpg
```

List the sizes of objects in a specified folder

The following code provides an example on how to query the sizes of objects in a specified folder:

```
# -*- coding: utf-8 -*-
import oss2
def CalculateFolderLength(bucket, folder):
    length = 0
    for obj in oss2.ObjectIterator(bucket, prefix=folder):
        length += obj.size
    return length
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
for obj in oss2.ObjectIterator(bucket, delimiter='/'):
    if obj.is_prefix():  # folder
        length = CalculateFolderLength(bucket, obj.key)
        print('directory: ' + obj.key + '  length:' + str(length) + "Byte.")
    else: # object
        print('file:' + obj.key + '  length:' + str(obj.size) + "Byte.")
```

6.1.2.2.8.6. Query objects

This topic describes how to use SelectObject in OSS SDK for Python to query CSV and JSON objects.

OSS SDK for Python examples

The following code provides an example on how to query CSV and JSON objects:

```
import oss2
def select_call_back(consumed_bytes, total_bytes =  None):
        print('Consumed Bytes:' + str(consumed_bytes) + '\n')
access_key_id = '<yourAccessKeyId>'
access_key_secret = '<yourAccessKeySecret>'
bucket_name = '<yourtBucketName>'
endpoint = '<yourEndpoint>'
# Create an OSS bucket. All object-related methods must be called based on the bucket.
bucket = oss2.Bucket(oss2.Auth(access_key_id, access_key_secret), endpoint, bucket_name)
key =  'python_select.csv'
content =  'Tom Hanks,USA,45\r\n'*1024
filename =  'python_select.csv'
# Upload a CSV object.
bucket.put_object(key, content)
# Set the parameters for the SelectObject API operation.
csv_meta_params = {'RecordDelimiter': '\r\n'}
select_csv_params = {'CsvHeaderInfo': 'None',
                     'RecordDelimiter': '\r\n',
```

```
                    'LineRange': (500, 1000)}
csv_header = bucket.create_select_object_meta(key, csv_meta_params)
print(csv_header.rows)
print(csv_header.splits)
result = bucket.select_object(key, "select * from ossobject where _3 > 44", select_call_bac
k, select_csv_params)
select_content = result.read()
print(select_content)
result = bucket.select_object_to_file(key, filename,
      "select * from ossobject where _3 > 44", select_call_back, select_csv_params)
bucket.delete_object(key)
###JSON DOCUMENT
key =  'python_select.json'
content =  "{\"contacts\":[{\"key1\":1,\"key2\":\"hello world1\"},{\"key1\":2,\"key2\":\"he
llo world2\"}]}"
filename =  'python_select.json'
# Upload a JSON Document object.
bucket.put_object(key, content)
select_json_params = {'Json_Type': 'DOCUMENT'}
result = bucket.select_object(key, "select s.key2 from ossobject.contacts[*] s where s.key1
= 1", None, select_json_params)
select_content = result.read()
print(select_content)
result = bucket.select_object_to_file(key, filename,
      "select s.key2 from ossobject.contacts[*] s where s.key1 = 1", None, select_json_para
ms)
bucket.delete_object(key)
###JSON LINES
key =  'python_select_lines.json'
content =  "{\"key1\":1,\"key2\":\"hello world1\"}\n{\"key1\":2,\"key2\":\"hello world2\"}"
filename =  'python_select.json'
# Upload a JSON Lines object.
bucket.put_object(key, content)
select_json_params = {'Json_Type': 'LINES'}
json_header = bucket.create_select_object_meta(key,select_json_params)
print(json_header.rows)
print(json_header.splits)
result = bucket.select_object(key, "select s.key2 from ossobject s where s.key1 = 1", None,
select_json_params)
select_content =  result.read()
print(select_content)
result = bucket.select_object_to_file(key, filename,
          "select s.key2 from ossobject s where s.key1 = 1", None, select_json_params)
bucket.delete_object(key)
```

Python Select API

The following section describes the elements used for the SelectObject API operation in Python in detail. These elements include select_object, select_object_to_file, and create_select_object_meta.

- select_object

- The following code provides an example on how to set parameters for select_object:

```
def select_object(self, key, sql,
                  progress_callback=None,
                  select_params=None
                  byte_range=None
                  headers=None
                  ):
```

The preceding code example is used to execute an SQL statement on the object that has the specified key and return the query results.

- sql: the SQL statement that can be directly used as the value of the sql parameter and does not need to be Base64-encoded.
- Progress_callback: optional. This parameter specifies a callback function used to report the query progress.
- select_params: the parameters and actions of the SelectObject operation.
- headers: the header information included in the request. The header information functions the same as that for the GetObject operation. For example, you can configure the bytes field in the request header to specify the range of a CSV object to query.

- The following table describes the parameters supported by the select_params parameter.

Parameter	Description
Json_Type	■ By default, the object is a CSV object if this parameter is not specified. ■ The object is a JSON Document object if this parameter is set to DOCUMENT. ■ The object is a JSON Lines object if this parameter is set to LINES.
CsvHeaderInfo	The header information of the CSV object. Valid values: *None*, *Ignore*, and *Use*. ■ *None*: This object has no header information configured. ■ *Ignore*: This object has header information configured, which is not used when the SQL statement is executed. ■ *Use*: This object has header information configured. The column names in the header information are used when the SQL statement is executed.
CommentCharacter	The comment character in the CSV object. This parameter value can be only one character in length. The default value is None, which indicates that no comment characters are allowed.
RecordDelimiter	The row delimiter in the CSV object. This parameter value can be only one or two characters in length. Default value: \n.
OutputRecordDelimiter	The row delimiter in the output result of the SELECT statement. Default value: \n.

Parameter	Description
FieldDelimiter	The column delimiter in the CSV object. This parameter value can be only one character in length. Default value: comma (,).
OutputFieldDelimiter	The column delimiter in the output result of the SELECT statement. Default value: comma (,).
QuoteCharacter	The quote character for the columns in the CSV object. This parameter value can be only one character in length. Default value: double quotation marks ("). Row and column delimiters enclosed in quote characters are processed as normal characters.
SplitRange	The split range in multipart query. The parameter value is a closed interval in the (start, end) format, which indicates the range of splits to query.
LineRange	The row range in multipart query. The parameter value is a closed interval in the (start, end) format, which indicates the range of rows to query.
CompressionType	The format in which the object is compressed. Valid value: GZIP. Default value: None.
KeepAllColumns	If this parameter is set to true, columns that are excluded by the SELECT statement in the CSV object are left empty in the output result. However, the column positions are kept. Default value: false. Example: The columns in the CSV object are firstname, lastname, and age. The SQL statement is `select firstname, age from ossobject`. ■ If KeepAllColumns is set to *true*, the output result is firstname,,age, in which a comma (,) is added to indicate the position of the excluded lastname column. ■ If KeepAllColumns is set to *false*, the output result is firstname,age. **Note** By using this parameter, you can directly use the code that is used to process GetObject to process SelectObject without modifications.
OutputRawData	■ If this parameter is set to *True*, SelectObject directly returns the original data. If data is not returned for a long time, a timeout error may occur. ■ If this parameter is set to *False*, the output data is encapsulated in frames. Default value: False.
EnablePayloadCrc	Specifies whether a cyclic redundancy check (CRC) value is calculated for each frame. Default value: False.

Parameter	Description
OutputHeader	The header information in the first line of the output result. This parameter applies only to CSV objects.
SkipPartialDataRecord	If this parameter is set to True for a CSV object, the current record is skipped when a column of this record has no data. If this parameter is set to True for a JSON object, the current record is skipped when a key of this record does not exist. If this parameter is set to False, a column without data is left empty in the output result. Example: A row includes the columns firstname, lastname, and age. The SQL statement is `select _1, _4 from ossobject`. ■ If this parameter is set to True, this row is skipped. ■ If this parameter is set to False, firstname,\n is returned.
MaxSkippedRecordsAllowed	The maximum number of skipped rows. The default value is 0, which indicates that an error is returned if a row is skipped.
ParseJsonNumberAsString	■ If this parameter is set to True, all numbers in the JSON object are parsed as strings. ■ If this parameter is set to False, all numbers in the JSON object are parsed as integers or floating-point numbers. Default value: False. High-accuracy floating-point numbers in a JSON object suffer loss of accuracy when they are parsed as floating-point numbers. To keep the accuracy, you can set this parameter to True and use the CAST function to convert the parsed data to the decimal type.

- Returned results of select_object: A SelectObjectResult object is returned. You can use the read() function or the __iter__ method to obtain all results.

  Note If you call the read() function to read all results when there are multiple results to return, excess memory resources are used and you have to wait for a long time. We recommend that you use the __iter__ method (foreach chunk in result) to obtain results and process each chunk in the results. The __iter__ method reduces memory usage and enables the client to process each chunk request processed by the OSS server in a timely manner. This way, the client does not need to wait until all results are returned.

- select_object_to_file

```
def select_object_to_file(self, key, filename, sql,
                  progress_callback=None,
                  select_params=None
                  headers=None
                  ):
```

The preceding code example is used to execute an SQL statement on the object that has the specified key and write the query results to another specified object.

- create_select_object_meta
  - Syntax of create_select_object_meta:

    ```
    def create_select_object_meta(self, key, select_meta_params=None, header=None):
    ```

    The preceding code example is used to create Select Meta for or obtain Select Meta from the object that has the specified key. Select Meta includes the total number of rows, total number of columns (for CSV objects), and total number of splits in an object.

    If Select Meta has been created for an object, this function does not re-create Select Meta unless the value of the OverwriteIfExists parameter is set to true.

    To create Select Meta for an object, the object must be completely scanned.
  - The following table describes the parameters supported by the select_meta_params parameter.

Parameter	Description
Json_Type	■ By default, the object is a CSV object if this parameter is not specified. ■ If this parameter is specified, the parameter value must be LINES, which indicates that the object is a JSON Lines object. **Note** This operation does not apply to JSON Document objects.
RecordDelimiter	The row delimiter in the CSV object.
FieldDelimiter	The column delimiter in the CSV object.
QuoteCharacter	The quote character in the CSV object. Row and column delimiters enclosed in quote characters are processed as normal characters.
CompressionType	The format in which the object is compressed. No compression formats are supported. The default value is None.
OverwriteIfExists	Specifies whether the created Select Meta overwrites the original Select Meta. You do not need to set this parameter in most cases.

  - Returned results of create_select_object_meta: A GetSelectObjectMetaResult object is returned, which includes the rows and splits attributes. If the object is a CSV object, the select_resp object in the result includes the columns attribute, which indicates the number of columns in the CSV object.

6.1.2.2.8.7. Delete objects

This topic describes how to delete objects.

Warning Deleted objects cannot be restored. Exercise caution when you delete objects.

Delete a single object

The following code provides an example on how to delete an object named *exampleobject.txt* from a bucket named examplebucket:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Delete the object. <yourObjectName> indicates the full path of the object that you want t
o delete from OSS. The path must include the extension of the object name. Example: abc/efg
/123.jpg.
# To delete a folder, set <yourObjectName> to the corresponding folder name. If the folder
is not empty, you must delete all objects in the folder before you can delete the folder.
bucket.delete_object('<yourObjectName>')
```

Delete multiple objects

```
# Delete three objects at a time. A maximum of 1,000 objects can be deleted at a time.
result = bucket.batch_delete_objects(['<yourObjectName-a>', '<yourObjectName-b>', '<yourObj
ectName-c>'])
# Display the names of deleted objects.
print('\n'.join(result.deleted_keys))
```

Delete objects whose names contain a specified prefix

The following code provides an example on how to delete objects whose names contain a specified prefix:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
prefix = "<yourKeyPrefix>"
# Delete the objects whose names contain the specified prefix.
for obj in oss2.ObjectIterator(bucket, prefix=prefix):
    bucket.delete_object(obj.key)
```

6.1.2.2.8.8. Copy an object

You can copy an object from a source bucket to a destination bucket within the same region.

Object copy has the following limits:

- You must have read permissions on the source object and write permissions on the destination bucket.
- You cannot copy an object across regions.

Simple copy

You can use simple copy for objects up to 1 GB in size. The following code provides an example on how to perform simple copy:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourDestinationBucketNa
me>')
bucket.copy_object('<yourSourceBucketName>', '<yourSourceObjectName>', '<yourDestinationObj
ectName>')
```

Copy a large object

To copy an object larger than 1 GB, you must split the object into smaller parts and copy them sequentially by using UploadPartCopy. To implement multipart copy, perform the following operations:

1. Use bucket.init_multipart_upload to initiate a multipart copy task.
2. Use bucket.upload_part_copy to copy parts. All parts except for the last part must be greater than 100 KB.
3. Use bucket.complete_multipart_upload to complete the multipart copy task.

```
# -*- coding: utf-8 -*-
import oss2
from oss2.models import PartInfo
from oss2 import determine_part_size
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
src_object = '<yourSourceObjectName>'
dst_object = '<yourDestinationObjectName>'
total_size = bucket.head_object(src_object).content_length
part_size = determine_part_size(total_size, preferred_size=100 * 1024)
# Initiate a multipart upload task.
upload_id = bucket.init_multipart_upload(dst_object).upload_id
parts = []
# Copy each part sequentially.
part_number = 1
offset = 0
while offset < total_size:
    num_to_upload = min(part_size, total_size - offset)
    byte_range = (offset, offset + num_to_upload - 1)
    result = bucket.upload_part_copy(bucket.bucket_name, src_object, byte_range,dst_object,
upload_id, part_number)
    parts.append(PartInfo(part_number, result.etag))
    offset += num_to_upload
    part_number += 1
# Complete the multipart copy task.
bucket.complete_multipart_upload(dst_object, upload_id, parts)
```

6.1.2.2.9. Authorized access

This topic describes how to use Security Token Service (STS) and a signed URL to authorize access.

Use STS to authorize temporary access

Alibaba Cloud STS is a web service that provides a temporary access token to a cloud computing user. You can use STS to grant a third-party application or your RAM user an access credential with a customized validity period and permissions.

STS has the following benefits:

- You need only to generate an access token and send the access token to a third-party application, instead of exposing your long-term AccessKey pair to the third-party application. You can customize the access permissions and validity period of this token.
- The access token automatically expires when the validity period ends.

First, run the following command to install the official Python STS client:

```
pip install aliyun-python-sdk-sts
```

The Python version must be 2.0.6 or later. The following code provides an example on how to use STS to authorize temporary access to upload an object:

```
# -*- coding: utf-8 -*-
from aliyunsdkcore import client
from aliyunsdksts.request.v20150401 import AssumeRoleRequest
import json
import oss2
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
endpoint = 'oss-cn-hangzhou.aliyuncs.com'
access_key_id = '<yourAccessKeyId>'
access_key_secret = '<yourAccessKeySecret>'
bucket_name = '<yourBucketName>'
# The role_arn parameter specifies the resource descriptor of the role.
role_arn = '<yourRoleArn>'
clt = client.AcsClient(access_key_id, access_key_secret, 'cn-hangzhou')
req = AssumeRoleRequest.AssumeRoleRequest()
# Set the format of the returned value to JSON.
req.set_accept_format('json')
req.set_RoleArn(role_arn)
req.set_RoleSessionName('session-name')
body = clt.do_action(req)
# Use the AccessKey pair of the RAM user to apply for a temporary token from STS.
token = json.loads(body)
# Initialize the StsAuth instance based on the authentication information in the temporary
token.
auth = oss2.StsAuth(token['Credentials']['AccessKeyId'],
                    token['Credentials']['AccessKeySecret'],
                    token['Credentials']['SecurityToken'])
# Initialize the bucket based on the StsAuth instance.
bucket = oss2.Bucket(auth, endpoint, bucket_name)
# Upload a string.
bucket.put_object('object-name.txt', b'hello world')
```

For the complete sample code of STS usage, visit GitHub.

Download a private object by using a signed URL

You can generate a signed URL for users to access a private bucket.

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('Your AccessKey ID', 'Your AccessKey secret')
bucket = oss2.Bucket(auth, 'Your endpoint', 'Your bucket name')
print(bucket.sign_url('GET', 'object-in-bucket.txt', 60))
```

A signed URL is displayed after you run the preceding code. You can share the URL with other users so that they can download the objects in the bucket by accessing the URL through a browser or by using tools such as wget. The URL is valid only within 60 seconds after it is generated.

Use a signed URL to authorize temporary access

You can generate a signed URL and provide the URL to a visitor for temporary access. When you generate a signed URL, you can specify the validity period of the URL to limit the period of access from visitors. By default, the validity period of a signed URL is 3,600 seconds. The maximum validity period of a signed URL is 32,400 seconds.

The following code provides an example on how to use a signed URL to download an object:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
# Set the validity period of the signed URL to 60 seconds.
print(bucket.sign_url('GET', '<yourObjectName>', 60))
```

6.1.2.2.10. Chinese characters and time

This topic describes how to use Chinese characters and time in OSS SDK for Python.

Chinese characters

To use Chinese characters in Python code, you must include a character encoding declaration in the beginning of the code. Otherwise, errors occur when you run the code. Example of a character encoding statement:

```
# -*- coding: utf-8 -*-
```

- Date types

  The following table describes the data types supported by Python 2.x.

Date type	Description
str	The string type. Corresponds to the bytes type in Python 3.x.
unicode	Unicode streams. The length is calculated based on the number of Chinese characters. For example, the length of `u'中文'` is 2.

  The following table describes the data types supported by Python 3.x.

Data type	Description
str	The string type. Corresponds to the unicode type in Python 2.x.

Data type	Description
bytes	Byte streams. The length is calculated based on the number of bytes. For example, the length of `b'中文'` is calculated based on the encoding mode. If UTF-8 is used, the length is 6 bytes.

- Input and output limits

  The following table describes the limits on input data.

Input data	Type	Description
OSS object name	str	If the input data type is bytes, it must be encoded in UTF-8.
Local file name	str, unicode	If the input data type is bytes, it must be encoded in UTF-8. Example: the yourLocalFile parameter value used in bucket.get_object_to_file.
Input data stream	bytes	Example: data in bucket.put_object.

  The following table describes limits on output data.

Output data	Type	Description
The result obtained by parsing the XML document	str	Example: a string in the result obtained by using bucket.list_object.
Downloaded content	bytes	By default, data of the bytes type used by OSS SDK for Python must be encoded in UTF-8. Therefore, ensure that the source Python file is encoded in UTF-8.

- Type conversion functions

  OSS SDK for Python provides three functions for type conversion:

Function	Description
to_bytes	- Converts the unicode type to the str type in Python 2.x. Data of other types is returned without changes. - Converts the str type to the bytes type in Python 3.x. Data of other types is returned without changes.

Function	Description
to_unicode	- Converts the str type to the unicode type in Python 2.x. Data of other types is returned without changes. - Converts the bytes type to the str type in Python 3.x. Data of other types is returned without changes.
to_string	This function is equivalent to to_bytes in Python 2.x. This function is equivalent to to_unicode in Python 3.x.

Time

OSS SDK for Python converts timestamp strings of the datetime.datetime type that are obtained from the server to a Unix timestamp corresponding to the amount of time in seconds elapsed since UTC 00:00 on January 1, 1970. For example, the last_modified parameter returned for bucket.get_object is an int Unix timestamp.

You can use the datetime.datetime.fromtimestamp() method to convert time to obtain timestamp strings.

6.1.2.2.11. IMG

OSS Image Processing (IMG) is a secure, cost-effective, and highly reliable image processing service that can process large amounts of data. After you upload source images to OSS, you can call `RESTful` API operations to process the images anytime, anywhere, and on any Internet device. IMG provides image processing API operations. To upload images, use the upload API operations provided by OSS. You can use OSS IMG to build your own image processing service.

Basic features

OSS IMG provides the following features:

- Query image information.
- Convert image formats.
- Resize, crop, and rotate images.
- Apply image effect.
- Add image, text, and text-and-image watermarks to images.
- Customize image processing styles. Log on to the OSS console. Click a bucket name to go to the bucket details page. Click the **Image Processing (IMG)** tab and click **Create Rule** to customize an image processing style.
- Call multiple IMG features by using cascade processing.

Usage

You can use standard `HTTP GET` requests to access IMG. All processing parameters are encoded in the query string of a `URL`.

- Anonymous access

If the ACL of an image object is `public-read`, as described in the following table, anonymous users can access the image object.

Bucket ACL	Object ACL
public-read or public-read-write	default
Any ACL	public-read or public-read-write

You can access IMG anonymously by using a third-level domain in the following format:

```
http://bucket.<endpoint>/object?x-oss-process=image/action,parame_value
```

- bucket: the name of the bucket.
- endpoint: the domain name used to access the region.
- object: the image object stored in OSS.
- image: the identifier reserved by IMG.
- action: the operation performed on the image, such as resizing, cropping, or rotating.
- parame: the parameter corresponding to the operation performed on the image.

Example:

```
http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100
```

If you process an image by using a custom style, you can access IMG anonymously through a third-level domain in the following format:

```
http://bucket.<endpoint>/object?x-oss-process=x-oss-process=style/name
```

- style: the identifier reserved by the system for the custom style.
- name: the name of the custom style. The name is specified by the Rule Name parameter when you create the custom style in the console.

Example:

```
http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=style/oss-pic-style-w-100
```

You can use cascade processing to perform multiple operations in sequence on an image by using a URL in the following format:

```
http://bucket.<endpoint>/object?x-oss-process=image/action,parame_value/action,parame_value/...
```

Example:

```
http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100/rotate,90
```

IMG also supports HTTPS access. The following code provides an example:

```
https://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100
```

- Authorized access

  If the ACL of an image object is private, you must have permissions on the image object before you can perform operations on the image object.

Bucket ACL	Object ACL
private	default
Any permission	private

The following code provides an example on how to generate a signed URL to access IMG:

```
# -*- coding: utf-8 -*-
import oss2
endpoint = '<The OSS endpoint. Example: http://oss-cn-hangzhou.aliyuncs.com>'
access_key_id = '<access_key_id>'
access_key_secret = '<access_key_secret>'
bucket_name = '<bucket_name>'
key = 'example.jpg'
# Create a bucket. All object-related API operations can be called based on the bucket.
bucket = oss2.Bucket(oss2.Auth(access_key_id, access_key_secret), endpoint, bucket_name)
# Upload a sample image.
bucket.put_object_from_file(key, 'example.jpg')
# Generate a signed URL and set the validity period to 10 minutes.
style = 'image/resize,m_fixed,w_100,h_100/rotate,90'
url = bucket.sign_url('GET', key, 10 * 60, params={'x-oss-process': style})
print(url)
```

> **Note**
>
> - You can configure Create Style, HTTPS, and Cascading Processing for authorized access.
> - The validity period of sign_url is set in seconds.

- Access by using SDKs

  You can use `OSS SDKs` to access and process image objects of any ACLs.

> **Note**
>
> - For the complete IMG code, visit GitHub.
> - You can use OSS SDKs to process image objects by configuring Create Style, HTTPS, and Cascading Processing.

- Basic operations

  The following code provides an example on how to perform basic IMG operations including obtaining image information, converting image formats, resizing, cropping, rotating, watermarking, and applying effects:

```
# -*- coding: utf-8 -*-
import os
import oss2
endpoint = '<The OSS endpoint. Example: http://oss-cn-hangzhou.aliyuncs.com>'
access_key_id = '<access_key_id>'
access_key_secret = '<access_key_secret>'
bucket_name = '<bucket_name>'
key = 'example.jpg'
new_pic = 'example-new.jpg'
# Create a bucket. All object-related API operations can be called based on the bucket.
bucket = oss2.Bucket(oss2.Auth(access_key_id, access_key_secret), endpoint, bucket_name
)
# Upload a sample image.
bucket.put_object_from_file(key, 'example.jpg')
# Resize the image.
style = 'image/resize,m_fixed,w_100,h_100'
bucket.get_object_to_file(key, new_pic, process=style)
# Crop the image.
style = 'image/crop,w_100,h_100,x_100,y_100,r_1'
bucket.get_object_to_file(key, new_pic, process=style)
# Rotate the image.
style = 'image/rotate,90'
bucket.get_object_to_file(key, new_pic, process=style)
# Sharpen the image.
style = 'image/sharpen,100'
bucket.get_object_to_file(key, new_pic, process=style)
# Add a text watermark to the image.
style = 'image/watermark,text_SGVsbG8g5Zu-54mH5pyN5YqhIQ'
bucket.get_object_to_file(key, new_pic, process=style)
# Convert the image format.
style = 'image/format,png'
bucket.get_object_to_file(key, new_pic, process=style)
# Delete the sample image.
bucket.delete_object(key)
# Delete the local file.
os.remove(new_pic)
```

> **Note** `get_object` also supports the IMG feature.

- Custom styles

```
# -*- coding: utf-8 -*-
import os
import oss2
endpoint = '<The OSS endpoint. Example: http://oss-cn-hangzhou.aliyuncs.com>'
access_key_id = '<access_key_id>'
access_key_secret = '<access_key_secret>'
bucket_name = '<bucket_name>'
key = 'example.jpg'
new_pic = 'example-new.jpg'
# Create a bucket. All object-related API operations can be called based on the bucket.
bucket = oss2.Bucket(oss2.Auth(access_key_id, access_key_secret), endpoint, bucket_name
)
# Upload a sample image.
bucket.put_object_from_file(key, 'example.jpg')
# Customize the image style.
style = 'style/oss-pic-style-w-100'
# Process the image.
bucket.get_object_to_file(key, new_pic, process=style)
# Delete the sample image.
bucket.delete_object(key)
# Delete the local file.
os.remove(new_pic)
```

> **Note** `get_object` also supports the IMG feature.

- Cascading processing

```
# -*- coding: utf-8 -*-
import os
import oss2
endpoint = '<The OSS endpoint. Example: http://oss-cn-hangzhou.aliyuncs.com>'
access_key_id = '<access_key_id>'
access_key_secret = '<access_key_secret>'
bucket_name = '<bucket_name>'
key = 'example.jpg'
new_pic = 'example-new.jpg'
# Create a bucket. All object-related API operations can be called based on the bucket.
bucket = oss2.Bucket(oss2.Auth(access_key_id, access_key_secret), endpoint, bucket_name
)
# Upload a sample image.
bucket.put_object_from_file(key, 'example.jpg')
# Perform cascade processing.
style = 'image/resize,m_fixed,w_100,h_100/rotate,90'
# Process the image.
bucket.get_object_to_file(key, new_pic, process=style)
# Delete the sample image.
bucket.delete_object(key)
# Delete the local file.
os.remove(new_pic)
```

> **Note** `get_object` also supports the IMG feature.

6.1.2.2.12. Handle exceptions

OssError exceptions of OSS SDK for Python are classified into ClientError, RequestError, and ServerError. Definitions of these errors are provided in the submodule of oss2.exceptions .

The following table describes the variable, type, and description of exceptions.

Variable	Type	Description
status	int	• If a ServerError exception occurs, an HTTP status code is returned. • If a ClientError exception or a RequestError exception occurs, the error status is returned.
request_id	str	• If a ServerError exception occurs, the OSS server returns the request ID. • If a ClientError exception or a RequestError exception occurs, the request ID parameter in the response is empty.

Variable	Type	Description
code and message	str	This variable indicates the text in the Code and Message tags in an OSS error response.

Examples

The following code provides an example on how to handle an exception and display the HTTP status code of the error when you download an object that does not exist:

```
# -*- coding: utf-8 -*-
import oss2
auth = oss2.Auth('<yourAccessKeyId>', '<yourAccessKeySecret>')
# The endpoint of the China (Hangzhou) region is used in this example. Specify the actual e
ndpoint.
bucket = oss2.Bucket(auth, 'http://oss-cn-hangzhou.aliyuncs.com', '<yourBucketName>')
try:
    stream = bucket.get_object('random-key.txt')
except oss2.exceptions.NoSuchKey as e:
    print('status={0}, request_id={1}'.format(e.status, e.request_id))
```

ClientError

ClientError occurs due to incorrect inputs on the client. For example, the error occurs when you use bucket.batch_delete_objects and receive an empty object list. The status value of ClientError is oss2.exceptions.OSS_CLIENT_ERROR_STATUS.

ServerError

When the OSS server returns the HTTP error code, OSS SDK for Python converts the error code to ServerError. ServerError derives multiple subclasses based on the HTTP status code and OSS error code. The NotFound subclass corresponds to 404 HTTP status code. The Conflict subclass corresponds to 409 HTTP status code.

The following table describes common error codes.

Error	HTTP status code	OSS error code	Description
NotModified	304	None	The error message returned because no modifications are performed.
AccessDenied	403	AccessDenied	The error message returned because the access is denied.
NoSuchBucket	404	NoSuchBucket	The error message returned because the specified bucket does not exist.

Error	HTTP status code	OSS error code	Description
NoSuchKey	404	NoSuchKey	The error message returned because the specified object does not exist.
NoSuchUpload	404	NoSuchUpload	The error message returned because the specified multipart upload task does not exist.
NoSuchWebsite	404	NoSuchWebsiteConfiguration	The error message returned because static website hosting is not configured for the specified bucket.
NoSuchLifecycle	404	NoSuchLifecycle	The error message returned because no lifecycle rule is configured for the specified bucket.
NoSuchCors	404	NoSuchCORSConfiguration	The error message returned because CORS rules are not configured for the specified bucket.
BucketNotEmpty	409	BucketNotEmpty	The error message returned because the bucket is not empty.
PositionNotEqualToLength	409	PositionNotEqualToLength	The error message returned because the configured position is not equal to the object length.
ObjectNotAppendable	409	ObjectNotAppendable	The error message returned because the object is not appendable.

6.1.2.3. PHP-SDK

6.1.2.3.1. Preface

This topic provides the sample code of OSS SDK for PHP in various use cases.

Source code

For the source code of OSS SDK for PHP, visit GitHub.

Sample codes

OSS SDK for PHP provides a variety of sample code for your reference or use. The following table describes the sample codes.

Sample file	Description
Object.php	Shows you how to perform object-related operations, including upload, download, copy, delete, and list objects as well as object metadata-related operations.
MultipartUpload.php	Shows you how to upload large objects and perform multipart upload.
Signature.php	Shows you how to generate a signed URL to authorize access.
Callback.php	Shows you how to perform upload callback.
Image.php	Shows you how to use Image Processing (IMG).
LiveChannel.php	Shows you how to use LiveChannel.
Bucket.php	Shows you how to manage buckets, including create, delete, and list buckets as well as configure ACL for a bucket.
BucketLifecycle.php	Shows you how to configure, query, and delete the lifecycle rules for a bucket.
BucketLogging.php	Shows you how to configure, query, and delete the logging configurations for a bucket.
BucketReferer.php	Shows you how to configure, query, and delete the hotlink protection configurations for a bucket.
BucketWebsite.php	Shows you how to configure, query, and delete the static website hosting configurations for a bucket.
BucketCors.php	Shows you how to configure, query, and delete the CORS configurations for a bucket.

6.1.2.3.2. Installation

This topic describes how to install OSS SDK for PHP.

Preparation

OSS SDK for PHP is applicable to PHP 5.3 and later versions. This topic uses PHP 5.6.22 as an example.

- Install the environment

  You must install PHP and cURL extension:

  - If a message that indicates the specified module is unavailable is displayed, set extension_dir to `C:/Windows/System32/`.

- In Ubuntu, run the `sudo apt-get install php-curl` command to install the cURL extension of PHP by using apt-get.
- In CentOS, run the `sudo yum install php-curl` command to install the cURL extension of PHP by using yum.

- Check the PHP version
  - You can run the `php -v` command to view the current PHP version.
  - You can run the `php -m` command to check whether the cURL extension is installed.

Download OSS SDK for PHP

- Download from GitHub
- Download previous versions

For more information, see API Documentation.

Install OSS SDK for PHP

You can use one of the following method to install SDK:

- Composer
  i. Go to the root directory of your project and run the `composer require aliyuncs/oss-sdk-php` command or add the following dependency to the `composer.json` file:

```
"require": {
    "aliyuncs/oss-sdk-php": "~2.x.x"
}
```

  ii. Run the `composer install` command to install the dependency. After the dependency is installed, check whether your directory structure complies with the following structure:

```
.
├── app.php
├── composer.json
├── composer.lock
└── vendor
```

  In the preceding directory structure, `app.php` indicates your application, and the `vendor/` directory contains the dependent library. You need to add the following dependency to `app.php` :

```
require_once __DIR__ . '/vendor/autoload.php';
```

> **Note**
>
> - If `autoload.php` is imported to your project, you do not need to import it again after you add the dependency of OSS SDK for PHP.
> - If a network error occurs when you use Composer, you can use the image source of Composer China by running the `composer config -g repositories.packagist composer http://packagist.phpcomposer.com` command.

- PHAR
  i. Select the corresponding version and download the packaged PHAR file from GitHub.
  ii. Import the PHAR file in your code:

```
require_once '/path/to/oss-sdk-php.phar';
```

- Source code
  i. Select the required version and download the ZIP package from GitHub.
  ii. The decompressed root directory contains the `autoload.php` file. Import the file to the code:

```
require_once '/path/to/oss-sdk/autoload.php';
```

6.1.2.3.3. Initialization

An OSSClient serves as the OSS PHP client to manage OSS resources such as buckets and objects.

Create an OSSClient instance

To create an OSSClient instance, you must specify an endpoint. For more information about endpoints, see Obtain an endpoint.

To create an OSSClient, you must specify an AccessKey pair. For more information about how to obtain an AccessKey pair, see Obtain an AccessKey pair.

- Use an endpoint to create an OSSClient

  The following code provides an example on how to create an OSSClient instance based on an OSS endpoint. OSSClient supports concurrent tasks. Therefore, a project can contain one or more OSSClient instances.

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
} catch (OssException $e) {
    print $e->getMessage();
}
```

- Use STS to create an OSSClient

  The following code provides an example on how to create an OSSClient instance based on Security Token Service (STS):

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$securityToken = "<yourSecurityToken>";
try {
    $ossClient = new OssClient(
        $accessKeyId, $accessKeySecret, $endpoint, false, $securityToken);
} catch (OssException $e) {
    print $e->getMessage();
}
```

- Use a proxy server to create an OSSClient

  You can use a proxy server to create an OSSClient when you use OSS SDK for PHP version 5.3 and later. The following code provides an example on how to use a proxy server to create an OSSClient:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// Specify the IP address of the proxy server. Example: http://<username>:<password>@<pro
xyip>:<proxyport>.
$requestProxy = "<yourRequestProxy>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com>";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint, false, $request
Proxy);
} catch (OssException $e) {
    print $e->getMessage();
}
```

Configure network parameters

The following code provides an example on how to configure network parameters for an OSSClient:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
try {
    $ossClient = new OssClient(
        $accessKeyId, $accessKeySecret, $endpoint);
    // Set the timeout period for data transmission at the socket layer. Unit: seconds. Def
ault value: 5184000.
    $ossClient->setTimeout(3600);
    // Set the timeout period for connection establishment. Unit: seconds. Default value: 1
0.
    $ossClient->setConnectTimeout(10);
} catch (OssException $e) {
    print $e->getMessage();
}
```

6.1.2.3.4. Quick start

This topic describes how to use OSS SDK for PHP to perform routine operations, such as creating buckets, uploading objects, and downloading objects.

Create a bucket

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket = "<yourBucketName>";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->createBucket($bucket);
} catch (OssException $e) {
    print $e->getMessage();
}
```

For more information about how to obtain an AccessKey ID and AccessKey secret, see Obtain an AccessKey pair.

For more information about how to obtain an endpoint, see Obtain an endpoint.

Upload objects

The following code provides an example on how to upload objects to OSS by using stream upload:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= " <yourBucketName>";
// <yourObjectName> indicates the complete path of the object that you want to upload to OS
S. The path must include the extension of the object name. Example: abc/efg/123.jpg.
$object = " <yourObjectName>";
$content = "Hi, OSS.";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->putObject($bucket, $object, $content);
} catch (OssException $e) {
    print $e->getMessage();
}
```

Download objects

The following code provides an example on how to download an object:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= "<yourBucketName>";
// <yourObjectName> indicates the complete path of the object that you want to download fro
m OSS. The path must include the extension of the object name. Example: abc/efg/123.jpg.
$object = "<yourObjectName>";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $content = $ossClient->getObject($bucket, $object);
    print("object content: " . $content);
} catch (OssException $e) {
    print $e->getMessage();
}
```

List objects

The following code provides an example on how to list objects stored in a bucket named examplebucket. By default, a maximum of 100 objects are listed.

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= "<yourBucketName>";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $listObjectInfo = $ossClient->listObjects($bucket);
    $objectList = $listObjectInfo->getObjectList();
    if (! empty($objectList)) {
        foreach ($objectList as $objectInfo) {
        print($objectInfo->getKey() . "\t" . $objectInfo->getSize() . "\t" . $objectInfo->g
etLastModified() . "\n");
        }
    }
} catch (OssException $e) {
    print $e->getMessage();
}
```

Delete objects

The following code provides an example on how to delete an object:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= "<yourBucketName>";
// <yourObjectName> indicates the complete path of the object that you want to delete from
OSS. The path must include the extension of the object name. Example: abc/efg/123.jpg.
$object = "<yourObjectName>";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->deleteObject($bucket, $object);
} catch (OssException $e) {
    print $e->getMessage();
}
```

6.1.2.3.5. Buckets

6.1.2.3.5.1. Create buckets

A bucket is a container used to store objects in Object Storage Service (OSS). Each object is contained in a bucket. This topic describes how to create a bucket.

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= "<yourBucketName>";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    // Set the storage class of the bucket to Standard. The default storage class is Standa
rd.
    $options = array(
        OssClient::OSS_STORAGE => OssClient::OSS_STORAGE_Standard
    );
    // Set the ACL of the bucket to public read. The default bucket ACL is private.
    $ossClient->createBucket($bucket, OssClient::OSS_ACL_TYPE_PUBLIC_READ, $options);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

For the complete code used to create a bucket, visit GitHub.

6.1.2.3.5.2. List buckets

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $bucketListInfo = $ossClient->listBuckets();
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
$bucketList = $bucketListInfo->getBucketList();
foreach($bucketList as $bucket) {
    print($bucket->getLocation() . "\t" . $bucket->getName() . "\t" . $bucket->getCreatedat
e() . "\n");
}
```

6.1.2.3.5.3. Determine whether buckets exist

A bucket is a container used to store objects in Object Storage Service (OSS). Every object is contained in a bucket. This topic describes how to determine whether a bucket exists.

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= "<yourBucketName>";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $res = $ossClient->doesBucketExist($bucket);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
if ($res === true) {
    print(__FUNCTION__ . ": OK" . "\n");
} else {
    print(__FUNCTION__ . ": FAILED" . "\n");
}
```

6.1.2.3.5.4. Manage bucket ACLs

A bucket is a container used to store objects in Object Storage Service (OSS). Every object is contained in a bucket. This topic describes how to configure and query the access control list (ACL) of a bucket.

Configure ACL for a bucket

The following table describes the bucket ACLs.

ACL	Description	Value
Private	Only the owner or authorized users of the bucket can read and write the object.	OssClient::OSS_ACL_TYPE_PRIVATE
Public read	Only the owner or authorized users of this bucket can write the object. Other users, including anonymous users can only read the object. Exercise caution when you use this ACL.	OssClient::OSS_ACL_TYPE_PUBLIC_READ

ACL	Description	Value
Public read/write	Any users, including anonymous users can read and write the object. Exercise caution when you use this ACL.	OssClient::OSS_ACL_TYPE_PUBLIC_READ_WRITE

The following code provides an example on how to configure the ACL of a bucket:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= "<yourBucketName>";
// Set the ACL of the bucket to private.
$acl = OssClient::OSS_ACL_TYPE_PRIVATE;
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->putBucketAcl($bucket, $acl);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

Query the ACL of a bucket

The following code provides an example on how to query the ACL of a bucket:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= "<yourBucketName>";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $res = $ossClient->getBucketAcl($bucket);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
print('acl: ' . $res);
```

6.1.2.3.5.5. Delete buckets

Before you delete a bucket, ensure that all objects, LiveChannels, and parts that are generated from multipart upload in the bucket are deleted. The following code provides an example on how to delete a bucket:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= "<yourBucketName>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->deleteBucket($bucket);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

6.1.2.3.5.6. Manage lifecycle rules

Object Storage Service (OSS) allows you to configure lifecycle rules to delete expired objects and parts or convert the storage class of expired objects to Infrequent Access (IA) or Archive to reduce your storage costs. This topic describes how to manage lifecycle rules for buckets.

Background

Each lifecycle rule contains the following information:

- Policy: specifies the mode to match objects and parts.
  - Match by prefix: matches objects and parts by prefix. You can create multiple rules to configure different prefixes. Each prefix must be unique.
  - Match by bucket: matches all objects and parts contained in the bucket. You can create only one rule if you select this method.
- Object lifecycle policy: specifies the validity period or expiration data and the operation to perform on these objects after they expire.
  - Validity period: specifies the number of days within which parts can be retained after they are last modified. After the validity period, expired objects are deleted.
  - Expiration date: specifies a date. Objects that are last modified before this date expire and are deleted.
- Part lifecycle policy: specifies the validity period or expiration time and the delete operation to

perform on these objects after they expire.

- Validity period: specifies the number of days within which parts can be retained after they are last modified. After the validity period, expired parts are deleted.
- Expiration date: specifies a date. Parts that are last modified before this date expire and are deleted.

Lifecycle rules also apply to the parts uploaded by using uploadPart. In this case, the last modified time of an object is the time the multipart upload task is initiated.

Configure lifecycle rules

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
use OSS\Model\LifecycleConfig;
use OSS\Model\LifecycleRule;
use OSS\Model\LifecycleAction;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
// Set the rule ID and the prefix of the object names that match the rule.
$ruleId0 = "rule0";
$matchPrefix0 = "A0/";
$ruleId1 = "rule1";
$matchPrefix1 = "A1/";
$lifecycleConfig = new LifecycleConfig();
$actions = array();
// Specify that objects expire three days after they are last modified.
$actions[] = new LifecycleAction(OssClient::OSS_LIFECYCLE_EXPIRATION, OssClient::OSS_LIFECY
CLE_TIMING_DAYS, 3);
$lifecycleRule = new LifecycleRule($ruleId0, $matchPrefix0, "Enabled", $actions);
$lifecycleConfig->addRule($lifecycleRule);
$actions = array();
// Specify that the objects that are last modified before the specified date expire.
$actions[] = new LifecycleAction(OssClient::OSS_LIFECYCLE_EXPIRATION, OssClient::OSS_LIFECY
CLE_TIMING_DATE, '2022-10-12T00:00:00.000Z');
$lifecycleRule = new LifecycleRule($ruleId1, $matchPrefix1, "Enabled", $actions);
$lifecycleConfig->addRule($lifecycleRule);
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->putBucketLifecycle($bucket, $lifecycleConfig);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

View lifecycle rules

The following code provides an example on how to query the lifecycle rules configured for the bucket named examplebucket:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$lifecycleConfig = null;
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $lifecycleConfig = $ossClient->getBucketLifecycle($bucket);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
print($lifecycleConfig->serializeToXml() . "\n");
```

Delete lifecycle rules

The following code provides an example on how to delete lifecycle rules configured for the bucket named examplebucket:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->deleteBucketLifecycle($bucket);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

6.1.2.3.5.7. Configure hotlink protection

OSS provides hotlink protection to prevent unauthorized domain names from accessing your OSS data. You can configure the Referer field in the HTTP header.

To configure hotlink protection, you must configure the following parameters:

- Referer Whitelist: Only specified domain names are allowed to access OSS resources.
- Allow Empty Referer: If you do not allow empty Refer fields, a request is allowed to access OSS resources only if the request includes the Referer field configured in the HTTP or HTTPS header.

Configure hotlink protection

Run the following code to configure the referer whitelist:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
use OSS\Model\RefererConfig;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$refererConfig = new RefererConfig();
// Allow empty Referers.
$refererConfig->setAllowEmptyReferer(true);
// Add a Referer whitelist. You can use an asterisk (*) or a question mark (?) as a wildcar
d to set the Referer parameter.
$refererConfig->addReferer("www.aliiyun.com");
$refererConfig->addReferer("www.aliiyuncs.com");
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->putBucketReferer($bucket, $refererConfig);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

Query hotlink protection information

Run the following code to obtain a referer whiltelist:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
use OSS\Model\RefererConfig;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$refererConfig = null;
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $refererConfig = $ossClient->getBucketReferer($bucket);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
print($refererConfig->serializeToXml() . "\n");
```

Delete hotlink protection configurations

Run the following code to clear a referer whitelist:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
use OSS\Model\RefererConfig;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$refererConfig = new RefererConfig();
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    // You cannot delete hotlink protection configurations directly. To delete hotlink prot
ection configurations, you must create a rule that allows an empty Referer field to replace
the existing rule.
    $ossClient->putBucketReferer($bucket, $refererConfig);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

6.1.2.3.5.8. Configure logging

You can enable logging to record access to a bucket in log objects, which are stored in a specified bucket.

The log objects are in the following format: `<TargetPrefix><SourceBucket>-YYYY-mm-DD-HH-MM-SS-UniqueString`.

Enable logging

Run the following code to enable bucket access logging:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$option = array();
// Specify the bucket used to store log objects.
$targetBucket = "<yourBucketName>";
$targetPrefix = "access.log";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    // Enable logging.
    $ossClient->putBucketLogging($bucket, $targetBucket, $targetPrefix, $option);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

View logging configurations

Run the following code to view the access logging configurations for a bucket:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$loggingConfig = null;
$options = array();
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    // View the logging configurations.
    $loggingConfig = $ossClient->getBucketLogging($bucket, $options);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
print($loggingConfig->serializeToXml() . "\n");
```

Disable logging

Run the following code to disable access logging for a bucket:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    // Disable logging.
    $ossClient->deleteBucketLogging($bucket);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

6.1.2.3.5.9. Configure static website hosting

You can set the static website hosting mode for your bucket. After the configurations take effect, you can use the bucket domain name to access this static website and be redirected to a specified index page or error page.

For the complete static website hosting code, visit GitHub.

Configure static website hosting

Run the following code to configure static website hosting:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
use OSS\Model\WebsiteConfig;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
// Set the index page to index.html and the error page to error.html.
$websiteConfig = new WebsiteConfig("index.html", "error.html");
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->putBucketWebsite($bucket, $websiteConfig);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

View static website hosting configurations

Run the following code to view static website hosting configurations:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$websiteConfig = null;
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $websiteConfig = $ossClient->getBucketWebsite($bucket);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
print($websiteConfig->serializeToXml() . "\n");
```

Delete static website hosting configurations

Run the following code to delete static website hosting configurations:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->deleteBucketWebsite($bucket);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

6.1.2.3.5.10. Configure CORS

Cross-origin resource sharing (CORS) allows web applications to access resources that belong to different regions. OSS provides CORS operations to facilitate cross-origin access control.

For the complete CORS rule code, visit GitHub.

Configure CORS rules

Run the following code to configure CORS rules for the specified bucket:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
use OSS\Model\CorsConfig;
use OSS\Model\CorsRule;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$corsConfig = new CorsConfig();
$rule = new CorsRule();
// AllowedHeaders and ExposeHeaders do not support wildcards.
$rule->addAllowedHeader("x-oss-header");
// AllowedOlowedMethods allows only one wildcard asterisk (*). Asterisks (*) indicate that
all domain names or operations are allowed.
$rule->addAllowedOrigin("http://www.b.com");
$rule->addAllowedMethod("POST");
$rule->setMaxAgeSeconds(10);
// A maximum of 10 rules can be configured for each bucket.
$corsConfig->addRule($rule);
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    // The existing rules are replaced.
    $ossClient->putBucketCors($bucket, $corsConfig);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

Query CORS rules

Run the following code to obtain CORS rules:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$corsConfig = null;
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $corsConfig = $ossClient->getBucketCors($bucket);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
print($corsConfig->serializeToXml() . "\n");
```

Delete CORS rules

Run the following code to delete all CORS rules for a specified bucket:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->deleteBucketCors($bucket);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

6.1.2.3.6. Upload objects

6.1.2.3.6.1. Overview

Objects are the basic unit for data operations in OSS. OSS SDK for PHP provides a variety of methods to upload objects.

You can upload objects to OSS by using one of the following methods:

- Simple upload: uploads an object up to 5 GB in size.
- Append upload: uploads an object up to 5 GB in size.
- Multipart upload: uploads an object up to 48.8 TB in size. Use multipart upload for large objects.

6.1.2.3.6.2. Simple upload

In simple upload, you can upload strings or local files. This topic describes how to upload strings and local files.

String upload

The following code provides an example on how to upload a string to the exampleobject.txt object in the exampledir directory of the examplebucket bucket:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= "<yourBucketName>";
// Specify the object name.
$object = "<yourObjectName>";
// Configure the object content.
$content = "Hello OSS";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->putObject($bucket, $object, $content);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
// You can configure headers in upload requests to specify the information of the uploaded
object. For example, you can set the object ACL to private and configure the user metadata
of the object.
$options = array(
    OssClient::OSS_HEADERS => array(
        'x-oss-object-acl' => 'private',
        'x-oss-meta-info' => 'your info'
    ),
);
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->putObject($bucket, $object, $content, $options);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

Local file upload

The following code provides an example on how to upload a local file to OSS:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= "<yourBucketName>";
// Specify the object name.
$object = "<yourObjectName>";
// <yourLocalFile> consists of a local file path and a file name with an extension. Example
: /users/local/myfile.txt.
$filePath = "<yourLocalFile>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->uploadFile($bucket, $object, $filePath);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

6.1.2.3.6.3. Append upload

You can append strings and local files when you use append upload. The CopyObject operation cannot be performed on append objects.

Append strings

The following code provides an example on how to upload strings to OSS by using append upload:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= "<yourBucketName>";
// Specify the object name.
$object = "<yourObjectName>";
// Query the content of the object to upload.
$content_array = array('Hello OSS', 'Hi OSS', 'OSS OK');
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    // Start the first append. // If the object is appended for the first time, the append
position is 0. The return value is the position for the next append. The position to start
the next append is the total length of appended bytes and the append object.
    $position = $ossClient->appendObject($bucket, $object, $content_array[0], 0);
    $position = $ossClient->appendObject($bucket, $object, $content_array[1], $position);

    $position = $ossClient->appendObject($bucket, $object, $content_array[2], $position);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

Append local files

The following code provides an example on how to upload local files to OSS by using append upload:

```
 <? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
// Specify the bucket name.
$bucket= "<yourBucketName>";
// Specify the object name.
$object = "<yourObjectName>";
// Obtain Local File 1.
$filePath = "<yourLocalFile1>";
// Obtain Local File 2.
$filePath1 = "<yourLocalFile2>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $position = $ossClient->appendFile($bucket, $object, $filePath, 0);
    $position = $ossClient->appendFile($bucket, $object, $filePath1, $position);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

6.1.2.3.6.4. Multipart upload

OSS allows you to use multipart upload to split an object into several parts and upload them separately. After all parts are uploaded, you can combine the uploaded parts into a complete object to complete the upload.

To implement multipart upload, perform the following operations:

1. Initiate a multipart upload task.

   Call the ossClient.initiateMultipartUpload method to obtain a unique upload ID in OSS.

2. Upload the parts.

   Call the ossClient.uploadPart method to upload the parts.

> **Note**
>
> - Part numbers identify the relative positions of parts in an object that share the same upload ID. If you have uploaded a part and used its part number again to upload another part, the latter part overwrites the former part.
> - OSS includes the MD5 hash of part data in the ETag header and returns the MD5 hash to the user.
> - OSS calculates the MD5 hash of uploaded data and compares it with the MD5 hash calculated by the SDK. If the two hashes are different, the InvalidDigest error code is returned.

3. Complete the multipart upload task.

   After all parts are uploaded, call the ossClient.completeMultipartUpload method to combine these parts into a complete object.

For the complete multipart upload code, visit GitHub.

The following code provides a complete example that describes the process of multipart upload:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
use OSS\Core\OssUtil;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
$uploadFile = "<yourLocalFile>";
/**
 * Step 1. Initiate a multipart upload task and obtain the upload ID.
 */
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    // An upload ID is returned. It is the unique identifier for a multipart upload task. Y
ou can initiate related operations such as cancel or query a multipart upload task based on
the upload ID.
    $uploadId = $ossClient->initiateMultipartUpload($bucket, $object);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": initiateMultipartUpload FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": initiateMultipartUpload OK" . "\n");
/*
```

```
 * Step 2. Upload parts.
 */
$partSize = 10 * 1024 * 1024;
$uploadFileSize = filesize($uploadFile);
$pieces = $ossClient->generateMultiuploadParts($uploadFileSize, $partSize);
$responseUploadPart = array();
$uploadPosition = 0;
$isCheckMd5 = true;
foreach ($pieces as $i => $piece) {
    $fromPos = $uploadPosition + (integer)$piece[$ossClient::OSS_SEEK_TO];
    $toPos = (integer)$piece[$ossClient::OSS_LENGTH] + $fromPos - 1;
    $upOptions = array(
        $ossClient::OSS_FILE_UPLOAD => $uploadFile,
        $ossClient::OSS_PART_NUM => ($i + 1),
        $ossClient::OSS_SEEK_TO => $fromPos,
        $ossClient::OSS_LENGTH => $toPos - $fromPos + 1,
        $ossClient::OSS_CHECK_MD5 => $isCheckMd5,
    );
    // Perform the MD5 verification.
    if ($isCheckMd5) {
        $contentMd5 = OssUtil::getMd5SumForFile($uploadFile, $fromPos, $toPos);
        $upOptions[$ossClient::OSS_CONTENT_MD5] = $contentMd5;
    }
    try {
        // Upload the parts.
        $responseUploadPart[] = $ossClient->uploadPart($bucket, $object, $uploadId, $upOpti
ons);
    } catch(OssException $e) {
        printf(__FUNCTION__ . ": initiateMultipartUpload, uploadPart - part#{$i} FAILED\n")
;
        printf($e->getMessage() . "\n");
        return;
    }
    printf(__FUNCTION__ . ": initiateMultipartUpload, uploadPart - part#{$i} OK\n");
}
// $uploadParts is an array that consists of the ETags and the PartNumbers of each part.
$uploadParts = array();
foreach ($responseUploadPart as $i => $eTag) {
    $uploadParts[] = array(
        'PartNumber' => ($i + 1),
        'ETag' => $eTag,
    );
}
/**
 * Step 3. Complete the multipart upload task.
 */
try {
    // You must provide all valid $uploadParts when you perform this operation. OSS verifie
s the validity of each part after it receives the submitted $uploadParts. After all parts a
re verified, OSS combines these parts into a complete object.
    $ossClient->completeMultipartUpload($bucket, $object, $uploadId, $uploadParts);
}  catch(OssException $e) {
    printf(__FUNCTION__ . ": completeMultipartUpload FAILED\n");
    printf($e->getMessage() . "\n");
```

```
    return;
}
printf(__FUNCTION__ . ": completeMultipartUpload OK\n");
```

The following table describes the parameters contained in $options from the preceding sample code.

Parameter	Description
$ossClient::OSS_FILE_UPLOAD	Uploads the object.
OssClient::OSS_PART_NUM	The part number.
OssClient::OSS_SEEK_TO	The start position.
OssClient::OSS_LENGTH	The size of the object.
OssClient::OSS_PART_SIZE	The size of each part.
OssClient::OSS_CHECK_MD5	Specifies whether to enable MD5 verification. A value of true indicates that the MD5 verification is enabled.

Cancel a multipart upload task

You can call $ossClient->abortMultipartUpload to cancel a multipart upload task. If you cancel a multipart upload task, you cannot use the upload ID to perform any operations on the parts. The uploaded parts are deleted.

The following code provides an example on how to cancel a multipart upload task:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
$upload_id = "<yourUploadId>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->abortMultipartUpload($bucket, $object, $upload_id);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

Multipart upload of local files

The following code provides an example on how to upload a local file to OSS by using multipart upload:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
$file = "<yourLocalFile>";
$options = array(
    OssClient::OSS_CHECK_MD5 => true,
    OssClient::OSS_PART_SIZE => 1,
);
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->multiuploadFile($bucket, $object, $file, $options);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ":  OK" . "\n");
```

Multipart upload of local folders

The following code provides an example on how to upload a local folder including all files in the folder to OSS by using multipart upload:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$localDirectory = ".";
$prefix = "samples/codes";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->uploadDir($bucket, $prefix, $localDirectory);
}  catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ":  OK" . "\n");
```

List uploaded parts

The following code provides an example on how to list uploaded parts:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
$uploadId = "<yourUploadId>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $listPartsInfo = $ossClient->listParts($bucket, $object, $uploadId);
    foreach ($listPartsInfo->getListPart() as $partInfo) {
        print($partInfo->getPartNumber() . "\t" . $partInfo->getSize() . "\t" . $partInfo->
getETag() . "\t" . $partInfo->getLastModified() . "\n");
    }
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

List multipart upload tasks

The following code provides an example on how to list multipart upload tasks:

```
<? php
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$options = array(
    'delimiter' => '/',
    'max-uploads' => 100,
    'key-marker' => '',
    'prefix' => '',
    'upload-id-marker' => ''
);
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $listMultipartUploadInfo = $ossClient->listMultipartUploads($bucket, $options);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": listMultipartUploads FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
printf(__FUNCTION__ . ": listMultipartUploads OK\n");
$listUploadInfo = $listMultipartUploadInfo->getUploads();
var_dump($listUploadInfo);
```

The following table describes the parameters contained in $options from the preceding sample code.

Parameter	Description
delimiter	Groups objects by name. Objects whose names contain the same string from the prefix and the next occurrence of the delimiter are grouped as a single result element in CommonPrefixes.
key-marker	All multipart upload tasks with objects whose names start with the letter that comes after the key-marker value in the alphabetical order. You can use key-marker and upload-id-marker together to specify the position after which the next list begins.
max-uploads	The maximum number of multipart upload tasks to list this time. The default value is 1000. The maximum value is 1000.

Parameter	Description
prefix	Specifies the prefix that returned object names must contain. Note that if you use a prefix for a query, the returned object names contain the prefix.
upload-id-marker	The upload ID of the multipart upload task after which the list begins. This parameter is used together with the key-marker parameter. If key-marker is not configured, upload-id-marker is invalid. If the key-marker parameter is configured, the query result includes: • All objects whose names start with a letter that comes after the key-marker parameter value in alphabetical order. • All objects whose names start with the letter the same as the value of key-marker. The value of uploadId is greater than that of upload-id-marker.

6.1.2.3.6.5. Upload callback

This topic describes how to use upload callback in simple upload and multipart upload.

Configure callback for simple upload

The following code provides an example on how to configure callback for simple upload:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
$ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
// Configure callback for upload.
// callbackUrl is the IP address of the callback server. Examples: http://oss-demo.aliyuncs
.com:23450 and http://127.0.0.1:9090.
// Optional. callbackHost is the value of the host field carried in the callback request.
$url =
    '{
        "callbackUrl":"<yourCallbackServerUrl>",
        "callbackHost":"<yourCallbackServerHost>",
        "callbackBody":"bucket=${bucket}&object=${object}&etag=${etag}&size=${size}&mimeTyp
e=${mimeType}&imageInfo.height=${imageInfo.height}&imageInfo.width=${imageInfo.width}&image
Info.format=${imageInfo.format}&my_var1=${x:var1}&my_var2=${x:var2}",
        "callbackBodyType":"application/x-www-form-urlencoded"
    }';
// Configure custom parameters for the callback request. Each custom parameter consists of
a key and a value. The key must start with x:.
$var =
    '{
        "x:var1":"value1",
        "x:var2":"value2"
    }';
$options = array(OssClient::OSS_CALLBACK => $url,
    OssClient::OSS_CALLBACK_VAR => $var
);
$result = $ossClient->putObject($bucket, $object, file_get_contents(__FILE__), $options);
print_r($result['body']);
print_r($result['info']['http_code']);
```

Configure callback for multipart upload

The following code provides an example on how to configure callback for multipart upload:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
```

```
/
use OSS\OssClient;
use OSS\Core\OssException;
use OSS\Core\OssUtil;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
$uploadFile = "<yourLocalFile>";
/**
 * Step 1. Initiate a multipart upload task and obtain the uploadId.
 */
$ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
// An upload ID is returned. It is the unique identifier for a multipart upload task. You c
an initiate related operations such as cancel or query a multipart upload task based on the
upload ID.
$uploadId = $ossClient->initiateMultipartUpload($bucket, $object);
print(__FUNCTION__ . ": initiateMultipartUpload OK" . "\n");
/*
 * Step 2. Upload parts.
 */
$partSize = 10 * 1024 * 1024;
$uploadFileSize = filesize($uploadFile);
$pieces = $ossClient->generateMultiuploadParts($uploadFileSize, $partSize);
$responseUploadPart = array();
$uploadPosition = 0;
$isCheckMd5 = true;
foreach ($pieces as $i => $piece) {
    $fromPos = $uploadPosition + (integer)$piece[$ossClient::OSS_SEEK_TO];
    $toPos = (integer)$piece[$ossClient::OSS_LENGTH] + $fromPos - 1;
    $upOptions = array(
        $ossClient::OSS_FILE_UPLOAD => $uploadFile,
        $ossClient::OSS_PART_NUM => ($i + 1),
        $ossClient::OSS_SEEK_TO => $fromPos,
        $ossClient::OSS_LENGTH => $toPos - $fromPos + 1,
        $ossClient::OSS_CHECK_MD5 => $isCheckMd5,
    );
    // Perform the MD5 verification.
    if ($isCheckMd5) {
        $contentMd5 = OssUtil::getMd5SumForFile($uploadFile, $fromPos, $toPos);
        $upOptions[$ossClient::OSS_CONTENT_MD5] = $contentMd5;
    }
    try {
        // Upload the parts.
        $responseUploadPart[] = $ossClient->uploadPart($bucket, $object, $uploadId, $upOpti
ons);
    } catch(OssException $e) {
        printf(__FUNCTION__ . ": initiateMultipartUpload, uploadPart - part#{$i} FAILED\n")
;
        printf($e->getMessage() . "\n");
        return;
    }
```

```
    printf(__FUNCTION__ . ": initiateMultipartUpload, uploadPart - part#{$i} OK\n");
}
// $uploadParts is an array that consists of the ETags and the PartNumbers of each part.
$uploadParts = array();
foreach ($responseUploadPart as $i => $eTag) {
    $uploadParts[] = array(
        'PartNumber' => ($i + 1),
        'ETag' => $eTag,
    );
}
/**
 * Step 3. Complete the multipart upload task.
 */
// callbackUrl is the IP address of the callback server. Examples: http://oss-demo.aliyuncs
.com:23450 and http://127.0.0.1:9090.
// Optional. callbackHost is the value of the host field carried in the callback request.
$json =
    '{
        "callbackUrl":"<yourCallbackServerUrl>",
        "callbackHost":"<yourCallbackServerHost>",
        "callbackBody":"{\"mimeType\":${mimeType},\"size\":${size},\"x:var1\":${x:var1},\"x
:var2\":${x:var2}}",
        "callbackBodyType":"application/json"
    }';
// Configure custom parameters for the callback request. Each custom parameter consists of
a key and a value. The key must start with x:.
$var =
    '{
        "x:var1":"value1",
        "x:var2":"value2"
    }';
$options = array(OssClient::OSS_CALLBACK => $json,
    OssClient::OSS_CALLBACK_VAR => $var);
// You must provide all valid $uploadParts when you perform this operation. OSS verifies th
e validity of each part after it receives the submitted $uploadParts. After all parts are v
erified, OSS combines these parts into a complete object.
$ossClient->completeMultipartUpload($bucket, $object, $uploadId, $uploadParts, $options);
printf(__FUNCTION__ . ": completeMultipartUpload OK\n");
```

6.1.2.3.7. Download objects

6.1.2.3.7.1. Overview

Objects are the basic unit for data operations in OSS. OSS SDK for PHP provides a variety of methods to download objects.

You can use one of the following methods to download objects:

- Download to local files
- Download objects to local memory
- Range download

- Conditional download

6.1.2.3.7.2. Download to local files

This topic describes how to use OSS SDK for PHP to download specific objects to local files.

The following code provides an example on how to download a specific object to a local file:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
// <yourObjectName> indicates the complete path of the object you want to download from OSS
. The path must include the extension of the object name. Example: abc/efg/123.jpg.
$object = "<yourObjectName>";
// <yourLocalFile> consists of a local file path and a file name with an extension. Example
: /users/local/myfile.txt.
$localfile = "<yourLocalFile>";
$options = array(
        OssClient::OSS_FILE_DOWNLOAD => $localfile
    );
// Use try catch to catch exceptions. If an exception is returned, the download fails. If n
o exceptions are returned, the object is downloaded.
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->getObject($bucket, $object, $options);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK, please check localfile: 'upload-test-object-name.txt'" . "\n");
```

6.1.2.3.7.3. Download objects to local memory

This topic describes how to use OSS SDK for PHP to download specified objects to local memory.

The following code provides an example on how to download a specified object to local memory and display the content of the object:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
// Specify the object name.
$object = "<yourObjectName>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $content = $ossClient->getObject($bucket, $object);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print($content);
print(__FUNCTION__ . ": OK" . "\n");
```

Note If a power outage occurs, data stored in the memory is lost. For more information about how to store the downloaded object in a local disk, see Download to local files.

6.1.2.3.7.4. Range download

If you need only part of the data in an object, you can use range download to download data within the specified range.

The following code provides an example on how to download data within the range from byte 0 to byte 4 in an object to local memory:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
// Query the data within the range from byte 0 to byte 4, including a total of 5 bytes of d
ata. If the specified range is invalid, for example, the specified range includes a negativ
e number, or the specified value is larger than the object size, the entire object is downl
oaded.
$options = array(OssClient::OSS_RANGE => '0-4');
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $content = $ossClient->getObject($bucket, $object, $options);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print ($content);
print(__FUNCTION__ . ": OK" . "\n");
```

6.1.2.3.7.5. Conditional download

OSS allows you to configure one or more conditions for object download. If the specified conditions are met, the object is downloaded. If the specified conditions are not met, an error is returned and the object is not downloaded.

The following table describes the conditions that you can configure for object download.

Parameter	Description	Configuration method
If-Modified-Since	If the specified time is earlier than the time the object is modified, the object is downloaded. Otherwise, 304 Not modified is returned.	OssClient::OSS_IF_MODIFIED_SINCE

Parameter	Description	Configuration method
If-Unmodified-Since	If the specified time is later than or equal to the time the object is modified, the object is downloaded. Otherwise, 412 Precondition failed is returned.	OssClient::OSS_IF_UNMODIFIED_SINCE
If-Match	If the specified ETag matches that of an object, the object is downloaded. Otherwise, 412 Precondition failed is returned.	OssClient::OSS_IF_MATCH
If-None-Match	If the specified ETag does not match that of an object, the object is downloaded. Otherwise, 304 Not modified is returned.	OssClient::OSS_IF_NONE_MATCH

> **Note**
>
> - You can use If-Modified-Since and If-Unmodified-Since as object download conditions at the same time. You can use If-Match and If-None-Match as object download conditions at the same time.
> - You can use $ossClient->getObjectMeta to obtain the ETag.

You can use conditional download to download objects to the local file or local memory. The following code provides an example on how to perform conditional download:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
try{
    $options = array(
        OssClient::OSS_HEADERS => array(
            OssClient::OSS_IF_MODIFIED_SINCE => "Fri, 13 Nov 2015 14:47:53 GMT"),
    );
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $content = $ossClient->getObject($bucket, $object, $options);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print ($content);
print(__FUNCTION__ . ": OK" . "\n");
```

6.1.2.3.8. Manage objects

6.1.2.3.8.1. Overview

You can manage objects in a bucket by using a variety of operations including SetObjectAcl, GetObjectAcl, ListObjects, DeleteObject, and CopyObject.

By using the preceding operations, you can perform the following operations:

- Determine whether objects exist
- Manage object ACLs
- Manage object metadata
- List objects
- Delete objects
- Copy an object

6.1.2.3.8.2. Determine whether objects exist

This topic describes how to determine whether an object exists.

Use the following code to determine whether a specified object exists:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $exist = $ossClient->doesObjectExist($bucket, $object);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
var_dump($exist);
```

6.1.2.3.8.3. Manage object ACLs

This topic describes how to manage the access control list (ACL) of an object.

The following table describes the ACLs that can be configured for an object.

ACL	Description	Value
Inherited from the bucket	The ACL of an object is the same as that of the bucket to which the object belongs.	default
Private	Only the owner or authorized users of the bucket can read and write the object.	private
Public read	Only the owner or authorized users of this bucket can write the object. Other users, including anonymous users can only read the object. Exercise caution when you use this ACL.	public-read

ACL	Description	Value
Public read/write	Any users, including anonymous users can read and write the object. Exercise caution when you use this ACL.	public-read-write

The ACL of objects take precedence over that of buckets. For example, if the ACL of a bucket is private, while the object ACL is public read-write, all users can read and write the object. If an object is not configured with an ACL, its ACL is the same as that of its bucket by default.

Configure ACL for an object

You can run the following code to configure an ACL for a specified object:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
// Set the ACL for the object to public read. By default, the ACL for the object inherit th
e ACL for the bucket.
$acl = "public-read";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->putObjectAcl($bucket, $object, $acl);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

Query the ACL for an object

You can run the following code to obtain the ACL for a specified object:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $objectAcl = $ossClient->getObjectAcl($bucket, $object);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
var_dump($objectAcl);
```

6.1.2.3.8.4. Manage object metadata

This topic describes how to manage object metadata.

Configure object metadata

The following code provides an example on how to configure object metadata:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
$content = file_get_contents(__FILE__);
$options = array(
    OssClient::OSS_HEADERS => array(
        'Expires' => '2012-10-01 08:00:00',
        'Content-Disposition' => 'attachment; filename="xxxxxx"',
        'x-oss-meta-self-define-title' => 'user define meta info',
    ));
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->putObject($bucket, $object, $content, $options);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

Modify object metadata

The following code provides an example on how to modify object metadata:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$fromBucket = "<yourFromBucketName>";
$fromObject = "<yourFromObjectName>";
$toBucket = "<yourToBucketName>";
$toObject = "<yourToObjectName>";
$copyOptions = array(
    OssClient::OSS_HEADERS => array(
        'Expires' => '2018-10-01 08:00:00',
        'Content-Disposition' => 'attachment; filename="xxxxxx"',
        'x-oss-meta-location' => 'location',
    ),
);
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->copyObject($fromBucket, $fromObject, $toBucket, $toObject, $copyOptions);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

Query object metadata

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $objectMeta = $ossClient->getObjectMeta($bucket, $object);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
if (isset($objectMeta[strtolower('Content-Disposition')]) &&
    'attachment; filename="xxxxxx"' === $objectMeta[strtolower('Content-Disposition')]
) {
    print(__FUNCTION__ . ": ObjectMeta checked OK" . "\n");
} else {
    print(__FUNCTION__ . ": ObjectMeta checked FAILED" . "\n");
}
```

6.1.2.3.8.5. List objects

This topic describes how to list all objects or objects that meet specific conditions in a specified bucket.

List all objects

The following code provides an example on how to list all the objects in a specified bucket:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
$nextMarker = '';
while (true) {
    try {
        $options = array(
            'delimiter' => '',
            'marker' => $nextMarker,
        );
        $listObjectInfo = $ossClient->listObjects($bucket, $options);
    } catch (OssException $e) {
        printf(__FUNCTION__ . ": FAILED\n");
        printf($e->getMessage() . "\n");
        return;
    }
    // Obtain nextMarker to list the remaining objects. The reading starts from the object
next to the last object previously obtained through the listObjects operation.
    $nextMarker = $listObjectInfo->getNextMarker();
    $listObject = $listObjectInfo->getObjectList();
    $listPrefix = $listObjectInfo->getPrefixList();
    if (! empty($listObject)) {
        print("objectList:\n");
        foreach ($listObject as $objectInfo) {
            print($objectInfo->getKey() . "\n");
        }
    }
    if (! empty($listPrefix)) {
        print("prefixList: \n");
        foreach ($listPrefix as $prefixInfo) {
            print($prefixInfo->getPrefix() . "\n");
        }
    }
    if ($listObjectInfo->getIsTruncated() ! == "true") {
       break;
    }
}
```

Note

- In the preceding sample code, $options is optional and can be used to list all objects in the entire bucket or in a folder.
- The listObjects method is used to obtain a list of objects. For information about how to obtain attributes such as the name and size of an object, see Manage object metadata.

List the objects that meet specific conditions

The following code provides an example on how to list objects that meet specific conditions:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
$prefix = 'dir/';
$delimiter = '/';
$nextMarker = '';
$maxkeys = 10;
$options = array(
    'delimiter' => $delimiter,
    'prefix' => $prefix,
    'max-keys' => $maxkeys,
    'marker' => $nextMarker,
);
try {
    $listObjectInfo = $ossClient->listObjects($bucket, $options);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
$objectList = $listObjectInfo->getObjectList(); // object list
$prefixList = $listObjectInfo->getPrefixList(); // directory list
if (! empty($objectList)) {
    print("objectList:\n");
    foreach ($objectList as $objectInfo) {
        print($objectInfo->getKey() . "\n");
    }
}
if (! empty($prefixList)) {
    print("prefixList: \n");
    foreach ($prefixList as $prefixInfo) {
        print($prefixInfo->getPrefix() . "\n");
    }
}
```

The following table describes the parameters contained in $options from the preceding sample code.

Parameter	Description	Required
delimiter	Specifies the character used to group objects by name. CommonPrefixes specifies a set of substrings of objects whose names share a specific prefix and end with the next occurrence of the specified delimiter.	No
prefix	Specifies the prefix that the returned object names must contain.	No
max-keys	Specifies the maximum number of objects that can be listed each time. The default value is 100. The maximum value is 1000.	No
marker	Specifies the name of the object after which the list begins.	No

6.1.2.3.8.6. Delete objects

This topic describes how to delete objects.

Note

Delete a single object

The following code provides an example on how to delete an object named *exampleobject.txt* from a bucket named examplebucket:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->deleteObject($bucket, $object);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

Delete multiple objects

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$objects = array();
$objects[] = "<yourObjectName1>";
$objects[] = "<yourObjectName2>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->deleteObjects($bucket, $objects);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

Note If you use try{}catch{} and an exception is returned, a single object or multiple objects fail to be deleted. You can use $e->getMessage to obtain the error message and analyze causes.

6.1.2.3.8.7. Copy an object

This topic describes how to copy an object.

Object copy has the following limits:

- You must have read permissions on the source object and write permissions on the destination bucket.
- You cannot copy an object across regions.

Copy a small object

You can call $ossClient->copyObject to copy an object smaller than or equal to 1 GB from the source bucket to the destination bucket within the same region.

The following code provides an example on how to copy a small object:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$from_bucket = "<yourFromBucketName>";
$from_object = "<yourFromObjectName>";
$to_bucket = $bucket;
$to_object = $from_object . '.copy';
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $ossClient->copyObject($from_bucket, $from_object, $to_bucket, $to_object);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

Copy a large object

To copy an object larger than 1 GB, you must split the object into smaller parts and copy them sequentially by using UploadPartCopy. To implement multipart copy, perform the following operations:

1. Call $ossClient->initiateMultipartUpload to initiate a multipart copy task.
2. Call $ossClient->uploadPartCopy to perform multipart copy. All parts except for the last part, must be larger than 100 KB.
3. Call $ossClient->completeMultipartUpload to complete the multipart copy task.

The following code provides an example on how to perform multipart copy:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
```

```
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$src_bucket = "<yourSourceBucketName>";
$src_object = "<yourSourceObjectName>";
$dst_bucket = "<yourDestinationBucketName>";
$dst_object = "<yourDestinationObjectName>";
// Set the part size.
$part_size = 256*1024*1024;
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
    $objectMeta = $ossClient->getObjectMeta($src_bucket, $src_object);
    $length = $objectMeta['content-length'] + 0;
    // Initiate a multipart copy task.
    $upload_id = $ossClient->initiateMultipartUpload($dst_bucket, $dst_object);
    // Copy each part sequentially.
    $pieces = $ossClient->generateMultiuploadParts($length, $part_size);
    $response_upload_part = array();
    $copyId = 1;
    $upload_position = 0;
    foreach ($pieces as $i => $piece) {
        $from_pos = $upload_position + (integer)$piece['seekTo'];
        $to_pos = (integer)$piece['length'] + $from_pos - 1;
        $up_options = array(
            'start' => $from_pos,
            'end' => $to_pos,
        );
        $response_upload_part[] = $ossClient->uploadPartCopy( $src_bucket, $src_object, $dst_bucket, $dst_object, $copyId, $upload_id, $up_options);
        $copyId = $copyId + 1;
    }
    // Complete the multipart copy task.
    $upload_parts = array();
    foreach ($response_upload_part as $i => $etag) {
        $upload_parts[] = array(
            'PartNumber' => ($i + 1),
            'ETag' => $etag,
        );
    }
    $result = $ossClient->completeMultipartUpload($dst_bucket, $dst_object, $upload_id, $upload_parts);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": OK" . "\n");
```

6.1.2.3.9. Authorized access

This topic describes how to use Security Token Service (STS) and a signed URL to authorize access.

Use STS to authorize temporary access

Alibaba Cloud STS is a web service that provides a temporary access token to a cloud computing user. You can use STS to grant a third-party application or your RAM user an access credential with a customized validity period and permissions.

STS has the following benefits:

- You need only to generate an access token and send the access token to a third-party application, instead of exposing your long-term AccessKey pair to the third-party application. You can customize the access permissions and validity period of this token.
- The access token automatically expires when the validity period ends.

The following code provides an example on how to create a signature request by using STS:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
$securityToken = "<yourSecurityToken>";
$content = "Hi, OSS.";
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint, false, $securityT
oken);
    $ossClient->putObject($bucket, $object, $content);
} catch (OssException $e) {
    print $e->getMessage();
}
```

Use a signed URL to authorize temporary access

You can generate a signed URL and provide the URL to a visitor for temporary access. When you generate a signed URL, you can specify the validity period of the URL to limit the period of access from visitors. By default, the validity period of a signed URL is 3,600 seconds. The maximum validity period of a signed URL is 32,400 seconds.

For the complete code of authorized access, visit GitHub.

- Generate a signed URL to download an object

  The following code provides an example on how to generate a signed URL to download an object:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
use OSS\Http\RequestCore;
use OSS\Http\ResponseCore;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
$securityToken = "<yourSecurityToken>";
// Set the validity period of a URL to 3,600 seconds.
$timeout = 3600;
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint, false, $securit
yToken);
    // Generate the signed URL for GetObject.
    $signedUrl = $ossClient->signUrl($bucket, $object, $timeout);
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": signedUrl: " . $signedUrl . "\n");
// You can run code to access the signed URL, or access the signed URL in a browser.
$request = new RequestCore($signedUrl);
// Set GET as the default method to access the singed URL.
$request->set_method('GET');
$request->add_header('Content-Type', '');
$request->send_request();
$res = new ResponseCore($request->get_response_header(), $request->get_response_body(), $
request->get_response_code());
if ($res->isOK()) {
    print(__FUNCTION__ . ": OK" . "\n");
} else {
    print(__FUNCTION__ . ": FAILED" . "\n");
};
```

- Generate a signed URL to upload an object

  The following code provides an example on how to generate a signed URL to upload an object:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
use OSS\Core\OssException;
use OSS\Http\RequestCore;
use OSS\Http\ResponseCore;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
$securityToken = "<yourSecurityToken>";
$timeout = 3600;
try {
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint, false, $securit
yToken);
    // Generate the signed URL for PutObject.
    $signedUrl = $ossClient->signUrl($bucket, $object, $timeout, "PUT");
} catch (OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print(__FUNCTION__ . ": signedUrl: " . $signedUrl . "\n");
$content = "Hello OSS.";
$request = new RequestCore($signedUrl);
// Set PUT as the default method to access the signed URL.
$request->set_method('PUT');
$request->add_header('Content-Type', '');
$request->add_header('Content-Length', strlen($content));
$request->set_body($content);
$request->send_request();
$res = new ResponseCore($request->get_response_header(),
    $request->get_response_body(), $request->get_response_code());
if ($res->isOK()) {
    print(__FUNCTION__ . ": OK" . "\n");
} else {
    print(__FUNCTION__ . ": FAILED" . "\n");
};
```

6.1.2.3.10. IMG

OSS Image Processing (IMG) is a secure, cost-effective, and highly reliable image processing service that can process large amounts of data. After you upload source images to OSS, you can call RESTful API operations to process the images anytime, anywhere, and on any Internet device.

For the complete IMG code, visit GitHub.

Basic features

OSS IMG provides the following features:

- Query image information.
- Convert image formats.
- Resize, crop, and rotate images.
- Apply image effect.
- Add image, text, and text-and-image watermarks to images.
- Customize image processing styles. Log on to the OSS console. Click a bucket name to go to the bucket details page. Click the **Image Processing (IMG)** tab and click **Create Rule** to customize an image processing style.
- Use cascade processing to call multiple IMG features.

Usage

You can use standard `HTTP GET` requests to access IMG. All processing parameters are encoded in the query string of a URL.

If the ACL of an image object is public-read, as described in the following table, anonymous users can access the image object.

Bucket ACL	Object ACL
public-read or public-read-write	default
Any ACL	public-read or public-read-write

You can anonymously access IMG by using a third-level domain in the following format:

```
http://bucket.<endpoint>/object?x-oss-process=image/action,parame_value
```

Parameter	Description
bucket	The name of the bucket.
endpoint	The domain name used to access the region.
object	The name of the image object.
image	The identifier reserved by IMG.
action	The operations performed on images, such as scaling, cropping, and rotating.

Parameter	Description
param	The parameters corresponding to the operations performed on the images.

- Basic operations

  For example, you can scale an image to a width of 100 and adjust the height based on the ratio:

  ```
  http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100
  ```

- Customize an image style

  You can anonymously access IMG by using a third-level domain in the following format:

  ```
  http://<yourBucketName>.<yourEndpoint>/<yourObjectName>?x-oss-process=style/<yourStyleName>
  ```

  - style: the identifier reserved by IMG for the custom style.
  - yourStyleName: the name of the custom style. The name is specified by the Rule Name parameter when you create the custom style in the console.

  Example:

  ```
  http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=style/oss-pic-style-w-100
  ```

- Cascade processing

  You can use cascade processing to perform multiple operations in sequence on an image by using a URL in the following format:

  ```
  http://<yourBucketName>.<yourEndpoint>/<yourObjectName>?x-oss-process=image/<yourAction1>,<yourParamValue1>/<yourAction2>,<yourParamValue2>/...
  ```

  Example:

  ```
  http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100/rotate,90
  ```

- Access by using HTTPS

  IMG supports access by using HTTPS. Example:

  ```
  https://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100
  ```

- Authorized access

  If the ACL of an image object is private, you must have permissions on the image object before you can perform operations on the image object.

Bucket ACL	Object ACL
private	default

Bucket ACL	Object ACL
Any ACL	private

The following code provides an example on how to generate a signed URL to access IMG:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actua
l endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
$object = "<yourObjectName>";
$ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
// Generate a signed URL that you can directly access by using a browser. The validity pe
riod of the URL is 3,600 seconds.
$timeout = 3600;
$options = array(
    OssClient::OSS_PROCESS => "image/resize,m_lfit,h_100,w_100" );
$signedUrl = $ossClient->signUrl($bucket, $object, $timeout, "GET", $options);
print("rtmp url: \n" . $signedUrl);
```

- Access by using SDKs

  You can use OSS SDKs to access and process the image objects of any ACL.

  - Basic operations

    The following code provides an example on how to perform basic IMG operations including obtaining image information, converting image formats, resizing, cropping, rotating, watermarking, and applying effects:

    ```
    <? php
    if (is_file(__DIR__ . '/../autoload.php')) {
        require_once __DIR__ . '/../autoload.php';
    }
    if (is_file(__DIR__ . '/../vendor/autoload.php')) {
        require_once __DIR__ . '/../vendor/autoload.php';
    }
    use OSS\OssClient;
    $accessKeyId = "<yourAccessKeyId>";
    $accessKeySecret = "<yourAccessKeySecret>";
    // The endpoint of the China (Hangzhou) region is used in this example. Specify the act
    ual endpoint.
    $endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
    $bucket = "<yourBucketName>";
    ```

```
$object = "<yourObjectName>";
$download_file = "download.jpg";
$ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
// Upload a sample image.
$ossClient->uploadFile($bucket, $object, "example.jpg");
// Resize the image.
$options = array(
    OssClient::OSS_FILE_DOWNLOAD => $download_file,
    OssClient::OSS_PROCESS => "image/resize,m_fixed,h_100,w_100" );
$ossClient->getObject($bucket, $object, $options);
// Crop the image.
$options = array(
    OssClient::OSS_FILE_DOWNLOAD => $download_file,
    OssClient::OSS_PROCESS => "image/crop,w_100,h_100,x_100,y_100,r_1" );
$ossClient->getObject($bucket, $object, $options);
// Rotate the image.
$options = array(
    OssClient::OSS_FILE_DOWNLOAD => $download_file,
    OssClient::OSS_PROCESS => "image/rotate,90" );
$ossClient->getObject($bucket, $object, $options);
// Sharpen the image.
$options = array(
    OssClient::OSS_FILE_DOWNLOAD => $download_file,
    OssClient::OSS_PROCESS => "image/sharpen,100" );
$ossClient->getObject($bucket, $object, $options);
// Add watermarks to the image.
$options = array(
    OssClient::OSS_FILE_DOWNLOAD => $download_file,
    OssClient::OSS_PROCESS => "image/watermark,text_SGVsbG8g5Zu-54mH5pyN5YqhIQ" );
$ossClient->getObject($bucket, $object, $options);
// Convert the image format.
$options = array(
    OssClient::OSS_FILE_DOWNLOAD => $download_file,
    OssClient::OSS_PROCESS => "image/format,png" );
$ossClient->getObject($bucket, $object, $options);
// Obtain the image information.
$options = array(
    OssClient::OSS_FILE_DOWNLOAD => $download_file,
    OssClient::OSS_PROCESS => "image/info" );
$ossClient->getObject($bucket, $object, $options);
// Delete the sample image.
$ossClient->deleteObject($bucket, $object);
```

- Custom image styles

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the act
ual endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket = "<yourBucketName>";
$object = "<yourObjectName>";
$download_file = "download.jpg";
$ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
// Upload a sample image.
$ossClient->uploadFile($bucket, $object, "example.jpg");
// Customize the image style.
$style = "style/oss-pic-style-w-300";
$options = array(
    OssClient::OSS_FILE_DOWNLOAD => $download_file,
    OssClient::OSS_PROCESS => $style);
$ossClient->getObject($bucket, $object, $options);
// Delete the sample image.
$ossClient->deleteObject($bucket, $object);
```

- Cascade processing

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the act
ual endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket = "<yourBucketName>";
$object = "<yourObjectName>";
$download_file = "download.jpg";
$ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint, false);
// Upload a sample image.
$ossClient->uploadFile($bucket, $object, "example.jpg");
// Perform cascade processing.
$style = "image/resize,m_fixed,w_100,h_100/rotate,90";
$options = array(
    OssClient::OSS_FILE_DOWNLOAD => $download_file,
    OssClient::OSS_PROCESS => $style);
$ossClient->getObject($bucket, $object, $options);
// Delete the sample image.
$ossClient->deleteObject($bucket, $object);
```

Persistent storage of processed images

The following code provides an example on how to save processed images:

```
<? php
if (is_file(__DIR__ . '/../autoload.php')) {
    require_once __DIR__ . '/../autoload.php';
}
if (is_file(__DIR__ . '/../vendor/autoload.php')) {
    require_once __DIR__ . '/../vendor/autoload.php';
}
use OSS\OssClient;
$accessKeyId = "<yourAccessKeyId>";
$accessKeySecret = "<yourAccessKeySecret>";
// The endpoint of the China (Hangzhou) region is used in this example. Specify the actual
endpoint.
$endpoint = "http://oss-cn-hangzhou.aliyuncs.com";
$bucket= "<yourBucketName>";
// Specify the object name.
$object = "<yourObjectName>";
// Specify the object name for the processed image.
$targetObject = "<yourTargetObjectName>";
try{
    $ossClient = new OssClient($accessKeyId, $accessKeySecret, $endpoint);
// The following code provides an example on how to convert the image format of a processed
image. To crop, rotate, or watermark an image, modify the $options parameters.
$options = array(
  OssClient::OSS_PROCESS => "image/format,png"
);
$content = $ossClient->getObject($bucket, $object, $options);
$ossClient->putObject($bucket, $targetObject, $content);
} catch(OssException $e) {
    printf(__FUNCTION__ . ": FAILED\n");
    printf($e->getMessage() . "\n");
    return;
}
print($content);
print(__FUNCTION__ . ": OK" . "\n");
```

6.1.2.3.11. Error handling

OSS SDK for PHP exceptions (OssException) include errors caused by invalid parameters and objects that do not exist. You can use getMessage to obtain an error message.

For more information about OssException, visit GitHub.

Error handling example

The following code provides an example on how to rectify an error and display the error information when you create a bucket that already exists:

```
try {
    $ossClient->createBucket($bucket);
} catch (OssException $e) {
    print("Exception:" . $e->getMessage() . "\n");
}
```

The following table describes the error messages you can obtain.

Parameter	Description
HTTPStatus	The HTTP status code that can be obtained by using getHTTPStatus.
ErrorCode	The error code returned by OSS. The error code can be obtained by using getErrorCode.
ErrorMessage	The error information returned by OSS. The error information can be obtained by using getErrorMessage.
RequestId	The UUID used to uniquely identify the request. If the problem persists, you can provide the request ID of a problem to the OSS development engineers for help. You can obtain the UUID by using getRequestId.
Details	The error information details returned by OSS. You can obtain the error message details by using getDetails.

OSS error codes

Error code	Error message	HTTP status code
AccessDenied	The error message returned because the access is denied.	403
BucketAlreadyExists	The error message returned when the bucket already exists.	409
BucketNotEmpty	The error message returned when the bucket is not empty.	409
EntityTooLarge	The error message returned because the entity exceeds the maximum allowed size.	400
EntityTooSmall	The error message returned because the entity is smaller than the minimum allowed size.	400
FileGroupTooLarge	The error message returned because the object group exceeds the maximum allowed size.	400

Error code	Error message	HTTP status code
FilePartNotExist	The error message returned because the specified part does not exist.	400
FilePartStale	The error message returned because the part has expired.	400
InvalidArgument	The error message returned because the parameter format is invalid.	400
InvalidAccessKeyId	The error message returned because the specified AccessKey ID does not exist.	403
InvalidBucketName	The error message returned because the bucket name is invalid.	400
InvalidDigest	The error message returned because the digest is invalid.	400
InvalidObjectName	The error message returned because the object name is invalid.	400
InvalidPart	The error message returned because the part is invalid.	400
InvalidPartOrder	The error message returned because the part order is invalid.	400
InvalidTargetBucketForLogging	The error message returned because the target bucket specified for logging is invalid.	400
InternalError	The error message returned because an internal OSS error occurs.	500
MalformedXML	The error message returned because the XML format is invalid.	400
MethodNotAllowed	The error message returned because the method is not supported.	405
MissingArgument	The error message returned because a parameter is missing.	411

Error code	Error message	HTTP status code
MissingContentLength	The error message returned because the content length is not specified.	411
NoSuchBucket	The error message returned because the specified bucket does not exist.	404
NoSuchKey	The error message returned because the specified object does not exist.	404
NoSuchUpload	The error message returned because the specified multipart upload ID does not exist.	404
NotImplemented	The error message returned because the method cannot be implemented.	501
PreconditionFailed	The error message returned because a precondition error occurs.	412
RequestTimeTooSkewed	The error message returned because the difference between the time on the client when the request is sent and the time on the server when the request is received is greater than 15 minutes.	403
RequestTimeout	The error message returned because the request times out.	400
SignatureDoesNotMatch	The error message returned because a signature error occurs.	403
InvalidEncryptionAlgorithmError	The error message returned because the specified encryption algorithm based on entropy encoding is invalid.	400

6.1.2.4. C-SDK

6.1.2.4.1. Preface

This topic describes the information about OSS SDK for C.

Compatibility

- For OSS SDK for C V3.*.*: *. compatible.
- For OSS SDK for C V2. *. *.*:
  - Compatible with Windows
  - Compatible with Linux API operations and incompatible with the following linked list (aos_list_t) traversal API operations:
    - aos_list_for_each_entry
    - aos_list_for_each_entry_reverse
    - aos_list_for_each_entry_safe
    - aos_list_for_each_entry_safe_reverse
- For OSS SDK for C V1.*.*: compatible except the following structures and API operations:
  - oss_request_options_t
  - oss_get_object_to_buffer
  - oss_get_object_to_file
  - oss_get_object_to_buffer_by_url
  - oss_get_object_to_file_by_url
  - oss_init_multipart_upload
  - oss_complete_multipart_upload
- For OSS SDK for C V0.0.*: incompatible.

SDK source code

For the source code of OSS SDK for C, visit GitHub.

Sample codes

The OSS SDK for C provides a variety of sample codes for your reference or use. The following table describes the sample codes provided by OSS SDK for C.

Document	Description
oss_put_object_sample	Shows you how to upload objects, including upload objects from the memory, upload objects by using MD5 verification, upload objects with object metadata, and upload objects based on a signed URL.
oss_get_object_sample.c	Shows you how to download objects, including download objects to the memory or local files, range download, and object download based on a signed URL.
oss_append_object_sample.c	Shows you how to perform append upload, including append upload from the memory and append upload from local files.
oss_multipart_upload_sample.c	Shows you how to perform multipart upload, including multipart upload from the memory, multipart upload from local files, and multipart upload cancellation.
oss_resumable_sample.c	Shows you how to perform resumable upload.
oss_head_object_sample.c	Shows you how to query object metadata.

Document	Description
oss_delete_object_sample.c	Shows you how to delete objects, including the deletion of a single object and multiple objects.
oss_callback_sample.c	Shows you how to perform upload callback, including object upload callback and multipart upload callback.
oss_progress_sample.c	Shows you how to use a progress bar during object upload, append upload, multipart upload, and download.
oss_crc_sample.c	Shows you how to perform CRC in object upload and download.
oss_image_sample.c	Shows you how to use Image Processing (IMG).

6.1.2.4.2. Installation

This topic describes how to install OSS SDK for C.

Install OSS SDK for C on Linux

- Install CMake and third-party libraries

  When you install OSS SDK for C on Linux, you must install CMake and the following third-party libraries: cRUL, APR, APR-util, and Mini-XML.

  The following table describes parameters required to install CMake and the third-party libraries.

Parameter	Description	Version
CMake	Manages the build process of software by using a compiler-independent method.	2.6.0 or later
curl	Resolves network issues.	7.32.0 or later
apr-util	Resolves the issues of memory and different platforms.	1.5.2 or later
minixml	Parses the XML data returned by a request.	2.9

  Install CMake and the third-party libraries based on the following systems:

  - Ubuntu and Debian
    - Install CMake

      ```
      sudo apt-get install cmake
      ```

    - Install third-party libraries

      ```
      sudo apt-get install libcurl4-openssl-dev libapr1-dev libaprutil1-dev libmxml-dev
      ```

- RedHat, Aliyun, and CentOS
  - Install CMake

    ```
    sudo yum install cmake
    ```

  - Install third-party libraries

    ```
    sudo yum install curl-devel apr-devel apr-util-devel  mxml mxml-devel
    ```

    If the YUM source does not contain the MXML installation package, use RPM to install MXML. Download the RPM package based on your operating system:

    - 64-bit: MXML-2.9-1.x86_64.rpm
    - 32-bit: MXML-2.9-1.i386.rpm

    Use the RPM package to install MXML:

    ```
    rpm -ivh mxml-2.9-1.x86_64.rpm
    ```

- SuSE
  - Install CMake

    ```
    zypper install cmake
    ```

  - Install third-party libraries

    ```
    zypper install libcurl-devel libapr1-devel libapr-util1-devel mxml-devel
    ```

- Other Linux-based systems
  - Install CMake

    Download CMake, and run the following commands to install CMake:

    ```
    ./configure
    make
    make install
    ```

    > **Note** When you run ./configure, the default installation path is /usr/local/. To specify the installation path, add the -prefix option when you run ./configure.

  - Install libcurl

    Download libcurl, and run the following commands to install libcurl:

    ```
    ./configure
    make
    make install
    ```

  - Install APR

    Download APR, and run the following commands to install APR:

    ```
    ./configure
    make
    make install
    ```

  - Install APR-util

    Download APR-util, and run the following commands to install APR-util:

    ```
    // You must specify the --with-APR option when you install APR-util.
    ./configure --with-apr=/your/apr/install/path
    make
    make install
    ```

  - Install Mini-XML

    > **Note** Use Mini-XML 2.x for installation.

    Download Mini-XML, and run the following commands to install Mini-XML:

    ```
    ./configure
    make
    sudo make install
    ```

- Download the SDK
  - Download directly
  - Download from GitHub
  - Download previous versions
- Install the SDK

- If third-party libraries cRUL, APR, APR-util, and MXML are installed in the default path, run the following commands to install OSS SDK for C:

```
cmake .
make
make install
```

- You can specify a path to which third-party libraries cRUL, APR, APR-util, and MXML are installed. Run the following commands to install OSS SDK for C:

```
cmake -f CMakeLists.txt
// Set the build type to Release. Typical build types include Debug, Release, RelWithDe
bInfo, and MinSizeRel. By default, Debug is used.
-DCMAKE_BUILD_TYPE=Release
// Set the directory to install the SDK.
-DCMAKE_INSTALL_PREFIX=/usr/local/
// Specify the path where third-party libraries cRUL, APR, APR-util, and XML are instal
led.
-DCURL_INCLUDE_DIR=/usr/include/curl
-DCURL_LIBRARY=/usr/lib64/libcurl.so
-DAPR_INCLUDE_DIR=/usr/include/apr-1
-DAPR_LIBRARY=/usr/lib64/libapr-1.so
-DAPR_UTIL_INCLUDE_DIR=/usr/include/apr-1
-DAPR_UTIL_LIBRARY=/usr/lib64/libaprutil-1.so
-DMINIXML_INCLUDE_DIR=/usr/include
-DMINIXML_LIBRARY=/usr/lib64/libmxml.so
// If the 'Could not find APR-config/APR-1-config' error is reported during compilation
, one possible reason is that the APR-1-config file does not exist in the default path.
Add the following options:
-DAPR_CONFIG_BIN=/path/to/bin/apr-1-config
// If the 'Could not find apu-config/apu-1-config' error is reported, add the following
options:
-DAPU_CONFIG_BIN=/path/to/bin/apu-1-config
```

Install OSS SDK for C on Windows

- Download the SDK
  - Download directly
  - Download from GitHub
  - Download previous versions
- Install the SDK

  For more information about how to use Visual Studio to compile OSS SDK for C, visit Use Alibaba Cloud OSS SDK for C on Windows.

  > **Note** If you use Visual Studio 2012 or later, you are prompted to choose whether to upgrade the project version to adapt to the latest versions of the compiler and libraries. We recommend that you use versions that match your project. If the project uses the compiler and libraries of the latest versions, upgrade the project. Otherwise, you do not need to upgrade the project.

6.1.2.4.3. Initialization

You must initialize oss_request_options_t and specify an endpoint to use OSS SDK for C.

You must specify an endpoint when you initialize OSS SDK for C. For more information about endpoints, see Obtain an endpoint.

You must specify an AccessKey pair when you initialize OSS SDK for C. For more information about how to obtain an AccessKey pair, see Obtain an AccessKey pair.

Use the OSS domain name to initialize request options

The following code provides an example on how to use the OSS domain name to initialize request options:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters. The second parameter in this function indicates the ow
nership of ctl. By default, the value is 0. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main() {
    aos_pool_t *p;
    oss_request_options_t *options;
    /* Initialize global variables, which are run before the program starts. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        return -1;
    }
    /* Initialize the memory pool and options. */
    aos_pool_create(&p, NULL);
    options = oss_request_options_create(p);
    init_options(options);
    /* The code for logic operations is omitted. */
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(p);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

> **Note** For more information about how to set the request options, see How to set parameters for cRUL-based communication in OSS SDK for C.

Use the custom domain name to initialize request options

The following code provides an example on how to use custom domain name to initialize request options:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourCustomEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
void init_options(oss_request_options_t *options) {
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Enable the CNAME and bind the custom domain name to the bucket. */
    options->config->is_cname = 1;
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main() {
    aos_pool_t *p;
    oss_request_options_t *options;
    /* Initialize global variables, which are run before the program starts. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        return -1;
    }
    /* Initialize the memory pool and options. */
    aos_pool_create(&p, NULL);
    options = oss_request_options_create(p);
    init_options(options);
    /* The code for logic operations is omitted. */
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(p);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Use STS to initialize request options

The following code provides an example on how to use STS to initialize request options:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *sts_token = "<yourSecurityToken>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Configure STS. */
    aos_str_set(&options->config->sts_token, sts_token);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main() {
    aos_pool_t *p;
    oss_request_options_t *options;
    /* Initialize global variables, which are run before the program starts. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        return -1;
    }
    /* Initialize the memory pool and options. */
    aos_pool_create(&p, NULL);
    options = oss_request_options_create(p);
    init_options(options);
    /* The code for logic operations is omitted. */
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(p);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Configure a timeout period

The following code provides an example on how to configure a timeout period:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters. The second parameter in this function indicates the ow
nership of ctl. By default, the value is 0. */
    options->ctl = aos_http_controller_create(options->pool, 0);
    /* Set the connection timeout period. Default value: 10 seconds. */
    options->ctl->options->connect_timeout = 10;
    /* Set the DNS cache timeout period. Default value: 60 seconds. */
    options->ctl->options->dns_cache_timeout = 60;
    /*
    Configure the request timeout period:
    Set the value of speed_limit to specify the minimum acceptable speed. Default value: 1
KB/s.
    Set the value of speed_time to specify the minimum acceptable speed. Default value: 15
seconds.
    The default values indicate that if the transmission speed is continuously smaller than
1 KB/s for 15 consecutive seconds, the request times out.
    */
    options->ctl->options->speed_limit = 1024;
    options->ctl->options->speed_time = 15;
}
```

6.1.2.4.4. Quick start

This topic describes how to use OSS SDK for C to complete routine operations such as bucket creation, object upload, and object download.

Sample projects

- Sample projects for Linux
  i. Download a sample project and decompress it.
  ii. When you install oss-c-sdk-demo-specified-installation, you must specify the installation directory: **/home/your/oss/csdk**. You do not need to specify installation directories for other sample projects because other sample projects are automatically installed based on OSS SDK for C and other dependent third-party libraries.
  iii. Set OSS_ENDPOINT, ACCESS_KEY_ID, ACCESS_KEY_SECRET, and BUCKET_NAME in the sample code to valid values. If OSS SDK for C and the dynamic libraries of the dependent libraries are not in the

system directory, use `LD_LIBRARY_PATH` to specify the directory of OSS SDK for C and the dynamic libraries of the dependent libraries.

iv. Go to the oss-c-sdk-demo-xxx directory. Run `make` to compile the sample project. Run `./main` to run the executable program. To re-compile the project, run `make clean`.

For more information about the sample projects, see Use Alibaba Cloud OSS SDK for C in Linux.

- Sample projects for Windows

i. Download a sample project and decompress it.

For more sample projects, visit GitHub.

ii. Use Visual Studio to open the sample project, and then set the following parameters in the oss_config.c file to valid values: OSS_ENDPOINT, ACCESS_KEY_ID, ACCESS_KEY_SECRET, BUCKET_NAME, OBJECT_NAME, MULTIPART_UPLOAD_FILE_PATH, and DIR_NAME. Compile and run the project. You can develop your own project based on the sample project.

> **Note** For more information about how to use Visual Studio, see Use Alibaba Cloud OSS SDK for C in Windows.

Create a bucket

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
```

```
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Create the bucket. */
    aos_status_t *resp_status;
    aos_table_t *resp_headers;
    oss_acl_e oss_acl = OSS_ACL_PRIVATE;
    aos_string_t bucket;
    /* Assign the char* data to the bucket. */
    aos_str_set(&bucket, bucket_name);
    resp_status = oss_create_bucket(oss_client_options, &bucket, oss_acl, &resp_headers);
    /* Determine whether the bucket is created. */
    if (aos_status_is_ok(resp_status)) {
        printf("create bucket succeeded\n");
    } else {
        printf("create bucket failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Upload objects

The following code provides an example on how to upload objects to OSS by using stream upload:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */

    aos_http_io_deinitialize();
    return 0;
}
```

List objects

The following code provides an example on how to list objects in a specified bucket.

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool = NULL;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
```

```
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options = NULL;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_status_t *resp_status = NULL;
    oss_list_object_params_t *params = NULL;
    oss_list_object_content_t *content = NULL;
    int size = 0;
    char *line = NULL;
    aos_str_set(&bucket, bucket_name);
    params = oss_create_list_object_params(pool);
    /* List objects. */
    resp_status = oss_list_object(oss_client_options, &bucket, params, NULL);
    /* Determine whether the list request is successful. */
    if (! aos_status_is_ok(resp_status))
    {
        printf("list object failed\n");
    }
    else{
        /* Display the objects. */
        printf("Object\tSize\tLastModified\n");
        aos_list_for_each_entry(oss_list_object_content_t, content, &params->object_list, n
ode) {
            ++size;
            line = apr_psprintf(pool, "%.*s\t%.*s\t%.*s\n", content->key.len, content->key.
data,
                content->size.len, content->size.data,
                content->last_modified.len, content->last_modified.data);
            printf("%s", line);
        }
        printf("Total %d\n", size);
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Delete objects

The following code provides an example on how to delete an object:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
```

```
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool = NULL;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options = NULL;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_status_t *resp_status = NULL;
    aos_table_t *resp_headers = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    /* Delete the object. */
    resp_status = oss_delete_object(oss_client_options, &bucket, &object, &resp_headers);
    /* Determine whether the object is deleted. */
    if (aos_status_is_ok(resp_status)) {
        printf("delete object succeeded\n");
    } else {
        printf("delete object failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
```

```
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.5. Buckets

6.1.2.4.5.1. Create buckets

A bucket is a container used to store objects in Object Storage Service (OSS). Each object is contained in a bucket. This topic describes how to create a bucket.

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources such
as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t *pool is equivalent to apr_pool_t.
The code to create a memory pool is included in the apr library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, acces_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
```

```
    aos_string_t bucket;
    oss_acl_e oss_acl = OSS_ACL_PRIVATE;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    /* Assign the char* data to the aos_string_t bucket. */
    aos_str_set(&bucket, bucket_name);
    /* Create the bucket. */
    resp_status = oss_create_bucket(oss_client_options, &bucket, oss_acl, &resp_headers);
    /* Determine whether the bucket is created. */
    if (aos_status_is_ok(resp_status)) {
        printf("create bucket succeeded\n");
    } else {
        printf("create bucket failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

The following code provides an example on how to set the ACL of a bucket when you create the bucket:

```
    /* Create a bucket and set the ACL of the bucket to public read (the default ACL is pri
vate). */
    resp_status = oss_create_bucket(oss_client_options, &bucket, OSS_ACL_PUBLIC_READ, &resp
_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("create bucket succeeded\n");
    } else {
        printf("create bucket failed\n");
    }
```

6.1.2.4.5.2. List buckets

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
```

```
    /* Configure network parameters such as the timeout period. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources such
as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t *pool is equivalent to apr_pool_t.
The code to create a memory pool is included in the apr library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, acces_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    oss_list_buckets_params_t *params = NULL;
    oss_list_bucket_content_t *content = NULL;
    int size = 0;
    params = oss_create_list_buckets_params(pool);
    /* List the buckets. */
    resp_status = oss_list_bucket(oss_client_options, params, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("list buckets succeeded\n");
    } else {
        printf("list buckets failed\n");
    }
    /* Display the list of buckets. */
    aos_list_for_each_entry(oss_list_bucket_content_t, content, &params->bucket_list, node)
{
        printf("BucketName: %s\n", content->name.data);
        ++size;
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.5.3. Manage bucket ACLs

A bucket is a container used to store objects in Object Storage Service (OSS). Every object is contained in a bucket. This topic describes how to configure and query the access control list (ACL) of a bucket.

Configure ACL for a bucket

The following table describes the bucket ACLs.

ACL	Description	Value
Private	Only the owner or authorized users of the bucket can read and write the object.	OSS_ACL_PRIVATE
Public read	Only the owner or authorized users of this bucket can write the object. Other users, including anonymous users can only read the object. Exercise caution when you use this ACL.	OSS_ACL_PUBLIC_READ
Public read/write	Any users, including anonymous users can read and write the object. Exercise caution when you use this ACL.	OSS_ACL_PUBLIC_READ_WRITE

The following code provides an example on how to configure the ACL of a bucket:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
```

```
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    /* Assign char* data to the aos_string_t bucket. */
    aos_str_set(&bucket, bucket_name);
    /* Set the ACL of the bucket to public read (OSS_ACL_PUBLIC_READ).
    resp_status = oss_put_bucket_acl(oss_client_options, &bucket, OSS_ACL_PUBLIC_READ, &res
p_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("set bucket acl succeeded\n");
    } else {
        printf("set bucket acl failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Query the ACL of a bucket

The following code provides an example on how to query the ACL of a bucket:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
```

```
used. */
    options->config->is_cname = 0;

    /* Query the ACL of the bucket. */
    resp_status = oss_get_bucket_acl(oss_client_options, &bucket, &oss_acl, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("get bucket acl succeeded : %s \n", oss_acl.data);
    } else {
        printf("get bucket acl failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.5.4. Delete buckets

Note Before you delete a bucket, you must delete all objects in the bucket and parts generated by multipart upload.

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources such
as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t *pool is equivalent to apr_pool_t.
The code to create a memory pool is included in the apr library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, acces_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    /* Assign the char* data to the aos_string_t bucket. */
    aos_str_set(&bucket, bucket_name);
    /* Delete the bucket. */
    resp_status = oss_delete_bucket (oss_client_options, &bucket, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("delete bucket succeeded\n");
    } else {
        printf("delete bucket failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
```

```
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.5.5. Manage lifecycle rules

Object Storage Service (OSS) allows you to configure lifecycle rules to delete expired objects and parts or convert the storage class of expired objects to Infrequent Access (IA) or Archive to reduce your storage costs. This topic describes how to manage lifecycle rules for buckets.

Background

Each lifecycle rule contains the following information:

- Policy: specifies the mode to match objects and parts.
  - Match by prefix: matches objects and parts by prefix. You can create multiple rules to configure different prefixes. Each prefix must be unique.
  - Match by bucket: matches all objects and parts contained in the bucket. You can create only one rule if you select this method.
- Object lifecycle policy: specifies the validity period or expiration data and the operation to perform on these objects after they expire.
  - Validity period: specifies the number of days within which parts can be retained after they are last modified. After the validity period, expired objects are deleted.
  - Expiration date: specifies a date. Objects that are last modified before this date expire and are deleted.
- Part lifecycle policy: specifies the validity period or expiration time and the delete operation to perform on these objects after they expire.
  - Validity period: specifies the number of days within which parts can be retained after they are last modified. After the validity period, expired parts are deleted.
  - Expiration date: specifies a date. Parts that are last modified before this date expire and are deleted.

Lifecycle rules also apply to the parts uploaded by using uploadPart. In this case, the last modified time of an object is the time the multipart upload task is initiated.

Configure lifecycle rules

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
```

```
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter includes global configuration informat
ion, such as endpoint, access_key_id, acces_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_list_t lifecycle_rule_list;
    /* Create lifecycle rules for the bucket. */
    aos_str_set(&bucket, bucket_name);
    aos_list_init(&lifecycle_rule_list);
    /* Specify the validity period. */
    oss_lifecycle_rule_content_t *rule_content_days = oss_create_lifecycle_rule_content(poo
l);
    aos_str_set(&rule_content_days->id, "rule-1");
    aos_str_set(&rule_content_days->prefix, "obsoleted");
    aos_str_set(&rule_content_days->status, "Enabled");
    rule_content_days->days = 3;
    aos_list_add_tail(&rule_content_days->node, &lifecycle_rule_list);
    /* Specify the expiration date. */
    oss_lifecycle_rule_content_t *rule_content_date = oss_create_lifecycle_rule_content(poo
l);
    aos_str_set(&rule_content_date->id, "rule-2");
    aos_str_set(&rule_content_date->prefix, "delete");
    aos_str_set(&rule_content_date->status, "Enabled");
    aos_str_set(&rule_content_date->date, "2022-10-11T00:00:00.000Z");
    aos_list_add_tail(&rule_content_date->node, &lifecycle_rule_list);
    /* Configure the lifecycle rules. */
```

```
    resp_status = oss_put_bucket_lifecycle(oss_client_options, &bucket, &lifecycle_rule_lis
t, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("put bucket lifecycle succeeded\n");
    } else {
        printf("put bucket lifecycle failed, code:%d, error_code:%s, error_msg:%s, request_
id:%s\n",
            resp_status->code, resp_status->error_code, resp_status->error_msg, resp_status
->req_id);
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

View lifecycle rules

The following code provides an example on how to query the lifecycle rules configured for the bucket named examplebucket:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
```

```
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_list_t lifecycle_rule_list;
    oss_lifecycle_rule_content_t *rule_content;
    char *rule_id;
    char *prefix;
    char *status;
    int days = INT_MAX;
    char* date = "";
    aos_str_set(&bucket, bucket_name);
    /* Query and display the lifecycle rules configured for the bucket. */
    aos_list_init(&lifecycle_rule_list);
    resp_status = oss_get_bucket_lifecycle(oss_client_options, &bucket, &lifecycle_rule_lis
t, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("get bucket lifecycle succeeded\n");
        aos_list_for_each_entry(oss_lifecycle_rule_content_t, rule_content, &lifecycle_rule
_list, node) {
            rule_id = apr_psprintf(pool, "%.*s", rule_content->id.len, rule_content->id.dat
a);
            prefix = apr_psprintf(pool, "%.*s", rule_content->prefix.len, rule_content->pre
fix.data);
            status = apr_psprintf(pool,"%.*s", rule_content->status.len, rule_content->stat
us.data);
            date = apr_psprintf(pool, "%.*s", rule_content->date.len, rule_content->date.da
ta);
            days = rule_content->days;
        }
        printf("rule_id: %s \n", rule_id);
        printf("prefix: %s \n", prefix);
        printf("status: %s \n", status);
        printf("date: %s \n", date);
        printf("days: %d \n", days);
    } else {
        printf("get bucket lifecycle failed, code:%d, error_code:%s, error_msg:%s, request_
id:%s\n",
            resp_status->code, resp_status->error_code, resp_status->error_msg, resp_status
->req_id);
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
```

```
    return 0;
}
```

Delete lifecycle rules

The following code provides an example on how to delete lifecycle rules configured for the bucket named examplebucket:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    /* Delete the lifecycle rules configured for the bucket. */
    aos_str_set(&bucket, bucket_name);
```

```
    resp_status = oss_delete_bucket_lifecycle(oss_client_options, &bucket, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("delete bucket lifecycle succeeded\n");
    } else {
        printf("delete bucket lifecycle failed, code:%d, error_code:%s, error_msg:%s, reque
st_id:%s\n",
            resp_status->code, resp_status->error_code, resp_status->error_msg, resp_status
->req_id);
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.5.6. CORS

Cross-origin resource sharing (CORS) allows web applications to access resources that belong to different regions. OSS provides CORS operations to facilitate cross-origin access control.

Configure CORS rules

Run the following code to configure CORS rules for a specified bucket:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
```

```
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_list_t cors_rule_list;
    oss_cors_rule_t *cors_rule1 = NULL, *cors_rule2 = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_list_init(&cors_rule_list);
    cors_rule1 = oss_create_cors_rule(pool);
    aos_list_add_tail(&cors_rule1->node, &cors_rule_list);
    oss_create_sub_cors_rule(pool, &cors_rule1->allowed_origin_list, "allowed_origin_1_1");
    oss_create_sub_cors_rule(pool, &cors_rule1->allowed_origin_list, "allowed_origin_1_1");
    oss_create_sub_cors_rule(pool, &cors_rule1->allowed_method_list, "PUT");
    oss_create_sub_cors_rule(pool, &cors_rule1->allowed_method_list, "GET");
    oss_create_sub_cors_rule(pool, &cors_rule1->allowed_head_list, "Authorization");
    oss_create_sub_cors_rule(pool, &cors_rule1->expose_head_list, "expose_head_1_1");
    oss_create_sub_cors_rule(pool, &cors_rule1->expose_head_list, "expose_head_1_1");
    cors_rule2 = oss_create_cors_rule(pool);
    aos_list_add_tail(&cors_rule2->node, &cors_rule_list);
    oss_create_sub_cors_rule(pool, &cors_rule2->allowed_origin_list, "allowed_origin_2_1");
    oss_create_sub_cors_rule(pool, &cors_rule2->allowed_origin_list, "allowed_origin_2_2");
    oss_create_sub_cors_rule(pool, &cors_rule2->allowed_method_list, "PUT");
    oss_create_sub_cors_rule(pool, &cors_rule2->allowed_method_list, "GET");
    oss_create_sub_cors_rule(pool, &cors_rule2->allowed_head_list, "Authorization");
    oss_create_sub_cors_rule(pool, &cors_rule2->expose_head_list, "expose_head_2_1");
    oss_create_sub_cors_rule(pool, &cors_rule2->expose_head_list, "expose_head_2_2");
    /* Configure the CORS rules. */
    resp_status = oss_put_bucket_cors(oss_client_options, &bucket, &cors_rule_list, &resp_h
eaders);
    if (aos_status_is_ok(resp_status)) {
        printf("put bucket cors succeeded\n");
    } else {
        printf("put bucket cors failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Query CORS rules

Run the following code to obtain CORS rules:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }

    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Delete CORS rules

Run the following code to delete all CORS rules for the specified bucket:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
```

```
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    /* Delete the CORS rules. */
    resp_status = oss_delete_bucket_cors(oss_client_options, &bucket, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("get bucket cors succeeded\n");
    } else {
        printf("get bucket cors failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.5.7. Configure logging

You can enable logging to record access to a bucket in log objects, which are stored in a specified bucket.

The name of log objects is in the following format: `<TargetPrefix><SourceBucket>-YYYY-mm-DD-HH-MM-SS-UniqueString`.

Enable logging

Run the following code to enable bucket access logging:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *target_bucket_name = "<yourTargetBucketName>";
const char *target_logging_prefix = "<yourTargetPrefix>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize parameters. */
    aos_string_t bucket;
    oss_logging_config_content_t *content;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    content = oss_create_logging_rule_content(pool);
    aos_str_set(&content->target_bucket, target_bucket_name);
    aos_str_set(&content->prefix, target_logging_prefix);
    /* Enable logging for the bucket. */
    resp_status = oss_put_bucket_logging(oss_client_options, &bucket, content, &resp_header
s);
    if (aos_status_is_ok(resp_status)) {
```

```
        printf("put symlink succeeded\n");
    } else {
        printf("put symlink failed, code:%d, error_code:%s, error_msg:%s, request_id:%s\n",
            resp_status->code, resp_status->error_code, resp_status->error_msg, resp_status
->req_id);
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

View logging configurations

Run the following code to view the access logging configurations for a bucket:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
```

```
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    oss_logging_config_content_t *content;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    content = oss_create_logging_rule_content(pool);
    /* View logging configurations of the bucket. */
    resp_status = oss_get_bucket_logging(oss_client_options, &bucket, content, &resp_header
s);
    if (aos_status_is_ok(resp_status)) {
        printf("get bucket logging succeeded\n");
    } else {
        printf("get bucket logging failed, code:%d, error_code:%s, error_msg:%s, request_id
:%s\n",
            resp_status->code, resp_status->error_code, resp_status->error_msg, resp_status
->req_id);
    }
    printf("bucket:%s, prefix:%s\n", content->target_bucket.data, content->prefix.data);
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Disable logging

Run the following code to disable access logging for a bucket:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
```

```
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    /* Disable logging. */
    resp_status = oss_delete_bucket_logging(oss_client_options, &bucket, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("delete bucket logging succeeded\n");
    } else {
        printf("delete bucket logging failed, code:%d, error_code:%s, error_msg:%s, request
_id:%s\n",
            resp_status->code, resp_status->error_code, resp_status->error_msg, resp_status
->req_id);
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.5.8. Configure hotlink protection

OSS provides hotlink protection to prevent unauthorized domain names from accessing your OSS data. You can configure the Referer field in the HTTP header.

To configure hotlink protection, you must configure the following parameters:

- Referer Whitelist: Only specified domain names are allowed to access OSS resources.
- Allow Empty Referer: If you do not allow empty Refer fields, a request is allowed to access OSS resources only if the request includes the Referer field configured in the HTTP or HTTPS header.

Configure hotlink protection

Run the following code to configure the referer whitelist:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    oss_referer_config_t referer_config;
    aos_str_set(&bucket, bucket_name);
    aos_list_init(&referer_config.referer_list);
    oss_create_and_add_refer(pool, &referer_config, "http://www.aliyun.com");
    oss_create_and_add_refer(pool, &referer_config, "https://www.aliyun.com");
    referer_config.allow_empty_referer = 0;
    /* Add a Referer whitelist. You can use an asterisk (*) or a question mark (?) as a wil
dcard character to set the Referer parameter. */
```

```
wildcard character to set the Referer parameter. */
    resp_status = oss_put_bucket_referer(oss_client_options, &bucket, &referer_config, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("put bucket referer succeeded\n");
    } else {
        printf("put bucket referer failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request. */
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Query hotlink protection information

Run the following code to obtain a referer whiltelist:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The code used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that the pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration information such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
```

```
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    oss_referer_config_t referer_config;
    oss_referer_t *referer;
    aos_str_set(&bucket, bucket_name);
    aos_list_init(&referer_config.referer_list);
    /* Query the Referer whitelist of the bucket. */
    resp_status = oss_get_bucket_referer(oss_client_options, &bucket, &referer_config, &res
p_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("get bucket referer succeeded\n");
        aos_list_for_each_entry(oss_referer_t, referer, &referer_config.referer_list, node)
{
            printf("get referer %s\n", referer->referer.data);
        }
    } else {
        printf("get bucket referer failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Delete hotlink protection configurations

Run the following code to clear a referer whitelist:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
```

```
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */

    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.5.9. Configure static website hosting

You can set the static website hosting mode for your bucket. After configurations take effect, you can use the bucket domain name to access this static website and be redirected to a specified index page or error page.

Configure static website hosting

Run the following code to configure static website hosting:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    oss_website_config_t website_config;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&website_config.suffix_str, "index.html");
    aos_str_set(&website_config.key_str, "error.html");
```

```
    /* Configure static web hosting: The index page is index.html and the error page is err
or.html. */
    resp_status = oss_put_bucket_website(oss_client_options, &bucket, &website_config, &res
p_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("put bucket website succeeded\n");
    } else {
        printf("put bucket website failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

View static website hosting configurations

Run the following code to view static website hosting configurations:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
```

```
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    oss_website_config_t website_config;
    aos_str_set(&bucket, bucket_name);
    /* View the static website hosting configurations. */
    resp_status = oss_get_bucket_website(oss_client_options, &bucket, &website_config, &res
p_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("get bucket website succeeded\n");
        printf("website_config: %s  %s \n", website_config.suffix_str.data, website_config.
key_str.data);
    } else {
        printf("get bucket website failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Delete static website hosting configurations

Run the following code to delete static website hosting configurations:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
```

```
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The code used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that the pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration information such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    /* Delete the static website hosting configurations. */
    resp_status = oss_delete_bucket_website(oss_client_options, &bucket, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("delete bucket website succeeded\n");
    } else {
        printf("delete bucket website failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request. */
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.6. Upload objects

6.1.2.4.6.1. Overview

Objects are the basic unit for data operations in OSS. OSS SDK for C provides a variety of methods to upload objects.

You can upload an object to OSS by using one of the following methods:

- Simple upload: includes streaming upload and object upload. You can use this method to upload an object up to 5 GB in size.
- Append upload: uploads an object up to 5 GB in size.

- Resumable upload: supports concurrent upload and resumable upload, and you can define the size of each part. This method is suitable for the upload of large objects. You can use this method to upload an object up to 48.8 TB in size.
- Multipart upload: supports the upload of an object up to 48.8 TB in size. This method is suitable for the upload of large objects.

During object upload, you can configure object metadata and view upload progress by using progress bars. For more information about progress bar, see Use progress bars. After the object is uploaded, you can perform upload callback. For more information about upload callback, see Upload callback.

6.1.2.4.6.2. Simple upload

This topic describes how to use simple upload.

For the complete code that is used to perform simple upload, visit GitHub.

Upload data from memory

The following code provides an example on how to upload data from memory:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *object_content = "More than just cloud.";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
```

```
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_list_t buffer;
    aos_buf_t *content = NULL;
    aos_table_t *headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_list_init(&buffer);
    content = aos_buf_pack(oss_client_options->pool, object_content, strlen(object_content)
);
    aos_list_add_tail(&content->node, &buffer);
    /* Upload the object. */
    resp_status = oss_put_object_from_buffer(oss_client_options, &bucket, &object, &buffer,
headers, &resp_headers);
    /* Determine whether the object is uploaded. */
    if (aos_status_is_ok(resp_status)) {
        printf("put object from buffer succeeded\n");
    } else {
        printf("put object from buffer failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Upload a local file

The following code provides an example on how to upload a local file to OSS:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *local_filename = "<yourLocalFilename>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
```

```
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_string_t file;
    aos_table_t *headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_str_set(&file, local_filename);
    /* Upload the object. */
    resp_status = oss_put_object_from_file(oss_client_options, &bucket, &object, &file, hea
ders, &resp_headers);
    /* Determine whether the object is uploaded. */
    if (aos_status_is_ok(resp_status)) {
        printf("put object from file succeeded\n");
    } else {
        printf("put object from file failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

FAQ: How can I upload objects whose names contain Chinese characters?

On Windows systems, you can use UTF-8 to encode the object names that contain Chinese characters and upload the object. The following code provides an example on how to upload objects whose names contain Chinese characters:

```
#include "oss_api.h"
#include "aos_http_io.h"
#include <wchar.h>
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *local_filename_ch = "c:\\测试.txt";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
char* multibyte_to_utf8(const char * ch, char *str, int size)
{
    if (! ch || ! str || size <= 0)
        return NULL;
    int chlen = strlen(ch);
    int multi_byte_cnt = 0;
    for (int i = 0; i < chlen - 1; i++) {
        if ((ch[i] & 0x80) && (ch[i + 1] & 0x80)) {
            i++;
            multi_byte_cnt++;
        }
    }
    if (multi_byte_cnt == 0)
        return ch;
    int len = MultiByteToWideChar(CP_ACP, 0, ch, -1, NULL, 0);
    if (len <= 0)
        return NULL;
    wchar_t *wch = malloc(sizeof(wchar_t) * (len + 1));
    if (! wch)
        return NULL;
    wmemset(wch, 0, len + 1);
    MultiByteToWideChar(CP_ACP, 0, ch, -1, wch, len);
    len = WideCharToMultiByte(CP_UTF8, 0, wch, -1, NULL, 0, NULL, NULL);
```

```
    if ((len <= 0) || (size < len + 1)) {
        free(wch);
        return NULL;
    }
    memset(str, 0, len + 1);
    WideCharToMultiByte(CP_UTF8, 0, wch, -1, str, len, NULL, NULL);
    free(wch);
    return str;
}
int main(int argc, char argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as networks
and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The co
de used to create a memory pool is included in the APR library. */
    aos_pool_t pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that the
pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_string_t file;
    aos_table_t *headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    /* Use UTF-8 to encode the object names that contain multibyte Chinese characters */
    char local_filename_buf[1024];
    char * local_filename = multibyte_to_utf8(local_filename_ch, local_filename_buf, 1024);
    aos_str_set(&file, local_filename);
    /* Upload the object. */
    resp_status = oss_put_object_from_file(oss_client_options, &bucket, &object, &file, hea
ders, &resp_headers);
    /* Determine whether the object is uploaded. */
    if (aos_status_is_ok(resp_status)) {
        printf("put object from file succeeded\n");
    } else {
        printf("put object from file failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request. *
/
    aos_pool_destroy(pool);
```

```
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.6.3. Append upload

You can append strings and files during append upload. You cannot perform CopyObject for append objects.

> **Note** You cannot perform CopyObject for append objects.

Append data from memory

The following code provides an example on how to append data from memory:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *object_content = "More than just cloud.";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);

    aos_http_io_deinitialize();
    return 0;
}
```

Append data from a local file

The following code provides an example on how to append data from a local file:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
```

```
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *local_filename = "<yourLocalFilename>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */

    aos_table_t *headers2 = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_str_set(&file, local_filename);
    /* Obtain the position where the object is appended for the first time. */
    resp_status = oss_head_object(oss_client_options, &bucket, &object, headers1, &resp_hea
ders);
    if(aos_status_is_ok(resp_status)) {
```

```
    if(aos_status_is_ok(resp_status)) {
        next_append_position = (char*)(apr_table_get(resp_headers, "x-oss-next-append-posit
ion"));
        position = atoi(next_append_position);
    }
    /* Append the object. */
    resp_status = oss_append_object_from_file(oss_client_options, &bucket, &object, positio
n, &file, headers2, &resp_headers);
    /* Determine whether the append upload is successful. */
    if (aos_status_is_ok(resp_status)) {
        printf("append object from file succeeded\n");
    } else {
        printf("append object from file failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.6.4. Resumable upload

If the system stops responding during multipart upload, you can resume the upload by using the ListMultipartUploads and ListParts operations to retrieve all multipart upload tasks on an object and list the uploaded parts in each task. This method allows an upload task to be resumed from the last uploaded part.

Current upload progress is recorded into a checkpoint file during the upload. If a part fails to be uploaded during the process, the object is uploaded from the part recorded in the checkpoint file when the upload restarts, that is, the resumable upload. After the upload is complete, the checkpoint is deleted.

You can use `oss_resumable_clt_params_t` to perform resumable upload. The following table describes the parameters you can configure for this method.

Parameter	Description
thread_num	The number of concurrent threads. Default value: 1.
enable_checkpoint	Specifies whether to enable resumable upload. By default, resumable upload is disabled.
partSize	The size of each part. The part size ranges from 100 KB to 5 GB.
checkpoint_path	The path of the checkpoint file. Default value: {upload_file_path}.cp.

You can run the following code to perform resumable upload:

```
#include "oss_api.h"
#include "aos_http_io.h"
```

```
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *local_filename = "<yourLocalFilename>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_string_t file;
    aos_list_t resp_body;
    aos_table_t *headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    oss_resumable_clt_params_t *clt_params;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_str_set(&file, local_filename);
    aos_list_init(&resp_body);
    /* Start resumable upload. */
    clt_params = oss_create_resumable_clt_params_content(pool, 1024 * 100, 3, AOS_TRUE, NUL
```

```
L);
    resp_status = oss_resumable_upload_file(oss_client_options, &bucket, &object, &file, he
aders, NULL, clt_params, NULL, &resp_headers, &resp_body);
    if (aos_status_is_ok(resp_status)) {
        printf("resumable upload succeeded\n");
    } else {
        printf("resumable upload failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.6.5. Multipart upload

OSS allows you to use multipart upload to split an object into several parts and upload them separately. After all parts are uploaded, you can combine the uploaded parts into a complete object to complete the upload.

To implement multipart upload, perform the following operations:

1. Initiate a multipart upload task.

   Call the ossClient.initiateMultipartUpload method to obtain a unique upload ID in OSS.

2. Upload the parts.

   Call the ossClient.uploadPart method to upload the parts.

   > **Note**
   > - Part numbers identify the relative positions of parts in an object that share the same upload ID. If you have uploaded a part and used its part number again to upload another part, the latter part overwrites the former part.
   > - OSS includes the MD5 hash of part data in the ETag header and returns the MD5 hash to the user.
   > - OSS calculates the MD5 hash of uploaded data and compares it with the MD5 hash calculated by the SDK. If the two hashes are different, the InvalidDigest error code is returned.

3. Complete the multipart upload task.

   After all parts are uploaded, call the ossClient.completeMultipartUpload method to combine these parts into a complete object.

The following code provides an example on how to perform multipart upload:

```
#include "oss_api.h"
#include "aos_http_io.h"
#include <sys/stat.h>
const char *endpoint = "<yourEndpoint>";
const char *access key id = "<yourAccessKeyId>";
```

```
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *local_filename = "<yourLocalFilename>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int64_t get_file_size(const char *file_path)
{
    int64_t filesize = -1;
    struct stat statbuff;
    if(stat(file_path, &statbuff) < 0){
        return filesize;
    } else {
        filesize = statbuff.st_size;
    }
    return filesize;
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    oss_upload_file_t *upload_file = NULL;
    aos_string_t upload_id;
    aos_table_t *headers = NULL;
```

```
    aos_table_t *complete_headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_str_null(&upload_id);
    headers = aos_table_make(p, 1);
    complete_headers = aos_table_make(p, 1);
    int part_num = 1;
    /* Initiate a multipart upload task and obtain an upload ID. */
    resp_status = oss_init_multipart_upload(oss_client_options, &bucket, &object, &upload_i
d, headers, &resp_headers);
    /* Determine whether the multipart upload task is initiated. */
    if (aos_status_is_ok(resp_status)) {
        printf("Init multipart upload succeeded, upload_id:%.*s\n",
               upload_id.len, upload_id.data);
    } else {
        printf("Init multipart upload failed, upload_id:%.*s\n",
               upload_id.len, upload_id.data);
    }
    /* Upload the parts. */
    int64_t file_length = 0;
    int64_t pos = 0;
    file_length = get_file_size(local_filename);
    while(pos < file_length) {
        upload_file = oss_create_upload_file(pool);
        aos_str_set(&upload_file->filename, local_filename);
        upload_file->file_pos = pos;
        pos += 100 * 1024;
        upload_file->file_last = pos < file_length ? pos : file_length;
        resp_status = oss_upload_part_from_file(oss_client_options, &bucket, &object, &uplo
ad_id, part_num++, upload_file, &resp_headers);
        if (aos_status_is_ok(resp_status)) {
            printf("Multipart upload part from file succeeded\n");
        } else {
            printf("Multipart upload part from file failed\n");
        }
    }
    oss_list_upload_part_params_t *params = NULL;
    aos_list_t complete_part_list;
    /* Query the uploaded parts. */
    params = oss_create_list_upload_part_params(pool);
    params->max_ret = 1000;
    aos_list_init(&complete_part_list);
    resp_status = oss_list_upload_part(oss_client_options, &bucket, &object, &upload_id, pa
rams, &resp_headers);
    /* Determine whether all parts are listed. */
    if (aos_status_is_ok(resp_status)) {
        printf("List multipart succeeded\n");
    } else {
        printf("List multipart failed\n");
    }
    oss_complete_part_content_t *complete_part_content = NULL;
    oss_list_part_content_t *part_content = NULL;
```

```
    aos_list_for_each_entry(oss_list_part_content_t, part_content, &params->part_list, node
) {
        complete_part_content = oss_create_complete_part_content(pool);
        aos_str_set(&complete_part_content->part_number, part_content->part_number.data);
        aos_str_set(&complete_part_content->etag, part_content->etag.data);
        aos_list_add_tail(&complete_part_content->node, &complete_part_list);
    }
    /* Complete the multipart upload task. */
    resp_status = oss_complete_multipart_upload(oss_client_options, &bucket, &object, &uplo
ad_id,
            &complete_part_list, complete_headers, &resp_headers);
    /* Determine whether the multipart upload task is complete. */
    if (aos_status_is_ok(resp_status)) {
        printf("Complete multipart upload from file succeeded, upload_id:%.*s\n",
               upload_id.len, upload_id.data);
    } else {
        printf("Complete multipart upload from file failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Note Query the uploaded parts. You must provide the ETag value of each part to call the oss_complete_multipart_upload operation. You can use one of the following method to obtain the ETag values: First, the response of a part upload contains the ETag value of the part. You can save the values for future use. Second, you can call the oss_list_upload_part operation to query the ETag values of the uploaded parts. In this example, the second method is used.

Cancel a multipart upload task

The following code provides an example on how to cancel a multipart upload task:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
```

```
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_string_t upload_id;
    aos_table_t *headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_str_null(&upload_id);
    /* Initiate a multipart upload task and obtain an upload ID. */
    resp_status = oss_init_multipart_upload(oss_client_options, &bucket, &object, &upload_i
d, headers, &resp_headers);
    /* Determine whether the multipart upload task is initiated. */
    if (aos_status_is_ok(resp_status)) {
        printf("Init multipart upload succeeded, upload_id:%.*s\n",
               upload_id.len, upload_id.data);
    } else {
        printf("Init multipart upload failed, upload_id:%.*s\n",
               upload_id.len, upload_id.data);
    }
    /* Cancel the multipart upload task. */
    resp_status = oss_abort_multipart_upload(oss_client_options, &bucket, &object, &upload_
id, &resp_headers);
    /* Determine whether the multipart upload task is canceled. */
    if (aos_status_is_ok(resp_status)) {
        printf("Abort multipart upload succeeded, upload_id::%.*s\n",
               upload_id.len, upload_id.data);
    } else {
        printf("Abort multipart upload failed\n");
    }
```

```
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Note If a multipart upload task is canceled, the upload ID can no longer be used to upload any parts. The parts uploaded by using that upload ID are also deleted.

6.1.2.4.6.6. Use progress bars

Progress bars are used to indicate the progress of an upload or download.

For the complete code of upload progress bars, visit GitHub.

The following code uses PutObject as an example to show you how to view progress information:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *local_filename = "<yourLocalFilename>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}

```

```
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_string_t file;
    aos_list_t resp_body;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_str_set(&file, local_filename);
    /* View the upload progress information when you upload an object. */
    resp_status = oss_do_put_object_from_file(oss_client_options, &bucket, &object, &file,
NULL, NULL, percentage, &resp_headers, &resp_body);
    if (aos_status_is_ok(resp_status)) {
        printf("put object from file succeeded\n");
    } else {
        printf("put object from file failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

You cannot use progress bars when you use oss_put_object_from_file and oss_put_object_from_buffer.

6.1.2.4.6.7. Upload callback

This topic describes how to use upload callback.

For the complete code used to implement upload callback, visit GitHub.

The following code provides an example on how to use upload callback:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access key secret = "<yourAccessKeySecret>";
```

```
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *object_content = "More than just cloud.";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    aos_pool_t *p = NULL;
    aos_status_t *s = NULL;
    aos_string_t bucket;
    aos_string_t object;
    aos_table_t *headers = NULL;
    oss_request_options_t *options = NULL;
    aos_table_t *resp_headers = NULL;

    /* Add callback to the header. */
    b64_len = aos_base64_encode((unsigned char*)callback, strlen(callback), b64_buf);
    b64_buf[b64_len] = '\0';
    headers = aos_table_make(p, 1);
    apr_table_set(headers, OSS_CALLBACK, b64_buf);
    /* Configure upload callback. */
    s = oss_do_put_object_from_buffer(options, &bucket, &object, &buffer,
        headers, NULL, NULL, &resp_headers, &resp_body);
    if (aos_status_is_ok(s)) {
        printf("put object from buffer succeeded\n");
    } else {
        printf("put object from buffer failed\n");
    }
    /* Obtain the buffer length. */
    len = aos_buf_list_len(&resp_body);
    buf = (char *)aos_pcalloc(p, (apr_size_t)(len + 1));
    buf[len] = '\0';
    /* Copy the content from the buffer to the memory. */
    aos_list_for_each_entry(aos_buf_t, content, &resp_body, node) {
        size = aos_buf_size(content);
        memcpy(buf + pos, content->pos, (size_t)size);
        pos += size;
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(p);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.7. Download objects

6.1.2.4.7.1. Overview

Objects are the basic unit for data operations in OSS. OSS SDK for C provides a variety of methods to upload objects.

For the complete object download code, visit GitHub.

You can use one of the following methods to download a single object:

- Download to local files
- Download to local memory
- Range download
- Resumable download

You can view the download progress by using the progress bar. For more information, see Use progress bars.

6.1.2.4.7.2. Download to local files

This topic describes how to download an object to a local file.

For the complete code of object download, visit GitHub.

The following code provides an example on how to download a specified object to a local file:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *local_filename = "<yourLocalFilename>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
```

```
    aos_string_t file;
    aos_table_t *params;
    aos_table_t *headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_str_set(&file, local_filename);
    params = aos_table_make(pool, 0);
    /* Download the object to your local file. If the name of the object is the same as tha
t of the local file, the object replaces the local file. If the name of the object is diffe
rent from that of the local file, the object is downloaded. */
    resp_status = oss_get_object_to_file(oss_client_options, &bucket, &object, headers, par
ams, &file, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("Get object from file succeeded\n");
    } else {
        printf("Get object from file failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Note Compared with OSS SDK for C V1.0.0, this version adds the params parameter to the oss_get_object_to_file operation, and the values of the headers and params parameters can be NULL.

6.1.2.4.7.3. Download to local memory

This topic describes how to download an object to local memory.

For the complete code that is used to download objects, visit GitHub.

The following code provides an example on how to download a specified object to local memory:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
```

```
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_list_t buffer;
    aos_buf_t *content = NULL;
    aos_table_t *params = NULL;
    aos_table_t *headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    char *buf = NULL;
    int64_t len = 0;
    int64_t size = 0;
    int64_t pos = 0;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_list_init(&buffer);
    /* Download the object to local memory. */
    resp_status = oss_get_object_to_buffer(oss_client_options, &bucket, &object,
                                headers, params, &buffer, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("get object to buffer succeeded\n");
        /* Copy the downloaded content to the buffer. */
        len = aos_buf_list_len(&buffer);
        buf = aos_pcalloc(pool, len + 1);
        buf[len] = '\0';
        aos_list_for_each_entry(aos_buf_t, content, &buffer, node) {
        size = aos_buf_size(content);
            memcpy(buf + pos, content->pos, size);
```

```
            pos += size;
        }
    }
    else {
        printf("get object to buffer failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.7.4. Range download

If you need only part of the data in an object, you can use range download to download data within the specified range.

The following code provides an example on how to perform range download:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
```

```
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_list_t buffer;
    aos_buf_t *content = NULL;
    aos_table_t *params = NULL;
    aos_table_t *headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    char *buf = NULL;
    int64_t len = 0;
    int64_t size = 0;
    int64_t pos = 0;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_list_init(&buffer);
    headers = aos_table_make(pool, 1);
    /* Set the range to byte 20 to byte 100. */
    apr_table_set(headers, "Range", "bytes=20-100");
    /* Download the object to local memory. */
    resp_status = oss_get_object_to_buffer(oss_client_options, &bucket, &object, headers, p
arams, &buffer, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("get object to buffer succeeded\n");
        /* Obtain the buffer length. */
        aos_list_for_each_entry(aos_buf_t, content, &buffer, node) {
            len += aos_buf_size(content);
        }
        buf = aos_pcalloc(pool, (apr_size_t)(len + 1));
        buf[len] = '\0';
        /* Copy the content in the buffer to the memory. */
        aos_list_for_each_entry(aos_buf_t, content, &buffer, node) {
            size = aos_buf_size(content);
            memcpy(buf + pos, content->pos, (size_t)size);
            pos += size;
        }
    }
    else {
        printf("get object to buffer failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
```

```
}
```

6.1.2.4.7.5. Resumable download

You may fail to download a large object if the network is unstable or other exceptions occur. In some cases, you may still fail to download the object even after multiple attempts. To solve this problem, OSS provides the resumable download feature.

To enable resumable download, you need to split the object you want to download into multiple parts and download them separately. After you have downloaded all parts, these parts will be combined into a complete object.

You can use the `oss_resumable_clt_params_t` method to implement resumable download. The following table describes the parameters included in `oss_resumable_clt_params_t`.

Parameter	Description
thread_num	The number of concurrent threads. Default value: 1.
enable_checkpoint	Specifies whether to enable resumable upload. By default, resumable upload is disabled.
partSize	The size of each part. Valid values: 1 byte to 5 GB.
checkpoint_path	The path of the checkpoint file. Default value: {upload_file_path}.cp.

The `checkpoint` file stores information about the download progress.If you fail to download a part, the download continues based on the progress recorded in the `checkpoint` file. The `checkpoint` file is deleted after resumable download is complete.

Run the following code for resumable download:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *local_filename = "<yourLocalFilename>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
```

```
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_string_t file;
    aos_table_t *headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    oss_resumable_clt_params_t *clt_params;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_str_set(&file, local_filename);
    /* Use resumable download to download the object. */
    clt_params = oss_create_resumable_clt_params_content(pool, 1024 * 100, 3, AOS_TRUE, NUL
L);
    resp_status = oss_resumable_download_file(oss_client_options, &bucket, &object, &file,
headers, NULL, clt_params, NULL, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("download succeeded\n");
    } else {
        printf("download failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.7.6. Use progress bars

Progress bars are used to indicate the progress of an upload or download.

For the complete code of download progress bars, visit GitHub.

The following code provides an example on how to view the progress information:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *local_filename = "<yourLocalFilename>";
const char *download_filename = "<yourDownloadFilename>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
void percentage(int64_t consumed_bytes, int64_t total_bytes)
{
    assert(total_bytes >= consumed_bytes);
    printf("%%%" APR_INT64_T_FMT "\n", consumed_bytes * 100 / total_bytes);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos string t file;
```

```
    aos_table_t *resp_headers = NULL;
    aos_list_t resp_body;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_str_set(&file, local_filename);
    /* View the upload progress while you upload an object. */
    resp_status = oss_do_put_object_from_file(oss_client_options, &bucket, &object, &file,
NULL, NULL, percentage, &resp_headers, &resp_body);
    if (aos_status_is_ok(resp_status)) {
        printf("put object from file succeeded\n");
    } else {
        printf("put object from file failed\n");
    }
    /* View the download progress while you download an object. */
    aos_pool_create(&pool, NULL);
    oss_client_options = oss_request_options_create(pool);
    init_options(oss_client_options);
    aos_str_set(&file, download_filename);
    resp_status = oss_do_get_object_to_file(oss_client_options, &bucket, &object, NULL, NUL
L, &file, percentage, NULL);
    if (aos_status_is_ok(resp_status)) {
        printf("get object to file succeeded\n");
    } else {
        printf("get object to file failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

oss_get_object_from_file and oss_get_object_from_buffer does not support the progress bar feature.

6.1.2.4.8. Manage objects

6.1.2.4.8.1. Overview

You can manage objects in a bucket by using a variety of operations including SetObjectAcl, GetObjectAcl, ListObjects, DeleteObject, and CopyObject.

By using the preceding operations, you can perform the following operations:

- Manage object ACLs
- Manage object metadata
- List objects
- Delete objects
- Copy objects

6.1.2.4.8.2. Manage object ACLs

This topic describes how to manage the access control list (ACL) of an object.

The following table describes the ACLs that can be configured for an object.

ACL	Description	Value
Inherited from the bucket	The ACL of an object is the same as that of the bucket in which the object is stored.	OSS_ACL_DEFAULT
Private	Only the owner or authorized users of the bucket can read and write the object.	OSS_ACL_PRIVATE
Public read	Only the owner or authorized users of this bucket can write the object. Other users, including anonymous users can only read the object. Exercise caution when you use this ACL.	OSS_ACL_PUBLIC_READ
Public read/write	Any users, including anonymous users can read and write the object. Exercise caution when you use this ACL.	OSS_ACL_PUBLIC_READ_WRITE

The ACL of objects take precedence over that of buckets. For example, if the ACL of a bucket is private, while the object ACL is public read-write, all users can read and write the object. If an object is not configured with an ACL, its ACL is the same as that of its bucket by default.

You can run the following code to configure an ACL for an object:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
```

```
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources such
as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    oss_acl_e oss_acl = OSS_ACL_PUBLIC_READ;
    /* Configure the object ACL. */
    resp_status = oss_put_object_acl(oss_client_options, &bucket, &object, oss_acl, &resp_h
eaders);
    if (aos_status_is_ok(resp_status)) {
        printf("put object acl success! \n");
    } else {
        printf("put object acl failed! \n");
    }
    /* Query the ACL of the object. */
    aos_string_t oss_acl_string;
    resp_status = oss_get_object_acl(oss_client_options, &bucket, &object, &oss_acl_string,
&resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("get object acl success! \n");
        printf("acl: %s \n", oss_acl_string.data);
    } else {
        printf("get object acl failed! \n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.8.3. Manage object metadata

After you upload an object to OSS or before you read an object from OSS, you can use the `oss_get_object_meta` operation to query object metadata such as the content length and object type.

The following code provides an example on how to configure and query object metadata:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources such
as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_table_t *headers;
    aos_list_t buffer;
    aos_table_t *resp_headers = NULL;
```

```
    aos_status_t *resp_status = NULL;
    aos_buf_t *content = NULL;
    char *content_length_str = NULL;
    char *object_type = NULL;
    char *object_author = NULL;
    int64_t content_length = 0;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    headers = aos_table_make(pool, 2);
    /* Configure user metadata. */
    apr_table_set(headers, "Expires", "Fri, 28 Feb 2032 05:38:42 GMT");
    apr_table_set(headers, "x-oss-meta-author", "oss");
    aos_list_init(&buffer);
    content = aos_buf_pack(oss_client_options->pool, object_content, strlen(object_content)
);
    aos_list_add_tail(&content->node, &buffer);
    /* Configure the object ACL. Upload object from the buffer. */
    resp_status = oss_put_object_from_buffer(oss_client_options, &bucket, &object,
                &buffer, headers, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("put object from buffer with md5 succeeded\n");
    } else {
        printf("put object from buffer with md5 failed\n");
    }
    /* Query the ACL of the object. */
    resp_status = oss_get_object_meta(oss_client_options, &bucket, &object, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        content_length_str = (char*)apr_table_get(resp_headers, OSS_CONTENT_LENGTH);
        if (content_length_str ! = NULL) {
            content_length = atol(content_length_str);
        }
        object_author = (char*)apr_table_get(resp_headers, OSS_AUTHORIZATION);
        object_type = (char*)apr_table_get(resp_headers, OSS_OBJECT_TYPE);
        printf("get object meta succeeded, object author:%s, object type:%s, content_length
:%ld\n", object_author, object_type, content_length);
    } else {
        printf("req:%s, get object meta failed\n", resp_status->req_id);
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Note For more information about HTTP headers, see RFC 2616.

6.1.2.4.8.4. List objects

This topic describes how to list the objects stored in a bucket.

For the complete code used to list objects, visit GitHub.

Objects are listed in alphabetical order. You can use `oss_list_object` to list objects in a bucket. The following table describes common parameters.

Parameter	Description
delimiter	Groups objects by name. Objects whose names contain the same string from the prefix and the next occurrence of the delimiter are grouped as a single result element in CommonPrefixes.
prefix	Specifies the prefix that returned object names must contain.
max_ret	Specifies the maximum number of objects that can be listed at a time. The default value is 100. The maximum value is 1000.
marker	Specifies the name of the object after which the listing begins.

List all objects

The following code provides an example on how to list all objects in a bucket:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize the aos_string_t data type. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as network
s and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the apr library. */
    aos_pool_t *pool;
```

```
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter includes global configuration informat
ion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_status_t *resp_status = NULL;
    oss_list_object_params_t *params = NULL;
    oss_list_object_content_t *content = NULL;
    int size = 0;
    char *line = NULL;
    char *prefix = "";
    char *nextMarker = "";
    aos_str_set(&bucket, bucket_name);
    params = oss_create_list_object_params(pool);
    params->max_ret = 100;
    aos_str_set(&params->prefix, prefix);
    aos_str_set(&params->marker, nextMarker);
    printf("Object\tSize\tLastModified\n");
    /* List all objects. */
    do {
        resp_status = oss_list_object(oss_client_options, &bucket, params, NULL);
        if (! aos_status_is_ok(resp_status))
        {
            printf("list object failed\n");
            break;
        }
        aos_list_for_each_entry(oss_list_object_content_t, content, &params->object_list, n
ode) {
            ++size;
            line = apr_psprintf(pool, "%.*s\t%.*s\t%.*s\n", content->key.len, content->key.
data,
                content->size.len, content->size.data,
                content->last_modified.len, content->last_modified.data);
            printf("%s", line);
        }
        nextMarker = apr_psprintf(pool, "%.*s", params->next_marker.len, params->next_marke
r.data);
        aos_str_set(&params->marker, nextMarker);
        aos_list_init(&params->object_list);
        aos_list_init(&params->common_prefix_list);
    } while (params->truncated == AOS_TRUE);
    printf("Total %d\n", size);
    /* Release the memory pool. The memory allocated to various resources used for the requ
est is released. */
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
```

```
    return 0;
}
```

Note If a bucket contains more than 1,000 objects, only the first 1,000 objects are returned, and the value of the truncated parameter in the response is true. Additionally, the next_marker parameter is returned as the start point for the next read. To list more than 1,000 objects at a time, you can modify the max_ret parameter. You can also use the marker parameter to perform multiple read operations.

List a specified number of objects

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize the aos_string_t data type. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;

}
```

Folder simulation

OSS does not use folders. All elements are stored as objects. To simulate a folder on the OSS console, you actually create a 0 MB object whose name ends with a forward slash (/). This object can be uploaded and downloaded. By default, the OSS console displays an object whose name ends with a forward slash (/) as a folder.

The delimiter and prefix parameters can be used to simulate folder functions.

- Prefix: specifies the prefix as the name of a folder. The folder is used to list all files (in the folder) and subfolders (directories in the folder) that start with this prefix. These files and subfolders are included in the Objects list.
- Delimiter: If the delimiter is specified as a forward slash (/), only the files and subfolders (directories) are displayed. Subfolders (directories) are included in the CommonPrefixes list, while the files and folders in subfolders are not displayed.

For the complete code used to create a folder, visit GitHub.

Assume that the following objects are stored in a bucket: oss.jpg, fun/test.jpg, fun/movie/001.avi, and fun/movie/007.avi. Forward slashes (/) are used as delimiters for folders. The subsequent examples show how to simulate folder functions.

- List all objects in a bucket

  Run the following code to list all objects in a bucket:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize the aos_string_t data type. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is n
ot used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call aos_http_io_initialize in main() to initialize global resources such as netwo
rks and memory. */
```

```
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The
code used to create a memory pool is included in the apr library. */

6.1.2.4.8.5. Delete objects

This topic describes how to delete objects.

> **Warning** Deleted objects cannot be recovered. Exercise caution when you delete objects.

For the complete code used to delete objects, visit GitHub.

Delete a single object

The following code provides an example on how to delete an object named *exampleobject.txt* from a bucket named examplebucket:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources such
as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    /* Assign char* data to the aos_string_t bucket. */
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    /* Delete the object. */
    resp_status = oss_delete_object(oss_client_options, &bucket, &object, &resp_headers);
    /* Determine whether the object is deleted. */
```

```
    if (aos_status_is_ok(resp_status)) {
        printf("delete object succeed\n");
    } else {
        printf("delete object failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Delete multiple objects

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name1 = "<yourObjectName1>";
const char *object_name2 = "<yourObjectName2>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources such
as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
```

```
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object1;
    aos_string_t object2;
    int is_quiet = 1;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object1, object_name1);
    aos_str_set(&object2, object_name2);
    /* Create a list of objects you want to delete. */
    aos_list_t object_list;
    aos_list_t deleted_object_list;
    oss_object_key_t *content1;
    oss_object_key_t *content2;
    aos_list_init(&object_list);
    aos_list_init(&deleted_object_list);
    content1 = oss_create_oss_object_key(pool);
    aos_str_set(&content1->key, object_name1);
    aos_list_add_tail(&content1->node, &object_list);
    content2 = oss_create_oss_object_key(pool);
    aos_str_set(&content2->key, object_name2);
    aos_list_add_tail(&content2->node, &object_list);
    /* Delete objects in the list. `is_quiet` specifies whether to return the deletion resu
lt. */
    resp_status = oss_delete_objects(oss_client_options, &bucket, &object_list, is_quiet, &
resp_headers, &deleted_object_list);
    if (aos_status_is_ok(resp_status)) {
        printf("delete objects succeeded\n");
    } else {
        printf("delete objects failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Delete multiple objects whose names contain a specified prefix

You can delete multiple objects whose names contain a specified prefix to delete a folder. For example, if you delete objects whose names contain dir/, the dir folder is deleted. The following code provides an example on how to delete multiple objects whose names contain a specified prefix:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
```

```
const char *bucket_name = "<yourBucketName>";
const char *object_prefix = "<yourObjectNamePrefix>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources such
as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode used to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration informa
tion such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t prefix;
    aos_status_t *resp_status = NULL;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&prefix, object_prefix);
    /* Delete the objects whose names contain the specified prefix. */
    resp_status = oss_delete_objects_by_prefix(oss_client_options, &bucket, &prefix);
    if (aos_status_is_ok(resp_status)) {
        printf("delete objects by prefix succeeded\n");
    } else {
        printf("delete objects by prefix failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the request.
*/
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

```
}
```

Warning If you set the prefix to an empty string or NULL, all objects in the bucket are deleted. Exercise caution when you use this operation.

6.1.2.4.8.6. Copy objects

This topic describes how to copy an object.

Limits on object copying:

- You must have read permissions on the source object and write permissions on the destination bucket.
- You cannot copy an object across regions.

Copy a small object

The following code provides an example on how to copy an object smaller than or equal to 1 GB in size:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *source_bucket_name = "<yourSourceBucketName>";
const char *source_object_name = "<yourSourceObjectName>";
const char *dest_bucket_name = "<yourDestBucketName>";
const char *dest_object_name = "<yourDestObjectName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize the aos_string_t data type. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as the timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources such
as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode to create a memory pool is included in the APR library. */
```

```
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter includes global configuration informat
ion such as endpoint, access_key_id, acces_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t source_bucket;
    aos_string_t source_object;
    aos_string_t dest_bucket;
    aos_string_t dest_object;
    aos_table_t *headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_str_set(&source_bucket, source_bucket_name);
    aos_str_set(&source_object, source_object_name);
    aos_str_set(&dest_bucket, dest_bucket_name);
    aos_str_set(&dest_object, dest_object_name);
    headers = aos_table_make(pool, 0);
    /* Copy the object. */
    resp_status = oss_copy_object(oss_client_options, &source_bucket, &source_object, &dest
_bucket, &dest_object, headers, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("copy object succeeded\n");
    } else {
        printf("copy object failed\n");
    }
    /* Release the memory pool. The memory allocated to various resources used for the requ
est is released. */
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Copy a large object

We recommend that you use the oss_upload_part_copy operation to copy an object larger than 1 GB in size. The following code provides an example on how to perform multipart copy:

```
#include "oss_api.h"
#include "aos_http_io.h"
#include <sys/stat.h>
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *source_bucket_name = "<yourSourceBucketName>";
const char *source_object_name = "<yourSourceObjectName>";
const char *dest_bucket_name = "<yourDestBucketName>";
```

```
const char *dest_object_name = "<yourDestObjectName>";
const char *local_filename = "<yourLocalFilename>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize the aos_string_t data type. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as the timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int64_t get_file_size(const char *file_path)
{
    int64_t filesize = -1;
    struct stat statbuff;
    if(stat(file_path, &statbuff) < 0){
        return filesize;
    } else {
        filesize = statbuff.st_size;
    }
    return filesize;
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources such
as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter includes global configuration informat
ion such as endpoint, access_key_id, acces_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t dest_bucket;
    aos_string_t dest_object;
    aos_string_t upload_id;
    aos_table_t *headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    oss_list_upload_part_params_t *list_upload_part_params;
```

```
    oss_upload_part_copy_params_t *upload_part_copy_params1;
    oss_upload_part_copy_params_t *upload_part_copy_params2;

        printf("complete multipart upload failed\n");
    }
    /* Release the memory pool. The memory allocated to various resources used for the request is released. */
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.9. Authorized access

This topic describes how to authorize access to OSS by using Security Token Service (STS) or a signed URL.

Use STS to authorize temporary access

Alibaba Cloud STS is a web service that provides a temporary access token to a cloud computing user. You can use STS to grant a third-party application or your RAM user an access credential with a customized validity period and permissions.

STS provides the following benefits:

- You need only to generate an access token and send the access token to a third-party application, instead of exposing your AccessKey pair to the third-party application. You can define the access permissions and validity period of this token.

- The token automatically expires after the validity period. Therefore, you do not need to manually revoke the access permissions of a token.

The following code provides an example on how to use STS to authorize temporary access to upload an object:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *sts_token = "<yourStsToken>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *object_content = "More than just cloud.";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize the aos_string_t data type. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    aos_str_set(&options->config->sts_token, sts_token);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not
used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as the timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources such
as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The c
ode to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that th
e pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter includes global configuration informat
ion such as endpoint, access_key_id, acces_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_list_t buffer;
    aos_buf_t *content = NULL;
    aos table t *headers = NULL;
```

```
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    /* Assign the char * data to the bucket. */
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_list_init(&buffer);
    content = aos_buf_pack(oss_client_options->pool, object_content, strlen(object_content)
);
    aos_list_add_tail(&content->node, &buffer);
    /* Start to upload the object. */
    resp_status = oss_put_object_from_buffer(oss_client_options, &bucket, &object, &buffer,
headers, &resp_headers);
    /* Determine whether the upload is successful. */
    if (aos_status_is_ok(resp_status)) {
        printf("put object from buffer succeeded\n");
    } else {
        printf("put object from buffer failed\n");
    }
    /* Release the memory pool. The memory allocated to various resources used for the requ
est is released. */
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

Use a signed URL to authorize temporary access

You can generate a signed URL and provide the URL to a visitor for temporary access. When you generate a signed URL, you can specify the validity period of the URL to limit the period of access from visitors. By default, the validity period of a signed URL is 3,600 seconds. The maximum validity period of a signed URL is 32,400 seconds.

- Use a signed URL to upload an object

  The following code provides an example on how to upload an object by using a signed URL:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *local_filename = "<yourLocalFilename>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize the aos_string_t data type. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is n
```

```
ot used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as the timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources su
ch as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The
code to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that
the pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter includes global configuration inform
ation such as endpoint, access_key_id, acces_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_string_t file;
    aos_table_t *headers = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_http_request_t *req;
    apr_time_t now;
    char *url_str;
    aos_string_t url;
    int64_t expire_time;
    int one_hour = 3600;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_str_set(&file, local_filename);
    expire_time = now / 1000000 + one_hour;
    headers = aos_table_make(pool, 0);
    req = aos_http_request_create(pool);
    req->method = HTTP_PUT;
    now = apr_time_now(); /* Unit: microseconds */
    expire_time = now / 1000000 + one_hour;
    /* Generate a signed URL. */
    url_str = oss_gen_signed_url(oss_client_options, &bucket, &object, expire_time, req);
    aos_str_set(&url, url_str);
    printf ("The signed URL: %s\n", url_str);
    /* Use the signed URL to upload the object. */
    resp_status = oss_put_object_from_file_by_url(oss_client_options, &url, &file, header
s, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
```

```
    if (aos_status_is_ok(resp_status)) {
        printf("put objects by signed url succeeded\n");
    } else {
        printf("put objects by signed url failed\n");
    }
    /* Release the memory pool. The memory allocated to various resources used for the request is released. */
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

- Use a signed URL to download an object

  The following code provides an example on how to download a specified object by using a signed URL:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
const char *local_filename = "<yourLocalFilename>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize the aos_string_t data type. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME to access OSS. A value of 0 indicates that CNAME is not used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as the timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources such as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The code to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This parameter indicates that the pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter includes global configuration information such as endpoint, access_key_id, acces_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate a memory chunk in the memory pool to options. */
```

```
    /* Allocate a memory chunk in the memory pool to options. */
    oss_client_options = oss_request_options_create(pool);
    /* Call oss_client_options to initialize the client options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_string_t file;
    aos_table_t *headers = NULL;
    aos_table_t *params = NULL;
    aos_table_t *resp_headers = NULL;
    aos_status_t *resp_status = NULL;
    aos_http_request_t *req;
    apr_time_t now;
    char *url_str;
    aos_string_t url;
    int64_t expire_time;
    int one_hour = 3600;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    aos_str_set(&file, local_filename);
    expire_time = now / 1000000 + one_hour;
    headers = aos_table_make(pool, 0);
    params = aos_table_make(pool, 0);
    req = aos_http_request_create(pool);
    req->method = HTTP_GET;
    now = apr_time_now(); /* Unit: microseconds */
    expire_time = now / 1000000 + one_hour;
    /* Generate a signed URL. */
    url_str = oss_gen_signed_url(oss_client_options, &bucket, &object, expire_time, req);
    aos_str_set(&url, url_str);
    /* Use the signed URL to download the object. */
    resp_status = oss_get_object_to_file_by_url(oss_client_options, &url, headers, params
, &file, &resp_headers);
    if (aos_status_is_ok(resp_status)) {
        printf("get object succeeded\n");
    } else {
        printf("get object failed\n");
    }
    /* Release the memory pool. The memory allocated to various resources used for the re
quest is released. */
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.10. IMG

OSS Image Processing (IMG) is a secure, cost-effective, and highly reliable image processing service that can process large amounts of data. After you upload source images to OSS, you can call RESTful API operations to process the images anytime, anywhere, and on any Internet device.

For the complete IMG code, visit GitHub.

Basic features

OSS IMG provides the following features:

- Query image information.
- Convert image formats.
- Resize, crop, and rotate images.
- Apply image effect.
- Add image, text, and text-and-image watermarks to images.
- Customize image processing styles. Log on to the OSS console. Click a bucket name to go to the bucket details page. Click the **Image Processing (IMG)** tab and click **Create Rule** to customize an image processing style.
- Use cascade processing to call multiple IMG features.

Usage

You can use standard `HTTP GET` requests to access IMG. All processing parameters are encoded in the query string of a URL.

- Anonymous access

  You can anonymously access a processed image by using a third-level domain in the following format:

  ```
  http://<yourBucketName>.<yourEndpoint>/<yourObjectName>?x-oss-process=image/<yourAction>,<yourParamValue>
  ```

Parameter	Description
bucket	The name of the bucket.
endpoint	The domain name used to access the region.
object	The name of the image object.
image	The identifier reserved by IMG.
action	The operations performed on images, such as scaling, cropping, and rotating.
param	The parameters corresponding to the operations performed on the images.

  - Basic operations

    For example, you can scale an image to a width of 100 and adjust the height based on the ratio:

    ```
    http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100
    ```

- Customize an image style

  You can anonymously access IMG by using a third-level domain in the following format:

  ```
  http://<yourBucketName>.<yourEndpoint>/<yourObjectName>?x-oss-process=style/<yourStyleName>
  ```

  - style: the identifier reserved by IMG for the custom style.
  - yourStyleName: the name of the custom style. The name is specified by the Rule Name parameter when you create the custom style in the console.

  Example:

  ```
  http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=style/oss-pic-style-w-100
  ```

- Cascade processing

  You can use cascade processing to perform multiple operations in sequence on an image by using a URL in the following format:

  ```
  http://<yourBucketName>.<yourEndpoint>/<yourObjectName>?x-oss-process=image/<yourAction1>,<yourParamValue1>/<yourAction2>,<yourParamValue2>/...
  ```

  Example:

  ```
  http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100/rotate,90
  ```

- Access by using HTTPS

  IMG supports access by using HTTPS. Example:

  ```
  https://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100
  ```

- Authorized access

  If the ACL of an image object is private, you must have permissions on the image object before you can perform operations on the image object.

Bucket ACL	Object ACL
private	default
Any ACL	private

The following code provides an example on how to generate a signed URL to access IMG:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
void init_options(oss_request_options_t *options)
```

```
{
    options->config = oss_config_create(options->pool);
    /* Use a char* string to initialize aos_string_t. */
    aos_str_set(&options->config->endpoint, endpoint);
    aos_str_set(&options->config->access_key_id, access_key_id);
    aos_str_set(&options->config->access_key_secret, access_key_secret);
    /* Specify whether to use CNAME. A value of 0 indicates that CNAME is not used. */
    options->config->is_cname = 0;
    /* Configure network parameters such as timeout periods. */
    options->ctl = aos_http_controller_create(options->pool, 0);
}
int main(int argc, char *argv[])
{
    /* Call the aos_http_io_initialize method in main() to initialize global resources su
ch as networks and memory. */
    if (aos_http_io_initialize(NULL, 0) ! = AOSE_OK) {
        exit(1);
    }
    /* Create a memory pool to manage memory. aos_pool_t is equivalent to apr_pool_t. The
code to create a memory pool is included in the APR library. */
    aos_pool_t *pool;
    /* Create a memory pool. The second parameter is NULL. This value indicates that the
pool does not inherit any other memory pool. */
    aos_pool_create(&pool, NULL);
    /* Create and initialize options. This parameter specifies global configuration infor
mation such as endpoint, access_key_id, access_key_secret, is_cname, and curl. */
    oss_request_options_t *oss_client_options;
    /* Allocate the memory resources in the memory pool to the options. */
    oss_client_options = oss_request_options_create(pool);
    /* Initialize oss_client_options. */
    init_options(oss_client_options);
    /* Initialize the parameters. */
    aos_string_t bucket;
    aos_string_t object;
    aos_table_t *params = NULL;
    aos_http_request_t *req;
    char *url_str;
    apr_time_t now;
    int64_t expire_time;
    aos_str_set(&bucket, bucket_name);
    aos_str_set(&object, object_name);
    /* Process the image. */
    params = aos_table_make(pool, 1);
    apr_table_set(params, OSS_PROCESS, "image/resize,m_fixed,w_100,h_100");
    req = aos_http_request_create(pool);
    req->method = HTTP_GET;
    req->query_params = params;
    /* Specify the validity period (expire_time) in seconds. */
    now = apr_time_now();
    expire_time = now / 1000000 + 10 * 60;
    /* Generate a signed URL. */
    url_str = oss_gen_signed_url(oss_client_options, &bucket, &object, expire_time, req);
    printf("url: %s\n", url_str);
    /* Release the memory pool, which releases memory resources allocated for the request
```

```
. */
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

- Access by using SDKs

  You can use OSS SDKs to access and process image objects of any ACLs.

  - Basic operations

    The following code provides an example on how to perform basic IMG operations including obtaining image information, converting image formats, resizing, cropping, rotating, watermarking, and applying effects:

```
#include "oss_api.h"
#include "aos_http_io.h"
const char *endpoint = "<yourEndpoint>";
const char *access_key_id = "<yourAccessKeyId>";
const char *access_key_secret = "<yourAccessKeySecret>";
const char *bucket_name = "<yourBucketName>";
const char *object_name = "<yourObjectName>";
void init_options(oss_request_options_t *options)
{
    options->config = oss_config_create(options->pool);

        printf("get object to file succeeded\n");
    } else {
        printf("get object to file failed\n");
    }
    /* Release the memory pool, which releases memory resources allocated for the reque
st. */
    aos_pool_destroy(pool);
    /* Release the allocated global resources. */
    aos_http_io_deinitialize();
    return 0;
}
```

6.1.2.4.11. Error handling

This topic describes how to handle errors when you use OSS SDK for C.

Exception handling

If an error occurs when you send a request by using OSS SDK for C, an corresponding error message is returned by aos_status_s. The following table describes the attributes of aos_status_s.

Error code	Description	Type
code	The HTTP status code of the error request.	Integer
error_code	The error code returned by OSS.	String
error_msg	The error message returned by OSS.	String
req_id	The UUID that identifies the request. You can provide req_id to OSS development engineers for help.	String

Timeout handling

If the code in the returned aos_status_t parameter is not 2xx and error_code indicates -992 or -995, the connection or request times out. You can send the request again.

You can use aos_should_retry(aos_status_t *) in the aos_status.h file to determine whether the error code returned requires a retry. If a value of 1 is returned, you can try again.

Common error codes

Error code	Error message	HTTP status code
AccessDenied	The error message returned because the access is denied.	403
BucketAlreadyExists	The error message returned because the bucket already exists.	409
BucketNotEmpty	The error message returned because the bucket is not empty.	409
EntityTooLarge	The error message returned because the entity exceeds the maximum allowed size.	400
EntityTooSmall	The error message returned because the entity is smaller than the minimum allowed size.	400
FileGroupTooLarge	The error message returned because the object group exceeds the maximum allowed size.	400
FilePartNotExist	The error message returned because the specified part does not exist.	400
FilePartStale	The error message returned because the part has expired.	400
InvalidArgument	The error message returned because the parameter format is invalid.	400
InvalidAccessKeyId	The error message returned because the specified Accesskey ID does not exist.	403
InvalidBucketName	The error message returned because the bucket name is invalid.	400
InvalidDigest	The error message returned because the digest is invalid.	400

Error code	Error message	HTTP status code
InvalidObjectName	The error message returned because the object name is invalid.	400
InvalidPart	The error message returned because the part is invalid.	400
InvalidPartOrder	The error message returned because the part order is invalid.	400
InvalidTargetBucketForLogging	The error message returned because the target bucket specified for logging is invalid.	400
InternalError	The error message returned because an internal OSS error occurs.	500
MalformedXML	The error message returned because the XML format is invalid.	400
MethodNotAllowed	The error message returned because the method is not supported.	405
MissingArgument	The error message returned because the required parameters are not set.	411
MissingContentLength	The error message returned because the content length is not specified.	411
NoSuchBucket	The error message returned because the specified bucket does not exist.	404
NoSuchKey	The error message returned because the specified object does not exist.	404
NoSuchUpload	The error message returned because the specified multipart upload ID does not exist.	404
NotImplemented	The error message returned because the method cannot be implemented.	501
PreconditionFailed	The error message returned because a precondition error occurs.	412

Error code	Error message	HTTP status code
RequestTimeTooSkewed	The error message returned because the difference between the time on the client when the request is sent and the time on the server when the request is received is greater than 15 minutes.	403
RequestTimeout	The error message returned because the request times out.	400
SignatureDoesNotMatch	The error message returned because the signature is invalid.	403
TooManyBuckets	The error message returned because the number of the buckets managed by a user exceeds the limit.	400

6.1.2.5. Go-SDK

6.1.2.5.1. Preface

This topic describes the sample code of OSS SDK for Go in various use cases.

SDK source code and API documents

For the source code of OSS SDK for Go, visit GitHub. For more information, see OSS SDK for Go API documents.

Sample programs

OSS SDK for Go provides a variety of sample programs for your reference or use. The following table describes the sample programs provided.

Sample file	Description
new_bucket.go	Shows you how to initialize a client.
put_object.go	Shows you how to use simple upload and resumable upload.
append_object.go	Shows you how to use append upload.
get_object.go	Shows you how to use streaming download, range download, and resumable download.
delete_object.go	Shows you how to delete a single object and multiple objects.
copy_object.go	Shows you how to use object copy and resumable copy.

Sample file	Description
list_objects.go	Shows you how to list objects, including list by default or specified parameter.
object_meta.go	Shows you how to configure and query object metadata.
object_acl.go	Shows you how to configure and query object ACL.
cname_sample.go	Shows you how to use CNAME.
create_bucket.go	Shows you how to create a bucket.
list_buckets.go	Shows you how to list buckets, including list by default or specified parameter.
bucket_acl.go	Shows you how to configure and query bucket ACL.
bucket_referer.go	Shows you how to configure, query, and delete the Referer whitelist for a bucket.
bucket_logging.go	Shows you how to configure, query, and delete access logs for a bucket.
bucket_lifecycle.go	Shows you how to configure, query, and delete lifecycle rules for objects in a bucket.
bucket_cors.go	Shows you how to configure, query, and delete the cross-origin resource sharing (CORS) rules for a bucket.

6.1.2.5.2. Installation

This topic describes how to install OSS SDK for Go.

Prerequisites

- Environment

  Go 1.6 or later is required.

  For more information about how to download and install the environment for Go, visit Installing Go from source. After Go is installed, create a new system variable GOPATH, and set the value to your code directory. For more information about GOPATH, run the `go help gopath` command.

- Check the Go version

  Run the `go version` command to view the version of Go.

Download OSS SDK for Go

- Download from GitHub
- Download previous versions

Install OSS SDK for Go

Run the following command to install OSS SDK for Go:

```
go get github.com/aliyun/aliyun-oss-go-sdk/oss
```

Note When you run the go get command to install the SDK, no prompts are displayed. If the installation times out, run the preceding command again.

View the version of OSS SDK for Go

Run the following code to view the version of OSS SDK for Go:

```
package main
import (
  "fmt"
  "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
  fmt.Println("OSS Go SDK Version: ", oss.Version)
}
```

6.1.2.5.3. Initialization

OSSClient serves as the client of OSS SDK for Go to manage OSS resources such as buckets and objects.

To create an OSSClient instance, you must specify an endpoint. For more information about endpoints, see Obtain an endpoint.

To create an OSSClient instance, you must specify an AccessKey pair. For more information about how to obtain an AccessKey pair, see Obtain an AccessKey pair.

The following table describes the parameters you can configure for this operation.

Parameter	Description	Default
UseCname	Specifies whether to use CNAME.	No
Timeout	The timeout period for request, including the connection timeout period and socket read/write timeout period. Unit: seconds.	The connection timeout period is 30 seconds. The read/write timeout period is 60 seconds.
SecurityToken	The temporary security token for users.	None
EnableMD5	Specifies whether to enable MD5 verification. We recommend that you enable CRC, which is more efficient than MD5 verification.	No
EnableCRC	Specifies whether to enable CRC.	Yes

Parameter	Description	Default
Proxy	The proxy server. Example: `http://8.8.8.8:3128`.	None
AuthProxy	The proxy server that requires an account and a password to log on.	None

Create an OSSClient instance based on an OSS endpoint

The following code provides an example on how to create an OSSClient instance based on an OSS endpoint:

```
import "github.com/aliyun/aliyun-oss-go-sdk/oss"
client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
if err ! = nil {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
```

Create an OSSClient instance based on a custom domain name

For the complete code of custom domain names, visit GitHub.

The following code provides an example on how to create an OSSClient instance based on a custom domain name:

```
import "github.com/aliyun/aliyun-oss-go-sdk/oss"
// oss.UseCname(true) indicates that CNAME is enabled. If CNAME is enabled, a custom domain
name can be bound to a bucket.
client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>", oss.
UseCname(true))
if err ! = nil {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
```

Notice When you use CNAME, you cannot list buckets because a custom domain name is bound to a specified bucket.

Create an OSSClient instance based on STS

The following code provides an example on how to create an OSSClient instance based on Security Token Service (STS):

```
import "github.com/aliyun/aliyun-oss-go-sdk/oss"
client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>", oss.
SecurityToken("<yourSecurityToken>"))
if err ! = nil {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
```

Configure the connection timeout period

The following code provides an example on how to configure the connection timeout period:

```
import "github.com/aliyun/aliyun-oss-go-sdk/oss"
// oss.Timeout(10, 120) indicates that the HTTP connection timeout period is 10 seconds and
the HTTP read/write timeout period is 120 seconds. The default HTTP connection timeout peri
od is 30 seconds. The default HTTP read/write timeout period is 60 seconds. A value of 0 in
dicates that the connection never times out.
client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>", oss.
Timeout(10, 120))
if err ! = nil {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
```

Disable CRC

By default, CRC is enabled to ensure data integrity when you upload or download objects. The following code provides an example on how to disable CRC:

Warning We recommend that you do not disable CRC. If you disable CRC, data integrity may be affected during object upload and download.

```
import "github.com/aliyun/aliyun-oss-go-sdk/oss"
client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>", oss.
EnableCRC(false))
if err ! = nil {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
```

6.1.2.5.4. Quick start

This topic describes how to use OSS SDK for Go to perform routine operations, such as creating buckets, uploading objects, and downloading objects.

Create buckets

A bucket is a global namespace in OSS. A bucket is a container for objects stored in OSS. The following code provides an example on how to create a bucket:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func handleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    // The endpoint of the China (Hangzhou) region is used in this example. Specify the act
ual endpoint.
    endpoint := "http://oss-cn-hangzhou.aliyuncs.com"
    accessKeyId := "<yourAccessKeyId>"
    accessKeySecret := "<yourAccessKeySecret>"
    bucketName := "<yourBucketName>"
    // Create an OSSClient instance.
    client, err := oss.New(endpoint, accessKeyId, accessKeySecret)
    if err ! = nil {
        handleError(err)
    }
    // Create a bucket.
    err = client.CreateBucket(bucketName)
    if err ! = nil {
        handleError(err)
    }
}
```

For more information about how to obtain an AccessKey ID and AccessKey secret, see Obtain an AccessKey pair.

For more information about how to obtain an endpoint, see Obtain an endpoint.

Upload objects

The following code provides an example on how to upload objects to OSS by using stream upload:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func handleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    // The endpoint of the China (Hangzhou) region is used in this example. Specify the act
ual endpoint.
    endpoint := "http://oss-cn-hangzhou.aliyuncs.com"
    accessKeyId := "<yourAccessKeyId>"
    accessKeySecret := "<yourAccessKeySecret>"
    bucketName := "<yourBucketName>"
    // <yourObjectName> indicates the complete path of the object that you want to upload t
o OSS. The path must include the extension of the object name. Example: abc/efg/123.jpg.
    objectName := "<yourObjectName>"
    // <yourLocalFileName> consists of a local file path and an object name with extension.
Example: /users/local/myfile.txt.
    localFileName := "<yourLocalFileName>"
    // Create an OSSClient instance.
    client, err := oss.New(endpoint, accessKeyId, accessKeySecret)
    if err ! = nil {
        handleError(err)
    }
    // Specify the bucket name.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        handleError(err)
    }
    // Upload the object.
    err = bucket.PutObjectFromFile(objectName, localFileName)
    if err ! = nil {
        handleError(err)
    }
}
```

Download objects

The following code provides an example on how to download an object to a local file:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func handleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    // The endpoint of the China (Hangzhou) region is used in this example. Specify the act
ual endpoint.
    endpoint := "http://oss-cn-hangzhou.aliyuncs.com"
    accessKeyId := "<yourAccessKeyId>"
    accessKeySecret := "<yourAccessKeySecret>"
    bucketName := "<yourBucketName>"
    // <yourObjectName> indicates the complete path of the object that you want to download
from OSS. The path must include the extension of the object name. Example: abc/efg/123.jpg.
    objectName := "<yourObjectName>"
    downloadedFileName := "<yourDownloadedFileName>"
    // Create an OSSClient instance.
    client, err := oss.New(endpoint, accessKeyId, accessKeySecret)
    if err ! = nil {
        handleError(err)
    }
    // Specify the bucket name.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        handleError(err)
    }
    // Download the object.
    err = bucket.GetObjectToFile(objectName, downloadedFileName)
    if err ! = nil {
        handleError(err)
    }
}
```

List objects

The following code provides an example on how to list objects in a specified bucket. By default, a maximum of 100 objects can be listed.

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func HandleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        HandleError(err)
    }
    // Specify the bucket name.
    bucketName := "<yourBucketName>"
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        HandleError(err)
    }
    // List objects.
    marker := ""
    for {
        lsRes, err := bucket.ListObjects(oss.Marker(marker))
        if err ! = nil {
            HandleError(err)
        }
        // Display the listed objects. By default, 100 records are returned each time.
        for _, object := range lsRes.Objects {
            fmt.Println("Bucket: ", object.Key)
        }
        if lsRes.IsTruncated {
            marker = lsRes.NextMarker
        } else {
            break
        }
    }
}
```

Delete objects

The following code provides an example on how to delete an object:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func handleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    // The endpoint of the China (Hangzhou) region is used in this example. Specify the act
ual endpoint.
    endpoint := "http://oss-cn-hangzhou.aliyuncs.com"
    accessKeyId := "<yourAccessKeyId>"
    accessKeySecret := "<yourAccessKeySecret>"
    bucketName := "<yourBucketName>"
    // <yourObjectName> indicates the complete path of the object that you want to delete f
rom OSS. The path must include the extension of the object name. Example: abc/efg/123.jpg.
    objectName := "<yourObjectName>"
    // Create an OSSClient instance.
    client, err := oss.New(endpoint, accessKeyId, accessKeySecret)
    if err ! = nil {
        handleError(err)
    }
    // Specify the bucket name.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        handleError(err)
    }
    // Delete the object.
    err = bucket.DeleteObject(objectName)
    if err ! = nil {
        handleError(err)
    }
}
```

6.1.2.5.5. Buckets

6.1.2.5.5.1. Create buckets

A bucket is a container used to store objects in Object Storage Service (OSS). Each object is contained in a bucket. This topic describes how to create a bucket.

For the complete code used to create a bucket, visit GitHub.

```
package main
    import (
        "fmt"
        "os"
        "github.com/aliyun/aliyun-oss-go-sdk/oss"
    )
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Create a bucket. By default, the storage class of the bucket is Standard, and the AC
L of the bucket is private.
    err = client.CreateBucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

6.1.2.5.5.2. List buckets

For the complete code used to list buckets, visit GitHub.

List all buckets

Buckets are listed in alphabetical order. You can list all buckets or the buckets that meet specified conditions.

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // List all buckets.
    marker := ""
    for {
        lsRes, err := client.ListBuckets(oss.Marker(marker))
        if err ! = nil {
            fmt.Println("Error:", err)
            os.Exit(-1)
        }
        // By default, a maximum of 100 buckets are listed each time.
        for _, bucket := range lsRes.Buckets {
            fmt.Println("Bucket: ", bucket.Name)
        }
        if lsRes.IsTruncated {
            marker = lsRes.NextMarker
        } else {
            break
        }
    }
}
```

List buckets whose names contain a specified prefix

```
// List the buckets whose names contain a specified prefix.
    lsRes, err = client.ListBuckets(oss.Prefix("<yourBucketPrefix>"))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Display the list of buckets.
    fmt.Println("Buckets with prefix: ", lsRes.Buckets)
    for _, bucket := range lsRes.Buckets {
        fmt.Println("Bucket with prefix: ", bucket.Name)
    }
```

List buckets whose names come after a specified marker

```
    // List buckets whose names come after the specified marker.
    lsRes, err = client.ListBuckets(oss.Marker("<yourBucketMarker>"))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Display the list of buckets.
    fmt.Println("My buckets with marker :", lsRes.Buckets)
    for _, bucket := range lsRes.Buckets {
        fmt.Println("Bucket with marker: ", bucket.Name)
    }
```

List a specified number of buckets

```
    // Set the maximum number of buckets to list each time to 500. The default value is 100
. The maximum value is 1000.
    lsRes, err = client.ListBuckets(oss.MaxKeys(500))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Display the list of buckets.
    fmt.Println("My buckets max num:", lsRes.Buckets)
    for _, bucket := range lsRes.Buckets {
        fmt.Println("Bucket with maxKeys: ", bucket.Name)
    }
```

6.1.2.5.5.3. Manage bucket ACLs

A bucket is a container used to store objects in Object Storage Service (OSS). Every object is contained in a bucket. This topic describes how to configure and query the access control list (ACL) of a bucket.

For the complete code used to manage the ACL of a bucket, visit GitHub.

Configure ACL for a bucket

The following table describes the bucket ACLs.

ACL	Description	Value
Private	Only the owner or authorized users of the bucket can read and write the object.	oss.ACLPrivate
Public read	Only the owner or authorized users of this bucket can write the object. Other users, including anonymous users can only read the object. Exercise caution when you use this ACL.	oss.ACLPublicRead

ACL	Description	Value
Public read/write	Any users, including anonymous users can read and write the object. Exercise caution when you use this ACL.	oss.ACLPublicReadWrite

The following code provides an example on how to configure the ACL of a bucket:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Set the ACL of the bucket to public read.
    err = client.SetBucketACL("<yourBucketName>", oss.ACLPublicRead)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

Query the ACL of a bucket

The following code provides an example on how to query the ACL of a bucket:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Query the ACL of the bucket.
    aclRes, err := client.GetBucketACL("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Bucket ACL:", aclRes.ACL)
}
```

6.1.2.5.5.4. Delete buckets

Before you delete a bucket, ensure that all objects, LiveChannels, and parts that are generated from multipart upload in the bucket are deleted. The following code provides an example on how to delete a bucket:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Delete the bucket.
    err = client.DeleteBucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

6.1.2.5.5.5. Manage lifecycle rules

Object Storage Service (OSS) allows you to configure lifecycle rules to delete expired objects and parts or convert the storage class of expired objects to Infrequent Access (IA) or Archive to reduce your storage costs. This topic describes how to manage lifecycle rules for buckets.

Background

Each lifecycle rule contains the following information:

- Policy: specifies the mode to match objects and parts.
  - Match by prefix: matches objects and parts by prefix. You can create multiple rules to configure different prefixes. Each prefix must be unique.
  - Match by bucket: matches all objects and parts contained in the bucket. You can create only one rule if you select this method.
- Object lifecycle policy: specifies the validity period or expiration data and the operation to perform on these objects after they expire.
  - Validity period: specifies the number of days within which parts can be retained after they are last modified. After the validity period, expired objects are deleted.
  - Expiration date: specifies a date. Objects that are last modified before this date expire and are deleted.
- Part lifecycle policy: specifies the validity period or expiration time and the delete operation to perform on these objects after they expire.
  - Validity period: specifies the number of days within which parts can be retained after they are last modified. After the validity period, expired parts are deleted.
  - Expiration date: specifies a date. Parts that are last modified before this date expire and are deleted.

Lifecycle rules also apply to the parts uploaded by using uploadPart. In this case, the last modified time of an object is the time the multipart upload task is initiated.

Configure lifecycle rules

The following code provides an example on how to configure lifecycle rules:

```
package main
import (
    "fmt"
     "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // rule1 (id:"rule1", enable:true, prefix:"foo/", expiry:Days 3) indicates that objects
whose names contain prefix foo/ expire three days after they are last modified.
    rule1 := oss.BuildLifecycleRuleByDays("rule1", "foo/", true, 3)
    rules := []oss.LifecycleRule{rule1}
    // Configure the lifecycle rules.
    bucketName := "<yourBucketName>"
    err = client.SetBucketLifecycle(bucketName, rules)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

View lifecycle rules

The following code provides an example on how to query the lifecycle rules configured for the bucket named examplebucket:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // View the lifecycle rules.
    lcRes, err := client.GetBucketLifecycle(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Lifecycle Rules:", lcRes.Rules)
}
```

Delete lifecycle rules

The following code provides an example on how to delete lifecycle rules configured for the bucket named examplebucket:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Delete the lifecycle rules.
    err = client.DeleteBucketLifecycle(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
```

6.1.2.5.5.6. Hotlink protection

OSS provides hotlink protection to prevent unauthorized domain names from accessing your OSS data. You can configure the Referer field in the HTTP header.

To configure hotlink protection, you must configure the following parameters:

- Referer Whitelist: Only specified domain names are allowed to access OSS resources.
- Allow Empty Referer: If you do not allow empty Refer fields, a request is allowed to access OSS resources only if the request includes the Referer field configured in the HTTP or HTTPS header.

Configure hotlink protection

Run the following code to configure the referer whitelist:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Add a Referer whitelist. Specify that an empty Referer field is not allowed. You can
use an asterisk (*) or a question mark (?) as a wildcard to set the Referer parameter.
    referers := []string{"http://www.aliyun.com",
                         "http://www.???.aliyuncs.com",
                         "http://www. *.com"}
    err = client.SetBucketReferer(bucketName, referers, false)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

Query hotlink protection configurations

Run the following code to obtain a referer whiltelist:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Query hotlink protection information.
    refRes, err := client.GetBucketReferer(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Referers: ", refRes.RefererList)
    fmt.Println("AllowEmptyReferer: ", refRes.AllowEmptyReferer)
}
```

Delete hotlink protection configurations

Run the following code to clear a referer whitelist:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Delete hotlink protection configurations. // You cannot delete hotlink protection co
nfigurations directly. To delete hotlink protection configurations, you must create a rule
that allows an empty Referer field to replace the existing rule.
    err = client.SetBucketReferer(bucketName, []string{}, true)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

6.1.2.5.5.7. Configure logging

You can enable logging to record access to a bucket in log objects. The log objects are stored in a specified bucket.

The log file format is as follows:

```
<TargetPrefix><SourceBucket>-YYYY-mm-DD-HH-MM-SS-UniqueString
```

For the complete code of logging, visit GitHub.

Enable logging

Run the following code to enable bucket access logging:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    targetBucketName := "<yourTargetBucketName>"
    targetPrefix := "<yourTargetPrefix>"
    // Enable logging for the bucket. targetBucketName specifies the bucket that stores log
objects. targetPrefix specifies the prefix of the stored log objects. The log objects are s
tored in the targetPrefix folder.
    err = client.SetBucketLogging(bucketName, targetBucketName, targetPrefix, true)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

View logging configurations

Run the following code to view the access logging configurations for a bucket:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // View logging configurations of the bucket.
    logRes, err := client.GetBucketLogging(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Target Bucket: ", logRes.LoggingEnabled.TargetBucket)
    fmt.Println("Target Prefix: ", logRes.LoggingEnabled.TargetPrefix)
}
```

Disable logging

Run the following code to disable access logging for a bucket:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    // client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>
")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Disable logging.
    err = client.DeleteBucketLogging(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

6.1.2.5.5.8. Static website hosting

You can set the static website hosting mode for your bucket. After the configurations take effect, you can use the bucket domain to access this static website and be redirected to a specified index page or error page.

Configure static website hosting

Run the following code to configure static website hosting:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Configure static web hosting. Set the index page to index.html and the error page to
error.html.
    err = client.SetBucketWebsite(bucketName, "index.html", "error.html")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

View static website hosting configurations

Run the following code to view static website hosting configurations:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // View the static website hosting configurations.
    wsRes, err := client.GetBucketWebsite(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("indexWebsite: ", wsRes.IndexDocument.Suffix)
    fmt.Println("errorWebsite: ", wsRes.ErrorDocument.Key)
}
```

Delete static website hosting configurations

Run the following code to delete static website hosting configurations:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Delete the static website hosting configurations.
    err = client.DeleteBucketWebsite(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

6.1.2.5.5.9. CORS

Cross-origin resource sharing (CORS) allows web applications to access resources that belong to different regions. OSS provides CORS operations to facilitate cross-origin access control.

For the complete CORS rule code, visit GitHub.

Configure CORS rules

Run the following code to configure CORS rules for the specified bucket:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    rule1 := oss.CORSRule{
        AllowedOrigin: []string{"*"},
        AllowedMethod: []string{"PUT", "GET"},
        AllowedHeader: []string{},
        ExposeHeader:  []string{},
        MaxAgeSeconds: 200,
    }
    rule2 := oss.CORSRule{
        AllowedOrigin: []string{"http://www.a.com", "http://www.b.com"},
        AllowedMethod: []string{"POST"},
        AllowedHeader: []string{"Authorization"},
        ExposeHeader:  []string{"x-oss-test", "x-oss-test1"},
        MaxAgeSeconds: 100,
    }
    // Configure the CORS rules.
    err = client.SetBucketCORS(bucketName, []oss.CORSRule{rule1, rule2})
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

Query CORS rules

Run the following code to obtain CORS rules:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Query the CORS rules.
    corsRes, err := client.GetBucketCORS(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Bucket CORS:", corsRes.CORSRules)
}
```

Delete CORS rules

Run the following code to delete all CORS rules for the specified bucket:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Delete the CORS rules.
    err = client.DeleteBucketCORS(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

6.1.2.5.6. Upload objects

6.1.2.5.6.1. Overview

Objects are the basic unit for data operations in OSS. OSS SDK for PHP provides the following object upload methods:

You can upload objects to OSS by using one of the following methods:

- Simple upload: uploads an object up to 5 GB in size.
- Append upload: uploads an object up to 5 GB in size.
- Resumable upload: supports concurrent upload and resumable upload. You can define the size of each part. This method is suitable for the upload of large objects. You can use this method to upload an object up to 48.8 TB in size.
- Multipart upload: uploads an object up to 48.8 TB in size. This method is suitable for the upload of large objects.

During object upload, you can configure object metadata and view upload progress by using progress bars. For more information, see Use a progress bar.

6.1.2.5.6.2. Simple upload

This topic describes how to use simple upload.

For the complete code used to perform simple upload, visit GitHub.

Upload a string

The following code provides an example on how to upload a string to the exampleobject.txt object in the exampledir directory of the examplebucket bucket:

```
package main
import (
    "fmt"
    "os"
    "strings"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket to which to upload the object.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Set the storage class to Standard. The default storage class is Standard.
    storageType := oss.ObjectStorageClass(oss.StorageStandard)
    // Set the object ACL to public read. By default, the object inherits the bucket ACL.
    objectAcl := oss.ObjectACL(oss.ACLPublicRead)
    // Upload the string.
    err = bucket.PutObject("<yourObjectName>", strings.NewReader("yourObjectValue"), storag
eType, objectAcl)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

Upload a byte array

The following code provides an example on how to upload a byte array:

```
package main
import (
    "fmt"
    "os"
    "bytes"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket to which to upload the object.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Upload the byte array.
    err = bucket.PutObject("<yourObjectName>", bytes.NewReader([]byte("yourObjectValueByteA
rrary")))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

Upload a file stream

The following code provides an example on how to upload a file stream:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket to which to upload the object.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Read the local file.
    fd, err := os.Open("<yourLocalFile>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    defer fd.Close()
    // Upload the file stream.
    err = bucket.PutObject("<yourObjectName>", fd)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

Upload a local file

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket to which to upload the object.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Upload the local file.
    err = bucket.PutObjectFromFile("<yourObjectName>", "<yourLocalFile>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

6.1.2.5.6.3. Append upload

This topic describes how to perform append upload.

You cannot perform the copyObject operation on append objects. If the object to append does not exist, you can call `AppendObject` to create an append object. If the object to append exists, you can call `AppendObject` to append content to the end of the object.

Run the following code to upload a file with append upload:

```
package main
import (
    "fmt"
    "os"
    "strings"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket to which to upload the object.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    var nextPos int64 = 0
    // If the object is appended for the first time, the append position is 0. The returned value is the position for the next append. The position to start the next append is the total length of appended bytes and the append object.
    nextPos, err = bucket.AppendObject("<yourObjectName>", strings.NewReader("YourObjectAppendValue1"), nextPos)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Start the second append.
    nextPos, err = bucket.AppendObject("<yourObjectName>", strings.NewReader("YourObjectAppendValue2"), nextPos)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // You can append content to an object multiple times.
}
```

You can specify object metadata when you perform the first append from the position of 0. Object metadata cannot be specified during subsequent append operations.

```
    // Specify the metadata of a new object when you perform the first append.
    nextPos, err = bucket.AppendObject("<yourObjectName>", strings.NewReader("YourObjectValue"), 0, oss.Meta("MyProp", "MyPropVal"))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
```

6.1.2.5.6.4. Resumable upload

If the system stops responding during multipart upload, you can resume the upload by using the ListMultipartUploads and ListParts operations to retrieve all multipart upload tasks on an object and list the uploaded parts in each task. This method allows an upload task to be resumed from the last uploaded part.

The progress of the current upload is recorded in the checkpoint file during the upload process. If the upload of a part fails during the process, the next upload attempt starts from the recorded position in the checkpoint file. The checkpoint file is deleted after the resumable upload task is complete.

> **Note**
>
> - The SDK records the upload progress in the checkpoint file. Make sure that you have write permissions on the checkpoint file. The checkpoint file contains a checksum. This file cannot be edited. If the checkpoint file is damaged, you must upload all parts again.
> - If the object being uploaded is modified, you must upload the entire object again.

You can use `Bucket.UploadFile` to perform resumable upload. The following table describes the parameters of this operation.

Parameter	Description
objectKey	The name of the object to upload to OSS.
filePath	The local file path from which to upload the object.
partSize	The size of each part. Valid values: 100 KB to 5 GB.
options	The optional parameters, including: • Routines: the number of concurrent upload threads. The default value is 1, indicating that only one thread is used to upload the parts. • Checkpoint: specifies whether to enable resumable upload and the path of the checkpoint file. By default, resumable upload is disabled. For example, `oss.Checkpoint(true, "")` indicates that resumable upload is enabled and the checkpoint file is `file.cp` contained in the same directory as the source local file. `file` is a variable that indicates the local file name. You can also use `oss.Checkpoint(true, "your-cp-file.cp")` to specify the checkpoint file. • For other object metadata, see Manage object metadata.

The following code provides an example on how to perform resumable upload by using multipart upload:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket to which to upload the object.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // The part size is 100 KB. Start resumable upload. Upload the parts by using three con
current threads.
    // <yourObjectName> is equivalent to objectKey and indicates the complete path of the o
bject that you want to upload to OSS. The path must include the extension of the object nam
e. Example: abc/efg/123.jpg.
    // LocalFile is the filePath value. 100*1024 is the partSize value.
    err = bucket.UploadFile("<yourObjectName>", "LocalFile", 100*1024, oss.Routines(3), oss
.Checkpoint(true, ""))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

6.1.2.5.6.5. Multipart upload

OSS allows you to use multipart upload to split an object into several parts and upload them separately. After all parts are uploaded, you can combine the uploaded parts into a complete object to complete the upload.

To implement multipart upload, perform the following operations:

1. Initiate a multipart upload task.

   Call the ossClient.initiateMultipartUpload method to obtain a unique upload ID in OSS.

2. Upload the parts.

   Call the ossClient.uploadPart method to upload the parts.

> **Note**
>
> - Part numbers identify the relative positions of parts in an object that share the same upload ID. If you have uploaded a part and used its part number again to upload another part, the latter part overwrites the former part.
> - OSS includes the MD5 hash of part data in the ETag header and returns the MD5 hash to the user.
> - OSS calculates the MD5 hash of uploaded data and compares it with the MD5 hash calculated by the SDK. If the two hashes are different, the InvalidDigest error code is returned.

3. Complete the multipart upload task.

   After all parts are uploaded, call the ossClient.completeMultipartUpload method to combine these parts into a complete object.

The following code provides an example on how to perform multipart upload:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    locaFilename := "<yourLocalFilename>"
    // Specify the name of the bucket to which to upload the object.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    chunks, err := oss.SplitFileByPartNum(locaFilename, 3)
    fd, err := os.Open(locaFilename)
    defer fd.Close()
    // Set the storage class to Standard. The default storage class is Standard.
    storageType := oss.ObjectStorageClass(oss.StorageStandard)
    // Set the storage class to Archive.
    // storageType := oss.ObjectStorageClass(oss.StorageArchive)
    // Step 1: Initiate a multipart upload task. Set the storage class to Standard.
    imur, err := bucket.InitiateMultipartUpload(objectName, storageType)
    // Step 2: Upload the parts.
    var parts []oss.UploadPart
    for _, chunk := range chunks {
        fd.Seek(chunk.Offset, os.SEEK_SET)
        // Call the UploadPart method to upload each part.
        part, err := bucket.UploadPart(imur, fd, chunk.Size, chunk.Number)
        if err ! = nil {
            fmt.Println("Error:", err)
            os.Exit(-1)
        }
        parts = append(parts, part)
    }
    // Set the object ACL to public read. By default, the object inherits the bucket ACL.
    objectAcl := oss.ObjectACL(oss.ACLPublicRead)
    // Step 3: Complete the multipart upload task. Set the object ACL to public read.
    cmur, err := bucket.CompleteMultipartUpload(imur, parts, objectAcl)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("cmur:", cmur)
}
```

Cancel a multipart upload task

You can call the bucket.AbortMultipartUpload method to cancel a multipart upload task. If you cancel a multipart upload task, you cannot use the upload ID to upload any parts. The uploaded parts are deleted.

The following code provides an example on how to cancel a multipart upload task:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket to which to upload the object.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Initiate a multipart upload task.
    imur, err := bucket.InitiateMultipartUpload("<yourObjectName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Cancel the multipart upload task.
    err = bucket.AbortMultipartUpload(imur)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

List uploaded parts

The following code provides an example on how to list the parts that are uploaded during a specified multipart upload task:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
```

```
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    locaFilename := "<yourLocalFilename>"
    uploadID := "<yourUploadID>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Split the local file. In this example, the local file is split into three parts.
    chunks, err := oss.SplitFileByPartNum(locaFilename, 3)
    fd, err := os.Open(locaFilename)
    defer fd.Close()
    // Initiate a multipart upload task.
    imur, err := bucket.InitiateMultipartUpload(objectName)
    uploadID = imur.UploadID
    fmt.Println("InitiateMultipartUpload UploadID: ", uploadID)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Upload the parts.
    var parts []oss.UploadPart
    for _, chunk := range chunks {
        fd.Seek(chunk.Offset, os.SEEK_SET)
        // Call the UploadPart method to upload each part.
        part, err := bucket.UploadPart(imur, fd, chunk.Size, chunk.Number)
        if err ! = nil {
            fmt.Println("Error:", err)
            os.Exit(-1)
        }
        fmt.Println("UploadPartNumber: ", part.PartNumber, ", ETag: ", part.ETag)
        parts = append(parts, part)
    }
    // List the uploaded parts based on the result obtained by using the InitiateMultipartU
ploadResult operation.
    lsRes, err := bucket.ListUploadedParts(imur)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Display the uploaded parts.
    fmt.Println("\nParts:", lsRes.UploadedParts)
    for _, upload := range lsRes.UploadedParts {
        fmt.Println("List PartNumber:  ", upload.PartNumber, ", ETag: " ,upload.ETag, ", La
stModified: ", upload.LastModified)
    }
    // List all the uploaded parts based on the result that is obtained by using the Initia
teMultipartUploadResult operation. The result is generated based on the specified object na
```

```
me and upload ID. In this case, the object name and upload ID are known.
    var imur_with_uploadid oss.InitiateMultipartUploadResult
    imur_with_uploadid.Key = objectName
    imur_with_uploadid.UploadID = uploadID
    // List all the uploaded parts.
    lsRes, err = bucket.ListUploadedParts(imur_with_uploadid)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Display the uploaded parts.
    fmt.Println("\nListUploadedParts by UploadID: ", uploadID)
    for _, upload := range lsRes.UploadedParts {
        fmt.Println("List PartNumber:  ", upload.PartNumber, ", ETag: " ,upload.ETag, ", La
stModified: ", upload.LastModified)
    }
    // Complete the multipart upload task.
    cmur, err := bucket.CompleteMultipartUpload(imur, parts)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("cmur:", cmur)
}
```

List multipart upload tasks

You can call the `Bucket.ListMultipartUploads` method to list all ongoing multipart upload tasks that are initiated but not completed or that are canceled. The following table describes the parameters you can configure.

Parameter	Description
Delimiter	The character used to group objects by name. Objects whose names contain the same string from the prefix and the next occurrence of the delimiter are grouped as a single result element in CommonPrefixes.
MaxUploads	The maximum number of multipart upload tasks to list this time. The default value is 1000. The maximum value is 1000.
KeyMarker	Specifies the key-marker value from which to start the list. Multipart upload tasks are listed in alphabetical order of their object names. You can use this parameter with the UploadIDMarker parameter to specify the start position to list the returned results.
Prefix	Specifies the prefix that returned object names must contain. Note that if you use a prefix for a query, the returned object names contain the prefix.

Parameter	Description

UploadIDMarker	The start position from which to list the returned results. This parameter is used together with the KeyMarker parameter.
	• This parameter is ignored if the KeyMarker parameter is not set.
	• If the KeyMarker parameter is set, the response includes the following tasks:
	  ○ Specifies the key-marker value from which to start the list. Multipart upload tasks are listed in alphabetical order of their object names.
	  ○ All multipart upload tasks in which the object names come after the KeyMarker value and the upload IDs are greater than the UploadIDMarker value.

- List multipart upload tasks by using default parameter values

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>"
)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket to which to upload the object.
    bucketName := "<yourBucketName>"
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // List all multipart upload tasks.
    keyMarker := ""
    uploadIdMarker := ""
    for {
        // By default, up to 1,000 records are listed each time.
        lsRes, err := bucket.ListMultipartUploads(oss.KeyMarker(keyMarker), oss.UploadIDM
arker(uploadIdMarker))
        if err ! = nil {
            fmt.Println("Error:", err)
            os.Exit(-1)
        }
        // Display all multipart upload tasks.
        for _, upload := range lsRes.Uploads {
            fmt.Println("Upload: ", upload.Key, ", UploadID: ",upload.UploadID)
        }
        if lsRes.IsTruncated {
            keyMarker = lsRes.NextKeyMarker
            uploadIdMarker = lsRes.NextUploadIDMarker
        } else {
            break
        }
    }
}
```

- List multipart upload tasks by specifying a prefix

```
    lsRes, err := bucket.ListMultipartUploads(oss.Prefix("<yourObjectNamePrefix>"))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Uploads:", lsRes.Uploads)
```

- List up to 100 multipart upload tasks

```
    lsRes, err := bucket.ListMultipartUploads(oss.MaxUploads(100))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Uploads:", lsRes.Uploads)
```

- List multipart upload tasks by specifying a prefix and the maximum number of records to returned

```
    lsRes, err := bucket.ListMultipartUploads(oss.Prefix("<yourObjectNamePrefix>"), oss.M
axUploads(100))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Uploads:", lsRes.Uploads)
```

6.1.2.5.6.6. Use a progress bar

Progress bars are used to indicate the progress of an upload or download.

The following code provides an example on how to use a progress bar when you call Bucket.PutObjectFromFile to upload an object:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
// Define a progress bar listener.
type OssProgressListener struct {
}
// Define the progress event handler.
func (listener *OssProgressListener) ProgressChanged(event *oss.ProgressEvent) {
    switch event.EventType {
    case oss.TransferStartedEvent:
        fmt.Printf("Transfer Started, ConsumedBytes: %d, TotalBytes %d.\n",
            event.ConsumedBytes, event.TotalBytes)
    case oss.TransferDataEvent:
        fmt.Printf("\rTransfer Data, ConsumedBytes: %d, TotalBytes %d, %d%%.",
            event.ConsumedBytes, event.TotalBytes, event.ConsumedBytes*100/event.TotalBytes
)
    case oss.TransferCompletedEvent:
        fmt.Printf("\nTransfer Completed, ConsumedBytes: %d, TotalBytes %d.\n",
            event.ConsumedBytes, event.TotalBytes)
    case oss.TransferFailedEvent:
        fmt.Printf("\nTransfer Failed, ConsumedBytes: %d, TotalBytes %d.\n",
            event.ConsumedBytes, event.TotalBytes)
    default:
    }
}
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    localFile := "<yourLocalFile>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // View the upload progress information while you upload an object.
    err = bucket.PutObjectFromFile(objectName, localFile, oss.Progress(&OssProgressListener
{}))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

6.1.2.5.7. Download objects

6.1.2.5.7.1. Overview

Objects are the basic unit for data operations in OSS. OSS SDK for Go provides a variety of object download methods.

For the complete code that is used to download objects, visit GitHub.

You can use one of the following methods to download objects:

- Streaming download
- Range download
- Download to local files
- Resumable download
- Conditional download

You can view the download progress by using progress bars. For more information, see Use a progress bar.

6.1.2.5.7.2. Streaming download

This topic describes how to use streaming download.

Download an object to a stream

The following code provides an example on how to download an object to a stream:

```
package main
import (
    "fmt"
    "os"
    "io/ioutil"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Download the object to a stream.
    body, err := bucket.GetObject("<yourObjectName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // If you do not close the connection after it is used, connection leaks may occur. Con
sequently, no connections are available and the program cannot run properly.
    defer body.Close()
    data, err := ioutil.ReadAll(body)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("data:", string(data))
}
```

Download an object to the buffer

The following code provides an example on how to download an object to the buffer:

```
package main
import (
    "fmt"
    "os"
    "io"
    "bytes"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Download the object to the buffer.
    body, err := bucket.GetObject("<yourObjectName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    defer body.Close()
    buf := new(bytes.Buffer)
    io.Copy(buf, body)
    fmt.Println("buf:", buf)
}
```

Download an object to a local file stream

The following code provides an example on how to download a specified object to a local file stream:

```
package main
import (
    "fmt"
    "os"
    "io"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Download the object to a local file stream.
    body, err := bucket.GetObject("<yourObjectName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    defer body.Close()
    fd, err := os.OpenFile("LocalFile", os.O_WRONLY|os.O_CREATE, 0660)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    defer fd.Close()
    io.Copy(fd, body)
}
```

6.1.2.5.7.3. Range download

If you need only part of the data in an object, you can use range download to download data within the specified range.

Specify a valid range

The following code provides an example on how to specify a valid range to download data:

```
package main
import (
  "fmt"
  "os"
  "io/ioutil"
  "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
  // Create an OSSClient instance.
  client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
  if err ! = nil {
    fmt.Println("Error:", err)
    os.Exit(-1)
  }
  // Specify the name of the bucket.
  bucket, err := client.Bucket("<yourBucketName>")
  if err ! = nil {
    fmt.Println("Error:", err)
    os.Exit(-1)
  }
  // Query the data that is within the range from byte 15 to byte 35, which includes a tota
l of 21 bytes.
  If the specified range is invalid, for example, the specified range includes a negative n
umber, or the specified value is larger than the object size, the entire object is download
ed.
  body, err := bucket.GetObject("<yourObjectName>", oss.Range(15, 35))
  if err ! = nil {
    fmt.Println("Error:", err)
    os.Exit(-1)
  }
  // If you do not close the connection after it is used, connection leaks may occur. Conse
quently, no connections are available and the program cannot run properly.
  defer body.Close()
  data, err := ioutil.ReadAll(body)
  if err ! = nil {
    fmt.Println("Error:", err)
    os.Exit(-1)
  }
  fmt.Println("data:", string(data))
}
```

Specify an invalid range

The valid range for an object whose size is 1,000 bytes is from byte 0 to byte 999. If the specified range is not within the range, the range does not take effect. Then, OSS returns the 200 HTTP status code and the data of the entire object. The following list provides examples of invalid requests and the returned results:

- If you set Range: bytes to 500-2000, the value at the end of the range is invalid. Then, OSS returns the 200 HTTP status code and the data of the entire object.
- If you set Range: bytes to 1000-2000, the value at the start of the range is invalid. Then, OSS returns the 200 HTTP status code and the data of the entire object.

Compatible download

If you add x-oss-range-behavior:standard to the request header, the download behavior is modified when the specified range is not within the valid range. Example: Use range download to download an object whose size is 1,000 bytes.

- If you set Range: bytes to 500-2000, the value at the end of the range is invalid. Then, OSS returns HTTP status code 206 and the data that is within the range from byte 500 to byte 999.
- If you set Range: bytes to 1000-2000, the value at the start of the range is invalid. Then, OSS returns HTTP status code 416 and error code InvalidRange.

The following code provides an example on how to specify compatible behaviors to download data by range:

```
package main
import (
    "fmt"
    "io/ioutil"
    "os"
    "strings"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Upload 1,000 bytes.
    strContent := ""
    for i := 0; i < 100; i++ {
        strContent += "abcdefghij"
    }
    fmt.Printf("content len:%d\n", len(strContent))
    // Upload a string.
    err = bucket.PutObject("<yourObjectName>", strings.NewReader(strContent))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // If you set Range: bytes to 500-2000, the value at the end of the range is invalid. O
SS returns the 206 HTTP status code and the data that is within the range from byte 500 to
byte 999.
    // If you set Range: bytes to 1000-2000, the value at the start of the range is invalid
. OSS returns the 416 HTTP status code and the error code InvalidRange.
    body, err := bucket.GetObject("<yourObjectName>", oss.Range(500, 2000), oss.RangeBehavi
or("standard"))
    if err ! = nil {
```

```
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // If you do not close the connection after it is used, connection leaks may occur. Con
sequently, no connections are available and the program cannot run properly.
    defer body.Close()
    data, err := ioutil.ReadAll(body)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    if len(data) ! = 500 {
        fmt.Println("read data error, len:%d", len(data))
        os.Exit(-1)
    }
    fmt.Println("data:", string(data))
}
```

6.1.2.5.7.4. Download to local files

This topic describes how to download an object to a local file.

The following code provides an example on how to download a specified object to a local file:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Download the object to the local file.
    err = bucket.GetObjectToFile("<yourObjectName>", "LocalFile")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

6.1.2.5.7.5. Resumable download

You may fail to download a large object if the network is unstable or if the program stops responding. In some cases, you may still fail to download the object even after multiple attempts. To solve this problem, OSS provides the resumable download feature.

To enable resumable download, you need to split the object you want to download into multiple parts and download them separately. After you have downloaded all parts, these parts will be combined into a complete object.

During the download, the download progress is recorded in a checkpoint file. If the download of a part fails, the next download starts from the position recorded in the checkpoint file. The checkpoint file is deleted after resumable download is complete.

> **Note**
>
> - The SDK records the download progress in the checkpoint file. Ensure that you have write permissions on the checkpoint file. The checkpoint file contains a checksum. This file cannot be edited. If the checkpoint file is damaged, you must download the entire object again.
> - If the object being downloaded is modified (the ETag value of the object changes) or some parts are missing or modified, you must download the entire object again.

You can use `Bucket.DownloadFile` to download an object by using resumable download. The following table describes the parameters of this operation.

Parameter	Description
objectKey	The name of the object to download.
filePath	The local file path to which to download the object.
partSize	The size of each part. The part size ranges from 1 byte to 5 GB.

Parameter	Description
options	The optional parameters, including: • Routines: the number of concurrent download threads. The default value is 1, indicating that only one thread is used to download parts. • Checkpoint: specifies whether resumable download is enabled and the path of the checkpoint file. By default, resumable download is disabled. For example, `oss.Checkpoint(true, "")` indicates that resumable download is enabled and the checkpoint file is the `file.cp` file contained in the same directory as the destination local file. `file` is a variable that indicates the local file name. You can also use `oss.Checkpoint(true, "your-cp-file.cp")` to specify the checkpoint file. • Conditions: conditions for multipart download. For more information about the conditions, seeManage object metadata.

Run the following code for resumable download:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Start resumable download. Download the parts by using three threads concurrently.
    // yourObjectName is equivalent to objectKey and indicates the complete path of the obj
ect that you want to download from OSS. The path must include the extension of the object n
ame. Example: abc/efg/123.jpg.
    // LocalFile is the filePath value. 100*1024 is the partSize value.
    err = bucket.DownloadFile("<yourObjectName>", "LocalFile", 100*1024, oss.Routines(3), o
ss.Checkpoint(true, ""))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

6.1.2.5.7.6. Conditional download

OSS allows you to configure one or more conditions for object downloads. If the specified conditions are met, the object can be downloaded. If the specified conditions are not met, an error is returned and the object cannot be downloaded.

The following table describes the download conditions.

Parameter	Description	Configuration method
IfModifiedSince	If the specified time is earlier than the time the object is modified, the object can be downloaded. Otherwise, error code 304 Not modified is returned.	oss.IfModifiedSince

Parameter	Description	Configuration method
IfUnmodifiedSince	If the specified time is later than or equal to the time the object is modified, the object can be downloaded. Otherwise, error code 412 Precondition failed is returned.	oss.IfUnmodifiedSince
IfMatch	If the specified ETag matches that of an object, the object can be downloaded. Otherwise, error code 412 Precondition failed is returned.	oss.IfMatch
IfNoneMatch	If the specified ETag does not match that of an object, the object can be downloaded. Otherwise, error code 304 Not modified is returned.	oss.IfNoneMatch

You can use If-Modified-Since and If-Unmodified-Since as object download conditions at the same time. You can use If-Match and If-None-Match as object download conditions at the same time. To obtain the ETag value of an object, use the Bucket.GetObjectDetailedMeta method.

You can use Bucket.GetObjectDetailedMeta to Obtain the ETag.

```
package main
import (
    "fmt"
    "os"
    "time"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Configure the download conditions.
    date := time.Date(2015, time.November, 10, 23, 0, 0, 0, time.UTC)
    // The object is not downloaded if it does not meet the specified conditions.
    err = bucket.GetObjectToFile("<yourObjectName>", "LocalFile", oss.IfModifiedSince(date)
)
    if err == nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // The object is downloaded if it meets the specified conditions.
    err = bucket.GetObjectToFile("<yourObjectName>", "LocalFile", oss.IfUnmodifiedSince(dat
e))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

6.1.2.5.7.7. Use a progress bar

Progress bars are used to indicate the progress of an upload or download.

The following code provides an example on how to use a progress bar when you use Bucket.GetObjectToFile to download an object:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
// Define the progress bar listener.
```

```
type OssProgressListener struct {
}
// Define the progress event handler.
func (listener *OssProgressListener) ProgressChanged(event *oss.ProgressEvent) {
    switch event.EventType {
    case oss.TransferStartedEvent:
        fmt.Printf("Transfer Started, ConsumedBytes: %d, TotalBytes %d.\n",
            event.ConsumedBytes, event.TotalBytes)
    case oss.TransferDataEvent:
        fmt.Printf("\rTransfer Data, ConsumedBytes: %d, TotalBytes %d, %d%%.",
            event.ConsumedBytes, event.TotalBytes, event.ConsumedBytes*100/event.TotalBytes
)
    case oss.TransferCompletedEvent:
        fmt.Printf("\nTransfer Completed, ConsumedBytes: %d, TotalBytes %d.\n",
            event.ConsumedBytes, event.TotalBytes)
    case oss.TransferFailedEvent:
        fmt.Printf("\nTransfer Failed, ConsumedBytes: %d, TotalBytes %d.\n",
            event.ConsumedBytes, event.TotalBytes)
    default:
    }
}
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    localFile := "<yourLocalFile>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // View the download progress while you download an object.
    err = bucket.GetObjectToFile(objectName, localFile, oss.Progress(&OssProgressListener{}
))
    if err ! = nil {
    fmt.Println("Error:", err)
    os.Exit(-1)
    }
    fmt.Println("Transfer Completed.")
}
```

6.1.2.5.8. Manage objects

6.1.2.5.8.1. Overview

You can manage objects in a bucket by using a variety of operations including SetObjectAcl, GetObjectAcl, ListObjects, DeleteObject, and CopyObject.

By using the preceding operations, you can perform the following operations:

- Determine whether objects exist
- Manage object ACLs
- Manage object metadata
- List objects
- Delete objects
- Copy objects

6.1.2.5.8.2. Determine whether objects exist

This topic describes how to determine whether an object exists.

Run the following code to determine whether a specified object exists:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Determine whether the object exists.
    isExist, err := bucket.IsObjectExist("<yourObjectName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Exist:", isExist)
}
```

6.1.2.5.8.3. Manage object ACLs

This topic describes how to manage the access control list (ACL) of an object.

For the complete code used to manage the ACL of an object, visit GitHub.

The following table describes the ACLs that can be configured for objects.

ACL	Description	Value
Inherited from bucket	The ACL of an object is the same as that of the bucket in which the object is stored.	oss.ACLDefault
Private	Only the owner or authorized users of the bucket can read and write the object.	oss.ACLPrivate
Public read	Only the owner or authorized users of this bucket can write the object. Other users, including anonymous users can only read the object. Exercise caution when you use this ACL.	oss.ACLPublicRead
Public read/write	Any users, including anonymous users can read and write the object. Exercise caution when you use this ACL.	oss.PublicReadWrite

The ACL privileges of objects take precedence over that of buckets. For example, if the ACL of a bucket is private, while the object ACL is public read-write, all users can read and write the object. If an object is not configured with an ACL, its ACL is the same as that of its bucket by default.

The following code provides a complete example on how to configure and query the ACL of an object:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Configure ACL for the object.
    err = bucket.SetObjectACL("<yourObjectName>", oss.ACLPublicReadWrite)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Query the ACL of the object.
    aclRes, err := bucket.GetObjectACL("<yourObjectName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Object ACL:", aclRes.ACL)
}
```

6.1.2.5.8.4. Manage object metadata

This topic describes how to use OSS SDK for Go to configure, modify and query object metadata.

For the complete code used to manage object metadata, visit GitHub.

Configure object metadata

You can configure the metadata of an object when you upload the object. The following table describes the metadata that you can configure.

Parameter	Description
CacheControl	Specifies the caching behavior of a web page when the object is downloaded.

Parameter	Description
ContentDisposition	Specifies the name of the object when it is downloaded.
ContentEncoding	Specifies the encoding format that is used when the object is downloaded.
Expires	Specifies the expiration time of the cache in GMT.
ServerSideEncryption	Specifies the server-side encryption algorithm to use when OSS creates the object. Valid value: AES256.
ObjectACL	Specifies the ACL of the created object.
Meta	Specifies the user metadata of the object. The parameters of user metadata are prefixed with `X-Oss-Meta-`.

The following code provides an example on how to configure object metadata:

```
package main
import (
    "fmt"
    "os"
    "time"
    "strings"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Configure object metadata: Set the expiration time to 23:00:00, 10 January 2049 in G
MT, ACL to public read, and MyProp to MyPropVal as user metadata.
    expires := time.Date(2049, time.January, 10, 23, 0, 0, 0, time.UTC)
    options := []oss.Option{
        oss.Expires(expires),
        oss.ObjectACL(oss.ACLPublicRead),
        oss.Meta("MyProp", "MyPropVal"),
    }
    // Use a data stream to upload the object.
    err = bucket.PutObject("<yourObjectName>", strings.NewReader("MyObjectValue"), options.
..)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Query the object metadata.
    props, err := bucket.GetObjectDetailedMeta("<yourObjectName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Object Meta:", props)
}
```

Modify object metadata

The following code provides an example on how to modify a single or multiple object metadata parameters at a time:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Modify a single object metadata parameter at a time.
    err = bucket.SetObjectMeta(objectName, oss.Meta("MyMeta", "MyMetaValue1"))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Modify multiple object metadata parameters at a time.
    options := []oss.Option{
        oss.Meta("MyMeta", "MyMetaValue2"),
        oss.Meta("MyObjectLocation", "HangZhou"),
    }
    err = bucket.SetObjectMeta(objectName, options...)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Query the object metadata.
    props, err := bucket.GetObjectDetailedMeta(objectName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Object Meta:", props)
}
```

Obtain object metadata

The following code provides an example on how to obtain object metadata:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Query the object metadata.
    props, err := bucket.GetObjectDetailedMeta(objectName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Object Meta:", props)
}
```

6.1.2.5.8.5. List objects

This topic describes how to list the objects that are contained in a bucket.

Objects in a bucket are sorted alphabetically. You can use `Bucket.ListObjects` to list the objects in a bucket. The following table describes the parameters for Bucket.ListObjects.

Parameter	Description
delimiter	Groups objects by name. Objects whose names contain the same string from the prefix and the next occurrence of the delimiter are grouped as a single result element in commonPrefixes.
prefix	Specifies the prefix that returned object names must contain.
maxKeys	Specifies the maximum number of objects that can be listed each time. The default value is 100. The maximum value is 1000.
marker	Specifies the name of the object after which the list begins.

For the complete code that is used to list objects, visit GitHub.

Simple list

You can use the default parameters to query the list of objects in a bucket. By default, a maximum of 100 objects are listed. The following code provides an example on how to perform simple list:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func HandleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        HandleError(err)
    }
    // Specify the name of the bucket.
    bucketName := "<yourBucketName>"
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        HandleError(err)
    }
    // List all objects.
    marker := ""
    for {
        lsRes, err := bucket.ListObjects(oss.Marker(marker))
        if err ! = nil {
            HandleError(err)
        }
        // Display the listed objects. By default, a maximum of 100 records are returned ea
ch time.
        for _, object := range lsRes.Objects {
            fmt.Println("Bucket: ", object.Key)
        }
        if lsRes.IsTruncated {
            marker = lsRes.NextMarker
        } else {
            break
        }
    }
}
```

List a specified number of objects

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Set the maximum number of objects to list and list the objects.
    lsRes, err := bucket.ListObjects(oss.MaxKeys(200))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Display the listed objects.
    fmt.Println("Objects:", lsRes.Objects)
    for _, object := range lsRes.Objects {
        fmt.Println("Object:", object.Key)
    }
}
```

List objects whose names contain a specified prefix

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // List the objects whose names contain the specified prefix. By default, a maximum of
100 objects are listed.
    lsRes, err := bucket.ListObjects(oss.Prefix("my-object-"))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Display the listed objects.
    fmt.Println("Objects:", lsRes.Objects)
    for _, object := range lsRes.Objects {
        fmt.Println("Object:", object.Key)
    }
}
```

List objects whose names come after a specified marker

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // List the objects whose names come after the specified marker. By default, a maximum
of 100 objects are listed.
    lsRes, err := bucket.ListObjects(oss.Marker("my-object-xx"))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Display the listed objects.
    fmt.Println("Objects:", lsRes.Objects)
    for _, object := range lsRes.Objects {
        fmt.Println("Object:", object.Key)
    }
}
```

List all objects by page

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // List all objects by page, with up to 200 objects on each page.
    marker := oss.Marker("")
    for {
        lsRes, err := bucket.ListObjects(oss.MaxKeys(200), marker)
        if err ! = nil {
            fmt.Println("Error:", err)
            os.Exit(-1)
        }
        marker = oss.Marker(lsRes.NextMarker)
        fmt.Println("Objects:", lsRes.Objects)
        if ! lsRes.IsTruncated {
            break
        }
    }
}
```

List objects whose names come after a specified marker by page

The following code provides an example on how to list the objects that follow a specified marker by page. The maximum number of objects that can be listed on each page is specified by MaxKeys.

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // List the objects whose names come after the specified marker by page, with up to 50
objects on each page.
    marker = oss.Marker("my-object-xx")
    for {
        lsRes, err := bucket.ListObjects(oss.MaxKeys(50), marker)
        if err ! = nil {
            fmt.Println("Error:", err)
            os.Exit(-1)
        }
        marker = oss.Marker(lsRes.NextMarker)
        fmt.Println("Objects:", lsRes.Objects)
        if ! lsRes.IsTruncated {
            break
        }
    }
}
```

List objects whose names contain a specified prefix by page

The following code provides an example on how to list the objects whose names contain a specified prefix by page. The maximum number of objects to list on each page is specified by maxKeys.

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // List the objects whose names contain the specified prefix by page, with up to 80 obj
ects on each page.
    prefix := oss.Prefix("my-object-")
    marker := oss.Marker("")
    for {
        lsRes, err := bucket.ListObjects(oss.MaxKeys(80), marker, prefix)
        if err ! = nil {
            fmt.Println("Error:", err)
            os.Exit(-1)
        }
        prefix = oss.Prefix(lsRes.Prefix)
        marker = oss.Marker(lsRes.NextMarker)
        fmt.Println("Objects:", lsRes.Objects)
        if ! lsRes.IsTruncated {
            break
        }
    }
}
```

List the information about the objects whose names contain a specified prefix

The following code provides an example on how to list the information about the objects whose names contain a specified prefix. Such information includes the object size, the time when the object was last modified, and the object name.

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Traverse the objects.
    marker := oss.Marker("")
    prefix := oss.Prefix("<yourObjectPrefix>")
    for {
        lor, err := bucket.ListObjects(marker, prefix)
        if err ! = nil {
            fmt.Println("Error:", err)
            os.Exit(-1)
        }
        for _, object := range lor.Objects {
            fmt.Printf("%s %d %s\n", object.LastModified, object.Size, object.Key)
        }
        prefix = oss.Prefix(lor.Prefix)
        marker = oss.Marker(lor.NextMarker)
        if ! lor.IsTruncated {
            break
        }
    }
}
```

List the information about the subfolders whose names contain a specified prefix

The following code provides an example on how to list the information about the subfolders whose names contain a specified prefix:

```
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    marker := oss.Marker("")
    prefix := oss.Prefix("<yourDirPrefix>")
    for {
        lor, err := bucket.ListObjects(marker, prefix, oss.Delimiter("/"))
        if err ! = nil {
            fmt.Println("Error:", err)
            os.Exit(-1)
        }
        for _, dirName := range lor.CommonPrefixes {
            fmt.Println(dirName)
        }
        prefix = oss.Prefix(lor.Prefix)
        marker = oss.Marker(lor.NextMarker)
        if ! lor.IsTruncated {
            break
        }
    }
}
```

6.1.2.5.8.6. Delete objects

This topic describes how to delete objects.

Warning Deleted objects cannot be recovered. Exercise caution when you delete objects.

For the complete code used to delete objects, visit GitHub.

Delete a single object

The following code provides an example on how to delete an object named *exampleobject.txt* from a bucket named examplebucket:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Delete a single object. objectName indicates the full path that includes the extensi
on of the object. Example: abc/efg/123.jpg.
    // To delete a folder, set objectName to the folder name. If the folder is not empty, y
ou must delete all objects from the folder before you can delete it.
    err = bucket.DeleteObject(objectName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

Delete multiple objects

You can call the `Bucket.DeleteObjects` operation to delete multiple objects and specify the `DeleteObjectsQuiet` parameter to specify whether to return results of delete operations. By default, information of deleted objects is returned.

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify that information of deleted objects is returned.
    delRes, err := bucket.DeleteObjects([]string{"my-object-1", "my-object-2"})
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    fmt.Println("Deleted Objects:", delRes.DeletedObjects)
    // Specify that results of delete operations are not returned.
    _, err = bucket.DeleteObjects([]string{"my-object-3", "my-object-4"},
    oss.DeleteObjectsQuiet(true))
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

Delete objects whose names contain a specified prefix

The following code provides an example on how to delete objects whose names contain a specified prefix:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify the name of the bucket.
    bucket, err := client.Bucket("<yourBucketName>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // List and delete objects whose names contain the specified prefix.
    marker := oss.Marker("")
    prefix := oss.Prefix("<yourObjectPrefix>")
    count := 0
    for {
        lor, err := bucket.ListObjects(marker, prefix)
        if err ! = nil {
            fmt.Println("Error:", err)
            os.Exit(-1)
        }
        objects := []string{}
        for _, object := range lor.Objects {
            objects = append(objects, object.Key)
        }
        delRes, err := bucket.DeleteObjects(objects, oss.DeleteObjectsQuiet(true))
        if err ! = nil {
            fmt.Println("Error:", err)
            os.Exit(-1)
        }
        if len(delRes.DeletedObjects) > 0 {
            fmt.Println("these objects deleted failure,", delRes.DeletedObjects)
            os.Exit(-1)
        }
        count += len(objects)
        prefix = oss.Prefix(lor.Prefix)
        marker = oss.Marker(lor.NextMarker)
        if ! lor.IsTruncated {
            break
        }
    }
    fmt.Printf("success,total delete object count:%d\n", count)
}
```

6.1.2.5.8.7. Copy objects

This topic describes how to copy objects.

For the complete code that is used to copy objects, visit GitHub.

Copy objects within a bucket

The following code provides an example on how to copy an object within a bucket:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    destObjectName := "<yourDestObjectName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Copy the object to another object within the bucket.
    _, err = bucket.CopyObject(objectName, destObjectName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

Copy objects across buckets

You can copy objects from other buckets to the current bucket or copy objects from the current bucket to other buckets. The following code provides an example on how to copy objects across buckets:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    srcBucketName := "<yourSrcBucketName>"
    dstBucketName := "<yourDstBucketName>"
    srcObjectName := "<yourSrcObjectName>"
    dstObjectName := "<yourDstObjectName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Copy srcObjectName from srcBucketName to the current bucket.
    bucket.CopyObjectFrom(srcBucketName, srcObjectName, dstObjectName)
    if err ! = nil {
        fmt.Println("CopyObjectFrom Error:", err)
        os.Exit(-1)
    }
    // Copy srcObjectName from the current bucket to dstBucketName.
    bucket.CopyObjectTo(dstBucketName, dstObjectName, srcObjectName)
    if err ! = nil {
        fmt.Println("CopyObjectTo Error:", err)
        os.Exit(-1)
    }
}
```

Process object metadata during object copy

You can use MetadataDirective to process object metadata during object copy. Valid values of MetadataDirective:

- oss.MetaCopy: This is the default value. Copy metadata of the source object. The metadata of the destination object is the same as the metadata of the source object.
- oss.MetaReplace: overwrites the source object metadata by using the specified object metadata.

Notice All metadata of the source object is overwritten if you use oss.MetaReplace. The metadata of the source object cannot be recovered. Exercise caution when you perform this operation.

The following table describes the parameter you can configure when you set MetadataDirective to oss.MetaReplace.

Parameter	Description
CacheControl	Specifies the caching behavior of a web page when the destination object is downloaded.
ContentDisposition	Specifies the name of the destination object when it is downloaded.
ContentEncoding	Specifies the encoding format that is used when the destination object is downloaded.
Expires	Specifies the expiration time of the cache in GMT.
ServerSideEncryption	Specifies the server-side encryption algorithm that is used when OSS creates the destination object. Valid value: AES256.
ObjectACL	Specifies the ACL of the destination object.
Meta	Specifies the user metadata of the destination object. The parameters of user metadata are prefixed with `X-Oss-Meta-` .

The following code provides an example on how to process object metadata during object copy:

```
package main
import (
    "fmt"
    "os"
    "time"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    destObjectName := "<yourDestObjectName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // Specify metadata for the destination object.
    expires := time.Date(2049, time.January, 10, 23, 0, 0, 0, time.UTC)
    options := []oss.Option{
        oss.MetadataDirective(oss.MetaReplace),
        oss.Expires(expires),
        oss.ObjectACL(oss.ACLPublicRead),
        oss.Meta("MyMeta", "MyMetaValue")}
    // Overwrite the metadata of the source object by using the specified metadata.
    _, err = bucket.CopyObject(objectName, destObjectName, options...)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
}
```

Conditional copy

OSS allows you to configure one or more conditions for object copy. If the specified conditions are met, the object can be copied. If the specified conditions are not met, an error code is returned and the object cannot be copied. The following table describes the conditions that you can configure in object copy.

Parameter	Description
CopySourceIfMatch	If the ETag of the source object is the same as that of the destination object, the object is copied. Otherwise, an error is returned.

Parameter	Description
CopySourceIfNoneMatch	If the ETag of the source object is different from that of the destination object, the object is copied. Otherwise, an error is returned.
CopySourceIfModifiedSince	If the specified time is earlier than the actual modified time of the object, the object is copied. Otherwise, an error is returned.
CopySourceIfUnmodifiedSince	If the specified time is equal to or later than the actual modified time of the object, the object is copied. Otherwise, an error is returned.

You can set CopySourceIfMatch and CopySourceIfNoneMatch at the same time. You can set CopySourceIfModifiedSince and CopySourceIfUnmodifiedSince at the same time.

The following code provides an example on how to perform conditional copy:

```
package main
import (
    "fmt"
    "os"
    "time"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    // bucketName := "<yourBucketName>"
    // objectName := "<yourObjectName>"
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    destMatchObjectName := "<yourMatchDestObjectName>"
    destUnMatchObjectName := "<yourUnmatchDestObjectName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        fmt.Println("Error:", err)
        os.Exit(-1)
    }
    date := time.Date(2011, time.November, 10, 23, 0, 0, 0, time.UTC)
    // Copy the objects that meet the specified condition.
    _, err = bucket.CopyObject(objectName, destMatchObjectName, oss.CopySourceIfModifiedSin
ce(date))
    if err ! = nil {
        fmt.Println("CopyObject CopySourceIfModifiedSince Error:", err)
    }
    // Do not copy the objects that cannot meet the specified condition.
    _, err = bucket.CopyObject(objectName, destUnMatchObjectName, oss.CopySourceIfUnmodifie
dSince(date))
    if err ! = nil {
        fmt.Println("CopyObject CopySourceIfUnmodifiedSince Error:", err)
    }
}
```

6.1.2.5.9. Authorized access

This topic describes how to use STS and a signed URL to authorize access.

Use STS to authorize temporary access

Alibaba Cloud Security Token Service (STS) is a web service that provides a temporary access token to a cloud computing user. You can use STS to grant a third-party application or your RAM user an access credential with a customized validity period and permissions.

STS provides the following benefits:

- You need only to generate an access token and send the access token to a third-party application, instead of exposing your AccessKey pair to the third-party application. You can define the access permissions and validity period of this token.
- The token automatically expires after the validity period. Therefore, you do not need to manually revoke the access permissions of a token.

The following code provides an example on how to create a signature request by using STS:

```
import "github.com/aliyun/aliyun-oss-go-sdk/oss"
// After you obtain a temporary STS credential for your OSSClient, an OSSClient instance is
created based on the security token and temporary AccessKey pair (AccessKey ID and AccessKe
y secret) that are contained in the credential.
// Create an OSSClient instance.
client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>", oss.
SecurityToken("<yourSecurityToken>"))
if err ! = nil {
    fmt.Println("Error:", err)
    os.Exit(-1)
// Perform an operation in OSS.
}
```

Use a signed URL to authorize temporary access

You can generate a signed URL and provide the URL to a visitor for temporary access. When you generate a signed URL, you can specify the validity period of the URL to limit the period of access from visitors. By default, the validity period of a signed URL is 3,600 seconds. The maximum validity period of a signed URL is 32,400 seconds.

For the complete code of using a signed URL to authorize temporary access, visit GitHub.

- Use a signed URL to upload an object

```
package main
import (
    "fmt"
    "os"
    "strings"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func HandleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>"
)
    if err ! = nil {
        HandleError(err)
    }
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    localFilename := "<yourLocalFilename>"
    // Specify the name of the bucket to which to upload the object.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        HandleError(err)
    }
    // Upload the object by using the signed URL.
    signedURL, err := bucket.SignURL(objectName, oss.HTTPPut, 60)
    if err ! = nil {
        HandleError(err)
    }
    var val = "Go with Alibaba Cloud"
    err = bucket.PutObjectWithURL(signedURL, strings.NewReader(val))
    if err ! = nil {
        HandleError(err)
    }
    // Upload the object by using the signed URL with optional parameters configured.
    options := []oss.Option{
        oss.Meta("myprop", "mypropval"),
        oss.ContentType("image/tiff"),
    }
    signedURL, err = bucket.SignURL(objectName, oss.HTTPPut, 60, options...)
    if err ! = nil {
        HandleError(err)
    }
    err = bucket.PutObjectFromFileWithURL(signedURL, localFilename, options...)
    if err ! = nil {
        HandleError(err)
    }
}
```

Note For more information, see Manage object metadata.

- Use a signed URL to download an object

```
package main
import (
    "fmt"
    "os"
    "io/ioutil"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func HandleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>"
)
    if err ! = nil {
        HandleError(err)
    }
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    localDownloadedFilename := "<yourDownloadedFilename>"
    // Specify the name of the bucket from which to download the object.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        HandleError(err)
    }
    // Download the object to a stream by using the signed URL.
    signedURL, err := bucket.SignURL(objectName, oss.HTTPGet, 60)
    if err ! = nil {
        HandleError(err)
    }
    body, err := bucket.GetObjectWithURL(signedURL)
    if err ! = nil {
        HandleError(err)
    }
    // Read the object content.
    data, err := ioutil.ReadAll(body)
    body.Close()
    data = data // use data
    // Download the object to a local file by using the signed URL.
    err = bucket.GetObjectToFileWithURL(signedURL, localDownloadedFilename)
    if err ! = nil {
        HandleError(err)
    }
}
```

6.1.2.5.10. IMG

OSS Image Processing (IMG) is a secure, cost-effective, and highly reliable image processing service that can process large amounts of data. After you upload source images to OSS, you can call RESTful API operations to process the images anytime, anywhere, and on any Internet device.

Basic features

OSS IMG provides the following features:

- Query image information.
- Convert image formats.
- Resize, crop, and rotate images.
- Apply image effect.
- Add image, text, and text-and-image watermarks to images.
- Customize image processing styles. Log on to the OSS console. Click a bucket name to go to the bucket details page. Click the **Image Processing (IMG)** tab and click **Create Rule** to customize an image processing style.
- Use cascade processing to call multiple IMG features.

Usage

You can use standard `HTTP GET` requests to access IMG. All processing parameters are encoded in the query string of a URL.

- Anonymous access

  You can anonymously access a processed image by using a third-level domain in the following format:

  ```
  http://<yourBucketName>.<yourEndpoint>/<yourObjectName>?x-oss-process=image/<yourAction>,<yourParamValue>
  ```

Parameter	Description
bucket	The name of the bucket.
endpoint	The domain name used to access the region.
object	The name of the image object.
image	The identifier reserved by IMG.
action	The operations performed on images, such as scaling, cropping, and rotating.
param	The parameters corresponding to the operations performed on the images.

  - Basic operations

    For example, you can scale an image to a width of 100 and adjust the height based on the ratio:

    ```
    http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100
    ```

- Customize an image style

  You can anonymously access IMG by using a third-level domain in the following format:

  ```
  http://<yourBucketName>.<yourEndpoint>/<yourObjectName>?x-oss-process=style/<yourStyleName>
  ```

  - style: the identifier reserved by IMG for the custom style.
  - yourStyleName: the name of the custom style. The name is specified by the Rule Name parameter when you create the custom style in the console.

  Example:

  ```
  http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=style/oss-pic-style-w-100
  ```

- Cascade processing

  You can use cascade processing to perform multiple operations in sequence on an image by using a URL in the following format:

  ```
  http://<yourBucketName>.<yourEndpoint>/<yourObjectName>?x-oss-process=image/<yourAction1>,<yourParamValue1>/<yourAction2>,<yourParamValue2>/...
  ```

  Example:

  ```
  http://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100/rotate,90
  ```

- Access by using HTTPS

  IMG supports access by using HTTPS. Example:

  ```
  https://image-demo.oss-cn-hangzhou.aliyuncs.com/example.jpg?x-oss-process=image/resize,w_100
  ```

- Authorized access

  If the ACL of an image object is private, you must have permissions on the image object before you can perform operations on the image object.

Bucket ACL	Object ACL
private	default
Any ACL	private

  The following code provides an example on how to generate a signed URL to access IMG:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func HandleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>"
)
    if err ! = nil {
    HandleError(err)
    }
    // Obtain the bucket.
    bucketName := "<yourBucketName>"
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
    HandleError(err)
    }
    ossImageName := "<yourImageName>"
    signedURL, err := bucket.SignURL(ossImageName, oss.HTTPGet, 600, oss.Process("image/f
ormat,png"))
    if err ! = nil {
    HandleError(err)
    } else {
    fmt.Println(signedURL)
    }
}
```

- Access by using SDKs

  You can use OSS SDKs to access and process image objects of any ACLs.

  - Basic operations

    The following code provides an example on how to perform basic IMG operations including obtaining image information, converting image formats, resizing, cropping, rotating, watermarking, and applying effects:

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func HandleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret
```

```
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret
>")
    if err ! = nil {
    HandleError(err)
    }
    // Obtain the bucket.
    bucketName := "<yourBucketName>"
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
    HandleError(err)
    }
    // Resize the image.
    sourceImageName := "example.png"
    targetImageName := "example-resize.png"
    style := "image/resize,m_fixed,w_100,h_100"
    err = bucket.GetObjectToFile(sourceImageName, targetImageName, oss.Process(style))
    if err ! = nil {
    HandleError(err)
    }
    // Crop the image.
    targetImageName = "example-crop.png"
    style = "image/crop,w_100,h_100,x_100,y_100,r_1"
    err = bucket.GetObjectToFile(sourceImageName, targetImageName, oss.Process(style))
    if err ! = nil {
    HandleError(err)
    }
    // Rotate the image.
    targetImageName = "example-rotate.png"
    style = "image/rotate,90"
    err = bucket.GetObjectToFile(sourceImageName, targetImageName, oss.Process(style))
    if err ! = nil {
    HandleError(err)
    }
    // Sharpen the image.
    targetImageName = "example-sharpen.png"
    style = "image/sharpen,100"
    err = bucket.GetObjectToFile(sourceImageName, targetImageName, oss.Process(style))
    if err ! = nil {
    HandleError(err)
    }
    // Add watermarks to the image.
    targetImageName = "example-watermark.png"
    style = "image/watermark,text_SGVsbG8g5Zu-54mH5pyN5YqhIQ"
    err = bucket.GetObjectToFile(sourceImageName, targetImageName, oss.Process(style))
    if err ! = nil {
    HandleError(err)
    }
    // Convert the image format.
    targetImageName = "example-formatconvert.jpg"
    style = "image/format,jpg"
    err = bucket.GetObjectToFile(sourceImageName, targetImageName, oss.Process(style))
    if err ! = nil {
    HandleError(err)
    }
}
```

- Custom image styles

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func HandleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret
>")
    if err ! = nil {
    HandleError(err)
    }
    // Obtain the bucket.
    bucketName := "<yourBucketName>"
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
     HandleError(err)
    }
    // Customize the image style.
    sourceImageName := "example.png"
    targetImageName := "example-custom.png"
    style := "style/<yourCustomStyleName>"
    err = bucket.GetObjectToFile(sourceImageName, targetImageName, oss.Process(style))
    if err ! = nil {
    HandleError(err)
    }
}
```

- Cascade processing

```
package main
import (
    "fmt"
    "os"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func HandleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret
>")
    if err ! = nil {
    HandleError(err)
    }
    // Obtain the bucket.
    bucketName := "<yourBucketName>"
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
    HandleError(err)
     }
    // Customize the image style.
    sourceImageName := "example.png"
    targetImageName := "example-cascade.png"
    style := "image/resize,m_fixed,w_100,h_100/rotate,90"
    err = bucket.GetObjectToFile(sourceImageName, targetImageName, oss.Process(style))
    if err ! = nil {
     HandleError(err)
    }
}
```

Persistent storage of processed images

```
package main
import (
    "fmt"
    "os"
    "encoding/base64"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
func HandleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
    HandleError(err)
    }
```

```
    // Obtain the bucket.
    bucketName := "<yourBucketName>"
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
     HandleError(err)
    }
    // Scale the image and store the processed image. By default, the processed image is st
ored in the same bucket as the original image.
    sourceImageName := "example.png"
    targetImageName := "example-resize.png"
    style := "image/resize,m_fixed,w_100,h_100"
    process := fmt.Sprintf("%s|sys/saveas,o_%v", style, base64.URLEncoding.EncodeToString([
]byte(targetImageName)))
    result, err := bucket.ProcessObject(sourceImageName, process)
    if err ! = nil {
    HandleError(err)
    } else {
        fmt.Println(result)
    }
    // Scale the image and store the processed image. The processed image is stored in the
different bucket from the original image.
    targetBucketName := "<yourTargetBucketName>"
    targetImageName = "example-crop-different-bucket.png"
    style = "image/resize,m_fixed,w_100,h_100"
    process = fmt.Sprintf("%s|sys/saveas,o_%v,b_%v", style, base64.URLEncoding.EncodeToStri
ng([]byte(targetImageName)), base64.URLEncoding.EncodeToString([]byte(targetBucketName)))
    result, err = bucket.ProcessObject(sourceImageName, process)
    if err ! = nil {
    HandleError(err)
    } else {
        fmt.Println(result)
    }
    // Crop the image and store the processed image.
    targetImageName = "example-crop.png"
    style = "image/crop,w_100,h_100,x_100,y_100,r_1"
    process = fmt.Sprintf("%s|sys/saveas,o_%v", style, base64.URLEncoding.EncodeToString([]
byte(targetImageName)))
    result, err = bucket.ProcessObject(sourceImageName, process)
    if err ! = nil {
    HandleError(err)
    } else {
        fmt.Println(result)
    }
    // Rotate the image and store the processed image.
    targetImageName = "example-rotate.png"

       fmt.Println(result)
    }
    // Add watermarks to the image and store the processed image.
    targetImageName = "example-watermark.png"
    style = "image/watermark,text_SGVsbG8g5Zu-54mH5pyN5YqhIQ"
    process = fmt.Sprintf("%s|sys/saveas,o_%v", style, base64.URLEncoding.EncodeToString([]
byte(targetImageName)))
    result, err = bucket.ProcessObject(sourceImageName, process)
    if err ! = nil {
    HandleError(err)
    } else {
        fmt.Println(result)
    }
    // Convert the image format and store the processed image.
    targetImageName = "example-formatconvert.jpg"
    style = "image/format,jpg"
    process = fmt.Sprintf("%s|sys/saveas,o_%v", style, base64.URLEncoding.EncodeToString([]
byte(targetImageName)))
    result, err = bucket.ProcessObject(sourceImageName, process)
    if err ! = nil {
    HandleError(err)
    } else {
        fmt.Println(result)
    }
}
```

6.1.2.5.11. Error handling

This topic describes how to handle errors when you use OSS SDK for Go.

Client errors

If errors occur when you use OSS SDK for Go, a unified operation used to handle errors is returned. The following code defines the error operation:

```
type error interface {
    Error() string
}
```

Other specific errors are further defined based on this error operation. The following code provides an example of the operation used to handle an HTTP request error:

```
//net.Error
type Error interface {
    error
    Timeout() bool   // Is the error a timeout
    Temporary() bool // Is the error temporary
}
```

Server errors

If request errors occur when you use OSS SDK for Go, corresponding errors are returned. In case of HTTP request errors and I/O errors, errors defined in OSS SDK for Go are returned. If an error occurs when the OSS server processes a request, the following error is returned, which is an implementation of the error operation:

```
type ServiceError struct {
    Code       string    // The error code returned by OSS.
    Message    string    // The error details provided by OSS.
    RequestId  string    // The UUID used to identify the request.
    HostId     string    // The host ID used to identify the accessed OSS cluster.
    StatusCode int       // The HTTP status code.
}
```

If the HTTP status code returned by OSS is not as expected, the following error is returned, which is an implementation of the error operation:

```
type UnexpectedStatusCodeError struct {
    allowed []int    // The expected HTTP status code returned by OSS.
    got     int      // The actual HTTP status code returned by OSS.
}
```

Example

The following code provides an example on how to handle errors:

```
package main
import (
    "fmt"
    "os"
    "strings"
    "github.com/aliyun/aliyun-oss-go-sdk/oss"
)
// The function used to handle the error.
func HandleError(err error) {
    fmt.Println("Error:", err)
    os.Exit(-1)
}
func main() {
    // Create an OSSClient instance.
    client, err := oss.New("<yourEndpoint>", "<yourAccessKeyId>", "<yourAccessKeySecret>")
    if err ! = nil {
        HandleError(err)
    }
    bucketName := "<yourBucketName>"
    objectName := "<yourObjectName>"
    // Specify the name of the bucket.
    bucket, err := client.Bucket(bucketName)
    if err ! = nil {
        HandleError(err)
    }
    // Use simple upload to upload strings.
    err = bucket.PutObject(objectName, strings.NewReader("yourObjectValueContentString"))
    if err ! = nil {
        HandleError(err)
}
```

OSS error codes

The following table describes the OSS error codes.

Error code	Error message	HTTP status code
AccessDenied	The error message returned because access is denied.	403
BucketAlreadyExists	The error message returned because the bucket already exists.	409
BucketNotEmpty	The error message returned because the bucket is not empty.	409
EntityTooLarge	The error message returned because the entity exceeds the maximum allowed size.	400

Error code	Error message	HTTP status code
EntityTooSmall	The error message returned because the entity is smaller than the minimum allowed size.	400
FileGroupTooLarge	The error message returned because the object group exceeds the maximum allowed size.	400
InvalidLinkName	The error message returned because the symbolic link points to an object that has the same name as the symbolic link.	400
LinkPartNotExist	The error message returned because the symbolic link points to an object that does not exist.	400
ObjectLinkTooLarge	The error message returned because the number of objects the symbolic link points to exceeds the limit.	400
FieldItemTooLong	The error message returned because the total length of the form fields in the POST request exceeds the limit.	400
FilePartInterity	The error message returned because the part is modified.	400
FilePartNotExist	The error message returned because the specified part does not exist.	400
FilePartStale	The error message returned because the part expires.	400
IncorrectNumberOfFilesInPOSTRequest	The error message returned because the number of objects in the POST request is invalid.	400
InvalidArgument	The error message returned because the parameter format is invalid.	400
InvalidAccessKeyId	The error message returned because the specified Accesskey ID does not exist.	403
InvalidBucketName	The error message returned because the bucket name is invalid.	400

Error code	Error message	HTTP status code
InvalidDigest	The error message returned because the digest is invalid.	400
InvalidEncryptionAlgorithmError	The error message returned because the specified encryption algorithm based on entropy encoding is invalid.	400
InvalidObjectName	The error message returned because the object name is invalid.	400
InvalidPart	The error message returned because the part is invalid.	400
InvalidPartOrder	The error message returned because the part sequence is invalid.	400
InvalidPolicyDocument	The error message returned because the policy document is invalid.	400
InvalidTargetBucketForLogging	The error message returned because the destination bucket specified for logging is invalid.	400
InternalError	The error message returned when an internal OSS error occurs.	500
MalformedXML	The error message returned because the XML format is invalid.	400
MalformedPOSTRequest	The error message returned because the format of the POST request body is invalid.	400
MaxPOSTPreDataLengthExceededError	The error message returned because the size of the POST request body, excluding the object content to upload, exceeds the limit.	400
MethodNotAllowed	The error message returned because the method is not supported.	405
MissingArgument	The error message returned because the required parameters are not set.	411

Error code	Error message	HTTP status code
MissingContentLength	The error message returned because the content length is not specified.	411
NoSuchBucket	The error message returned because the specified bucket does not exist.	404
NoSuchKey	The error message returned because the specified object does not exist.	404
NoSuchUpload	The error message returned because the specified multipart upload ID does not exist.	404
NotImplemented	The error message returned because the method cannot be implemented.	501
PreconditionFailed	The error message returned because a precondition error occurs.	412
RequestTimeTooSkewed	The error message returned because the difference between the time on the client when the request is sent and the time on the server when the request is received is greater than 15 minutes.	403
RequestTimeout	The error message returned because the request times out.	400
RequestIsNotMultiPartContent	The error message returned because the content-type value specified in the POST request is invalid.	400
SignatureDoesNotMatch	The error message returned because the signature is invalid.	403
TooManyBuckets	The error message returned because the number of the buckets managed by a user exceeds the limit.	400
InvalidEncryptionAlgorithmError	The error message returned because the specified encryption algorithm based on entropy encoding is invalid.	400

> **Note** In the preceding table, the error code is specified by the OssServiceError.Code parameter. The HTTP status code is specified by the OssServiceError.StatusCode parameter.

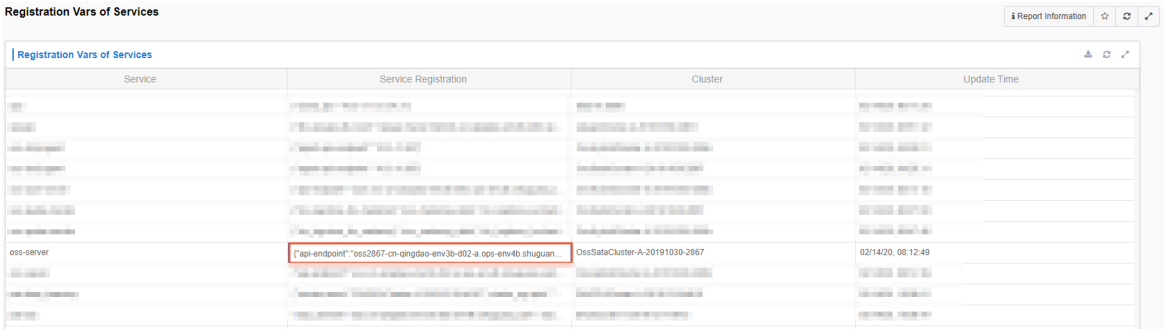
6.1.3. Obtain an endpoint

You can obtain an endpoint of a service in the Apsara Uni-manager Operations Console.

Procedure

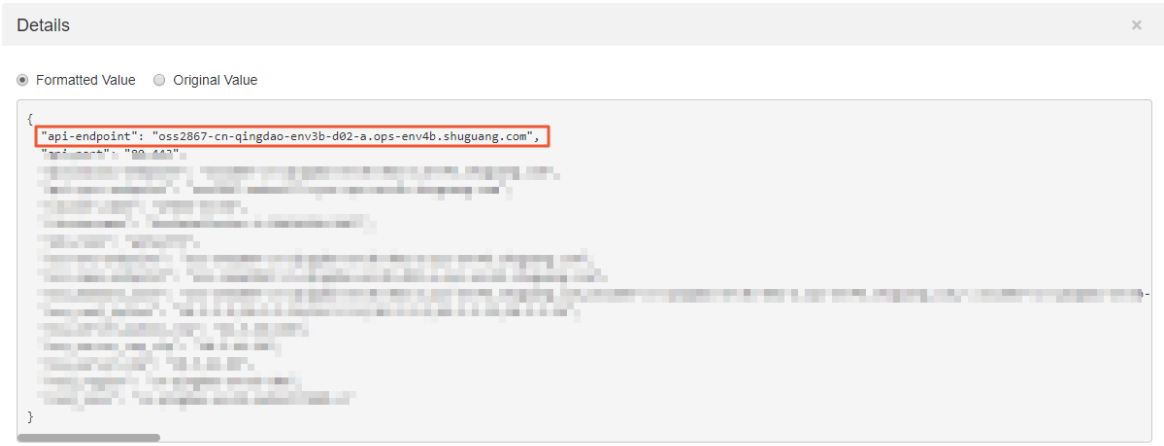
1. Log on to the Apsara Uni-manager Operations console.

   For more information about how to log on to the Apsara Uni-manager Operations console, see *Log on to the Apsara Uni-manager Operations console* in *Operations and Maintenance Guide*.
2. In the left-side navigation pane, choose **Products > Product List** to go to the Product List page. In the Apsara Stack O&M section, click **Apsara Infrastructure Management Framework**.
3. Click **Reports**.
4. In the list, click **Registration Vars of Services**.
5. In the top navigation bar, choose **Reports > System Reports**.
6. On the **Registration Vars of Services** page, find the **oss-server** row. Right-click the **Service Registration** column and choose **Show More** from the shortcut menu.



7. Click **Formatted Value**.

   The value of **api-endpoint** is the OSS endpoint.



6.1.4. Obtain an AccessKey pair

An AccessKey pair consists of an AccessKey ID and an AccessKey secret. AccessKey pairs are used to implement symmetric encryption to verify the identity of requesters. The AccessKey ID is used to identify a user. The AccessKey secret is used to encrypt a signature string. This topic describes how to obtain an AccessKey pair.

Prerequisites

Only operations administrators or level-1 organization administrators can obtain the AccessKey pair of an organization.

Obtain the AccessKey pair of an organization

To obtain the AccessKey pair of an organization, perform the following operations:

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, click **Enterprise**.
5. In the left-side navigation pane of the **Enterprise** page, click **Organizations**.
6. In the organization navigation tree, click an organization name.
7. In the Current Organization section, click **Obtain an accesskey**.
8. In the AccessKey message, view the AccessKey pair of the organization.

   > **Note** An AccessKey pair is automatically allocated to each level-1 organization. Subordinate organizations use the same AccessKey pair of their level-1 organization.

Obtain the AccessKey pair of a personal account

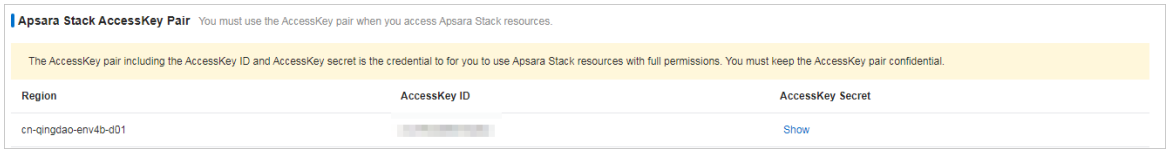
To obtain the AccessKey pair of a personal account, perform the following steps:

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

> **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
>
> - Uppercase or lowercase letters
> - Digits
> - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the upper-right corner of the homepage, move the pointer over the profile picture and click **User Information**.
5. In the **Apsara Stack AccessKey Pair** section, view your AccessKey pair.



> **Note** The AccessKey pair consists of an AccessKey ID and an AccessKey secret. AccessKey pairs of accounts grant you full permissions to access Apsara Stack resources. You must keep your AccessKey pair confidential.

7.Tablestore

7.1. Developer Guide

7.1.1. API reference

7.1.1.1. API

7.1.1.1.1. API-based operations

7.1.1.1.1.1. GetRow

Action

You can use the GetRow API to read data in a single row based on a specified primary key.

Request structure

```
message GetRowRequest {
    required string table_name = 1;
    required bytes primary_key = 2;   // The PlainBuffer encoding is binary.
    repeated string columns_to_get = 3; // If this parameter is not specified, all columns
are read.
    optional TimeRange time_range = 4;
    optional int32 max_versions = 5;
    optional bytes filter = 7;
    optional string start_column = 8;
    optional string end_column = 9;
    optional bytes token = 10;
}
```

table_name:

- Type: string
- Required: yes
- This parameter specifies the name of the table containing the data to be read.

primary_key:

- Type: bytes
- Required: yes
- This parameter specifies all primary key columns in the row, including the primary key names and values. The primary key columns are encoded in the PlainBuffer format.

columns_to_get:

- Type: repeated string
- Required: no

- This parameter specifies the names of all columns to be returned. If the parameter is not configured, all columns of this row are returned.
- If the specified column does not exist, data in this column is not returned.
- If a duplicate column name exists, the response only includes this column once.
- In columns_to_get, the maximum number of strings is 128.

time_range:

- Type: TimeRange
- Required: At least one of the time_range and max_versions parameters must be specified.
- This parameter specifies the range of timestamps to read versions of data.
- The minimum timestamp value is 0. The maximum timestamp value is INT64.MAX.
- To query data within a time range, specify start_time and end_time.
- To query data within a specific timestamp, specify specific_time.
- Example: If the value of time_range is (100, 200), the timestamp of the returned column data must be within the range of [100, 200).

max_versions:

- Type: int32
- Required: At least one of the max_versions and time_range parameters must be specified.
- This parameter specifies the maximum number of versions of data to be returned.
- Example: If the value of max_versions is 2, data of a maximum of two versions is returned for each column.

filter:

- Type: bytes
- Required: no
- This parameter specifies the expression of the filtering condition.
- It indicates the binary data after the filter is serialized in the Protobuf format.

start_column:

- Type: string
- Required: no
- This parameter specifies the column to start to read from and is used to read wide rows.
- The response contains the specified starting column.
- The column names are sorted lexicographically.
- Example: If a table contains columns A, B, and C, and the value of start_column is B, the data is read starting from column B. Columns B and C are returned.

end_column:

- Type: string
- Required: no
- This parameter specifies the column to stop reading data and is used to read wide rows.

- The response does not contain the specified ending column.
- The column names are sorted lexicographically.
- Example: If a table contains columns A, B, and C, and the value of end_column is B, the reading stops at column B. Only column A is returned.

Response structure

```
message GetRowResponse {
    required ConsumedCapacity consumed = 1;
    required bytes row = 2; // The PlainBuffer encoding is binary.
}
```

consumed:

- Type: CapacityUnit
- This parameter specifies the number of CUs consumed by this operation.

row:

- Type: bytes
- The read data is encoded in the PlainBuffer format.
- If this row does not exist, null is returned.

CU consumption:

- If the requested row does not exist, one read CU is consumed.
- If the requested row exists, the number of consumed read CUs is calculated based on the following formula: Number of consumed read CUs = [(Size of all primary key columns in the row + Size of actually read attribute columns)/4 KB] rounded up.
- If the request times out and the results are undefined, a CU may or may not be consumed.
- If an internal error code is returned (HTTP status code: 5XX), this operation does not consume CUs. If other errors are returned, one read CU is consumed.

7.1.1.1.1.2. PutRow

Action

You can use the PutRow API to insert data into the specified row. If the row does not exist, a new row is added. If the row exists, the original row is overwritten.

Request structure

```
message PutRowRequest {
    required string table_name = 1;
    required bytes row = 2; // The PlainBuffer encoding is binary.
    required Condition condition = 3;
    optional ReturnContent return_content = 4;
}
```

table_name:

- Type: string
- Required: yes
- This parameter specifies the name of the table to write data to.

row:

- Type: bytes
- Required: yes
- This parameter specifies the data to be written into the row. It is in the PlainBuffer format and contains the primary key and attribute columns.

condition:

- Type: Condition
- Required: yes
- This parameter determines whether to perform the row existence check before writing data. It can be one of three values:
  - IGNORE indicates that the row existence check is not performed.
  - EXPECT_EXIST indicates that the row is expected to exist.
  - EXPECT_NOT_EXIST indicates that the row is not expected to exist.
- If the row is not expected to exist but it does, the row cannot be inserted and an error is returned. If the row is expected to exist but it does not, the row also fails to be inserted and an error is returned.

return_content:

- Type: ReturnContent
- Required: no
- This parameter specifies the data type after the row is written. Only the primary key is returned. It is used for the auto-increment function of the primary key column.

Response structure

```
message PutRowResponse {
 required ConsumedCapacity consumed = 1;
 optional bytes row = 2;
}
```

consumed:

- Type: ConsumedCapacity
- This parameter specifies the number of CUs consumed by this operation.

CU consumption:

- If this row does not exist:
  - If the value of the condition parameter is IGNORE, the number of consumed write CUs is calculated based on the following formula: Number of consumed write CUs = [(Size of primary key columns in the row + Size of attribute columns to be inserted)/4 KB] rounded up.

- If the value of the condition parameter is EXPECT_NOT_EXIST, both write and read CUs are consumed. The number of consumed write CUs is calculated based on the following formula: Number of consumed write CUs = [(Size of primary key columns in the row + Size of attribute columns to be inserted)/4 KB] rounded up. The number of consumed read CUs is calculated based on the following formula: Number of consumed read CUs = (Size of primary key columns in the row/4 KB) rounded up.
- If the value of the condition parameter is EXPECT_EXIST, the row fails to be inserted. One write CU and one read CU are consumed.

- If this row exists:
  - If the value of the condition parameter is IGNORE, the number of consumed write CUs is calculated based on the following formula: Number of consumed write CUs = [(Size of all primary key columns in the row + Size of attribute columns to be inserted)/4 KB] rounded up.
  - If the value of the condition parameter is EXPECT_EXIST, both write and read CUs are consumed. The number of consumed write CUs is calculated based on the following formula: Number of consumed write CUs = [(Size of all primary key columns in the row + Size of attribute columns to be inserted)/4 KB] rounded up. The number of consumed read CUs is calculated based on the following formula: Number of consumed read CUs = (Size of all primary key columns in the row/4 KB) rounded up.
  - If the value of the condition parameter is EXPECT_NOT_EXIST, the row fails to be inserted. One write CU and one read CU are consumed.
- Conditional Update:
  - If the operation succeeds, the number of consumed CUs are calculated based on the preceding formulas.
  - If the operation fails, one write CU and one read CU are consumed.
- If an internal error code is returned (HTTP status code: 5XX), this operation does not consume CUs. If other errors are returned, one write CU is consumed.
- If the request times out and the results are undefined, a CU may or may not be consumed.

row:

- Type: bytes
- This parameter specifies the returned data when return_content is set.
- If return_content is not set or no value is returned, NULL is returned.
- It is in the PlainBuffer format.

7.1.1.1.1.3. UpdateRow

Description

You can call this operation to update the data of a specified row. If the specified row does not exist, a new row is added. If the specified row exists, the values in the specified columns are added, modified, or deleted based on the request.

Request structure

```
message UpdateRowRequest {
 required string table_name = 1;
 required bytes row_change = 2;
 required Condition condition = 3;
 optional ReturnContent return_content = 4;
}
```

table_name:

- Type: string
- Required: yes
- This parameter specifies the name of the table whose data is to be updated.

row_change:

- Type: bytes
- Required: yes
- This parameter specifies the data that you use to update the row, including primary key columns and attribute columns. The data is in the PlainBuffer format.
- This parameter specifies all the attribute columns whose data you want to update for this row. Tablestore adds, modifies, or deletes the values in the specified attribute columns based on each specified update type in row_change.
- Columns that exist in this row but are not specified by row_change are not affected.
- Valid values of UpdateType:
  - PUT: The value you use to update the specified column must be a valid attribute column value. This update type indicates that if the specified column does not exist, a new column is added. If the specified column exists, the existing column is overwritten.
  - DELETE: The value you use to update the specified column must be empty, and a timestamp must be specified. This update type indicates that data of the specified version is deleted from the column.
  - DELETE_ALL: The value you use to update the specified column and the timestamp must be empty. This update type indicates that all versions of data in the column are deleted.

> **Note** A row exists even if all attribute columns in the row are deleted. To delete a row, use the DeleteRow operation.

condition:

- Type: Condition
- Required: yes
- This parameter determines whether to perform existence check before data is updated. You can set this parameter to one of the following values:
  - IGNORE: the row existence check is not performed.
  - EXPECT_EXIST: the row is expected to exist.
- If a row that is expected to exist does not exist, the row cannot be updated and an error is returned. If the existence of the row is ignored, the operation result is not affected by the row existence.

return_content:

- Type: ReturnContent

- Required: no
- This parameter specifies the type of the data to return after the row is updated. Only the primary key is returned. It is used for the auto-increment function of the primary key column.

Response structure

```
message UpdateRowResponse {
 required ConsumedCapacity consumed = 1;
 optional bytes row = 2;
}
```

consumed:

- Type: ConsumedCapacity
- This parameter specifies the number of capacity units (CUs) consumed by this operation.

CU consumption:

- If the row does not exist:
  - If the value of the condition parameter is IGNORE, the number of consumed write CUs is calculated based on the following formula: Number of consumed write CUs = [(Size of primary key columns in the row + Size of attribute columns to be updated)/4 KB] rounded up. If UpdateRow specifies an attribute column to delete, the length of the column name is calculated as the column size.
  - If the value of the condition parameter is EXPECT_EXIST, the row fails to be inserted. One write CU and one read CU are consumed.
- If the row exists:
  - If the value of the condition parameter is IGNORE, the number of consumed write CUs is calculated based on the following formula: Number of consumed write CUs = [(Size of primary key columns in the row + Size of attribute columns to be updated)/4 KB] rounded up. If UpdateRow specifies an attribute column to delete, the length of the column name is calculated as the column size.
  - If the value of the condition parameter is EXPECT_EXIST, both write and read CUs are consumed. The number of consumed write CUs is calculated by using the same method that is used when the value of the condition parameter is IGNORE. The number of consumed read CUs is calculated based on the following formula: Number of consumed read CUs = (Size of primary key columns in the row/4 KB) rounded up.
- If the request times out and the results are undefined, CUs may or may not be consumed.
- If an internal error is returned and the 5xx HTTP status code is displayed, this operation does not consume CUs. If other errors are returned, one write CU and one read CU are consumed.

row:

- Type: bytes
- This parameter indicates the returned data when return_content is set.
- If return_content is not set or no value is returned, NULL is returned.
- The returned data is in the PlainBuffer format.

7.1.1.1.1.4. DeleteRow

Action

You can use the DeleteRow API to delete a row of data.

Request structure

```
message DeleteRowRequest {
    required string table_name = 1;
    required bytes primary_key = 2; // The PlainBuffer encoding is binary.
    required Condition condition = 3;
    optional ReturnContent return_content = 4;
}
```

table_name:

- Type: string
- Required: yes
- This parameter specifies the name of the table whose data is to be updated.

primary_key:

- Type: bytes
- Required: yes
- This parameter specifies the primary key of the row to be deleted, which is in the PlainBuffer format.

condition:

- Type: Condition
- Required: yes
- This parameter determines whether to perform existence check before data updates. It can be one of two values:
  - IGNORE indicates that the row existence check is not performed.
  - EXPECT_EXIST indicates that the row is expected to exist.
- If this row is expected to exist but does not, the delete operation fails and an error is returned. If the existence of the row is ignored, this operation succeeds regardless of the row existence.

return_content:

- Type: ReturnContent
- Required: no
- This parameter specifies the data type after the row is written. Only the primary key is returned. It is used for the auto-increment function of the primary key column.

Response structure

```
message DeleteRowResponse {
 required ConsumedCapacity consumed = 1;
 optional bytes row = 2;
}
```

consumed:

- Type: ConsumedCapacity
- This parameter specifies the number of capacity units (CUs) consumed by this operation.

CU consumption:

- If this row does not exist:
  - If the value of the condition parameter is IGNORE, the number of consumed write CUs is calculated based on the following formula: Number of consumed write CUs = (Size of primary key columns in the row/4 KB) rounded up.
  - If the value of the condition parameter is EXPECT_EXIST, the row fails to be deleted, and one write CU and one read CU are consumed.
- If this row exists:
  - If the value of the condition parameter is IGNORE, the number of consumed write CUs is calculated based on the following formula: Number of consumed write CUs = (Size of primary key columns in the row/4 KB) rounded up.
  - If the value of the condition parameter is EXPECT_EXIST, both write and read CUs are consumed. The number of consumed write CUs and the number of consumed read CUs are calculated based on the following formula: Number of consumed read/write CUs = (Size of primary key columns in the row/4 KB) rounded up.
- If an internal error code is returned (HTTP status code: 5XX), this operation does not consume CUs. If other errors are returned, one write CU is consumed.
- If the request times out and the results are undefined, a CU may or may not be consumed.

row:

- Type: bytes
- This parameter specifies the returned data when return_content is set.
- If return_content is not set or no value is returned, NULL is returned.
- The returned data is in the PlainBuffer format.

7.1.1.1.1.5. GetRange

Description

You can call this operation to read data within the specified primary key range.

Request structure

```
message GetRangeRequest {
    required string table_name = 1;
    required Direction direction = 2;
    repeated string columns_to_get = 3;  // If this parameter is not specified, all columns are read.
    optional TimeRange time_range = 4;
    optional int32 max_versions = 5;
    optional int32 limit = 6;
    required bytes inclusive_start_primary_key = 7; // Encode the parameter value in the PlainBuffer format to obtain binary data.
    required bytes exclusive_end_primary_key = 8; // Encode the parameter value in the PlainBuffer format to obtain binary data.
    optional bytes filter = 10;
    optional string start_column = 11;
    optional string end_column = 12;
}
```

table_name:

- Type: string
- Required: yes
- This parameter specifies the name of the table that contains the data to read.

direction:

- Type: Direction
- Required: yes
- This parameter specifies the query direction. If the query direction is forward, the value of inclusive_start_primary must be smaller than that of exclusive_end_primary, and the rows in the response are sorted in ascending order of primary key values. If the query direction is backward, the value of inclusive_start_primary must be greater than that of exclusive_end_primary, and the rows in the response are sorted in descending order of primary key values.

columns_to_get:

- Type: repeated string
- Required: no
- This parameter specifies the names of all columns to return. If the parameter is not configured, all columns of each row in the read results are returned.
- If a duplicate column name exists, the response only includes this column once.
- The maximum number of strings that can be specified in columns_to_get is 128.

time_range:

- Type: TimeRange
- Required: At least one of the time_range and max_versions parameters must be specified.
- This parameter specifies the range of timestamps to read versions of data.
- The timestamp in the value of time_range ranges from 0 to INT64.MAX.
- To query data of a time range, specify start_time and end_time.
- To query data of a specific timestamp, specify specific_time.
- Example: If the value of time_range is (100, 200), the timestamp of the returned column data must be within the range of [100, 200).

max_versions:

- Type: int32
- Required: At least one of the time_range and max_versions parameters must be specified.
- This parameter specifies the maximum number of versions of data to return.
- Example: If the value of max_versions is 2, a maximum of two versions of data is returned for each column.

limit:

- Type: int32
- Required: no
- This parameter specifies the maximum number of rows to read and return in a single operation. If the number of rows queried exceeds this value, the response includes a breakpoint to record the position where read ends in this operation. The next read continues from the recorded position. This value must be greater than 0.
- Tablestore returns a maximum of 5,000 rows of data if this parameter is not set. The total data size does not exceed 4 MB.

inclusive_start_primary_key:

- Type: bytes
- Required: yes
- This parameter specifies a start primary key. The read starts from the row that contains the start primary key. If the row exists, the response contains this row. The start primary key is encoded in the PlainBuffer format.

exclusive_end_primary_key:

- Type: bytes
- Required: yes
- This parameter specifies an end primary key. The read stops at the row that contains the end primary key. The response does not contain the row regardless of the row existence. The end primary key is encoded in the PlainBuffer format.
- For GetRange, the type of Column in inclusive_start_primary_key or exclusive_end_primary_key can be set to INF_MIN or INF_MAX. If the type of column is set to INF_MIN, the value of the column is always smaller than that of other columns. If the type of column is set to INF_MAX, the value of the column is always greater than that of other columns. Columns.

filter:

- Type: bytes
- Required: no
- This parameter specifies the expression of the filter condition.
- It indicates the binary data after the filter is serialized in the Protobuf format.

start_column:

- Type: string
- Required: no
- This parameter specifies the column from which the read of each row starts. This parameter is used to read wide rows.
- The response contains the specified start column.

- The columns are sorted based on their names in alphabetical order.
- Example: If a table contains columns a, b, and c, and the value of start_column is b, the read of data starts from column b. Columns b and c are returned.

end_column:

- Type: string
- Required: no
- This parameter specifies the column where the read of each row ends. This parameter is used to read wide rows.
- The response does not contain the specified end column.
- The columns are sorted based on their names in alphabetical order.
- Example: If a table contains columns a, b, and c, and the value of end_column is b, the read of data stops at column b. Only column a is returned.

Response structure

```
message GetRangeResponse {
    required ConsumedCapacity consumed = 1;
    required bytes rows = 2;
    optional bytes next_start_primary_key = 3;
}
```

consumed:

- Type: ConsumedCapacity
- This parameter specifies the number of capacity units (CUs) consumed by this operation.

rows:

- Type: bytes
- It is encoded in the PlainBuffer format.
- This parameter indicates all the read data. If the direction specified in the request is forward, all rows are sorted in ascending order of primary key values. If the direction specified in the request is backward, all rows are sorted in descending order of primary key values.
- primary_key_columns and attribute_columns for each row only contain the columns specified by columns_to_get. Their orders may not be consistent with the order of columns_to_get in the request. The order of primary_key_columns may not be consistent with the order specified when the table is created.
- If the specified columns_to_get in the request does not contain any primary key column, rows that do not contain any attribute column specified in columns_to_get are not included in the response although the primary key column of the rows is within the query range.

next_start_primary_key:

- Type: bytes
- This parameter specifies the breakpoint information for this GetRange operation. It is encoded in the PlainBuffer format.
- If this parameter is not specified, the response to this GetRange operation contains all data within the request range.
- If this parameter is specified, the response to this GetRange operation includes only the data within the [inclusive_start_primary_key, next_start_primary_key) range. If you want to obtain the remaining

data, you must use next_start_primary_key as inclusive_start_primary_key, and retain exclusive_end_primary_key in the original request to continue the GetRange operation.

> **Note** Tablestore limits the number of rows in the response to a GetRange operation to 5,000 rows, whose size cannot exceed 4 MB. Furthermore, the volume of returned data cannot exceed the remaining reserved read throughput. Even if no limit is set in the GetRange request, next_start_primary_key may still appear in the response. Therefore, when you use GetRange, you must check whether the response contains next_start_primary_key and proceed accordingly.

CU consumption:

- The number of read CUs consumed by the GetRange operation is calculated based on the following formula: Number of read CUs consumed by the GetRange operation = [(Size of primary key columns of the row within the query range + Size of actually read attribute columns)/4 KB] rounded up.
- If the request times out and the results are undefined, CUs may or may not be consumed.
- If an internal error is returned (HTTP status code: 5xx), this operation does not consume CUs. If other errors are returned, one read CU is consumed.

7.1.1.1.1.6. BatchGetRow

Action

You can use the BatchGetRow API to simultaneously read data in several rows from one or more tables.

The BatchGetRow operation is a set of multiple GetRow operations. The execution, returning of results, and CU consumption of each individual operation are carried out independently.

Compared with the execution of a large number of GetRow operations, the use of BatchGetRow can reduce the request response time and increase the data read rate.

Request structure

```
message BatchGetRowRequest {
    repeated TableInBatchGetRowRequest tables = 1;
}
```

tables:

- Type: repeated TableInBatchGetRowRequest
- Required: yes
- This parameter specifies the information of rows to be read.
- The entire operation fails and returns an error if any of the following conditions appears in tables:
  - Any table listed in the tables parameter does not exist.
  - The name of any table does not comply with the table naming conventions.
  - The primary key is not specified for any row in a table, the primary key column name does not comply with the conventions, or the primary key column type is incorrect.
  - A column name in columns_to_get of any table does not comply with the column naming conventions.
  - Tables with the same name exist.
  - Any table in the tables contains rows with identical primary keys.

- The total number of RowInBatchGetRowRequest in all tables exceeds 100.
- Any table in the tables does not contain any RowInBatchGetRowRequest.
- The value of columns_to_get of any table exceeds 128.

Response structure

```
message BatchGetRowResponse {
    repeated TableInBatchGetRowResponse tables = 1;
}
```

tables:

- Type: repeated TableInBatchGetRowResponse
- The value of this parameter corresponds to the data to be read in each table.
- The TableInBatchGetRowResponse object order in the response is the same as the TableInBatchGetRowRequest object order in BatchGetRowRequest. The object order of each RowInBatchGetRowResponse under TableInBatchGetRowResponse is the same as that of RowInBatchGetRowRequest under TableInBatchGetRowRequest.
- If a row does not exist or contains no data in the specified columns_to_get, a corresponding RowInBatchGetRowResponse still appears in TableInBatchGetRowResponse. However, the primary_key_columns and attribute_columns of the row are null.
- If a row fails to be read, the is_ok value in RowInBatchGetRowResponse for the row is false and the row is null.

> **Note** The BatchGetRow operation may partially fail at the row level. However, it still returns an HTTP status code of 200. The application must check for errors in RowInBatchGetRowResponse to confirm the execution results for each row and then proceed accordingly.

CU consumption:

- If the entire operation fails, it does not consume any CU.
- If the request times out and the results are undefined, a CU may or may not be consumed.
- In other situations, each RowInBatchGetRowRequest operation is considered as one GetRow operation when write CUs are calculated.

7.1.1.1.1.7. BatchWriteRow

Action

You can use the BatchWriteRow API to simultaneously insert, modify, or delete data in several rows in one or more tables.

It is a set of multiple PutRow, UpdateRow, and DeleteRow operations. The execution, returning of results, and capacity unit (CU) consumption of each individual operation are carried out independently.

Compared with the execution of a large number of write operations, the use of BatchWriteRow can reduce the request response time and increase the data write rate.

Request structure

```
message BatchWriteRowRequest {
    repeated TableInBatchWriteRowRequest tables = 1;
}
```

tables:

- Type: repeated TableInBatchWriteRowRequest
- Required: yes
- This parameter specifies the information of rows that require write operations.
- An error is returned if any of the following conditions occurs:
  - Any table listed in the tables parameter does not exist.
  - Tables with the same name exist.
  - The name of any table does not comply with the table naming conventions.
  - The primary key is not specified for any row in a table, the primary key column name does not comply with the conventions, or the primary key column type is incorrect.
  - For any attribute column in a table, the column name does not comply with the column naming conventions.
  - Any row in a table contains an attribute column with the same name as the primary key column.
  - The value of any primary key or attribute column in a table exceeds the upper limit.
  - Any table in the tables contains rows with identical primary keys.
  - The total number of rows for all tables listed in the tables parameter exceeds 200 or the total size of the data exceeds 4 MB.
  - If any table contains no rows, the OTSParameterInvalidException error is returned.
  - The number of columns included in any PutRowInBatchWriteRowRequest of a table exceeds 1,024.
  - The number of ColumnUpdate objects included in any UpdateRowInBatchWriteRowRequest in a table exceeds 1,024.

Response structure

```
message BatchWriteRowResponse {
    repeated TableInBatchWriteRowResponse tables = 1;
}
```

tables:

- Type: TableInBatchWriteRowResponse
- This parameter specifies the response information corresponding to the operations for each table. The response information contains the execution results, error codes, and number of CUs consumed.
- The TableInBatchWriteRowResponse object order in the response is the same as the TableInBatchWriteRowRequest object order in BatchWriteRowRequest. The RowInBatchWriteRowResponse object orders contained in put_rows, update_rows, and delete_rows in each TableInBatchWriteRowRequest are the same as the respective PutRowInBatchWriteRowRequest, UpdateRowInBatchWriteRowRequest, and DeleteRowInBatchWriteRowRequestobject orders contained in put_rows, update_rows, and delete_rows in TableInBatchWriteRowRequest.
- If a row fails to be read, the is_ok value of the row in RowInBatchWriteRowResponse is false.

> **Note** The BatchWriteRow operation may partially fail at the row level. However, it still returns an HTTP status code of 200. The application must check for errors in RowInBatchWriteRowResponse to confirm the execution results for each row and then proceed accordingly.

CU consumption:

- If the entire operation fails, it does not consume any CUs.
- If the request times out and the results are undefined, a CU may or may not be consumed.
- In other situations, each PutRowInBatchWriteRowRequest, UpdateRowInBatchWriteRowRequestDelete, or RowInBatchWriteRowRequest operation is considered as one write operation when write CUs are calculated.

7.1.1.1.1.8. CreateTable

Action

You can use the CreateTable API to create a table based on the specified table structure information.

Request structure

```
message CreateTableRequest {
    required TableMeta table_meta = 1;
    required ReservedThroughput reserved_throughput = 2;
    optional TableOptions table_options = 3;
    optional StreamSpecification stream_spec = 5;
}
```

table_meta:

- Type: TableMeta
- Required: yes
- This parameter specifies the structural information of the table you want to create. The value of table_name must be unique among the current instance. The value of ColumnSchemas in primary_key must be between 1 and 4. The value of the name parameter in ColumnSchema of primary_key must comply with the naming conventions. The value of the type parameter can only be STRING, INTEGER, or BINARY.
- After a table is created, its schema cannot be modified.

reserved_throughput:

- Type: ReservedThroughput
- Required: yes
- This parameter specifies the initial reserved read/write throughput for the table to be created. The maximum reserved throughput is 5,000 for each table.
- The reserved read/write throughput settings for a table can be modified by using the UpdateTable operation.

table_options:

- Type: TableOptions
- Required: yes

- This parameter specifies TimeToLive and MaxVersions.

Response structure

```
message CreateTableResponse {
}
```

Note

- No read/write operation can be performed on a table immediately after it is created. Typically, you can perform read/write operations on a new table one minute after it is created.
- A single instance can contain up to 64 tables. If you need to raise the upper limit of the table quantity for a single instance, contact Alibaba Cloud customer service.

7.1.1.1.1.9. ListTable

Action

You can use the ListTable API to obtain the names of all tables created in the current instance.

Request structure

```
message ListTableRequest {
}
```

Response structure

```
message ListTableResponse {
    repeated string table_names = 1;
}
```

table_names:

- Type: repeated string
- This parameter specifies the names of all tables in the current instance.

Note

If a table is created, its table name can be returned by ListTableResponse, but this does not necessarily mean that this table can be read or written at the time.

7.1.1.1.1.10. DeleteTable

Action

You can use the DeleteTable API to delete the specified table in an instance.

Request structure

```
message DeleteTableRequest {
    required string table_name = 1;
}
```

table_name:

- Type: string
- Required: yes
- This parameter specifies the name of the table you want to delete.

Response structure

```
message DeleteTableResponse {
}
```

If the response of DeleteTable does not contain an error, the table has been deleted.

7.1.1.1.1.11. UpdateTable

Action

You can use the UpdateTable API to update the reserved read or write throughput settings of the specified table. New settings take effect within one minute of a successful update.

Request structure

```
message UpdateTableRequest {
    required string table_name = 1;
    optional ReservedThroughput reserved_throughput = 2;
    optional TableOptions table_options = 3;
    optional StreamSpecification stream_spec = 4;
}
```

table_name:

- Type: string
- Required: yes
- This parameter specifies the name of the table for which you want to modify the reserved read/write throughput settings.

reserved_throughput:

- Type: ReservedThroughput
- Required: yes
- This parameter specifies the reserved read/write throughput settings you want to modify for the table. New settings take effect within one minute of a successful update.
- You may modify the reserved read/write throughput settings of the table as required.
- You must specify a non-null value for either the read or write parameter of capacity_unit. Otherwise, the request fails and an error is returned.

table_options:

- Type: TableOptions
- Required: yes
- This parameter specifies TimeToLive and MaxVersions.

Response structure

```
message UpdateTableResponse {
    required ReservedThroughputDetails reserved_throughput_details = 1;
    required TableOptions table_options = 2;
}
```

reserved_throughput_details:

- Type: ReservedThroughputDetails
- After the update, the reserved read/write throughput settings information of the table contains the current reserved throughput settings, the time these settings were last updated, and the number of times they have been lowered on the current date.

table_options:

- Type: TableOptions
- The latest value of the table_options parameter after the modification.

Note

- The minimum interval between updates to the reserved read/write throughput of a table is two minutes. If the current UpdateTable operation is requested within two minutes of the previous operation, it will be rejected.
- The reserved read/write throughput of a table can be raised or lowered an unlimited number of times within a single day (from 00:00:00 to 00:00:00 the next day in UTC time).

7.1.1.1.1.12. DescribeTable

Action

You can use the DescribeTable API to query the structure information and reserved read/write throughput value of the specified table.

Request structure

```
message DescribeTableRequest {
 required string table_name = 1;
}
```

table_name:

- Type: string
- Required: yes
- This parameter specifies the name of the table you want to query.

Response structure

```
message DescribeTableResponse {
    required TableMeta table_meta = 1;
    required ReservedThroughputDetails reserved_throughput_details = 2;
    required TableOptions table_options = 3;
    optional StreamDetails stream_details = 5;
    repeated bytes shard_splits = 6;
}
```

table_meta:

- Type: TableMeta
- This parameter specifies the schema of the table. The schema is the same as the schema provided when the table is created.

reserved_throughput_details:

- Type: ReservedThroughputDetails
- This parameter specifies the reserved read/write throughput settings information of the table. The information contains the current reserved read/write throughput settings, the time these settings were last updated, and the number of times they have been lowered on the current date.

table_options:

- Type: TableOptions
- This parameter specifies the latest value of the table_options parameter.

StreamSpecification:

- Type: StreamSpecification
- Required: no
- This parameter specifies whether to enable Stream-related attributes.

shard_splits:

- Type: bytes
- This parameter specifies the split points of all partitions in the current table.

7.1.1.1.1.13. ComputeSplitPointsBySize

Action

You can use the ComputeSplitPointsBySize API to logically split data in a table into several partitions whose sizes are close to the specified size. The API can return the split points between the partitions and prompt about hosts where the partitions reside. This API is typically used to implement plans on compute engines, such as concurrency plans.

Request structure

```
message ComputeSplitPointsBySizeRequest {
    required string table_name = 1;
    required int64 split_size = 2; // in 100MB
}
```

table_name:

- Type: string
- Required: yes
- This parameter specifies the name of the table that contains the data you want to split.

split_size:

- Type: int64
- Required: yes
- This parameter specifies the approximate size of each partition, rounded to the nearest 100 MB.

Response structure

```
message ComputeSplitPointsBySizeResponse {
    required ConsumedCapacity consumed = 1;
    repeated PrimaryKeySchema schema = 2;
    /**
     * Split points between splits, in the ascending order.
     *
     * A split is a consecutive range of primary keys,
     * whose data size is approximately split_size specified in the request.
     * The size could be hard to be precise.
     *
     * A split point is an array of primary-key column w.r.t. table schema,
     * which is never longer than that of table schema.
     * Tailing -inf will be omitted to reduce transmission payloads.
     */
    repeated bytes split_points = 3;
    /**
     * Locations where splits lie.
     *
     * By the managed nature of TableStore, these locations are no more than hints.
     * If a location is not suitable to be seen, an empty string will be placed.
     */
     message SplitLocation {
         required string location = 1;
         required sint64 repeat = 2;
     }
     repeated SplitLocation locations = 4;
}
```

consumed:

- Type: ConsumedCapacity
- This parameter specifies the number of CUs consumed by this request.

schema:

- Type: PrimaryKeySchema
- This parameter specifies the schema of the table. The schema is the same as the schema provided when the table is created.

split_points:

- Type: repeated bytes
- The split points between partitions. The split points must increase monotonically between the

partitions. Each split point is a PlainBuffer-encoded line and contains only primary keys. The last -inf of each split point is not transmitted to reduce the volume of data transmitted.

locations:

- Type: repeated SplitLocation
- This parameter specifies the prompt about the hosts where the split points reside. It can be null.

For example, a table contains three columns of primary keys, where the first column is of the string type. After this API is called, five partitions are obtained, which are (-inf,-inf,-inf) to ("a",-inf,-inf), ("a",-inf,-inf) to ("b",-inf,-inf), ("b",-inf,-inf) to ("c",-inf,-inf), ("c",-inf,-inf) to ("d",-inf,-inf), and ("d",-inf,-inf) to (+inf,+inf,+inf). The first three partitions reside in machine-A, while the last two in machine-B. In this case, split_points is (example) `[("a"),("b"),("c"),("d")]`, whereas locations is (example) `"machine-A"*3, "machine-B"*2`.

CU consumption

The number of consumed read CUs is the same as that of the partitions. No write CUs are consumed.

7.1.1.1.1.14. ListStream

Action

You can use the ListStream API to obtain information about the stream that is enabled for all tables in the current instance.

Request structure

```
message ListStreamRequest {
    optional string table_name = 1;
}
```

table_name:

- Type: optional string
- This parameter specifies the name of the table for which the current stream is enabled.

Response structure

```
message ListStreamResponse {
    repeated Stream streams = 1;
}
message Stream {
    required string stream_id = 1;
    required string table_name = 2;
    required int64 creation_time = 3;
}
```

stream_id:

- Type: repeated string
- This parameter specifies the ID of the current stream.

table_name:

- Type: required string
- This parameter specifies the name of the table for which the current stream is enabled.

creation_time:

- Type: required int64
- This parameter specifies the time the current stream is enabled.

7.1.1.1.1.15. DescribeStream

Action

You can use the DescribeStream API to obtain information about the partitions of the current stream.

Request structure

```
message DescribeStreamRequest {
    required string stream_id = 1;
    optional string inclusive_start_shard_id = 2;
    optional int32 shard_limit = 3;
}
```

stream_id:

- Type: required string
- This parameter specifies the ID of the current stream.

inclusive_start_shard_id:

- Type: required string
- This parameter specifies the ID of the starting partition in a query.

shard_limit:

- Type: required string
- This parameter specifies the upper limit of the returned partition quantity in a single query.

Response structure

```
message DescribeStreamResponse {
    required string stream_id = 1;
    required int32 expiration_time = 2;
    required string table_name = 3;
    required int64 creation_time = 4;
    required StreamStatus stream_status = 5;
    repeated StreamShard shards = 6;
    optional string next_shard_id = 7;
}
message StreamShard {
    required string shard_id = 1;
    optional string parent_id = 2;
    optional string parent_sibling_id = 3;
}
```

stream_id:

- Type: required string
- This parameter specifies the ID of the current stream.

expiration_time:

- Type: required int32
- This parameter specifies the expiration time of the stream.

table_name:

- Type: required string
- This parameter specifies the name of the table for which the current stream is enabled.

creation_time:

- Type: required int32
- This parameter specifies the time the current stream is enabled.

stream_status:

- Type: required StreamStatus
- This parameter specifies the status of the current stream, which can be enabling or active.

shards:

- Type: required StreamShard
- This parameter specifies the information about the streamShard, including the partition ID, parent partition ID, and information about the neighbor partition of the parent partition (applicable when the parent partition is merged).

next_shard_id:

- Type: optional string
- This parameter specifies the start ID of the next partition in a paging query.

Note

Data reading for the parent partition must be completed before data of the current partition is read.

7.1.1.1.1.16. GetShardIterator

Action

You can use the GetShardIterator API to obtain the response of the start iterator for reading the record information of the current partition.

Request structure

```
message GetShardIteratorRequest {
    required string stream_id = 1;
    required string shard_id = 2;
}
```

stream_id:

- Type: required string

- This parameter specifies the ID of the current stream.

shard_id:

- Type: required string
- This parameter specifies the ID of the current partition.

Response structure

```
message GetShardIteratorResponse {
    required string shard_iterator = 1;
}
```

shard_iterator:

- Type: required string
- This parameter specifies the start iterator for reading the record of the current partition.

7.1.1.1.1.17. GetStreamRecord

Action

You can use the GetStreamRecord API to obtain the incremental content of the current partition.

Request structure

```
message GetStreamRecordRequest {
    required string shard_iterator = 1;
    optional int32 limit = 2;
}
```

shard_iterator:

- Type: required string
- This parameter specifies the iterator for reading the current partition next time.

Response structure

```
message GetStreamRecordResponse {
    message StreamRecord {
        required ActionType action_type = 1;
        required bytes record = 2;
    }
    repeated StreamRecord stream_records = 1;
    optional raw_string next_shard_iterator = 2;
    optional ConsumedCapacity consumed = 3;
}
```

StreamRecord:

- Type: repeated StreamRecord
- This parameter specifies the record entry for reading the current partition.

shard_iterator:

- Type: required string
- This parameter specifies the iterator for reading the current partition next time.

consumed:

- Type: ConsumedCapacity
- This parameter specifies the number of CUs consumed by this operation.
- The sum of data in all rows of a table for stream read is calculated based on the following formula: Number of consumed read CUs = (Size of actually read columns/4 KB) rounded up.

7.1.1.1.1.18. Tablestore ProtocolBuffer message definitions

This topic describes the detailed definitions of table_store.proto and table_store_filter.proto.

table_store.proto

```
package com.alicloud.openservices.tablestore.core.protocol;
message Error {
    required string code = 1;
    optional string message = 2;
}
enum PrimaryKeyType {
    INTEGER = 1;
    STRING = 2;
    BINARY = 3;
}
enum PrimaryKeyOption {
    AUTO_INCREMENT = 1;
}
message PrimaryKeySchema {
    required string name = 1;
    required PrimaryKeyType type = 2;
    optional PrimaryKeyOption option = 3;
}
message TableOptions {
    optional int32 time_to_live = 1; // This parameter value can be dynamically modified.
    optional int32 max_versions = 2; // This parameter value can be dynamically modified.
    optional int64 deviation_cell_version_in_sec = 5; // This parameter value can be dynami
cally modified.
}
message TableMeta {
    required string table_name = 1;
    repeated PrimaryKeySchema primary_key = 2;
}
enum RowExistenceExpectation {
    IGNORE = 0;
    EXPECT_EXIST = 1;
    EXPECT_NOT_EXIST = 2;
}
message Condition {
    required RowExistenceExpectation row_existence = 1;
    optional bytes column_condition      = 2;
```

```
}
message CapacityUnit {
    optional int32 read = 1;
    optional int32 write = 2;
}
message ReservedThroughputDetails {
    required CapacityUnit capacity_unit = 1; // This parameter indicates the current reserv
ed throughput of the table.
    required int64 last_increase_time = 2; // This parameter indicates the last time the re
served throughput was raised.
    optional int64 last_decrease_time = 3; // This parameter indicates the last time the re
served throughput was lowered.
}
message ReservedThroughput {
    required CapacityUnit capacity_unit = 1;
}
message ConsumedCapacity {
    required CapacityUnit capacity_unit = 1;
}
/* ############################################  CreateTable  ############################
################ */
/**
 * table_meta is used to store schema attributes that cannot be modified in a table. The Re
servedThroughput and TableOptions attributes that can be modified are stored as the paramet
ers for UpdateTable.

    required bytes filter = 2;  // Serialized string of filter of the type
}
```

7.1.1.1.1.19. CreateIndex

You can call this operation to create an index table for the specified base table.

Request syntax

```
message CreateIndexRequest {
    required string main_table_name = 1;
    required IndexMeta index_meta = 2;
    optional bool include_base_data = 3;
}
```

main_table_name

- Type: string.
- Required: yes.
- This parameter specifies the name of the base table for which to create an index table.

index_meta

- Type: IndexMeta.
- Required: yes.
- This parameter specifies the schema of the index table to be created.

include_base_data

- Type: Boolean.
- Required: no.
- This parameter specifies whether the existing data of the base table is included in the index table to be created.

Response syntax

```
message CreateIndexResponse {
}
```

7.1.1.1.1.20. DeleteIndex

You can call this operation to delete an index table from the specified base table.

Request syntax

```
message DropIndexRequest {
    required string main_table_name = 1;
    required string index_name = 2;
}
```

main_table_name

- Type: string.
- Required: yes.
- This parameter specifies the name of the base table from which to delete an index table.

index_name

- Type: string.
- Required: yes.
- This parameter specifies the name of the index table to be deleted.

Response syntax

```
message DropIndexResponse {
}
```

7.1.1.1.2. DataType

7.1.1.1.2.1. ActionType

ActionType specifies the operation type in the response of the GetStreamRecord operation. Operation types include:

- PUT_ROW indicates that the operation type is PutRow.
- UPDATE_ROW indicates that the operation type is UpdateRow.
- DELETE_ROW indicates that the operation type is DeleteRow.

Enumeration values

```
enum ActionType {
    PUT_ROW = 1;
    UPDATE_ROW = 2;
    DELETE_ROW = 3;
}
```

7.1.1.1.2.2. CapacityUnit

CapacityUnit specifies the number of CUs consumed in an operation, or reserved read/write throughput of a table.

Data structure

```
message CapacityUnit {
    optional int32 read = 1;
    optional int32 write = 2;
}
```

read:

- Type: int32
- Description: the number of read CUs consumed by this operation or the reserved read throughput for this table.

write:

- Type: int32
- Description: the number of write CUs consumed by this operation or the reserved write throughput for this table.

7.1.1.1.2.3. ColumnPaginationFilter

ColumnPaginationFilter specifies the filtering conditions for reading wide rows. This API is applicable to the Filter function.

Data structure

```
message ColumnPaginationFilter {
 required int32 offset = 1;
 required int32 limit = 2;
}
```

offset:

- Type: int32
- Description: the position of the column to start reading from.

limit:

- Type: int32
- Description: the number of columns to be read.

7.1.1.1.2.4. ComparatorType

ComparatorType is an arithmetical operator. It includes the following enumeration types:

- CT_EQUAL indicates equal to.
- CT_NOT_EQUAL indicates not equal to.
- CT_GREATER_THAN indicates greater than.
- CT_GREATER_EQUAL indicates not smaller than.
- CT_LESS_THAN indicates smaller than.
- CT_LESS_EQUAL indicates not greater than.

Enumeration values

```
enum ComparatorType {
 CT_EQUAL = 1;
 CT_NOT_EQUAL = 2;
 CT_GREATER_THAN = 3;
 CT_GREATER_EQUAL = 4;
 CT_LESS_THAN = 5;
 CT_LESS_EQUAL = 6;
}
```

7.1.1.1.2.5. CompositeColumnValueFilter

CompositeColumnValueFilter specifies a group of conditions, for example, column_a > 5 AND column_b = 10. This API is applicable to the ConditionUpdate and Filter functions.

Data structure

```
message CompositeColumnValueFilter {
 required LogicalOperator combinator = 1;
 repeated Filter sub_filters = 2;
}
```

combinator:

- Type: LogicalOperator

- Description: the logical operator.

sub_filter:

- Type: Filter
- Description: the sub-condition expression.

7.1.1.1.2.6. Condition

Condition specifies the row judgment conditions in PutRow, UpdateRow, and DeleteRow. It contains the row_existence and column_condition parameters.

Data structure

```
message Condition {
    required RowExistenceExpectation row_existence = 1;
    optional bytes column_condition      = 2;
}
```

row_existence:

- Type: RowExistenceExpectation
- Description: the row existence check settings for this row.

column_condition:

- Type: bytes
- Description: the column condition settings. This parameter indicates the binary data (in bytes) after the filter is serialized in the Protobuf format.

7.1.1.1.2.7. ConsumedCapacity

ConsumedCapacity indicates the number of capacity units (CUs) consumed by an operation.

Data structure

```
message ConsumedCapacity {
    required CapacityUnit capacity_unit = 1;
}
```

capacity_unit:

- Type: CapacityUnit
- Description: the number of CUs consumed by this operation.

7.1.1.1.2.8. Direction

Direction indicates the data query order in the GetRange operation. The two Direction operations are:

- FORWARD indicates that the query proceeds in ascending order of primary key values.
- BACKWARD indicates that the query proceeds in descending order of primary key values.

Enumeration values

```
enum Direction {
 FORWARD = 0;
 BACKWARD = 1;
}
```

7.1.1.1.2.9. Error

Error indicates an error message returned when an operation fails. This parameter is also used to indicate errors for single-row requests in the BatchGetRow and BatchWriteRow operations.

Data structure

```
Error {
 required string code = 1;
 optional string message = 2;
}
```

code:

- Type: string
- Description: the error code for the specified single-row operation.

message:

- Type: string
- Description: the error message for the specified single-row operation.

7.1.1.1.2.10. Filter

Filter specifies the column-based conditions. This API is applicable to the Conditional Update and Filter functions.

Data structure

```
message Filter {
 required FilterType type = 1;
 required bytes filter = 2;
}
```

type:

- Type: FilterType
- Description: the column condition type.

filter:

- Type: bytes
- Description: the binary data generated after the condition statements of CompositeColumnValueFilter, ColumnPaginationFilter, or SingleColumnValueFilter are serialized in the Protobuf format.

7.1.1.1.2.11. PrimaryKeyOption

PrimaryKeyOption specifies the attribute value of a primary key. Currently, it only supports AUTO_INCREMENT.

Enumeration values

```
enum PrimaryKeyOption {
 AUTO_INCREMENT = 1;
}
```

7.1.1.1.2.12. FilterType

FilterType specifies the type for condition updates or filters. The types include:

- FT_SINGLE_COLUMN_VALUE indicates a single-column condition.
- FT_COMPOSITE_COLUMN_VALUE indicates a multi-column composite condition.
- FT_COLUMN_PAGINATION indicates a wide-row read condition.

Enumeration values

```
enum FilterType {
 FT_SINGLE_COLUMN_VALUE = 1;
 FT_COMPOSITE_COLUMN_VALUE = 2;
 FT_COLUMN_PAGINATION = 3;
}
```

7.1.1.1.2.13. LogicalOperator

LogicalOperator specifies the enumeration type. The enumeration types include:

- LO_NOT indicates NOT.
- LO_AND indicates AND.
- LO_OR indicates OR.

Enumeration values

```
enum LogicalOperator {
 LO_NOT = 1;
 LO_AND = 2;
 LO_OR = 3;
}
```

7.1.1.1.2.14. OperationType

OperationType indicates the modification method for one column in UpdateRow. The types of operations include:

- PUT indicates that a column is inserted or data in this column is overwritten.
- UPDATE indicates that a column is updated.
- DELETE indicates that a column is deleted.

Enumeration values

```
enum OperationType {
 PUT = 1;
 UPDATE = 2;
 DELETE = 3;
}
```

7.1.1.1.2.15. PartitionRange

PartitionRange specifies the partition range.

Data structure

```
message PartitionRange {
    required bytes begin = 1; // encoded as SQLVariant
    required bytes end = 2; // encoded as SQLVariant
}
```

begin:

- Type: bytes
- Description: the starting key of the partition. The partition range is a left-closed right-open interval, which includes the starting key.

end:

- Type: bytes
- Description: the ending key of the partition. The partition range is a left-closed right-open interval, which excludes the ending key.

7.1.1.1.2.16. PlainBuffer

Compared with Protocol Buffer, PlainBuffer delivers better performance for serialization and resolution of small objects. Therefore, PlainBuffer is used to format data in Tablestore.

Format definition

```
plainbuffer = tag_header row1  [row2]  [row3]
row = ( pk [attr] | [pk] attr | pk attr ) [tag_delete_marker] row_checksum;
pk = tag_pk cell_1 [cell_2] [cell_3]
attr  = tag_attr cell1 [cell_2] [cell_3]
cell = tag_cell cell_name [cell_value] [cell_op] [cell_ts] cell_checksum
cell_name = tag_cell_name  formated_value
cell_value = tag_cell_value formated_value
cell_op = tag_cell_op  cell_op_value
cell_ts = tag_cell_ts cell_ts_value
row_checksum = tag_row_checksum row_crc8
cell_checksum = tag_cell_checksum row_crc8
formated_value = value_type value_len value_data
value_type = int8
value_len = int32
cell_op_value = delete_all_version | delete_one_version
cell_ts_value = int64
delete_all_version = 0x01 (1byte)
delete_one_version = 0x03 (1byte)
```

Tag values

```
tag_header = 0x75 (4byte)
tag_pk = 0x01 (1byte)
tag_attr = 0x02 (1byte)
tag_cell = 0x03 (1byte)
tag_cell_name = 0x04 (1byte)
tag_cell_value = 0x05 (1byte)
tag_cell_op = 0x06 (1byte)
tag_cell_ts = 0x07 (1byte)
tag_delete_marker = 0x08 (1byte)
tag_row_checksum = 0x09 (1byte)
tag_cell_checksum = 0x0A (1byte)
```

ValueType values

Valid values of value_type in formated_value:

```
VT_INTEGER = 0x0
VT_DOUBLE = 0x1
VT_BOOLEAN = 0x2
VT_STRING = 0x3
VT_NULL = 0x6
VT_BLOB = 0x7
VT_INF_MIN = 0x9
VT_INF_MAX = 0xa
VT_AUTO_INCREMENT = 0xb
```

Checksum calculation

The checksum is calculated based on the following basic logic:

- The name, value, type, and timestamp of each cell is calculated.

- The delete mark of each row is calculated. A byte of 1 is added for each row that has a delete mark. A byte of 0 is added for each row that does not have a delete mark.
- After the checksum is calculated for each cell in a row, these cell checksums are used to calculate the row checksum. The CRC is performed only on the cells in the row, instead of data in the row.

The following code provides an example on how to implement CRC in C++:

```
void GetChecksum(uint8_t* crc, const InplaceCell& cell)
{
    Crc8(crc, cell.GetName());
    Crc8(crc, cell.GetValue().GetInternalSlice());
    Crc8(crc, cell.GetTimestamp());
    Crc8(crc, cell.GetOpType());
}
void GetChecksum(uint8_t* crc, const InplaceRow& row)
{
    const std::deque<InplaceCell>& pk = row.GetPrimaryKey();
    for (size_t i = 0; i < pk.size(); i++) {
        uint8_t* cellcrc;
        *cellcrc = 0;
        GetChecksum(cellcrc, pk[i]);
        Crc8(crc, *cellcrc);
    }
    for (int i = 0; i < row.GetCellCount(); i++) {
        uint8_t* cellcrc;
        *cellcrc = 0;
        GetChecksum(cellcrc, row.GetCell(i));
        Crc8(crc, *cellcrc);
    }
    uint8_t del = 0;
    if (row.HasDeleteMarker()) {
        del = 1;
    }
    Crc8(crc, del);
}
```

Example

A row contains two primary key columns and four attribute columns. The data types of the primary key columns are string and integer, while the data types in the attribute columns are string, integer, and double. The versions are 1001, 1002, and 1003. The fourth attribute column indicates whether to delete all versions.

- Primary key columns:
  - [pk1:string:iampk]
  - [pk2:integer:100]
- Attribute columns:
  - [column1:string:bad:1001]
  - [column2:integer:128:1002]
  - [column3:double:34.2:1003]
  - [column4:del_all_versions]

Encoding:

```
<The start position for headers>[0x75]
<The start position for primary key columns>[0x1]
<Cell1>[0x3][0x4][3][pk1][0x5][3][5][iampk]
<Cell2>[0x3][0x4][3][pk2][0x5][0][100]
<The start position for attribute columns>[0x2]
<Cell1>[0x3][0x4][7][column1][0x5][0x3][3][bad][0x7][1001]
<Cell2>[0x3][0x4][7][column2][0x5][0x0][128][0x7][1002]
<Cell3>[0x3][0x4][7][column3][0x5][0x1][34.2][0x7][1003]
<Cell4>[0x3][0x4][7][column4][0x5][0x6][1]
```

7.1.1.1.2.17. PrimaryKeySchema

PrimaryKeySchema specifies the attribute value of a primary key.

Data structure

```
message PrimaryKeySchema {
 required string name = 1;
 required PrimaryKeyType type = 2;
 optional PrimaryKeyOption option = 3;
}
```

name:

- Type: string
- Description: the name of the column.

type:

- Type: PrimaryKeyType
- Description: the type of the column.

option:

- Type: PrimaryKeyOption
- Description: the additional attribute value of the column.

7.1.1.1.2.18. PrimaryKeyType

PrimaryKeyType specifies the type of a primary key.

Enumeration data types

- INTEGER
- STRING
- BINARY

```
enum PrimaryKeyType {
 INTEGER = 1;
 STRING = 2;
 BINARY = 3;
}
```

7.1.1.1.2.19. ReservedThroughput

ReservedThroughput indicates the reserved read/write throughput value for a table.

Data structure

```
message ReservedThroughput {
 required CapacityUnit capacity_unit = 1;
}
```

capacity_unit:

- Type: CapacityUnit
- Description: the current reserved read/write throughput value for the table.

7.1.1.1.2.20. ReservedThroughputDetails

ReservedThroughputDetails indicates the reserved read/write throughput information of a table.

Data structure

```
message ReservedThroughputDetails {
    required CapacityUnit capacity_unit = 1;
    required int64 last_increase_time = 2;
    optional int64 last_decrease_time = 3;
    required int32 number_of_decreases_today = 4;
}
```

capacity_unit:

- Type: CapacityUnit
- Description: the reserved read/write throughput value for this table.

last_increase_time:

- Type: int64
- Description: the last time the reserved read/write throughput capacity was raised for this table. The value uses UTC time, in seconds.

last_decrease_time:

- Type: int64
- Description: the last time the reserved read/write throughput capacity was lowered for this table. The value uses UTC time, in seconds.

number_of_decreases_today:

- Type: int32
- Description: the number of times the reserved read/write throughput capacity was lowered for this table on the current calendar day.

7.1.1.1.2.21. ReturnContent

ReturnContent specifies the content of the returned data.

Data structure

```
message ReturnContent {
    optional ReturnType return_type = 1;
}
```

return_type:

- Type: ReturnType
- Description: the type of the returned data.

7.1.1.1.2.22. ReturnType

ReturnType specifies the type of the returned data.

Enumeration data types

```
enum ReturnType {
    RT_NONE = 0;
    RT_PK = 1;
}
```

- RT_NONE: the default value. This parameter indicates that no value is returned.
- RT_PK: This parameter indicates that the primary key is returned.

7.1.1.1.2.23. RowExistenceExpectation

RowExistenceExpectation specifies conditions for row existence. Enumeration types are as follows:

- IGNORE indicates that the row existence check is not performed.
- EXPECT_EXIST indicates that the row is expected to exist.
- EXPECT_NOT_EXIST indicates that this row is not expected to exist.

Enumeration values

```
enum RowExistenceExpectation {
    IGNORE = 0;
    EXPECT_EXIST = 1;
    EXPECT_NOT_EXIST = 2;
}
```

7.1.1.1.2.24. RowInBatchGetRowResponse

RowInBatchGetRowResponse indicates a row of data in the response of the BatchGetRow operation.

Data structure

```
message RowInBatchGetRowResponse {
 required bool is_ok = 1 [default = true];
 optional Error error = 2;
 optional ConsumedCapacity consumed = 3;
 optional bytes row = 4;
 optional bytes next_token = 5;
}
```

is_ok:

- Type: bool
- Description: determines whether the operation for this row succeeds. If true is returned, the row is read and error is invalid. If false is returned, the row fails to be read and the row is invalid.

error:

- Type: Error
- Description: the error message for this row operation.

consumed:

- Type: ConsumedCapacity
- Description: the number of capacity units consumed by this row operation.

row:

- Type: bytes
- The read data is encoded in the PlainBuffer format.
- If this row does not exist, null is returned.

next_token:

- Type: bytes
- This parameter specifies the starting position of a wide row in the next read operation. This function is currently unavailable.

7.1.1.1.2.25. RowInBatchWriteRowRequest

RowInBatchWriteRowRequest indicates the information of the row to be written, updated, or deleted in the BatchWriteRow operation.

Data structure

```
message RowInBatchWriteRowRequest {
    required OperationType type = 1;
    required bytes row_change = 2; // It is encoded as InplaceRowChangeSet.
    required Condition condition = 3;
    optional ReturnContent return_content = 4;
}
```

type:

- Type: OperationType
- Description: the operation type.

row_change:

- Type: bytes
- Description: the data in a row that contains the primary key and attribute columns. The columns are encoded in the PlainBuffer format.

condition:

- Type: Condition
- Description: the value of conditional update, including the row existence condition and column-based condition.

return_content:

- Type: ReturnContent
- Required: no
- This parameter specifies the data type after the row is written. Currently, only the primary key is returned, which is used for the auto-increment function of the primary key column.

7.1.1.1.2.26. RowInBatchWriteRowResponse

RowInBatchWriteRowResponse indicates the write operation result for a row in the response of the BatchWriteRow operation.

Data structure

```
message RowInBatchWriteRowResponse {
 required bool is_ok = 1 [default = true];
 optional Error error = 2;
 optional ConsumedCapacity consumed = 3;
}
```

is_ok:

- Type: bool
- Description: determines whether the operation for this row succeeds. If the value is true, the row is written and error is invalid. If the value is false, this row fails to be written.

error:

- Type: Error
- Description: the error message for this row operation.

consumed:

- Type: ConsumedCapacity
- Description: the number of capacity units consumed by this row operation.

7.1.1.1.2.27. SingleColumnValueFilter

SingleColumnValueFilter specifies a single condition, for example, column_a > 5. This API is applicable to the ConditionUpdate and Filter functions.

Data structure

```
message SingleColumnValueFilter {
 required ComparatorType comparator = 1;
 required string column_name = 2;
 required bytes column_value = 3;
 required bool filter_if_missing = 4;
 required bool latest_version_only = 5;
}
```

comparator:

- Type: ComparatorType
- Description: the comparison type.

column_name:

- Type: string
- Description: the column name.

column_value:

- Type: bytes
- Description: the value of ColumnValue serialized by protobuf.

filter_if_missing:

- Type: bool
- Description: determines whether a filtering condition is applicable if the column of a row does not exist. Assume that the condition is column_a > 0, and the value of filter_if_missing is true. If column_a does not exist for a row, the condition column_a > 0 is true.

latest_version_only:

- Type: bool
- Description: determines whether a condition is applicable only for the latest version. If the value is true, the value of the latest version is checked to determine whether it meets the condition. If the value is false, the values of all versions are checked to determine whether they meet the conditions.

7.1.1.1.2.28. StreamDetails

StreamDetails indicates the stream information of a table.

Data structure

```
message StreamDetails {
    required bool enable_stream = 1;
    optional string stream_id = 2;
    optional int32 expiration_time = 3;
    optional int64 last_enable_time = 4;
}
```

enable_stream:

- Type: required bool
- Description: determines whether stream is enabled for the table.

stream_id:

- Type: optional string
- Description: the ID of the table stream.

expiration_time:

- Type: optional int32
- Description: the expiration time of the table stream.

last_enable_time:

- Type: optional int64
- Description: the time to enable the table stream.

7.1.1.1.2.29. StreamRecord

StreamRecord indicates a row of data in the response of the GetStreamRecord operation.

Data structure

```
message StreamRecord {
        required ActionType action_type = 1;
        required bytes record = 2;
}
```

action_type:

- Type: required ActionType
- Description: the operation type of the row.

record:

- Type: required bytes
- Description: the data content of the row.

7.1.1.1.2.30. StreamSpecification

StreamSpecification indicates the stream specification of a table.

Data structure

```
message StreamSpecification {
    required bool enable_stream = 1;
    optional int32 expiration_time = 2;
}
```

enable_stream:

- Type: bool
- Description: determines whether stream is enabled for the table.

expiration_time:

- Type: int32
- Description: the expiration time of the table stream.

7.1.1.1.2.31. TableInBatchGetRowRequest

TableInBatchGetRowRequest indicates the request information of the table to be read in the BatchGetRow operation.

Data structure

```
message TableInBatchGetRowRequest {
    required string table_name = 1;
    repeated bytes primary_key = 2; // The primary key columns are encoded in the PlainBuff
er format.
    repeated bytes token = 3;
    repeated string columns_to_get = 4;  // If this parameter is not specified, all columns
are read.
    optional TimeRange time_range = 5;
    optional int32 max_versions = 6;
    optional bool cache_blocks = 7 [default = true]; // This parameter specifies whether th
e read data is written to BlockCache.
    optional bytes filter = 8;
    optional string start_column = 9;
    optional string end_column = 10;
}
```

table_name:

- Type: string
- Description: the name of the table.

primary_key:

- Type: repeated bytes
- Required: yes
- This parameter specifies all primary key columns in the row, including the primary key names and values. The primary key columns are encoded in the PlainBuffer format.

token:

- Type: repeated bytes
- Required: no
- This parameter specifies the starting position of a wide row in the next read operation. This function is currently unavailable.

columns_to_get:

- Type: repeated string
- Description: the names of all columns to be returned from this table.

time_range:

- Type: TimeRange
- Required: At least one of the time_range and max_versions parameters must be specified.
- This parameter specifies the range of timestamps to read versions of data.
- Unit: millisecond. The minimum value of the timestamp is 0. The maximum value of the timestamp is INT64.MAX.

- To query data of a time range, specify start_time and end_time.
- To query data of a specific timestamp, specify specific_time.
- Example: If the value of time_range is (100, 200), the timestamp of the returned column data must be within the range of [100, 200).

max_versions:

- Type: int32
- Required: At least one of the max_versions and time_range parameters must be specified.
- This parameter specifies the maximum number of versions of data to be returned.
- Example: If the value of max_versions is 2, data of a maximum of two versions is returned for each column.

cache_blocks:

- Type: bool
- Required: no
- This parameter specifies whether the read data is written to BlockCache.
- The default value is true.
- This parameter cannot be set to false.

filter:

- Type: bytes
- Required: no
- This parameter specifies the expression of the filtering condition.
- It indicates the binary data after the filter is serialized in the Protobuf format.

start_column:

- Type: string
- Required: no
- This parameter specifies the first column to be read. It is useful for reading wide rows.
- The response contains the specified starting column.
- The column names are sorted lexicographically.
- Example: If a table contains columns A, B, and C, and the value of start_column is B, the data is read starting from column B. Columns B and C are returned.

end_column:

- Type: string
- Required: no
- This parameter specifies the last column to be read. It is useful for reading wide rows.
- The response does not contain the specified ending column.
- The column names are sorted lexicographically.
- Example: If a table contains columns A, B, and C, and the value of end_column is B, the reading stops at column B. Only column A is returned.

7.1.1.1.2.32. TableInBatchGetRowResponse

TableInBatchGetRowResponse indicates data in a table in the response of the BatchGetRow operation.

Data structure

```
message TableInBatchGetRowResponse {
 required string table_name = 1;
 repeated RowInBatchGetRowResponse rows = 2;
}
```

table_name:

- Type: string
- Description: the name of the table.

rows:

- Type: repeated RowInBatchGetRowResponse
- Description: data of all rows read from the table.

7.1.1.1.2.33. TableInBatchWriteRowRequest

TableInBatchWriteRowRequest indicates the request information of the table to be written in the BatchWriteRow operation.

Data structure

```
message TableInBatchWriteRowRequest {
 required string table_name = 1;
 repeated RowInBatchWriteRowRequest rows = 2;
}
```

table_name:

- Type: string
- Description: the name of the table.

rows:

- Type: repeated RowInBatchWriteRowRequest
- Description: the information of the row to be inserted, updated, or deleted in the table.

7.1.1.1.2.34. TableInBatchWriteRowResponse

TableInBatchWriteRowResponse indicates the write results for a table in the BatchWriteRow operation.

Data structure

```
message TableInBatchWriteRowResponse {
 required string table_name = 1;
 repeated RowInBatchWriteRowResponse put_rows = 2;
 repeated RowInBatchWriteRowResponse update_rows = 3;
 repeated RowInBatchWriteRowResponse delete_rows = 4;
}
```

table_name:

- Type: string

- Description: the name of the table.

put_rows:

- Type: RowInBatchWriteRowResponse
- Description: the result of the PutRow operation for the table.

update_rows:

- Type: RowInBatchWriteRowResponse
- Description: the result of the UpdateRow operation for the table.

delete_rows:

- Type: RowInBatchWriteRowResponse
- Description: the result of the DeleteRow operation for the table.

7.1.1.1.2.35. TableMeta

TableMeta indicates the structure information of a table.

Data structure

```
message TableMeta {
 required string table_name = 1;
 repeated PrimaryKeySchema primary_key = 2;
}
```

table_name:

- Type: string.
- Description: the name of the table.

primary_key:

- Type: PrimaryKeySchema
- Description: all primary key columns of the table.

7.1.1.1.2.36. TableOptions

TableOptions indicates the table parameters, including TimeToLive and MaxVersions.

Data structure

```
message TableOptions {
    optional int32 time_to_live = 1; // This parameter value can be dynamically modified.
    optional int32 max_versions = 2; // This parameter value can be dynamically modified.
    optional int64 deviation_cell_version_in_sec = 5; // This parameter value can be dynami
cally modified.
}
```

time_to_live:

- Type: int32
- Description: the retention time of data stored in this table, in seconds.

max_versions:

- Type: int32
- Description: the maximum number of versions stored in this table.

deviation_cell_version_in_sec:

- Type: int64
- Description: the maximum version deviation. This parameter is used to forbid writing data that deviates from the expected output. For example, if the value of deviation_cell_version_in_sec is 1,000 and the current timestamp is 10,000, the allowed timestamp range to be written is [10,000 - 1,000, 10,000 + 1,000].

7.1.1.1.2.37. TimeRange

TimeRange specifies the timestamp range or timestamp value to query.

Data structure

```
message TimeRange {
    optional int64 start_time = 1;
    optional int64 end_time = 2;
    optional int64 specific_time = 3;
}
```

start_time:

- Type: int64
- Description: the starting timestamp, in milliseconds. The minimum value of the timestamp is 0. The maximum value of the timestamp is INT64.MAX.

end_time:

- Type: int64
- Description: the ending timestamp, in milliseconds. The minimum value of the timestamp is 0. The maximum value of the timestamp is INT64.MAX.

specific_time:

- Type: int64
- Description: the specific timestamp, in milliseconds. You can set either specific_time to query a specific timestamp, or a combination of start_time and end_time to query a range of timestamps. The minimum value of the timestamp is 0. The maximum value of the timestamp is INT64.MAX.

7.1.2. SDK reference

7.1.2.1. SDK

7.1.2.1.1. Java SDK

7.1.2.1.1.1. Preface

This topic describes how to use Tablestore SDK for Java. This topic applies to Tablestore SDK for Java V5.0.0 and later.

Prerequisites

An authorized account is created, and an AccessKey pair (AccessKey ID and AccessKey secret) is obtained. For more information about how to obtain and view your AccessKey pair in the Apsara Uni-manager Management Console, see Obtain an AccessKey pair.

Compatibility

Latest version: 5.7.0

- Tablestore SDK for Java V4.x.x: compatible
- Tablestore SDK for Java V2.x.x: incompatible

7.1.2.1.1.2. Installation

This topic describes how to install Tablestore SDK for Java.

Preparations

To install Tablestore SDK for Java, you must use JDK 6.0 or later versions.

Install SDK

You can install Tablestore SDK for Java by using one of the two following methods:

- Add dependencies to a Maven project

  To use Tablestore SDK for Java in Maven, you need only to add the corresponding dependencies to the pom.xml file. Tablestore SDK for Java V5.4.0. is used in this example. Add the following content to <dependencies>:

  ```
  <dependency>
      <groupId>com.aliyun.openservices</groupId>
      <artifactId>tablestore</artifactId>
      <version>5.4.0</version>
  </dependency>
  ```

- Import JAR packages into Eclipse

  Take Tablestore SDK for Java V5.4.0 as an example. To import JAR packages into Eclipse, perform the following operations:

  i. Download the SDK for Java package.
  ii. Decompress the SDK for Java package.
  iii. Copy the tablestore-<versionId>.jar file and all files in the lib folder to your project.
  iv. Right-click your project name in Eclipse and choose **Properties > Java Build Path > Add JARs**.
  v. Select all JAR packages you copied in step 3.

Sample programs

Tablestore SDK for Java provides a variety of sample programs for your reference or use. You can decompress the downloaded SDK package and view the sample programs in the examples folder.

7.1.2.1.1.3. Initialization

OTSClient is the client for Tablestore. It provides a series of methods for you to manage tables and perform read and write operations on a single row or multiple rows. To use Tablestore SDK for Java to initiate a request, you must initialize an OTSClient instance and modify the default configuration items of ClientConfiguration.

Obtain an endpoint

An endpoint is the domain name used to access a Tablestore instance in a region. The following table lists the examples of endpoints in the supported format.

Examples	Description
`http://sun.cn-hangzhou.ots.aliyuncs.com`	The public endpoint used to access the sun instance in the China (Hangzhou) region over HTTP.
`https://sun.cn-hangzhou.ots.aliyuncs.com`	The public endpoint used to access the sun instance in the China (Hangzhou) region over HTTPS.

Note Tablestore supports access over the Internet and internal network.

To query the endpoints of your Tablestore instance, perform the following operations:

1. Log on to the Tablestore console.
2. Click the instance name to go to the **Instance Management** page.

   On the Instance Details tab, you can view the endpoints of the instance in Instance Access URL.

Configure an AccessKey pair

To access Apsara Stack Tablestore, you must have a valid AccessKey pair (AccessKey ID and AccessKey secret) for signature authentication. The following types of AccessKey pairs are supported:

- The AccessKey pair (AccessKey ID and AccessKey secret) of your Apsara Stack tenant account.
  i. Create an Apsara Stack tenant account on the official Alibaba Cloud website.
  ii. Log on to the Apsara Uni-manager Management Console to apply for an AccessKey pair.
- The AccessKey pair (AccessKey ID and AccessKey secret) of a RAM user authorized to access Tablestore.
  i. Use your Apsara Stack tenant account to access RAM and create a new RAM user or use an existing one.
  ii. Use your Apsara Stack tenant account to authorize the RAM user to access Tablestore.
  iii. You can then use the AccessKey pair (AccessKey ID and AccessKey secret) of the authorized RAM user to access Tablestore.
- The AccessKey pair in temporary access credentials.
  i. The application server uses RAM or STS to obtain access credentials that consist of a temporary AccessKey ID, an AccessKey secret, and a token. After the access credentials are obtained, the application server sends them to you.
  ii. Use the received AccessKey ID, AccessKey Secret, and token to access Tablestore.

Initialize a Tablestore client instance

After you obtain the AccessKey ID and AccessKey secret, you can perform the following operation to initialize a Tablestore client instance:

Create a client

When you use Tablestore SDKs, you must create a client and then call the operations in the client to access Tablestore. The operations in the client provide the same functions as the RESTful API provided by Tablestore.

Tablestore SDKs offer two client types: SyncClient and AsyncClient. SyncClient is designed for synchronous operations and AsyncClient is for asynchronous operations. After a synchronous operation is called, the service request succeeds. You can call synchronous operations to learn more about the various features of Tablestore. Compared with synchronous operations, asynchronous operations provide greater flexibility. If you require high performance, you can choose between the use of asynchronous operations and multithreading.

> **Note** Both SyncClient and AsyncClient are thread-safe and can internally manage threads and connection resources. You do not need to create a client for each thread or request. Instead, create a global client.

Examples

- The following code provides an example on how to use the default configurations to create a SyncClient:

```
        final String endPoint = "";
        final String accessKeyId = "";
        final String accessKeySecret = "";
        final String instanceName = "";
        SyncClient client = new SyncClient(endPoint, accessKeyId, accessKeySecret, instan
ceName);
```

- The following code provides an example on how to use the custom configurations to create a SyncClient:

```
        // ClientConfiguration provides multiple configuration items. Only the most commo
nly used items are listed.
        ClientConfiguration clientConfiguration = new ClientConfiguration();
        // Set the timeout period for establishing a connection.
        clientConfiguration.setConnectionTimeoutInMillisecond(5000);
        // Set the timeout period for the socket connection.
        clientConfiguration.setSocketTimeoutInMillisecond(5000);
        // Configure a retry policy. If you do not configure policies, the default retry
policy is used.
        clientConfiguration.setRetryStrategy(new AlwaysRetryStrategy());
        SyncClient client = new SyncClient(endPoint, accessId, accessKey, instanceName, c
lientConfiguration);
```

HTTPS

Upgrade to Java 7 for HTTPS access.

Multithreading

- Multithreading is supported.

- We recommend that you use the same OTSClient object to perform multithreading tasks.

7.1.2.1.1.4. Use Tablestore SDK for Java

Table-level operations

Tablestore SDK for Java provides the following table-level operations: CreateTable, ListTable, DeleteTable, UpdateTable, and DescribeTable.

CreateTable

When you create a table in Tablestore, you must specify TableMeta and TableOptions. You can also set ReservedThroughput.

> **Note** After the table is created, Tablestore loads partitions of the table to a specified node. And you can read data from or write data to the table within a few seconds. An exception may occur if you immediately attempt to read from or write to the table after you create the table.

- TableMeta

  TableMeta includes the name and primary key schema of the table.

Parameter	Description
TableName	The name of the table.
List	The definition of the primary key. ○ The primary key of a table can contain one to four primary key columns. Primary key columns are sorted in the order in which they are added. For example, PRIMARY KEY (A, B, C) and PRIMARY KEY (A, C, B) have different primary key schemas. Tablestore sorts rows based on the values of all primary key columns. ○ The first primary key column serves as the partition key. Data with the same partition key value is stored in the same partition. Therefore, we recommend that you assign no more than 10 GB of data with the same partition key value. Otherwise, individual partitions are too large and cannot be split. We recommend that you distribute requests in an even manner to read and write data to different partition keys for load balancing. ○ Attribute columns are optional. Different rows in Tablestore can have different data columns. The names of attribute columns can be specified when data is written.

- TableOptions

Parameter	Description

Parameter	Description
TTL	The time to live, which indicates the validity period of data. ○ The system determines whether data expires based on the timestamp, current time, and timeToLive parameters. Data expires and then is deleted if the values of the parameters meet the following formula: `current time - timestamp > timeToLive`. ○ When you create a table, you can set TTL to -1 if you expect that data never expires. After the table is created, you can call the UpdateTable operation to dynamically modify the TTL value. ○ When you write data configured with TTL, ensure that you specify a valid timestamp. We recommend that you set MaxTimeDeviation when you specify the timestamp. ○ Unit: seconds.
MaxTimeDeviation	The maximum offset between the timestamp of written data and the current system time. ○ By default, the system generates a timestamp for new data. The system checks whether data expires based on the timestamp. You can specify the timestamp of written data. When the offset between the timestamp of written data and the current system time is greater than the specified TTL, the written data immediately expires. To solve this problem, set MaxTimeDeviation. ○ When you create a table, Tablestore uses the default value of 86400 if you do not specify a max version offset. After the table is created, you can call the UpdateTable operation to dynamically modify the MaxTimeDeviation value. ○ Unit: seconds.
MaxVersions	The maximum number of versions that can be retained for data in attribute columns of the table. When the number of versions of data in attribute columns exceeds the MaxVersions value, Tablestore automatically deletes data of earlier versions. When you create a table, you can customize the maximum number of versions that can be retained for the data in an attribute column. After the table is created, you can call the UpdateTable operation to dynamically modify the MaxVersions value for the table.

- ReservedThroughput: the reserved read/write throughput configurations of the table.

  You can set the reserved read and write throughput only to 0 for capacity instances. Reserved throughput does not apply to these instances.

Examples

```
private static void createTable(SyncClient client) {
        TableMeta tableMeta = new TableMeta(TABLE_NAME);
        tableMeta.addPrimaryKeyColumn(new PrimaryKeySchema(PRIMARY_KEY_NAME, PrimaryKeyType
.STRING)); // Specify a primary key column for the base table.
        int timeToLive = -1; // Specify the validity period of data in seconds. A value of
-1 indicates that the data never expires. You must specify -1 as the TTL value when a table
has one or more index tables.
        int maxVersions = 1; // Specify the maximum number of versions that can be retained
. You must specify 1 as the maxVersions value when a table has one or more index tables.
        TableOptions tableOptions = new TableOptions(timeToLive, maxVersions);
        CreateTableRequest request = new CreateTableRequest(tableMeta, tableOptions);
        request.setReservedThroughput(new ReservedThroughput(new CapacityUnit(0, 0))); // S
et the reserved read/write throughout. You can set the value only to 0 for capacity instanc
es. However, you can set a non-zero value for high-performance instances.
        client.createTable(request);
    }
```

ListTable

You can call this operation to query the names of all tables created in the current instance.

Examples

The following code provides an example on how to query the names of all tables in an instance:

```
private static void listTable(SyncClient client) {
    ListTableResponse response = client.listTable();
    System.out.println("List of tables:");
    for (String tableName : response.getTableNames()) {
        System.out.println(tableName);
    }
}
```

UpdateTable

You can call this operation to update the reserved read/write throughput and table options of a table.

For more information about the ReservedThroughput and TableOptions parameters, see the CreateTable section. The minimum interval between attempts to modify the value of ReservedThroughput is one minute.

Examples

The following code provides an example on how to update the timeToLive and MaxVersions values of a table:

```
private static void updateTable(SyncClient client) {
    int timeToLive = -1;
    int maxVersions = 5; // Update the value of MaxVersions to 5.
    TableOptions tableOptions = new TableOptions(timeToLive, maxVersions);
    UpdateTableRequest request = new UpdateTableRequest(TABLE_NAME);
    request.setTableOptionsForUpdate(tableOptions);
    client.updateTable(request);
}
```

DescribeTable

You can call this operation to query the structure information, table option configurations, and reserved read/write throughput settings of a table.

For more information about the TableMeta and TableOptions parameters, see the CreateTable section. Besides the reserved read/write throughput, ReservedThroughputDetails shows the most recent time when the throughput was increased or decreased.

Examples

The following code provides an example on how to query the description of a table:

```
private static void describeTable(SyncClient client) {
    DescribeTableRequest request = new DescribeTableRequest(TABLE_NAME);
    DescribeTableResponse response = client.describeTable(request);
    TableMeta tableMeta = response.getTableMeta();
    System.out.println("The name of the table:" + tableMeta.getTableName());
    System.out.println("The primary key of the table:");
    for (PrimaryKeySchema primaryKeySchema : tableMeta.getPrimaryKeyList()) {
        System.out.println(primaryKeySchema);
    }
    TableOptions tableOptions = response.getTableOptions();
    System.out.println("TTL of the table:" + tableOptions.getTimeToLive());
    System.out.println("MaxVersions the table:" + tableOptions.getMaxVersions());
    ReservedThroughputDetails reservedThroughputDetails = response.getReservedThroughputDet
ails();
    System.out.println("Reserved read throughput of the table:"
            + reservedThroughputDetails.getCapacityUnit().getReadCapacityUnit());
    System.out.println("Reserved write throughput of the table:"
            + reservedThroughputDetails.getCapacityUnit().getWriteCapacityUnit());
}
```

DeleteTable

You can call this operation to delete a specified table from the current instance.

Examples

The following code provides an example on how to delete a specified table from the current instance:

```
private static void deleteTable(SyncClient client) {
    DeleteTableRequest request = new DeleteTableRequest(TABLE_NAME);
    client.deleteTable(request);
}
```

Single-row operations

Tablestore SDK for Java provides the following single-row operations: PutRow, GetRow, UpdateRow, and DeleteRow.

PutRow

You can call this operation to insert a row of data. If this row already exists, it is overwritten.

When you perform PutRow, you can use conditional update to set conditions for the existence of the row to write or values in certain columns of the existing row. For more information, see Conditional update.

- Example 1

  The following code provides an example on how to write a row that contains 10 attribute columns and write one version of data for each column. The version number (timestamp) is specified by the server.

```
private static void putRow(SyncClient client, String pkValue) {
    // Create the primary key.
    PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
    primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromString(pk
Value));
    PrimaryKey primaryKey = primaryKeyBuilder.build();
    RowPutChange rowPutChange = new RowPutChange(TABLE_NAME, primaryKey);
    // Add attribute columns.
    for (int i = 0; i < 10; i++) {
        rowPutChange.addColumn(new Column("Col" + i, ColumnValue.fromLong(i)));
    }
    client.putRow(new PutRowRequest(rowPutChange));
}
```

- Example 2

  The following code provides an example on how to write a row that contains 10 attribute columns and write three versions of data for each column. The version number (timestamp) is specified by the client.

```
private static void putRow(SyncClient client, String pkValue) {
    // Create the primary key.
    PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
    primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromString(pk
Value));
    PrimaryKey primaryKey = primaryKeyBuilder.build();
    RowPutChange rowPutChange = new RowPutChange(TABLE_NAME, primaryKey);
    // Add attribute columns.
    long ts = System.currentTimeMillis();
    for (int i = 0; i < 10; i++) {
        for (int j = 0; j < 3; j++) {
            rowPutChange.addColumn(new Column("Col" + i, ColumnValue.fromLong(j), ts + j)
);
        }
    }
    client.putRow(new PutRowRequest(rowPutChange));
}
```

- Example 3

  The following code provides an example on how to write data when the target row does not exist:

```
private static void putRow(SyncClient client, String pkValue) {
    // Create the primary key.
    PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
    primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromString(pk
Value));
    PrimaryKey primaryKey = primaryKeyBuilder.build();
    RowPutChange rowPutChange = new RowPutChange(TABLE_NAME, primaryKey);
    // Set a condition to specify that the target row does not exist.
    rowPutChange.setCondition(new Condition(RowExistenceExpectation.EXPECT_NOT_EXIST));
    // Add attribute columns.
    long ts = System.currentTimeMillis();
    for (int i = 0; i < 10; i++) {
        for (int j = 0; j < 3; j++) {
            rowPutChange.addColumn(new Column("Col" + i, ColumnValue.fromLong(j), ts + j)
);
        }
    }
    client.putRow(new PutRowRequest(rowPutChange));
}
```

- Example 4

  The following code provides an example on how to write data when the target row exists and the value of Col0 is greater than 100:

```
private static void putRow(SyncClient client, String pkValue) {
    // Create the primary key.
    PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
    primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromString(pk
Value));
    PrimaryKey primaryKey = primaryKeyBuilder.build();
    RowPutChange rowPutChange = new RowPutChange(TABLE_NAME, primaryKey);
    // Set a condition to specify that the target row exists and the value in Col0 of the
target row is greater than 100.
    Condition condition = new Condition(RowExistenceExpectation.EXPECT_EXIST);
    condition.setColumnCondition(new SingleColumnValueCondition("Col0",
            SingleColumnValueCondition.CompareOperator.GREATER_THAN, ColumnValue.fromLong
(100)));
    rowPutChange.setCondition(condition);
    // Add attribute columns.
    long ts = System.currentTimeMillis();
    for (int i = 0; i < 10; i++) {
        for (int j = 0; j < 3; j++) {
            rowPutChange.addColumn(new Column("Col" + i, ColumnValue.fromLong(j), ts + j)
);
        }
    }
    client.putRow(new PutRowRequest(rowPutChange));
}
```

GetRow

You can call this operation to read a single row of data. The following table describes the parameter you can use for this operation.

Parameter	Description
PrimaryKey	The primary key of the row to read. This parameter is required.
ColumnsToGet	The set of the columns to read. If you do not set this parameter, all columns are read.
MaxVersions	The maximum number of versions to read. You must set at least one of the following parameters: MaxVersions or TimeRange.
TimeRange	The range of versions to read. You must set at least one of the following parameters: MaxVersions or TimeRange.
Filter	Filters are used by the server to filter the read results based on the specified conditions.

- Example 1

  The following code provides an example on how to read the latest version of data in the columns specified by ColumnsToGet of a row:

```
        private static void getRow(SyncClient client, String pkValue) {
            // Create the primary key.
            PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuild
er();
            primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromS
tring(pkValue));
            PrimaryKey primaryKey = primaryKeyBuilder.build();
            // Read a row of data.
            SingleRowQueryCriteria criteria = new SingleRowQueryCriteria(TABLE_NAME, prim
aryKey);
            // Set MaxVersions to 1 to read the latest version of data.
            criteria.setMaxVersions(1);
            GetRowResponse getRowResponse = client.getRow(new GetRowRequest(criteria));
            Row row = getRowResponse.getRow();
            System.out.println("Read complete, result: ");
            System.out.println(row);
            // Specify the columns to read.
            criteria.addColumnsToGet("Col0");
            getRowResponse = client.getRow(new GetRowRequest(criteria));
            row = getRowResponse.getRow();
            System.out.println("Read complete, result:");
            System.out.println(row);
        }
```

- Example 2

  The following code provides an example on how to set a filter:

```
        private static void getRow(SyncClient client, String pkValue) {
            // Create the primary key.
            PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuild
er();
            primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromS
tring(pkValue));
            PrimaryKey primaryKey = primaryKeyBuilder.build();
            // Read a row of data.
            SingleRowQueryCriteria criteria = new SingleRowQueryCriteria(TABLE_NAME, prim
aryKey);
            // Set MaxVersions to 1 to read the latest version of data.
            criteria.setMaxVersions(1);
            // Set the filter so that this row is returned when the value in Col0 is 0.
            SingleColumnValueFilter singleColumnValueFilter = new SingleColumnValueFilter
("Col0",
                    SingleColumnValueFilter.CompareOperator.EQUAL, ColumnValue.fromLong(0
));
            // If Col0 does not exist, the data is not returned.
            singleColumnValueFilter.setPassIfMissing(false);
            criteria.setFilter(singleColumnValueFilter);
            GetRowResponse getRowResponse = client.getRow(new GetRowRequest(criteria));
            Row row = getRowResponse.getRow();
            System.out.println("Read complete, result: ");
            System.out.println(row);
        }
```

UpdateRow

You can call this operation to update a single row of data. If the target row does not exist, a new row is added.

The update operations include writing a column, deleting a column, and deleting a version of data in a column.

When you perform UpdateRow, you can use conditional update to configure conditions for the existence of the row to update or values in certain columns of the existing row. For more information, see Conditional update.

- Example 1

  The following code provides an example on how to update several columns, delete the specified version of data in a column, and delete the specified column:

```
        private static void updateRow(SyncClient client, String pkValue) {
            // Construct the primary key.
            PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuild
er();
            primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromS
tring(pkValue));
            PrimaryKey primaryKey = primaryKeyBuilder.build();
            RowUpdateChange rowUpdateChange = new RowUpdateChange(TABLE_NAME, primaryKey)
;
            // Update columns.
            for (int i = 0; i < 10; i++) {
                rowUpdateChange.put(new Column("Col" + i, ColumnValue.fromLong(i)));
            }
            // Delete a specified version of data in the specified column.
            rowUpdateChange.deleteColumn("Col10", 1465373223000L);
            // Delete the specified column.
            rowUpdateChange.deleteColumns("Col11");
            client.updateRow(new UpdateRowRequest(rowUpdateChange));
        }
```

- Example 2

  The following code provides an example on how to configure update conditions:

```
        private static void updateRow(SyncClient client, String pkValue) {
            // Create the primary key.
            PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuild
er();
            primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromS
tring(pkValue));
            PrimaryKey primaryKey = primaryKeyBuilder.build();
            RowUpdateChange rowUpdateChange = new RowUpdateChange(TABLE_NAME, primaryKey)
;
            // Update data when the specified row exists and the value in Col0 is greater
than 100.
            Condition condition = new Condition(RowExistenceExpectation.EXPECT_EXIST);
            condition.setColumnCondition(new SingleColumnValueCondition("Col0",
                    SingleColumnValueCondition.CompareOperator.GREATER_THAN, ColumnValue.
fromLong(100)));
            rowUpdateChange.setCondition(condition);
            // Update columns.
            for (int i = 0; i < 10; i++) {
                rowUpdateChange.put(new Column("Col" + i, ColumnValue.fromLong(i)));
            }
            // Delete a specified version of data in the specified column.
            rowUpdateChange.deleteColumn("Col10", 1465373223000L);
            // Delete the specified column.
            rowUpdateChange.deleteColumns("Col11");
            client.updateRow(new UpdateRowRequest(rowUpdateChange));
        }
```

DeleteRow

You can call this operation to delete a row.

When you perform DeleteRow, you can use conditional update to configure conditions for the existence of the row to delete or values in certain columns of the existing row. For more information, see Conditional update.

- Example 1

  The following code provides an example on how to delete a row:

```
        private static void deleteRow(SyncClient client, String pkValue) {
            // Create the primary key.
            PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuild
er();
            primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromS
tring(pkValue));
            PrimaryKey primaryKey = primaryKeyBuilder.build();
            RowDeleteChange rowDeleteChange = new RowDeleteChange(TABLE_NAME, primaryKey)
;
            client.deleteRow(new DeleteRowRequest(rowDeleteChange));
        }
```

- Example 2

  The following code provides an example on how to set deletion conditions:

```
        private static void deleteRow(SyncClient client, String pkValue) {
            // Create the primary key.
            PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuild
er();
            primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromS
tring(pkValue));
            PrimaryKey primaryKey = primaryKeyBuilder.build();
            RowDeleteChange rowDeleteChange = new RowDeleteChange(TABLE_NAME, primaryKey)
;
            // Delete data when the specified row exists and the value in Col0 exceeds 10
0.
            Condition condition = new Condition(RowExistenceExpectation.EXPECT_EXIST);
            condition.setColumnCondition(new SingleColumnValueCondition("Col0",
                    SingleColumnValueCondition.CompareOperator.GREATER_THAN, ColumnValue.
fromLong(100)));
            rowDeleteChange.setCondition(condition);
            client.deleteRow(new DeleteRowRequest(rowDeleteChange));
        }
```

Multi-row operations

Tablestore SDK for Java provides multi-row operations such as BatchGetRow, BatchWriteRow, GetRange, and createRangeIterator.

BatchGetRow

You can call this operation to read data from multiple rows by sending a single request. The parameters are the same as those of the GetRow operation. Note that BatchGetRow uses the same parameter configurations for all rows. For example, if ColumnsToGet is set to colA, only the value of colA is read for all the rows.

Similar to the use of the BatchWriteRow operation, you must check the response when you use the BatchGetRow operation. If the operation fails for some rows, an exception may not occur, but information about the failed rows is stored in BatchGetRowResponse. You can use the BatchGetRowResponse#getFailedRows method to query information about the failed rows. Use the BatchGetRowResponse#isAllSucceed method to determine whether all rows is obtained.

Examples

The following code provides an example on how to read 10 rows of data, and configure the version conditions, columns to read, and filters:

```
        private static void batchGetRow(SyncClient client) {
            MultiRowQueryCriteria multiRowQueryCriteria = new MultiRowQueryCriteria(TABLE_NAME);
            // Add 10 rows to read.
            for (int i = 0; i < 10; i++) {
                PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
                primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromString("pk" + i));
                PrimaryKey primaryKey = primaryKeyBuilder.build();
                multiRowQueryCriteria.addRow(primaryKey);
            }
            // Add conditions.
            multiRowQueryCriteria.setMaxVersions(1);
            multiRowQueryCriteria.addColumnsToGet("Col0");
            multiRowQueryCriteria.addColumnsToGet("Col1");
            SingleColumnValueFilter singleColumnValueFilter = new SingleColumnValueFilter("Col0",
                    SingleColumnValueFilter.CompareOperator.EQUAL, ColumnValue.fromLong(0));
            singleColumnValueFilter.setPassIfMissing(false);
            multiRowQueryCriteria.setFilter(singleColumnValueFilter);
            BatchGetRowRequest batchGetRowRequest = new BatchGetRowRequest();
            // BatchGetRow allows you to read data from multiple tables. A single multiRowQueryCriteria corresponds to a query condition for one table. You can add multiple multiRowQueryCriteria conditions to read data from multiple tables.
            batchGetRowRequest.addMultiRowQueryCriteria(multiRowQueryCriteria);
            BatchGetRowResponse batchGetRowResponse = client.batchGetRow(batchGetRowRequest);
            System.out.println("Were all successful:" + batchGetRowResponse.isAllSucceed());
            if (!batchGetRowResponse.isAllSucceed()) {
                for (BatchGetRowResponse.RowResult rowResult : batchGetRowResponse.getFailedRows()) {
                    System.out.println("Failed rows:" + batchGetRowRequest.getPrimaryKey(rowResult.getTableName(), rowResult.getIndex()));
                    System.out.println("Cause of failure:" + rowResult.getError());
                }
                /**
                 * You can use the createRequestForRetry method to construct another request to retry failed rows. Only the retry request is constructed here.
                 * We recommend that you use the custom retry policy in Tablestore SDK for Java as the retry method. This feature allows you to retry failed rows after batch operations. After you set the retry policy, you do not need to add retry code when you call the retry operation.
                 */
                BatchGetRowRequest retryRequest = batchGetRowRequest.createRequestForRetry(batchGetRowResponse.getFailedRows());
            }
        }
```

BatchWriteRow

You can call this operation to write data to multiple rows by sending a single request. The write operations include PutRow, UpdateRow, and DeleteRow. This operation also allows you to write data to multiple tables at a time.

The process to create a BatchWriteRow operation is the same as that to create a PutRow, UpdateRow, or DeleteRow operation. You can also set update conditions.

When you call the BatchWriteRow operation, you must check the response. When multiple rows are written, some rows may fail to be written. If the operation fails for some rows, an exception may not occur, but information about the index and error messages of the failed rows is stored in BatchWriteRowResponse. You can use the isAllSucceed method in BatchWriteRowResponse to determine whether all rows are written. We recommend that you check the response in case of failed operations. In some situations, exceptions may occur when you call the BatchWriteRow operation. For example, if the server detects incorrect parameters during some operations, a parameter exception may occur when none of the operations are completed for the request.

Examples

The following code provides an example of how to send a single BatchWriteRow request, which includes two PutRow operations, one UpdateRow operation, and one DeleteRow operation.

```
        private static void batchWriteRow(SyncClient client) {
            BatchWriteRowRequest batchWriteRowRequest = new BatchWriteRowRequest();
            // Construct rowPutChange1.
            PrimaryKeyBuilder pk1Builder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
            pk1Builder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromString("pk
1"));
            RowPutChange rowPutChange1 = new RowPutChange(TABLE_NAME, pk1Builder.build());
            // Add columns.
            for (int i = 0; i < 10; i++) {
                rowPutChange1.addColumn(new Column("Col" + i, ColumnValue.fromLong(i)));
            }
            // Add rowPutChange1 to the batch operation.
            batchWriteRowRequest.addRowChange(rowPutChange1);
            // Construct rowPutChange2.
            PrimaryKeyBuilder pk2Builder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
            pk2Builder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromString("pk
2"));
            RowPutChange rowPutChange2 = new RowPutChange(TABLE_NAME, pk2Builder.build());
            // Add columns.
            for (int i = 0; i < 10; i++) {
                rowPutChange2.addColumn(new Column("Col" + i, ColumnValue.fromLong(i)));
            }
            // Add rowPutChange2 to the batch operation.
            batchWriteRowRequest.addRowChange(rowPutChange2);
            // Construct rowUpdateChange.
            PrimaryKeyBuilder pk3Builder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
            pk3Builder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromString("pk
3"));
            RowUpdateChange rowUpdateChange = new RowUpdateChange(TABLE_NAME, pk3Builder.bu
ild());
            // Add columns.
            for (int i = 0; i < 10; i++) {
                rowUpdateChange.put(new Column("Col" + i, ColumnValue.fromLong(i)));
```

```
            }
            // Delete the specified column.
            rowUpdateChange.deleteColumns("Col10");
            // Add rowUpdateChange to the batch operation.
            batchWriteRowRequest.addRowChange(rowUpdateChange);
            // Construct rowDeleteChange.
            PrimaryKeyBuilder pk4Builder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
            pk4Builder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromString("pk
4"));
            RowDeleteChange rowDeleteChange = new RowDeleteChange(TABLE_NAME, pk4Builder.bu
ild());
            // Add rowDeleteChange to the batch operation.
            batchWriteRowRequest.addRowChange(rowDeleteChange);
            BatchWriteRowResponse response = client.batchWriteRow(batchWriteRowRequest);
            System.out.println("Were all successful:" + response.isAllSucceed());
            if (!response.isAllSucceed()) {
                for (BatchWriteRowResponse.RowResult rowResult : response.getFailedRows())
{
                    System.out.println("Failed rows:" + batchWriteRowRequest.getRowChange(r
owResult.getTableName(), rowResult.getIndex()).getPrimaryKey());
                    System.out.println("Cause of failure:" + rowResult.getError());
                }
                /**
                 * You can use the createRequestForRetry method to construct another reques
t to retry failed rows. Only the retry request is constructed here.
                 * We recommend that you use the custom retry policy in Tablestore SDK for
Java as the retry method. This feature allows you to retry failed rows after batch operatio
ns. After you set the retry policy, you do not need to add retry code when you call the ret
ry operation.
                 */
                BatchWriteRowRequest retryRequest = batchWriteRowRequest.createRequestForRe
try(response.getFailedRows());
            }
        }
```

GetRange

You can call this operation to read data within a range. In Tablestore tables, all rows are sorted by primary key. The primary key of a table sequentially consists of all primary key columns. Therefore, do not assume that the rows are sorted based on a certain primary key column.

The GetRange operation allows you to read data in a forward or backward direction within a specified range. You can also specify the number of rows to read. If the range is large and the number of scanned rows or the volume of data exceeds the limit, the scan stops and the read rows and the next primary key are returned. If the rows are not all read, you can initiate a request to start from where the last operation left off and read the remaining rows based on the next primary key returned by the previous operation.

The following table describes the parameters of GetRange requests.

Parameter	Description
Direction	The enumeration type. Valid values: FORWARD and BACKWARD.
InclusiveStartPrimaryKey	The primary key of the row from which the range read starts. The row that contains the start primary key is within the valid range to read. If you set Direction to **BACKWARD**, the value of the start primary key must be greater than that of the end primary key.
ExclusiveEndPrimaryKey	The primary key of the row at which the range read ends. The row that contains the end primary key is not within the valid range to read. If you set Direction to **BACKWARD**, the value of the start primary key must be greater than that of the end primary key.
Limit	The maximum number of rows to return for this request.
ColumnsToGet	The set of columns to read. If you do not specify this parameter, all columns are read.
MaxVersions	The maximum number of versions to read. You must set at least one of the following parameters: MaxVersions or TimeRange.
TimeRange	The range of versions to read. You must set at least one of the following parameters: MaxVersions or TimeRange.
Filter	Filters are used by the server to filter the read results based on the specified conditions.

Examples

The following code provides an example on how to read data within a specified range in forward order and return NextStartPrimaryKey. If the value of NextStartPrimaryKey is null, all data within the range is read.

```
        private static void getRange(SyncClient client, String startPkValue, String endPkVal
ue) {
            RangeRowQueryCriteria rangeRowQueryCriteria = new RangeRowQueryCriteria(TABLE_N
AME);
            // Specify the primary key to start from.
            PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder
();
            primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromStr
ing(startPkValue));
            rangeRowQueryCriteria.setInclusiveStartPrimaryKey(primaryKeyBuilder.build());
            // Specify the primary key to end with.
            primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
            primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromStr
ing(endPkValue));
            rangeRowQueryCriteria.setExclusiveEndPrimaryKey(primaryKeyBuilder.build());
            rangeRowQueryCriteria.setMaxVersions(1);
            System.out.println("GetRange result:");
            while (true) {
                GetRangeResponse getRangeResponse = client.getRange(new GetRangeRequest(ran
geRowQueryCriteria));
                for (Row row : getRangeResponse.getRows()) {
                    System.out.println(row);
                }
                // If the NextStartPrimaryKey value is not null, continue the read operatio
n.
                if (getRangeResponse.getNextStartPrimaryKey() != null) {
                    rangeRowQueryCriteria.setInclusiveStartPrimaryKey(getRangeResponse.getN
extStartPrimaryKey());
                } else {
                    break;
                }
            }
        }
```

createRangeIterator

You can call this operation to read data by iteration.

Examples

```
        private static void getRangeByIterator(SyncClient client, String startPkValue, Stri
ng endPkValue) {
            RangeIteratorParameter rangeIteratorParameter = new RangeIteratorParameter(TABL
E_NAME);
            // Specify the primary key to start from.
            PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder
();
            primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromStr
ing(startPkValue));
            rangeIteratorParameter.setInclusiveStartPrimaryKey(primaryKeyBuilder.build());
            // Specify the primary key to end with.
            primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
            primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromStr
ing(endPkValue));
            rangeIteratorParameter.setExclusiveEndPrimaryKey(primaryKeyBuilder.build());
            rangeIteratorParameter.setMaxVersions(1);
            Iterator<Row> iterator = client.createRangeIterator(rangeIteratorParameter);
            System.out.println("Results obtained when Iterator is used to implement GetRang
e:");
            while (iterator.hasNext()) {
                Row row = iterator.next();
                System.out.println(row);
            }
        }
```

Auto-increment function of the primary key column

This topic describes how to create an auto-increment primary key column. An auto-increment primary key column cannot be the partition key. If you write data to a table that contains an auto-increment primary key column, you do not need to specify a value for the auto-increment primary key column because Tablestore generates a value for the auto-increment primary key column. The generated value for the auto-increment primary key column is unique, and all values in auto-increment primary key columns increase sequentially in a partition. This feature applies to system design scenarios that require auto-increment primary key columns, such as item IDs on e-commerce websites, user IDs of large websites, post IDs in forums, and message IDs in chat tools.

> **Note** Tablestore SDK for Java V4.2.0 and later support auto-increment function of the primary key column.

Features

Auto-increment function of the primary key column have the following features:

- The values in auto-increment primary key columns are unique and increase sequentially but not always continuously in a partition.
- The data type of the value in an auto-increment primary key column is 64-bit signed long integer.
- You can create an auto-increment primary key column for a table. Tables that contain and do not contain auto-increment primary key columns can be in the same instance.

> **Note** Auto-increment function of the primary key column do not affect the rule of conditional update.

Limits

Auto-increment function of the primary key column has the following limits:

- You can create at most one auto-increment primary key column for a table. An auto-increment primary key column cannot be the partition key.
- You can create an auto-increment primary key column only when you create a table. You cannot create an auto-increment primary key column for an existing table.
- An auto-increment primary key column can only be an integer column. The data type of the generated value for an auto-increment primary key column is 64-bit signed long integer.
- An auto-increment column cannot be an attribute column.

API operations

The following table lists the operations for auto-increment function of the primary key column.

API operation	Description
CreateTable	When you create a table, you cannot set the partition key to be an auto-increment primary key column. If you set the partition key to be an auto-increment primary key column, values in the column cannot be generated automatically.
UpdateTable	After a table is created, you cannot use the UpdateTable operation to change a primary key column to an auto-increment primary key column.
PutRow	When you write data to a table, you do not need to specify a value for the auto-increment primary key column. Tablestore generates a value for the auto-increment primary key column. You can set ReturnType to RT_PK to obtain a complete primary key value and use the value in GetRow to query data.
UpdateRow	
BatchWriteRow	
GetRow	You must use a complete primary key value when you use GetRow. To obtain a complete primary key value, you can set ReturnType to RT_PK in PutRow, UpdateRow, or BatchWriteRow.
BatchGetRow	

Examples

The use of auto-increment primary key columns involve the CreateTable, PutRow, UpdateRow, and BatchWriteRow operations.

1. Create a table

   To create an auto-increment primary key column when you create a table, you must set AUTO_INCREMENT as the attribute of the primary key column.

```
private static void createTable(SyncClient client) {
        TableMeta tableMeta = new TableMeta("table_name");
        // Create the first primary key column, which is also the partition key.
        tableMeta.addPrimaryKeyColumn(new PrimaryKeySchema("PK_1", PrimaryKeyType.STRIN
G));
        // Create the second primary key column, and set it to be an auto-increment col
umn. The type is set to integer, and the attribute is set to AUTO_INCREMENT.
        tableMeta.addPrimaryKeyColumn(new PrimaryKeySchema("PK_2", PrimaryKeyType.INTEG
ER, PrimaryKeyOption.AUTO_INCREMENT));
        int timeToLive = -1;  // Specify that data never expires.
        int maxVersions = 1;  // Specify that only one version is saved.
        TableOptions tableOptions = new TableOptions(timeToLive, maxVersions);
        CreateTableRequest request = new CreateTableRequest(tableMeta, tableOptions);
        client.createTable(request);
    }
```

2. Write data

   When you write data to a table, you do not need to specify a value for the auto-increment primary key column. Instead, you can set the value in the auto-increment primary key column to AUTO_INCREMENT.

```
    private static void putRow(SyncClient client, String receive_id) {
        // Create the primary key.
        PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder
();
        // Specify the value in the first primary key column to the first four digits o
f md5(receive_id).
        primaryKeyBuilder.addPrimaryKeyColumn("PK_1", PrimaryKeyValue.fromString("Hangz
hou");
        // Specify the value in the second primary key column to AUTO_INCREMENT. The se
cond primary key column is an auto-increment primary key column, and you do not need to
specify a value for it. Tablestore generates a value for the auto-increment primary key
column.
        primaryKeyBuilder.addPrimaryKeyColumn("PK_2", PrimaryKeyValue.AUTO_INCREMENT);
        PrimaryKey primaryKey = primaryKeyBuilder.build();
        RowPutChange rowPutChange = new RowPutChange("table_name", primaryKey);
        // Set ReturnType to RT_PK to include the primary key value in the returned res
ult. If ReturnType is not set, no result is returned by default.
        rowPutChange.setReturnType(ReturnType.RT_PK);
        // Add attribute columns.
        rowPutChange.addColumn(new Column("content", ColumnValue.fromString(content)));
        // Write data to the table.
        PutRowResponse response = client.putRow(new PutRowRequest(rowPutChange));
        // Display the returned primary key value.
        Row returnRow = response.getRow();
        if (returnRow != null) {
            System.out.println("PrimaryKey:" + returnRow.getPrimaryKey().toString());
        }
        // Display the consumed capacity units (CUs).
        CapacityUnit  cu = response.getConsumedCapacity().getCapacityUnit();
        System.out.println("Read CapacityUnit:" + cu.getReadCapacityUnit());
        System.out.println("Write CapacityUnit:" + cu.getWriteCapacityUnit());
    }
```

Conditional update

If you use conditional update, data in the table can be updated only when the conditions are met. If the conditions are not met, the update fails.

Conditional update supports arithmetic operations including =, !, =, >, >=, <, and <= and logic operations including NOT, AND, and OR. You can use a combination of up to 10 conditions in an update operation. You can use conditional update in the PutRow, UpdateRow, DeleteRow, and BatchWriteRow operations.

Conditional updates can be used to implement optimistic locking. When you update a row, the value of the specified column is obtained. For example, the value in Column A is 1. Obtain the value in Column A and set a condition that **the value in Column A is 1**. Update **the value in Column A to 2**. If Column A of the row is updated by other clients, the update fails.

Column-based judgment conditions include column-based conditions and the row existence condition.

Column-based judgment condition	Description
Column-based condition	Column-based conditions support SingleColumnValueCondition and CompositeColumnValueCondition, which are used to perform the condition-based judgment based on the values of one or more columns. Column-based conditions are similar to the conditions used by Tablestore filters.
Row existence condition	When you update a table, the system checks the row existence condition. If the row existence condition is not met, an error occurs during the update. The row existence condition is classified into the following types: • IGNORE • EXPECT_EXIST • EXPECT_NOT_EXIST For more information, see Row existence condition update rules.

Row existence condition update rules

Note BatchWriteRow is a set of multiple PutRow, UpdateRow, and DeleteRow operations. when you manage data in the table by using the BatchWriteRow operation, see the update rules of the corresponding operation based on the operation type.

API operations	IGNORE	EXPECT_EXIST	EXPECT_NOT_EXIST
PutRow: The row exists.	Fail	Succeed	Fail
PutRow: The row does not exist.	Succeed	Fail	Fail
UpdateRow: The row exists.	Fail	Succeed	Fail
UpdateRow: The row does not exist.	Succeed	Fail	Fail

API operations	IGNORE	EXPECT_EXIST	EXPECT_NOT_EXIST
DeleteRow: The row exists.	Succeed	Succeed	Fail
DeleteRow: The row does not exist.	Fail	Fail	Fail

Examples

The following code provides examples on how to use column-based judgment conditions and implement optimistic locking:

- Construct a SingleColumnValueCondition.

```
 // Set the condition: Col0==0.
 SingleColumnValueCondition singleColumnValueCondition = new SingleColumnValueCondition("
Col0",
         SingleColumnValueCondition.CompareOperator.EQUAL, ColumnValue.fromLong(0));
 // If Col0 does not exist, the condition is not met.
 singleColumnValueCondition.setPassIfMissing(false);
 // Only check the latest version.
 singleColumnValueCondition.setLatestVersionsOnly(true);
```

- Construct a CompositeColumnValueCondition.

```
 // Set the condition composite1: (Col0 = 0) AND (Col1 > 100).
 CompositeColumnValueCondition composite1 = new CompositeColumnValueCondition(CompositeCo
lumnValueCondition.LogicOperator.AND);
 SingleColumnValueCondition single1 = new SingleColumnValueCondition("Col0",
         SingleColumnValueCondition.CompareOperator.EQUAL, ColumnValue.fromLong(0));
 SingleColumnValueCondition single2 = new SingleColumnValueCondition("Col1",
         SingleColumnValueCondition.CompareOperator.GREATER_THAN, ColumnValue.fromLong(10
0));
 composite1.addCondition(single1);
 composite1.addCondition(single2);
 // Set the condition composite2: ( (Col0 == 0) AND (Col1 > 100) ) OR (Col2 <= 10).
 CompositeColumnValueCondition composite2 = new CompositeColumnValueCondition(CompositeCo
lumnValueCondition.LogicOperator.OR);
 SingleColumnValueCondition single3 = new SingleColumnValueCondition("Col2",
         SingleColumnValueCondition.CompareOperator.LESS_EQUAL, ColumnValue.fromLong(10))
;
 composite2.addCondition(composite1);
 composite2.addCondition(single3);
```

- The following code provides an example of how to implement optimistic locking by incrementing the value of a column:

```
 private static void updateRowWithCondition(SyncClient client, String pkValue) {
     // Create the primary key.
     PrimaryKeyBuilder primaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
     primaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME, PrimaryKeyValue.fromString(p
kValue));
     PrimaryKey primaryKey = primaryKeyBuilder.build();
     // Read a row of data.
     SingleRowQueryCriteria criteria = new SingleRowQueryCriteria(TABLE_NAME, primaryKey)
;
     criteria.setMaxVersions(1);
     GetRowResponse getRowResponse = client.getRow(new GetRowRequest(criteria));
     Row row = getRowResponse.getRow();
     long col0Value = row.getLatestColumn("Col0").getValue().asLong();
     // Configure the conditional update to increment the value of Col0 by 1.
     RowUpdateChange rowUpdateChange = new RowUpdateChange(TABLE_NAME, primaryKey);
     Condition condition = new Condition(RowExistenceExpectation.EXPECT_EXIST);
     ColumnCondition columnCondition = new SingleColumnValueCondition("Col0", SingleColum
nValueCondition.CompareOperator.EQUAL, ColumnValue.fromLong(col0Value));
     condition.setColumnCondition(columnCondition);
     rowUpdateChange.setCondition(condition);
     rowUpdateChange.put(new Column("Col0", ColumnValue.fromLong(col0Value + 1)));
     try {
         client.updateRow(new UpdateRowRequest(rowUpdateChange));
     } catch (TableStoreException ex) {
         System.out.println(ex.toString());
     }
 }
```

Filters

Tablestore filters are used to filter the query results on the server side. The server returns only the rows or columns that match the filter conditions. Filters can be used for GetRow, BatchGetRow, and GetRange operations.

Tablestore supports only SingleColumnValueFilter and CompositeColumnValueFilter, which are used to determine whether to filter out a row based on reference column values. SingleColumnValueFilter can be used to determine whether to filter out of a row based on a single reference column value. CompositeColumnValueFilter can be used to determine whether to filter out of a row based on the combination of multiple reference column values.

Note that filters are used to filter the read data. Therefore, the reference columns used by SingleColumnValueFilter or CompositeColumnValueFilter must be included in the read data.

If the data to read does not contain the reference columns, filters cannot obtain the values in the reference columns.

Examples

- The following code provides an example on how to construct a SingleColumnValueFilter:

```
        // Set the filter so that when the value in Col0 is 0, the row is returned.
        SingleColumnValueFilter singleColumnValueFilter = new SingleColumnValueFilter("Co
l0",
                SingleColumnValueFilter.CompareOperator.EQUAL, ColumnValue.fromLong(0));
        // If Col0 does not exist, the data is not returned.
        singleColumnValueFilter.setPassIfMissing(false);
        // Only check the latest version.
        singleColumnValueFilter.setLatestVersionsOnly(true);
```

- The following code provides an example on how to construct a CompositeColumnValueFilter:

```
        // Set filters composite1: (Col0 == 0) AND (Col1 > 100).
        CompositeColumnValueFilter composite1 = new CompositeColumnValueFilter(CompositeC
olumnValueFilter.LogicOperator.AND);
        SingleColumnValueFilter single1 = new SingleColumnValueFilter("Col0",
                SingleColumnValueFilter.CompareOperator.EQUAL, ColumnValue.fromLong(0));
        SingleColumnValueFilter single2 = new SingleColumnValueFilter("Col1",
                SingleColumnValueFilter.CompareOperator.GREATER_THAN, ColumnValue.fromLon
g(100));
        composite1.addFilter(single1);
        composite1.addFilter(single2);
        // Set filters composite2: ( (Col0 == 0) AND (Col1 > 100) ) OR (Col2 <= 10).
        CompositeColumnValueFilter composite2 = new CompositeColumnValueFilter(CompositeC
olumnValueFilter.LogicOperator.OR);
        SingleColumnValueFilter single3 = new SingleColumnValueFilter("Col2",
                SingleColumnValueFilter.CompareOperator.LESS_EQUAL, ColumnValue.fromLong(
10));
        composite2.addFilter(composite1);
        composite2.addFilter(single3);
```

Global secondary indexes

This topic describes how to create, use, and delete a global secondary index.

Create a global secondary index

You can create a global secondary index when you create a table. You can also create a global secondary index for an existing table.

- Create a global secondary index when you create a table

```
   private static void createTable(SyncClient client) {
        TableMeta tableMeta = new TableMeta(TABLE_NAME);
        tableMeta.addPrimaryKeyColumn(new PrimaryKeySchema(PRIMARY_KEY_NAME_1, PrimaryKey
Type.STRING)); // Add a primary key column to the table.
        tableMeta.addPrimaryKeyColumn(new PrimaryKeySchema(PRIMARY_KEY_NAME_2, PrimaryKey
Type.INTEGER)); // Add a primary key column to the table.
        tableMeta.addDefinedColumn(new DefinedColumnSchema(DEFINED_COL_NAME_1, DefinedCol
umnType.STRING)); // Add a predefined attribute column to the table.
        tableMeta.addDefinedColumn(new DefinedColumnSchema(DEFINED_COL_NAME_2, DefinedCol
umnType.INTEGER)); // Add a predefined attribute column to the table.
        int timeToLive = -1; // Specify the validity period of data in seconds. A value o
f -1 indicates that the data never expires. You must specify -1 as the timeToLive value w
hen a table has one or more index tables.
        int maxVersions = 1; // Specify the maximum number of versions. You must specify
1 as the value when a table has one or more index tables.
        TableOptions tableOptions = new TableOptions(timeToLive, maxVersions);
        ArrayList<IndexMeta> indexMetas = new ArrayList<IndexMeta>();
        IndexMeta indexMeta = new IndexMeta(INDEX_NAME);
        indexMeta.addPrimaryKeyColumn(DEFINED_COL_NAME_1); // Add a primary key column to
the index table.
        indexMeta.addDefinedColumn(DEFINED_COL_NAME_2); // Add an attribute column to the
index table.
        indexMetas.Add(indexMeta);
        CreateTableRequest request = new CreateTableRequest(tableMeta, tableOptions, inde
xMetas); // Create an index table when you create a table.
        client.createTable(request);
    }
```

- Create a global secondary index for an existing table

  Note You can set the IncludeBaseData parameter in CreateIndexRequest to specify whether the index table includes the existing data in the table. When the IncludeBaseData parameter in CreateIndexRequest is set to true, the index table includes the existing data. When the value is false, the index table does not include the existing data.

```
private static void createIndex(SyncClient client) {
    IndexMeta indexMeta = new IndexMeta(INDEX_NAME); // Create an index named Meta.
    indexMeta.addPrimaryKeyColumn(DEFINED_COL_NAME_2); // Specify DEFINED_COL_NAME_2 as t
he first primary key column of the index table.
    indexMeta.addPrimaryKeyColumn(DEFINED_COL_NAME_1); // Specify DEFINED_COL_NAME_1 as t
he second primary key column of the index table.
    CreateIndexRequest request = new CreateIndexRequest(TABLE_NAME, indexMeta, true); //
Add the index to the base table. Specify that the existing data of the base table is incl
uded in the index table.
    CreateIndexRequest request = new CreateIndexRequest(TABLE_NAME, indexMeta, false); //
Add the index to the base table. Specify that the existing data of the base table is not
included in the index table.
    /**If you set IncludeBaseData to true, the existing data of the base table is synchro
nized to the index table. Then you can query all data from the index table. The time used
to synchronize data depends on the size of the existing data in the base table.
    */
    request.setIncludeBaseData(true);
    client.createIndex(request); // Create the index table.
}
```

Query data from a global secondary index

If the index table includes the attribute columns to return, you can query data from the index table. If the index table does not include the attribute columns to return, the base table is queried.

- Query data from the index table when the index table includes the attribute columns to return.

```
private static void scanFromIndex(SyncClient client) {
    RangeRowQueryCriteria rangeRowQueryCriteria = new RangeRowQueryCriteria(INDEX_NAME);
// Specify the index table name.
    // Specify the primary key from which the query starts.
    PrimaryKeyBuilder startPrimaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder(
);
    startPrimaryKeyBuilder.addPrimaryKeyColumn(DEFINED_COL_NAME_1, PrimaryKeyValue.INF_MI
N); // Specify the minimum value for an indexed attribute column.
    startPrimaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME_1, PrimaryKeyValue.INF_MI
N); // Specify the minimum value for a primary key column.
    startPrimaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME_2, PrimaryKeyValue.INF_MI
N); // Specify the minimum value for a primary key column.
    rangeRowQueryCriteria.setInclusiveStartPrimaryKey(startPrimaryKeyBuilder.build());
    // Specify the primary key at which the query ends.
    PrimaryKeyBuilder endPrimaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
    endPrimaryKeyBuilder.addPrimaryKeyColumn(DEFINED_COL_NAME_1, PrimaryKeyValue.INF_MAX)
; // Specify the maximum value for an indexed attribute column.
    endPrimaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME_1, PrimaryKeyValue.INF_MAX)
; // Specify the maximum value for a primary key column.
    endPrimaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME_2, PrimaryKeyValue.INF_MAX)
; // Specify the maximum value for a primary key column.
    rangeRowQueryCriteria.setExclusiveEndPrimaryKey(endPrimaryKeyBuilder.build());
    rangeRowQueryCriteria.setMaxVersions(1);
    System.out.println("The results returned from an index table:");
    while (true) {
        GetRangeResponse getRangeResponse = client.getRange(new GetRangeRequest(rangeRowQ
ueryCriteria));
        for (Row row : getRangeResponse.getRows()) {
            System.out.println(row);
        }
        // If the nextStartPrimaryKey value is not null, continue to read data.
        if (getRangeResponse.getNextStartPrimaryKey() != null) {
            rangeRowQueryCriteria.setInclusiveStartPrimaryKey(getRangeResponse.getNextSta
rtPrimaryKey());
        } else {
            break;
        }
    }
}
```

- Query data from the base table when the index table does not include the attribute columns to return.

```
private static void scanFromIndex(SyncClient client) {
    RangeRowQueryCriteria rangeRowQueryCriteria = new RangeRowQueryCriteria(INDEX_NAME);
// Specify the index table name.
    // Specify the primary key from which the query starts.
    PrimaryKeyBuilder startPrimaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder(
);
    startPrimaryKeyBuilder.addPrimaryKeyColumn(DEFINED_COL_NAME_1, PrimaryKeyValue.INF_MI
N); // Specify the minimum value for an indexed attribute column.
    startPrimaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME_1, PrimaryKeyValue.INF_MI
N); // Specify the minimum value for a primary key column.
    startPrimaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME_2, PrimaryKeyValue.INF_MI
```

```
N); // Specify the minimum value for a primary key column.
    rangeRowQueryCriteria.setInclusiveStartPrimaryKey(startPrimaryKeyBuilder.build());
    // Specify the primary key at which the query ends.
    PrimaryKeyBuilder endPrimaryKeyBuilder = PrimaryKeyBuilder.createPrimaryKeyBuilder();
    endPrimaryKeyBuilder.addPrimaryKeyColumn(DEFINED_COL_NAME_1, PrimaryKeyValue.INF_MAX)
; // Specify the maximum value for an indexed attribute column.
    endPrimaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME_1, PrimaryKeyValue.INF_MAX)
; // Specify the maximum value for a primary key column.
    endPrimaryKeyBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME_2, PrimaryKeyValue.INF_MAX)
; // Specify the maximum value for a primary key column.
    rangeRowQueryCriteria.setExclusiveEndPrimaryKey(endPrimaryKeyBuilder.build());
    rangeRowQueryCriteria.setMaxVersions(1);
    while (true) {
        GetRangeResponse getRangeResponse = client.getRange(new GetRangeRequest(rangeRowQ
ueryCriteria));
        for (Row row : getRangeResponse.getRows()) {
            PrimaryKey curIndexPrimaryKey = row.getPrimaryKey();
            PrimaryKeyColumn pk1 = curIndexPrimaryKey.getPrimaryKeyColumn(PRIMARY_KEY_NAM
E1);
            PrimaryKeyColumn pk2 = curIndexPrimaryKey.getPrimaryKeyColumn(PRIMARY_KEY_NAM
E2);
            PrimaryKeyBuilder mainTablePKBuilder = PrimaryKeyBuilder.createPrimaryKeyBuil
der();
            mainTablePKBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME1, pk1.getValue());
            mainTablePKBuilder.addPrimaryKeyColumn(PRIMARY_KEY_NAME2, ke2.getValue());
            PrimaryKey mainTablePK = mainTablePKBuilder.build(); // Construct the primary
key to query the base table based on the primary key of the index table.
            // Query the table.
            SingleRowQueryCriteria criteria = new SingleRowQueryCriteria(TABLE_NAME, main
TablePK);
            criteria.addColumnsToGet(DEFINED_COL_NAME3); // Read the DEFINED_COL_NAME3 at
tribute column from the base table.
            // Set the latest version to read.
            criteria.setMaxVersions(1);
            GetRowResponse getRowResponse = client.getRow(new GetRowRequest(criteria));
            Row mainTableRow = getRowResponse.getRow();
            System.out.println(row);
        }
        // If the nextStartPrimaryKey value is not null, continue to read data.
        if (getRangeResponse.getNextStartPrimaryKey() != null) {
            rangeRowQueryCriteria.setInclusiveStartPrimaryKey(getRangeResponse.getNextSta
rtPrimaryKey());
        } else {
            break;
        }
    }
}
```

Delete a global secondary index

Delete an index table.

```
private static void deleteIndex(SyncClient client) {
    DeleteIndexRequest request = new DeleteIndexRequest(TABLE_NAME, INDEX_NAME); // Specify the name of the index table that you want to delete and the name of the corresponding base table.
    client.deleteIndex(request); // Delete the index table.
}
```

7.1.2.1.1.5. Error handling

This topic describes the error handling methods in Tablestore SDK for Java.

Methods

Tablestore SDK for Python handles errors as exceptions. If an operation fails, an exception is returned.

> **Note** Batch operations such as BatchGetRow and BatchWriteRow can be called only after the system verifies that no exception is returned and that the status of each row is successful.

Exceptions

Tablestore SDK for Java has two types of exceptions: OTSClientError and OTSServiceError. Both are inherited from Exception.

- OTSClientError: an internal SDK exception, such as an invalid parameter value.
- OTSException: a server error parsed from a server error message. OTSServiceError contains the following parameters:
  - getHttpStatus(): an HTTP status code, such as 200 or 404.
  - getErrorCode(): an error type string returned by Tablestore.
  - getRequestId(): the UUID that identifies a request. If you cannot solve the problem, record this request ID and contact Tablestore technical support for help.

7.1.2.1.2. Python SDK

7.1.2.1.2.1. Preface

This topic describes how to use Tablestore SDK for Python. The content in this topic applies to Tablestore SDK for Python V4.x.x.

Prerequisites

An authorized account is created, and an AccessKey pair (AccessKey ID and AccessKey secret) is obtained. For more information about how to obtain and view your AccessKey pair in the Apsara Uni-manager Management Console, see Obtain an AccessKey pair.

Download Tablestore SDK for Python

- Download Tablestore SDK for Python by using the SDK package. For more information, see SDK package.
- Download Tablestore SDK for Python by using GitHub. For more information, visit GitHub.

Compatibility

- Tablestore SDK for Python V5.x.x: compatible.
- Tablestore SDK for Python V4.x.x: compatible.
- Tablestore SDK for Python V2.x.x: incompatible. Tablestore SDK for Python V2.x.x supports primary key columns in random order, which are no longer supported in Tablestore SDK for Python V4.0.0 and later. Tablestore SDK for Python V4.x.x and Tablestore SDK for Python V2.x.x are incompatible in the following respects:
  - The package name is changed from ots2 to tablestore.
  - The TableOptions parameter is added for the Client.create_table operation.
  - The type of the primary_key parameter is changed from dict to list for the put_row, get_row, and update_row operations to ensure the sequence of primary keys.
  - The type of the attribute_columns parameter is changed from dict to list for the put_row and update_row operations.
  - The timestamp parameter is added to the attribute_columns parameter for the put_row and update_row operations.
  - The max_version and time_range parameters are added for the get_row and get_range operations. You must specify at least one of max_version and time_range.
  - The return_type parameter is added for the put_row, update_row, and delete_row operations. Only RT_PK is supported to return the primary key value of the current row.
  - The return_row parameter is added for the put_row, update_row, and delete_row operations. If you set return_type to RT_PK in the request, the primary key value of the row is returned in return_row.

Version

Latest version: 5.1.0.

7.1.2.1.2.2. Installation

This topic describes how to install Tablestore SDK for Python.

Preparations

Python 2 or Python 3 is available.

Install Tablestore SDK for Python

- Method 1: Use pip.

  Run the following command to install Tablestore SDK for Python:

  ```
  sudo pip install tablestore
  ```

- Method 2: Use GitHub.

  Ensure that you have installed Git. For more information about how to download Git, visit Git. After Git is installed, run the following command:

  ```
  git clone https://github.com/aliyun/aliyun-tablestore-python-sdk.git
  sudo python setup.py  install
  ```

- Method 3: Use source code.
  i. Download the SDK package.
  ii. Decompress the SDK package, and then run the following command:

```
sudo python setup.py install
```

Verify Tablestore SDK for Python

To check the SDK version in the Python environment, enter python on the command line and then press Enter.

```
>>> import tablestore
>>> tablestore.__version__
'5.1.0'
```

Uninstall Tablestore SDK for Python

Use pip to uninstall Tablestore SDK for Python.

```
sudo pip uninstall tablestore
```

7.1.2.1.2.3. Initialization

OTSClient provides a series of methods for users to manage tables and perform read and write operations on one or more rows.

Obtain an endpoint

An endpoint is the domain name that is used to access a Tablestore instance in a region. To query an endpoint, perform the following operations:

1. Log on to the Tablestore console.
2. Click the instance name to go to the **Instance Management** page.

   On the Instance Details page, you can view the endpoints of the instance in Instance Access URL.

Configure an AccessKey pair

To access Apsara Stack Tablestore, you must have a valid AccessKey pair (AccessKey ID and AccessKey secret) for signature authentication.

After you obtain the AccessKey pair, you can perform the following operation to initialize an OTSClient instance by using an endpoint:

- API operation

```
    // Initialize the TableStoreClient instance.
    // endPoint indicates the endpoint that is used to access the Tablestore instance, wh
ich must start with https://. Example: https://instance.cn-hangzhou.ots.aliyun.com:80.
    // accessKeyId indicates the AccessKey ID that is used to access the Tablestore insta
nce. You can visit the official website or contact an administrator to obtain an AccessKe
y ID.
    // accessKeySecret indicates the AccessKey secret that is used to access the Tablesto
re instance. You can visit the official website or contact an administrator to obtain an
AccessKey secret.
    // instanceName indicates the name of the instance to access. You can create an insta
nce in the Tablestore console or contact an administrator to obtain the name of an existi
ng instance.
func NewClient(endPoint, instanceName, accessKeyId, accessKeySecret string, options ...Cl
ientOption) *TableStoreClient
```

- Examples

```
    client = NewClient("your_instance_endpoint",  "your_instance_name", "your_user_i
d", "your_user_key")
```

HTTPS

- HTTPS is supported in Python 2.0.8 and later.
- OpenSSL 0.9.8j or later is required. We recommend that you use OpenSSL 1.0.2d.
- The Python 2.0.8 release package contains a certifi package that can be installed and used. To update the root certificate, download the latest root certificate from Root Certificate.

7.1.2.1.2.4. Use the SDK

Table-level operations

Tablestore SDK for Python provides the following table-level operations: CreateTable, ListTable, DeleteTable, UpdateTable, and DescribeTable.

CreateTable

You can call this operation to create a table based on the specified table structure.

> **Note**
>
> - After the table is created, it takes several seconds to load the table. During this period, read and write operations on the table may fail. You can use applications to perform operations on the table data only after the table is loaded.
> - You must specify the primary key when you create a table. A primary key contains one to four primary key columns. Each primary key column has a name and a data type.

- API operation

```
       Description: You can call this operation to create a table based on the specified
table schema information.
        table_meta indicates an instance of the tablestore.metadata.TableMeta class. tabl
e_meta specifies the table name and primary key schema.
        For more information, see the documentation for the TableMeta class. After you cr
eate a table, it takes about several seconds to load the partitions in the table. You can
perform operations on the table only after the partitions are loaded.
        table_options is an instance of the tablestore.metadata.TableOptions class. table
_options contains the time_to_live, max_version, and max_time_deviation parameters.
        reserved_throughput is an instance of the tablestore.metadata.ReservedThroughput
class. reserved_throughput specifies the reserved read throughput and reserved write thro
ughput.
        Return value: none.
        def create_table(self, table_meta, reserved_throughput):
```

- Examples

  The following code provides an example on how to create a table. In this example, a table that contains two primary key columns is created. time_to_live is set to 31,536,000 seconds (one year), max_version to 3, max_time_deviation to 86,400 seconds (one day), and reserved_throughput to (0,0).

```
    # Create a schema for the primary key columns, including the quantity, names, and dat
a types of primary keys.
    # The first primary key column is of the integer type and named pk0. The first primar
y key column is partition key.
    # The second primary key column is of the integer type and named pk1. The data type i
s specified as integer in this example. You can also set the data type to string or binar
y.
    schema_of_primary_key = [('pk0', 'INTEGER'), ('pk1', 'INTEGER')]
    # Create a table_meta instance based on the table name and the schema of primary key
columns.
    table_meta = TableMeta('SampleTable', schema_of_primary_key)
    # Create a TableOptions instance. Set time_to_live to 31,536,000 seconds (one year) a
nd delete expired data, max_version to 3, and max_time_deviation to 86,400 seconds (one d
ay).
    table_options = TableOptions(31536000, 3, 86400)
    # Set both the reserved read throughput and reserved write throughput to 0.
    reserved_throughput = ReservedThroughput(CapacityUnit(0, 0))
    # Call the create_table method of the client. If no exceptions occur, the table is cr
eated. If an exception occurs, the table fails to be created.
    try:
        ots_client.create_table(table_meta, table_options, reserved_throughput)
        print "create table succeeded"
    # If the task fails, an exception is returned and handled.
    except Exception:
        print "create table failed."
```

  For the detailed sample code, visit CreateTable@GitHub.

ListTable

You can call this operation to obtain the names of all tables created in the current instance.

- API operation

```
```

- Examples

  The following code provides an example on how to obtain the names of all tables in an instance.

```
    try:
        list_response = ots_client.list_table()
        print 'table list:'
        for table_name in list_response:
            print table_name
        print "list table succeeded"
    except Exception:
        print "list table failed."
```

  For the detailed sample code, visit ListTable@GitHub.

UpdateTable

You can call this operation to update the maximum number of versions and the reserved read/write throughput of a table.

- API operation

```
    """
        Description: You can call this method to update the attributes of a table. This m
ethod can modify only the reserved read/write throughput of a table.
        ``table_name`` specifies the name of the table.
        ``table_options`` is an instance of the ``tablestore.metadata.TableOptions`` clas
s. It contains the time_to_live, max_version, and max_time_deviation parameters.
        ``reserved_throughput`` is an instance of the ``ots2.metadata.ReservedThroughput`
` class. It specifies the reserved read throughput and reserved write throughput.
        Return value: the time when the reserved read throughput or reserved write throug
hput was raised or lowered most recently for this table and the number of times it was lo
wered today.
        ``update_table_response`` indicates the update result. It is an instance of the o
ts2.metadata.UpdateTableResponse class.
        """
        def update_table(self, table_name, table_options, reserved_throughput):
```

- Examples

  The following code provides an example on how to update the maximum number of versions of a table to five.

```
        # Set both the reserved read throughput and reserved write throughput to 0.
        reserved_throughput = ReservedThroughput(CapacityUnit(0, 0))
        # Create a TableOptions instance. Set time_to_live to 31536000 seconds (one year)
and delete expired data, max_version to 3, and max_time_deviation to 86400 seconds (one d
ay).
        table_options = TableOptions(31536000, 5, 86400)
        try:
            # Call the operation to update the reserved read/write throughput of the tabl
e.
            ots_client.update_table('SampleTable', reserved_throughput)
            # If the task succeeds, no exception is returned.
            print "update table succeeded"
        except Exception:
            # If the task fails, an exception is returned and handled.
            print "update table failed"
```

For the detailed sample code, visit UpdateTable@GitHub.

DescribeTable

You can call this operation to query the structure information and reserved read/write throughput value of the specified table.

- API operation

```
        """
        Description: You can call this method to obtain the description of a table.
        ``table_name`` specifies the name of the table.
        Return value: the description of the table.
        ``describe_table_response`` indicates the description of the table, which is an i
nstance of the ots2.metadata.DescribeTableResponse class.
        """
        def describe_table(self, table_name):
```

- Examples

  The following code provides an example on how to obtain the description of a table.

```
    try:
        describe_response = ots_client.describe_table('myTable')
        # If no exception is returned, the description is obtained and the following info
rmation is displayed.
        print "describe table succeeded."
        print ('TableName: %s' % describe_response.table_meta.table_name)
        print ('PrimaryKey: %s' % describe_response.table_meta.schema_of_primary_key)
        print ('Reserved read throughput: %s' % describe_response.reserved_throughput_det
ails.capacity_unit.read)
        print ('Reserved write throughput: %s' % describe_response.reserved_throughput_de
tails.capacity_unit.write)
        print ('Last increase throughput time: %s' % describe_response.reserved_throughpu
t_details.last_increase_time)
        print ('Last decrease throughput time: %s' % describe_response.reserved_throughpu
t_details.last_decrease_time)
        print ('table options\'s time to live: %s' % describe_response.table_options.time
_to_live)
        print ('table options\'s max version: %s' % describe_response.table_options.max_v
ersion)
        print ('table options\'s max_time_deviation: %s' % describe_response.table_option
s.max_time_deviation)
    except Exception:
        # If the task fails, an exception is returned and handled.
        print "describe table failed."
```

For the detailed sample code, visit DescribeTable@GitHub.

DeleteTable

You can call this operation to delete a specified table from the current instance.

- API operation

```
        """
        Description: You can call this method to delete a table based on the table name.
        ``table_name`` specifies the name of the table.
        Return value: none.
        """
        def delete_table(self, table_name):
```

- Examples

  The following code provides an example on how to delete a table.

```
try:
    # Call the operation to delete the table named SampleTable.
    ots_client.delete_table('SampleTable')
    # If the task succeeds, no exception is returned.
    print "delete table succeeded"
    # If the task fails, an exception is returned and handled.
except Exception:
    print "delete table failed"
```

For the detailed sample code, visit DeleteTable@GitHub.

Single-row operations

Tablestore SDK for Python provides the following single-row operations: PutRow, GetRow, UpdateRow, and DeleteRow.

PutRow

You can call this operation to insert a row of data. If this row already exists, it is overwritten.

- API operation

```
        """
        Description: This operation writes a single row of data. Thu number of capacity u
nites (CUs) consumed by the operation is returned.
        table_name specifies the name of the table.
        row specifies the row you want to insert to the table, including a primary key an
d attribute columns.
        condition is an instance of the tablestore.metadata.Condition class. By specifyin
g conditions, the system checks whether the specified conditions are met before the syste
m performs the operation. If the conditions are met, the operation is performed. This fun
ction supports only row existence checks. Check conditions include IGNORE, EXPECT_EXIST,
and EXPECT_NOT_EXIST.
        return_type specifies the data type to return. return_type is an instance of the
tablestore.metadata.ReturnType class. You can only use return_type to specify the type of
primary key data to return. This parameter applies to auto-increment primary key columns.
        Response: the number of capacity units (CUs) consumed by this operation and the r
ow data to return.
        consumed is an instance of the tablestore.metadata.CapacityUnit class.  This para
meter indicates the number of CUs consumed by this operation.
        return_row indicates the row to return, including the primary key and attribute c
olumns.
        """
        def put_row(self, table_name, row, condition = None, return_type = None)
```

- Examples

  The following code provides an example on how to insert a row of data:

  > **Note**
  > - RowExistenceExpectation.IGNORE indicates that a row of data is inserted regardless of whether the specified row exists or not. If the specified row exists, the existing data is overwritten.
  > - RowExistenceExpectation.EXPECT_EXIST indicates that a row of data is inserted only when the specified row exists. The existing data is overwritten.
  > - RowExistenceExpectation.EXPECT_NOT_EXIST indicates that a row of data is inserted only when the specified row does not exist.
  > - In the following example, the data version in the age attribute column is 1498184687000, which indicates June 23, 2017. If the current time minus max_time_deviation (specified during table creation) is greater than 1498184687000, PutRow is disabled.

```
    ## The first primary key column of the primary key is gid and its value is the intege
r 1. The second primary key column is uid and its value is the integer 101.
    primary_key = [('gid',1), ('uid',101)]
    ## Insert the following attribute columns:
    ##                       The name of the first attribute column is name and its valu
e is the string John. The version is not specified, so the current system time is used as
the version.
    ##                       The name of the second attribute column is mobile and its v
alue is the integer 15100000000. The version is not specified, so the current system time
is used as the version.
    ##                       The name of the third attribute column is address and its v
alue is the binary string China. The version is not specified, so the current system time
is used as the version.
    ##                       The name of the fourth attribute column is age and its valu
e is 29.7. The version number is 1498184687.
    attribute_columns = [('name','John'), ('mobile',15100000000),('address', bytearray('C
hina')),('female', False), ('age', 29.7, 1498184687000)]
    ## Construct a row by using primary_key and attribute_columns.
    row = Row(primary_key, attribute_columns)
    # The condition for row check is that the expected row does not exist. If the specifi
ed row exists, the Condition Update Failed error occurs.
    condition = Condition(RowExistenceExpectation.EXPECT_NOT_EXIST)
    try :
        # If ReturnType is not specified when you call the put_row method, the value of r
eturn_row is None.
        consumed, return_row = client.put_row(table_name, row, condition)
        # The write CUs consumed by this request is displayed.

GetRow

You can call this opertaion to read a row of data.

The following results of the read request may be returned:

- If the row exists, the primary key columns and attribute columns of the row are returned.
- If the row does not exist, no row is returned and no error is reported.
- API operation

```
        """
        Description: This operation reads a single row of data.
        table_name specifies the name of the table.
        primary_key specifies the primary key. Type: list.
        columns_to_get is optional. This parameter specifies the columns to read. If you
do not specify this parameter, all columns are read. Type: list.
        column_filter is optional. This parameter specifies the filter conditions for col
umns. Only rows that meet the condition are returned.
        max_version is optional. This parameter specifies the maximum number of versions
that can be read. You must specify at least one of max_version and time_range.
        time_range is optional. This parameter specifies a range of versions to read or a
version of data to read. You must specify at least one of max_version and time_range.
        Response: the number of CUs consumed by this operation and the primary key column
s and attribute columns.
        consumed is an instance of the tablestore.metadata.CapacityUnit class. This param
eter indicates the number of CUs consumed by this operation.
        return_row indicates the row to return, including the primary key and attribute c
olumns. Type: list. Example: [('PK0',value0), ('PK1',value1)].
        next_token indicates the start column of a wide row to read next time. The data t
ype of the column is binary.
        """
        def get_row(self, table_name, primary_key, columns_to_get=None,

UpdateRow

You can call this operation to update data of a specified row. You can add or delete attribute columns of a row, delete a specified version of data from an attribute column, or update the existing data in an attribute column. If the row does not exist, a new row is added.

> **Note** If the UpdateRow request only contains columns to delete, and the specified row does not exist, a new row is not added.

- API operation

```
        """
        Description: This operation updates a single row of data.
        table_name specifies the name of the table.
        row specifies the row you want to delete, including a primary key and attribute c
olumns of the list type.
        condition is an instance of the tablestore.metadata.Condition class. By specifyin
g conditions, the system checks whether the specified conditions are met before the syste
m performs the operation. If the conditions are met, the operation is performed. This fun
ction supports row existence and column conditions checks. Check conditions for row inclu
de IGNORE, EXPECT_EXIST, and EXPECT_NOT_EXIST.
        return_type specifies the data type to return. return_type is an instance of the
tablestore.metadata.ReturnType class. You can only use return_type to specify the type of
primary key data to return. This parameter applies to auto-increment primary key columns.
        Response: the number of CUs consumed by this operation and the row data that is s
pecified by return_row to return.
        consumed is an instance of the tablestore.metadata.CapacityUnit class. This param
eter indicates the number of CUs consumed by this operation.
        return_row indicates the row to return.
        """
        def update_row(self, table_name, row, condition, return_type = None)
```

- Examples

  The following code provides an example on how to update the data of a specified row:

```
    # The first primary key column of the primary key is uid and its value is the integer 1. The second primary key column is gid and its value is the integer 101.
    primary_key = [('uid',1), ('gid',101)]
    # The update types include PUT, DELETE, and DELETE_ALL.
    # PUT: adds a value to the column or updates the existing value in the column. In the example, two columns are added. The first column is name and its value is David. The second column is address and its value is Hongkong.
    # DELETE: deletes a specified version (timestamp) of data. In this example, data of the 1488436949003 version in the address column is deleted.
    # DELETE_ALL: deletes the column. In the example, the date of all versions in the mobile and age columns are deleted.
    update_of_attribute_columns = {
        'PUT' : [('name','David'), ('address','Hongkong')],
        'DELETE' : [('address', None, 1488436949003)],
        'DELETE_ALL' : [('mobile'), ('age')],
    }

        print "update row failed, http_status:%d, error_code:%s, error_message:%s, reques
t_id:%s" % (e.get_http_status(), e.get_error_code(), e.get_error_message(), e.get_request
_id())
    print ('Delete succeed, consume %s write cu.' % consumed.write)
```

  For the detailed sample code, visit DeleteRow@GitHub.

Multi-row operations

Tablestore SDK for Python provides multi-row operations, such as BatchGetRow, BatchWriteRow, and GetRange.

BatchGetRow

You can call this operation to read several rows of data from one or more tables.

The BatchGetRow operation is a set of multiple GetRow operations. The execution, returning of results, and capacity unit (CU) consumption of each individual operation are carried out independently.

Compared with the execution of a large number of GetRow operations, the use of BatchGetRow can reduce the response time for requests and increase the data read rate.

- API operation

```
        """
        Description: This operation reads the specified rows of data.
        request = BatchGetRowRequest()
        request.add(TableInBatchGetRowItem(myTable0, primary_keys, column_to_get=None, co
lumn_filter=None))
        request.add(TableInBatchGetRowItem(myTable1, primary_keys, column_to_get=None, co
lumn_filter=None))
        request.add(TableInBatchGetRowItem(myTable2, primary_keys, column_to_get=None, co
lumn_filter=None))
        request.add(TableInBatchGetRowItem(myTable3, primary_keys, column_to_get=None, co
lumn_filter=None))
        response = client.batch_get_row(request)
        response: the response to the request. Type: tablestore.metadata.BatchGetRowRespo
nse
        """
        def batch_get_row(self, request):
```

- Examples

  The following code provides an example on how to read three rows of data at a time:

```
    # Specify the columns to return.
    columns_to_get = ['name', 'mobile', 'address', 'age']
    # Read three rows of data.
    rows_to_get = []
    for i in range(0, 3):
        primary_key = [('gid',i), ('uid',i+1)]
        rows_to_get.append(primary_key)
    # Configure filtering conditions. Set name to John and address to China.
    cond = CompositeColumnCondition(LogicalOperator.AND)
    cond.add_sub_condition(SingleColumnCondition("name", "John", ComparatorType.EQUAL))
    cond.add_sub_condition(SingleColumnCondition("address", 'China', ComparatorType.EQUAL
))
    # Create a request to read multiple rows.
    request = BatchGetRowRequest()
    # Add rows to read from table_name. The 1 parameter specifies that the latest version
is read.
    request.add(TableInBatchGetRowItem(table_name, rows_to_get, columns_to_get, cond, 1))
    # Add rows to read from notExistTable.
    request.add(TableInBatchGetRowItem('notExistTable', rows_to_get, columns_to_get, cond
, 1))
    try:
           result = client.batch_get_row(request)
        print ('Result status: %s'%(result.is_all_succeed()))
        table_result_0 = result.get_result_by_table(table_name)
        table_result_1 = result.get_result_by_table('notExistTable')
        print ('Check first table\'s result:')
        for item in table_result_0:
            if item.is_ok:
                print ('Read succeed, PrimaryKey: %s, Attributes: %s' % (item.row.primary
_key, item.row.attribute_columns))
            else:
                print ('Read failed, error code: %s, error message: %s' % (item.error_cod
e, item.error_message))
        print ('Check second table\'s result:')
        for item in table_result_1:
            if item.is_ok:
                print ('Read succeed, PrimaryKey: %s, Attributes: %s' % (item.row.primary
_key, item.row.attribute_columns))
            else:
                print ('Read failed, error code: %s, error message: %s' % (item.error_cod
e, item.error_message))
    # Client exceptions are caused by parameter errors or network exceptions.
    except OTSClientError as e:
        print "get row failed, http_status:%d, error_message:%s" % (e.get_http_status(),
e.get_error_message())
    # Server exceptions are caused by parameter or throttling errors.
    except OTSServiceError as e:
        print "get row failed, http_status:%d, error_code:%s, error_message:%s, request_i
d:%s" % (e.get_http_status(), e.get_error_code(), e.get_error_message(), e.get_request_id
())
```

For the detailed sample code, visit BatchGetRow@GitHub.

BatchWriteRow

You can call this operation to insert, modify, or delete several rows of data in one or more tables.

The BatchWriteRow operation is a set of multiple PutRow, UpdateRow, and DeleteRow operations. The execution, returning of results, and CU consumption of each individual operation are carried out independently.

- API operation

```
        """
        Description: This operation writes data to multiple rows.
        request = MiltiTableInBatchWriteRowItem()
        request.add(TableInBatchWriteRowItem(table0, row_items))
        request.add(TableInBatchWriteRowItem(table1, row_items))
        response = client.batch_write_row(request)
        response indicates the returned result. Type: tablestore.metadata.BatchWriteRowRe
sponse.
        """
        def batch_write_row(self, request):
```

- Examples

  The following code provides an example on how to write multiple rows of data.

```
    put_row_items = []
    # Add rows for PutRow.
    for i in range(0, 10):
        primary_key = [('gid',i), ('uid',i+1)]
        attribute_columns = [('name','somebody'+str(i)), ('address','somewhere'+str(i)),
('age',i)]
        row = Row(primary_key, attribute_columns)
        condition = Condition(RowExistenceExpectation.IGNORE)
        item = PutRowItem(row, condition)
        put_row_items.append(item)
    # Add rows for UpdateRow.
    for i in range(10, 20):

GetRange

You can call this operation to read data within the specified primary key range.

- API operation

```
        """
        Description: This operation reads data from multiple rows within the specified ra
nge.
        table_name: the name of the table.
        direction: the order for this query. Data type: string. Valid values: FORWARD and
BACKWARD.
        inclusive_start_primary_key: the primary key column from which the read starts. I
f the specified row exists, the row is included in the response.
        exclusive_end_primary_key: the primary key column at which the read ends. The end
primary key column is excluded from the response even if the row exists.
        columns_to_get: optional. This parameter specifies the names of columns to read.
If you do not specify this parameter, all columns are read. Type: list.
        limit: optional. This parameter specifies the maximum number of rows to read. If
you do not specify this parameter, all rows are read.
        column_filter: optional. This parameter specifies the filter conditions for colum
ns. Only rows that meet the condition are returned.
        max_version: optional. This parameter specifies the maximum number of versions to
return. You must specify at least one of max_version and time_range.
        time_range: optional. This parameter specifies the range of versions from which d
ata is read. You must specify at least one of max_version and time_range.
        start_column: optional. This parameter specifies the column from which the read s
tarts, which is used to read wide rows.
        end_column: optional. This parameter specifies the column at which the read ends,
which is used to read wide rows.
        token: optional. This parameter specifies the start column of a wide row to read
next time. The value of this parameter is returned by the last read request, and encoded
as binary data.
        Response: the results that meet the conditions.
        consumed: the number of CUs consumed by this operation. This parameter specifies
an instance of the tablestore.metadata.CapacityUnit class.
        next_start_primary_key indicates the primary key column from which you want to st
art the next get_range operation. Type: dict.
        row_list indicates the list of returned rows of data. Format: [Row, ...].
        """
   def get_range(self, table_name, direction,
                 inclusive_start_primary_key,

                max_version = 1
                time_range = (1557125059000, 1557129059000) # The start_time value is equ
al to or greater than 1557125059000. The end_time value is smaller than 1557129059000.
    )
        all_rows = []
        all_rows.extend(row_list)
        # If the next_start_primary_key value is not None, the read continues until all r
emaining data is read.
        while next_start_primary_key is not None:
            inclusive_start_primary_key = next_start_primary_key
            consumed, next_start_primary_key, row_list, next_token = client.get_range(
                table_name, Direction.FORWARD,
                inclusive_start_primary_key, exclusive_end_primary_key,
                columns_to_get, limit,
                column_filter = cond,
                max_version = 1
        )
            all_rows.extend(row_list)
        # Display the primary key and attribute columns.
        for row in all_rows:
            print (row.primary_key, row.attribute_columns)
        print ('Total rows: ', len(all_rows))
    # Client exceptions are caused by parameter errors or network exceptions.
    except OTSClientError as e:
        print "get row failed, http_status:%d, error_message:%s" % (e.get_http_status(),
e.get_error_message())
    # Server exceptions are caused by parameter or throttling errors.
    except OTSServiceError as e:
        print "get row failed, http_status:%d, error_code:%s, error_message:%s, request_i
d:%s" % (e.get_http_status(), e.get_error_code(), e.get_error_message(), e.get_request_id
())
```

For the detailed sample code, visit GetRange@GitHub.

Global secondary indexes

This topic describes how to create and delete a global secondary index.

Create a global secondary index

You can create a global secondary index when you create a table. You can also create a global secondary index for an existing table.

The fields of a global secondary index must be specified in defined_columns when you create a table.

- Create a global secondary index when you create a table

```
schema_of_primary_key = [('gid', 'INTEGER'), ('uid', 'STRING')]
defined_columns = [('i', 'INTEGER'), ('bool', 'BOOLEAN'), ('d', 'DOUBLE'), ('s', 'STRING'
), ('b', 'BINARY')]
table_meta = TableMeta(table_name, schema_of_primary_key, defined_columns)
table_option = TableOptions(-1, 1)
reserved_throughput = ReservedThroughput(CapacityUnit(0, 0))
secondary_indexes = [
    SecondaryIndexMeta('index1', ['i', 's'], ['bool', 'b', 'd']),
    ]
client.create_table(table_meta, table_option, reserved_throughput, secondary_indexes)
```

- Create a global secondary index for an existing table

```
index_meta = SecondaryIndexMeta('index2', ['i', 's'], ['bool', 'b', 'd'])
client.create_secondary_index(table_name, index_meta)
```

Delete a global secondary index

Delete an index table.

```
client.delete_secondary_index(table_name, 'index1')
```

7.1.2.1.2.5. Error handling

This topic describes the error handling methods and retry policies in Tablestore SDK for Python.

Methods

Tablestore SDK for Python handles errors as exceptions. If the operation succeeds, the called operation does not return an exception. If the operation fails, an exception is returned.

> **Note** Batch operations such as BatchGetRow and BatchWriteRow can be called only after the system verifies that no exception is returned and that the status of each row is successful.

Exceptions

Tablestore SDK for Python has two types of exceptions: OTSClientError and OTSServiceError. Both are inherited from Exception.

- OTSClientError: an internal SDK exception, such as an invalid parameter value or a failure to parse the results returned by the server.

- OTSServiceError: a server error that comes from the resolution of a server error message. OTSServiceError contains the following parameters:
  - get_http_status: an HTTP status code, such as 200 and 404.
  - get_error_code: an error type string returned by Tablestore.
  - get_error_message: an error message string returned by Tablestore.
  - get_request_id: the UUID that identifies a request. If you cannot solve the problem, record this request ID and contact Tablestore technical support for help.

Retry

- Tablestore SDK for Python automatically retries an operation when an error occurs. In the default retry policy, the maximum retry attempts is 20, and the maximum retry interval is 3,000 ms. For more information about the retry policies for throttling errors and internal server errors related to write operations, see tablestore/retry.py.
- You can also customize a retry policy by inheriting the RetryPolicy class, and configure the custom retry policy when you create an OTSClient object.

Tablestore SDK for Python provides the following retry policies:

- DefaultRetryPolicy: the default retry policy. Only read operations are retried. The maximum retry attempts is 20, and the maximum retry interval is 3,000 ms.
- NoRetryPolicy: no operation is retried.
- NoDelayRetryPolicy: a retry policy without any delays. Exercise caution when you configure this policy.
- WriteRetryPolicy: the write operations are retried based on the default retry policy.

7.1.2.1.3. Go SDK

7.1.2.1.3.1. Preface

This topic describes how to install and use Tablestore SDK for Go.

Prerequisites

An authorized account is created, and an AccessKey pair (AccessKey ID and AccessKey secret) is obtained. For more information about how to obtain and view your AccessKey pair in the Apsara Uni-manager Management Console, see Obtain an AccessKey pair.

Download and install Tablestore SDK for Go

- For the download path of SDK for Go, visit SDK package (including package, source code and examples).
- For more information about how to install Tablestore SDK for Go, see Installation.

Version

Latest version: 5.0.2

7.1.2.1.3.2. Installation

This topic describes how to install Tablestore SDK for Go.

Preparations

Go 1.4 or later is available.

Installation methods

Run the following command to install Tablestore SDK for Go:

```
    go get github.com/aliyun/aliyun-tablestore-go-sdk
```

7.1.2.1.3.3. Initialization

TableStoreClient provides a series of methods for users to manage tables and perform read/write operations on a single row or multiple rows.

Obtain an endpoint

An endpoint is the domain name that is used to access a Tablestore instance in a region. To query an endpoint, perform the following operations:

1. Log on to the Tablestore console.
2. Click the instance name to go to the **Instance Management** page.

   On the Instance Details tab, you can view the endpoints of the instance in Instance Access URL.

Configure an AccessKey pair

To access Apsara Stack Tablestore, you must have a valid AccessKey pair (AccessKey ID and AccessKey secret) for signature authentication.

After you obtain the AccessKey pair, you can perform the following operation to initialize an OTSClient instance by using an endpoint:

- API operation

```
    // Initialize the TableStoreClient instance.
    // endPoint indicates the endpoint used to access the Tablestore instance, which must start with https://. Example: https://instance.cn-hangzhou.ots.aliyun.com:80.
    // accessKeyId indicates the AccessKey ID used to access the Tablestore instance. You can visit the official website or contact an administrator to obtain an AccessKey ID.
    // accessKeySecret indicates the AccessKey secret used to access the Tablestore instance. You can visit the official website or contact an administrator to obtain an AccessKey secret.
    // instanceName indicates the name of the instance to access. You can create an instance in the Tablestore console or contact an administrator to obtain the name of an existing instance.
func NewClient(endPoint, instanceName, accessKeyId, accessKeySecret string, options ...ClientOption) *TableStoreClient
```

- Examples

```
    client = NewClient("your_instance_endpoint", &amp;nbsp;"your_instance_name", "your_user_id", "your_user_key")
```

7.1.2.1.3.4. Use the SDK

Table-level operations

Tablestore SDK for Go provides the following table-level operations: CreateTable, ListTable, DeleteTable, UpdateTable, and DescribeTable.

CreateTable

You can call this operation to create a table based on the specified table structure.

> **Note**
> - After a table is created, it takes several seconds to load the table. During this period, the read and write operations on the table may fail. You can use applications to perform operations on the table data only after the table is loaded.
> - You must specify the primary key when you create a table. A primary key can contain one to four primary key columns. Each primary key column has a name and a data type.

- API operation

```
  // Create a table based on the specified table structure.
  // request is an instance of the CreateTableRequest class, which contains tablemeta, Ta
bleOption, and ReservedThroughput.
  // For more information, see the documentation of the TableMeta class.
  After you create a table, it takes several seconds to load the partitions in the table.
You can perform operations on the table only after the partitions are loaded.
  // Response: CreateTableResponse
        CreateTable(request *CreateTableRequest) (*CreateTableResponse, error)
```

- Examples

  The following code provides an example on how to create a table that contains two primary key columns and a reserved read/write throughput of (0,0):

```
 //Create a schema for the primary key columns, which includes the quantity, names, and t
ypes of primary key columns.
 //The first primary key column is named pk0 and requires an integer value. The first pri
mary key column is also the partition key.
 //The second primary key column is named pk1 and requires an integer value.
 tableMeta := new(tablestore.TableMeta)
 tableMeta.TableName = tableName
 tableMeta.AddPrimaryKeyColumn("pk0", tablestore.PrimaryKeyType_INTEGER)
 tableMeta.AddPrimaryKeyColumn("pk1", tablestore.PrimaryKeyType_STRING)
 tableOption := new(tablestore.TableOption)
 tableOption.TimeToAlive = -1
 tableOption.MaxVersion = 3
 reservedThroughput := new(tablestore.ReservedThroughput)
 reservedThroughput.Readcap = 0
 reservedThroughput.Writecap = 0
 createtableRequest.TableMeta = tableMeta
 createtableRequest.TableOption = tableOption
 createtableRequest.ReservedThroughput = reservedThroughput
 response, err = client.CreateTable(createtableRequest)
 if (err != nil) {
     fmt.Println("Failed to create table with error:", err)
 } else {
    fmt.Println("Create table finished")
 }
```

For the detailed sample code, visit CreateTable@GitHub.

ListTable

You can call this operation to obtain the names of all tables created in the current instance.

- API operation

```
// List all tables. If the operation succeeds, names of all tables are returned.
ListTable() (*ListTableResponse, error)
```

- Examples

  The following code provides an example of how to obtain the names of all tables in an instance.

```
tables, err := client.ListTable()
if err != nil {
    fmt.Println("Failed to list table")
} else {
    fmt.Println("List table result is")
    for _, table := range (tables.TableNames) {
        fmt.Println("TableName: ", table)
    }
}
```

For the detailed sample code, visit ListTable@GitHub.

UpdateTable

You can use the UpdateTable API to update the reserved read/write throughput settings of the specified table.

- API operation

```
// Update the configurations of tableoptions and reservedthroughput for a table.
UpdateTable(request *UpdateTableRequest) (*UpdateTableResponse, error)
```

- Examples

  The following code provides an example on how to update the setting of MaxVersion of a table to 5:

```
updateTableReq := new(tablestore.UpdateTableRequest)
updateTableReq.TableName = tableName
updateTableReq.TableOption = new(tablestore.TableOption)
updateTableReq.TableOption.TimeToAlive = -1
updateTableReq.TableOption.MaxVersion = 5
_, err := client.UpdateTable(updateTableReq)
if (err != nil) {
    fmt.Println("failed to update table with error:", err)
} else {
    fmt.Println("update finished")
}
```

  For the detailed sample code, visit UpdateTable@GitHub.

DescribeTable

You can call this operation to query the structure information and the reserved read/write throughput settings of a table.

- API operation

```
// Query the description of a table by using the table name.
DescribeTable(request *DescribeTableRequest) (*DescribeTableResponse, error)
```

- Examples

  The following code provides an example on how to obtain the description of a table:

```
describeTableReq := new(tablestore.DescribeTableRequest)
describeTableReq.TableName = tableName
describ, err := client.DescribeTable(describeTableReq)
if err != nil {
    fmt.Println("failed to update table with error:", err)
} else {
    fmt.Println("DescribeTableSample finished. Table meta:", describ.TableOption.MaxVersi
on, describ.TableOption.TimeToAlive)
}
```

For the detailed sample code, visit DescribeTable@GitHub.

DeleteTable

You can call this operation to delete a specified table from the current instance.

- API operation

```
DeleteTable(request *DeleteTableRequest) (*DeleteTableResponse, error)
```

- Examples

  The following code provides an example on how to delete a table:

```
deleteReq := new(tablestore.DeleteTableRequest)
deleteReq.TableName = tableName
_, err := client.DeleteTable(deleteReq)
if (err != nil) {
    fmt.Println("Failed to delete table with error:", err)
} else {
    fmt.Println("Delete table finished")
}
```

  For the detailed sample code, visit DeleteTable@GitHub.

Single-row operations

Tablestore SDK for Go provides the following single-row operations: PutRow, GetRow, UpdateRow, and DeleteRow.

PutRow

You can call this operation to insert data into a specified row.

- API operation

```
    // @param PutRowRequest    Encapsulate the parameters required to perform the PutRow operation.
    // @return PutRowResponse
    PutRow(request *PutRowRequest) (*PutRowResponse, error)
```

- Examples

  The following code provides an example on how to insert a row of data:

  > **Note**
  > - RowExistenceExpectation.IGNORE indicates that new data is inserted into a row despite whether the specified row exists or not. If the specified row exists, the existing data is overwritten.
  > - RowExistenceExpectation.EXPECT_EXIST indicates that new data is inserted only when the specified row exists. The existing data is overwritten.
  > - RowExistenceExpectation.EXPECT_NOT_EXIST indicates that data is inserted only when the specified row does not exist.

```
    putRowRequest := new(tablestore.PutRowRequest)
    putRowChange := new(tablestore.PutRowChange)
    putRowChange.TableName = tableName
    putPk := new(tablestore.PrimaryKey)
    putPk.AddPrimaryKeyColumn("pk1", "pk1value1")
    putPk.AddPrimaryKeyColumn("pk2", int64(2))
    putPk.AddPrimaryKeyColumn("pk3", []byte("pk3"))
    putRowChange.PrimaryKey = putPk
    putRowChange.AddColumn("col1", "col1data1")
    putRowChange.AddColumn("col2", int64(3))
    putRowChange.AddColumn("col3", []byte("test"))
    putRowChange.SetCondition(tablestore.RowExistenceExpectation_IGNORE)
    putRowRequest.PutRowChange = putRowChange
    _, err := client.PutRow(putRowRequest)
    if err != nil {
        fmt.Println("putrow failed with error:", err)
    } else {
        fmt.Println("putrow finished")
    }
```

For the detailed sample code, visit PutRow@GitHub.

GetRow

You can call this operation to read a single row of data based on a specified primary key.

```
    //Return a row of data from a table.
    //
    // @param GetRowRequest             Encapsulate the parameters required to perform th
e GetRow operation.
    // @return  GetRowResponse          The content of the response to the GetRow operati
on.
    GetRow(request *GetRowRequest) (*GetRowResponse, error)
```

- Examples

  The following code provides an example on how to read a row of data:

```
getRowRequest := new(tablestore.GetRowRequest)
    criteria := new(tablestore.SingleRowQueryCriteria);
    putPk := new(tablestore.PrimaryKey)
    putPk.AddPrimaryKeyColumn("pk1", "pk1value1")
    putPk.AddPrimaryKeyColumn("pk2", int64(2))
    putPk.AddPrimaryKeyColumn("pk3", []byte("pk3"))
    criteria.PrimaryKey = putPk
    getRowRequest.SingleRowQueryCriteria = criteria
    getRowRequest.SingleRowQueryCriteria.TableName = tableName
    getRowRequest.SingleRowQueryCriteria.MaxVersion = 1
    getResp, err := client.GetRow(getRowRequest)
    if err != nil {
        fmt.Println("getrow failed with error:", err)
    } else {
        fmt.Println("get row col0 result is ", getResp.Columns[0].ColumnName, getResp.Col
umns[0].Value)
    }
```

For the detailed sample code, visit GetRow@GitHub.

UpdateRow

You can call this operation to update the data of a specified row. If the row does not exist, a new row is added. If the row exists, the values of the specified columns are added, modified, or deleted based on the request content.

- API operation

```
    // Update a row of data in a table.
    // @param UpdateRowRequest      Encapsulate the parameters required to perform the Up
dateRow operation.
    // @return UpdateRowResponse    The content of the response to the UpdateRow operatio
n.
    UpdateRow(request *UpdateRowRequest) (*UpdateRowResponse, error)
```

- Examples

  The following code provides an example on how to update the data of a specified row:

```
    updateRowRequest := new(tablestore.UpdateRowRequest)
    updateRowChange := new(tablestore.UpdateRowChange)
    updateRowChange.TableName = tableName
    updatePk := new(tablestore.PrimaryKey)
    updatePk.AddPrimaryKeyColumn("pk1", "pk1value1")
    updatePk.AddPrimaryKeyColumn("pk2", int64(2))
    updatePk.AddPrimaryKeyColumn("pk3", []byte("pk3"))
    updateRowChange.PrimaryKey = updatePk
    updateRowChange.DeleteColumn("col1")
    updateRowChange.PutColumn("col2", int64(77))
    updateRowChange.PutColumn("col4", "newcol3")
    updateRowChange.SetCondition(tablestore.RowExistenceExpectation_EXPECT_EXIST)
    updateRowRequest.UpdateRowChange = updateRowChange
    _, err := client.UpdateRow(updateRowRequest)
    if err != nil {
        fmt.Println("update failed with error:", err)
    } else {
        fmt.Println("update row finished")
    }
```

For the detailed sample code, visit UpdateRow@GitHub.

DeleteRow

You can call this operation to delete data you no longer need.

- API operation

```
    // Delete a row of data from a table.
    // @param DeleteRowRequest           Encapsulate the parameters required to perform t
he DeleteRow operation.
    // @return DeleteRowResponse         The content of the response to the DeleteRow ope
ration.
    DeleteRow(request *DeleteRowRequest) (*DeleteRowResponse, error)
```

- Examples

  The following code provides an example on how to delete a row of data:

```
    deleteRowReq := new(tablestore.DeleteRowRequest)
    deleteRowReq.DeleteRowChange = new(tablestore.DeleteRowChange)
    deleteRowReq.DeleteRowChange.TableName = tableName
    deletePk := new(tablestore.PrimaryKey)
    deletePk.AddPrimaryKeyColumn("pk1", "pk1value1")
    deletePk.AddPrimaryKeyColumn("pk2", int64(2))
    deletePk.AddPrimaryKeyColumn("pk3", []byte("pk3"))
    deleteRowReq.DeleteRowChange.PrimaryKey = deletePk
    deleteRowReq.DeleteRowChange.SetCondition(tablestore.RowExistenceExpectation_EXPECT_E
XIST)
    clCondition1 := tablestore.NewSingleColumnCondition("col2", tablestore.CT_EQUAL, int6
4(3))
    deleteRowReq.DeleteRowChange.SetColumnCondition(clCondition1)
    _, err := client.DeleteRow(deleteRowReq)
    if err != nil {
        fmt.Println("delete failed with error:", err)
    } else {
        fmt.Println("delete row finished")
    }
```

For the detailed sample code, visit DeleteRow@GitHub.

Multi-row operations

Tablestore SDK for Go provides multi-row operations such as BatchGetRow, BatchWriteRow, GetRange, and GetByIterator.

BatchGetRow

You can call this operation to simultaneously read multiple rows of data from one or more tables.

The BatchGetRow operation is a set of multiple GetRow operations. The execution, returning of results, and capacity unit (CU) consumption of each individual operation are carried out independently.

Compared with the execution of a large number of GetRow operations, the use of BatchGetRow can reduce the response time for requests and increase the data read rate.

- API operation

```
    // Return multiple rows of data from a table.
    //
    // @param BatchGetRowRequest            Encapsulate the parameters required to perfo
rm the BatchGetRow operation.
    // @return  BatchGetRowResponse         The content of the response to the BatchGetR
ow operation.
    BatchGetRow(request *BatchGetRowRequest) (*BatchGetRowResponse, error)
```

- Examples

  The following code provides an example on how to read 10 rows of data at a time:

  > **Note** You can use conditional statements to filter the returned results of BatchWriteRow operations.

```
batchGetReq := &tablestore.BatchGetRowRequest{}
mqCriteria := &tablestore.MultiRowQueryCriteria{}
for i := 0; i < 10; i++ {
    pkToGet := new(tablestore.PrimaryKey)
    pkToGet.AddPrimaryKeyColumn("pk1", "pk1value1")
    pkToGet.AddPrimaryKeyColumn("pk2", int64(i))
    pkToGet.AddPrimaryKeyColumn("pk3", []byte("pk3"))
    mqCriteria.AddRow(pkToGet)
    mqCriteria.MaxVersion = 1
}
mqCriteria.TableName = tableName
batchGetReq.MultiRowQueryCriteria = append(batchGetReq.MultiRowQueryCriteria, mqCriteria)
batchGetResponse, err := client.BatchGetRow(batchGetReq)
if err != nil {
    fmt.Println("batachget failed with error:", err)
} else {
    fmt.Println("batchget finished")
}
```

For the detailed sample code, visit BatchGetRow@GitHub.

BatchWriteRow

You can call this operation to simultaneously insert, modify, or delete multiple rows of data in one or more tables.

The BatchWriteRow operation is a set of multiple PutRow, UpdateRow, and DeleteRow operations. The execution, returning of results, and CU consumption of each individual operation are carried out independently.

- API operation

```
    // Add, delete, or modify multiple rows of data in multiple tables.
    //
    // @param BatchWriteRowRequest             Encapsulate the parameters required to per
form the BatchWriteRow operation.
    // @return  BatchWriteRowResponse          The content of the response to the BatchWr
iteRow operation.
    BatchWriteRow(request *BatchWriteRowRequest) (*BatchWriteRowResponse,error)
```

- Examples

  The following code provides an example on how to write 100 rows of data:

  > **Note** You can use conditional statements to filter the returned results of BatchWriteRow operations.

```
    batchWriteReq := &tablestore.BatchWriteRowRequest{}
    for i := 0; i < 100; i++ {
        putRowChange := new(tablestore.PutRowChange)
        putRowChange.TableName = tableName
        putPk := new(tablestore.PrimaryKey)
        putPk.AddPrimaryKeyColumn("pk1", "pk1value1")
        putPk.AddPrimaryKeyColumn("pk2", int64(i))
        putPk.AddPrimaryKeyColumn("pk3", []byte("pk3"))
        putRowChange.PrimaryKey = putPk
        putRowChange.AddColumn("col1", "fixvalue")
        putRowChange.SetCondition(tablestore.RowExistenceExpectation_IGNORE)
        batchWriteReq.AddRowChange(putRowChange)
    }
    response, err := client.BatchWriteRow(batchWriteReq)
    if err != nil {
        fmt.Println("batch request failed with:", response)
    } else {
        fmt.Println("batch write row finished")
    }
```

For the detailed sample code, visit BatchWriteRow@GitHub.

GetRange

You can call this operation to read data within a specified primary key range.

- API operation

```
    // Query multiple rows of data within a specified range in a table.
    //
    // @param GetRangeRequest            Encapsulate the parameters required to perform t
he GetRange operation.
    // @return GetRangeResponse          The content of the response to the GetRange oper
ation.
    GetRange(request *GetRangeRequest) (*GetRangeResponse,error)
```

- Examples

  The following code provides an example on how to read data within a specified range:

  > **Note**
  > - You can use conditional statements to filter the returned results of GetRange operations.
  > - Note that the data may be paged when you perform the GetRange operation.

```
getRangeRequest := &tablestore.GetRangeRequest{}
    rangeRowQueryCriteria := &tablestore.RangeRowQueryCriteria{}
    rangeRowQueryCriteria.TableName = tableName
    startPK := new(tablestore.PrimaryKey)
    startPK.AddPrimaryKeyColumnWithMinValue("pk1")
    startPK.AddPrimaryKeyColumnWithMinValue("pk2")
    startPK.AddPrimaryKeyColumnWithMinValue("pk3")
    endPK := new(tablestore.PrimaryKey)
    endPK.AddPrimaryKeyColumnWithMaxValue("pk1")
    endPK.AddPrimaryKeyColumnWithMaxValue("pk2")
    endPK.AddPrimaryKeyColumnWithMaxValue("pk3")
    rangeRowQueryCriteria.StartPrimaryKey = startPK
    rangeRowQueryCriteria.EndPrimaryKey = endPK
    rangeRowQueryCriteria.Direction = tablestore.FORWARD
    rangeRowQueryCriteria.MaxVersion = 1
    rangeRowQueryCriteria.Limit = 10
    getRangeRequest.RangeRowQueryCriteria = rangeRowQueryCriteria
    getRangeResp, err := client.GetRange(getRangeRequest)
    fmt.Println("get range result is " ,getRangeResp)
    for {
        if err != nil {
            fmt.Println("get range failed with error:", err)
        }
        for _, row := range getRangeResp.Rows {
            fmt.Println("range get row with key", row.PrimaryKey.PrimaryKeys[0].Value, ro
w.PrimaryKey.PrimaryKeys[1].Value, row.PrimaryKey.PrimaryKeys[2].Value)
        }
        if getRangeResp.NextStartPrimaryKey == nil {
            break
        } else {
            fmt.Println("next pk is :", getRangeResp.NextStartPrimaryKey.PrimaryKeys[0].V
alue, getRangeResp.NextStartPrimaryKey.PrimaryKeys[1].Value, getRangeResp.NextStartPrimar
yKey.PrimaryKeys[2].Value)
            getRangeRequest.RangeRowQueryCriteria.StartPrimaryKey = getRangeResp.NextStar
tPrimaryKey
            getRangeResp, err = client.GetRange(getRangeRequest)
        }
        fmt.Println("continue to query rows")
    }
    fmt.Println("putrow finished")
```

For the detailed sample code, visit GetRange@GitHub.

7.1.2.1.4. NodeJS SDK

7.1.2.1.4.1. Preface

This topic describes how to use Tablestore SDK for Node.js. The content in this topic applies to Tablestore SDK for Node.js V4.x.x.

Prerequisites

An authorized account is created, and an AccessKey pair (AccessKey ID and AccessKey secret) is obtained. For more information about how to obtain and view your AccessKey pair in the Apsara Uni-manager Management Console, see Obtain an AccessKey pair.

Download Tablestore SDK for Node.js

- SDK package
- GitHub

Version

Latest version: V4.1.0.

7.1.2.1.4.2. Installation

This topic describes how to install Tablestore SDK for Node.js.

Preparations

Node.js 4.0 or later is installed.

> **Note** We recommend that you do not use Node.js later than 12.0 and earlier than 12.14 to avoid compatibility problems.

Install Tablestore SDK for Node.js

Run the following command to install Tablestore SDK for Node.js:

```
npm install tablestore
```

> **Note** If you encounter any network problems when you use npm, you can use the npm image provided by Taobao.

Sample programs

Tablestore SDK for Node.js provides a variety of sample programs for your reference and use. You can obtain the sample programs by using one of the following methods:

- Download and decompress the Tablestore SDK for Node.js package. Find the sample programs in the examples folder.
- Access Tablestore SDK for Node.js on GitHub.

7.1.2.1.4.3. Initialization

TableStore.Client is the client for Tablestore. It provides a series of methods for you to perform operations on individual rows, multiple rows, or entire tables.

Obtain an endpoint

An endpoint is the domain name that is used to access a Tablestore instance in a region. To query an endpoint, perform the following operations:

1. Log on to the Tablestore console.
2. Click the instance name to go to the **Instance Management** page.

   On the Instance Details tab, you can view the endpoints of the instance in Instance Access URL.

Configure an AccessKey pair

To access Apsara Stack Tablestore, you must have a valid AccessKey pair (AccessKey ID and AccessKey secret) for signature authentication.

After you obtain the AccessKey pair, you can perform the following operation to initialize a Tablestore instance by using an endpoint:

```
var client = new TableStore.Client({
accessKeyId: '<your access key id>',
accessKeySecret: '<your access key secret>',
endpoint: '<your endpoint>',
instancename: '<your instance name>',
maxRetries:20,// The default number of retry attempts is 20. You can ignore this parameter.
    });
```

7.1.2.1.4.4. Data types

Tablestore supports five data types. This topic describes how each of these data types corresponds to those supported in Tablestore SDK for Node.js.

Data type in Tablestore	Data type in SDK for Node.js	Description
String	string	The basic data type in JavaScript.
Integer	int64	The type of data encapsulated by Node.js SDK.
Double	number	The basic data type in JavaScript.
Boolean	boolean	The basic data type in JavaScript.
Binary	Buffer	The Buffer object of Node.js.

The integer data in Tablestore is a 64-bit signed integer, which does not have a corresponding data type in JavaScript. Therefore, a data type that can indicate a 64-bit signed integer is required for Node.js. The following code provides an example on how to convert the integer data type of Tablestore:

```
var numberA = TableStore.Long.fromNumber(1000);
var numberB = TableStore.Long.fromString('2000');
var num = numberA.toNumber();
    num = numberA.toString();
var str = numberB.toNumber();
    str = numberB.toString();
```

7.1.2.1.4.5. Use the SDK

Table-level operations

Tablestore SDK for Node.js provides the following table-level operations: CreateTable, ListTable, DeleteTable, UpdateTable, and DescribeTable.

CreateTable

You can call this operation to create a table based on the specified table structure.

> **Note**
> - After the table is created, it can take several seconds to load the table. During this period, the read and write operations on the table may fail. You can use applications to perform operations on the table data only after the table is loaded.
> - You must specify the primary key when you create a table. A primary key can contain one to four primary key columns. Each primary key column has a name and a data type.

- API operation

```
/**
 * Create a table based on the specified table structure.
 */
createTable(params, callback)
```

- Examples

  The following code provides an example on how to create a table that has two primary key columns and a reserved read/write throughput of (0,0):

```
var client = require('./client');
var params = {
  tableMeta: {
    tableName: 'sampleTable',
    primaryKey: [
      {
        name: 'gid',
        type: 'INTEGER'
      },
      {
        name: 'uid',
        type: 'INTEGER'
      }
    ]
  },
  reservedThroughput: {
    capacityUnit: {
      read: 0,
      write: 0
    }
  },
  tableOptions: {
    timeToLive: -1,// Specify the validity period of data in seconds. A value of -1 indic
ates that the data never expires. If you set the validity period to a year, the value of
timeToLive is 365*24*3600.
    maxVersions: 1// Specify the maximum number of versions that can be saved in each col
umn. A value of 1 indicates that only the latest version is saved in each column.
  }
};
client.createTable(params, function (err, data) {
  if (err) {
    console.log('error:', err);
    return;
  }
  console.log('success:', data);
});
```

For the detailed sample code, visit CreateTable@GitHub.

ListTable

You can call this operation to obtain the names of all tables created in the current instance.

- API operation

```
  /**
   * Obtain the names of all tables in the current instance.
   */
  listTable(params, callback)
```

- Examples

The following code provides an example on how to obtain the names of all tables in the current instance:

```
var client = require('./client');
client.listTable({}, function (err, data) {
    if (err) {
        console.log('error:', err);
        return;
    }
    console.log('success:', data);
});
```

For the detailed sample code, visit ListTable@GitHub.

UpdateTable

You can call this operation to update the maximum number of versions and reserved read/write throughput of a table.

- API operation

```
  /**
   * Update the reserved read/write throughput of a specified table.
   */
  updateTable(params, callback)
```

- Examples

  Set the maximum number of versions of a table to 5.

```
var client = require('./client');
var params = {
    tableName: 'sampleTable',
    tableOptions: {
        maxVersions: 5,
    }
};
client.updateTable(params, function (err, data) {
    if (err) {
        console.log('error:', err);
        return;
    }
    console.log('success:', data);
});
```

For the detailed sample code, visit UpdateTable@GitHub.

DescribeTable

You can call this operation to query the structure information and the reserved read/write throughput settings of a table.

- API operation

```
  /**
   * Query the structure information and the reserved read/write throughput of the specif
ied table.
   */
  describeTable(params, callback)
```

- Examples

  The following code provides an example on how to obtain the description of a table:

```
var client = require('./client');
var params = {
    tableName: 'sampleTable'
};
client.describeTable(params, function (err, data) {
    if (err) {
        console.log('error:', err);
        return;
    }
    console.log('success:', data);
});
```

  For the detailed sample code, visit DescribeTable@GitHub.

DeleteTable

You can call this operation to delete a specified table from the current instance.

- API operation

```
  /**
   * Delete a specified table from the current instance.
   */
  deleteTable(params, callback)
```

- Examples

  The following code provides an example on how to delete a specified table from the current instance:

```
var client = require('./client');
var params = {
    tableName: 'sampleTable'
};
client.deleteTable(params, function (err, data) {
    if (err) {
        console.log('error:', err);
        return;
    }
    console.log('success:', data);
});
```

For the detailed sample code, visit DeleteTable@GitHub.

Single-row operations

Tablestore SDK for Node.js provides the following single-row operations: PutRow, GetRow, UpdateRow, and DeleteRow.

PutRow

You can call this operation to insert data into a specified row.

- API operation

```
  /**
   * Insert data into a specified row. If the row exists, the existing data is overwritte
n. Otherwise, a new row is added.
   */
  putRow(params, callback)
```

- Examples

> **Note**
>
> - RowExistenceExpectation.IGNORE indicates that new data is inserted into a row despite whether the specified row exists or not. If the specified row exists, the existing data is overwritten.
> - RowExistenceExpectation.EXPECT_EXIST indicates that new data is inserted only when the specified row exists. The existing data is overwritten.
> - RowExistenceExpectation.EXPECT_NOT_EXIST indicates that data is inserted only when the specified row does not exist.

```
var TableStore = require('../index.js');
var Long = TableStore.Long;
var client = require('./client');
var currentTimeStamp = Date.now();
var params = {
  tableName: "sampleTable",
  condition: new TableStore.Condition(TableStore.RowExistenceExpectation.IGNORE, null),
  primaryKey: [{ 'gid': Long.fromNumber(20013) }, { 'uid': Long.fromNumber(20013) }],
  attributeColumns: [
    { 'col1': 'Tablestore' },
    { 'col2': '2', 'timestamp': currentTimeStamp },
    { 'col3': 3.1 },
    { 'col4': -0.32 },
    { 'col5': Long.fromNumber(123456789) }
  ],
  returnContent: { returnType: TableStore.ReturnType.Primarykey }
};
client.putRow(params, function (err, data) {
  if (err) {
    console.log('error:', err);
    return;
  }
  console.log('success:', data);
});
```

For the detailed sample code, visit PutRow@GitHub.

GetRow

You can call this operation to read a single row of data based on a specified primary key.

- API operation

```
  /**
   * Read a single row of data based on a specified primary key.
   */
  getRow(params, callback)
```

- Examples

  The following code provides an example on how to read a row of data:

```
var TableStore = require('../index.js');
var Long = TableStore.Long;
var client = require('./client');
var params = {
  tableName: "sampleTable",
  primaryKey: [{ 'gid': Long.fromNumber(20004) }, { 'uid': Long.fromNumber(20004) }],
  maxVersions: 2 // The maximum number of versions that can be read. A value of 2 indicat
es that you can read a maximum of 2 versions of data.
};
var condition = new TableStore.CompositeCondition(TableStore.LogicalOperator.AND);
condition.addSubCondition(new TableStore.SingleColumnCondition('name', 'john', TableStore
.ComparatorType.EQUAL));
condition.addSubCondition(new TableStore.SingleColumnCondition('addr', 'china', TableStor
e.ComparatorType.EQUAL));
params.columnFilter = condition;
client.getRow(params, function (err, data) {
  if (err) {
    console.log('error:', err);
    return;
  }
  console.log('success:', data);
});
```

For the detailed sample code, visit GetRow@GitHub.

UpdateRow

You can call this operation to update the data of a specified row. If the row does not exist, a new row is added. If the row exists, the values in the specified columns are added, modified, or deleted based on the request.

- API operation

```
  /**
   * Update the data of the specified row. If the row does not exist, a new row is added.
If the row exists, the values of the specified columns are added, modified, or deleted ba
sed on the request content.
   */
  updateRow(params, callback)
```

- Examples

  The following code provides an example on how to update the data of a specified row:

```
var TableStore = require('../index.js');
var Long = TableStore.Long;
var client = require('./client');
var params = {
    tableName: "sampleTable",
    condition: new TableStore.Condition(TableStore.RowExistenceExpectation.IGNORE, null),
    primaryKey: [{ 'gid': Long.fromNumber(9) }, { 'uid': Long.fromNumber(90) }],
    updateOfAttributeColumns: [
        { 'PUT': [{ 'col4': Long.fromNumber(4) }, { 'col5': '5' }, { 'col6': Long.fromNum
ber(6) }] },
        { 'DELETE': [{ 'col1': Long.fromNumber(1496826473186) }] },
        { 'DELETE_ALL': ['col2'] }
    ]
};
client.updateRow(params,
    function (err, data) {
        if (err) {
            console.log('error:', err);
            return;
        }
        console.log('success:', data);
    });
```

For the detailed sample code, visit UpdateRow@GitHub.

DeleteRow

You can call this operation to delete data you no longer need.

- API operation

```
  /**
   * Delete a row of data.
   */
  deleteRow(params, callback)
```

- Examples

  The following code provides an example on how to delete a row of data:

```
var TableStore = require('../index.js');
var Long = TableStore.Long;
var client = require('./client');
var params = {
    tableName: "sampleTable",
    condition: new TableStore.Condition(TableStore.RowExistenceExpectation.IGNORE, null),
    primaryKey: [{ 'gid': Long.fromNumber(8) }, { 'uid': Long.fromNumber(80) }]
};
client.deleteRow(params, function (err, data) {
    if (err) {
        console.log('error:', err);
        return;
    }
    console.log('success:', data);
});
```

For the detailed sample code, visit DeleteRow@GitHub.

Multi-row operations

Tablestore SDK for Node.js provides multi-row operations, such as BatchGetRow, BatchWriteRow, and GetRange.

BatchGetRow

You can call this operation to simultaneously read multiple rows of data from one or more tables.

The BatchGetRow operation is a set of multiple GetRow operations. The execution, returning of results, and capacity unit (CU) consumption of each individual operation are carried out independently.

Compared with the execution of a large number of GetRow operations, the use of BatchGetRow can reduce the response time for requests and increase the data read rate.

- API operation

```
/**
 * Simultaneously read multiple rows of data from one or more tables.
 */
batchGetRow(params, callback)
```

- Examples

  The following code provides an example of how to simultaneously read multiple rows of data from multiple tables, and retry the operation if an error occurs in the read of a single row:

  > **Note** You can use conditional statements to filter the returned results of BatchWriteRow operations.

```
var client = require('./client');
var TableStore = require('../index.js');
var Long = TableStore.Long;
var params = {
    tables: [{
        tableName: 'sampleTable',
        primaryKey: [
```

```
        primaryKey: [
            [{ 'gid': Long.fromNumber(20013) }, { 'uid': Long.fromNumber(20013) }],
            [{ 'gid': Long.fromNumber(20015) }, { 'uid': Long.fromNumber(20015) }]
        ],
        startColumn: "col2",
        endColumn: "col4"
    },
    {
        tableName: 'notExistTable',
        primaryKey: [
            [{ 'gid': Long.fromNumber(10001) }, { 'uid': Long.fromNumber(10001) }]
        ]
    }
    ],
};
var maxRetryTimes = 3;
var retryCount = 0;
function batchGetRow(params) {
    client.batchGetRow(params, function (err, data) {
        if (err) {
            console.log('error:', err);
            return;
        }
        var isAllSuccess = true;
        var retryRequest = { tables: [] };
        for (var i = 0; i < data.tables.length; i++) {
            var faildRequest = { tableName: data.tables[i][0].tableName, primaryKey: [] }
;
            for (var j = 0; j < data.tables[i].length; j++) {
                if (!data.tables[i][j].isOk && null != data.tables[i][j].primaryKey) {
                    isAllSuccess = false;
                    var pks = [];
                    for (var k in data.tables[i][j].primaryKey) {
                        var name = data.tables[i][j].primaryKey[k].name;
                        var value = data.tables[i][j].primaryKey[k].value;
                        var kp = {};
                        kp[name] = value;
                        pks.push(kp);
                    }
                    faildRequest.primaryKey.push(pks);
                } else {
                    // get success data
                }
            }
            if (faildRequest.primaryKey.length > 0) {
                retryRequest.tables.push(faildRequest);
            }
        }
        if (!isAllSuccess && retryCount++ < maxRetryTimes) {
            batchGetRow(retryRequest);
        }
        console.log('success:', data);
    });
}
batchGetRow(params, maxRetryTimes);
```

```
```

For the detailed sample code, visit BatchGetRow@GitHub.

BatchWriteRow

You can call this operation to simultaneously insert, modify, or delete multiple rows of data in one or more tables.

The BatchWriteRow operation is a set of multiple PutRow, UpdateRow, and DeleteRow operations. The execution, returning of results, and CU consumption of each individual operation are carried out independently.

- API operation

```
/**
 * Simultaneously modify multiple rows of data.
 */
batchWriteRow(params, callback)
```

- Examples

  The following code provides an example of how to simultaneously write multiple rows of data:

  > **Note** You can use conditional statements to filter the returned results of BatchWriteRow operations.

```
var client = require('./client');
var TableStore = require('../index.js');
var Long = TableStore.Long;
var params = {
    tables: [{
        tableName: 'sampleTable',
        rows: [{
            type: 'PUT',
            condition: new TableStore.Condition(TableStore.RowExistenceExpectation.IGNORE
, null),
            primaryKey: [{ 'gid': Long.fromNumber(8) }, { 'uid': Long.fromNumber(80) }],
            attributeColumns: [{ 'attrCol1': 'test1' }, { 'attrCol2': 'test2' }],
            returnContent: { returnType: TableStore.ReturnType.Primarykey }
        }],
    }],
};
client.batchWriteRow(params, function (err, data) {
    if (err) {
        console.log('error:', err);
        return;
    }
    console.log('success:', data);
});
```

For the detailed sample code, visit BatchWriteRow@GitHub.

GetRange

You can call this operation to read data within a specified primary key range.

- API operation

```
/**
 * Read data within the specified primary key range.
 */
getRange(params, callback)
```

- Examples

  The following code provides an example on how to read data within a specified range:

  > **Note**
  > - You can use conditional statements to filter the data read from a specified range.
  > - Note that the data may be paged when you perform the GetRange operation.

```
var Long = TableStore.Long;
var client = require('./client');
var params = {
  tableName: "sampleTable",
  direction: TableStore.Direction.FORWARD,
  inclusiveStartPrimaryKey: [{ "gid": TableStore.INF_MIN }, { "uid": TableStore.INF_MIN }
],
  exclusiveEndPrimaryKey: [{ "gid": TableStore.INF_MAX }, { "uid": TableStore.INF_MAX }],
  limit: 50
};
client.getRange(params, function (err, data) {
  if (err) {
    console.log('error:', err);
    return;
  }
  //If the value of data.next_start_primary_key is not null, the read operation is contin
ued.
  if (data.next_start_primary_key) {
  }
  console.log('success:', data);
});
```

  For the detailed sample code, visit GetRange@GitHub.

7.1.2.1.4.6. Error handling

This topic describes the error handling methods and retry policies in Tablestore SDK for Node.js.

Methods

Tablestore SDK for Node.js handles errors as exceptions. If the operation succeeds, the called operation does not return an exception. If the operation fails, an exception is returned.

> **Note** Batch operations such as BatchGetRow and BatchWriteRow can be called only after the system verifies that no exception is returned and that the status of each row is successful.

Exceptions

All errors are handled by Tablestore SDK for Node.js in a unified manner, and are returned as the value of the err parameter by using the callback method. Before you obtain the returned data, you must check whether the err parameter has a value. If an error occurs at the server side of Tablestore, the request ID is returned. The request ID is the UUID that identifies a request. If you cannot solve the problem, record this request ID and contact Tablestore technical support for help.

Retry

The system automatically retries the operation when an error occurs in the SDK. The default policy sets a maximum of 20 retry attempts and a maximum retry interval of 3000 ms. For more information about how the system retries the operation on throttling errors and read-related internal server errors, see `tablestore/lib/retry.js`.

7.1.2.1.5. .NET SDK

7.1.2.1.5.1. Preface

This topic describes how to use Tablestore SDK for .NET.

Prerequisites

An authorized account is created, and an AccessKey pair (AccessKey ID and AccessKey secret) is obtained. For more information about how to obtain and view your AccessKey pair in the Apsara Uni-manager Management Console, see Obtain an AccessKey pair.

Download Tablestore SDK for .NET

- Download the SDK installation package from NuGet. For more information about the download path, visit https://www.nuget.org/packages/Aliyun.TableStore.SDK/4.1.4.
- Download the source code from GitHub. For more information about the download path, visit GitHub.

Compatibility

For SDKs V3.x.x: compatible.

For SDKs V2.x.x:

- Some operations are incompatible. The Condition.IGNORE, Condition.EXPECT_EXIST, and Condition.EXPECT_NOT_EXIST parameters are deleted.
- The DLL file name is changed from Aliyun.dll to Aliyun.TableStore.dll.

Version

Latest version: 4.1.4.

7.1.2.1.5.2. Installation

This topic describes how to install Tablestore SDK for .NET.

Version dependency

Windows

- .NET 4.0 or later is required.
- Visual Studio 2010 or later is required.

Install Tablestore SDK for .NET in Windows

- Install by using NuGet
  i. After you install NuGet, create a project or open an existing project in Visual Studio, and then choose **Tools > NuGet Package Manager > Manage NuGet Packages for Solution**.

  > **Note** If Visual Studio does not have NuGet installed, download and install NuGet. For more information about the download path, visit NuGet.

  ii. Enter aliyun.tablestore in the search box and click Search. Find Aliyun.TableStore.SDK in the search results.
  iii. Select the latest version, and click **Install**.

  After the installation is complete. Tablestore SDK for .NET is added to the project for application.
- Install by importing a project
  i. Download the source code from GitHub. For more information about the download path, visit GitHub.

  > **Note** If Git is not installed, download and install Git. For more information about the download path, visit git.

  ii. In Visual Studio, right-click and select **Solution** from the menu that appears, choose **Add > Existing projects**.
  iii. In the dialog box that appears, select the *aliyun-tablestore-sdk.csproj* file, and click **Open**.
  iv. Right-click and select **Your project**. Choose **References > Add Reference** from the shortcut menu. In the dialog box that appears, click the **Projects** tab, and select the aliyun-tablestore-sdk project.
  v. Click **OK**.

7.1.2.1.5.3. Initialization

TableStoreClient provides a series of methods for users to manage tables and perform read/write operations on one or more rows.

Obtain an endpoint

An endpoint is the domain name that is used to access a Tablestore instance within a region. To query an endpoint, perform the following operations:

1. Log on to the Tablestore console.
2. Click the instance name to go to the **Instance Management** page.

   On the Instance Details page, you can view the endpoints of an instance in Instance Access URL.

Configure an AccessKey pair

To access Apsara Stack Tablestore, you must have a valid AccessKey pair (AccessKey ID and AccessKey secret) for signature authentication.

After you obtain the AccessKey pair, you can perform the following operation to initialize an OTSClient instance by using an endpoint:

- API operation

```
    /// <summary>
    /// OTSClient constructor.
    /// </summary>
    /// <param name="endPoint">The endpoint of the Tablestore instance. Example: https://
instance.cn-hangzhou.ots.aliyun.com:80. It must start with https://. </param>
    /// <param name="accessKeyID">The AccessKey ID to access the Tablestore instance. You
can apply for an AccessKey ID on the Alibaba Cloud official website. </param>
    /// <param name="accessKeyID">The AccessKey secret that is used to access the Tablest
ore instance. You can apply for an AccessKey secret on the Alibaba Cloud official website
. </param>
    /// <param name="instanceName">The name of the Tablestore instance. You can create an
instance name in the Tablestore console. </param>
public OTSClient(string endPoint, string accessKeyID, string accessKeySecret, string inst
anceName);
    /// <summary>
    /// Create an OTSClient instance by configuring the instance of the OTSClientConfig c
lass.
    /// </summary>
    /// <param name="config">The instance for client configurations.</param>
    public OTSClient(OTSClientConfig config);
```

- Examples

> **Note**
>
> - You can set the ConnectionLimit parameter in the OTSClientConfig instance. If you do not specify the value of the ConnectionLimit parameter, the default value 300 is used.
> - You can set OTSDebugLogHandler and OTSErrorLogHandler in OTSClientConfig to specify whether to enable logging.
> - The retry logic is customizable and controlled by RetryPolicy in OTSClientConfig. A default retry policy is provided.

```
    // Create an OTSClientConfig instance.
    var config = new OTSClientConfig(Endpoint, AccessKeyId, AccessKeySecret, InstanceName
);
    // Disable logging. By default, logging is enabled.
    config.OTSDebugLogHandler = null;
    config.OTSErrorLogHandler = null;
    // Create an OTSClient instance by using OTSClientConfig.
    var otsClient = new OTSClient(config);
    // Use OTSClient to insert or query data.
```

Multithreading

- Multithreading is supported.
- We recommend that you use the same OTSClient instance to perform multithreading tasks.

7.1.2.1.5.4. Use the SDK

Table-level operations

Tablestore SDK for .NET provides the following table-level operations: CreateTable, ListTable, DeleteTable, UpdateTable, and DescribeTable.

CreateTable

You can call this operation to create a table based on the specified table structure.

> **Note**
> - After the table is created, it takes several seconds to load the table. During this period, read and write operations on the table may fail. You can use applications to perform operations on the table data only after the table is loaded.
> - You must specify the primary key when you create a table. A primary key contains one to four primary key columns. Each primary key column has a name and a data type.

- API operation

```
/// <summary>
 /// Create a table based on table information including the table name, primary key sche
ma, and reserved read/write throughput.
 /// </summary>
 /// <param name="request">Request parameter</param>
 /// <returns>Information returned by CreateTable. The result is null.
 /// </returns>
        public CreateTableResponse CreateTable(CreateTableRequest request);
        /// <summary>
        /// Asynchronous mode of CreateTable.
        /// </summary>
        public Task<CreateTableResponse> CreateTableAsync(CreateTableRequest request);
```

- Examples

  The following code provides an example on how to create a table that contains two primary key columns and a reserved read/write throughput of (0,0):

```
 //Create a schema for the primary key columns, which includes the quantity, names, and t
ypes of primary key columns.
 //The first primary key column is named pk0, and is also the partition column.
 //The second primary key column is named pk1, and requires a string value.
 var primaryKeySchema = new PrimaryKeySchema();
 primaryKeySchema.Add("pk0", ColumnValueType.Integer);
 primaryKeySchema.Add("pk1", ColumnValueType.String);
 //Create a tableMeta class based on the table name and the schema for primary key column
s.
 var tableMeta = new TableMeta("SampleTable", primaryKeySchema);
 // Set the reserved read throughput and reserved write throughput to 0.
 var reservedThroughput = new CapacityUnit(0, 0);
 try
 {
     // Construct the CreateTableRequest object.
     var request = new CreateTableRequest(tableMeta, reservedThroughput);
     // Call the CreateTable operation of the client. If the table is created, no excepti
on is returned. Otherwise, an exception is returned.
     otsClient.CreateTable(request);
     Console.WriteLine("Create table succeeded.") ;
 }
 // If the task fails, an exception is returned and handled.
 catch (Exception ex)
 {
     Console.WriteLine("Create table failed, exception:{0}", ex.Message);
 }
```

For the detailed sample code, visit CreateTable@GitHub.

ListTable

You can call this operation to query the names of all tables created in the current instance.

- API operation

```
 /// <summary>
 /// Query the names of all tables created in the current instance.
 /// </summary>
 /// <param name="request">Request parameter</param>
 /// <returns>Information returned by ListTable that contains the table name list.</retur
ns> </returns>
 public ListTableResponse ListTable(ListTableRequest request);
 /// <summary>
 /// Asynchronous mode of ListTable.
 /// </summary>
 public Task<ListTableResponse> ListTableAsync(ListTableRequest request);
```

- Examples

  The following code provides an example on how to obtain the names of all tables in the current instance:

```
var request = new ListTableRequest();
try
{
    var response = otsClient.ListTable(request);
    foreach (var tableName in response.TableNames)
    {
        Console.WriteLine("Table name:{0}", tableName);
    }
    Console.Writeline("List table succeeded.");
}
catch (Exception ex)
{
    Console.WriteLine("List table failed, exception:{0}", ex.Message);
}
```

UpdateTable

You can call this operation to update the settings of reserved read/write throughput of a table.

- API operation

```
/// <summary>
/// Update the reserved read/write throughput settings of the specified table. New setti
ngs take effect within a minute after the update succeeds.
/// </summary>
/// <param name="request">Request parameter, including the table name and reserved read/
write throughput.</param>
/// <returns>Contains information such as the updated reserved read/write throughput.</r
eturns>
public UpdateTableResponse UpdateTable(UpdateTableRequest request);
/// <summary>
/// Asynchronous mode of UpdateTable.
/// </summary>
public Task<UpdateTableResponse> UpdateTableAsync(UpdateTableRequest request);
```

- Examples

  The following code provides an example on how to update the numbers of read capacity units (CUs) of a table to 1 and write CUs to 2:

```
// Update the reserved read throughput to 1 and the reserved write throughput to 2.
var reservedThroughput = new CapacityUnit(1, 2);
// Construct an UpdateTableRequest object.
var request = new UpdateTableRequest("SampleTable", reservedThroughput);
try
{
    // Call the API to update the reserved read/write throughput of the table.
    otsClient.UpdateTable(request);
    // If the task succeeds, no exception is returned.
    Console.Writeline("Update table succeeded.");
}
catch (Exception ex)
{
    // If the task fails, an exception is returned and handled.
    Console.WriteLine("Update table failed, exception:{0}", ex.Message);
}
```

For the detailed sample code, visit UpdateTable@GitHub.

DescribeTable

You can call this operation to query the structure information and reserved read/write throughput value of the specified table.

- API operation

```
/// <summary>
/// Query the structure information and reserved read/write throughput settings of the s
pecified table.
/// </summary>
/// <param name="request">Request parameter, including the table name.</param>
/// <returns>Contains the structure information and reserved read/write throughput setti
ngs of the specified table.</returns> </returns>
public DescribeTableResponse DescribeTable(DescribeTableRequest request);
/// <summary>
/// Asynchronous mode of DescribeTable.
/// </summary>
public Task<DescribeTableResponse> DescribeTableAsync(DescribeTableRequest request);
```

- Examples

  The following code provides an example on how to obtain the description of a table:

```
 try
 {
     var request = new DescribeTableRequest("SampleTable");
     var response = otsClient.DescribeTable(request);
     //Display the descriptive information of the specified table.
     Console.Writeline("Describe table succeeded.") ;
     Console.WriteLine("LastIncreaseTime: {0}", response.ReservedThroughputDetails.LastIn
creaseTime);
     Console.WriteLine("LastDecreaseTime: {0}", response.ReservedThroughputDetails.LastDe
creaseTime);
     Console.WriteLine("NumberOfDecreaseToday: {0}", response.ReservedThroughputDetails.L
astIncreaseTime);
     Console.WriteLine("ReadCapacity: {0}", response.ReservedThroughputDetails.CapacityUn
it.Read);
     Console.WriteLine("WriteCapacity: {0}", response.ReservedThroughputDetails.CapacityU
nit.Write);
 }
 catch (Exception ex)
 {
     // If the task fails, an exception is returned and handled.
     Console.WriteLine("Describe table failed, exception:{0}", ex.Message);
        }
```

For the detailed sample code, visit DescribeTable@GitHub.

DeleteTable

You can call this operation to delete a specified table from an instance.

- API operation

```
/// <summary>
/// Delete the table of the specified name.
/// </summary>
/// <param name="request">Request parameter, including the table name.</param>
/// <returns>Information returned by DeleteTable. The result is null.
/// </returns>
public DeleteTableResponse DeleteTable(DeleteTableRequest request);
/// <summary>
/// Asynchronous mode of DeleteTable.
/// </summary>
public Task<DeleteTableResponse> DeleteTableAsync(DeleteTableRequest request);
```

- Examples

  The following code provides an example on how to delete a table:

```
var request = new DeleteTableRequest("SampleTable");
try
{
    otsClient.DeleteTable(request);
    Console.Writeline("Delete table succeeded.");
}
catch (Exception ex)
{
    Console.WriteLine("Delete table failed, exception:{0}", ex.Message);
}
```

For the detailed sample code, visit DeleteTable@GitHub.

Single-row operations

The Tablestore SDK provides the following APIs for single-row operations: PutRow, GetRow, UpdateRow, and DeleteRow.

PutRow

You can use the PutRow API to insert data into a specified row.

API

```
        /// <summary>
        /// Write a row of data based on the specified table name, primary keys, and attrib
utes. Thu number of CUs consumed by the operation is returned.
        /// </summary>
        /// <param name="request">Data insertion request</param>
        /// <returns>The number of CUs consumed by the operation</returns>
        public PutRowResponse PutRow(PutRowRequest request);
        /// <summary>
        /// Asynchronous mode of PutRow.
        /// </summary>
        public Task<PutRowResponse> PutRowAsync(PutRowRequest request);
```

Example 1

The following code provides an example of how to insert a row of data:

```
        // Define the primary keys of the row. These primary keys must be consistent with t
he primary keys defined in TableMeta during table creation.
        var primaryKey = new PrimaryKey();
        primaryKey.Add("pk0", new ColumnValue(0));
        primaryKey.Add("pk1", new ColumnValue("abc"));
        // Define the attribute columns of the row.
        var attribute = new AttributeColumns();
        attribute.Add("col0", new ColumnValue(0));
        attribute.Add("col1", new ColumnValue("a"));
        attribute.Add("col2", new ColumnValue(true));
        try
        {
            // Construct the request object for data insertion. RowExistenceExpectation.IGN
ORE indicates that data is inserted regardless of whether the specified row exists.
            var request = new PutRowRequest("SampleTable", new Condition(RowExistenceExpect
ation.IGNORE),
                                    primaryKey, attribute);
            // Call the PutRow API to insert data.
            otsClient.PutRow(request);
            // If task execution succeeds, no exception is thrown.
            Console.WriteLine("Put row succeeded.");
        }
        catch (Exception ex)
        {
            // If task execution fails, an exception is thrown and an error message is disp
layed.
            Console.WriteLine("Put row failed, exception:{0}", ex.Message);
        }
```

Note

- Condition.IGNORE, Condition.EXPECT_EXIST, and Condition.EXPECT_NOT_EXIST are deprecated in V3.0.0 and later. Use new Condition (RowExistenceExpectation. IGNORE), new Condition (RowExistenceExpectation.EXPECT_EXIST), and new Condition (RowExistenceExpectation. EXPECT_NOT_EXIST) instead.
- RowExistenceExpectation.IGNORE indicates that new data is inserted regardless of whether the specified row exists. If the row exists, the existing data is overwritten.
- RowExistenceExpectation.EXPECT_EXIST indicates that new data is inserted only when the specified row exists. The existing data is overwritten.
- RowExistenceExpectation.EXPECT_NOT_EXIST indicates that data is inserted only when the specified row does not exist.
- In addition to row conditions, the Condition parameter also supports column conditions in V2.2.0 and later.
- To view the detailed code, see PutRow@GitHub.

Example 2

The following code provides an example of how to insert a row of data based on specified conditions.

Assume that data is inserted only when a specified row exists and the value of col1 is greater than 24.

```
        // Define the primary keys of the row. These primary keys must be consistent with t
he primary keys defined in TableMeta during table creation.
        var primaryKey = new PrimaryKey();
        primaryKey.Add("pk0", new ColumnValue(0));
        primaryKey.Add("pk1", new ColumnValue("abc"));
        // Define the attribute columns of the row.
        AttributeColumns attribute = new AttributeColumns();
        attribute.Add("col0", new ColumnValue(0));
        attribute.Add("col1", new ColumnValue("a"));
        attribute.Add("col2", new ColumnValue(true));
        var request = new PutRowRequest(tableName, new Condition(RowExistenceExpectation.EX
PECT_EXIST),
                                        primaryKey, attribute);
        // When the value of col0 is greater than 24, rerun PutRow to overwrite the existin
g value.
        try
        {
            request.Condition.ColumnCondition = new RelationalCondition("col0",
                                                RelationalCondition.CompareOperator.GREATER
_THAN,
                                                new ColumnValue(24));
            otsClient.PutRow(request);
            Console.WriteLine("Put row succeeded.");
        }
        catch (Exception ex)
        {
            Console.WriteLine("Put row failed. error:{0}", ex.Message);
        }
```

Note

- You can set a single condition or a combination of conditions. For example, you can set two conditions for data insertion such as col1 > 5 and pk2 < 'xyz'.
- Attribute columns and primary key columns can be used to set conditions.
- When the column specified in a condition does not exist in a row, PassIfMissing in RelationCondition determines the next action. The default value is true.
- To view the detailed code, see ConditionPutRow@GitHub.

Example 3

The following code provides an example of how to asynchronously insert a row of data:

```
        try
        {
            var putRowTaskList = new List<Task<PutRowResponse>>();
            for (int i = 0; i < 100; i++)
            {
                // Define the primary keys of the row. These primary keys must be consisten
t with the primary keys defined in TableMeta during table creation.
                var primaryKey = new PrimaryKey();
                primaryKey.Add("pk0", new ColumnValue(i));
                primaryKey.Add("pk1", new ColumnValue("abc"));
                // Define the attribute columns of the row.
                var attribute = new AttributeColumns();
                attribute.Add("col0", new ColumnValue(i));
                attribute.Add("col1", new ColumnValue("a"));
                attribute.Add("col2", new ColumnValue(true));
                var request = new PutRowRequest(TableName, new Condition(RowExistenceExpect
ation.IGNORE),
                                                primaryKey, attribute);
                putRowTaskList.Add(TabeStoreClient.PutRowAsync(request));
            }
            // Wait until each asynchronous invocation returns results and displays the con
sumed CUs.
            foreach (var task in putRowTaskList)
            {
                task.Wait();
                Console.WriteLine("consumed read:{0}, write:{1}", task.Result.ConsumedCapac
ityUnit.Read,
                                        task.Result.ConsumedCapacityUnit.Write);
            }
            // Data is inserted if no exception is thrown.
            Console.WriteLine("Put row async succeeded.");
        }
        catch (Exception ex)
        {
            // If task execution fails, an exception is thrown and an error message is disp
layed.
            Console.WriteLine("Put row async failed. exception:{0}", ex.Message);
        }
```

Note

- Each asynchronous invocation starts a thread. A timeout error may occur if too many asynchronous invocations are started consecutively and each invocation consumes an extended period of time.
- To view the detailed code, see PutRowAsync@GitHub.

GetRow

You can use the GetRow API to read a single row of data based on a specified primary key.

API

```
        /// <summary>
        /// Read a single row of data based on a specified primary key.
        /// </summary>
        /// <param name="request">Data query request</param>
        /// <returns>Response of GetRow</returns>
        public GetRowResponse GetRow(GetRowRequest request);
        /// <summary>
        /// Asynchronous mode of GetRow.
        /// </summary>
        public Task<GetRowResponse> GetRowAsync(GetRowRequest request);
```

Example 1

The following code provides an example of how to read a row of data:

```
        // Define the primary keys of the row. These primary keys must be consistent with t
he primary keys defined in TableMeta during table creation.
        PrimaryKey primaryKey = new PrimaryKey();
        primaryKey.Add("pk0", new ColumnValue(0));
        primaryKey.Add("pk1", new ColumnValue("abc"));
        try
        {
            // Construct a query request object. The entire row is read if no column is spe
cified.
            var request = new GetRowRequest(TableName, primaryKey);
            // Call the GetRow API to query data.
            var response = otsClient.GetRow(request);
            // Generate the data of the row. The generated data is not shown here. For more
information, see the GitHub link.
            // If task execution succeeds, no exception is thrown.
            Console.WriteLine("Get row succeeded.");
        }
        catch (Exception ex)
        {
            // If task execution fails, an exception is thrown and an error message is disp
layed.
            Console.WriteLine("Update table failed, exception:{0}", ex.Message);
        }
```

Note

- If you query a row of data, the system returns the data in all columns of the row. You can use the columnsToGet parameter to read data from specified columns. For example, the system returns only the data in col0 and col1 if col0 and col1 are inserted into columnsToGet.
- Conditional filtering is supported. For example, you can configure the system to return results only when the value of col0 is greater than 24.
- When the columnsToGet and Condition parameters are both used, the system returns results based on columnsToGet, and then filters the returned columns by the Condition parameter.
- When the specified column does not exist, PassIfMissing determines the next action.
- To view the detailed code, see GetRow@GitHub.

Example 2

The following code provides an example of how to use the filter feature to read a row of data.

In the example, data is queried. Only data in col0 and col1 is returned. The data in col0 is filtered based on the condition of col0=24.

```
        // Define the primary keys of the row. These primary keys must be consistent with t
he primary keys defined in TableMeta during table creation.
        PrimaryKey primaryKey = new PrimaryKey();
        primaryKey.Add("pk0", new ColumnValue(0));
        primaryKey.Add("pk1", new ColumnValue("abc"));
        var rowQueryCriteria = new SingleRowQueryCriteria("SampleTable");
        rowQueryCriteria.RowPrimaryKey = primaryKey;
        // Condition 1: The value of col0 is 5.
        var filter1 = new RelationalCondition("col0",
                    RelationalCondition.CompareOperator.EQUAL,
                    new ColumnValue(5));
        // Condition 2: The value of col1 is not ff.
        var filter2 = new RelationalCondition("col1", RelationalCondition.CompareOperator.N
OT_EQUAL, new ColumnValue("ff"));
        // Construct a combination of Condition 1 and Condition 2 with the OR relationship.
        var filter = new CompositeCondition(CompositeCondition.LogicOperator.OR);
        filter.AddCondition(filter1);
        filter.AddCondition(filter2);
        rowQueryCriteria.Filter = filter;
        // Configure the rows you want to query with the condition [col0, col1], and then f
ilter the queried data based on the previously specified conditions.
        rowQueryCriteria.AddColumnsToGet("col0");
        rowQueryCriteria.AddColumnsToGet("col1");
        // Construct GetRowRequest.
        var request = new GetRowRequest(rowQueryCriteria);
        try
        {
            // Query data.
            var response = otsClient.GetRow(request);
            // Generate data or perform the related logical operation (omitted).
            // If task execution succeeds, no exception is thrown.
            Console.WriteLine("Get row with filter succeeded.");
        }
        catch (Exception ex)
        {
            // If task execution fails, an exception is thrown and an error message is disp
layed.
            Console.WriteLine("Get row with filter failed, exception:{0}", ex.Message);
        }
```

Note To view the detailed code, see GetRowWithFilter@GitHub.

UpdateRow

You can use the UpdateRow API to update the data of a specified row. If the row does not exist, a new row is added. If the row exists, the values of the specified columns are added, modified, or deleted based on the request content.

API

```
        /// <summary>
        /// Update the data of the specified row. If the row does not exist, a new row is a
dded. If the row exists, the values of the specified columns are added, modified, or delete
d based on the request content.
        /// </summary>
        /// <param name="request">Request instance</param>
        public UpdateRowResponse UpdateRow(UpdateRowRequest request);
        /// <summary>
        /// Asynchronous mode of UpdateRow.
        /// </summary>
        /// <param name="request"></param>
        /// <returns></returns>
        public Task<UpdateRowResponse> UpdateRowAsync(UpdateRowRequest request);
```

Examples

The following code provides an example of how to update the data of a specified row:

```
        // Define the primary keys of the row. These primary keys must be consistent with t
he primary keys defined in TableMeta during table creation.
        PrimaryKey primaryKey = new PrimaryKey();
        primaryKey.Add("pk0", new ColumnValue(0));
        primaryKey.Add("pk1", new ColumnValue("abc"));
        // Define the attribute columns of the row.
        UpdateOfAttribute attribute = new UpdateOfAttribute();
        attribute.AddAttributeColumnToPut("col0", new ColumnValue(0));
        attribute.AddAttributeColumnToPut("col1", new ColumnValue("b")); // Change the orig
inal value a to b.
        attribute.AddAttributeColumnToPut("col2", new ColumnValue(true));
        try
        {
            // Construct the request object for row updating. RowExistenceExpectation.IGNOR
E indicates that data is updated regardless of whether the specified row exists.
            var request = new UpdateRowRequest(TableName, new Condition(RowExistenceExpecta
tion.IGNORE),
                                       primaryKey, attribute);
            // Call the UpdateRow API to run the following line of code:
            otsClient.UpdateRow(request);
            // If task execution succeeds, no exception is thrown.
            Console.Writeline("Update row succeeded.");
        }
        catch (Exception ex)
        {
            // If task execution fails, an exception is thrown and an error message is disp
layed.
            Console.WriteLine("Update row failed, exception:{0}", ex.Message);
        }
```

> **Note**
> - You can use conditional statements to update rows.
> - To view the detailed code, see UpdateRow@GitHub.

DeleteRow

API

```
        /// <summary>
        /// Delete a row of data based on the specified table name and primary keys.
        /// </summary>
        /// <param name="request">Request instance</param>
        /// <returns>Response instance</returns>
        public DeleteRowResponse DeleteRow(DeleteRowRequest request);
        /// <summary>
        /// Asynchronous mode of DeleteRow.
        /// </summary>
        public Task<DeleteRowResponse> DeleteRowAsync(DeleteRowRequest request);
```

Examples

The following code provides an example of how to delete a row of data:

```
        // The values of the primary key columns of the row to be deleted are 0 and "abc".
        var primaryKey = new PrimaryKey();
        primaryKey.Add("pk0", new ColumnValue(0));
        primaryKey.Add("pk1", new ColumnValue("abc"));
        try
        {
            // Construct a request. Condition.EXPECT_EXIST indicates that the row is delete
d only when it exists.
            var deleteRowRequest = new DeleteRowRequest("SampleTable", Condition.EXPECT_EXI
ST, primaryKey);
            // Call the DeleteRow API to delete the row.
            otsClient.DeleteRow(deleteRowRequest);
            // If task execution succeeds, no exception is thrown.
            Console.Writeline("Delete table succeeded.");
        }
        catch (Exception ex)
        {
            // If task execution fails, an exception is thrown and an error message is disp
layed.
            Console.WriteLine("Delete table failed, exception:{0}", ex.Message);
        }
```

> **Note**
> - You can use conditional statements to delete rows.
> - To view the detailed code, see DeleteRow@GitHub.

Multiple-row operations

The Tablestore SDK provides the following APIs for multiple-row operations: BatchGetRow, BatchWriteRow, GetRange, and GetRangeIterator.

BatchGetRow

You can use the BatchGetRow API to simultaneously read several rows of data from one or more tables.

The BatchGetRow operation is a set of multiple GetRow operations. The execution, returning of results, and capacity unit (CU) consumption of each individual operation are carried out independently.

Compared with the execution of a large number of GetRow operations, the use of BatchGetRow can reduce the request response time and increase the data read rate.

API

```
        /// <summary>
        /// <para>Simultaneously read several rows of data from one or more tables. </para>
        /// <para>The BatchGetRow operation is a set of multiple GetRow operations. The exe
cution, returning of results, and CU consumption of each individual operation are carried o
ut independently. </para>
        /// Compared with the execution of a large number of GetRow operations, the use of
BatchGetRow can reduce the request response time and increase the data read rate.
        /// </summary>
        /// <param name="request">Request instance</param>
        /// <returns>Response instance</returns>
        public BatchGetRowResponse BatchGetRow(BatchGetRowRequest request);
        /// <summary>
        /// Asynchronous mode of BatchGetRow.
        /// </summary>
        public Task<BatchGetRowResponse> BatchGetRowAsync(BatchGetRowRequest request);
```

Examples

The following code provides an example of how to simultaneously read 10 rows of data:

```
        // Construct a batch-read request object, including the primary key values of the 1
0 rows.
        List<PrimaryKey> primaryKeys = new List<PrimaryKey>();
        for (int i = 0; i < 10; i++)
        {
            PrimaryKey primaryKey = new PrimaryKey();
            primaryKey.Add("pk0", new ColumnValue(i));
            primaryKey.Add("pk1", new ColumnValue("abc"));
            primaryKeys.Add(primaryKey);
        }
        try
        {
            BatchGetRowRequest request = new BatchGetRowRequest();
            request.Add(TableName, primaryKeys);
            // Call BatchGetRow to read 10 rows of data.
            var response = otsClient.BatchGetRow(request);
            var tableRows = response.RowDataGroupByTable;
            var rows = tableRows[TableName];
            // Enter the input data for the rows. The input data is not shown here. For mor
e information, see the GitHub link.
            // BatchGetRow may partially fail. Therefore, you must check the status of each
row. For more information, see the GitHub link.
        }
        catch (Exception ex)
        {
            // If task execution fails, an exception is thrown and an error message is disp
layed.
            Console.WriteLine("Batch get row failed, exception:{0}", ex.Message);
        }
```

Note

- You can use conditional statements to filter the results returned by a BatchGetRow operation.
- To view the detailed code, see BatchGetRow@GitHub.

BatchWriteRow

You can use the BatchWriteRow API to insert, modify, or delete several rows of data in one or more tables.

The BatchWriteRow operation is a set of multiple PutRow, UpdateRow, and DeleteRow operations. The execution, returning of results, and CU consumption of each individual operation are carried out independently.

API

```
        /// <summary>
        /// <para>You can use the BatchWriteRow API to insert, modify, or delete several ro
ws of data in one or more tables. </para>
        /// <para>The BatchWriteRow operation is a set of multiple PutRow, UpdateRow, and D
eleteRow operations. The execution, returning of results, and CU consumption of each indivi
dual operation are carried out independently. </para>
        /// <para>Compared with the execution of a large number of write operations, the us
e of BatchWriteRow can reduce the request response time and increase the data write rate. <
/para>
        /// </summary>
        /// <param name="request">Request instance</param>
        /// <returns>Response instance</returns>
        public BatchWriteRowResponse BatchWriteRow(BatchWriteRowRequest request);
        /// <summary>
        /// Asynchronous mode of BatchWriteRow.
        /// </summary>
        /// <param name="request"></param>
        /// <returns></returns>
        public Task<BatchWriteRowResponse> BatchWriteRowAsync(BatchWriteRowRequest request)
;
```

Examples

The following code provides an example of how to simultaneously import 100 rows of data:

```
        // Construct a batch-import request object, including the primary key values of the
100 rows.
        var request = new BatchWriteRowRequest();
        var rowChanges = new RowChanges();
        for (int i = 0; i < 100; i++)
        {
            PrimaryKey primaryKey = new PrimaryKey();
            primaryKey.Add("pk0", new ColumnValue(i));
            primaryKey.Add("pk1", new ColumnValue("abc"));
            // Define the attribute columns of the 100 rows.
            UpdateOfAttribute attribute = new UpdateOfAttribute();
            attribute.AddAttributeColumnToPut("col0", new ColumnValue(0));
            attribute.AddAttributeColumnToPut("col1", new ColumnValue("a"));
            attribute.AddAttributeColumnToPut("col2", new ColumnValue(true));
            rowChanges.AddUpdate(new Condition(RowExistenceExpectation.IGNORE), primaryKey,
attribute);
        }
        request.Add(TableName, rowChanges);
        try
        {
            // Call the BatchWriteRow API.
            var response = otsClient.BatchWriteRow(request);
            var tableRows = response.TableRespones;
            var rows = tableRows[TableName];
            // BatchWriteRow may partially fail. Therefore, you must check the status of ea
ch row. For more information, see the GitHub link.
        }
        catch (Exception ex)
        {
            // If task execution fails, an exception is thrown and an error message is disp
layed.
            Console.WriteLine("Batch put row failed, exception:{0}", ex.Message);
        }
```

Note

- You can use conditional statements to filter the results returned by a BatchWriteRow operation.
- To view the detailed code, see BatchWriteRow@GitHub.

GetRange

You can use the GetRange API to read data within the specified primary key range.

API

```
        /// <summary>
        /// Obtain data from multiple rows within a specified range.
        /// </summary>
        /// <param name="request">Request instance</param>
        /// <returns>Response instance</returns>
        public GetRangeResponse GetRange(GetRangeRequest request);
        /// <summary>
        /// Asynchronous mode of GetRange.
        /// </summary>
        /// <param name="request"></param>
        /// <returns></returns>
        public Task<GetRangeResponse> GetRangeAsync(GetRangeRequest request);
```

Examples

The following code provides an example of how to read data within the specified range:

```
        // Read all rows in the range from (0, INF_MIN) to (100, INF_MAX).
        var inclusiveStartPrimaryKey = new PrimaryKey();
        inclusiveStartPrimaryKey.Add("pk0", new ColumnValue(0));
        inclusiveStartPrimaryKey.Add("pk1", ColumnValue.INF_MIN);
        var exclusiveEndPrimaryKey = new PrimaryKey();
        exclusiveEndPrimaryKey.Add("pk0", new ColumnValue(100));
        exclusiveEndPrimaryKey.Add("pk1", ColumnValue.INF_MAX);
        try
        {
            // Construct a read request object in the specified range.
            var request = new GetRangeRequest(TableName, GetRangeDirection.Forward,
                            inclusiveStartPrimaryKey, exclusiveEndPrimaryKey);
            var response = otsClient.GetRange(request);
            // Continue the read operation if only partial data is returned.
            var rows = response.RowDataList;
            var nextStartPrimaryKey = response.NextPrimaryKey;
            while (nextStartPrimaryKey != null)
            {
                request = new GetRangeRequest(TableName, GetRangeDirection.Forward,
                                nextStartPrimaryKey, exclusiveEndPrimaryKey);
                response = otsClient.GetRange(request);
                nextStartPrimaryKey = response.NextPrimaryKey;
                foreach (RowDataFromGetRange row in response.RowDataList)
                {
                    rows.Add(row);
                }
            }
            // Generate the data of the rows. The generated data is not shown here. For mor
e information, see the GitHub link.
            // If task execution succeeds, no exception is thrown.
            Console.WriteLine("Get range succeeded");
        }
        catch (Exception ex)
        {
            // If task execution fails, an exception is thrown and an error message is disp
layed.
            Console.WriteLine("Get range failed, exception:{0}", ex.Message);
        }
```

> **Note**
>
> - You can use conditional statements to filter the read data returned from the specified range.
> - To view the detailed code, see GetRange@GitHub.

GetRangeIterator

You can use the GetRangeIterator API to obtain an iterator within the specified range.

API

```
        /// <summary>
        /// Obtain data from multiple rows within the specified range. Return the iterator
used to process each row of data.
        /// </summary>
        /// <param name="request"><see cref="GetIteratorRequest"/></param>
        /// <returns>Return the <see cref="RowDataFromGetRange"/> iterator. </returns>
        public IEnumerable<RowDataFromGetRange> GetRangeIterator(GetIteratorRequest request
);
```

Examples

The following code provides an example of how to obtain an iterator:

```
        // Read all rows in the range from (0, "a") to (1000, "xyz").
        PrimaryKey inclusiveStartPrimaryKey = new PrimaryKey();
        inclusiveStartPrimaryKey.Add("pk0", new ColumnValue(0));
        inclusiveStartPrimaryKey.Add("pk1", new ColumnValue("a"));
        PrimaryKey exclusiveEndPrimaryKey = new PrimaryKey();
        exclusiveEndPrimaryKey.Add("pk0", new ColumnValue(1000));
        exclusiveEndPrimaryKey.Add("pk1", new ColumnValue("xyz"));
        // Construct a CapacityUnit to record the number of CUs consumed by iteration.
        var cu = new CapacityUnit(0, 0);
        try
        {
            // Construct a GetIteratorRequest. Filter conditions are supported.
            var request = new GetIteratorRequest(TableName, GetRangeDirection.Forward, incl
usiveStartPrimaryKey,
                                                 exclusiveEndPrimaryKey, cu);
            var iterator = otsClient.GetRangeIterator(request);
            // Iterator that reads data in a traversal method.
            foreach (var row in iterator)
            {
                // Processing logic.
            }
            Console.WriteLine("Iterate row succeeded");
        }
        catch (Exception ex)
        {
            Console.WriteLine("Iterate row failed, exception:{0}", ex.Message);
        }
```

> **Note**
>
> - You can use conditional statements to filter the data read through an iterator.
> - To view the detailed code, see GetRangeIterator@GitHub.

7.1.2.1.5.5. Error handling

This topic describes the error handling methods and retry policies in Tablestore SDK for .NET.

Method

The Tablestore .NET SDK adopts the Exception method to handle errors. If an operation succeeds, the called API does not throw an exception. If the operation fails, an exception is thrown.

> **Note** Batch operation APIs such as BatchGetRow and BatchWriteRow are called only when the status check of each row is successful.

Error

The Tablestore .NET SDK has two types of exceptions: OTSClientException and OTSServerException. Both are inherited from Exception.

- OTSClientException: indicates an internal SDK exception, such as an incorrect parameter value or a failure to parse the results returned by the server.
- OTSServerException: indicates a server error arising from the resolution of a server error message. OTSServerException has the following components:
  - HttpStatusCode: an HTTP status code, such as 200 or 404.
  - ErrorCode: an error type string returned by Tablestore.
  - ErrorMessage: an error message string returned by Tablestore.
  - RequestId: the UUID that uniquely identifies a request. If a problem persists, submit the request ID to Tablestore technical support personnel to obtain help.

Retry

- The system retries an operation when an error occurs in the SDK. The operation is retried three times at a maximum interval of two seconds by default. For more information, see the Aliyun.OTS.Retry.DefaultRetryPolicy class.
- You can modify RetryPolicy in OTSClientConfig to customize a retry policy.

7.1.2.1.6. Obtain an AccessKey pair

An AccessKey pair consists of an AccessKey ID and an AccessKey secret. The AccessKey pair is used to implement symmetric encryption to verify the identity of the requester. The AccessKey ID is used to identify a user. The AccessKey secret is used to encrypt the signature string. This topic describes how to obtain an AccessKey pair.

Prerequisites

Only operations administrators and level-1 organization administrators can obtain the AccessKey pair of an organization.

Obtain the AccessKey pair of an organization

To obtain the AccessKey pair of an organization, perform the following operations:

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

> **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
>
> - Uppercase or lowercase letters
> - Digits
> - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, click **Enterprise**.
5. In the left-side navigation pane of the **Enterprise** page, click **Organizations**.
6. In the organization navigation tree, click an organization name.
7. In the Current Organization section, click **Obtain an accesskey**.
8. In the AccessKey message, view the AccessKey pair of the organization.

> **Note** An AccessKey pair is automatically allocated to each level-1 organization. Subordinate organizations use the same AccessKey pair of their level-1 organization.

Obtain the AccessKey pair of a personal account

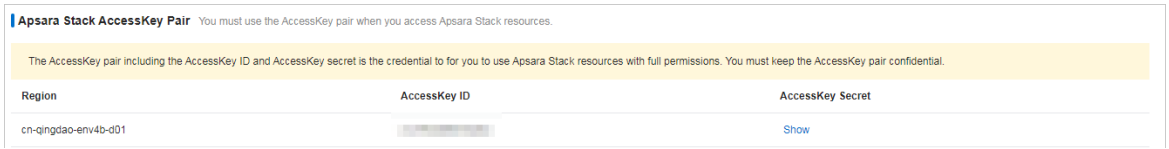
To obtain the AccessKey pair of a personal account, perform the following steps:

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the upper-right corner of the homepage, move the pointer over the profile picture and click **User Information**.
5. In the **Apsara Stack AccessKey Pair** section, view your AccessKey pair.



> **Note** The AccessKey pair consists of an AccessKey ID and an AccessKey secret. AccessKey pairs of accounts grant you full permissions to access Apsara Stack resources. You must keep your AccessKey pair confidential.

8.ApsaraDB RDS

8.1. Developer Guide

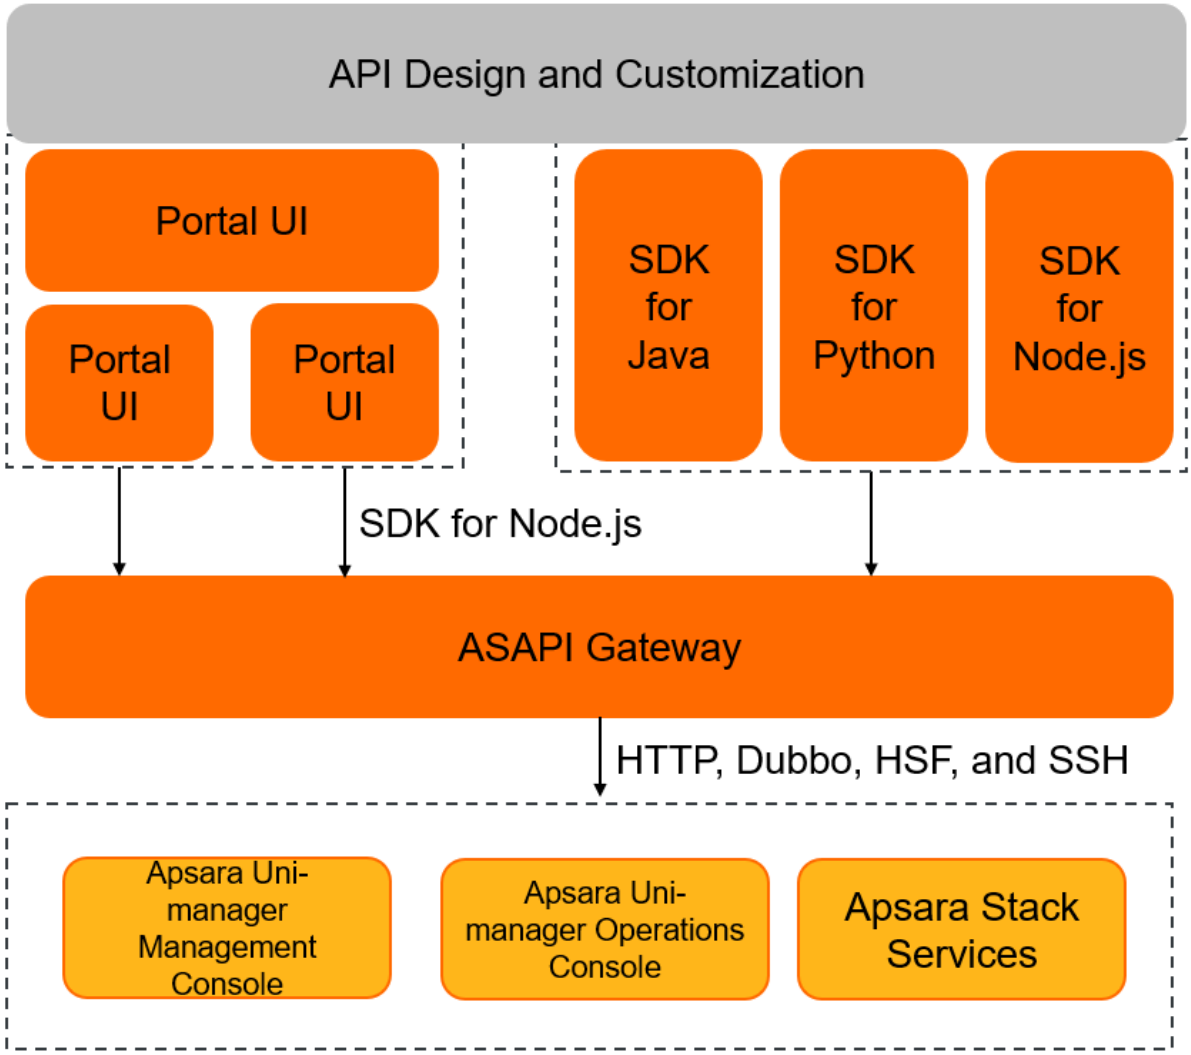
8.1.1. Use ASAPI to call Apsara Stack SDKs

8.1.1.1. 文档标题缺失，请补全后重新导出

8.1.1.1.1. ASAPI overview

This topic describes the architecture and features of the Apsara Stack API (ASAPI).

The ASAPI is a unified ingress gateway for Apsara Stack services and a main component of the Apsara Uni-manager Management Console. The ASAPI provides a unified method for you to manage and make API calls. You can use Apsara Stack SDK to centrally make API calls to Apsara Stack services, including Elastic Compute Service (ECS) and Virtual Private Cloud (VPC).



The ASAPI allows you to make API calls to manage and maintain Apsara Stack services.

- Make API calls to implement enterprise-grade management. For example, you can manage organizations, users, roles, resource sets, and logon policies. These operations are provided by the Apsara Uni-manager Management Console.
- Make API calls to manage operations. For example, you can manage quotas, usage statistics, specifications, and password policies. These operations are provided by the Apsara Uni-manager Management Console.
- Make API calls to manage resources. For example, you can create, delete, query, or modify cloud resources. These operations are provided by Apsara Stack services. If you call an API operation to create an ECS instance or a VPC, the API operation is provided by ECS or VPC.
- Make API calls to query monitoring metrics of Apsara Stack services. These operations are provided by the Apsara Uni-manager Management Console.
- Make API calls to perform O&M. For example, you can manage monitoring and alerting, inventories, tasks, and physical servers. These operations are provided by the Apsara Uni-manager Operations Console.

For more information, see the developer guide of the corresponding Apsara Stack service. For information about API operations used to manage organization users, see *Apsara Uni-manager Management Console Developer Guide*. For information about the API operation used to create an ECS instance, see *ECS Developer Guide*.

> **Note** If the "Use Apsara Stack SDK to make API calls" section is included in the developer guide of an Apsara Stack service, the ASAPI is supported by the Apsara Stack service. In this case, you can make API calls based on the developer guide.

8.1.1.1.2. Preparations

8.1.1.1.2.1. Log on to the API Tool console

You can log on to the API Tool console from the Apsara Uni-manager Management Console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

> **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 10 to 32 characters in length and must contain at least two of the following character types:
>
> - Uppercase or lowercase letters
> - Digits
> - Special characters, which include ! @ # $ %

3. Click **Log On**.
4. In the top navigation bar, choose **Products > Others > API Tool**.

8.1.1.1.2.2. View information about API operations

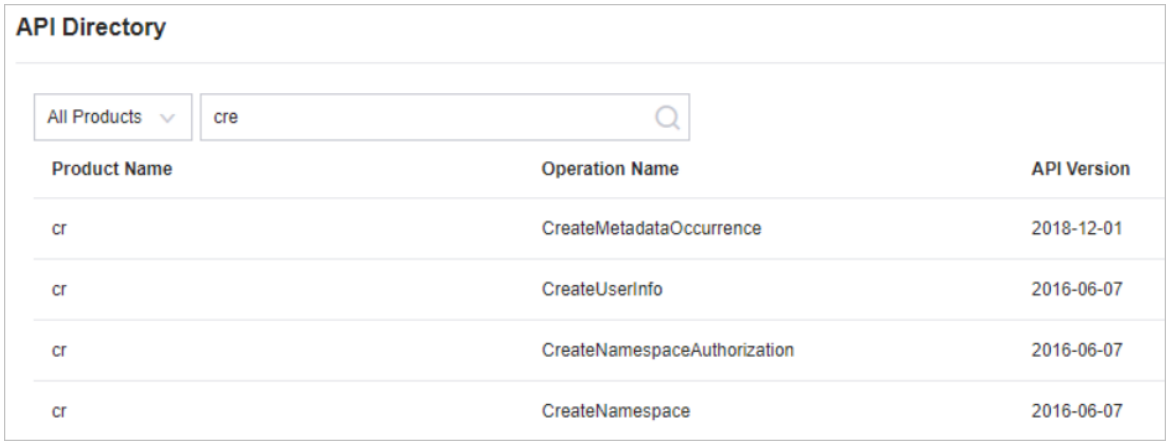
This topic describes how to view information about API operations. Before you use SDKs, obtain service names, API operation names, and API operation versions.

Context

The API operations on the API Directory page are only for reference. For information about how to call API operations, see developer guides of the corresponding cloud services. If the information on the API Directory page is inconsistent with that in the developer guide of the corresponding cloud service, the information in the developer guide prevails.

Procedure

1. Go to the API Tool console. For more information, see Log on to the API Tool console.
2. In the left-side navigation pane, click **API Directory**.
3. On the **API Directory** page, select the desired service from the drop-down list, enter a keyword of an API operation name in the search box, and then click the search icon.



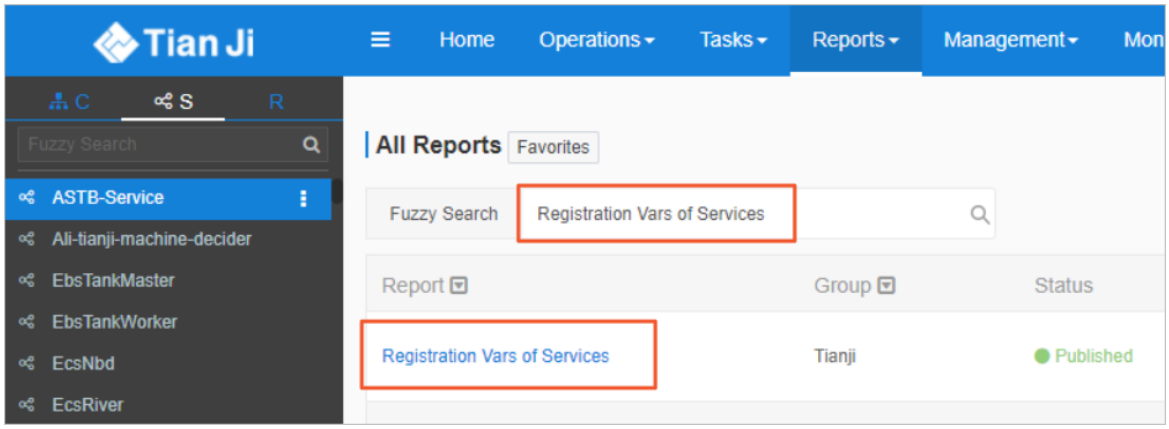
4. Then, you can view the service name, API operation name, and API operation version.

8.1.1.1.2.3. Generate an endpoint for the ASAPI

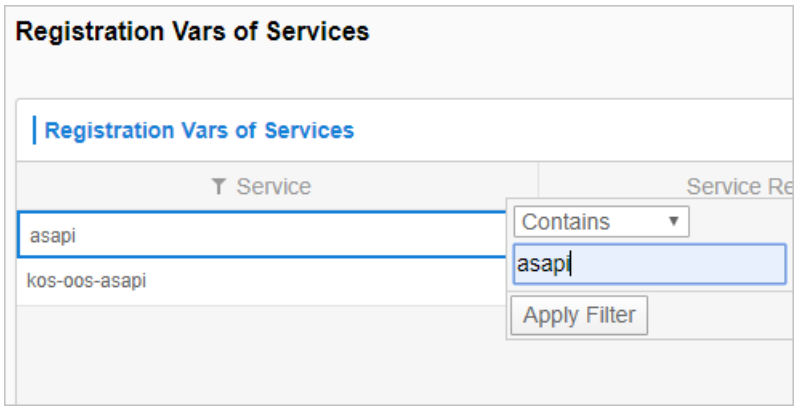
This topic describes three methods used to generate an endpoint for the Apsara Stack API (ASAPI).

Method 1: Use Registration Vars of Services to generate an endpoint

1. Log on to Apsara Infrastructure Management Framework.
   i. Log on to the Apsara Uni-manager Operations Console.
   ii. In the top navigation bar, click **O&M**.
   iii. In the left-side navigation pane, choose **Product Management** > **Products**.
   iv. In the Apsara Stack O&M section, click **Apsara Infrastructure Management Framework**.
2. In the left-side navigation pane, click **Reports**.
3. On the **All Reports** page, search for `Registration Vars of Services` and click the report name.



4. On the **Registration Vars of Services** page, click the icon next to **Service** and search for `asapi`.



5. Find the asapi service, right-click in the **Service Registration** column, and then select **Show More** from the shortcut menu.

   In the **Details** dialog box, obtain the value of **asapi.public.endpoint**.
6. Generate an endpoint for the ASAPI based on the following format:

```
https://<asapi.public.endpoint>/asapi/v3
```

Method 2: Use cluster resources to generate an endpoint

1. Log on to Apsara Infrastructure Management Framework.
   i. Log on to the Apsara Uni-manager Operations Console.

ii. In the top navigation bar, click **O&M**.

iii. In the left-side navigation pane, choose **Product Management** > **Products**.

iv. In the Apsara Stack O&M section, click **Apsara Infrastructure Management Framework**.

2. Go to the cluster operations page.

i. In the left-side navigation pane, choose Operations > Cluster Operations.

ii. In the **Cluster** search box, enter `ascm`.

iii. Find the cluster that you want to manage and click **Operations** in the **Actions** column.

3. Obtain the value of the domain parameter.

i. Click the Cluster Resources tab.

ii. In the **Name** field, search for `asapi_dns_public`.

iii. Click **Details** in the **Application Parameter** column.

In the **Application Parameter** message, obtain the value of the **domain** parameter.

4. Generate an endpoint for the ASAPI based on the following format:

```
https://<domain>/asapi/v3
```

Method 3: Concatenate strings to generate an endpoint

You can also concatenate strings to generate an endpoint based on the following format:

```
https://public.asapi.<region>.<internet-domain>/asapi/v3
```

> **Note**
>
> 1. Replace <region> with your actual region ID. For information about how to query a region ID, see Query a region ID.
> 2. Replace <internet-domain> with the root domain of your Apsara Stack service. To obtain the root domain, contact Apsara Stack O&M personnel. Take note of this point: Use the internet-domain parameter instead of the intranet-domain parameter.

If the **region** value is `cn-****-****-d01` and the **internet-domain** value is `inter.****.****.com`, the following endpoint can be generated:

```
https://public.asapi.cn-****-****-d01.inter.****.****.com/asapi/v3
```

8.1.1.1.2.4. Obtain Apsara Stack SDKs

The Apsara Stack API (ASAPI) is a unified portal provided by Apsara Stack. You can use the ASAPI to connect to all Apsara Stack services. Apsara Stack provides SDKs for API calls.

For more information about how to obtain Apsara Stack SDKs, see Apsara Stack documentation.

8.1.1.1.2.5. Obtain an AccessKey pair

An AccessKey pair that consists of an AccessKey ID and an AccessKey secret is used to implement symmetric encryption. This helps you verify the identity of a requester. The AccessKey ID is used to identify a user. The AccessKey secret is used to encrypt the signature string. This topic describes how to obtain an AccessKey pair.

Prerequisites

An account of the operations administrator or the level-1 organization administrator is obtained. Only an operations administrator or a level-1 organization administrator can obtain an AccessKey pair.

Context

If you need to make API calls to the Apsara Uni-manager Management Console or other Apsara Stack services, we recommend that you use the AccessKey pair of a personal account. If you use the AccessKey pair of a personal account, configure the request headers that are described in the following table for access control. Otherwise, an error that indicates insufficient permissions can occur.

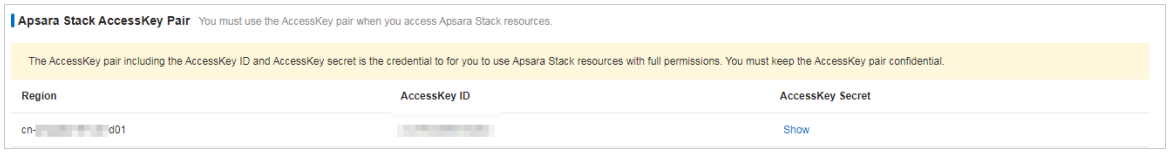
Parameter	Description
x-acs-regionid	The ID of the region, for example, cn-hangzhou-*.
x-acs-organizationid	The ID of the organization in the Apsara Uni-manager Management Console. For information about how to obtain an organization ID, see the "GetOrganizationList" section in Apsara Uni-manager Management Console Developer Guide.
x-acs-resourcegroupid	The ID of the resource set in the Apsara Uni-manager Management Console. For information about how to obtain a resource set ID, see the "ListResourceGroup" section in Apsara Uni-manager Management Console Developer Guide.
x-acs-instanceid	The ID of the instance to which you make API calls. If you need to make API calls to an Elastic Compute Service (ECS) instance, obtain the ID of the ECS instance on the Instances page.

Warning The AccessKey pair of a personal account is managed and controlled by the permission system of the Apsara Uni-manage Management Console. If you need to obtain the AccessKey pair of an account that has permissions on an organization, make sure that your operation is allowed by an administrator. This ensures security. The account that has permissions on an organization is a privileged account.

Obtain the AccessKey pair of a personal account

To obtain the AccessKey pair of a personal account, perform the following operations:

1. Log on to the Apsara Uni-manager Management Console.
2. In the upper-right corner of the homepage, move the pointer over the profile picture and click **User Information**.
3. In the **Apsara Stack AccessKey Pair** section, obtain the AccessKey pair.



> **Note** The AccessKey pair that consists of an AccessKey ID and an AccessKey secret is the credential for you to have full permissions on Apsara Stack resources. Keep your AccessKey pair confidential.

Obtain the AccessKey pair of an account that has permissions on an organization

To obtain the AccessKey pair of an account that has permissions on an organization, perform the following operations:

1. Log on to the Apsara Uni-manager Management Console as an administrator.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Organizations**.
4. In the Organizations navigation tree, click the name of the organization that you want to manage.
5. On the right side of the page, click **Obtain AccessKey Pair**.
6. In the message that appears, obtain the AccessKey pair of the account that has permissions on the organization.

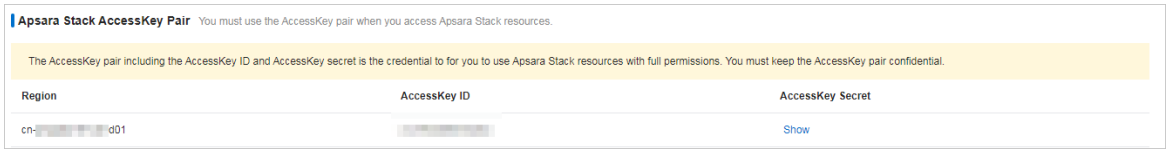
> **Note** The system automatically allocates an AccessKey pair to the account that has permissions on the level-1 organization. The same AccessKey pair is used by the accounts that have permissions on the subordinate organizations.

8.1.1.1.2.6. Query a region ID

When you use Apsara Stack SDK for Node.js to make API calls, specify a region ID. You can obtain a region ID in the Apsara Uni-manager Management Console.

Procedure

1. Log on to the Apsara Uni-manager Management Console as an administrator.
2. In the upper-right corner of the homepage, move the pointer over the profile picture and click **User Information**.
3. In the **Apsara Stack AccessKey Pair** section, view the region ID.



8.1.1.1.3. Common parameters

Common request parameters must be included in all API requests.

Sample common parameters

The following table describes the common parameters that are used when you call API operations supported by the Apsara Stack API (ASAPI).

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. For more information, see View information about API operations.
Product	String	Yes	The name of the service.
Version	String	Yes	The version of the API operation. For more information, see View information about API operations.
RegionId	String	Yes	The ID of the region. For more information, see Query a region ID.
AccessKeyId	String	Yes	The AccessKey ID used to connect to the service. For more information, see Obtain an AccessKey pair.
Signature	String	Yes	The signature string of the current request. For more information about how signatures are calculated, see Request signatures.

Parameter	Type	Required	Description
SignatureMethod	String	Yes	The encryption method of the signature string. Valid values: HMAC-SHA1 and HMAC-SHA256.
SignatureVersion	String	Yes	The version of the signature encryption algorithm. Valid values: 1.0 and 2.0.
SignatureNonce	String	Yes	A unique, random number used to prevent replay attacks. You must use different numbers for different requests.
Timestamp	String	Yes	The timestamp of the request. Specify the time in the ISO 8601 standard in the yyyy-MM-ddTHH:mm:ssZ format. The time must be in UTC. Sample value: 2018-01-01T12:00:00Z.
Format	String	Yes	The format in which to return the response. Set the value to JSON.

Note

The `Signature`, `SignatureMethod`, `SignatureVersion`, `SignatureNonce`, `Timestamp`, and `Format` parameters are encapsulated into Apsara Stack SDK. You do not need to configure these parameters.

8.1.1.1.4. SDK description

8.1.1.1.4.1. Use Apsara Stack SDK for Java to call API operations

This topic describes how to obtain and use Apsara Stack SDK for Java to call API operations.

Prerequisites

- An authorized account and an AccessKey pair are obtained. The AccessKey pair consists of an AccessKey ID and an AccessKey secret. For more information about how to obtain an AccessKey pair in the Apsara Uni-manager Management Console, see Obtain an AccessKey pair.
- The endpoint of the Apsara Stack API (ASAPI) is obtained. For more information, see Generate an endpoint for the ASAPI.
- Apsara Stack SDK for Java 1.8 or later is installed.

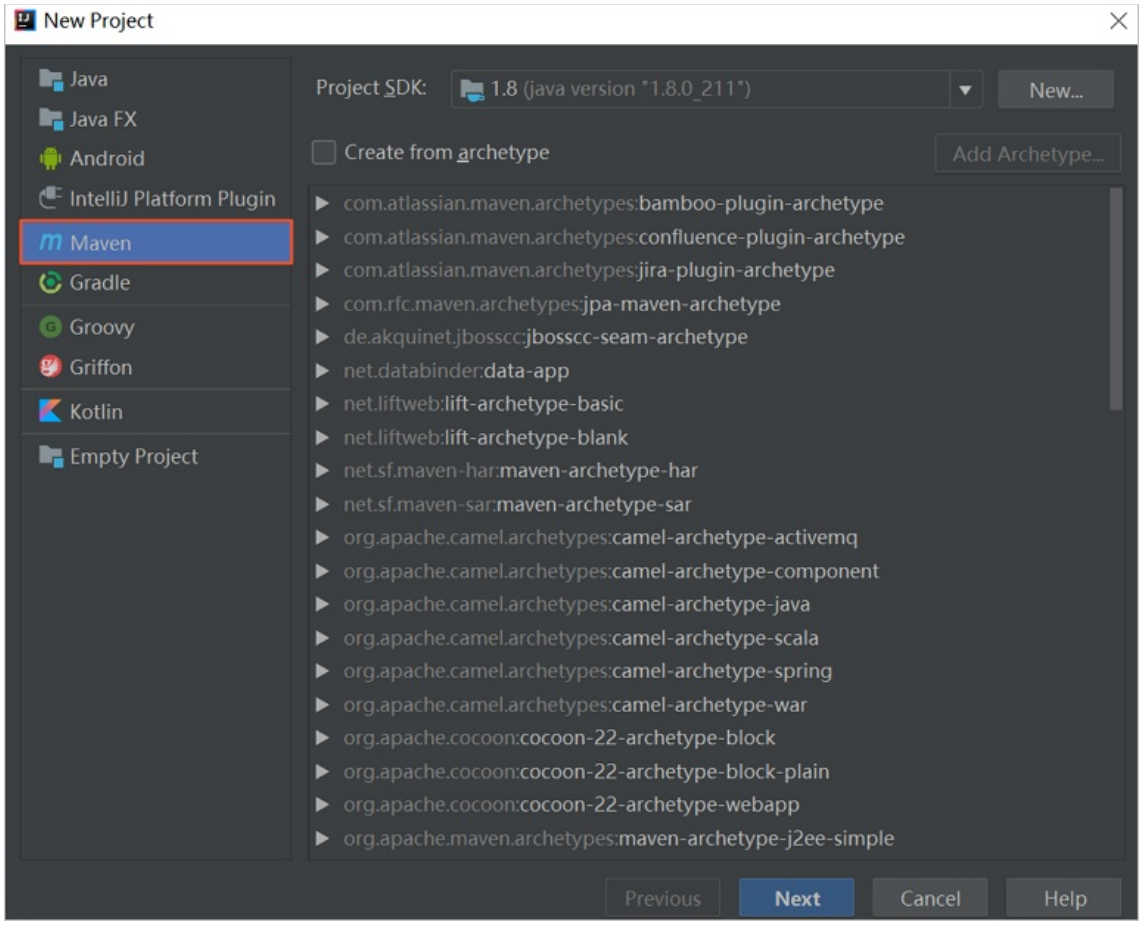
Background information

The help center of Apsara Stack provides Maven dependencies and JAR files for Apsara Stack SDK for Java. You can write code to use Apsara Stack SDK for Java to call API operations.

In this example, the Windows 10 64-bit OS and IntelliJ IDEA are used.

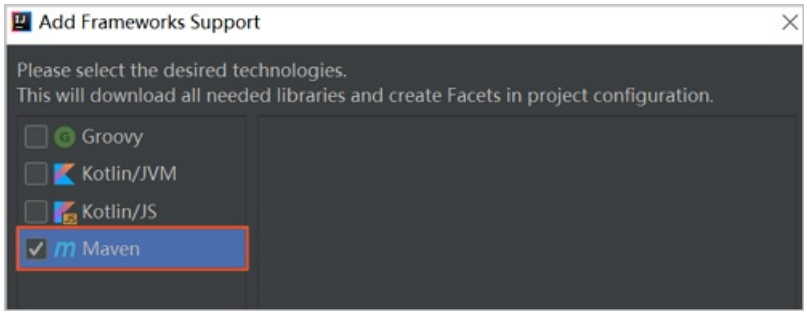
Procedure

1. Use one of the following methods to configure Maven in IntelliJ IDEA. Maven is a tool used for project management.
   - Use Maven that is integrated in IntelliJ IDEA.
   - Download Maven based on the OS that you are using from the official website and configure Maven. For more information, see Download Maven.
2. Obtain the Maven dependencies for Apsara Stack SDK for Java from the official website. For more information about how to obtain the dependencies, see Obtain the core package for ASAPI.
3. Use one of the following methods to create a Maven project:
   - Method 1: Create a Maven project in IntelliJ IDEA.

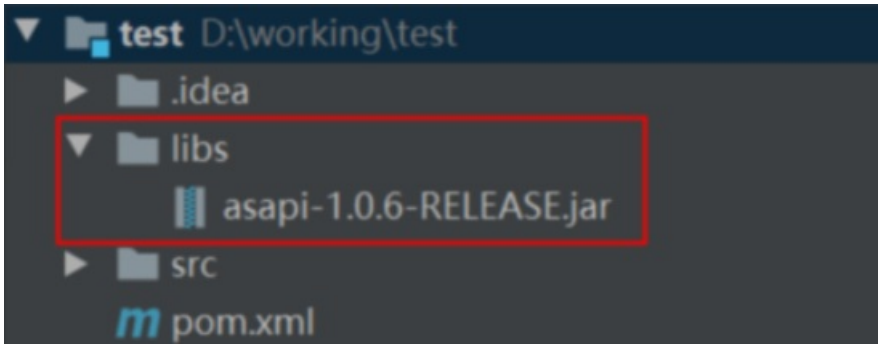


- Method 2: Convert an existing project to a Maven project.
  a. Right-click the project that you want to convert and select **Add Framework Support...**.

  b. Select **Maven** and click **OK**.



4. Create a folder named libs in the root directory of the project. Then, add the JAR file of Apsara Stack SDK for Java to the libs folder, as shown in the following figure.



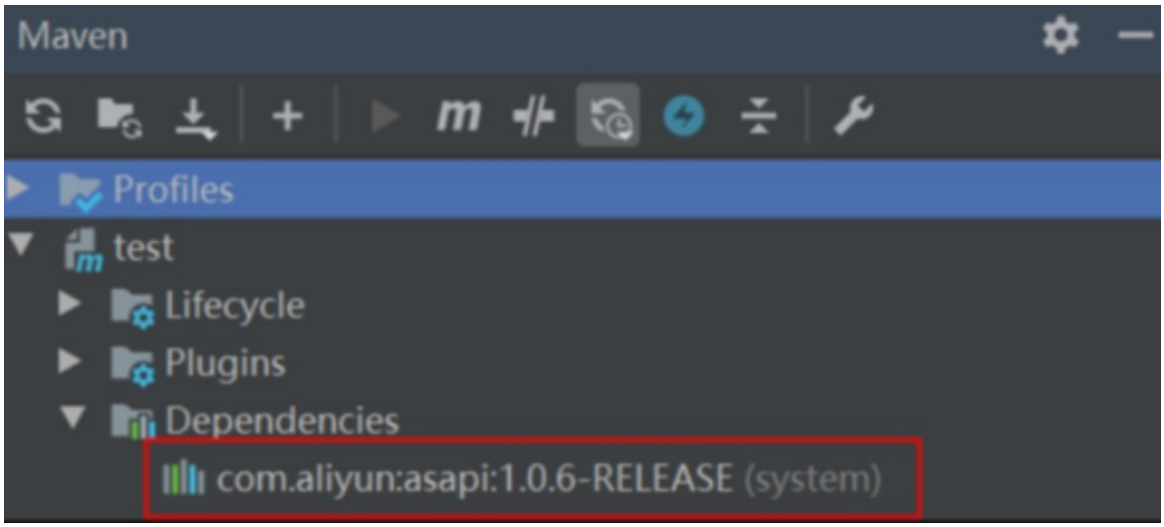
5. Add the dependencies of Apsara Stack SDK for Java to the pom.xml file in the project directory.

```
<dependencies>
    <dependency>
        <groupId>com.aliyun</groupId>
        <artifactId>asapi</artifactId>
        <version>1.0.6-RELEASE</version>
        <scope>system</scope>
        <systemPath>${project.basedir}/libs/asapi-1.0.6-RELEASE.jar</systemPath>
    </dependency>
  <dependency>
        <groupId>com.alibaba</groupId>
        <artifactId>alicrypto-java-aliyun</artifactId>
    <version>1.0.4</version>
    <systemPath>${project.basedir}/libs/alicrypto-java-aliyun-1.0.4.jar</systemPath>
  </dependency>
  <dependency>
    <groupId>com.aliyun</groupId>
    <artifactId>gmsse</artifactId>
    <version>1.1.0</version>
    <systemPath>${project.basedir}/libs/gmsse-1.1.0.jar</systemPath>
  </dependency>
</dependencies>
```

> **Note** Replace `1.0.6-RELEASE` with the actual version of Apsara Stack SDK for Java.

6. On the right side of IntelliJ IDEA, view information in the Maven section.

If the information in the following figure appears, the dependencies are added.



Use Apsara Stack SDK for Java

You can use the GET or POST method to call API operations provided by the ASAPI. The following sample code shows how to call API operations:

```
// 1. Create a connection to an ASClient object.
ASClient client = new ASClient();
// 2. Configure the identifier of the requester. This parameter is required and used only f
or identification. You can set this parameter to a random value.
client.setSdkSource("<The identifier of the requester>");
Map<String, Object> parameters = new HashMap<String, Object>();
// 3. Configure the parameters for authorization. The parameter values vary based on your e
nvironment.
// The AccessKey ID of your Apsara Stack tenant account.
parameters.put("AccessKeyId","<AccessKey ID>");
// The AccessKey secret of your Apsara Stack tenant account.
parameters.put("AccessKeySecret", "<AccessKey Secret>");
// The ID of the region.
parameters.put("RegionId", "<your RegionID>");
// 4. Configure parameters for an API call. In this example, the Product, Action, and Versi
on parameters are configured.
parameters.put("Product", "<The name of the service>");
parameters.put("Action", "<The name of the API operation>");
parameters.put("Version", "<The version of the API operation>");
// 5. Configure operation-specific parameters.
parameters.put("<The name of the operation-specific parameter>", "<The value of the operati
on-specific parameter>");
// 6. Configure request headers and the encryption method for the signature string. Valid v
alues of the SignatureMethod parameter: HMAC-SHA1 and HMAC-SHA256. By default, HMAC-SHA256
is used.
Map<String, String> headers = new HashMap<String, String>();
//headers.put("SignatureMethod", "HMAC-SHA1");
headers.put("x-acs-regionid", "<your-regionid>");
headers.put("x-acs-resourcegroupid", "<your-resourcegroupid>");
headers.put("x-acs-organizationid", "<your-organizationid>");
headers.put("x-acs-instanceid", "<your-instanceid>");
// 7. Make an API call. We recommend that you use the doPost() method.
// Configure the time-out period for a connection.
//client.setConnectTimeout(10000);
// Configure the time-out period for a request.
// client.setSocketTimeout(10000);
String result = client.doPost(endpoint, headers, parameters);
System.out.println(result);
```

Configure a proxy

If you need to use a proxy to make API calls, use the following sample code to configure the proxy:

```
Cloud cloud = new Cloud();
// Configure the IP address of the proxy.
cloud.setConfig("proxy_host", "<IP>");
// Configure the port used by the proxy.
cloud.setConfig("proxy_port", "<Port>");
// 1. Create a connection to an ASClient object.
ASClient client = new ASClient(cloud);
```

Request headers

Parameter	Description
x-acs-regionid	The ID of the region. For more information about how to obtain a region ID, see Query the region ID.
x-acs-organizationid	The ID of the organization in the Apsara Uni-manager Management Console.
x-acs-resourcegroupid	The ID of the resource set in the Apsara Uni-manager Management Console.
x-acs-instanceid	The ID of the instance to which you make API calls.

8.1.1.1.4.2. Use Apsara Stack SDK for Python to call API operations

This topic describes how to use Apsara Stack SDK for Python to call API operations provided by the Apsara Stack API (ASAPI).

Preparations

- An authorized account and an AccessKey pair are obtained. The AccessKey pair consists of an AccessKey ID and an AccessKey secret. For more information about how to obtain an AccessKey pair in the Apsara Uni-manager Management Console, see Obtain an AccessKey pair.
- The endpoint of the ASAPI is obtained. For more information, see Generate an endpoint for the ASAPI.

Install Apsara Stack SDK for Python

1. Download the required version of Apsara Stack SDK for Python. For more information, see Obtain Apsara Stack SDKs.
2. Upload the compressed file of Apsara Stack SDK for Python to the host from which you want to send API requests and extract the file. Then, run the following code in the directory of the extracted files to install Apsara Stack SDK for Python:

```
# Install Apsara Stack SDK for Python 2.x.
pip install aliyun-python2-sdk-asapi-2.4.7.tar.gz
# Install Apsara Stack SDK for Python 3.x.
pip3 install aliyun-python3-sdk-asapi-2.4.7.tar.gz
```

> **Note**
>
> Replace `2.4.7` with the actual version of Apsara Stack SDK for Python.

Sample requests

You can use the GET or POST method to call API operations provided by the ASAPI.

```
    # 1. Import dependencies.
    from aliyunsdkasapi.ASClient import ASClient
    from aliyunsdkasapi.AsapiRequest import AsapiRequest

    if __name__ == '__main__':
     # 2. Create a request. The Product parameter specifies the name of the service. The Ver
sion parameter specifies the version of the API operation. The Action parameter specifies t
he operation that you want to perform. The asapi-endpoint parameter specifies the endpoint
of the ASAPI.
     req = AsapiRequest("<Product>", "<Version>", "<Action>", "<asapi-endpoint>")
     # 3. Configure operation-specific parameters.
     req.add_body_params("<key>", "<value>")
     # 4. Configure request headers.
     req.add_header("x-acs-resourcegroupid", "<your-resourcegroupid>");
     req.add_header("x-acs-organizationid", "<your-organizationid>");
     req.add_header("x-acs-regionid", "<your-regionid>");
     req.add_header("x-acs-instanceid", "<your-instanceid>");
     # 5. Configure a request method.
     req.set_method("POST")
     # 6. Configure initialization parameters for an ASClient object. The parameter values v
ary based on your environment. The timeout parameter specifies the time-out period for a re
quest. The cert_file parameter specifies the certificate. The verify parameter specifies wh
ether to verify the certificate.
     as_client = ASClient("<accesskeyid>", "<accesskeysecret>", "<regionid>",timeout=1000,
             cert_file=None,
             verify=False)
     # Configure the identifier of the requester. This parameter is required and used only f
or identification. You can set this parameter to a random value.
     as_client.setSdkSource("<The identifier of the requester>")
     response = as_client.do_request(req)
     print(response)
```

Request headers

Parameter	Description
x-acs-resourcegroupid	The ID of the resource set in the Apsara Uni-manager Management Console.
x-acs-organizationid	The ID of the organization in the Apsara Uni-manager Management Console.
x-acs-regionid	The ID of the region. For more information about how to obtain a region ID, see Query a region ID.
x-acs-instanceid	The ID of the instance to which you make API calls.

Configure a proxy

Perform the following steps to configure a proxy:

1. Import OS dependencies.

```
import os
```

2. Configure one or more proxies.

```
# Before you make an API call, configure one or more proxies.
os.environ['http_proxy'] = "http://x.x.x.x:xxxx"
os.environ['https_proxy'] = "https://x.x.x.x:xxxx"
```

8.1.1.1.4.3. Use Apsara Stack SDK for Node.js to call API operations

This topic describes how to obtain and use Apsara Stack SDK for Node.js to call API operations.

Preparations

- An authorized account and an AccessKey pair are obtained. The AccessKey pair consists of an AccessKey ID and an AccessKey secret. For more information about how to obtain an AccessKey pair in the Apsara Uni-manager Management Console, see Obtain an AccessKey pair.
- The endpoint of the Apsara Stack API (ASAPI) is obtained. For more information, see Generate an endpoint for the ASAPI.
- A region ID is obtained. For more information about how to obtain a region ID, see Query the region ID.

Add dependencies

Run the following command to install Apsara Stack SDK for Node.js:

```
tnpm install --save @ali/asapi-nodejs-sdk
```

Use Apsara Stack SDK for Node.js

The following sample code shows how to use Apsara Stack SDK for Node.js to make API calls:

```
// 1. Import the dependencies of Apsara Stack SDK for Node.js.
const Controller = require('egg').Controller;
const ASAPIClient = require('@ali/asapi-nodejs-sdk');
// 2. Configure the parameters.
const cnofig = {
    API_GATEWAY: '<The endpoint of the ASAPI>',
    regionId: '<The ID of the region in which the Apsara Stack service is deployed>',
    accessKeyId: '<The AccessKey ID of your Apsara Stack tenant account>',
    accessKeySecret: '<The AccessKey secret of your Apsara Stack tenant account>'
};
// 3. Initialize a client for API calls.
const AsapiClient = new ASAPIClient(cnofig, this.ctx);
// 4. Configure request parameters.
const params = {
    "Action": "<The name of the API operation>",
    "Product": "<The name of the service that provides the API operation>",
    "Version": "<The version of the API operation>",
    "regionId": '<The ID of the region in which the Apsara Stack service is deployed>',
      "<The name of the operation-specific parameter required by the API operation>": "<The
value of the operation-specific parameter>"
}
// 5. Configure request headers.
AsapiClient.addHeader('x-acs-caller-sdk-source', '<The identifier of the requester>')
AsapiClient.addHeader('x-acs-roleid', '<The ID of the role>')
AsapiClient.addHeader('x-acs-userid', '<The ID of the user>')
AsapiClient.addHeader('x-acs-organizationid', '<your-organizationid>')
AsapiClient.addHeadert("x-acs-regionid", "<your-regionid>");
AsapiClient.addHeader("x-acs-resourcegroupid", "<your-resourcegroupid>");
AsapiClient.addHeader("x-acs-instanceid", "<your-instanceid>");
// 6. Make an API call and obtain the response.
try {
  const res = await AsapiClient.doRequest(cnofig.API_GATEWAY, params, {
    method: 'POST', // The request method.
    formatParams: false, // Specifies whether to format parameters and capitalize the first
letter of each parameter.
    enableProxy: true, // Specifies whether to configure a proxy.
    proxy: 'http://x.x.x.x:xxxx',
    timeout: 10000, // The time-out period.
  // ca: , // The certificate issued by a certificate authority (CA). For more information,
visit https://nodejs.org/api/https.html#https_https_request_options_callback.
  })
  console.log(res)
} catch (e) {
  console.log(e)
}
```

Disable certificate validation

The following sample code shows how to disable certificate validation:

```
Configure the environment variable.
NODE_TLS_REJECT_UNAUTHORIZED=0
```

Request headers

Parameter	Description
x-acs-regionid	The ID of the region. For more information about how to obtain a region ID, see Query the region ID.
x-acs-organizationid	The ID of the organization in the Apsara Uni-manager Management Console.
x-acs-resourcegroupid	The ID of the resource set in the Apsara Uni-manager Management Console.
x-acs-instanceid	The ID of the instance to which you make API calls.
x-acs-caller-sdk-source	The custom name of the requester or the system. This parameter is used to identify the source of the API request.
x-acs-roleid	The ID of the role.
x-acs-userid	The ID of the user.

8.1.1.1.4.4. SDK for POP

SDK for Java

Before you use Apsara Stack API (ASAPI) SDK for POP for Java to access ASAPI, you must know the remote procedure call (RPC) and resource-oriented architecture (ROA) styles that are supported for API calls. ASAPI is compatible with both styles. Their difference lies in the ASAPI endpoints that are used for API calls.

Prerequisites

- An Alibaba Cloud SDK package is downloaded for the service that you want to access. The required dependencies are installed.
- SSL certificate validation is ignored for requests over HTTPS.

Background information

ASAPI supports only the HTTPS request protocol.

Difference between two styles

When you use the RPC or ROA style to make API calls, take note that the two styles use different ASAPI endpoints.

```
# ASAPI endpoint for the RPC style:
public.asapi.<global:region>.<global:internet-domain>/asapi/v3
# ASAPI endpoint for the ROA style:
public.asapi.<global:region>.<global:internet-domain>/asapi/v3/roa
```

Call examples

The following sample code provides an example on how to use the RPC style to make an API call. In this example, the DescribeInstances operation of Elastic Compute Service (ECS) is called, and the API version is 2014-05-26.

Sample code:

```
package com.aliyuns.client.pop.ecs;

import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.ecs.model.v20140526.DescribeInstancesRequest;
import com.aliyuncs.ecs.model.v20140526.DescribeInstancesResponse;
import com.aliyuncs.http.HttpClientConfig;
import com.aliyuncs.http.ProtocolType;
import com.aliyuncs.profile.DefaultProfile;

import java.util.List;

public class DescribeInstancesTest {
    public static void main(String[] args) {
        // Specify the endpoint of ASAPI.
        String endpoint = "public.asapi.<global:region>.<global:internet-domain>/asapi/v3";
        // Specify the region where the ECS service resides.
        String region = "<global:region>";
        // Specify the name of the service that you want to access.
        String product = "ECS";
        // Specify your AccessKey pair.
        String ak = "<accessKeyId>";
        String sk = "<accessKeySecret>";
        try {
            DefaultProfile clientProfile = DefaultProfile.getProfile(region, ak, sk);
            // Ignore SSL certificate validation.
            HttpClientConfig clientConfig = HttpClientConfig.getDefault();
            clientConfig.setIgnoreSSLCerts(true);
            // Set the connection timeout period.
            clientConfig.setConnectionTimeoutMillis(3000L);
            // Set the read timeout period.
            clientConfig.setReadTimeoutMillis(10000L);
            clientProfile.setHttpClientConfig(clientConfig);
            // Create a connection.
            DefaultAcsClient acsClient = new DefaultAcsClient(clientProfile);
            // Create a request.
            DescribeInstancesRequest request = new DescribeInstancesRequest();
            // Specify the endpoint of ASAPI.
            request.setSysEndpoint(endpoint);
            // Specify the name of the service that you want to access and the region where
the service resides.
            request.setSysLocationProduct(product);
            request.setSysRegionId(region);
            // Set the request protocol to HTTPS.
            request.setSysProtocol(ProtocolType.HTTPS);
            DescribeInstancesResponse result =  acsClient.getAcsResponse(request);
            List<DescribeInstancesResponse.Instance> instances = result.getInstances();
            for (DescribeInstancesResponse.Instance instance: instances) {
                System.out.println(instance.getInstanceId());
                System.out.println(instance.getInstanceName());
```

```
            }

        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

The following sample code provides an example on how to use the ROA style to make an API call. In this example, the GetNamespaceList operation of Container Registry is called, and the API version is 2016-06-07.

Sample code:

```
package com.aliyuns.client.pop.cr;

import com.aliyuncs.CommonRequest;
import com.aliyuncs.CommonResponse;
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.IAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.exceptions.ServerException;
import com.aliyuncs.http.FormatType;
import com.aliyuncs.http.HttpClientConfig;
import com.aliyuncs.http.MethodType;
import com.aliyuncs.http.ProtocolType;
import com.aliyuncs.profile.DefaultProfile;

public class GetNamespaceListTest {
    public static void main(String[] args) {
        // Specify the endpoint of ASAPI.
        String endpoint = "public.asapi.<global:region>.<global:internet-domain>/asapi/v3/r
oa";
        // Specify the region where the Container Registry service resides.
        String region = "<global:region>";
        // Specify the name of the service that you want to access.
        String product = "cr";
        // Specify your AccessKey pair.
        String ak = "<accessKeyId>";
        String sk = "<accessKeySecret>";
        DefaultProfile profile = DefaultProfile.getProfile(region, ak, sk);
        // Ignore SSL certificate validation.
        HttpClientConfig clientConfig = HttpClientConfig.getDefault();
        clientConfig.setIgnoreSSLCerts(true);
        // Set the connection timeout period.
        clientConfig.setConnectionTimeoutMillis(3000L);
        // Set the read timeout period.
        clientConfig.setReadTimeoutMillis(10000L);
        profile.setHttpClientConfig(clientConfig);
        // Create a connection for the client.
        IAcsClient client = new DefaultAcsClient(profile);
        // Create a request.
        CommonRequest request = new CommonRequest();
        // Set the request protocol to HTTPS.
```

```
        request.setSysProtocol(ProtocolType.HTTPS);
        // Specify the request method.
        request.setSysMethod(MethodType.GET);
        // Specify the endpoint of ASAPI.
        request.setSysDomain(endpoint);
        // Specify the version of the API.
        request.setSysVersion("2016-06-07");
        // Specify the pattern of the uniform resource identifier (URI).
        request.setSysUriPattern("/namespace");
        // Specify the name of the service that you want to access and the region where the
service resides.
        request.setSysLocationProduct(product);

        request.putHeadParameter("Content-Type", "application/json");
        String requestBody = "" +
                "{}";
        request.setHttpContent(requestBody.getBytes(), "utf-8", FormatType.JSON);
        try {
            CommonResponse response = client.getCommonResponse(request);
            System.out.println(response.getData());
        } catch (ServerException e) {
            e.printStackTrace();
        } catch (ClientException e) {
            e.printStackTrace();
        }
    }
}
```

> **Notice**
>
> If you send a request over HTTPS, you must enable the request to ignore SSL certificate validation.

SDK for Go

This topic describes how to use Apsara Stack API (ASAPI) SDK for POP for Go.

Prerequisites

An Alibaba Cloud SDK package is downloaded for the service that you want to access. The required dependencies are installed.

Background information

Only the remote procedure call (RPC) style is supported for API calls.

Call examples

The following sample code provides an example on how to make an API call. In this example, the DescribeInstances operation of Elastic Compute Service (ECS) is called, and the API version is 2014-05-26.

Sample code:

```
package main
```

```
import (
 "fmt"
 "time"

 "github.com/aliyun/alibaba-cloud-sdk-go/sdk"
 "github.com/aliyun/alibaba-cloud-sdk-go/sdk/auth/credentials"
 "github.com/aliyun/alibaba-cloud-sdk-go/sdk/requests"
 "github.com/aliyun/alibaba-cloud-sdk-go/sdk/responses"
)

func getSdkConfig() *sdk.Config {
 return sdk.NewConfig().
  WithTimeout(time.Duration(30) * time.Second).
  WithEnableAsync(true).
  WithGoRoutinePoolSize(100).
  WithMaxTaskQueueSize(10000).
  WithDebug(false).
  WithScheme("HTTP")
}

func main(){
 ak := "<The AccessKey ID of your Apsara Stack tenant account.>"
 sk := "<The AccessKey secret of your Apsara Stack tenant account.>"
 regionId := "<The region where the ECS service resides.>"
 endpoint := "<The endpoint of ASAPI.>" // No network protocol.
 request := requests.NewCommonRequest()
  request.SetReadTimeout(10 * time.Second) // Set the read timeout period of the request to
10 seconds.
  request.SetConnectTimeout(5 * time.Second)  // Set the connection timeout period of the r
equest to 5 seconds.
 request.Method = requests.GET
 request.Domain = endpoint         // Location Service will not be enabled if the host is s
pecified. For example, the service with a certification type-bearer token must be specified
.
 request.Version = "2014-05-26"            // Specify the version of the API.
 request.Scheme = "https"                // Specify the request protocol. Default value: ht
tp.
 request.ApiName = "DescribeInstances"
 request.QueryParams["Product"] = "Ecs"  // Specify the name of the service that you want t
o access.
 request.TransToAcsRequest()
 client, err := sdk.NewClientWithOptions(regionId,getSdkConfig(),credentials.NewAccessKeyCr
edential(ak,sk))
 // If relevant parameters are not set for the request, the client settings are used.
  //client.SetReadTimeout(10 * time.Second)              // Set the read timeout period of
the client to 10 seconds.
 //client.SetConnectTimeout(5 * time.Second)            // Set the connection timeout perio
d of the client to 5 seconds.
  resp := responses.BaseResponse{}
  err = client.DoAction(request, &resp)
    if err != nil {
        panic(err)
    }
 fmt.Print(endpoint)
```

```
}
```

Configure proxies

You can configure proxies in one of the following ways:

- Configure proxies by using environment variables.

  Set the HTTP_PROXY and HTTPS_PROXY environment variables, or set the NO_PROXY environment variable.

  Sample code:

```
import (
    "os"
)
func main(){
 os.Setenv("HTTP_PROXY", "http://x.x.x.x:xxxx") // Set the HTTP_PROXY environment variabl
e.
 os.Setenv("HTTPS_PROXY", "https://x.x.x.x:xxxx") // Set the HTTPS_PROXY environment vari
able.
}
```

- Configure proxies on the client.

  Sample code:

```
// The proxies that are configured on the client take precedence over those that are conf
igured by using environment variables.
client.SetHttpProxy("http://x.x.x.x:xxxx")   // Configure the HTTP proxy.
client.GetHttpProxy()                          // Query the HTTP proxy.

client.SetHttpsProxy("https://x.x.x.x:xxxx")   // Configure the HTTPS proxy.
client.GetHttpsProxy()                           // Query the HTTPS proxy.

client.SetNoProxy("127.0.0.1,localhost")     // Configure the proxy whitelist.
client.GetNoProxy()                          // Query the proxy whitelist.
```

SDK for Python

This topic describes how to use Apsara Stack API (ASAPI) SDK for POP for Python.

Prerequisites

An Alibaba Cloud SDK package is downloaded for the service that you want to access. The required dependencies are installed.

Background information

Only the remote procedure call (RPC) style is supported for API calls.

Call examples

The following sample code provides an example on how to make an API call. In this example, the DescribeInstances operation of Elastic Compute Service (ECS) is called, and the API version is 2014-05-26.

Sample code:

```
from aliyunsdkcore.client import AcsClient
from aliyunsdkcore.acs_exception.exceptions import ClientException
from aliyunsdkcore.acs_exception.exceptions import ServerException
from aliyunsdkecs.request.v20140526 import DescribeInstancesRequest
import os

# Create an AcsClient instance.
client = AcsClient(
   "<your-access-key-id>",
   "<your-access-key-secret>",
   "<your-region-id>",

   timeout=1000,  # Set the timeout period.
    verify=False, # Ignore certificate validation. or verify='<The location where the certi
ficate is stored.>'
);
# Set the following parameters for the HTTPS request protocol:
# client.set_verify(False)
# os.environ["HTTPS_PROXY"] = "http://127.0.0.1:8080"

# os.environ["HTTP_PROXY"] = "http://127.0.0.1:8080"
def hello_ecs_instance():
    # Create a request and set the parameters.
    request = DescribeInstancesRequest.DescribeInstancesRequest()

    params = {"PageNumber":"1", "Product":"Ecs","Version": "2014-05-26","Action": "Describe
Instances"};
    request.set_body_params(params)
    # The endpoint that contains no network protocol is in the following format: ASAPI doma
in name/asapi/v3.
    request.set_endpoint('<The endpoint of ASAPI.>')
    # Set the following parameter if the endpoint contains no network protocol:
    request.set_protocol_type("https")

    request.set_PageSize(10)
    # Initiate the API request and obtain the response.
    response = client.do_action_with_exception(request)
    print(response)

if __name__ == '__main__':
    print("Hello Aliyun OpenApi!")
    hello_ecs_instance()
```

Configure proxies

Set the HTTP_PROXY and HTTPS_PROXY environment variables.

Sample code:

```
# Configure the HTTPS proxy.
os.environ["HTTPS_PROXY"] = "http://x.x.x.x:xxxx"

# Configure the HTTP proxy.
os.environ["HTTP_PROXY"] = "https://x.x.x.x:xxxx"
```

8.1.1.1.5. HTTP requests

8.1.1.1.5.1. Overview

This topic describes how to make API requests and is intended for users who use API URLs to initiate HTTP GET requests.

If you are using an SDK to initiate requests, you can skip this topic.

The request URL consists of different parameters and has a fixed syntax. The URL contains common request parameters, your signature, and operation-specific parameters. Sample request URLs are provided for each API operation. These URLs are not encoded to make them easy to read. Before you make a request, you must encode the request URL. After the authentication process is complete based on your signature, the results are returned to you. Response parameters are returned if the call is successful, whereas an error message is returned if the call fails. You can troubleshoot issues based on the error message.

8.1.1.1.5.2. Request syntax

The Apsara Stack API (ASAPI) allows you to call API operations by sending HTTP GET requests based on URLs. Each URL must include request parameters. This topic describes the syntax of HTTP GET requests and provides the endpoint of the ASAPI.

Sample request

GetOrganizationList is used in the following unencoded URL request:

```
https://public.asapi.aliyuns.com/asapi/v3?Action=GetOrganizationList&Product=ascm&Version=2019-05-10&Id=<Organization ID>&<Common parameters>
```

- `https`: the protocol used to transmit the request.
- `public.asapi.aliyuns.com/asapi/v3`: the endpoint of the ASAPI.
- `Action=GetOrganizationList Product=ascm Version=2019-05-10`: the API operation to call.
- `Id`: the ID of the organization.
- `<Common parameters>`: the common parameters specified in the system.

Protocol

The ASAPI supports only HTTPS.

Endpoint

For more information about how to obtain an endpoint, see Generate an endpoint for the ASAPI.

Parameter

To specify an API operation, use the `Action, Product, and Version` parameters. For example, set `Action` to GetOrganizationList, Product to ascm, and Version to 2019-05-10. You must also specify other operation-specific parameters and common parameters. For more information, see Common parameters.

8.1.1.1.5.3. Request signatures

This topic describes how to sign HTTP API requests. ASAPI uses the request signature to verify the identity of the request sender. ASAPI implements symmetric encryption by using an AccessKey pair to verify the identity of the request sender.

> **Note**
>
> - An AccessKey pair consists of an AccessKey ID and an AccessKey secret, which are issued to each user or organization in the Apsara Uni-manager Management Console.
> - The AccessKey ID is used to verify identities of users, and the AccessKey secret is used to encrypt and verify signature strings. You must keep your AccessKey secret confidential.
> - ASAPI provides SDKs for Node.js, Python, and Java to facilitate complex signature calculation. For more information, see Obtain the core package for ASAPI.

Step 1: Create a canonicalized query string

1. Arrange the request parameters in alphabetical order, including all common and operation-specific parameters except the `Signature` parameter.

   > **Note**
   >
   > If you use the GET method to send a request,these parameters are connected by ampersands (&) and included in the request URL. The first request parameter follows a question mark (?).

2. Encode the request parameters and their values in UTF-8 based on RFC 3986. The following rules apply in the encoding process:
   - Letters, digits, and special characters such as hyphens (`-`), underscores (`_`), and periods (`.`) do not need to be encoded.
   - Other characters must be percent encoded in the `%XY` format. `XY` represents the ASCII code of the characters in hexadecimal notation. For example, double quotation marks (`"`) are encoded as `%22` .

- Extended UTF-8 characters are encoded in the `%XY%ZA...` format.
- Spaces must be encoded as `%20`. Do not encode spaces as plus signs (`+`).

  This encoding method is similar to but different from the `application/x-www-form-urlencoded` MIME encoding algorithm.

  If you use `java.net.URLEncoder` from the Java standard library, use `percentEncode` to encode request parameters and their values. In the encoded query string, replace the plus signs (`+`) with `%20` , asterisks (`*`) with `%2A` , and `%7E` with tildes (`~`). This way, you can obtain an encoded string that matches the preceding encoding rules.

  ```
  private static final String ENCODING = "UTF-8";
  private static String percentEncode(String value) throws UnsupportedEncodingException
  {
      return value != null ? URLEncoder.encode(value, ENCODING).replace("+", "%20").rep
  lace("*", "%2A").replace("%7E", "~") : null;
  }
  ```

3. Use equal signs (`=`) to connect the encoded request parameters and their values.
4. Use ampersands (`&`) to connect the encoded request parameters. These parameters must be arranged in the same order as those in Step 1.

Then, a canonicalized query string that follows the request structure is obtained. For more information, see Request structure.

Step 2: Create a string-to-sign

1. Create a `string-to-sign` . You can also use `percentEncode` to encode the canonicalized query string created in Step 1 based on the following rules:

   ```
   StringToSign=
       HTTPMethod + "&" + //HTTPMethod: the HTTP method that is used to send a request, su
   ch as GET.
       percentEncode("/") + "&" + //percentEncode("/"): Encode the forward slash (/) in UT
   F-8 as %2F.
       percentEncode(CanonicalizedQueryString) // Encode the canonicalized query string cr
   eated in Step 1.
   ```

2. Calculate the RFC 2104-compliant HMAC-SHA1 or HMAC-256 value of `StringToSign` . In the following example, Java Base64 is used:

   ```
   String signature = Base64.getEncoder().encodeToString(signData);
   ```

> **Note**
>
> When you calculate the signature, the key value specified by RFC 2104 is your `AccessKey secret` plus an ampersand (&), which has an ASCII value of 38. For more information, see Obtain an AccessKey pair.

3. Encode the `Signature` parameter based on RFC 3986 and add it to the canonicalized query string.

Example 1: Concatenate parameters

`GetOrganizationList` is used in this example to query regions. For example, `AccessKeyID` is set to testid and `AccessKeySecret` is set to testsecret. Perform the following operations:

1. Construct a canonicalized query string.

```
https://public.asapi.aliyuns.com/asapi/v3/?AccessKeyId=testid&Action=GetOrganizationList&Format=JSON&Id=1&Product=ascm&RegionId=cn-region-test&SignatureMethod=HMAC-SHA1&SignatureNonce=43967c6e-e3ad-44fa-b06b-fcf3db5f39d2&SignatureVersion=1.0&Timestamp=2020-09-15T08%3A50%3A40Z&Version=2019-05-10
```

2. Create a `string-to-sign` .

```
GET&%2F&AccessKeyId%3Dtestid%26Action%3DGetOrganizationList%26Format%3DJSON%26Id%3D1%26Product%3Dascm%26RegionId%3Dcn-region-test%26SignatureMethod%3DHMAC-SHA1%26SignatureNonce%3D43967c6e-e3ad-44fa-b06b-fcf3db5f39d2%26SignatureVersion%3D1.0%26Timestamp%3D2020-09-15T08%253A50%253A40Z%26Version%3D2019-05-10
```

3. Calculate the signature.

   Calculate the signature. The key value used for calculation is `testsecret&` because `AccessKeySecret` is set to testsecret. The calculated signature is `OLeaidS1JvxuMvnyHOwuJ+uX5qY=` . Java Base64 is used in the following sample code:

   `String signature = Base64.getEncoder().encodeToString(signData);` Encode `Signature=hvqv9Ll5RE6kQ4YsQXFAf9VuRIY=` based on RFC 3986 and add it to the canonicalized query string.

```
https://public.asapi.aliyuns.com/asapi/v3/?AccessKeyId=testid&Action=GetOrganizationList&Format=JSON&Id=1&Product=ascm&RegionId=cn-region-test&SignatureMethod=HMAC-SHA1&SignatureNonce=43967c6e-e3ad-44fa-b06b-fcf3db5f39d2&SignatureVersion=1.0&Timestamp=2020-09-15T08%3A50%3A40Z&Version=2019-05-10
```

You can use browsers or tools such as cURL and Wget to initiate an HTTP request for calling the `DescribeRegions` operation to query the Alibaba Cloud region list.

Example 2: Use the standard library of the programming language

`GetOrganizationList` is used in this example to query regions. For example, `AccessKeyID` is set to testid, `AccessKeySecret` is set to testsecret, and all request parameters are stored in a Java `Map<String, String>` object.

1. Predefine an encoding method.

```
private static final String ENCODING = "UTF-8";
private static String percentEncode(String value) throws UnsupportedEncodingException {
        return value != null ? URLEncoder.encode(value, ENCODING).replace("+", "%20").r
eplace("*", "%2A").replace("%7E", "~") : null;
}
```

2. Predefine the time format for the `Timestamp` parameter. Specify the `Timestamp` parameter in the ISO 8601 format. The time must be in UTC+0.

```
private static final String ISO8601_DATE_FORMAT = "yyyy-MM-dd'T'HH:mm:ss'Z'";
private static String formatIso8601Date(Date date) {
    SimpleDateFormat df = new SimpleDateFormat(ISO8601_DATE_FORMAT);
    df.setTimeZone(new SimpleTimeZone(0, "GMT"));
    return df.format(date);
}
```

3. Create a request string.

```
final String HTTP_METHOD = "GET";
Map parameters = new HashMap();
// Specify request parameters.
parameters.put("Product", "ascm");
parameters.put("Action", "GetOrganizationList");
parameters.put("Version", "2019-05-10");
parameters.put("AccessKeyId", "testid");
parameters.put("RegionId", "cn-region-test");
parameters.put("Timestamp", formatIso8601Date(new Date()));
parameters.put("SignatureMethod", "HMAC-SHA1");
parameters.put("SignatureVersion", "1.0");
parameters.put("SignatureNonce", UUID.randomUUID().toString());
parameters.put("Format", "JSON");
parameters.put("Id", "1");
// Arrange request parameters.
String[] sortedKeys = parameters.keySet().toArray(new String[]{});
Arrays.sort(sortedKeys);
final String SEPARATOR = "&";
// Create a string-to-sign.
StringBuilder stringToSign = new StringBuilder();
stringToSign.append(HTTP_METHOD).append(SEPARATOR);
stringToSign.append(percentEncode("/")).append(SEPARATOR);
StringBuilder canonicalizedQueryString = new StringBuilder();
for(String key : sortedKeys) {
    // Encode the key and the value.
    canonicalizedQueryString.append("&")
    .append(percentEncode(key)).append("=")
    .append(percentEncode(parameters.get(key)));
}
//Encode the canonicalized query string.
stringToSign.append(percentEncode(
canonicalizedQueryString.toString().substring(1)));
```

4. The signature. The key value used for calculation is `testsecret&` because `AccessKeySecret` is set to testsecret. The calculated signature is `OLeaidS1JvxuMvnyHOwuJ%2BuX5qY%3D` .

```
// The following sample code shows how to calculate the signature:
final String ALGORITHM = "HmacSHA1";
final String ENCODING = "UTF-8";
key = "testsecret&";
Mac mac = Mac.getInstance(ALGORITHM);
mac.init(new SecretKeySpec(key.getBytes(ENCODING), ALGORITHM));
byte[] signData = mac.doFinal(stringToSign.getBytes(ENCODING));
String signature = Base64.getEncoder().encodeToString(signData);
```

Encode the Signature parameter based on RFC 3986 and add it to the canonicalized query string. The following URL is obtained:

```
https://public.asapi.aliyuns.com/asapi/v3/?AccessKeyId=testid&Action=GetOrganizationLis
t&Format=JSON&Id=1&Product=ascm&RegionId=cn-region-test&SignatureMethod=HMAC-SHA1&Signa
tureNonce=43967c6e-e3ad-44fa-b06b-fcf3db5f39d2&SignatureVersion=1.0&Timestamp=2020-09-1
5T08%3A50%3A40Z&Version=2019-05-10
```

5. Use browsers or tools such as cURL and Wget to initiate an HTTP request.

8.1.1.1.5.4. Response

Responses are returned only in the JSON format. If a return code is greater than or equal to 200 and less than 300, a success response is returned. Otherwise, an error response is returned.

Sample success response

If a request is successful, the request ID and operation-specific parameter values are returned. For more information, see the developer guide of the corresponding Apsara Stack service.

```
 {
    "eagleEyeTraceId": "xxx-xxx-xxx-xxx", // The trace ID provided by EagleEye.
    "asapiSuccess": true,
    "RequestId": "xxxxxxxxxx",
    "Regions": { // The regions returned after you call the DescribeRegions operation.
        "Region": [
            {
                "RegionId": "",
                "RegionEndpoint": "",
                "LocalName": ""
            }
        ]
    }
}
```

Sample error response

If a request fails, the following information is returned. For more information, see the developer guide of the corresponding Apsara Stack service.

```
{
    "code": "asapi.server.api.notfound",// The error code.
    "eagleEyeTraceId": "xxx-xxx-xxx-xxx", // The trace ID provided by EagleEye.
    "asapiSuccess": false, // Indicates whether the request is successful.
    "hostId": "xxxx", // The ID of the host.
    "message": "Failed to ....", // The message returned.
    "asapiErrorMessage": "Failed to ....", // The error message provided by the ASAPI.
    "asapiErrorCode": "asapi.server.api.notfound" // The error code provided by the ASAPI.
}
```

8.1.2. API reference

8.1.2.1. Instance management

8.1.2.1.1. CreateDBInstance

Description

Creates an ApsaraDB RDS instance. For information about instance types, see Instance types in Appendix.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateDBInstance.
RegionId	String	Yes	The region ID of the instance. It can be up to 50 characters in length. You can call the DescribeRegions operation to query the most recent region list.
ZoneId	String	No	The zone ID of the instance. You can call the DescribeRegions operation to query the most recent zone list.
Engine	String	Yes	The engine of the database. Valid values: • MySQL • SQLServer • PostgreSQL • POLARDB
EngineVersion	String	Yes	The engine version of the database. Valid values: • MySQL: 5.6, 5.7, and 8.0 • SQL Server: 2008 R2, 2012_ent_ha, 2012_std_ha, 2016_ent_ha, and 2016_std_ha • PostgreSQL: 9.4 and 10.0 • PolarDB: 11
DBInstanceClass	String	Yes	The instance type.
DBInstanceStorage	Integer	Yes	The user-defined storage space. Valid values: MySQL High-availability Edition: 5 to 2000 PolarDB High-availability Edition: 5 to 2000 This value must be in 5 GB increments. Unit: GB.
DBInstanceNetType	String	Yes	The network connection type of the instance. Valid values: • Internet • Intranet
DBInstanceDescription	String	No	The description of the instance. It must be 2 to 256 bytes in length , https:// and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and cannot start with http:// or https://.

Parameter	Type	Required	Description
SecurityIPList	String	Yes	The IP addresses that are allowed to access all databases on the instance. You can add a maximum of 1,000 IP addresses and separate them with commas (,). Format: %, 0.0.0.0/0, IP address (example: 10.23.12.24), or CIDR block (example: 10.23.12.24/24). /24 indicates that the prefix of each IP address is 24-bit long. You can replace 24 with a value within the range of 1 to 32. 0.0.0.0/0 indicates that the instance can be accessed by all devices.
ClientToken	String	Yes	The client token that is used to ensure the idempotence of the request.
InstanceNetworkType	String	No	The network type of the instance. Valid values: VPC and Classic. Default value: Classic.
ConnectionMode	String	No	The access mode of the instance. Valid values: Performance and Safe. If no value is specified, the system assigns an access mode.
VPCId	String	No	The ID of the VPC.
VSwitchId	String	No	The ID of the vSwitch.
PrivateIpAddress	String	No	The VPC IP address that belongs to the specified vSwitch. If no value is specified, the system assigns a VPC IP address.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.
DBInstanceId	String	The ID of the instance.
OrderId	String	The ID of the order.
ConnectionString	String	The endpoint that is used to connect to the database.
Port	String	The port that is used to connect to the database.

Examples

- XML format

  Sample success responses

```
<CreateDBInstanceResponse>
<OrderId>100789370xxxxx</OrderId>
<ConnectionString>xxxxx.mysql.rds.aliyuncs.com </ConnectionString>
<DBInstanceId>rds-xxxxx</DBInstanceId>
<port>3306</port>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</CreateDBInstanceResponse>
```

- JSON format

```
{ "OrderId": "100789370230206",
"ConnectionString": "rds-xxxxx.mysql.rds.aliyuncs.com",
"DBInstanceId": "rds-xxxxx",
"Port": "3306",
"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.1.2. DeleteDBInstance

Releases an ApsaraDB RDS instance.

Before you call this operation, make sure that the following requirements are met:

- The instance is in the running state.
- The read/write splitting feature is disabled for the instance.
- The instance is a primary, read-only, disaster recovery, or temporary instance.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	DeleteDBInstance	The operation that you want to perform. Set the value to DeleteDBInstance.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxxxx	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	N/A	Common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=DeleteDBInstance
&DBInstanceId=rm-uf6wjk5xxxxxxxxxx
&<[Common request parameters]>
```

Sample success responses

- XML format

```
<DeleteDBInstanceResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</DeleteDBInstanceResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

8.1.2.1.3. RestartDBInstance

Restarts an ApsaraDB RDS instance.

If a large number of transactions need to be submitted or rolled back, the restart process may be delayed for a minute.

Before you call this operation, make sure that the following requirements are met:

- The instance is in the running state.
- The instance does not have ongoing backup tasks.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	RestartDBInstance	The operation that you want to perform. Set the value to RestartDBInstance.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxx	The ID of the instance.
ClientToken	String	No	ETnLKlblzczshOTUbOCzxxxxxx	The client token that is used to ensure the idempotence of the request. You can use the client to generate the value, but you must make sure that it is unique among different requests. The token can contain only ASCII characters and cannot exceed 64 characters in length.

Response parameters

Parameter	Type	Description
<Common response parameters>	N/A	Common response parameters.

Examples

Sample requests

```
http(s)://rds.example.com/?Action=RestartDBInstance
&DBInstanceId=rm-uf6wjk5xxxxxxxxxx
&<Common request parameters>
```

Sample success responses

`XML` format

```
<RestartDBInstanceResponse>
      <RequestId> 65BDA532-28AF-4122-AA39-B382721EEE64</RequestId></RestartDBInstanceRespon
se>
```

`JSON` format

```
{
    "RequestId": " 65BDA532-28AF-4122-AA39-B382721EEE64"
}
```

8.1.2.1.4. DescribeDBInstanceAttribute

Description

You can call this operation to query attributes of an instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceAttribute.
DBInstanceId	String	Yes	The ID of the instance. Up to 30 IDs can be entered at a time. Separate multiple IDs with commas (,).

Response parameters

Parameter	Type	Example	Description
Items			The array that consists of DBInstanceAttribute data.

Parameter	Type	Example	Description
└DBInstanceId	String	rm-bpvxxxxx	The ID of the instance.
└ DBInstanceType	String	Primary	The role of the instance. Valid values: • Primary: primary instance • Readonly: read-only instance • Guard: disaster recovery instance • Temp: temporary instance
└Category	String	Basic	The RDS edition of the instance. Valid values: • Basic: Basic Edition • Standard: High-availability Edition • Enterprise: Enterprise Edition
└InstanceNetworkType	String	Classic	The network type of the instance. Valid values: • Classic • VPC
└RegionId	String	cn-hangzhou	The region ID of the instance.
└ZoneId	String	cn-hangzhou-a	The zone ID of the instance.
└ConnectionString	String	rds-xxxxx.mysql.rds.aliyuncs.com	The endpoint used to connect to the instance.
└Port	String	3306	The port used to connect to the instance.
└Engine	String	MySQL	The engine of the database.
└EngineVersion	String	5.5	The engine version of the database.
└DBInstanceClassType	String	s	The family of the instance. Valid values: • s: shared instance • x: general-purpose instance • d: dedicated instance • h: dedicated host
└DBInstanceClass	String	rds.mys2.small	The type of the instance.
└DBInstanceMemory	Long	240	The memory capacity of the instance. Unit: MB.
└DBInstanceStorage	Integer	10	The storage space of the instance. Unit: GB.

Parameter	Type	Example	Description
└DBInstanceNetType	String	Internet	The network connection type of the instance. Valid values: • Internet • Intranet
└DBInstanceStatus	String	Running	The status of the instance. For more information, see Instance states in Appendix.
└DBInstanceDescription	String	Test instance	The description of the instance.
└LockMode	String	Unlock	The lock status of the instance. Valid values: • Unlock: normal • ManualLock: locked manually • LockByExpiration: locked automatically upon expiration • LockByRestoration: locked automatically before instance rollback • LockByDiskQuota: locked automatically due to full disk space
└LockReason	String	None	The reason why the instance is locked.
└DBMaxQuantity	Integer	200	The maximum number of databases that can be created for an instance.
└AccountMaxQuantity	Integer	50	The maximum number of accounts that can be created for an instance.
└CreationTime	String	2011-05-30T12:11:4Z	The time when the instance was created. The time follows the ISO 8601 standard in the `YYYY-MM-DDThh:mm:ssZ` format. Example: `2011-05-30T12:11:4Z`.
└ExpireTime	String	None	The expiration time of the instance. This parameter is not returned for pay-as-you-go instances.

Parameter	Type	Example	Description
└MaintainTime	String	00:00Z-02:00Z	The scheduled maintenance window of the instance. For example, `00:00Z-02:00Z` indicates that routine maintenance can be performed from 00:00 to 02:00.
└AvailabilityValue	String	100.0%	The availability status of the instance. Unit: %.
└MaxIOPS	Integer	150	The maximum number of I/O operations per second (IOPS).
└MaxConnections	Integer	60	The maximum number of concurrent connections to the instance.
└MasterInstanceId	String	null	The ID of the primary instance. If this parameter is not returned (null), the instance is a primary instance.
└IncrementSourceDBInstanceId	String	null	The instance ID of the incremental data source. For example, the incremental data source of a disaster recovery instance or read-only instance is the primary instance, and the incremental data source of the primary instance is null.
└GuardDBInstanceId	String	None	The ID of the disaster recovery instance attached to the instance.
└TempDBInstanceId	String	None	The ID of the temporary instance attached to the instance.
└ReadOnlyDBInstanceIds		rr-xxxxx	The IDs of the read-only instances attached to the instance.
└DBInstanceId	String	rm-bpxxxxx	The ID of the instance.
└VpcCloudInstanceId	String	vpc-xxxxx	The ID of the VPC.
└ResourceGroupId	String	3653788125	The ID of the resource group.
RequestId	String	1AD222E9-E606-4A42-BF6D-8A4442913CEF	The ID of the request.

DBInstanceAttribute parameters

Note You can call the DescribeDBInstanceHAConfig operation to query information of the primary and secondary instances.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeDBInstanceAttribute
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

8.1.2.1.5. DescribeDBInstances

Description

You can call this operation to query instances and RAM-authorized instances.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	DescribeDBInstances	The operation that you want to perform. Set the valuer to DescribeDBInstances.
RegionId	String	Yes	cn-hangzhou	The region ID of the instance.
ConnectionMode	String	No	Performance	The access mode of the instance. Valid values: • Performance: standard access mode • Safe: safe access mode • If no value is specified, instances in both access modes are returned.

Parameter	Type	Required	Example	Description
DBInstanceType	String	No	Primary	The role of the instance. Valid values: • Primary: primary instance • Readonly: read-only instance • Guard: disaster recovery instance • Temp: temporary instance • If no value is specified, instance of all roles are returned.
InstanceNetworkType	String	No	Classic	The network type of the instance. Valid values: • VPC: VPC instance • Classic: classic network instance • If no value is specified, instance of both network types are returned.
PageNumber	Integer	No	1	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.

Parameter	Type	Required	Example	Description
PageSize	Integer	No	30	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.
Tags	String	No	{ “key1” :” value 1” }	The tag of the instance, in the JSON format. The tag includes a key-value pair of TagKey and TagValue. TagValue can be left empty, but TagValue cannot. Example: { “key1” :” value 1” }.

Response parameters

Parameter	Type	Example	Description
PageNumber	Integer	1	The number of the page returned.
TotalRecordCount	Integer	1	The total number of entries.
PageRecordCount	Integer	1	The number of instances on the current page.
Items			The array that consists of instance data.
└DBInstanceId	String	rm-xxxxx	The ID of the instance.
└DBInstanceDescription	String	testforRemarks	The description of the instance.
└PayType	String	Postpaid	The billing method of the instance. Valid values: • Postpaid: pay-as-you-go • Prepaid: subscription

Parameter	Type	Example	Description
└DBInstanceType	String	Primary	The role of the instance. Valid values: • Primary: primary instance • ReadOnly: read-only instance • Guard: disaster recovery instance • Temp: temporary instance
└InstanceNetworkType	String	Classic	The network type of the instance. Valid values: • Classic: classic network instance • VPC: VPC instance
└ConnectionMode	String	Performance	The access mode of the instance. Valid values: • Performance: standard access mode • Safe: safe access mode
└RegionId	String	cn-hangzhou	The region ID of the instance.
└ExpireTime	String	None	The expiration time of the instance. This parameter is not returned for pay-as-you-go instances.
└DBInstanceStatus	String	Intranet	The status of the instance. For more information, see Instance states in Appendix.
└Engine	String	MySQL	The type of the database.

Parameter	Type	Example	Description
└DBInstanceNetType	String	Internet	The network connection type of the instance. Valid values: • Internet: public network • Intranet: internal network
└LockMode	String	Unlock	The lock status of the instance. Valid values: • Unlock: normal • ManualLock: locked manually • LockByExpiration: locked automatically upon expiration • LockByRestoration: locked automatically before instance rollback • LockByDiskQuota: locked automatically for full disk space
└LockReason	String	None	The reason why the instance is locked.
└MasterInstanceId	String	null	The ID of the primary instance. If this parameter is not returned (null), the instance is a primary instance.
└GuardDBInstanceId	String	None	The ID of the disaster recovery instance attached to the instance.
└TempDBInstanceId	String	None	The ID of the temporary instance attached to the instance.
└VpcCloudInstanceId	String	vpc-xxxxx	The ID of the VPC instance.
└ReadOnlyDBInstanceIds			None
└DBInstanceId	String	rm-xxxxx	The ID of the instance.

Parameter	Type	Example	Description
RequestId	String	1AD222E9-E606-4A42-BF6D-8A4442913CEF	The ID of the request.

Examples

```

8.1.2.1.6. ModifyDBInstanceSpec

Description

You can call this operation to change the type or storage space of an instance. Before you call this operation, make sure that the following requirements are met:

- The instance is in the running state.
- The instance is not performing a backup task.
- One of the instance type (DBInstanceClass) and storage space (DBInstanceStorage) parameters is specified in the request.
- When you downgrade the disk space configuration, the input disk space is no less than 1.1 times the actually used space.
- Only primary and read-only instances allow specification changes. Specifications of disaster recovery and temporary instances cannot be changed.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ModifyDBInstanceSpec	The operation that you want to perform. Set the value to ModifyDBInstanceSpec.
DBInstanceId	String	Yes	rm-bpxxxx	The ID of the instance.
AccessKeyId	String	No	LTAIKw8gqxxxxx	The AccessKey ID provided by Alibaba Cloud.
ClientToken	String	No	ETnLKlblzczshOTUbOCziJZNwHlYBQ	The client token that is used to ensure idempotence of the request.
DBInstanceClass	String	No	rds.mys2.small	The instance type. For more information, see Instance types in Appendix.
DBInstanceStorage	Integer	No	20	The user-defined storage space. Unit: GB. This value must be in 5 GB increments. For more information, see the Instance types topic in the User Guide of ApsaraDB RDS.
EffectiveTime	String	No	Immediate	The time when the changes take effect. Valid values: Immediate and MaintainTime. Default value: Immediate.
OwnerAccount	String	No	testuser@aliyun.com	The Apsara Stack tenant account.

Response parameters

Parameter	Type	Example	Description
RequestId	String	1AD222E9-E606-4A42-BF6D-8A4442913CEF	The ID of the request.

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyDBInstanceSpec
&DBInstanceId=rds-xxxxx
&PayType=Postpaid
&DBInstanceStorage=10
&<Common request parameters>
```

Sample success responses

- XML format

```
<ModifyDBInstanceSpecResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifyDBInstanceSpecResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

Sample error responses

JSON format

```
{ "Code":"UnsupportedOperation",
"HostId":"rds.aliyuncs.com",
"Message":"The specified action is not supported.",
"RequestId":"7463B73D-35CC-4D19-A010-6B8D65D242EF"}
```

8.1.2.1.7. DescribeDBInstanceNetInfo

Queries the connection information of an instance.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	DescribeDBInstanceNetInfo	The operation that you want to perform. Set the value to **DescribeDBInstanceNetInfo**.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxx	The ID of the instance.

Parameter	Type	Required	Example	Description
ClientToken	String	No	ETnLKlblzczshOTUbOCzxxxxxxxxxx	The client token that is used to ensure the idempotence of the request. You can use the client to generate the value, but you must make sure that it is unique among different requests. The token can contain only ASCII characters and cannot exceed 64 characters in length.
Flag	String	No	N/A	A hidden parameter.
DBInstanceNetRWSplitType	String	No	Normal	The type of the endpoint. Valid values: • **Normal** • **ReadWriteSplitting** **Note** By default, the system returns both types of endpoints.

Response parameters

Parameter	Type	Example	Description
DBInstanceNetInfos	Array		Details about the instance endpoint.
DBInstanceNetInfo			
ConnectionString	String	rm-uf6wxxxxx.mysql.rds.aliyuncs.com	The endpoint of the instance.
IPAddress	String	192.168.12.84	The IP address of the instance.

Parameter	Type	Example	Description

IPType	String	Public	The network type of the instance.
			• Valid values when the instance resides in the classic network:
			  ◦ **Inner**: internal network
			  ◦ **Public**: Internet
			• Valid values when the instance resides in a virtual private cloud (VPC):
			  ◦ **Private**: internal network
			  ◦ **Public**: Internet

Port	String	3306	The port that is used to connect to the instance.
VPCId	String	vpc-uf6f7l4fg90xxxxxxxxxx	The ID of the VPC.
VSwitchId	String	vsw-uf6adz52c2pxxxxxxxxxx	The ID of the vSwitch.
ConnectionStringType	String	Normal	The type of the endpoint. Valid values: • **Normal** • **ReadWriteSplitting**
MaxDelayTime	String	12	The latency threshold. This parameter is returned only for a read/write splitting endpoint. Unit: seconds. **Note** If the latency on a read-only instance exceeds the specified threshold, ApsaraDB RDS no longer routes read requests to the read-only instance.
DistributionType	String	Standard	The policy that is used to allocate read weights. This parameter is returned only for a read/write splitting endpoint. Valid values: • **Standard**: ApsaraDB RDS allocates a read weight to each instance based on the instance specifications. • **Custom**: You must manually assign a read weight to each instance.

Parameter	Type	Example	Description
DBInstanceWeights	Array		Details about the weight. This parameter is returned only when the read/write splitting feature is enabled for the instance.
DBInstanceWeight			
DBInstanceId	String	rm-uf6wjk5xxxxxxx	The ID of the instance.
DBInstanceType	String	Master	The role of the instance. Valid values: • **Master**: primary instance • **Readonly**: read-only instance
Weight	String	100	The weight of the instance.
Availability	String	Unavailable	The availability of the instance. Valid values: • **Unavailable** • **Available**
ExpiredTime	String	1209534	The remaining time of the classic network in hybrid access mode. Unit: seconds.
SecurityIPGroups	Array		Details about the IP address whitelist.
securityIPGroup			
SecurityIPGroupName	String	Default	The name of the IP address whitelist.
SecurityIPs	String	127.0.0.1	The IP addresses contained in the IP address whitelist.
Upgradeable	String	Disabled	Indicates whether the IP version can be updated. Valid values: **Enable and Disabled**. **Note** The IP version can be updated from IPv4 to IPv6.

Parameter	Type	Example	Description
InstanceNetworkType	String	VPC	The network type of the instance. Valid values: • **Classic** • **VPC**
RequestId	String	777C4593-8053-427B-99E2-105593277CAB	The ID of the request.
SecurityIPMode	String	safety	The whitelist mode of the instance. Valid values: • **normal**: standard whitelist mode • **safety**: enhanced whitelist mode

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeDBInstanceNetInfo
&DBInstanceId=rm-uf6wjk5xxxxxxx
&<Common request parameters>
```

Sample success responses

`XML` format

```
<DescribeDBInstanceNetInfoResponse>
      <dBInstanceNetInfos>
            <connectionString>rm-uf6wjk5xxxxxxx.mysql.rds.aliyuncs.com</connectionString>
            <connectionStringType>Normal</connectionStringType>
            <iPAddress>192.168.xx.xx</iPAddress>
            <iPType>Public</iPType>
            <port>3306</port>
            <upgradeable>Disabled</upgradeable>
            <vPCId></vPCId>
      </dBInstanceNetInfos>
      <instanceNetworkType>Classic</instanceNetworkType>
      <requestId>777C4593-8053-427B-99E2-105593277CAB</requestId>
</DescribeDBInstanceNetInfoResponse>
```

`JSON` format

```
{
    "dBInstanceNetInfos": [
        {
            "connectionString": "rm-uf6wjk5xxxxxxx.mysql.rds.aliyuncs.com",
            "connectionStringType": "Normal",
            "dBInstanceWeights": [],
            "iPAddress": "192.168.xx.xx",
            "iPType": "Public",
            "port": "3306",
            "securityIPGroups": [],
            "upgradeable": "Disabled",
            "vPCId": ""
        }
    ],
    "instanceNetworkType": "Classic",
    "requestId": "777C4593-8053-427B-99E2-105593277CAB"
}
```

8.1.2.1.8. ModifyDBInstanceConnectionString

Description

You can call this operation to modify the endpoint and port of a connection string.

ApsaraDB RDS provides the internal and public endpoints and allows both types to coexist in a specific access mode.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceConnectionString.
DBInstanceId	String	Yes	The ID of the instance.
CurrentConnectionString	String	Yes	The endpoint used by the instance.
ConnectionStringPrefix	String	No	The endpoint to be used by the instance.
Port	String	No	The port to be used by the instance.

Response parameters

This operation returns only common response parameters.

8.1.2.1.9. ModifyDBInstanceNetworkType

Changes the network type of an ApsaraDB RDS instance.

This operation is used to switch the network type of an instance between VPC and classic network.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ModifyDBInstanceNetworkType	The operation that you want to perform. Set the value to **ModifyDBInstanceNetworkType**.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxx	The ID of the instance.
InstanceNetworkType	String	Yes	Classic	The new network type of the instance. Valid values: • **VPC** • **Classic**
VPCId	String	No	vpc-uf6f7l4fg90xxxxx	The ID of the VPC.
VSwitchId	String	No	vsw-uf6adz52c2pxxxx	The ID of the vSwitch. This parameter is required if the value of **VPCId** is specified.
PrivateIpAddress	String	No	172.10.40.25	The internal IP address of the instance, which must be within the CIDR block supported by the specified vSwitch. The system assigns an internal IP address based on the **VPCId** and **VSwitchId** parameters.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyDBInstanceNetworkType
&DBInstanceId=rm-uf6wjk5xxxxxxx
&InstanceNetworkType=Classic
&<Common request parameters>
```

Sample success responses

`XML` format

```
<ModifyDBInstanceNetworkTypeResponse>
      <RequestId> 65BDA532-28AF-4122-AA39-B382721EEE64</RequestId>
</ModifyDBInstanceNetworkTypeResponse>
```

`JSON` format

```
{
  "RequestId": " 65BDA532-28AF-4122-AA39-B382721EEE64"
}
```

Error codes

For more information, see Common errors.

8.1.2.1.10. DescribeDBInstanceIPArrayList

Description

You can call this operation to query the IP whitelist of an instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceIPArrayList.
DBInstanceId	String	Yes	The ID of the instance whose IP whitelist is queried.

Response parameters

Parameter	Type	Description
<Common response parameters>		Common response parameters.
Items	List<DBInstanceIPArray>	The array that consists of DBInstanceIPArray data.

DBInstanceIPArray parameters

Parameter	Type	Description
DBInstanceIPArrayName	String	The name of the IP whitelist.
DBInstanceIPArrayAttribute	String	The attribute of the IP whitelist. Default value: null. Whitelists tagged with "hidden" are not displayed in the console.

Parameter	Type	Description
SecurityIPList	String	The IP addresses in an IP address whitelist. Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats of IP addresses are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or Classless Inter-Domain Routing (CIDR) blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix. The IP address prefix can consist of 1 to 32 bits.

8.1.2.1.11. ModifySecurityIps

Modifies an IP address whitelist of an instance.

Before you call this operation, make sure that the following requirements are met:

- The instance is in the running state.
- The instance is not locked by the system.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ModifySecurityIps	The operation that you want to perform. Set the value to ModifySecurityIps.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxx	The ID of the instance.
SecurityIps	String	Yes	10.23.12.24	The IP addresses in an IP address whitelist. Separate multiple IP addresses with commas (,). Each IP address in the IP address whitelist must be unique. You can add IP addresses in the following formats: • IP addresses, such as 10.23.12.24. • Classless Inter-Domain Routing (CIDR) blocks, such as 10.23.12.0/24. In this case, /24 indicates that the prefix of each IP address is 24-bit long. You can replace 24 with a value within the range of 1 to 32. **Note** A maximum of 1,000 IP addresses and CIDR blocks can be configured for each instance. If you want to add a large number of IP addresses, we recommend that you merge them into CIDR blocks, such as 10.23.12.0/24.

Parameter	Type	Required	Example	Description
DBInstanceIPArrayName	String	No	test	The name of the IP address whitelist to be modified. Default value: Default. **Note** A maximum of 200 IP address whitelists can be configured for each instance.
DBInstanceIPArrayAttribute	String	No	hidden	The attribute of the IP address whitelist. This parameter is empty by default. **Note** The IP address whitelists that have the hidden attribute are not displayed in the ApsaraDB RDS console. These IP address whitelists are used to access Alibaba Cloud services such as Data Transmission Service (DTS).

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=ModifySecurityIps
&DBInstanceId=rds-xxxxx
&SecurityIps=192.168.1.2
&<Common request parameters>
```

Sample success responses

- XML format

```
<ModifySecurityIpsResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifySecurityIpsResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.1.12. DescribeRegions

Description

You can call this operation to query the available RDS regions and zones.

Before you call the CreateInstance operation, call this operation to query region IDs.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeRegions.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.
Regions	List<RDSRegion>	The array that consists of RDSRegion data.

RDSRegion parameters

Parameter	Type	Description
RegionId	String	The region ID.
ZoneId	String	The zone ID.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeRegions
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeRegionsResponse>
<Regions>
<RDSRegion>
<RegionId>cn-hangzhou</RegionId>
<ZoneId>cn-hangzhou-a</RegionId>
</RDSRegion>
<RDSRegion>
<RegionId>cn-hangzhou</RegionId
><ZoneId>cn-hangzhou-b</ZoneId>
</RDSRegion>
</Regions>
<RequestId>A36D9720-7902-42A4-B8B9-014A2135E6C3</RequestId>
</DescribeRegionsResponse>
```

- JSON format

```
{ "Regions":
    { "RDSRegion":
        [ {"RegionId": "cn-hangzhou",
            "ZoneId":"cn-hangzhou-a"},
          {"RegionId": "cn-hangzhou",
            "ZoneId":"cn-hangzhou-b"},
             ]},
    "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"
}
```

8.1.2.1.13. DescribeDBInstanceHAConfig

Queries the high availability mode and data replication mode of an ApsaraDB RDS instance.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	DescribeDBInstanceHAConfig	The operation that you want to perform. Set the value to DescribeDBInstanceHAConfig.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxx	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	N/A	Common response parameters.
DBInstanceId	String	The ID of the instance.
SyncMode	String	The synchronization mode. Valid values: Semi-sync and Async.
HAMode	String	The high availability mode. RPO: Data persistence is preferred. RTO: Instance availability is preferred.
HostInstanceInfos	List<NodeInfo>	Details about primary and secondary instances.

NodeInfo parameters

Parameter	Type	Description
NodeId	String	The unique ID of the primary or secondary instance.
NodeType	String	The role of the instance. Master: primary instance. Slave: secondary instance.
RegionId	String	The region ID of the instance.
ZoneId	String	The zone ID of the instance.
SyncStatus	String	The synchronization status of the instance. NotAvailable: Synchronization is unavailable because a failure has occurred. Syncing: Synchronization is in process, with a probability of data loss during failovers. Synchronized: Synchronization is complete. NotSupport: Synchronization is not supported by the engine type or version.
LogSyncTime	String	The time when the secondary instance receives logs.
DataSyncTime	String	The time when the secondary instance receives data.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeDBInstanceHAConfig
&DBInstanceId=rm-uf6wjk5xxxxxx
&<Common request parameters>
```

Sample success responses

`XML` format

```
<DescribeDBInstanceHAConfigResponse>
      <dBInstanceId>rm-uf6wjk5xxxxxx</dBInstanceId>
      <hAMode>RPO</hAMode>
      <hostInstanceInfos>
            <logSyncTime>2018-01-19T12:33:06Z</logSyncTime>
            <nodeId>3397027</nodeId>
            <nodeType>Slave</nodeType>
            <regionId>cn-shenzhen</regionId>
            <syncStatus>Syncing</syncStatus>
            <zoneId>cn-shenzhen-b</zoneId>
      </hostInstanceInfos>
      <hostInstanceInfos>
            <logSyncTime>2018-01-19T12:33:06Z</logSyncTime>
            <nodeId>3397029</nodeId>
            <nodeType>Master</nodeType>
            <regionId>cn-shenzhen</regionId>
            <syncStatus>Syncing</syncStatus>
            <zoneId>cn-shenzhen-a</zoneId>
      </hostInstanceInfos>
      <requestId>F051AEB2-7655-4F0A-BC46-7E0C18A7910C</requestId>
      <syncMode>Semi-sync</syncMode>
</DescribeDBInstanceHAConfigResponse>
```

`JSON` format

```
{
    "dBInstanceId": "rm-uf6wjk5xxxxxx",
    "hAMode": "RPO",
    "hostInstanceInfos": [
        {
            "logSyncTime": "2018-01-19T12:33:06Z",
            "nodeId": "3397027",
            "nodeType": "Slave",
            "regionId": "cn-shenzhen",
            "syncStatus": "Syncing",
            "zoneId": "cn-shenzhen-b"
        },
        {
            "logSyncTime": "2018-01-19T12:33:06Z",
            "nodeId": "3397029",
            "nodeType": "Master",
            "regionId": "cn-shenzhen",
            "syncStatus": "Syncing",
            "zoneId": "cn-shenzhen-a"
        }
    ],
    "requestId": "F051AEB2-7655-4F0A-BC46-7E0C18A7910C",
    "syncMode": "Semi-sync"
}
```

8.1.2.1.14. MigrateToOtherZone

Migrates an ApsaraDB RDS instance across zones within the same region.

For example, if Instance 1 is located in Hangzhou Zone A, you can call this operation to migrate the instance to Hangzhou Zone B.

> **Note** In cross-zone migration, instances must be migrated within the same region. For example, instances in a zone of the China (Hangzhou) region cannot be migrated to a zone of the China (Qingdao) region.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	MigrateToOtherZone	The operation that you want to perform. Set the value to MigrateToOtherZone.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxxxx	The ID of the instance.
ZoneId	String	Yes	cn-hangzhou-b	The ID of the destination zone. You can call the operation to query available zones.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=MigrateToOtherZone
&DBInstanceId=rm-uf6wjk5xxxxxxxxxx
&ZoneId=cn-hangzhou-b
&<Common request parameters>
```

Sample success responses

- XML format

```
<MigrateToOtherZoneResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</MigrateToOtherZoneResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.1.15. PurgeDBInstanceLog

Clears logs of an ApsaraDB RDS instance.

- For an ApsaraDB RDS for MySQL instance, this operation clears all binlogs of the instance.
- For an ApsaraDB RDS for SQL Server instance, this operation generates a temporary backup and compresses transaction logs to release space.

> **Note** This operation is available only for instances that run MySQL or SQL Server.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	PurgeDBInstanceLog	The operation that you want to perform. Set the value to PurgeDBInstanceLog.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxx	The ID of the instance.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=PurgeDBInstanceLog
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample success responses

- XML format

```
<PurgeDBInstanceLogResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</PurgeDBInstanceLogResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.1.16. ModifyDBInstanceDescription

Description

You can call this operation to modify the description of an instance to identify the instance easily. For example, you can modify the description of an instance to *Alibaba Cloud testing environment instance*.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceDescription.
DBInstanceId	String	Yes	The ID of the instance whose description is modified.
DBInstanceDescription	Sting	Yes	The description of the instance.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyDBInstanceDescription
&DBInstanceId=rds-xxxxx
&DBInstanceDescription=testdescribe
&<Common request parameters>
```

Sample responses

- XML format

```
<ModifyDBInstanceDescriptionResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifyDBInstanceDescriptionResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.1.17. ModifyDBInstanceMaintainTime

Modifies the maintenance time of an ApsaraDB RDS instance.

You can set the maintenance time to a period of time during off-peak hours. Alibaba Cloud performs routine maintenance within the maintenance window to minimize impacts on your business.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ModifyDBInstanceMaintainTime	The operation that you want to perform. Set the value to ModifyDBInstanceMaintainTime.

Parameter	Type	Required	Example	Description
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxx	The ID of the instance.
MaintainTime	String	Yes	22:00Z-02:00Z	The maintenance window of the instance. Specify the time in the ISO 8601 standard in the *HH:mm*Z-*HH:mm*Z format. The time must be in UTC.
ClientToken	String	No	ETnLKlblzczshOTUbOCzxxxxxxxxxx	The client token that is used to ensure the idempotence of the request. You can use the client to generate the value, but you must make sure that it is unique among different requests. The token can contain only ASCII characters and cannot exceed 64 characters in length.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyDBInstanceMaintainTime
&DBInstanceId=rds-xxxxx
&MaintainTime=22:00Z-02:00Z
&<Common request parameters>
```

Sample success responses

- XML format

```
<ModifyDBInstanceMaintainTimeResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifyDBInstanceMaintainTimeResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

8.1.2.1.18. ModifyDBInstanceHAConfig

Description

You can call this operation to modify the instance data replication mode and high availability switching rules.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceHAConfig.
DBInstanceId	String	Yes	The ID of the instance.
SyncMode	String	Yes	The synchronization mode of the instance. Valid values: Semi-sync and Async.
HAMode	String	Yes	The HA mode of the instance. RPO: Data persistence is preferred. RTO: Instance availability is preferred.

Response parameters

This operation returns only common response parameters.

8.1.2.1.19. SwitchDBInstanceHA

Switches services between a primary ApsaraDB RDS instance and its secondary instance.

This operation switches services between the primary and secondary ApsaraDB RDS instances that do not run the Basic Edition. After the switchover, the secondary instance takes over services as the primary instance.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	SwitchDBInstanceHA	The operation that you want to perform. Set the value to SwitchDBInstanceHA.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxxxx	The ID of the primary instance.
NodeId	String	Yes	349054	The unique ID of the secondary instance.
Force	String	No	No	Specifies whether to enable forced switching. Valid values: • Yes: forced • No: unforced Default value: No

Parameter	Type	Required	Example	Description
EffectiveTime	String	No	Immediate	The time when you want the specified settings to take effect. Valid values: • Immediate: The switching immediately takes effect. • MaintainTime: The switching takes effect during the maintenance window. Default value: Immediate.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=SwitchDBInstanceHA
&DBInstanceId=rm-uf6wjk5xxxxxxxxxx
&NodeId=349054
&<Common request parameters>
```

Sample success responses

`XML` format

```
<SwitchDBInstanceHAResponse>
      <RequestId>1E43AAE0-BEE8-43DA-860D-EAF2AA0724DC</RequestId>
</SwitchDBInstanceHAResponse>
```

`JSON` format

```
{
    "RequestId": "1E43AAE0-BEE8-43DA-860D-EAF2AA0724DC"
  }
```

8.1.2.1.20. CreateReadOnlyDBInstance

Description

Creates a read-only instance for a primary ApsaraDB RDS instance. Before you call this operation, make sure that the following requirements are met:

- The primary instance is in the running state, but not in the failover state.
- The read-only instance and the primary instance are in the same region.
- A primary ApsaraDB RDS instance can have up to five read-only instances.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateReadOnlyDBInstance.
RegionId	String	Yes	The region ID of the instance. It can be up to 50 characters in length. You can call the DescribeRegions operation to query the most recent region list.
ZoneId	String	Yes	The zone ID of the instance. You can call the DescribeRegions operation to query the most recent zone list.
DBInstanceId	String	Yes	The ID of the primary instance.
EngineVersion	String	Yes	The database engine version that the read-only instance runs. The read-only instance must run the same engine version as the primary instance. Valid values: • 8.0 • 5.7 • 5.6
DBInstanceClass	String	Yes	The instance type.
DBInstanceStorage	Integer	Yes	The user-defined storage capacity. Valid values: 5 to 1000. This value must be in 5 GB increments. Unit: GB.
DBInstanceDescription	String	No	The description of the instance. It must be 2 to 256 bytes in length , https:// and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and cannot start with http:// or https://.
ClientToken	String	Yes	The client token that is used to ensure idempotence of the request.
InstanceNetworkType	String	No	The network type of the instance. Valid values: VPC and Classic. Default value: Classic.
VPCId	String	No	The ID of the VPC.
VSwitchId	String	No	The ID of the vSwitch.
PrivateIpAddress	String	No	The IP address of the VPC that belongs to VSwitchId. If no value is specified, the system allocates a VPC IP address based on VPCId and VSwitchId.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.

Parameter	Type	Description
DBInstanceId	String	The ID of the instance.
OrderId	String	The ID of the order.
ConnectionString	String	The endpoint that is used to connect to the database.
Port	String	The port that is used to connect to the database.

Examples

Sample requests

```
https://rds.example.com/?Action=CreateReadOnlyDBInstance
&RegionId=cn-hangzhou
&ZoneId=cn-hangzhou-b
&DBInstanceId=rds-xxxxx
&EngineVersion=5.6
&DBInstanceClass=rds.mys2.small
&DBInstanceStorage=10
&PayType=Postpaid
&ClientToken=ETnLKxxxxx
&<[Common request parameters]>
```

Sample success responses

- XML format

```
<CreateDBInstanceResponse>
<OrderId>10078937xxxxx</OrderId>
<ConnectionString>rds-xxxxx.mysql.rds.aliyuncs.com </ConnectionString>
<DBInstanceId>rds-xxxxx</DBInstanceId>
<port>3306</port>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</CreateDBInstanceResponse>
```

- JSON format

```
{ "OrderId": "100789370230206",
"ConnectionString": "rds-xxxxx.mysql.rds.aliyuncs.com",
"DBInstanceId": "rds-xxxxx",
"Port": "3306",
"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

8.1.2.1.21. DescribeDBInstanceSSL

Queries Secure Sockets Layer (SSL) settings of an ApsaraDB RDS instance.

This operation is available for instances that run MySQL 5.6, MySQL 5.7, or SQL Server.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	DescribeDBInstanceSSL	The operation that you want to perform. Set the value to DescribeDBInstanceSSL.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxx	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	N/A	Common response parameters.
ConnectionString	String	The endpoint that is protected by SSL encryption.
SSLExpireTime	String	The expiration time of the SSL certificate. This time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format.
RequireUpdate	String	Indicates whether an immediate update is required. Valid values: Yes and No.
RequireUpdateReason	String	The reason why an update is required.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeDBInstanceSSL
&DBInstanceId=rm-uf6wjk5xxxxxxx
&<Common request parameters>
```

Sample success responses

`XML` format

```
<DescribeDBInstanceSSLResponse>
      <items>
            <ConnectionString>rm-uf6wjk5xxxxxx.mysql.rds.aliyuncs.com</ConnectionString>
            <SSLExpireTime>2018-01-17T12:18:15Z</SSLExpireTime>
            <RequireUpdate>Yes</RequireUpdate>
            <RequireUpdateReason></RequireUpdateReason>
      </items>
      <requestId>1AD222E9-E606-4A42-BF6D-8A4442913CEF</requestId>
</DescribeDBInstanceSSLResponse>
```

`JSON` format

```
{
    "items": [
        {
            "ConnectionString": "rm-uf6wjk5xxxxxx.mysql.rds.aliyuncs.com",
            "SSLExpireTime": "2018-01-17T12:18:15Z",
            "RequireUpdate": "Yes",
            "RequireUpdateReason": ""
        }
    ],
    "requestId": "1AD222E9-E606-4A42-BF6D-8A4442913CEF"
}
```

8.1.2.1.22. ModifyDBInstanceSSL

Description

You can call this operation to modify the SSL link of an instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBInstanceSSL.
DBInstanceId	String	Yes	The ID of the instance.
ConnectionString	String	Yes	Each instance can only have one endpoint protected by the SSL certificate. The SSL certificate can be created or updated for the endpoint.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.
SSLExpireTime	String	The expiration time of the SSL certificate. The time follows the ISO 8601 standard in the YYYY-MM-DDThh:mm:ssZ format.

8.1.2.1.23. DescribeDBInstanceTDE

Queries the Transparent Data Encryption (TDE) status of an ApsaraDB RDS instance.

This operation is available only for instances that run MySQL 5.6 or SQL Server EE.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	DescribeDBInstanceTDE	The operation that you want to perform. Set the value to DescribeDBInstanceTDE.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxx	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	N/A	Common response parameters.
TDEStatus	String	The TDE status of the instance. Valid values: Enabled and Disabled.
Databases	List<DataBase>	Details about the database.

Database parameters

Parameter	Type	Description
DBName	String	The name of the database.
TDEStatus	String	The TDE status of the database. Valid values: Enabled and Disabled.

8.1.2.1.24. ModifyDBInstanceTDE

Enables or disables the Transparent Data Encryption (TDE) feature for an ApsaraDB RDS instance.

This operation is available only for instances that run MySQL 5.6, MySQL 5.7, or SQL Server 2008 R2.

- For instances that run MySQL 5.6 or MySQL 5.7, TDE can be enabled only on instances and cannot be disabled. You cannot specify the DBName value to modify the TDE status of a database.
- For instances that run SQL Server 2008 R2, TDE can be enabled or disabled only on databases. When TDE is enabled on a database, the TDE feature of the instance is enabled and cannot be disabled.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ModifyDBInstanceTDE	The operation that you want to perform. Set the value to ModifyDBInstanceTDE.

Parameter	Type	Required	Example	Description
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxx	The ID of the instance.
TDEStatus	String	Yes	Enabled	The TDE status of the instance. Valid values: Enabled and Disabled.
DBName	String	No	testDB	The name of the database for which you want to enable TDE. Up to 50 names can be entered in a single request. Separate multiple names with commas (,).

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyDBInstanceTDE
&DBInstanceId=rm-uf6wjk5xxxxxxx
&TDEStatus=Enabled
&<Common request parameters>
```

Sample success responses

`XML` format

```
<ModifyDBInstanceTDEResponse>
      <requestId>777C4593-8053-427B-99E2-105593277CAB</requestId>
</ModifyDBInstanceTDEResponse>
```

`JSON` format

```
{
    "requestId": "777C4593-8053-427B-99E2-105593277CAB"
}
```

8.1.2.2. Database management

8.1.2.2.1. CreateDatabase

Description

You can call this operation to create a new database in an instance. Before you call this operation, make sure that the following requirements are met:

- The instance is in the running state.
- The instance is not locked.
- The maximum number of databases in the instance is not reached.
- The instance is a primary instance.

> **Note** This operation is not supported on PolarDB. You can create databases in PolarDB instances by executing CREATE DATABASE statements.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateDatabase.
DBInstanceId	String	Yes	The ID of the instance.
DBName	String	Yes	The unique name of the database. The name can be up to 64 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a letter. For information about invalid characters, see Forbidden keywords.
CharacterSetName	String	Yes	The character set. Valid values: • MySQL: utf8, gbk, latin1, and utf8mb4 • SQL Server: Chinese_PRC_CI_AS, Chinese_PRC_CS_AS, SQL_Latin1_General_CP1_CI_AS, SQL_Latin1_General_CP1_CS_AS, and Chinese_PRC_BIN
DBDescription	String	No	The description of the database. It must be 2 to 256 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and cannot start with http:// or https://.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=CreateDatabase
&CharacterSetName=gbk
&DBName=testDB
&DBInstanceId=rds-xxxxx
&<[Common request parameters]>
```

Sample success responses

- XML format

```
<CreateDatabaseResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</CreateDatabaseResponse>
```

- JSON format

```
{ "RequestID":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

8.1.2.2.2. DeleteDatabase

Description

You can call this operation to delete a database from an instance.

Before you call this operation, make sure that the following requirements are met:

- The instance is in the running state.
- The instance is a primary instance.

Note This operation is not supported on PolarDB. You can delete databases from PolarDB instances by executing DROP DATABASE statements.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteDatabase.
DBInstanceId	String	Yes	The ID of the instance.
DBName	String	Yes	The name of the database.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=DeleteDatabase
&DBName=testDB
&DBInstanceId=rds-xxxxx
&<[Common request parameters]>
```

Sample success responses

- XML format

```
<DeleteDatabaseResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</DeleteDatabaseResponse>
```

- JSON format

```
{ "RequestId":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

8.1.2.2.3. DescribeDatabases

Description

You can call this operation to query the databases of a specified instance or information of a specified database. If the request parameters are entered incorrectly, an error prompt is returned, and the returned data is empty.

> **Note** This operation is not supported on PolarDB.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDatabases.
DBInstanceId	String	Yes	The ID of the instance.
DBName	String	No	The name of the database.
DBStatus	String	No	The state of the database. Valid values: Creating, Running, and Deleting.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.

Parameter	Type	Description
Databases	List<Database>	The array that consists of Database data.

Database parameters

Parameter	Type	Description
DBName	String	The name of the database.
DBInstanceId	String	The ID of the instance to which the database belongs.
Engine	String	The engine of the database.
DBStatus	String	The status of the database. Valid values: Creating, Running, and Deleting.
CharacterSetName	String	The character set.
DBDescription	String	The description of the database.
Accounts	List<AccountPrivilegeInfo>	The array that consists of AccountPrivilegeInfo data.
Account	String	The name of the account.
AccountPrivilege	String	The permissions of the account on the database.

AccountPrivilegeInfo parameters

Parameter	Type	Description
Account	String	The name of the account.
AccountPrivilege	String	The permissions of the account on the database.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeDatabases
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample success responses

- XML format

```
<DescribeDatabasesResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<Databases>
<Database>
<Engine>MySQL</Engine>
<DBName>testdb</DBName>
<CharacterSetName>utf8</CharacterSetName>
<DBStatus>Creating</DBStatus>
<DBInstanceId>rds-xxxxx</DBInstanceId>
<Accounts>
<AccountPrivilegeInfo></AccountPrivilegeInfo>
<Accounts>
</Database>
</Databases>
</DescribeDatabasesResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC",
"Databases":
    { "Database":
        [ { "Engine": "MySQL",
            "CharacterSetName": "utf8",
            "DBStatus": "Creating",
            "DBDescription": "",
            "DBInstanceId": "rds-xxxxx",
            "Accounts": { " AccountPrivilegeInfo": [] },
            "DBName": "testdb" }] }
            }
```

8.1.2.2.4. ModifyDBDescription

Description

You can call this operation to modify the description of a database to facilitate user records. For example, you can modify the description of a database to Database A for Alibaba Cloud testing environment.

> **Note** This operation is not supported on PolarDB.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyDBDescription.
DBInstanceId	String	Yes	The ID of the instance.
DBName	String	Yes	The name of the database.

Parameter	Type	Required	Description
DBDescription	String	Yes	The description of the database.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyDBDescription
&DBInstanceId=rds-xxxxx
&DBInstanceDescription=testDBdescribe
&<Common request parameters>
```

Sample success responses

- XML format

```
<ModifyDBDescriptionResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifyDBDescriptionResponse>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

8.1.2.3. Account management

8.1.2.3.1. CreateAccount

Description

In the same instance, one account can manage multiple databases by using different permissions.

You can call this operation to create an account for a database. Before you call this operation, make sure that the following requirements are met:

- The instance is in the running state.
- The database is in the running state.
- The instance is not locked.
- The maximum number of accounts for a single instance is not reached.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateAccount.
DBInstanceId	String	Yes	The ID of the instance.
AccountName	String	Yes	The unique name of the account. The name can be up to 16 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a letter. For information about invalid characters, see Forbidden keywords.
AccountPassword	String	Yes	The password for the account. It must be 6 to 32 characters in length and can contain letters, digits, and underscores (_).
AccountType	String	No	The type of the account. Valid values: Normal and Super. Default value: Normal. PolarDB can have only a single initial account. You must use the initial account to log on to the database and create other types of accounts.
AccountDescription	String	No	The description of the account. It must be 2 to 256 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter and cannot start with http:// or https://.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=CreateAccount
&AccountName=testacc02
&AccountPassword=pwxxxxx
&DBInstanceId=rds-xxxxx
&<[Common request parameters]>
```

Sample success responses

- XML format

```
<CreateAccountResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</CreateAccountResponse>
```

- JSON format

```
{ "RequestId":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

8.1.2.3.2. DeleteAccount

Description

You can call this operation to delete a database account.

The instance must be in the running state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DeleteAccount.
DBInstanceId	String	Yes	The ID of the instance to which the database belongs.
AccountName	String	Yes	The unique name of the account. The name can be up to 16 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a letter. For more information about invalid characters, see Forbidden keywords.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=DeleteAccount
&DBInstanceId=rds-xxxxx
&AccountName=testacc01
&<[Common request parameters]>
```

Sample responses

- XML format

```
<DeleteAccountResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</DeleteAccountResponse>
```

- JSON format

```
{ "RequestID":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

8.1.2.3.3. DescribeAccounts

Description

You can call this operation to query the accounts for a specified instance and database or the information of a specified account.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeAccounts.
DBInstanceId	String	Yes	The ID of the instance.
AccountName	String	Yes	The name of the account.

Response parameters

Parameter	Type	Description
<Common response parameters>		Common response parameters.
Accounts	List<DBInstanceAccount>	The array that consists of DBInstanceAccount data.

DBInstanceAccount parameters

Parameter	Type	Description
DBInstanceId	String	The ID of the instance to which the account belongs.
AccountName	String	The name of the database account.
AccountStatus	String	The account status. Valid values: Unavailable and Available.
AccountDescription	String	The description of the account.
DatabasePrivileges	List<DatabasePrivilege>	The array that consists of DatabasePrivileges data.
AccountType	String	The type of the account. Valid values: Normal and Super.

DatabasePrivilege parameters

Parameter	Type	Description
DBName	String	The name of the database.
AccountPrivilege	String	The name of the database account.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeAccounts
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeAccountsResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<Accounts>
<DBInstanceAccount>
<AccountName>MySQL</AccountName>
<DBInstanceId>testdb</DBInstanceId>
<AccountStatus>utf8</AccountStatus>
<AccountDescription>
</AccountDescription>
<DatabasePrivileges>
<DatabasePrivilege></DatabasePrivilege>
</DatabasePrivileges>
<DBInstanceAccount>
</Accounts>
</DescribeAccountsResponse>
```

- JSON format

```
{ "Accounts":
    { "DBInstanceAccount":
        [ { "AccountDescription": "",
            "DBInstanceId": "rds-xxxxx",
            "DatabasePrivileges": { "DatabasePrivilege": [] },
            "AccountStatus": "Unavailable",
            "AccountName": "testaccount" } ] },
    "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

8.1.2.3.4. GrantAccountPrivilege

Grants database permissions to an account.

The instance must be in the running state.

> **Note**
>
> - An account can be authorized to access one or more databases.
> - If the specified account already has access permissions on the specified database, the operation directly returns a successful response.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	GrantAccountPrivilege	The operation that you want to perform. Set the value to GrantAccountPrivilege.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxx	The ID of the instance.
AccountName	String	Yes	test1	The name of the account.
DBName	String	Yes	testDB	The name of the database to be accessed by the account.
AccountPrivilege	String	Yes	ReadOnly	The permissions of the database account. Valid values: • ReadOnly • ReadWrite

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=GrantAccountPrivilege
&AccountName=testacc02
&AccountPrivilege=readwrite
&DBName=testdb03
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample success responses

- XML format

```
<GrantAccountPrivilegeResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</GrantAccountPrivilegeResponse>
```

- JSON format

```
{ "RequestId":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.3.5. RevokeAccountPrivilege

Revokes database permissions of an account.

Before you call this operation, make sure that the following requirements are met:

- The instance is in the running state.

- The database is in the running state.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	RevokeAccountPrivilege	The operation that you want to perform. Set the value to RevokeAccountPrivilege.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxx	The ID of the instance.
AccountName	String	Yes	test1	The name of the account.
DBName	String	Yes	testDB	The name of the database.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=RevokeAccountPrivilege
&AccountName=testacc02
&DBName=testdb03
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample success responses

- XML format

```
<RevokeAccountPrivilegeResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</RevokeAccountPrivilegeResponse>
```

- JSON format

```
{ "RequestId":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.3.6. ModifyAccountDescription

Description

You can call this operation to modify the description of an account to facilitate user records. For example, you can modify the description of an account to Account A for Alibaba Cloud testing environment.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyAccountDescription.
DBInstanceId	String	Yes	The ID of the instance for which the account description is modified.
AccountName	String	Yes	The unique name of the account. The name can be up to 16 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a letter. For more information about invalid characters, see Forbidden keywords.
AccountDescription	String	Yes	The description of the account. It can be up to 256 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It cannot start with http:// or https://. It must start with a letter.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyAccountDescription
&DBInstanceId=rds-xxxxx
&AccountName=testacc01
&AccountDescription=testAccoutdescribe
&<Common request parameters>
```

Sample responses

- XML format

```
<ModifyAccountDescription>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifyAccountDescription>
```

- JSON format

```
{ "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.3.7. ResetAccountPassword

Resets the password of an account on an ApsaraDB RDS instance.

Description

Before you call this operation, make sure that the following requirements are met:

The instance is in the running state and not locked by the system.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ResetAccountPassword	The operation that you want to perform. Set the value to **ResetAccountPassword**.
AccountName	String	Yes	test1	The name of the account.
AccountPassword	String	Yes	Test123456	The new password for the account. **Note** • The password must be 8 to 32 characters in length. • The password must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. • Special characters include !@ # $ & ; % ^ * ( ) _ + - =
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxx	The ID of the instance.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=ResetAccountPassword
&AccountName=testacc02
&AccountPassword=pwxxxxx
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample success responses

- XML format

```
<ResetAccountPasswordResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ResetAccountPasswordResponse>
```

- JSON format

```
{ "RequestId":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.3.8. ResetAccount

Description

You can call this operation to reset the initial account of an instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ResetAccount.
DBInstanceId	String	Yes	The ID of the instance.
AccountName	String	Yes	The name of the account.
AccountPassword	String	Yes	The password of the account.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.

8.1.2.4. Backup and restoration

8.1.2.4.1. CreateBackup

Description

You can call this operation to manually create a backup. Up to 10 backups can be created for an instance in a single day.

Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- The most recent backup has been completed.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateBackup.
DBInstanceId	String	Yes	The ID of the instance.
BackupMethod	String	No	The backup method. Valid values: Logical and Physical. Default value: Physical. Logical backup cannot be used for instances without databases. SQL Server instances only support physical backup.
BackupStrategy	String	No	The logical backup range. Valid values: db: single-database backup. instance: instance backup. This parameter is valid only when BackupMethod is set to Logical.
DBName	String	No	The name of the database for logical single-database backup. This parameter is valid only when BackupMethod is set to Logical and BackupStrategy is set to db.
BackupType	String	No	The backup type. Valid values: Auto: specifies whether it is a full backup or an incremental backup through automatic calculation. FullBackup: specifies a full backup. Default value: Auto.

Response parameters

Parameter	Type	Description
<Common response parameters>	N/A	Common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action= CreateBackup
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample success responses

- XML format

```
<CreateBackupResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</CreateBackupResponse>
```

- JSON format

```
{ "RequestId":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.4.2. CloneDBInstance

Restores the data of an original ApsaraDB RDS instance to a new instance. The new instance is called a cloned instance.

Before you call this operation, make sure that the following requirements are met:

- The original instance is in the running state.
- The original instance does not have ongoing migration tasks.
- The log backup feature is enabled for the original instance to support point-in-time recovery.

> **Note**
>
> The new instance has the same whitelist, SQL audit, alert threshold, backup, and parameter settings as the original instance.
>
> The data in the new instance is the same as historical data in the backup file. The clone feature is available only for instances that run MySQL.
>
> Database account information varies based on the following account types:
>
> - If the original instance has a privileged account, instances that are cloned from it also carry the same privileged account information.
> - If the original instance has only standard accounts, instances that are cloned from it also carry the information of the account used when the backup file is generated or at the specified point in time.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	CloneDBInstance	The operation that you want to perform. Set the value to CloneDBInstance.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxxxx	The ID of the instance.

Parameter	Type	Required	Example	Description
PayType	String	Yes	Postpaid	The billing method of the instances. Valid values: • Postpaid: pay-as-you-go • Prepaid: subscription
ClientToken	String	Yes	ETnLKlblzczshOTUbOCzxxxxxxx	The client token that is used to ensure the idempotence of the request. You can use the client to generate the value, but you must make sure that it is unique among different requests. The token can contain only ASCII characters and cannot exceed 64 characters in length.
BackupId	String	No	9026262	The ID of the backup set. You can call the DescribeBackups operation to query backup set IDs.
RestoreTime	String	No	2011-06-11T16:00:00Z	A point in time within the backup retention period to obtain a backup set from. Specify the time in the ISO 8601 standard in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T16:00:00Z. You must specify at least one of BackupId and RestoreTime.
DBInstanceClass	String	No	mysql.n1.micro.1	Optional. The instance type of the instance. For more information, see Instance types in Appendix. If this parameter is not specified, the new instance is of the same instance type as the original instance.
DBInstanceStorage	String	No	1000	The disk space. Unit: GB. This value must be in 5 GB increments and is the same as that of the primary instance by default. Set the value to 3000 for ApsaraDB RDS instances that are of the dedicated host instance family. Valid values for ApsaraDB RDS instances that are of other instance families: 5 to 2000.
InstanceNetworkType	String	No	VPC	The network type of the new instance. Valid values: • VPC • Classic **Note** The default value is the network type of the original instance.
VPCId	String	No	vpc-uf6f7l4fg90xxxxxxxxxx	The ID of the virtual private cloud (VPC).

Parameter	Type	Required	Example	Description
VSwitchId	String	No	vsw-uf6adz52c2pxxxxxxxxxx	The ID of the vSwitch.
PrivateIpAddress	String	No	172.16.201.69	The internal IP address of the new instance, which must be within the CIDR block supported by the specified vSwitch. The system assigns an internal IP address based on the **VPCId** and **VSwitchId** parameters.

Response parameters

Parameter	Type	Description
<Common response parameters>	N/A	Common response parameters.
DBInstanceId	String	The ID of the instance.
OrderId	Integer	The ID of the order.

Examples

Sample requests

```
https://rds.example.com/?Action=CloneDBInstance
&DBInstanceId=rm-uf6wjk5xxxxxxxxxx
&PayType=Postpaid
&ClientToken=ETnLKlblzczshOTUbOCzxxxxxxx
&<[Common request parameters]>
```

Sample success responses

- XML format

```
<CloneDBInstanceResponse>
      <OrderId>100789370xxxxx</OrderId>
      <DBInstanceId>rm-uf6wjk5xxxxxxx</DBInstanceId>
      <RequestId>1E43AAE0-BEE8-43DA-860D-EAF2AA0724DC</RequestId>
</CloneDBInstanceResponse>
```

- JSON format

```
{
    "OrderId": "100789370xxxxx",
    "DBInstanceId": "rm-uf6wjk5xxxxxxx",
    "RequestId": "1E43AAE0-BEE8-43DA-860D-EAF2AA0724DC"
}
```

8.1.2.4.3. DescribeBackups

Queries the backup sets of an ApsaraDB RDS instance.

Only backup sets in the **Backup Succeeded** state can be used for database restoration.

ApsaraDB RDS allows you to download backup files.

- If DownloadLink is NULL, ApsaraDB RDS does not provide a download URL.
- If DownloadLink is not NULL, you can use the provided URL to download backup files by using Wget (with double quotation marks), a browser, or a user program. The expiration time for this URL is specified by LinkExpiredTime. Use it before the expiration time.

  If the URL has expired, the following error code is displayed:

```
<?xml version="1.0" encoding="UTF-8" ?><Error><Code>AccessDenied</Code><Message>Request has expired.</Message><Expires>2012-12-25T09:47:52.000Z</Expires><ServerTime>2012-12-25T09:49:00.000Z</ServerTime><RequestId>50D9768CA801C2F102005C70</RequestId><HostId>oss-test.aliyun-inc.com</HostId></Error>
```

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	DescribeBackups	The operation that you want to perform. Set the value to DescribeBackups.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxx	The ID of the instance.
BackupId	String	No	327329803	The ID of the backup set.
BackupStatus	String	No	Success	The status of the backup set. Valid values: • Success • Failed
BackupMode	String	No	Automated	The backup mode. Valid values: • Automated • Manual
StartTime	String	No	2011-06-01T16:00Z	The beginning of the time range to query. Specify the time in the ISO 8601 standard in the *yyyy-MM-dd*T*HH:mm*Z format. The time must be in UTC.
EndTime	String	No	2011-06-15T16:00Z	The end of the time range to query. The end time must be later than the start time. Specify the time in the ISO 8601 standard in the *yyyy-MM-dd*T*HH:mm*Z format. The time must be in UTC.

Parameter	Type	Required	Example	Description
PageSize	Integer	No	30	The number of entries to return on each page. Valid values: • 30 • 50 • 100 Default value: 30
PageNumber	Integer	No	1	The number of the page to return. Valid values: non-zero positive integers. Default value: **1**.

Response parameters

Parameter	Type	Description
TotalRecordCount	String	The total number of entries returned.
PageNumber	String	The page number of the returned page.
PageRecordCount	String	The number of backup sets on the page.
Items	Array	Details about the backup set.
Backup		
BackupId	String	The ID of the backup set.
DBInstanceId	String	The ID of the instance.
HostInstanceID	String	The No. of the instance that generates the backup set. This parameter is used to indicate whether the primary or secondary instance generates the backup set.
BackupStatus	String	The status of the backup set.
BackupStartTime	String	The start time of the backup. The time follows the ISO 8601 standard in the *yyyy-MM-dd*T*HH:mm*Z format. The time is displayed in UTC.
BackupEndTime	String	The end time of the backup. The time follows the ISO 8601 standard in the *yyyy-MM-dd*T*HH:mm*Z format. The time is displayed in UTC.
BackupType	String	The backup type. Valid values: • FullBackup • IncrementalBackup

Parameter	Type	Description
BackupMode	String	The backup mode. Valid values: • Automated • Manual
BackupMethod	String	The backup method. Valid values: • Logical • Physical
BackupDownloadURL	String	The URL that is used to download the backup file over the Internet. If the URL is unavailable, an empty string is returned.
BackupIntranetDownloadURL	String	The URL that is used to download the backup file over an internal network. If the URL is unavailable, an empty string is returned.
BackupSize	Long	The size of the backup set. Unit: bytes.
StoreStatus	String	Indicates whether the backup set can be deleted. Valid values: • Enabled: The backup set can be deleted. • Disabled: The backup set cannot be deleted.
BackupInitiator	String	The initiator of the backup task. Valid values: • System • User
ConsistentTime	Long	The point in time at which the data in the backup set is consistent. The value of this parameter is a timestamp. **Note** If the instance runs MySQL 5.6, a timestamp is returned. Otherwise, the value 0 is returned.
CopyOnlyBackup	String	The backup mode. Valid values: • 0: the standard mode. This mode supports full backup and incremental backup. • 1: the copy-only mode. This mode supports only full backup. **Note** If the instance runs SQL Server, this parameter is returned.

Parameter	Type	Description
IsAvail	Integer	Indicates whether the backup set is available. Valid values: • 0: unavailable • 1: available
MetaStatus	String	The status of the backup set that is used to restore individual databases or tables. Valid values: • OK: The backup set is normal. • LARGE: The backup set contains an abnormally large number of tables. It cannot be used to restore individual databases or tables. • EMPTY: The backup set is generated from a failed backup task. **Note** If an empty string is returned, the backup set cannot be used to restore individual databases or tables.
StorageClass	String	The storage media that is used to store the backup set. Valid values: • 0: normal storage • 1: archived storage
RequestId	String	The ID of the request.
TotalEcsSnapshotSize	Long	The size of the snapshot chain of the instance. Unit: bytes.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeBackups
&DBInstanceId=rm-uf6wjk5xxxxxxx
&<Common request parameters>
```

Sample success responses

`XML` format

```
<DescribeBackupsResponse>
  <TotalRecordCount>1</TotalRecordCount>
  <PageRecordCount>1</PageRecordCount>
  <TotalEcsSnapshotSize>0</TotalEcsSnapshotSize>
  <RequestId>B0BBC25A-6B3E-4BFD-A052-48664294E20D</RequestId>
  <PageNumber>1</PageNumber>
  <Items>
        <Backup>
              <BackupMethod>Snapshot</BackupMethod>
              <BackupInitiator>System</BackupInitiator>
              <StorageClass>0</StorageClass>
              <BackupMode>Automated</BackupMode>
              <BackupSize>161061273600</BackupSize>
              <BackupId>677987116</BackupId>

8.1.2.4.4. CreateTempDBInstance

Description

Note You can create a temporary instance based on a backup set or a point in time within the past seven days. When a temporary instance is created, accounts and databases inherit the backup set data.

You can call this operation to create a temporary instance. Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- The instance is not undergoing any migration tasks.
- The instance is not locked by the system.
- The current status of the instance backup set is Success.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateTempDBInstance.
DBInstanceId	String	Yes	The ID of the instance to be created.
BackupId	Integer	No	The ID of the backup set.
RestoreTime	String	No	The restoration time of the backup set. It can be any time within the past seven days that is more than 30 minutes before the current time. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. The time must be in UTC. Example: 2011-06-11T16:00:00Z.

Response parameters

Parameter	Type	Description
<Common response parameters>		Common response parameters.
TempDBInstanceId	String	The ID of the temporary instance.

Examples

Sample requests

```
https://rds.example.com/?Action=CreateTempDBInstance
&BackupId=90262
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample responses

- XML format

```
<CreateTempDBInstanceResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<TempDBInstanceId>sub-xxxxx</TempDBInstanceId>
</CreateTempDBInstanceResponse>
```

- JSON format

```
{ "RequestId":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC",
"TempDBInstanceId":"sub-xxxxx"}
```

8.1.2.4.5. DescribeBackupPolicy

Description

You can call this operation to query the backup policy configured for the system. RDS periodically backs up an instance based on the user-defined system configuration.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeBackupPolicy.
DBInstanceId	String	Yes	The ID of the instance for which the backup policy is queried.

Response parameters

Parameter	Type	Description
<Common response parameters>		Common response parameters.
BackupRetentionPeriod	String	The data backup retention period. Unit: days. Valid values: 1 to 30.
PreferredBackupTime	String	The backup time. The time is in the HH:mmZ to HH:mmZ format.
PreferredBackupPeriod	String	The backup day. Valid values: Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, and Sunday.
BackupLog	String	The log backup status. Valid values: Enable and Disabled.
LogBackupRetentionPeriod	String	The log backup retention period. Unit: days. Valid values: 1 to 30.

8.1.2.4.6. ModifyBackupPolicy

Description

You can call this operation to modify a backup policy. RDS periodically backs up instances based on the user-defined system configuration.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyBackupPolicy.
DBInstanceId	String	Yes	The ID of the instance for which the backup policy is modified.
PreferredBackupTime	String	Yes	The backup time. Format: HH:mmZ to HH:mmZ.

Parameter	Type	Required	Description
PreferredBackupPeriod	String	Yes	The backup day. Valid values: Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, and Sunday.
BackupRetentionPeriod	String	No	The data backup retention period. Unit: days. Valid values: 1 to 30. Default value: 7.
BackupLog	String	No	The log backup status. Valid values: Enable and Disabled. Default value: Enable.
LogBackupRetentionPeriod	String	No	The log backup retention period. It cannot exceed BackupRetentionPeriod. Unit: days. Valid values: 1 to 30. When you enable log backup, you can configure the log backup retention period. This operation is only supported on MySQL, PostgreSQL, and PPAS.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyBackupPolicy
&DBInstanceId=rds-xxxxx
&PreferredBackupTime=00:00Z-01:00Z
&PreferredBackupPeriod=Monday
&<Common request parameters>
```

Sample responses

- XML format

```
<ModifyBackupPolicyResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifyBackupPolicyResponse>
```

- JSON format

```
{ "RequestId":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.4.7. RestoreDBInstance

Description

Restores a backup set to an instance.

Before you call this operation, make sure that the following requirements are met:

- The instance is in the running state.
- The instance is not undergoing migration tasks.
- The instance is not locked by the system.
- The backup set is in the Backup Succeeded state.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to RestoreDBInstance.
DBInstanceId	String	Yes	The ID of the instance.
BackupId	Integer	Yes	The ID of the backup set.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=RestoreDBInstance
&BackupId=103312
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample success responses

- XML format

```
<RestoreDBInstanceResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</RestoreDBInstanceResponse>
```

- JSON format

```
{"RequestId":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.4.8. DeleteBackup

Deletes backup sets of an instance.

Backup sets of only the instance itself are deleted. Backup sets of the associated instances such as read-only, disaster recovery, and cloned instances are not deleted.

Before you call this operation, make sure that the following requirements are met:

- The instance is in the running state.
- The instance runs MySQL, PostgreSQL, or PolarDB.
- If the log backup feature is disabled, ApsaraDB RDS instances cannot be restored by point in time. You can delete data backup sets that are retained for more than seven days.
- If the log backup feature is enabled and the retention period of log backups is less than the retention period of data backups, the data backup sets that are retained for more than the retention period of log backups can be deleted.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	DeleteBackup	The operation that you want to perform. Set the value to DeleteBackup.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxx	The ID of the instance.
BackupId	String	Yes	324909958	The ID of the backup set. You can call the DescribeBackups operation to query the backup set IDs. You can enter up to 100 backup set IDs in a single request. Separate multiple IDs with commas (,). Among the query results of DescribeBackups, you can delete backup sets that are only in the enabled state.

Response parameters

This operation returns only common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=DeleteBackup
&DBInstanceId=rm-uf6wjk5xxxxxxx
&BackupId=324909958
&<Common request parameters>
```

Sample success responses

`XML` format

```
<DeleteBackupResponse>
      <RequestId>37441409-FFD1-40AA-8EC5-9ECF5E2F7C29</RequestId>
</DeleteBackupResponse>
```

`JSON` format

```
{
    "RequestId": "37441409-FFD1-40AA-8EC5-9ECF5E2F7C29"
}
```

8.1.2.5. Monitoring management

8.1.2.5.1. DescribeResourceUsage

Description

You can call this operation to query the resource usage information of an instance. When this operation is called, the system returns the amount of space occupied by the specified instance.

DBInstanceId is used to obtain instance resource usage information.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeResourceUsage.
DBInstanceId	String	Yes	The ID of the instance for which the resource usage information is queried.

Response parameters

Parameter	Type	Description
<Common response parameters>		Common response parameters.
DBInstanceId	String	The ID of the instance for which the resource usage information was queried.
Engine	String	The type of the database.
DiskUsed	Integer	The total space occupied by both data files and log files. Unit: Byte. -1 indicates no data.
DataSize	Integer	The disk space that is used to store user data. Unit: Byte. -1 indicates no data.
LogSize	Integer	The disk space that is used to store log files. Unit: Byte. -1 indicates no data.
BackupSize	Integer	The total space occupied by backup data. Unit: Byte. -1 indicates no data.

Parameter	Type	Description
ColdBackupSize	Integer	The total space occupied by cold backup data. Unit: Byte. -1 indicates no data.
SQLSize	Integer	The total space occupied by SQL data. Unit: Byte. -1 indicates no data.

8.1.2.5.2. DescribeDBInstancePerformance

Description

You can call this operation to query the performance metrics of an instance over a specified period of time based on the performance parameters.

There are three output formats based on different query time ranges:

- When the query time range is less than or equal to one day, performance metrics are displayed at one-minute intervals.
- Queries with the time range from one to seven days are not supported.
- When the query time range is greater than seven days but less than or equal to 15 days, performance metrics are displayed at one-hour intervals.
- Queries with the time range greater than 15 days but less than 30 days are not supported.
- When the query time range is greater than or equal to 30 days but less than or equal to one year, performance metrics are displayed at one-day intervals.

Note When the instance space usage key is MySQL_SpaceUsage or SQLServer_SpaceUsage, performance metrics can be queried only when the time range is less than or equal to one day.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstancePerformance.
DBInstanceId	String	Yes	The ID of the instance.
Key	Integer	Yes	The performance metrics. Separate performance metrics with commas (,). For more information, see Performance parameters.
StartTime	String	Yes	The beginning of the time range to query. Specify the time in the ISO 8601 standard in the YYYY-MM-DDTHH:mmZ format. Example: 2012-06-11T15:00Z.
EndTime	String	Yes	The end of the time range to query. Specify the time in the ISO 8601 standard in the YYYY-MM-DDTHH:mmZ format. Example: 2012-06-11T15:00Z.

Response parameters

Parameter	Type	Description
<Common response parameters>	N/A	Common response parameters
DBInstanceId	String	The ID of the instance.
Engine	String	The engine of the database.
StartTime	String	The beginning of the time range where the query was executed. The time follows the ISO 8601 standard in the YYYY-MM-DDTHH:mmZ format. Example: 2011-05-30T03:29Z.
EndTime	String	The end of the time range where the query was executed. The time follows the ISO 8601 standard in the YYYY-MM-DDTHH:mmZ format. Example: 2011-05-30T03:29Z. The end time must be later than the start time.
PerformanceKeys	List<PerformanceKey>	The array that consists of PerformanceKey data. Format: {perf1, perf2, perf3, ...}.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeDBInstancePerformance
&DBInstanceId=rds-xxxxx
&key= MySQL_xxxxx
&StartTime=2013-01-11T15:00:00Z
&EndTime=2013-06-05T15:00:00Z
&<Common request parameters>
```

Sample success responses

- XML format

```
<DescribeDBInstancePerformanceResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<DBInstanceID>rds-xxxxx</DBInstanceID>
<StartTime>2013-01-11T15:00:00Z</StartTime>
<EndTime>2013-10-17T15:00Z</EndTime>
<Engine>MySQL</Engine>
<PerformanceKeys>
<PerformanceKey>
<Key>MySQL_xxxxx</Key>
<Unit>KB</Unit>
<ValueFormat>recv_k&amp;sent_k</ValueFormat>
<Values><Values/>
</PerformanceKey>
</PerformanceKeys>
</DescribeDBInstancePerformanceResponse>
```

- JSON format

```
{ "RequestId"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC,
"DBInstanceID": rds-xxxxx,
"StartTime": "2012-06-11T15:00Z",
"EndTime": "2013-10-17T15:00Z",
"Engine": "MySQL",
"PerformanceKeys":
    { PerformanceKey[ {
        "Key": "MySQL_xxxxx",
        "Unit": "KB",
        "ValueFormat": "recv_k&sent_k",
        "Values": { "PerformanceValue":[] } } ] }}
```

8.1.2.5.3. DescribeDBInstanceMonitor

Description

You can call this operation to query the monitoring behavior of an instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeDBInstanceMonitor.
DBInstanceId	String	Yes	The ID of the instance for which the monitoring behavior is queried.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.

Parameter	Type	Description
Period	String	The monitoring period. Unit: seconds.

8.1.2.5.4. ModifyDBInstanceMonitor

Changes the monitoring frequency of an ApsaraDB RDS instance.

Request parameters

Parameter	Type	Required	Example	Description
Action	String	Yes	ModifyDBInstanceMonitor	The operation that you want to perform. Set the value to ModifyDBInstanceMonitor.
DBInstanceId	String	Yes	rm-uf6wjk5xxxxxxx	The ID of the instance.
Period	String	Yes	60	The monitoring frequency. Valid values: • 60 • 300 Unit: seconds.

Response parameters

Parameter	Type	Description
<Common response parameters>	N/A	Common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyDBInstanceMonitor
&DBInstanceId=rm-uf6wjk5xxxxxxx
&Period=60
&<Common request parameters>
```

Sample success responses

`XML` format

```
<ModifyDBInstanceMonitorResponse>
      <requestId>52B9805C-432C-4ED1-83FD-2F916B6D2733</requestId>
</ModifyDBInstanceMonitorResponse>
```

`JSON` format

```
{
    "requestId": "52B9805C-432C-4ED1-83FD-2F916B6D2733"
}
```

8.1.2.6. Parameter management

8.1.2.6.1. DescribeParameterTemplates

Description

You can call this operation to query the parameter template list. The list includes parameter names, default parameter values, whether they can be modified, whether the database must be restarted for the parameters to take effect, and regular expressions acting as parameter validation rules.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeParameterTemplates.
Engine	String	Yes	The engine of the database. Valid values: • mysql: MySQL • mssql: SQL Server • PostgreSQL: PostgreSQL • POLARDB: PolarDB
EngineVersion	String	Yes	The engine version of the database. Valid values: • MySQL: 5.6 and 5.7 • SQL Server: 2008 R2 • PostgreSQL: 9.4 and 10.0 • PolarDB: 11

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.
Engine	String	The engine of the database.

Parameter	Type	Description
EngineVersion	String	The engine version of the database.
ParameterCount	Integer	The number of parameters.
Parameters	List<TemplateRecord>	The array that consists of TemplateRecord data. Format: {parameter1, parameter2, parameter3, ...}.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeParameterTemplates
&Engine=MySQL
&EngineVersion=5.6
&<Common request parameters>
```

Sample success responses

- XML format

```
<DescribeParameterTemplatesResponse>
<Engine>mysql</Engine>
<EngineVersion>5.6</EngineVersion>
<ParameterCount>1</ParameterCount>
<Parameters>
<TemplateRecord>
<CheckingCode>[0-100]</CheckingCode>
<ForceRestart>True</ForceRestart>
<Factor>1</Factor>
<ParameterDescription>test</ParameterDescription>
<ParameterName>fill factor</ParameterName>
<ParameterValue>0</ParameterValue>
<ForceModify>True</ForceModify>
<Unit>INT</Unit>
</TemplateRecord>
</Parameters>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</DescribeParameterTemplatesResponse>
```

- JSON format

```
{"Engine": "mysql",
"EngineVersion": "5.6",
"ParameterCount":1,
"Parameters":
    { "TemplateRecord": [ {
        "ParameterDescription": "test",
        "ForceRestart": "True",
        "CheckingCode": "[0-100]"
        "Factor":"1",
        "ParameterName":"fill factor",
        "ParameterValue":"0",
        "ForceModify":"True",
        "Unit":"INT" } ] },
"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.6.2. DescribeParameters

Description

You can call this operation to query the current instance parameter configuration.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeParameters.
DBInstanceId	String	Yes	The ID of the instance.

Response parameters

Parameter	Type	Description
<Common response parameters>	N/A	Common response parameters.
Engine	String	The engine of the database.
EngineVersion	String	The engine version of the database.
RunningParameters	List<DBInstanceParameter>	The array that consists of running DBInstanceParameter data. Format: {parameter1,parameter2,parameter3, ...}.

ConfigParameters	List<DBInstanceParameter>	The array that consists of synchronizing DBInstanceParameter data. Format: {parameter1,parameter2,parameter3, ...}.

DBInstanceParameter parameters

Parameter	Type	Description
ParameterName	String	The name of the parameter.
ParameterValue	String	The value of the parameter.
ParameterDescription	String	The description of the parameter.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeParameters
&DBInstanceId=rds-xxxxx
&<Common request parameters>
```

Sample success responses

- XML format

```
<DescribeParametersResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<Engine>mysql</Engine >
<EngineVersion>5.6</EngineVersion>
<RunningParameters>
<DBInstanceParameter>
<ParameterDescription>test</ParameterDescription>
<ParameterName>fill factor</ParameterName>
<ParameterValue>0</ParameterValue>
</DBInstanceParameter>
</RunningParameters>
<ConfigParameters>
<DBInstanceParameter>
<ParameterDescription>test1</ParameterDescription>
<ParameterName>fill factor</ParameterName>
<ParameterValue>50</ParameterValue>
</DBInstanceParameter>
</ConfigParameters>
</DescribeParametersResponse>
```

- JSON format

```
{ "ConfigParameters": {
    "DBInstanceParameter": [ {
        "ParameterDescription": "test",
        "ParameterName": "fill factor",
        "ParameterValue": "50" } ] },
    "Engine": "mysql",
    "EngineVersion": "5.6",
    "RunningParameters": {
        "DBInstanceParameter": [ {
            "ParameterDescription": "test1",
            "ParameterName": "fill factor",
            "ParameterValue": "0" } ] },
    "RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.6.3. ModifyParameter

Description

You can call this operation to modify instance parameters. After you submit a request, RDS assigns a task to apply new parameters to the instance. If there are any parameter modifications that require the database to be restarted, RDS restarts the database.

Before you call this operation, ensure that the following requirements are met:

- The instance is in the running state.
- The instance is not locked by the system.

There are three types of parameter values:

- 1 to 65,535: indicates a numerical range. Regular identification is used to extract the minimum and maximum values. The input parameter is then verified based on the extracted minimum and maximum values. The parameter must be a multiple of a divisible factor.
- utf8 | gbk | latin1: indicates a set value determination rule. Regular identification is used to extract the fixed value. The input parameter is then verified based on these fixed values.
- Others: These must be implemented with regular expressions.

Before assigning the task, RDS checks the parameter as follows:

1. Whether the parameter exist.
2. Whether the parameter can be modified.
3. Whether the parameter is valid.

   If the parameter is invalid, RDS returns the 400 HTTP status code and information about the invalid parameter. Example:

```
{"HttpStatusCode":400,
"Code":"InvalidParameter.Format",
"Message":"Specified parameter is not valid.[auto_increment_increment:a,character_set_client:41]"}
```

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifyParameter.
DBInstanceId	String	Yes	The ID of the instance for which parameters are modified.
Parameters	String	Yes	The JSON string for the parameter and its value. The parameter value must be of the string type. {"auto_increment_increment":"1", "character_set_client":"utf8"}.
Forcerestart	String	No	Specifies whether to forcibly restart the database. Valid values: true and false. If a parameter can take effect only after database restart, Forcerestart must be set to true. Otherwise, the parameter modification will not take effect. Default value: false.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=ModifyeParameter
&DBInstanceId=rds-xxxxx
&Parameters={"key_buffer_size":"456","character_set_client":"gbk"}
&<Common request parameters>
```

Sample responses

- XML format

```
<ModifyeParameterResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</ModifyeParameterResponse>
```

- JSON format

```
{ "RequestId":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC",}
```

8.1.2.7. Log management

8.1.2.7.1. DescribeSlowLogs

Description

You can call this operation to query the slow log summary of the databases in a specified instance over a specified period of time.

This operation supports paged query.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSlowLogs.
DBInstanceId	String	Yes	The ID of the instance.
StartTime	String	Yes	The beginning of the time range to query. Specify the date in the ISO 8601 standard in the YYYY-MM-DDZ format. Example: 2011-05-30Z.
EndTime	String	Yes	The end of the time range to query. The end date must be later than the start date. Specify the date in the ISO 8601 standard in the YYYY-MM-DDZ format. Example: 2011-05-30Z.
DBName	String	No	The name of the database.
SortKey	String	No	The basis on which query results are sorted. Valid values: TotalExecutionCounts: in descending order of execution times. TotalQueryTimes: in descending order of the total execution duration. TotalLogicalReads: in descending order of the total number of logical reads. TotalPhysicalReads: in descending order of the total number of physical reads. This parameter is applicable to SQL Server instances. It must be used when you query SQL Server Instances.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>		Common response parameters.
Engine	String	The engine of the database.
StartTime	String	The beginning of the time range where the query was executed. The date follows the ISO 8601 standard in the YYYY-MM-DDZ format. Example: 2011-05-30Z.
EndTime	String	The end of the time range where the query was executed. The date follows the ISO 8601 standard in the YYYY-MM-DDZ format. Example: 2011-05-30Z.
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The page number of the returned page.
PageRecordCount	Integer	The number of SQL slow queries on the current page.
Items	List<SQLSlowLog>	The list of slow logs.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeSlowLogs
&DBInstanceId=rds-xxxxx
&StartTime=2011-06-11Z
&EndTime=2011-12-11Z
&SortKey= Totaxxxxx
&<Common request parameters>
```

Sample success responses

```

8.1.2.7.2. DescribeSlowLogRecords

Description

You can call this operation to query the slow log details of the databases in a specified instance over a specified period of time. This operation is only supported on MySQL instances.

Request parameters

Parameter	Type	Required	Description

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSlowLogRecords.
DBInstanceId	String	Yes	The ID of the instance to which the database belongs.
StartTime	String	Yes	The beginning of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T15:00Z.
EndTime	String	Yes	The end of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T16:00Z.
DBName	String	No	The name of the database.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>		Common response parameters.
Engine	String	The type of the database.
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of SQL slow queries on the current page.
Items	List<SQLSlowRecord>	-

SQLSlowLog parameters

Parameter	Type	Description
HostAddress	String	The host address to connect the database.
DBName	String	The name of the database.
SQLText	String	The query statement.

Parameter	Type	Description
QueryTimes	Long	The execution time of the slow query. Unit: seconds.
LockTimes	Long	The lock time of the slow query. Unit: seconds.
ParseRowCounts	Long	The number of entries parsed.
ReturnRowCounts	Long	The number of entries returned.
ExecutionStartTime	String	The beginning of the time range where the query was executed. The time is in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T15:00:08Z.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeSlowLogRecords
&DBInstanceId=rds-xxxxx
&StartTime=2011-06-11T15:00Z
&EndTime=2011-06-11T16:00Z
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeSlowLogRecordsResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>

        QueryTimes:”123”,
        LockTimes:”12”,
        ParseRowCounts:”125”,
        ReturnRowCounts:”1”,
        ExecutionStartTime:”2011-06-11T15:00:08Z”}]}}
```

8.1.2.7.3. DescribeErrorLogs

Description

You can call this operation to query the error logs generated for an instance over a specified period of time.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeErrorLogs.
DBInstanceId	String	Yes	The ID of the instance for which error logs are queried.
StartTime	String	Yes	The beginning of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-05-30T12:10Z.
EndTime	String	Yes	The end of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-05-30T20:10Z.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>		Common response parameters.
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of error logs on the current page.
Items	List<ErrorLogs>	-

ErrorLogs parameters

Parameter	Type	Description
ErrorInfo	String	The error log information.
CreateTime	String	The time when the error log was generated. The time is in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-05-30T12:11:4Z.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeErrorLogs.
&DBInstanceId=rds-xxxxx
&StartTime=2011-06-11T15:00Z
&EndTime=2011-06-11T20:00Z
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeErrorLogsResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<TotalRecordCount>1</TotalRecordCount>
<PageNumber>1</PageNumber>
<PageRecordCount>1<PageRecordCount>
<Items>
<ErrorLog>
<ErrorInfo>spid52 DBCC TRACEON 3499, server process ID (SPID) 52. This is an informationa
l message only; no user action is required</ErrorInfo>

"TotalRecordCount":1,
"PageRecordCount":1,
"Items":{
    "ErrorLog":[{
        ErrorInfo:”spid52 DBCC TRACEON 3499, server process ID (SPID) 52. This is an info
rmational message only; no user action is required”,
        CreateTime:”2013-06-04T15:00:00”}]}}
```

8.1.2.7.4. DescribeBinlogFiles

Description

You can call this operation to query binlogs of a MySQL instance. This operation supports querying by page. RDS provides binlog files for you to download.

- When the DownloadLink is NULL, RDS does not provide a download URL.
- When DownloadLink is not NULL, you can use this URL to download the backup file through Wget (with double quotation marks), a browser, or a user program. The expiration time for this URL is specified by LinkExpiredTime. Use it before the expiration time.

  If the BackupSet has expired, the following error code is displayed:

```
<Error>
<Code>AccessDenied</Code>
<Message>Request has expired. </Message>
<Expires>2012-12-25T09:47:52.000Z</Expires>
<ServerTime>2012-12-25T09:49:00.000Z</ServerTime>
<RequestId>50D9768CA801C2F102005C70</RequestId>
<HostId>oss-test.aliyun-inc.com</HostId>
</Error>
```

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeBinlogFiles.
DBInstanceId	String	Yes	The ID of the instance for which binlogs are queried.
StartTime	String	Yes	The beginning of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format.
EndTime	String	Yes	The end of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. The end time must be later than the start time.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.

Parameter	Type	Required	Description
PageNumber	Integer	No	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.
TotalRecordCount	Integer	The total number of binlog files.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of binlog files on the current page.
Items	List<BinLogFile>	-

BinLogFile parameters

Parameter	Type	Description
FileSize	Long	The size of a binlog file. Unit: Byte.
LogBeginTime	String	The beginning of the time range where the binlog was executed.
LogEndTime	String	The end of the time range where the binlog was executed.
DownloadLink	String	The HTTP-compliant download URL. If this parameter is set to NULL, no download URL exists.
HostInstanceID	String	The ID of the instance to which the binlog belongs. This parameter indicates whether the binlog is from the primary or secondary instance.
LinkExpiredTime	String	The URL expiration time. The time is in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T15:00:00Z.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeBinlogFiles
&DBInstanceId=rds-xxxxx
&StartTime=2011-06-11T15:00:00Z
&EndTime=2013-06-05T15:00:00Z
&<Common request parameters>
```

Sample responses

- XML format

```

```

8.1.2.7.5. DescribeSQLCollectorPolicy

Description

You can call this operation to check whether SQL collection is enabled for a specified RDS instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSQLCollectorPolicy.
DBInstanceId	String	Yes	The ID of the instance for which SQL collection is enabled or disabled.

Response parameters

Parameter	Type	Description
<Common response parameters>		Common response parameters.
SQLCollectorStatus	String	Indicates whether SQL collection is enabled. Valid values: Enable and Disabled.

8.1.2.7.6. ModifySQLCollectorPolicy

Description

You can call this operation to enable or disable SQL collection for the specified RDS instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ModifySQLCollectorPolicy.
DBInstanceId	String	Yes	The ID of the instance for which SQL collection is enabled or disabled.
SQLCollectorStatus	String	Yes	Specifies whether to enable SQL collection. Valid values: Enable and Disabled.

Response parameters

This operation returns only common response parameters.

8.1.2.7.7. DescribeSQLLogRecords

Description

You can call this operation to query the SQL audit logs generated for an instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSQLLogRecords.
DBInstanceId	String	Yes	The ID of the instance for which SQL audit logs are queried.

Parameter	Type	Required	Description
Database	String	No	The name of the database. All databases are selected by default.
User	String	No	The name of the user. All users are selected by default.
Form	String	No	The file generation form for audit logs. Valid values: File and Stream. If this parameter is set to File, only common parameters are returned, and you must call the DescribeSQLLogFiles operation to obtain the final download file address. If this parameter is set to Stream, data streams are returned. Default value: Stream.
QueryKeywords	String	No	The keywords used for query. Up to 10 keywords can be entered at a time. Separate multiple keywords with spaces.
StartTime	String	Yes	The beginning of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format.
EndTime	String	Yes	The end of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. The end time must be later than the start time.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, 100, and 200. Default value: 100.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of SQL logs on the current page.
Items	List<SQLRecord>	The array that consists of SQLRecord data.

SQLRecord parameters

Parameter	Type	Description
DBName	String	The name of the database.
AccountName	String	The name of the account.

Parameter	Type	Description
HostAddress	String	The IP address of the client.
SQLText	String	The SQL statement.
TotalExecutionTimes	Long	The amount of time taken to execute the operation. Unit: microseconds.
ReturnRowCounts	Long	The number of entries returned.
ThreadID	String	The thread ID.
ExecuteTime	String	The execution time. The time is in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-05-30T12:11:20Z.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeSQLLogRecords
&DBInstanceId=rds-xxxxx
&StartTime=2011-06-11T15:00:00Z
&EndTime=2013-06-05T15:00:00Z
&<Common request parameters>
```

Sample responses

- XML format

```
<DescribeSQLLogRecordsResponse>
<PageNumber>1</PageNumber>
    <RequestId>08A3B71B-FE08-4B03-974F-CC7EA6DB1828</RequestId>
    <TotalRecordCounts>1</TotalRecordCounts>
    <SQLItems>
        <SQLItem>
            <ReturnRowCounts>34</ReturnRowCounts>
            <TotalExecutionTimes>12</TotalExecutionTimes>
            <HostAddress>192.168.xx.xx</HostAddress>
            <ExecuteTime>2011-06-11T15:00:23Z</ExecuteTime>
            <SQLText>update test.zxb set id=0 limit 1</SQLText>
            <AccountName>accounttest</AccountName>
            <DBName>test</DBName>
        </SQLItem>
    </SQLItems>
    <ItemsCounts>1</ItemsCounts>
</DescribeSQLLogRecordsResponse>
```

- JSON format

```

                "HostAddress":"192.168.xx.xx",
                "ExecuteTime":"2011-06-11T15:00:23Z",
                "SQLText":"update test.zxb set id=0 limit 1",
                "AccountName":"accounttest",
                "DBName":"test"
            }
        ]
    },
    "ItemsCounts":1
}
```

8.1.2.7.8. DescribeSQLLogFiles

Description

You can call this operation to query SQL audit files.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeSQLLogFiles.
DBInstanceId	String	Yes	The ID of the instance for which SQL audit files are queried.

Response parameters

Parameter	Type	Description
<Common response parameters>		Common response parameters.
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of entries on the current page.
Items	List<LogFile>	The array that consists of audit file data.

LogFile parameters

Parameter	Type	Description
FileID	Integer	The ID of an audit log file.
DBInstanceId	String	The ID of the instance for which SQL audit files were queried.
LogStatus	String	The status of SQL audit files. Valid values: • Success • Failed • Generating
LogStartTime	String	The beginning of the time range where the audit log was executed.
LogEndTime	String	The end of the time range where the audit log was executed.
LogDownloadURL	String	The file download URL. If the download URL is unavailable, this parameter will be empty.
LogSize	Long	The size of an audit log file. Unit: Byte.

8.1.2.8. Data migration

8.1.2.8.1. CreateUploadPathForSQLServer

Description

You can call this operation to create the account and password of the file server and the file path. Based on this information, you can upload data files. After the upload is complete, you can migrate external data.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CreateUploadPathForSQLServer.
DBInstanceId	String	Yes	The ID of the instance.
DBName	String	Yes	The name of the database.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.
InternetFtpServer	String	The IP address of the file server on the public network.

Parameter	Type	Description
InternetPort	Integer	The port of the file server on the public network.
IntranetFtpServer	String	The IP address of the file server on the internal network.
IntranetPort	Integer	The port of the file server on the internal network.
UserName	String	The username used to log on to the file server.
Password	String	The password used to log on to the file server.
FileName	String	The name of the data file with the extension.

Examples

Sample requests

```
https://rds.example.com/?Action= CreateUploadPathForSQLServer
&DBInstanceId=rds-xxxxx
&DBName=testdb01
&<Common request parameters>
```

Sample success responses

- XML format

```
<CreateUploadPathForSQLServerResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<InternetFtpServer>10.230.239.1</InternetFtpServer>
<InternetPort>3021</InternetPort>
<IntranetFtpServer></IntranetFtpServer>
<UserName>userxxx</UserName>
<Password>pwxxxxx</Password>
<FileName>testdb01_xxxxx.bak</FileName>
</CreateUploadPathForSQLServerResponse>
```

- JSON format

```
{"RequestId":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC",
 "InternetFtpServer ":"10.230.239.1",
 "InternetPort":3021,
 "IntranetFtpServer":"",
 "UserName":"userxxx",
 "Password":"pwxxxxx",
 "FileName":"testdb01_xxxxx.bak"}
```

8.1.2.8.2. DescribeFilesForSQLServer

Description

You can call this operation to query files on the file server.

SQLServer users can obtain their accounts to upload data files to the file server by calling the CreateUploadPathForSQLServer operation.

After the data files are uploaded, RDS updates their status. You can also call this operation to check whether the data files are available. If they are available, you can import data and obtain the information about the import process.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeFilesForSQLServer.
DBInstanceId	String	Yes	The ID of the instance for which files are queried.
StartTime	String	Yes	The beginning of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T15:00Z.
EndTime	String	Yes	The end of the time range where the query is performed. Specify the time in the yyyy-MM-ddTHH:mm:ssZ format. Example: 2011-06-11T16:00Z. The end time must be later than the start time.
PageSize	Integer	No	The number of entries to return on each page. Valid values: 30, 50, and 100. Default value: 30.
PageNumber	Integer	No	The number of the page to return. Pages start from page 1 but must be equal to or smaller than the maximum Integer value. Default value: 1.

Response parameters

Parameter	Type	Description
DBInstanceId	String	The ID of the instance for which files were queried.
TotalRecordCount	Integer	The total number of entries.
PageNumber	Integer	The number of the page returned.
PageRecordCount	Integer	The number of SQL slow queries on the current page.
Items	List<SQLServerUploadFile>	-

SQLServerUploadFile parameters

Parameter	Type	Description
DBName	String	The name of the database.

Parameter	Type	Description
FileName	String	The name of the data file, with the extension.
FileSize	Long	The size of the data file. Unit: bytes.
InternetFtpServer	String	The file server.
InternetPort	Integer	The port of the file server on the public network.
IntranetFtpserver	String	The IP address of the file server on the internal network.
Intranetport	Integer	The port of the file server on the internal network.
UserName	String	The username used to log on to the file server.
Password	String	The password used to log on to the file server.
FileStatus	String	The file status. Valid values: Unavailable, Available, NotStarted, Uploading, UploadFailed, Virus, Deleted, and Success.
CreationTime	String	The time when the FTP file was created. The time is in the yyyy-MM-ddThh:mmZ format. Example: 2011-05-30 T12:11:4Z.

Examples

Sample requests

```
https://rds.example.com/?Action=DescribeFilesForSQLServer
&DBInstanceId=rds-xxxxx
&StartTime=2014-06-11T15:00Z
&EndTime=2014-06-11T16:00Z
&<Common request parameter>
```

Sample responses

- XML format

```
<DescribeFilesForSQLServerResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
<TotalRecordCount>1</TotalRecordCount>
<PageNumber>1</PageNumber>
<PageRecordCount>1</PageRecordCount>
<Items>
<SQLServerUploadFile>
<DBName>testdb01</DBName>
<FileName>testdb01_xxxxx.bak</FileName>
<FileSize>1243435</FileSize>
<InternetFtpServer>10.xxx. 239.1</InternetFtpServer>
<InternetPort>3021</InternetPort>
<IntranetFtpServer></IntranetFtpServer>
<UserName>userxxx</UserName>
<Password>pwxxxxx</Password>
<FileStatus>Success</FileStatus>
<CreationTime>2014-06-11T15:02:40Z</CreationTime>
</SQLServerUploadFile>
</Items>
</DescribeFilesForSQLServerResponse>
```

- JSON format

```
{"PageNumber":1,
"TotalRecordCount":1,
"PageRecordCount":1,
"Items":{
 "SQLServerUploadFile":[{
  "DBName":"testdb01",
  "FileName":"testdb01_xxxxx.bak",
  "FileSize ":"1243435",
  "InternetFtpServer":"10.xxx. 239.1",
  "InternetPort":3021,
  "IntranetFtpServer":"",
  "UserName":"userxxx",
  "Password":"pwxxxxx",
  "FileStatus":"Success",
  "CreationTime":"2014-06-11T15:02:40Z"} ]},
"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.8.3. ImportDatabaseBetweenInstances

Description

You can call this operation to migrate data from one ApsaraDB RDS instance to another. This operation is supported only on dedicated ApsaraDB RDS for MySQL instances.

ApsaraDB RDS for MySQL instances support batch database migration. During migration, the source instance status changes to Migrating and the destination instance status changes to Importing Data.

Database migration is performed between different instances that belong to the same user. Before you call this operation, make sure that the following requirements are met:

- The instance is in the running state.

- The database is in the running state.
- The destination instance is not locked by the system.
- The reserved storage space of the destination instance is greater than the space calculated by the following formula: Space occupied by the destination instance - Database space of the destination instance + Database space of the source instance.
- Databases to be migrated exist in both the source and destination instances and are activated.

ApsaraDB RDS for SQL Server instances support batch database migration. During migration, the source instance status changes to Migrating and the destination instance status changes to Importing Data.

Database migration is performed between different instances that belong to the same user. Before you call this operation, make sure that the following requirements are met:

- The instance is in the running state.
- The database is in the running state.
- The destination instance is not locked by the system.
- The reserved storage space of the destination instance is greater than the space calculated by the following formula: Space occupied by the destination instance - Database space of the destination instance + Database space of the source instance.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to ImportDatabaseBetweenInstances.
DBInstanceId	String	Yes	The ID of the instance.
SourceDBInstanceId	String	Yes	The ID of the source instance. It cannot be the same as that of the destination instance.
DBInfo	String	Yes	The information of the database to be migrated. Specify this parameter in the JSON format. For ApsaraDB RDS for MySQL instances, the parameter value is an array. Example: {"DBNames":["mydb","mydb2"]}. The names of the source and destination databases must be the same. In this example, data is migrated from the mydb and mydb2 databases. These databases must exist in both the source and destination instances.

DBInfo parameters

Parameter	Type	Required	Description
DBNames	List	Yes	The names of databases to be migrated. Example: ["mydb","mydb2"].

Response parameters

Parameter	Type	Description
<Common response parameters>		Common response parameters.
ImportId	Integer	The ID of the destination instance.

Examples

Sample requests

```
https://rds.example.com/?Action=ImportDatabaseBetweenInstances
&DBInstanceId=rds-xxxxx
&SourceDBInstanceId=rds-xxxxx
&{"DBNames":["mydb","mydb2"]}
&<Common request parameters>
```

Sample success responses

- XML format

```
<ImportDatabaseBetweenInstancesResponse>
 <ImportId>2122321</ImportId>
 <RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
 </ImportDatabaseBetweenInstancesResponse>
```

- JSON format

```
{"ImportId":2122321",
 RequestId":"1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC"}
```

8.1.2.8.4. CancelImport

Description

You can call this operation to cancel migration tasks from ApsaraDB RDS for MySQL instances.

Migration tasks from MySQL instances can be canceled.

Request parameters

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to CancelImport.
DBInstanceId	String	Yes	The ID of the instance.
ImportId	Integer	Yes	The migration task ID.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.

Examples

Sample requests

```
https://rds.example.com/?Action=CancelImport
&DBInstanceId=rds-xxxxx
&ImportId=127562
&<Common request parameters>
```

Sample success responses

- XML format

```
<CancelImportResponse>
<RequestId>1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC</RequestId>
</CancelImportResponse>
```

- JSON format

```
{"RequestId": "1E3D5A1E0-67CA-43DA-24BC-EAF2D5A1E4DC" }
```

8.1.2.9. Tag management

8.1.2.9.1. AddTagsToResource

Description

You can call this operation to bind existing or newly created tags to instances. Before you call this operation, ensure that the following requirements are met:

Each tag is composed of a TagKey and a TagValue. The TagKey cannot be blank, but the TagValue can.

- The values of TagKey and TagValue cannot start with aliyun.
- The values of TagKey and TagValue are not case sensitive.
- The maximum length of TagKey is 64 characters and the maximum length of TagValue is 128 characters.
- Each instance can only be bound to a maximum of 10 tags. Each tag bound to the same instance must have a unique TagKey. If tags with duplicate TagKeys are bound to the same instance, the tag bound last overwrites the existing tag.

Request parameters

Parameter	Type	Required	Description

Parameter	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to AddTagsToResource.
RegionId	String	Yes	The region ID of the instance for which a tag is be bound.
DBInstanceId	String	Yes	The ID of the instance for which a tag is be bound. Up to 30 IDs can be entered in a single request. Separate multiple IDs with commas (,) Format: instance1,instance2,instance3.
Tags	JSON string	Yes	The tag pair to be bound. This parameter must include a TagKey, but does not need to include a corresponding TagValue. Up to five tag pairs can be entered in a single request. The TagKey is required, and TagValue is optional. Format: { “key1” :” value1” , “key2” :” ” }.

Response parameters

Parameter	Type	Description
<Common response parameters>	-	Common response parameters.

8.1.2.9.2. DescribeTags

Description

You can call this operation to view the bound tag information of an RDS instance belonging to the current account. This operation must meet the following requirements:

If a specified instance ID is provided, all tags bound to this instance are queried and the other filter criteria are ignored.

- If the TagKey of a key is provided without a TagValue, the results of all tags matching the TagKey criteria are returned.
- If both TagKey and TagValue are provided, only the results that match both parameters are returned.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to DescribeTags.
RegionId	String	Yes	The region ID of the instance.

Name	Type	Required	Description
DBInstanceId	String	No	The name of the instance. If this parameter is provided, all the other filter criteria are ignored.
Tags	Json string	No	The tag pair. This parameter must include a TagKey, but does not need to include a corresponding TagValue. The TagKey cannot be blank, but the TagValue can. Format: {"key1":"value1 "}.

Response parameters

Name	Type	Description
<Common response parameters>	-	Common response parameters.
Items	List<TagInfos>	The array that consists of tag data.

TagInfos parameters

Name	Type	Description
TagKey	String	The TagKey.
TagValue	String	The TagValue.
DBInstanceIds	List<DBInstanceId>	The IDs of instances bound to this tag.

DBInstanceIds parameters

Name	Type	Description
DBInstanceId	String	The name of the instance.

8.1.2.9.3. RemoveTagsFromResource

Description

You can call this operation to unbind tags from an instance. This operation must meet the following requirements:

A maximum of 10 tags can be unbound in a single request.

If a tag is unbound from all of its bound instances, the tag itself is automatically deleted.

If the TagKey of a key is provided without a TagValue, all tags matching the TagKey criteria are unbound.

Request parameters

Name	Type	Required	Description
Action	String	Yes	The operation that you want to perform. Set the value to RemoveTagsFromResource.
RegionId	String	Yes	The region ID of the instance.
DBInstanceId	String	Yes	The name of the instance.
Tags	Json string	Yes	The tag pair to be unbound. This parameter must include a TagKey, but does not need to include a corresponding TagValue. The TagKey cannot be blank, but the TagValue can. Format: {"key1":"value1 "}.

Response parameters

Name	Type	Description
<Common response parameters>	-	Common response parameters.

8.1.2.10. RAM authorization

Use RAM for RDS resource authorization

All RDS instances created through an Apsara Stack tenant account are resources owned by that account. By default, you have full operation permissions on the resources under your account.

Resource Access Management (RAM) allows you to grant RAM users the access and management permissions on RDS resources owned by an Apsara Stack tenant account.

If you do not need to use RAM, ignore this topic.

Resource types in RAM

The only type of RDS resources that can be authorized through RAM is dbinstance. The following table lists the resource description method when the resources are authorized through RAM.

Resource	Resource description in authorization policy
Instance	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid acs:rds:$regionid:$accountid:dbinstance/ *acs:rds::: dbinstance/*

The $regionid field must be the ID of a region or an asterisk (*). The $instanceid field must be the ID of an instance or an asterisk (*). Similarly, $account-id is the numerical ID of your Apsara Stack tenant account, which can be replaced by an asterisk (*).

Authorization operations in RAM

In RAM, the following operations can be authorized to an RDS resource.

Operation 1	Operation 2
CreateDBInstance	ModifyDBInstanceSpec
DeleteDBInstance	CreateReadonlyDBInstance
DescribeDBInstances	DescribeDBInstanceAttribute
SwitchDBInstanceNetType	RestartDBInstance
ModifyDBInstanceDescription	ModifySecurityIps
ModifyDBInstanceMaintainTime	UpgradeDBInstanceEngineVersion
PurgeDBInstanceLog	CreateDatabase
DeleteDatabase	DescribeDatabases
ModifyDBDescription	ModifyeParameter
DescribeParameters	DescribeOptimizeAdviceByDBA
DescribeOptimizeAdviceOnMissIndex	ImportDataBaseBetweenInstances
CancelImport	CreateAccount
ResetAccountPassword	GrantAccountPrivilege
RevokeAccountPrivilege	DescribeAccounts
DeleteAccount	ModifyAccountDescription
CreateBackup	DescribeBackups
CreateTempDBInstance	DescribeBackupPolicy
ModifyBackupPolicy	DescribeResourceUsage
DescribeDBInstancePerformance	DescribeSlowLogs
DescribeSlowLogRecords	DescribeErrorLogs
DescribeBinlogFiles	DescribeSQLLogReports
DescribeSQLLogRecords	DescribeOptimizeAdviceOnStorage
DescribeOptimizeAdviceOnMissPK	DescribeOptimizeAdviceOnExcessIndex

> **Note** All operations except DescribeRegions and DescribeParameterTemplates can be authorized.

RAM authentication rules of API operations

When you call API operations to access resources as a RAM user, the RDS backend checks whether the RAM user is granted the required permissions by querying RAM. The permissions to be checked are determined by the resources used by the API operation. The following table lists the authentication rules for each API operation.

Operation	Authentication rule
CreateDBInstance	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DeleteDBInstance	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeDBInstances	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
SwitchDBInstanceNetType	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
ModifyDBInstanceDescription	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
ModifyDBInstanceMaintainTime	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
PurgeDBInstanceLog	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DeleteDatabase	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
ModifyDBDescription	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
CancelImport	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
ResetAccountPassword	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
RevokeAccountPrivilege	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DeleteAccount	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
CreateBackup	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
CreateTempDBInstance	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
ModifyBackupPolicy	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeDBInstancePerformance	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeSlowLogRecords	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeBinlogFiles	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeSQLLogRecords	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeOptimizeAdviceOnMissPK	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid

Operation	Authentication rule
DescribeOptimizeAdviceOnMissIndex	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeParameters	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
CreatePrepaidDBInstanceForChannel	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
ModifyPrepaidDBInstanceSpec	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
CreatePostpaidDBInstanceForChannel	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
ModifyPostpaidDBInstanceSpec	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeDBInstanceAttribute	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
RestartDBInstance	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
ModifySecurityIps	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
UpgradeDBInstanceEngineVersion	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
CreateDatabase	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeDatabases	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
ImportDataBaseBetweenInstances	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
CreateAccount	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
GrantAccountPrivilege	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeAccounts	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
ModifyAccountDescription	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeBackups	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeBackupPolicy	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeResourceUsage	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeSlowLogs	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeErrorLogs	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeSQLLogReports	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeOptimizeAdviceOnStorage	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeOptimizeAdviceOnExcessIndex	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid
DescribeOptimizeAdviceByDBA	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid

Operation	Authentication rule
ModifyeParameter	acs:rds:$regionid:$accountid:dbinstance/$dbinstanceid

8.1.2.11. Appendix

8.1.2.11.1. Error codes on the client

8.1.2.11.1.1. Common errors

Error code	Error message	HTTP status code
MissingParameter	The input parameter "parameter name" that is mandatory for processing this request is not supplied.	400
InvalidParameter	The specified parameter "Action or Version" is not valid.	400
InvalidAccessKeyId.NotFound	The Access Key ID provided does not exist in our records.	404
IncompleteSignature	The request signature does not conform to Aliyun standards.	400
IllegalTimestamp	The input parameter "Timestamp" that is mandatory for processing this request is not supplied.	400
InvalidOwnerId	The specified OwnerId is not valid.	400
InvalidOwnerAccount	The specified OwnerAccount is not valid.	400
InvalidOwner	OwnerId and OwnerAccount can't be used at one API access.	400
Throttling	Request was denied due to request throttling.	400
InvalidAction	The specified action is not valid.	403
ActionUnauthorized	The specified action is not available for you	403
UnsupportedHTTPMethod	This http method not supported.	403
UnsupportedParameter	The parameter "<parameter name>" is not supported.	400
Forbidden.InstanceNotFound	The specified Instance is not found.	404
Forbidden.RAM	User not authorized to operate on the specified resource, or this API doesn't support RAM.	403
Forbedden.NotSupportRAM	This action does not support accessed by RAM mode.	403

Error code	Error message	HTTP status code
Forbidden.RiskControl	This operation is forbidden by Aliyun Risk Control system.	403
InsufficientBalance	Your account does not have enough balance.	400
Forbidden.Authentication	This operation is forbidden by Aliyun Realname Authentication system.	403
Invalid<parameter name>.ValueNotSupported	The specified parameter “parameter name” is not valid.	400
Invalid<parameter name>.Malformed	The specified parameter "parameter name n" is not valid.	400
InvalidParameter	The specified parameter " parameter name n " is not valid.	400

8.1.2.11.1.2. Specific errors

Error code	Error message	HTTP status code
InvalidRegionId.NotFound	The DBInstanceId provided does not exist in our records.	404
InvalidSecurityIPList.Duplicate	The Security IP address is not in the available range or occupied.	400
InvalidSecurityIPListLength.Malformed	The quota of security ip exceeds.	400
InvalidEngineVersionInRegion.NotAvailable	The EngineVersion in the Region is not available.	403
InvaildEngineInRegion.NotAvailable	The Engine in the Region is not available.	403
InvaildDBInstanceClassInRegion.NotAvailable	The DBInstanceClass in the Region is not available.	403
OperationDenied	The resource is out of usage.	403
RegionUnauthorized	There is no authority to create instance in the specified region.	403
QuotaExceeded.CreateInstance	The quota of create instance exceeds.	403
InvalidDBInstanceId.NotFound	The DBInstanceId provided does not exist in our records.	404

Error code	Error message	HTTP status code
MissingParameter	The input parameters "DBInstanceClass" and "DBInstanceStorage" all blank or no change.	400
OperationDenied.DBInstanceType	The operation is not permitted due to type of instance.	400
OperationDenied.DBInstanceStorageReduce	The operation is not permitted due to reduce storage.	403
OperationDenied.DBInstanceStatus	The operation is not permitted due to instance status.	403
DependencyViolation	The operation is not permitted due to instance mount read only or guard instance.	403
InvalidConnectionStringPrefix.Duplicate	The connection string is not in the available range or occupied.	400
QuotaExceeded.SwitchTime	The quota of switch time exceed.	400
OperationDenied.LockMode	The operation is not permitted due to lock of instance.	403
InvalidSecurityIps.Duplicate	The quota of security ip exceeds.	400
OperationDenied.CurrentEngineVersion	The operation is not permitted due to specified current version.	400
OperationDenied.ReadOnlyDBInstanceLower	The operation is not permitted due to higher read only instance version.	403
OperationDenied.GuardDBInstanceLower	The operation is not permitted due to higher guard instance version.	403
OperationDenied.MasterDBInstanceState	The operation is not permitted due to status of master instance.	403
QuotaExceeded.DBName	The quota of db exceeds.	400
InvalidDBName.Duplicate	The Security db Name is not in the available range or occupied.	400
InvalidParameter.Keyword	The specified parameter "DBName" is keyword	400
OperationDenied.DBStatus	The operation is not permitted due to status of database.	403
OperationDenied.DBInstanceEngine	The operation is not permitted due to engine of instance.	403

Error code	Error message	HTTP status code
FTPServiceUnavailable	The request has failed due to a temporary failure of the FTP server.	403
QuotaExceeded.Upload	The quota of file exceeds.	403
InvalidFileName.NotCompleted	The specified "FileName" is not completed.	404
InvalidFileName.NotAvailable	The specified "FileName" is not Available.	404
QuotaExceeded.FileSize	The quota of file size exceeds.	403
QuotaExceeded.DBInstanceStorage	The quota of instance storage exceeds.	403
InvalidDBInfo.Malformed	The specified parameter "DBInfo" is not valid or db not exist.	400
OperationDenied.Region	The operation is not permitted due to different region.	403
OperationDenied.Engine	The operation is not permitted due to different engine.	403
OperationDenied.DBInstanceId	The operation is not permitted due to DBInstanceId and SourceDBInstanceId is same.	403
InvalidTaskId.NotFound	The ImportId provided does not exist in our records.	400
OperationDenied.IncorrectTaskStatus	The operation is not permitted due to status of import.	403
InvalidAccountName.keyword	The specified parameter "AccountName" is a keyword.	400
InvalidAccountName.Duplicate	The Security db Name is not in the available range or occupied.	400
QuotaExceeded.AccountName	The quota of account exceeds.	403
OperationDenied.AccountStatus	The operation is not permitted due to status of account.	403
InvalidDBName.NotFound	The DBName provided does not exist in our records.	404
OperationDenied.AccountType	The operation is not permitted due to type of account.	403
OperationDenied.BackupJobExists	The operation is not permitted due to backup job exist.	403

Error code	Error message	HTTP status code
OperationDenied.NoDatabase	The operation is not permitted due to no database.	403
InvalidStartTimeAndEndTime.Malformed	The end time must be greater than the start time	400
OperationDenied.BackupJobExists	The operation is not permitted due to backup job exist.	403
InvalidBackupId.NotFound	The BackupId provided does not exist in our records.	404
OperationDenied.NotFoundBackup	The operation is not permitted due to no backup.	403
OperationDenied.BackupStatus	The operation is not permitted due to type of backup.	403
OperationDenied.BackupMethod	The operation is not permitted method of backup.	403
OperationDenied.TempDBInstanceExists	The operation is not permitted due to temp instance exist.	403
Forbidden.Authentication	The operation is forbidden by Aliyun Realname Authentication System.	403
IncorrectDBInstanceConnType	Current DB instance conn type does not support this operation.	404
IncorrecttVpcId.Mismatch	The specified parameter "VpcId" is not valid.	400
IntranetNetTypeNotExists	Current DB instance net type does not support this operation.	404
InvalidDBInstanceName.NotFound	The DBInstanceId provided does not exist in our records.	403
InvalidConnectionMode.ValueNotSupported	The specified parameter "ConnectionMode" is not valid.	400
InvalidConnectionString.DuplicateSpecified	connection string already exists in the Aliyun RDS.	403
InvalidConnectionString.DuplicateSpecified	connection string or port want to be modified is the same with current net type.	400
InvalidConnectionStringPrefix.Duplicated	Specified connection string already exists in the Aliyun RDS.	403
InvalidCurrentConnectionString.NotFound	Specified current connection string doesn't exist.	400

Error code	Error message	HTTP status code
InvalidDBInstanceId.NotFound	The DBInstanceId provided does not exist in our records.	400
InvalidDBInstanceId.QuotaExceeded	The quota of instance id exceeds.	400
InvalidDBInstanceNetType.NotFound	The Specified DB instance net type is not found.	404
InvalidDBinstanceNetType.ValueNotSupport	The specified parameter "DBinstanceNetType" is not valid.	400
InvalidDBInstanceType.ValueNotSupport	The specified parameter "DBInstanceType" is not valid.	400
InvalidEngineVersion.Malformed	The specified parameter "EngineVersion" is not valid.	400
InvalidInstanceNetworkType.ValueNotSupported	The specified parameter "InstanceNetworkType" is not valid.	400
InvalidParameter	The specified parameter "dbInstanceId" is not valid.	400
InvalidPort.Malformed	Specified port is not valid.	400
InvalidPrivateIpAddress.Duplicated	Specified private IP address is duplicated.	400
InvalidPrivateIpAddress.Mismatch	Specified private IP address is not in the CIDR block of virtual switch.	400
InvalidVPCId.NotFound	Specified virtual vpc is not found.	400
InvalidVSwitchId.Mismatch	Specified instance and virtual switch are not in the same zone.	400
InvalidVSwitchId.NotFound	Specified virtual switch is not found in specified VPC.	400
NetTypeExists	Specified net type already existed.	400
NetTypeExists	Specified public net type already existed.	403
OperationDenied.DBInstanceNetType	The operation is not permitted due to net type of instance.	403
OperationDenied.DBInstanceStatus	The operation is not permitted due to status of instance.	403
OperationDenied.DBInstanceType	The operation is not permitted due to type of instance.	403

Error code	Error message	HTTP status code
OperationDenied.LockMode	The operation is not permitted due to lock of instance.	403
OperationDenied.Switch	Specified instance cannot be switched.	400
OperationDenied.Switch	Specified instance cannot be switched to VPC.	403
OperationDenied.SwitchToVPC	Specified instance cannot be switched to VPC.	403
OperationDenied	The resource is out of usage.	403
OperationDenied	The vpc cloudinstanceIp is use, please check params.	406
OperationDenied	The vpc service is error, please check params.	400
PARAMETER_ERROR	The vpc request parameter may not be null.	406
PARAMETER_MUST_NOT_NULL	The parameter must not be null.	406
PublicConnectionExists	PublicConnection exists.	403
bpcIzNoNotEqualsRdsMultIzNo	Specified vpc IzNo not equal rds IzNo.	400
OperationDenied.DBInstanceStatus	The operation is not permitted due to status of instance.	403
OperationDenied.DBInstanceType	The operation is not permitted due to type of instance.	403
OperationDenied.LockMode	The operation is not permitted due to lock of instance.	403
OperationDenied.Switch	Specified instance cannot be switched.	400
OperationDenied.SwitchToVPC	Specified instance cannot be switched to VPC.	403
OperationDenied	The resource is out of usage.	403
OperationDenied	The vpc cloudinstanceIp is use, please check params.	406
OperationDenied	The vpc service is error, please check params.	400
PARAMETER_ERROR	The vpc request parameter may not be null.	406
PARAMETER_MUST_NOT_NULL	The parameter must not be null.	406
PublicConnectionExists	PublicConnection exists.	403

Error code	Error message	HTTP status code
bpcIzNoNotEqualsRdsMultIzNo	Specified vpc IzNo not equal rds IzNo.	400

8.1.2.11.2. Error codes on the server

Error code	Error message	HTTP status code
ServiceUnavailable	The request has failed due to a temporary failure of the server.	503
InternalError	The request processing has failed due to some unknown error, exception or failure.	500

8.1.2.11.3. Instance states

State	Description
Creating	An instance is being created.
Running	An instance is in the running state.
Deleting	An instance is being deleted.
Rebooting	An instance is being restarted.
DBInstanceClassChanging	An instance is being upgraded or downgraded.
TRANSING	Data is being migrated.
EngineVersionUpgrading	Engine version is being upgraded.
TransingToOthers	Data is being migrated to other RDS instances.
GuardDBInstanceCreating	A disaster recovery instance is being created.
Restoring	A backup is being restored.
Importing	Data is being imported.
ImportingFromOthers	Data is being imported from other RDS instances.
DBInstanceNetTypeChanging	The network type is being switched between Intranet and Internet.
GuardSwitching	The instance is undergoing disaster recover failover.
INS_CLONING	The instance is being cloned.

8.1.2.11.4. Performance parameters

ApsaraDB RDS for MySQL

API parameter	Description
MySQL_NetworkTraffic	The average inbound traffic to a MySQL instance per second and average outbound traffic from a MySQL instance per second. Unit: KB.
MySQL_QPSTPS	The average number of SQL statements executed per second and average number of transactions per second.
MySQL_Sessions	The number of active connections and total number of current connections.
MySQL_InnoDBBufferRatio	The read hit rate of the InnoDB buffer pool, utilization of the InnoDB buffer pool, and percentage of dirty data blocks in the InnoDB buffer pool.
MySQL_InnoDBDataReadWritten	The average volume of data that InnoDB reads per second and average volume of data that InnoDB writes per second. Unit: KB.
MySQL_InnoDBLogRequests	The average number of reads from the InnoDB buffer pool per second and average number of writes to the InnoDB buffer pool per second.
MySQL_InnoDBLogWrites	The average number of log write requests per second, average number of physical writes performed on log files per second, and average number of fsync() writes to log files per second.
MySQL_TempDiskTableCreates	The number of temporary tables automatically created in the hard disk when MySQL statements are executed.
MySQL_MyISAMKeyBufferRatio	The average key buffer utilization of MyISAM per second, average key buffer read hit rate of MyISAM per second, and average key buffer write hit rate of MyISAM per second.
MySQL_MyISAMKeyReadWrites	The average number of data reads from the buffer pool by MyISAM per second, average number of data writes to the buffer pool by MyISAM per second, average number of data reads from the hard disk by MyISAM per second, and average number of data writes to the hard disk by MyISAM per second.
MySQL_COMDML	The average number of DELETE statements executed per second, average number of INSERT statements executed per second, average number of INSERT_SELECT statements executed per second, average number of REPLACE statements executed per second, and average number of REPLACE_SELECT statements executed per second, average number of SELECT statements executed per second, and average number of UPDATE statements executed per second.
MySQL_RowDML	The average number of rows read from the InnoDB table per second, average number of rows updated in the InnoDB table per second, average number of rows deleted from the InnoDB table per second, average number of rows inserted into the InnoDB table per second, and average number of physical writes to log files per second.

API parameter	Description
MySQL_MemCpuUsage	The CPU utilization and memory usage of a MySQL instance within the entire operating system.
MySQL_IOPS	The IOPS of a MySQL instance.
MySQL_DetailedSpaceUsage	The disk space occupied by a MySQL instance, including ins_size (total space), data_size (data space), log_size (log space), tmp_size (temporary space), and other_size (system space).
slavestat	The latency of read-only instances.

ApsaraDB RDS for SQL Server

API parameter	Description
SQLServer_Transactions	The average number of transactions per second.
SQLServer_Sessions	The total number of current connections.
SQLServer_BufferHit	The buffer hit rate.
SQLServer_FullScans	The average number of full table scans per second.
SQLServer_SQLCompilations	The number of SQL compilations per second.
SQLServer_CheckPoint	The number of checkpoints written to pages per second.
SQLServer_Logins	The number of logons per second.
SQLServer_LockTimeout	The number of lock timeouts per second.
SQLServer_Deadlock	The number of deadlocks per second.
SQLServer_LockWaits	The number of lock waits per second.
SQLServer_NetworkTraffic	The average inbound/outbound traffic to/from an SQL Server instance per second. Unit: KB.
SQLServer_QPS	The average number of SQL statements executed per second.
SQLServer_InstanceCPUUsage	The CPU utilization of an SQL Server instance within the entire operating system.
SQLServer_IOPS	The IOPS of an SQL server instance.
SQLServer_SpaceUsage	The space usage of an SQL Server instance within the entire operating system.
