- Compared with YYYYWEEK, YYYYWEEK_OPT maintains the even distribution of data among ApsaraDB RDS for MySQL instances as the timeline increases. The effect is similar to YYYYMM_OPT.
- YYYYWEEK_OPT distributes data evenly to each ApsaraDB RDS for MySQL instance, helping to maximize the performance of each ApsaraDB RDS for MySQL instance.
- How to choose between YYYYWEEK and YYYYWEEK_OPT:
  - YYYYWEEK_OPT can be used to distribute data evenly to each ApsaraDB RDS for MySQL instance if the time of service data increases sequentially and the data volume does not differ much between time points.
  - YYYYWEEK is applicable if the time of data generation increases randomly rather than sequentially.

Routing method

- Calculate the hash value based on the year and weeks of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.
- The hash calculation based on the database and table shard key considers the data distribution among the ApsaraDB RDS for MySQL instances that connect to the PolarDB-X instances.

Scenarios

- Databases and tables are partitioned by year and week, respectively.
- Data must be evenly distributed to each ApsaraDB RDS for MySQL instance that connects to the PolarDB-X instance.
- The time of the shard key increases sequentially rather than randomly, and the data volume is relatively average from week to week. For example, the number of weekly journal logs increases every week, and the log data is not concentrated on the same ApsaraDB RDS for MySQL instance.

Precautions

- YYYYWEEK_OPT does not support distributing data from every week in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle over weeks (for example, a cycle exists between the first week of 2012 and the first week of 2013), data from the same week after a cycle may be routed to the same database shard or table shard, depending on the actual number of table shards.

11.11.6.15. YYYYDD_OPT

Requirements

- The shard key must be of the DATE, DATETIME, or TIMESTAMP type.
- The version of the PolarDB-X instance must be 5.1.28-1320920 or later. For more information, see View the instance version.

Optimizations

- Compared with YYYYDD, YYYYDD_OPT maintains the even distribution of data among ApsaraDB RDS for MySQL instances as the timeline increases. The effect is similar to YYYYMM_OPT.
- YYYYDD_OPT distributes data evenly to each ApsaraDB RDS for MySQL instance, helping to maximize the performance of each ApsaraDB RDS for MySQL instance.
- How to choose between YYYYDD and YYYYDD_OPT:
  - YYYYDD_OPT can be used to distribute data evenly to each ApsaraDB RDS for MySQL instance if the time of service data generation increases sequentially and the data volume does not differ much between time points.
  - YYYYDD is applicable if the time of data generation increases randomly rather than sequentially.

Routing method

- Calculate the hash value based on the year and days of the year in the time value of the database shard key and then perform the remainder operation on the hash value based on the number of database shards. This completes route computing.
- The hash calculation based on the database and table shard key considers the data distribution among the ApsaraDB RDS for MySQL instances that connect to the PolarDB-X instances.

Scenarios

- Databases and tables need to be partitioned by year and by day, respectively.
- Data must be evenly distributed to each ApsaraDB RDS for MySQL instance that connects to the PolarDB-X instance.
- The time of the shard key increases sequentially rather than randomly, and the data volume is relatively average from day to day. For example, the number of daily journal logs increases every day, and the log data is not concentrated on the same ApsaraDB RDS for MySQL instance.

Precautions

- YYYYDD_OPT does not support distributing data from every day in every year to a separate table shard. Instead, the number of table shards must be fixed.
- After a cycle of a specific date (for example, a cycle exists between 2012-03-01 and 2013-03-01), data from the same date may be routed to the same database shard or table shard, depending on the actual number of table shards.

11.12. Automatic protection of important SQL statements

In Distributed Relational Database Service (DRDS), the data manipulation language (DML) statements are the same as MySQL statements.

We recommend that you include the shard key in the **SELECT** and **UPDATE** statements of DRDS. The **INSERT** statement of DRDS must include the shard key and a non-empty key value.

By default, DRDS disables full-table deletion and updating to avoid misoperation.

The following statements are prohibited by default:

- A DELETE statement without the WHERE or LIMIT condition
- An UPDATE statement without the WHERE or LIMIT condition

If you need to perform full-table deletion or update, you can temporarily skip this limit by using the following hint:

```
HINT: /! TDDL:FORBID_EXECUTE_DML_ALL=false*/
```

Examples

- Full-table deletion is intercepted by default.

```
mysql> delete from tt;
ERR-CODE: [TDDL-4620][ERR_FORBID_EXECUTE_DML_ALL] Forbid execute DELETE ALL or UPDATE ALL sql. More: [http://middleware.alibaba-inc.com/faq/faqByFaqCode.html?faqCode=TDDL-4620]
```

  The operation is successful if the following hint is added:

```
mysql> /! TDDL:FORBID_EXECUTE_DML_ALL=false*/delete from tt;
Query OK, 10 rows affected (0.21 sec)
```

- Full-table update is intercepted by default.

```
mysql> update tt set id = 1;
ERR-CODE: [TDDL-4620][ERR_FORBID_EXECUTE_DML_ALL] Forbid execute DELETE ALL or UPDATE ALL sql. More: [http://middleware.alibaba-inc.com/faq/faqByFaqCode.html?faqCode=TDDL-4620]
```

  The operation is successful if the following HINT is added:

```
mysql> /! TDDL:FORBID_EXECUTE_DML_ALL=false*/update tt set id = 1;
Query OK, 10 rows affected (0.21 sec)
```

- This limit does not apply to DELETE or UPDATE statements that contain the WHERE or LIMIT condition.

```
mysql> delete from tt where id = 1;
Query OK, 1 row affected (0.21 sec)
```

11.13. PolarDB-X sequence

11.13.1. Overview

A Distributed Relational Database Service (DRDS) sequence is a 64-digit number that corresponds to the signed BIGINT type in MySQL. It is used to create a globally unique and sequentially incremental numeric sequence, such as the values of primary key columns and unique index columns.

DRDS sequences are used in the following two ways:

- Explicit sequences are created and maintained by using sequence-specific data definition language (DDL) syntax and can be used independently. The sequence value can be acquired by using `select seq.nextval;`, in which `seq` indicates the sequence name.
- Implicit sequences are used to automatically fill in primary keys with AUTO_INCREMENT defined and are automatically maintained by DRDS.

> **Notice** DRDS creates implicit sequences only after AUTO_INCREMENT is defined for partitioned tables and broadcast tables. This is not the case for non-partition tables. The AUTO_INCREMENT value of a non-partition table is created by ApsaraDB RDS for MySQL.

Types and features of DRDS sequences

Currently, three types of DRDS sequences are supported.

Type (abbreviation)	Globally unique	Consecutive	Monotonically increasing	Monotonically increasing within the same connection	Non-single point	Data type	Readability
Group sequence (GROUP)	Yes	No	No	Yes	Yes	All integer types	High
Time-based sequence (TIME)	Yes	No	Monotonically increasing at the macro level and non-monotonically increasing at the micro level	Yes	Yes	Only BIGINT is supported	Low
Simple sequence (SIMPLE)	Yes	Yes	Yes	Yes	No	All integer types	High

Concepts:

- **Consecutive:** If the current value is n, the next value must be n + 1. If the next value is not n + 1, it is nonconsecutive.
- **Monotonically increasing:** If the current value is n, the next value must be a number greater than n.
- **Single point:** The risk of single point of failure exists.
- **Monotonically increasing at the macro level and non-monotonically increasing at the micro level:** An example of this is `1, 3, 2, 4, 5, 7, 6, 8, ...`

Group sequence (GROUP, used by default)

Features

A group sequence is a globally unique sequence with natural numeric values, which are not necessarily consecutive or monotonically increasing. If the sequence type is not specified, DRDS uses the group sequence type by default.

- **Advantages:** A group sequence is globally unique and provides excellent performance, preventing single point of failure.
- **Disadvantages:** A group sequence may contain nonconsecutive values, which may not necessarily start from the initial value and do not cycle.

Implementation

The values of a group sequence are created by multiple nodes to ensure high availability. The values in a segment are nonconsecutive if the values are not all used, such as in the case of disconnection.

Time-based sequence

Features

A time-based sequence consists of **a timestamp, node ID, and serial number**. It is globally unique and automatically increments at the macro level. Value updates are database-independent and not persistently stored in databases. Only names and types are stored in databases. This delivers good performance to time-based sequences, which create values like 776668092129345536, 776668098018148352, 776668111578333184, and 776668114812141568.

> **Notice** **Sequence values must be of the BIGINT type** when used in the auto-increment columns of tables.

- **Advantages:** Time-based sequences are globally unique with good performance.
- **Disadvantages:** The values of a time-based sequence are nonconsecutive. The START WITH, INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE parameters are invalid for time-based sequences.

Simple sequence

Features

Only simple sequences support the START WITH, INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE parameters.

- **Advantages:** Simple sequences are globally unique and monotonically increasing with consecutive values.
- **Disadvantages:** Simple sequences are prone to single point of failure, poor performance, and bottlenecks. Use them with caution.

Implementation

Each sequence value must be persistently stored.

Scenarios

Group sequences, time-based sequences, and simple sequences are globally unique and can be used in **primary key columns** and **unique index columns**.

- We recommend that you use **group sequences**.
- Use only simple sequences for services that strongly depend on consecutive sequence values. Pay attention to sequence performance.
- We recommend that you use time-based sequences if you have high requirements for sequence performance, the amount of data inserted to tables is small, and large sequence values are acceptable. Time-based sequences are CPU-bound with no requirements on computing lock, database dependence, or persistent storage.

The following example shows how to create a sequence with an initial value of 100000 and a step of 1.

- A **simple sequence** creates globally unique, consecutive, and monotonically increasing values, such as 100000, 100001, 100002, 100003, 100004, ..., 200000, 200001, 200002, 200003... The values of a simple sequence are persistently stored. Even after services are restarted upon a single point of failure, values are still created consecutively from the breakpoint. However, simple sequences have poor performance because each value is persistently stored once it is created.
- A **group sequence** may create values like 200001, 200002, 200003, 200004, 100001, 100002, 100003...

  > **Notice**
  > - The initial value of a group sequence is not necessarily the same as the START WITH value (which is 100000 in this example) but is invariably greater than this value. In this example, the initial value is 200001.
  > - A group sequence is globally unique but may contain nonconsecutive values, which may occur when a node is faulty or the connection that only uses partial values is closed. The group sequence in this example contains nonconsecutive values because the values between 200004 and 100001 are missing.

- A **time-based sequence** may create values like 776668092129345536, 776668098018148352, 776668111578333184, 776668114812141568...

11.13.2. Explicit sequence usage

This topic describes how to use data definition language (DDL) statements to create, modify, delete, and query sequences and how to acquire the values of explicit sequences.

Create a sequence

Syntax:

```
CREATE [ GROUP | SIMPLE | TIME ] SEQUENCE <name>
[ START WITH <numeric value> ] [ INCREMENT BY <numeric value> ]
[ MAXVALUE <numeric value> ] [ CYCLE | NOCYCLE ]
```

Parameters:

Parameter	Description	Applicable To
START WITH	The initial sequence value. If it is not set, the default value is 1.	Simple sequence and group sequence
INCREMENT BY	The increment (or interval value or step) of each sequence increase. If it is not set, the default value is 1.	Simple sequence
MAXVALUE	The maximum sequence value. If it is not specified, the default value is the maximum value of the signed BIGINT type.	Simple sequence
CYCLE or NOCYCLE	Indicates whether to repeat the sequence value which starts from the value specified by START WITH after the sequence value reaches the maximum value. If it is not specified, the default value is NOCYCLE.	Simple sequence

> **Note**
>
> - If the sequence type is not specified, the group sequence type is used by default.
> - The INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE parameters are invalid for group sequences.
> - The START WITH, INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE parameters are invalid for time-based sequences.
> - Group sequences are nonconsecutive. The START WITH parameter only provides reference for group sequences. **The initial group sequence value is not necessarily the same as but is greater than the value of START WITH.**

Example 1: Create a group sequence.

- Method 1:

```
mysql> CREATE SEQUENCE seq1;
Query OK, 1 row affected (0.27 sec)
```

- Method 2:

```
mysql> CREATE GROUP SEQUENCE seq1;
Query OK, 1 row affected (0.27 sec)
```

Example 2: Create a time-based sequence.

```
mysql> CREATE TIME SEQUENCE seq1;
Query OK, 1 row affected (0.27 sec)
```

Example 3: Create a simple sequence with an initial value of 1000, step of 2, and maximum value of 99999999999, which does not repeat after increasing to the maximum value.

```
mysql> CREATE SIMPLE SEQUENCE seq2 START WITH 1000 INCREMENT BY 2 MAXVALUE 99999999999 NOCYCLE;
Query OK, 1 row affected (0.03 sec)
```

Modify a sequence

Distributed Relational Database Service (DRDS) allows you to modify sequences in the following ways:

- For simple sequences, change the values of START WITH, INCREMENT BY, MAXVALUE, and CYCLE or NOCYCLE.
- For group sequences, change the value of START WITH.
- Convert the sequence type to another.

Syntax:

```
ALTER SEQUENCE <name> [ CHANGE TO GROUP | SIMPLE | TIME ]
START WITH <numeric value> [ INCREMENT BY <numeric value> ]
[ MAXVALUE <numeric value> ] [ CYCLE | NOCYCLE ]
```

Parameters:

Parameter	Description	Applicable To
START WITH	The initial sequence value. If it is not set, the default value is 1.	Simple sequence and group sequence
INCREMENT BY	The increment (or interval value or step) of each sequence increase. If it is not set, the default value is 1.	Simple sequence
MAXVALUE	The maximum sequence value. If it is not specified, the default value is the maximum value of the signed BIGINT type.	Simple sequence
CYCLE or NOCYCLE	Indicates whether to repeat the sequence value which starts from the value specified by START WITH after the sequence value reaches the maximum value. If it is not specified, the default value is NOCYCLE.	Simple sequence

> Note
>
> - Group sequences are nonconsecutive. The START WITH parameter only provides reference for group sequences. **The initial group sequence value is not necessarily the same as but is greater than the value of START WITH.**
> - If you set START WITH when modifying a simple sequence, the START WITH value takes effect immediately. The following sequence value starts from the new START WITH value. For example, if you change the START WITH value to 200 when the sequence value increases to 100, the following sequence value starts from 200.
> - Before changing the START WITH value, you need to analyze the existing sequence values and the speed of creating sequence values to avoid conflicts. Do not change the START WITH value unless necessary.

Example: Change the initial value, step, and maximum value of the simple sequence named seq2 to 3000, 5, and 1000000 respectively, and set CYCLE.

```
mysql> ALTER SEQUENCE seq2 START WITH 3000 INCREMENT BY 5 MAXVALUE 1000000 CYCLE;
Query OK, 1 row affected (0.01 sec)
```

Convert the sequence type to another

- Use the `CHANGE TO <sequence_type>` clause of `ALTER SEQUENCE`.
- If the `CHANGE TO` clause of `ALTER SEQUENCE` is specified, add the `START WITH` parameter to prevent duplicate values. This parameter is optional if `CHANGE TO` is not specified.

Example: Convert a group sequence to a simple sequence.

```
mysql> ALTER SEQUENCE seq1 CHANGE TO SIMPLE START WITH 1000000;
Query OK, 1 row affected (0.02 sec)
```

Delete a sequence

Syntax:

```
DROP SEQUENCE <name>
```

Example:

```
mysql> DROP SEQUENCE seq3;
Query OK, 1 row affected (0.02 sec)
```

Query sequences

Syntax:

```
SHOW SEQUENCES
```

Example: The TYPE column lists the sequence types in the abbreviated form.

```
mysql> SHOW SEQUENCES;
+------------+--------------------+-------------+------------+---------------------+-------+--------+
| NAME       | VALUE              | INCREMENT_BY | START_WITH | MAX_VALUE           | CYCLE | TYPE   |
+------------+--------------------+-------------+------------+---------------------+-------+--------+
| AUTO_SEQ_1 | 91820513           | 1           | 91820200   | 9223372036854775807 | N     | SIMPLE |
| AUTO_SEQ_4 | 91820200           | 2           | 1000       | 9223372036854775807 | Y     | SIMPLE |
| seq_test   | N/A                | N/A         | N/A        | N/A                 | N/A   | TIME   |
| AUTO_SEQ_2 | 100000             | N/A         | N/A        | N/A                 | N/A   | GROUP  |
| AUTO_SEQ_3 | 200000             | N/A         | N/A        | N/A                 | N/A   | GROUP  |
+------------+--------------------+-------------+------------+---------------------+-------+--------+
5 rows in set (0.01 sec)
```

Get the sequence value

Syntax:

```
< sequence name >.NEXTVAL
```

Example:

```
SELECT sample_seq.nextVal FROM dual;
+--------------------+
| SAMPLE_SEQ.NEXTVAL |
+--------------------+
|             101001 |
+--------------------+
1 row in set (0.04 sec)
```

You can also write SAMPLE_SEQ.nextVal as a value to the SQL statement:

```
mysql> INSERT INTO some_users (name,address,gmt_create,gmt_modified,intro) VALUES ('sun',SAMPLE_SEQ.nextVal,now(),now(),'aa');
Query OK, 1 row affected (0.01 sec)
```

> **Note** If you set the AUTO_INCREMENT parameter when creating a table, you do not need to specify an auto-increment column when running the INSERT statement. The auto-increment column is automatically maintained by DRDS.

Acquire the values of sequences in batches

Syntax:

```
SELECT < sequence name >.NEXTVAL FROM DUAL WHERE COUNT = < numeric value >
```

Example:

```
SELECT sample_seq.nextVal FROM dual WHERE count = 10;
+--------------------+
| SAMPLE_SEQ.NEXTVAL |
+--------------------+
|             101002 |
|             101003 |
|             101004 |
|             101005 |
|             101006|
|             101007 |
|             101008 |
|             101009 |
|             101010 |
|             101011 |
+--------------------+
10 rows in set (0.04 sec)
```

11.13.3. Implicit sequence usage

After AUTO_INCREMENT is set for a primary key, the primary key is automatically filled in by using a sequence which is maintained by Distributed Relational Database Service (DRDS).

CREATE TABLE

The standard CREATE TABLE syntax is extended to add the sequence type for auto-increment columns. If the type keyword is not specified, the default type is GROUP. The sequence names that are automatically created by DRDS and associated with tables are prefixed with AUTO_SEQ_ and suffixed with the table name.

```
CREATE TABLE <name> (
  <column> ... AUTO_INCREMENT [ BY GROUP | SIMPLE | TIME ],
  <column definition>,
  ...
) ... AUTO_INCREMENT=<start value>
```

SHOW CREATE TABLE

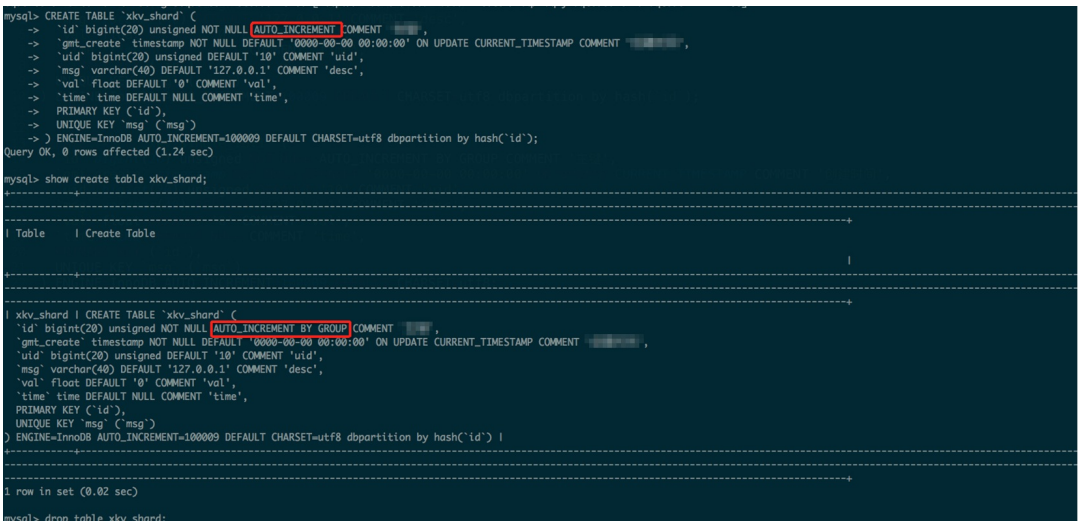
The sequence type is displayed for the auto-increment column of a table shard or broadcast table.

```
SHOW CREATE TABLE <name>
```

Examples

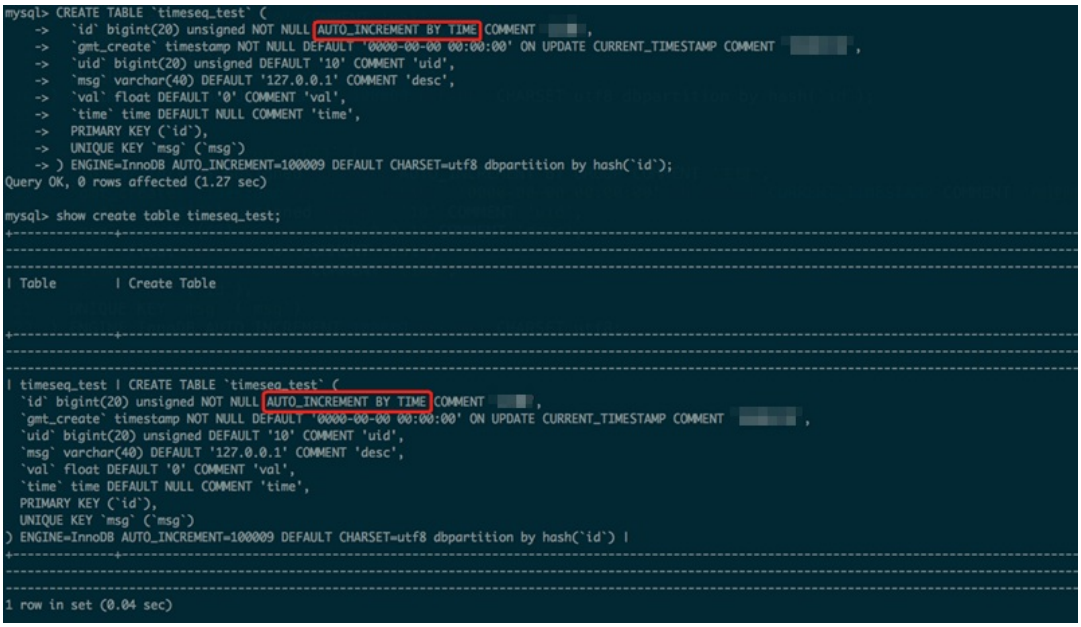
- If AUTO_INCREMENT is set but the sequence type is not specified when a table is created, the group sequence type is used by default.

  Example 1



- When creating a table, set AUTO_INCREMENT and specify a time-based sequence as the primary key value.

  Example 2



ALTER TABLE

Currently, **ALTER TABLE** cannot be used to change the sequence type but can be used to change the initial value. If you want to modify the data of the implicit sequence type in a table, run **SHOW SEQUENCES** to find the names and types of sequences and run **ALTER SEQUENCE** to modify the data.

```
ALTER TABLE <name> ... AUTO_INCREMENT=<start value>
```

Notice Exercise caution when changing the initial value of AUTO_INCREMENT after DRDS sequences are used. You need to analyze the existing sequence values and the speed of creating sequence values to avoid conflicts.

11.13.4. Limits and precautions for sequences

This topic describes the limits and precautions for sequences.

Limits and precautions

- When a time-based sequence is used in the auto-increment column of a table, the column must be of the BIGINT type.
- `START WITH` must be set when the sequence is changed to another type.
- When the `INSERT` statement is executed on a PolarDB-X database in non-partition mode where only one ApsaraDB RDS for MySQL database is bound or on a database in partition mode that has only one table but no broadcast table, PolarDB-X automatically optimizes and sends the statement. and bypasses the part of the optimizer that allocates the sequence value. In this case, `INSERT INTO ... VALUES (seq.nextval, ...)` is not supported. We recommend that you use the ApsaraDB RDS for MySQL auto-increment column feature instead.
- If the hint for a specific database shard is used by the `INSERT` statement such as `INSERT INTO ... VALUES ···` or `INSERT INTO ··· SELECT···` and the target table uses a sequence, PolarDB-X bypasses the optimizer and directly sends the statement so that the sequence does not take effect. The target table creates an ID by using the auto-increment feature of the ApsaraDB RDS for MySQL table.
- The auto-increment ID allocation method for the same table must be kept consistent, which may be based on PolarDB-X sequences or the auto-increment column of the ApsaraDB RDS for MySQL. If both of the two allocation methods are used for the same table, duplicate IDs may be created and making location difficult.

Troubleshoot primary key conflicts

Assume that data is directly written to ApsaraDB RDS for MySQL and that the related primary key value is not the sequence value created by PolarDB-X. If PolarDB-X automatically creates a primary key and writes it to the database, this primary key may conflict with that of the directly written data. This problem can be resolved as follows:

1. View the existing sequences by using the PolarDB-X-specified SQL statement. The sequence prefixed with `AUTO_SEQ_` is an implicit sequence. This sequence is generated when a table is created with the `AUTO_INCREMENT` parameter.

   ```
   mysql> SHOW SEQUENCES;
   +-------------------------+-------+--------------+------------+-----------+-------+-------+
   | NAME                    | VALUE | INCREMENT_BY | START_WITH | MAX_VALUE | CYCLE | TYPE  |
   +-------------------------+-------+--------------+------------+-----------+-------+-------+
   | AUTO_SEQ_timeseq_test   | N/A   | N/A          | N/A        | N/A       | N/A   | TIME  |
   | AUTO_SEQ_xkv_shard_tbl1 | 0     | N/A          | N/A        | N/A       | N/A   | GROUP |
   | AUTO_SEQ_xkv_shard      | 0     | N/A          | N/A        | N/A       | N/A   | GROUP |
   +-------------------------+-------+--------------+------------+-----------+-------+-------+
   3 rows in set (0.04 sec)
   ```

2. For example, if the t_item table contains conflicts and its primary key is ID, then retrieve the maximum primary key value of this table from PolarDB-X:

```
mysql> SELECT MAX(id) FROM t_item;
+-----------+
| max(id)   |
+-----------+
| 8231 |
+-----------+
1 row in set (0.01 sec)
```

3. Update the related value in the PolarDB-X sequence table to a value greater than 8231, such as 9000. Then, no error is returned for the auto-increment primary key created by the subsequent INSERT statement.

```
mysql> ALTER SEQUENCE AUTO_SEQ_USERS START WITH 9000;
Query OK, 1 row affected (0.01 sec)
```

11.14. Best practices

11.14.1. Select a shard key

A shard key is a field for database sharding and table sharding, which is used to create sharding rules during horizontal partitioning. PolarDB-X partitions a logical table horizontally into the physical database shards on each ApsaraDB RDS for MySQL instance based on the shard key.

The primary principle of sharding is to identify the business logic-specific subject of data in a table as much as possible and confirm that most (or core) database operations are performed based on this subject. Then, use the subject-related field as the shard key to perform database sharding and table sharding.

The business logic-specific subject is related to business scenarios. The following typical scenarios include business logic-specific subjects that can be used as shard keys:

- User-oriented Internet applications are operated to meet user requirements. Users are the business logic-specific subject and the user-related field can be used as the shard key.
- Seller-oriented e-commerce applications are operated to meet seller requirements. Sellers are the business logic-specific subject and the seller-related field can be used as the shard key.
- Game-oriented applications are operated to meet gamer requirements. Gamers are the business logic-specific subject and the gamer-related field can be used as the shard key.
- Internet of Vehicles (IoV) applications are operated based on vehicle information. Vehicles are the business logic-specific subject and the vehicle-related field can be used as the shard key.
- Tax-oriented applications are operated based on taxpayer information to provide frontend services. Taxpayers are the business logic-specific subject and the taxpayer-related field can be used as the shard key.

In other scenarios, you can also use the appropriate subject of business logic as the shard key.

For example, in a seller-oriented e-commerce application, the following single table must be horizontally partitioned:

```
CREATE TABLE sample_order (
 id INT(11) NOT NULL,
 sellerId INT(11) NOT NULL,
 trade_id INT(11) NOT NULL,
 buyer_id INT(11) NOT NULL,
 buyer_nick VARCHAR(64) DEFAULT NULL,
 PRIMARY KEY (id)
)
```

The sellerId field is used as the shard key because seller is the business logic-specific subject. In the case of database sharding but no table sharding, the distributed data definition language (DDL) statement for table creation is as follows:

```
CREATE TABLE sample_order (
 id INT(11) NOT NULL,
 sellerId INT(11) NOT NULL,
 trade_id INT(11) NOT NULL,
 buyer_id INT(11) NOT NULL,
 buyer_nick VARCHAR(64) DEFAULT NULL,
 PRIMARY KEY (id)
) DBPARTITION BY HASH(sellerId)
```

If no business logic-specific subject can be used as the shard key, use the following methods to select an appropriate shard key:

- Determine the shard key based on the distribution and access of data. Distribute the data in a table to different physical database shards and table shards as evenly as possible. This method is applicable to scenarios with massive analytical queries, in which query concurrency stays at 1.
- Determine the shard key for database sharding and table sharding by combining fields of the numeric (string) type and time type. This method is applicable to log retrieval.

For example, a log system records all user operations and needs to horizontally partition the following single log table:

```
CREATE TABLE user_log (
 userId INT(11) NOT NULL,
 name VARCHAR(64) NOT NULL,
 operation VARCHAR(128) DEFAULT NULL,
 actionDate DATE DEFAULT NULL
)
```

You can combine the user identifier with the time field to create a shard key for partitioning the table by week. The distributed DDL statement for table creation is as follows:

```
CREATE TABLE user_log (
 userId INT(11) NOT NULL,
 name VARCHAR(64) NOT NULL,
 operation VARCHAR(128) DEFAULT NULL,
 actionDate DATE DEFAULT NULL
) DBPARTITION BY HASH(userId) TBPARTITION BY WEEK(actionDate) TBPARTITIONS 7
```

For more information about shard key selection and table shard forms, see DDL statements.

> **Notice** Avoid using hotspot data as the shard key if possible.

11.14.2. Select the number of shards

Distributed Relational Database Service (DRDS) supports horizontal partitioning of databases and tables. By default, eight physical database shards are created on an ApsaraDB for RDS instance, and one or more physical table shards can be created on each physical database shard. The number of table shards is also called the number of shards.

Generally, we recommend that each physical table shard contain no more than 5 million rows of data. Generally, you can estimate the data growth in one to two years. Divide the estimated total data size by the total number of physical database shards, and then divide the result by the recommended maximum data size of 5 million, to obtain the number of physical table shards to be created on each physical database shard:

```
Number of physical table shards in each physical database shard = CEILING(Estimated total data size/(Number of Apsara DB for RDS instances x 8)/5,000,000)
```

Therefore, when the calculated number of physical table shards is equal to 1, only database sharding needs to be performed, that is, a physical table shard is created in each physical database shard. If the calculation result is greater than 1, we recommend that you perform both database sharding and table sharding, that is, there are multiple physical table shards in each physical database shard.

For example, if a user estimates that the total data size of a table will be about 0.1 billion rows two years later and the user has four ApsaraDB for RDS instances, then according to the preceding formula:

Number of physical table shards in each physical database shard = CEILING(100,000,000/(4 x 8)/5,000,000) = CEILING(0.625) = 1

If the result is 1, only database sharding is needed, that is, one physical table shard is created in each physical database shard.

If only one ApsaraDB for RDS instance is used in the preceding example, the formula is as follows:

Number of physical table shards in each physical database shard = CEILING(100,000,000/(1 x 8)/5,000,000) = CEILING(2.5) = 3

If the result is 3, we recommend that you create three physical table shards in each physical database shard.

11.14.3. Basic concepts of SQL optimization

Distributed Relational Database Service (DRDS) is an efficient and stable distributed relational database service that processes distributed relational computing. DRDS optimizes SQL statements differently from single-instance relational databases such as MySQL. DRDS focuses on the network I/O overheads in a distributed environment and pushes SQL operations down to the underlying database shards (such as databases on ApsaraDB for RDS instances) for execution, thereby reducing the network I/O overheads and improving the SQL execution efficiency.

DRDS provides commands for obtaining the SQL execution information to help SQL optimization, for example, EXPLAIN commands for obtaining SQL execution plans and TRACE commands for obtaining SQL execution processes and overheads. This topic describes the basic concepts and common commands related to SQL optimization in DRDS.

Execution plan

An SQL execution plan (or execution plan) is a set of ordered operation steps generated to access data. In DRDS, the execution plan is divided into the execution plan at the DRDS layer and the execution plan at the ApsaraDB for RDS layer. Execution plan analysis is an effective way to optimize SQL statements. Through execution plan analysis, you can know whether DRDS or ApsaraDB for RDS has generated optimal execution plans for SQL statements and whether further optimization can be made.

During SQL statement execution, based on the basic information of the SQL statement and related tables, the DRDS optimizer determines on which the database shards the SQL statement should be executed, and the specific SQL statement form, execution policy, and data merging and computing policy for each database shard. This process optimizes SQL statement execution and generates execution plans at the DRDS layer. The execution plan at the ApsaraDB for RDS layer is the native MySQL execution plan.

DRDS provides a set of EXPLAIN commands to display execution plans at different levels or with different levels of detail.

The following table briefly describes the EXPLAIN commands in DRDS.

EXPLAIN command description

Command	Description	Example

Command	Description	Example
EXPLAIN { SQL }	Displays the summary execution plan of SQL statements at the DRDS layer, including the database shards on which the SQL statement is run, physical statements, and general parameters.	EXPLAIN SELECT * FROM test
EXPLAIN DETAIL { SQL }	Displays the detailed execution plans of SQL statements at the DRDS layer, including the statement type, concurrency, returned field information, physical tables, and database groups.	EXPLAIN DETAIL SELECT * FROM test
EXPLAIN EXECUTE { SQL }	Displays the execution plan of the underlying ApsaraDB for RDS instance, which is equivalent to the EXPLAIN statement of MySQL.	EXPLAIN EXECUTE SELECT * FROM test

Execution plans at the DRDS layer

The following table describes the fields in the results returned for a DRDS-layer execution plan.

Description of fields in DRDS-layer execution plans

Field	Description
GROUP_NAME	The name of the DRDS database shard. The suffix identifies the specific database shard. The value is consistent with the result of the SHOW NODE command.
SQL	The SQL statement run on this database shard.
PARAMS	The SQL statement parameters used when DRDS communicates with ApsaraDB for RDS over the Prepare protocol.

The SQL field can be in two forms:

1. If an SQL statement does not contain the following parts, the execution plan is displayed as an SQL statement:
   - Aggregate function involving multiple database shards.
   - Distributed JOIN queries involving multiple shards.
   - Complex subqueries.

   Example:

```
mysql> EXPLAIN SELECT * FROM test;
+-----------------------------------------------+-----------------------------------------------+--------+
| GROUP_NAME                                    | SQL                                           | PARAMS |
+-----------------------------------------------+-----------------------------------------------+--------+
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0000_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}     |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0001_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}     |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0002_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}     |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0003_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}     |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0004_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}     |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0005_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}     |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0006_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}     |
| TESTDB_1478746391548CDTCTESTDB_OXGJ_0007_RDS | select `test`.`c1`,`test`.`c2` from `test` | {}     |
+-----------------------------------------------+-----------------------------------------------+--------+
8 rows in set (0.04 sec)
```

The group names displayed in the GROUP_NAME field can be found in the returned result of SHOW NODE:

```
mysql> SHOW NODE;
+----+-----------------------------------------------+------------------+-----------------+--------------------+--------------------+
| ID | NAME                                          | MASTER_READ_COUNT | SLAVE_READ_COUNT | MASTER_READ_PERCENT | SLAVE_READ_PERCENT |
+----+-----------------------------------------------+------------------+-----------------+--------------------+--------------------+
| 0 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0000_RDS |         69 |          0 | 100%          | 0%           |
| 1 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0001_RDS |         45 |          0 | 100%          | 0%           |
| 2 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0002_RDS |         30 |          0 | 100%          | 0%           |
| 3 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0003_RDS |         29 |          0 | 100%          | 0%           |
| 4 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0004_RDS |         11 |          0 | 100%          | 0%           |
| 5 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0005_RDS |          1 |          0 | 100%          | 0%           |
| 6 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0006_RDS |          8 |          0 | 100%          | 0%           |
| 7 | TESTDB_1478746391548CDTCTESTDB_OXGJ_0007_RDS |         50 |          0 | 100%          | 0%           |
+----+-----------------------------------------------+------------------+-----------------+--------------------+--------------------+
8 rows in set (0.10 sec)
```

2. Execution plans that cannot be expressed by SQL statements can be expressed by DRDS in custom format.

   Example:

```
mysql> EXPLAIN DETAIL SELECT COUNT(*) FROM test;
+-----------------------------------------------+---------------------------------+--------+
| GROUP_NAME                                    | SQL                             | PARAMS |
+-----------------------------------------------+---------------------------------+--------+
| TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0000_RDS | Merge as test
  queryConcurrency:GROUP_CONCURRENT
  columns:[count(*)]
  executeOn: TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0000_RDS
    Query from test as test
      queryConcurrency:SEQUENTIAL
      columns:[count(*)]
      tableName:test
      executeOn: TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0000_RDS
    Query from test as test
      queryConcurrency:SEQUENTIAL
      columns:[count(*)]
      tableName:test
      executeOn: TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0001_RDS
    ... ...
    Query from test as test
      queryConcurrency:SEQUENTIAL
      columns:[count(*)]
      tableName:test
      executeOn: TEST_DB_1478746391548CDTCTEST_DB_OXGJ_0007_RDS
| NULL   |
+-----------------------------------------------+---------------------------------+--------+
1 row in set (0.00 sec)
```

executeOn in the SQL statement field indicates the database shard on which the SQL statement is run. DRDS finally merges the results returned by the database shards.

Execution plans at the ApsaraDB for RDS layer

The execution plans at the ApsaraDB for RDS layer are the same as the native MySQL execution plan. For more information, see official MySQL documentation.

One DRDS logical table may consist of multiple shards distributed in different database shards. Therefore, you can view the execution plans at the ApsaraDB for RDS layer in multiple ways.

1. View the execution plan of an ApsaraDB for RDS database shard.

   If the query condition contains a shard key, directly run the EXPLAIN EXECUTE command to display the execution plan on the corresponding database shard. Example:

```
mysql> EXPLAIN EXECUTE SELECT * FROM test WHERE c1 = 1;
+----+-------------+-------+-------+---------------+---------+---------+-------+------+-------+
| id | select_type | table | type  | possible_keys | key     | key_len | ref   | rows | Extra |
+----+-------------+-------+-------+---------------+---------+---------+-------+------+-------+
|  1 | SIMPLE      | test  | const | PRIMARY       | PRIMARY | 4       | const |    1 | NULL  |
+----+-------------+-------+-------+---------------+---------+---------+-------+------+-------+
1 row in set (0.04 sec)
```

   > **Notice** If an SQL statement involves multiple shards (for example, its condition does not contain a shard key), the EXPLAIN EXECUTE command returns an execution plan on a random ApsaraDB for RDS database shard.

   To view the execution plan of an SQL statement on a specified database shard, you can use the Hint method. Example:

```
mysql> /! TDDL:node='TESTDB_1478746391548CDTCTESTDB_OXGJ_0000_RDS'*/EXPLAIN SELECT * FROM test;
+----+-------------+-------+------+---------------+-------+---------+-------+------+-------+
| id | select_type | table | type | possible_keys | key   | key_len | ref   | rows | Extra |
+----+-------------+-------+------+---------------+-------+---------+-------+------+-------+
|  1 | SIMPLE      | test  | ALL  | NULL          | NULL  | NULL    | NULL  |    2 | NULL  |
+----+-------------+-------+------+---------------+-------+---------+-------+------+-------+
1 row in set (0.04 sec)
```

2. View the execution plans of all ApsaraDB for RDS database shards.

   You can run SCAN Hint to display the execution plans of SQL statements on all database shards:

```
mysql> /! TDDL:scan='test'*/EXPLAIN SELECT * FROM test;
+----+-------------+-------+------+---------------+-------+---------+-------+------+-------+
| id | select_type | table | type | possible_keys | key   | key_len | ref   | rows | Extra |
+----+-------------+-------+------+---------------+-------+---------+-------+------+-------+
|  1 | SIMPLE      | test  | ALL  | NULL          | NULL  | NULL    | NULL  |    2 | NULL  |
|  1 | SIMPLE      | test  | ALL  | NULL          | NULL  | NULL    | NULL  |    3 | NULL  |
+----+-------------+-------+------+---------------+-------+---------+-------+------+-------+
2 rows in set (0.08 sec)
```

> **Notice**
>
> i. In Hint mode, DRDS only replaces the table names in case of database or table sharding, and then directly sends the logical SQL statement to ApsaraDB for RDS for execution. It will not process the result.
>
> ii. Execution plans obtained by using an EXPLAIN command are generated by static analysis and are not actually executed in databases.

TRACE command

The TRACE command in DRDS can track the SQL execution process and the overheads in each stage. It can be used together with the execution plan to facilitate SQL statement optimization.

The TRACE command contains two related commands: TRACE and SHOW TRACE, which must be used together.

11.14.4. SQL optimization methods

11.14.4.1. Overview

This topic describes the SQL optimization principles and methods for optimizing different types of SQL statements in PolarDB-X.

Basic principles of SQL optimization

In PolarDB-X, SQL computing that can be performed by ApsaraDB RDS for MySQL instances is called push-down computing. Push-down computing reduces data transmission, decreases overheads at the network layer and PolarDB-X layer, and improves the execution efficiency of SQL statements.

Therefore, the basic principle for SQL statement optimization in PolarDB-X is as follows: Push down as many computations as possible to ApsaraDB RDS for MySQL instances.

Push-down computations include:

- JOIN connections
- Filter conditions, such as `WHERE` or `HAVING` conditions
- Aggregate computing, such as `COUNT` and `GROUP BY`
- Sorting, such as `ORDER BY`

- Deduplication, such as `DISTINCT`
- Function computing, such as the `NOW()` function
- Subqueries

> **Notice** The preceding list only describes possible forms of push-down computations. It does not mean that all clauses or conditions or combinations of clauses or conditions can be pushed down for computing.

SQL statements of different types and containing different conditions can be optimized in different ways. The following uses some examples to describe how to optimize SQL statements:

- Single-table SQL optimization
  - Filter condition optimization
  - Optimization of the number of returned rows for a query
  - Grouping and sorting optimization
- JOIN query optimization
  - Optimization of push-down JOIN queries
  - Optimization of distributed JOIN queries
- Subquery optimization

11.14.4.2. Single-table SQL optimization

Single-table SQL optimization must follow the following principles:

- Make sure that the SQL statements contain the shard key.
- Use an equivalence condition for the shard key whenever possible.
- If the shard key is an IN condition, the number of values after IN should be as small as possible (far fewer than the number of shards, and remain unchanged as the business grows).
- If SQL statements do not contain a shard key, use only one of DISTINCT, GROUP BY, and ORDER BY in the same SQL statement.

Filter condition optimization

DRDS partitions data horizontally by the shard key. Therefore, the filter condition must contain the shard key as much as possible so that DRDS can push queries down to specific database shards based on the shard key value, to avoid scanning all tables in the DRDS instance.

For example, the shard key of the test table is c1. If the filter condition does not contain this shard key, full table scan is performed:

```
mysql> SELECT * FROM test WHERE c2 = 2;
+----+----+
| c1 | c2 |
+----+----+
| 2 | 2 |
+----+----+
1 row in set (0.05 sec)
```

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT * FROM test WHERE c2 = 2;
+-----------------------------------------------+-----------------------------------------------------------------------------+--------+
| GROUP_NAME                                    | SQL                                                                         | PARAMS |
+-----------------------------------------------+-----------------------------------------------------------------------------+--------+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0004_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0007_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0005_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0003_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0006_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0000_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0001_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c2` = 2) | {}     |
+-----------------------------------------------+-----------------------------------------------------------------------------+--------+
8 rows in set (0.00 sec)
```

The smaller the value range of the filter condition containing the shard key, the faster the DRDS query speed.

For example, in the query on the test table, the filter condition contains the value range of the shard key c1:

```
mysql> SELECT * FROM test WHERE c1 > 1 AND c1 < 4;
+----+----+
| c1 | c2 |
+----+----+
|  2 |  2 |
|  3 |  3 |
+----+----+
2 rows in set (0.04 sec)
```

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT * FROM test WHERE c1 > 1 AND c1 < 4;
+-----------------------------------------------+-----------------------------------------------------------------------------------------+--------+
| GROUP_NAME                                    | SQL                                                                                     | PARAMS |
+-----------------------------------------------+-----------------------------------------------------------------------------------------+--------+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `test`.`c1`,`test`.`c2` from `test` where ((`test`.`c1` > 1) AND (`test`.`c1` < 4)) | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0003_RDS | select `test`.`c1`,`test`.`c2` from `test` where ((`test`.`c1` > 1) AND (`test`.`c1` < 4)) | {}     |
+-----------------------------------------------+-----------------------------------------------------------------------------------------+--------+
2 rows in set (0.00 sec)
```

The equivalence condition is executed faster than the range condition. For example:

```
mysql> SELECT * FROM test WHERE c1 = 2;
+----+----+
| c1 | c2 |
+----+----+
|  2 |  2 |
+----+----+
1 row in set (0.03 sec)
```

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT * FROM test WHERE c1 = 2;
+-----------------------------------------------+-----------------------------------------------------------------------------------------+--------+
| GROUP_NAME                                    | SQL                                                                                     | PARAMS |
+-----------------------------------------------+-----------------------------------------------------------------------------------------+--------+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `test`.`c1`,`test`.`c2` from `test` where (`test`.`c1` = 2) | {}     |
+-----------------------------------------------+-----------------------------------------------------------------------------------------+--------+
1 row in set (0.00 sec)
```

In addition, if you want to insert data into a table shard, the inserted field must contain a shard key.

For example, data inserted into the test table contains the shard key c1:

```
mysql> INSERT INTO test(c1,c2) VALUES(8,8);
Query OK, 1 row affected (0.07 sec)
```

Optimization of the number of returned rows for a query

When DRDS runs a query containing **LIMIT** [*offset*,] *row_count*, DRDS actually reads records before *offset* in order and directly discards them. In this way, when the value of *offset* is large, the query is slow even if the value of *row_count* is small. Take the following SQL statement as an example:

```
SELECT *
FROM sample_order
ORDER BY sample_order.id
LIMIT 10000, 2
```

Although only the 10000th and 10001st records are returned, it takes about 12 seconds to run the SQL statement because DRDS actually reads 10,002 records.

```
mysql> SELECT * FROM sample_order ORDER BY sample_order.id LIMIT 10000,2;
+--------------+------------+--------------+--------------+------------+
| id           | sellerId   | trade_id     | buyer_id     | buyer_nick |
+--------------+------------+--------------+--------------+------------+
| 242012755468 | 1711939506 | 242012755467 | 244148116334 | zhangsan   |
| 242012759093 | 1711939506 | 242012759092 | 244148138304 | wangwu     |
+--------------+------------+--------------+--------------+------------+
2 rows in set (11.93 sec)
```

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT * FROM sample_order ORDER BY sample_order.id LIMIT 10000,2;
+------------------+-------------+------------+
| GROUP_NAME       | SQL         | PARAMS     |
+------------------+-------------+------------+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0004_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0007_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0005_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0003_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0006_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0000_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {}     |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0001_RDS | select `sample_order`.`id`,`sample_order`.`sellerId`,`sample_order`.`trade_id`,`sample_order`.`buyer_id`,`sample_order`.`buyer_nick` from `sample_order` order by `sample_order`.`id` asc limit 0,10002 | {}     |
+------------------+----------------------------+--------+
8 rows in set (0.01 sec)
```

To optimize the preceding SQL statement, find the ID set, and use IN to match the actual records. The modified SQL query is as follows:

```
SELECT *
FROM sample_order o
WHERE o.id IN (
    SELECT id
    FROM sample_order
    ORDER BY id
    LIMIT 10000, 2 )
```

The purpose is to cache IDs in the memory first (on the premise that the number of IDs is small). If the shard key of the sample_order table is an ID, DRDS can also push down such an IN query to different database shards through rule-based calculation, avoiding full table scan and unnecessary network I/O. Check the result of the rewritten SQL query:

```
mysql> SELECT *
  -> FROM sample_order o
  -> WHERE o.id IN ( SELECT id FROM sample_order ORDER BY id LIMIT 10000,2 );
+--------------+------------+--------------+--------------+------------+
| id           | sellerId   | trade_id     | buyer_id     | buyer_nick |
+--------------+------------+--------------+--------------+------------+
| 242012755468 | 1711939506 | 242012755467 | 244148116334 | zhangsan   |
| 242012759093 | 1711939506 | 242012759092 | 244148138304 | wangwu     |
+--------------+------------+--------------+--------------+------------+
2 rows in set (1.08 sec)
```

The execution time is significantly reduced from 12 seconds to 1.08 seconds.

The corresponding execution plan is as follows:

```
mysql> EXPLAIN SELECT *
  -> FROM sample_order o
  -> WHERE o.id IN ( SELECT id FROM sample_order ORDER BY id LIMIT 10000,2 );
+----------------------------------------------+-----------------------------------------------------------------------------------------------------------------
-------------------+--------+
| GROUP_NAME                    | SQL                                                                       | PARAMS |
+----------------------------------------------+-----------------------------------------------------------------------------------------------------------------
-------------------+--------+
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0002_RDS | select `o`.`id`,`o`.`sellerId`,`o`.`trade_id`,`o`.`buyer
_id`,`o`.`buyer_nick` from `sample_order` `o` where (`o`.`id` IN (10002)) | {}   |
| SEQPERF_1478746391548CDTCSEQPERF_OXGJ_0001_RDS | select `o`.`id`,`o`.`sellerId`,`o`.`trade_id`,`o`.`buyer
_id`,`o`.`buyer_nick` from `sample_order` `o` where (`o`.`id` IN (10001)) | {}   |
+----------------------------------------------+-----------------------------------------------------------------------------------------------------------------
-------------------+--------+
2 rows in set (0.03 sec)
```

Grouping and sorting optimization

In DRDS, if an SQL query must use DISTINCT, GROUP BY, and ORDER BY at the same time, try to ensure that the fields after DISTINCT, GROUP BY, and ORDER BY are the same and the fields are shard keys. In this way, only a small amount of data is returned for the SQL query. This minimizes the network bandwidth consumed by distributed queries and removes the need to retrieve a large amount of data and sort the data in a temporary table, thereby maximizing the system performance.

11.14.4.3. JOIN query optimization

JOIN queries in DRDS are classified into push-down JOIN queries and non-push-down JOIN queries (distributed JOIN queries). The optimization policies for these two types of JOIN queries are different.

Optimize push-down JOIN queries

Push-down JOIN queries are classified into the following types:

- JOIN queries between single tables (non-partition tables).
- The tables involved in the JOIN query contain the shard key in the filter condition and use the same sharding algorithm (that is, the data calculated by the sharding algorithm is distributed to the same shard).
- Tables involved in the JOIN query use the shard key as the JOIN condition and use the same sharding algorithm.
- JOIN query between broadcast tables (or small table broadcast) and table shards.

In DRDS, optimize JOIN queries to push-down JOIN queries that can be executed on database shards.

Take a JOIN query between a broadcast table and table shards as an example. The broadcast table is used as the JOIN driving table (the left table in the JOIN query is called the driving table). The DRDS broadcast table stores the same data in each database shard. When the broadcast table is used as the JOIN driving table, the JOIN query between this broadcast table and table shards can be converted into single-database JOIN queries and combined for computing to improve query performance.

For example, a JOIN query is performed on the following three tables, among which the sample_area table is the broadcast table, and the sample_item and sample_buyer tables are table shards. The query execution time is about 15s:

```
mysql> SELECT sample_area.name
  -> FROM sample_item i JOIN sample_buyer b ON i.sellerId = b.sellerId JOIN sample_area a ON b.province = a.id
  -> WHERE a.id < 110107
  -> LIMIT 0, 10;
+------+
| name |
+------+
| BJ |
| BJ |
| BJ |
| BJ |
| BJ |
| BJ |
| BJ |
| BJ |
| BJ |
| BJ |
+------+
10 rows in set (14.88 sec)
```

If you adjust the JOIN query order and move the broadcast table to the farthest left as the JOIN driving table, the JOIN query is pushed down to a single database shard in the DRDS instance:

```
mysql> SELECT sample_area.name
  -> FROM sample_area a JOIN sample_buyer b ON b.province = a.id JOIN sample_item i ON i.sellerId = b.sellerId
  -> WHERE a.id < 110107
  -> LIMIT 0, 10;
+------+
| name |
+------+
| BJ |
| BJ |
| BJ |
| BJ |
| BJ |
| BJ |
| BJ |
| BJ |
| BJ |
| BJ |
+------+
10 rows in set (0.04 sec)
```

The query execution time decreases from 15 seconds to 0.04 seconds, which is a significant improvement to the query performance.

> **Notice** The broadcast table achieves data consistency through the synchronization mechanism on database shards, with a latency of several seconds.

Optimize distributed JOIN queries

If a JOIN query cannot be pushed down (that is, the JOIN condition and filter condition do not contain the shard key), DRDS must complete part of the computing in the query. Such a query is a distributed JOIN query.

Tables in a distributed JOIN query are classified into two types based on the data size:

- Small table: A table that contains a small amount of data (less than 100 data records or less data than other tables) that is involved in JOIN computing after filtering.

- Large table: A table that contains a large amount of data (more than 100 data records or more data than other tables) that is involved in JOIN computing after filtering.

In most cases, Nested Loop and its derived algorithms are used in JOIN computing at the DRDS layer. If sorting is required for JOIN queries, the Sort Merge algorithm is used. When the Nested Loop algorithm is used, a smaller data size in the left table in a JOIN query indicates a smaller number of queries performed by DRDS on the right table. If the right table has indexes or contains a small amount of data, the JOIN query is even faster. Therefore, in DRDS, the left table of a distributed JOIN query is called the driving table. To optimize a distributed JOIN query, use a small table as the driving table and set as many filter conditions as possible for the driving table.

Take the following distributed JOIN query as an example. The query takes about 24 seconds:

```
mysql> SELECT t.title, t.price
  -> FROM sample_order o,
  ->     ( SELECT * FROM sample_item i WHERE i.id = 242002396687 ) t
  -> WHERE t.source_id = o.source_item_id AND o.sellerId < 1733635660;
+----------------------------------+--------+
| title                            | price  |
+----------------------------------+--------+
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
+----------------------------------+--------+
10 rows in set (23.79 sec)
```

The preceding JOIN query is an INNER JOIN query, with the actual size of the intermediate data involved in JOIN computing unknown. In this case, perform COUNT() on the o table and t table respectively to obtain the actual data size.

For the o table, o.sellerId < 1733635660 in the WHERE condition is only related to the o table. Then, extract and add it to the COUNT() condition of the o table. The following query result is returned:

```
mysql> SELECT COUNT(*) FROM sample_order o WHERE o.sellerId < 1733635660;
+----------+
| count(*) |
+----------+
|   504018 |
+----------+
1 row in set (0.10 sec)
```

The intermediate result of the o table contains about 500,000 records. Similarly, the t table is a subquery, which can be extracted directly for the COUNT() query:

```
mysql> SELECT COUNT(*) FROM sample_item i WHERE i.id = 242002396687;
+----------+
| count(*) |
+----------+
|        1 |
+----------+
1 row in set (0.01 sec)
```

The intermediate result of the t table contains only one record. Therefore, the o table is a large table and the t table is a small table. Use the small table as the driving table of the distributed JOIN query. The result of the adjusted JOIN query is as follows:

```
mysql> SELECT t.title, t.price
  -> FROM ( SELECT * FROM sample_item i WHERE i.id = 242002396687 ) t,
  ->     sample_order o
  -> WHERE  t.source_id = o.source_item_id AND o.sellerId < 1733635660;
+-----------------------------------+--------+
| title                             | price  |
+-----------------------------------+--------+
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
| Sample Item for Distributed JOIN | 239.00 |
+-----------------------------------+--------+
10 rows in set (0.15 sec)
```

The query execution time decreases from about 24 seconds to 0.15 seconds, with the query performance significantly improved.

11.14.4.4. Subquery optimization

When optimizing an SQL query that contains subqueries, push the subqueries down to database shards as much as possible to reduce the computing workload at the DRDS layer.

For this purpose, you can try two optimization methods:

- Rewrite subqueries into multi-table JOIN queries, and optimize the JOIN queries.
- Use the shard key in the JOIN condition or filter condition so that DRDS can push the query down to a specific database shard to avoid full table scan.

The following subquery is used as an example:

```
SELECT o. *
FROM sample_order o
WHERE NOT EXISTS
   (SELECT sellerId FROM sample_seller s WHERE o.sellerId = s.id)
```

Rewrite the subquery into a JOIN query query:

```
SELECT o. *
FROM sample_order o LEFT JOIN sample_seller s ON o.sellerId = s.id
WHERE s.id IS NULL
```

11.14.5. Select connection pools for an application

A database connection pool is used to manage database connections in a centralized manner, so as to improve application performance and reduce database loads.

- **Reuse resources**: Connections can be reused to avoid high performance overheads caused by frequent connection creation and release. Resource reuse can also improve the system stability.

- **Improve the system response efficiency**: After the connection initialization is complete, all requests can directly use the existing connections, which avoids the overheads of connection initialization and release and improves the system response efficiency.
- **Avoid connection leakage**: The connection pool forcibly revokes connections based on the preset de-allocation policy to avoid connection resource leakage.

We recommend that you use a connection pool to connect applications and databases for service operations. For Java programs, we recommend that you use the Druid connection pool.

The following is an example of standard Druid Spring configuration:

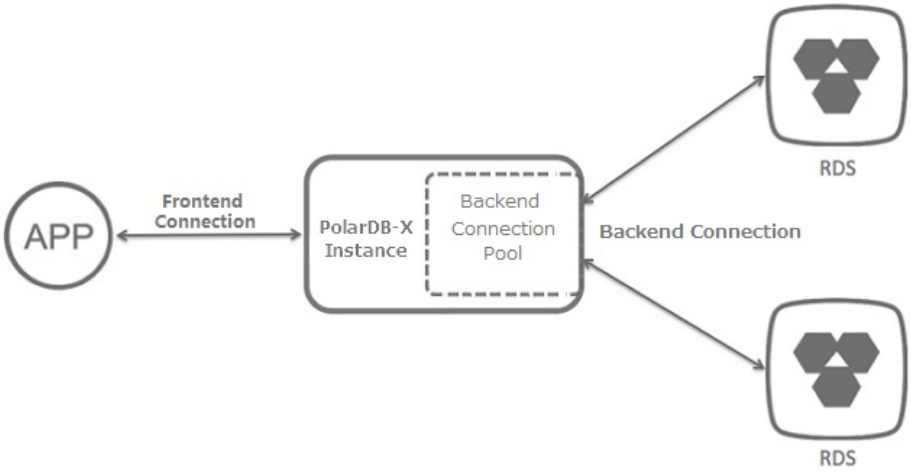
```
  <bean id="dataSource" class="com.alibaba.druid.pool.DruidDataSource" init-method="init" destroy-method="close"
>
    <property name="driverClassName" value="com.mysql.jdbc.Driver" />
    <! -- Basic attributes URL, user, and password -->
    <property name="url" value="jdbc:mysql://ip:port/db? autoReconnect=true&amp;rewriteBatchedStatements=true&
amp;socketTimeout=30000&amp;connectTimeout=3000" />
    <property name="username" value="root" />
    <property name="password" value="123456" />
    <! -- Configure the initial size, minimum value, and maximum value -->
    <property name="maxActive" value="20" />
    <property name="initialSize" value="3" />
    <property name="minIdle" value="3" />
    <! -- maxWait indicates the time-out period for obtaining the connection -->
    <property name="maxWait" value="60000" />
    <! -- timeBetweenEvictionRunsMillis indicates the interval for detecting idle connections to be closed, in milliseconds
-->
    <property name="timeBetweenEvictionRunsMillis" value="60000" />
    <! -- minEvictableIdleTimeMillis indicates the minimum idle time of a connection in the connection pool, in millisecon
ds-->
    <property name="minEvictableIdleTimeMillis" value="300000" />
    <! -- SQL statement used to check whether connections are available -->
    <property name="validationQuery" value="SELECT 'z'" />
    <! -- Whether to enable idle connection check -->
    <property name="testWhileIdle" value="true" />
    <! -- Whether to check the connection status before obtaining a connection -->
    <property name="testOnBorrow" value="false" />
    <! -- Whether to check the connection status before releasing a connection -->
    <property name="testOnReturn" value="false" />
  </bean>
```

11.14.6. Connections to PolarDB-X instances

When an application connects to a PolarDB-X instance for operation, there are two types of connections from the perspective of the PolarDB-X instance:

- Frontend connection: a connection established by an application to the logical database in the PolarDB-X instance.
- Backend connection: a connection established by a node in a PolarDB-X instance to a physical database in a backend ApsaraDB RDS for MySQL instance.

  PolarDB-X instance connection diagram



Frontend connection

Theoretically, the number of frontend connections is limited by the available memory size and the number of network connections to the nodes of the PolarDB-X instance. However, in actual application scenarios, when an application connects to a PolarDB-X instance, the nodes of the PolarDB-X instance usually manage a limited number of connections to perform requested operations, and do not maintain a large number of concurrent persistent connections (for example, tens of thousands of concurrent persistent connections). Therefore, the number of frontend connections that a PolarDB-X instance can accept can be considered to be unlimited.

Considering that the number of frontend connections is unlimited and a large number of idle connections are allowed, this method applies to scenarios where a large number of servers are deployed and need to maintain their connections to the PolarDB-X instance.

> **Note** Although the number of frontend connections is considered as unlimited, operation requests obtained from frontend connections are actually executed by internal threads of the PolarDB-X instance through backend connections. Due to the limited number of internal threads and backend connections, the total number of concurrent requests that can be processed by the PolarDB-X instance is limited.

Backend connection

Each node of a PolarDB-X instance creates a backend connection pool to automatically manage and maintain the backend connections to the physical databases in the ApsaraDB RDS for MySQL instance. Therefore, the maximum number of connections in the backend connection pool of a PolarDB-X instance is directly related to the maximum number of connections supported by the ApsaraDB RDS for MySQL instance. You can use the following formula to calculate the maximum number of connections in the backend connection pool of a PolarDB-X instance:

Maximum number of connections in a backend connection pool of a PolarDB-X instance = FLOOR (Maximum number of connections in an ApsaraDB RDS for MySQL instance/Number of physical database shards in the ApsaraDB RDS for MySQL instance/Number of nodes on the PolarDB-X instance)

For example, a user has purchased an ApsaraDB RDS for MySQL instance and a PolarDB-X instance of the following types:

- The ApsaraDB RDS for MySQL instance has eight physical database shards, four cores, and 16 GB memory, supporting a maximum number of 4,000 connections.
- The PolarDB-X dedicated instance has 32 cores and 32 GB memory, with each PolarDB-X node having two cores and 2 GB memory (that is, the instance has 16 PolarDB-X nodes).

You can use the following formula to calculate the maximum number of connections in the backend connection pool of the PolarDB-X instance:

Maximum number of connections in the backend connection pool of the PolarDB-X instance = FLOOR (4000/8/16) = FLOOR (31.25) = 31

> **Note**
>
> - The calculation result of the preceding formula is the maximum number of connections in the backend connection pool of the PolarDB-X instance. In actual use, to reduce the connection pressure on the ApsaraDB RDS for MySQL instance, the PolarDB-X instance adjusts the maximum number of connections in the backend connection pool to make it smaller than the upper limit.
> - We recommend that you create databases in a PolarDB-X instance on a dedicated ApsaraDB RDS for MySQL instance. Do not create databases for other applications or PolarDB-X instances on the dedicated ApsaraDB RDS for MySQL instance.

Relationship between frontend and backend connections

After an application establishes frontend connections to a PolarDB-X instance and sends SQL statement execution requests, the PolarDB-X nodes process the requests asynchronously and obtain backend connections through the internal backend connection pool, and then run optimized SQL statements on one or more physical databases.

PolarDB-X nodes process requests asynchronously and frontend connections are not bound to backend connections. Therefore, a small number of backend connections can process a large number of requests for short transactions and simple queries from many concurrent frontend connections. This is why you need to focus on the queries per second (QPS) in PolarDB-X, rather than the number of concurrent connections.

Although the number of frontend connections is considered to be unlimited, the maximum number of connections maintained in the backend connection pool of a PolarDB-X instance is limited. For more information, see "Backend connections." Therefore, note the following points in actual application scenarios:

- Avoid long or large transactions in applications. These transactions occupy many or even all backend connections when they are not committed or rolled back for a long time, which reduces the overall concurrent processing capability and increases the response time (RT).
- Monitor and optimize or remove slow SQL queries run in the PolarDB-X instance, to prevent them from occupying too many backend connections. Otherwise, the PolarDB-X instance or the ApsaraDB RDS for MySQL instance is under greater processing pressure, which may lead to reduced concurrent processing capability, increased RT, or higher SQL execution failure rate due to execution timeout. For troubleshooting and optimization of slow SQL queries, see Troubleshoot slow SQL statements in PolarDB-X and Overview.
- Under normal use of connections and execution of queries, if the maximum number of connections in the backend connection pool of the PolarDB-X instance is reached, contact Customer Services for assistance.

11.14.7. Perform instance upgrade

Database performance can be measured by the response time (RT) and queries per second (QPS). RT reflects the performance of a single SQL statement. This type of performance problem can be solved through SQL optimization. PolarDB-X upgrade expands the capacity to improve performance, and is suitable for database access services with low latency and high QPS.

The performance of a PolarDB-X instance depends on the performance of PolarDB-X and ApsaraDB RDS for MySQL. Insufficient performance of any PolarDB-X or ApsaraDB RDS for MySQL node can create a bottleneck in the overall performance. This topic describes how to observe the performance metrics of a PolarDB-X instance and upgrade the PolarDB-X instance to solve the performance bottleneck. For more information about how to determine the performance of an ApsaraDB RDS for MySQL instance and upgrade the ApsaraDB RDS for MySQL instance, see the ApsaraDB RDS for MySQL documentation.

Determine the performance bottleneck of a PolarDB-X instance

The QPS and CPU performance of a PolarDB-X instance are in positive correlation. When a PolarDB-X instance encounters a performance bottleneck, the CPU utilization of the PolarDB-X instance remains high.

Observe the CPU utilization

1. On the **Basic Information** page of the PolarDB-X instance, choose **Monitoring and Alerts > Instance Monitoring** from the left-side navigation pane.
2. On the Instance Monitoring page, select a monitoring dimension and the corresponding metrics to view details.

If the CPU utilization **exceeds 90%** or **remains above 80%**, the PolarDB-X instance faces a performance bottleneck. If there is no bottleneck for the ApsaraDB RDS for MySQL instance, the current PolarDB-X instance specifications cannot meet the QPS performance requirements of the business. In this case, the PolarDB-X instance needs to be upgraded.

For more performance-related service monitoring scenarios and methods for configuring the PolarDB-X CPU utilization alert.

Upgrade PolarDB-X

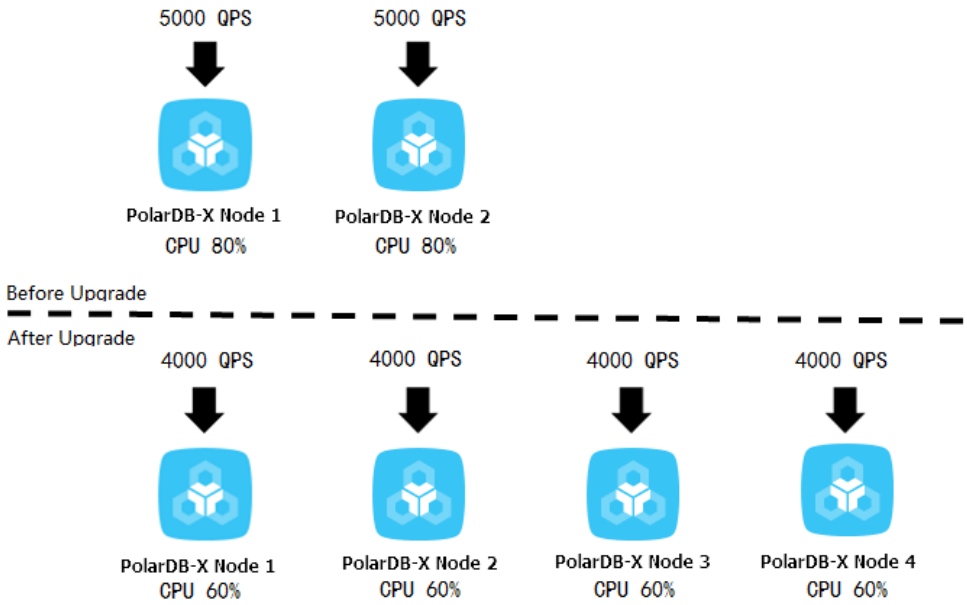
QPS is an important metric for determining whether the PolarDB-X instance specifications can meet the business requirements. Each type of instance specifications corresponds to a reference QPS value.

Some special SQL statements require more computing (such as temporary table sorting and aggregate computing) in PolarDB-X. In this case, the QPS supported by each PolarDB-X instance is lower than the standard value in its type.

PolarDB-X upgrade improves the processing performance of a PolarDB-X instance by adding nodes to share the QPS. As PolarDB-X nodes are stateless, this upgrade method linearly improves the performance of PolarDB-X instances.

For example, service A requires QPS of about 15 thousand. The current PolarDB-X instance has a 4-core virtual CPU (vCPU), 4 GB memory, and two nodes, supporting QPS of only 10 thousand. After finding that the CPU utilization of the PolarDB-X instance remains high, we upgraded the instance to 8-core vCPU and 8 GB memory, with each node handling about 4,000 QPS. Then, the performance meets service requirements, and the CPU utilization also drops to a reasonable level, as shown in the following figure.

PolarDB-X upgrade



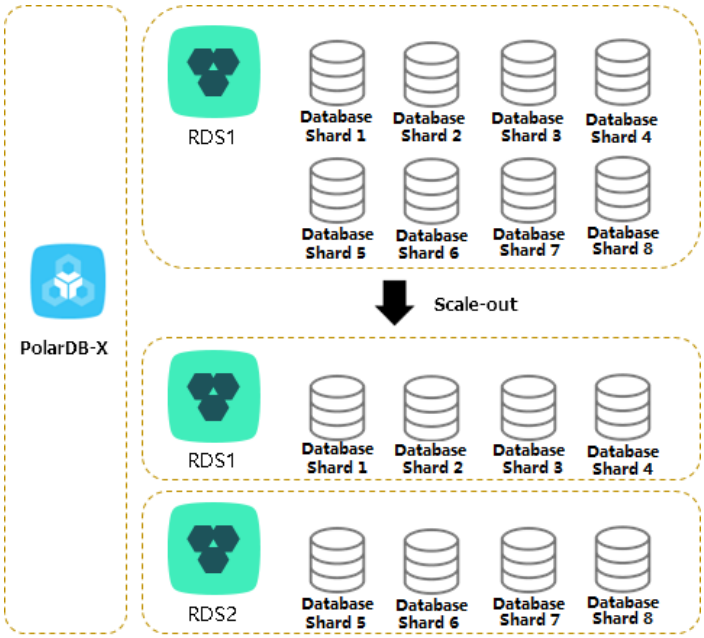
For more information about how to upgrade a PolarDB-X instance, see Change specifications.

11.14.8. Perform scale-out

In PolarDB-X, smooth scale-out improves the overall performance by increasing the number of ApsaraDB RDS for MySQL instances. You can increase the number of ApsaraDB RDS for MySQL instances through PolarDB-X smooth scale-out to increase the PolarDB-X database capacity when the following conditions are met: 1. The input/output operations per second (IOPS), CPU utilization, disk space, and other metrics of the ApsaraDB RDS for MySQL instance reach their bottlenecks. 2. The bottlenecks cannot be removed through SQL optimization or ApsaraDB RDS for MySQL upgrade (for example, the disk has been upgraded to the top configuration).

PolarDB-X smooth scale-out reduces the pressure on the original ApsaraDB RDS for MySQL instance by migrating database shards to the new ApsaraDB RDS for MySQL instance. For example, before scale-out, all the eight databases are deployed in one ApsaraDB RDS for MySQL instance. After scale-out, the eight databases are deployed in two ApsaraDB RDS for MySQL instances, and the pressure on a single ApsaraDB RDS for MySQL instance is significantly reduced, as shown in the following figure.

PolarDB-X scale-out



After multiple scale-out operations, if the number of ApsaraDB RDS for MySQL instances is equal to the number of database shards, you need to create another PolarDB-X instance and ApsaraDB RDS for MySQL databases with the expected capacity, and then migrate data to further increase the data capacity. This process is complex. We recommend that you consider the data growth expected in the next two to three years and plan the number of ApsaraDB RDS for MySQL instances properly when creating a PolarDB-X database.

Determine whether scale-out is required

You can determine whether PolarDB-X smooth scale-out is required based on three ApsaraDB RDS for MySQL metrics: IOPS, CPU utilization, and disk space. You can view these metrics in the ApsaraDB RDS for MySQL console. For more information, see the ApsaraDB RDS for MySQL documentation.

IOPS and CPU utilization

If you find that the IOPS or CPU utilization remains above 80% for a long time or you frequently receive alerts, follow these steps:

1. Optimize SQL statements. Generally, you can solve the high CPU utilization problem by this method.
2. If the problem persists, upgrade the ApsaraDB RDS for MySQL instance. For more information, see the ApsaraDB RDS for MySQL documentation.
3. When the CPU utilization or IOPS exceeds the threshold, you can set read-only databases to share the load on the primary database. However, read/write splitting affects read consistency. For more information, see the Read/write splitting documentation.
4. If the problem persists, scale out the PolarDB-X instance.

Disk space

ApsaraDB RDS for MySQL has the following types of disk space:

1. Data space: the space occupied by data. The space usage continues increasing as more data is inserted. We recommend that you keep the remaining disk space above 30%.
2. System file space: the space occupied by shared tables and error log files.
3. Binary log file space: the space occupied by binary logs generated during database operation. The more update transactions there are, the larger the occupied space is.

Whether scale-out is required depends on the data space. When the data space is about to or expected to exceed the disk capacity, you can distribute the data to the databases on multiple ApsaraDB RDS for MySQL instances through scale-out.

Scale-out risks and precautions

PolarDB-X scale-out consists of four steps: **configuration > migration > switchover > cleanup**. For more information, see the Perform smooth scale-out documentation.

Note the following points before scale-out:

- To reduce the pressure of read operations on the source ApsaraDB RDS for MySQL instance, perform scale-out when the load on the source ApsaraDB RDS for MySQL instance is low.
- During scale-out, do not submit data definition language (DDL) tasks in the console or connect to the PolarDB-X instance to directly run DDL SQL statements. Otherwise, the scale-out task may fail.
- Scale-out requires that the source database table have a primary key. If the source database does not have a primary key, add one first.
- During scale-out, the read and write traffic is switched to the new ApsaraDB RDS for MySQL instance. The switchover process takes three to five minutes. We recommend that you perform a switchover during off-peak hours.
- Scale-out does not affect the PolarDB-X instance before the switchover. Therefore, you can cancel the scale-out through rollback before the switchover.
- Scale-out creates pressure on databases. We recommend that you perform this operation during off-peak hours.

11.14.9. Troubleshoot slow SQL statements in DRDS

11.14.9.1. Details about a low SQL statement

PolarDB-X defines an SQL statement that takes more than 1 second to run as a slow SQL statement. Slow SQL statements in PolarDB-X are classified into slow logical SQL statements and slow physical SQL statements. In PolarDB-X, an SQL statement is run step by step on PolarDB-X and ApsaraDB RDS for MySQL nodes. Large execution loss on any node will result in slow SQL statements.

- Slow logical SQL statements are slow SQL statements sent by an application to PolarDB-X.
- Slow physical SQL statements are slow SQL statements sent by PolarDB-X to ApsaraDB RDS for MySQL.

Syntax

```
SHOW FULL {SLOW | PHYSICAL_SLOW} [WHERE where_condition]
                [ORDER BY col_name [ASC | DESC], ...]
                [LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

Description

The `SHOW FULL SLOW` command shows slow logical SQL statements, that is, SQL statements sent by an application to PolarDB-X.

The result set of the `SHOW FULL SLOW` command contains the following columns:

- TRACE_ID: the unique identifier of the SQL statement. A logical SQL statement and the physical SQL statements generated by the logical SQL statement have the same TRACE_ID. The TRACE_ID is also sent as a comment to ApsaraDB RDS for MySQL.
- HOST: the IP address of the client that sends the SQL statement.

  > **Notice** The client IP address may not be obtained when the network type is Virtual Private Cloud (VPC).

- START_TIME: the time when PolarDB-X starts running the SQL statement.
- EXECUTE_TIME: the time consumed by PolarDB-X to run the SQL statement.
- AFFECT_ROW: the number of records returned or the number of rows affected by the SQL statement.
- SQL: the statement that is run.

The `SHOW FULL PHYSICAL_SLOW` command shows the slow physical SQL statements, that is, SQL statements sent by PolarDB-X to ApsaraDB RDS for MySQL.

The result set of `SHOW FULL PHYSICAL_SLOW` contains the following columns:

- TRACE_ID: the unique identifier of the SQL statement. A logical SQL statement and the physical SQL statements generated by the logical SQL statement have the same TRACE_ID. The TRACE_ID is also sent as a comment to ApsaraDB RDS for MySQL.
- GROUP_NAME: the name of a database group. Grouping aims to manage multiple groups of databases with identical data, such as the primary and secondary databases after data replication through ApsaraDB RDS for MySQL, which are mainly used for read/write splitting and primary/secondary switchover.
- DBKEY_NAME: the name of the database shard on which the SQL statement is run.
- START_TIME: the time when PolarDB-X starts running the SQL statement.
- EXECUTE_TIME: the time consumed by PolarDB-X to run the SQL statement.
- SQL_EXECUTE_TIME: the time consumed by PolarDB-X to call ApsaraDB RDS for MySQL to run this SQL statement.
- GETLOCK_CONNECTION_TIME: the time that PolarDB-X takes to get connections from the connection pool. If the value is large, the ApsaraDB RDS for MySQL connections have been exhausted. This is typically due to a large number of slow SQL statements. You can log on to the corresponding ApsaraDB RDS for MySQL instance and run SHOW PROCESSLIST for troubleshooting.
- CREATE_CONNECTION_TIME: the time consumed by PolarDB-X to establish a connection to ApsaraDB RDS for MySQL. If the value is large, it is largely because the ApsaraDB RDS for MySQL instance is overloaded or faulty.
- AFFECT_ROW: the number of records returned or the number of rows affected by the SQL statement.
- SQL: the statement that is run.

Example 1

The following example describes how to locate the execution of a slow SQL statement on PolarDB-X and between PolarDB-X and ApsaraDB RDS for MySQL.

1. You can use certain conditions, such as the execution time and SQL string match, to obtain the specified slow SQL statement:

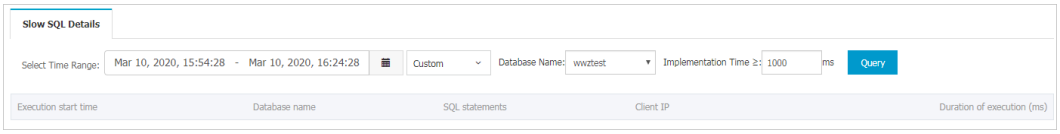
```
mysql> show full slow where `SQL` like '%select sleep(50)%';
+-----------------+-----------+-------------------------+--------------+------------+------------------+
| TRACE_ID        | HOST      | START_TIME              | EXECUTE_TIME | AFFECT_ROW | SQL              |
+-----------------+-----------+-------------------------+--------------+------------+------------------+
| ae0e565b8c00000 | 127.0.0.1 | 2017-03-29 19:28:43.028 |        50009 |          1 | select sleep(50) |
+-----------------+-----------+-------------------------+--------------+------------+------------------+
1 row in set (0.02 sec)
```

2. Based on the TRACE_ID of the slow logical SQL statement, run `SHOW FULL PHYSICAL_SLOW` to obtain the physical execution information of this SQL statement.

```
mysql> show full physical_slow where trace_id = 'ae0e565b8c00000';
+----------------+-------------------------------------------------+-------------------------------------------------+-----------------------+-----------------------+------------+-----------------+
| TRACE_ID       | GROUP_NAME                                      | DBKEY_NAME                                      | START_TIME            | EXECUTE_TIME | SQL_EXECUTE_TIME | GETLOCK_CONNECTION_TIME | CREATE_CONNECTION_TIME | AFFECT_ROW | SQL              |
+----------------+-------------------------------------------------+-------------------------------------------------+-----------------------+-----------------------+------------+-----------------+
| ae0e565b8c00000 | PRIV_TEST_1489167306631PJAFPRIV_TEST_APKK_0000_RDS | rdso6g5b6206sdq832ow_priv_test_apkk_0000_nfup | 2017-03-29 19:27:53.02 |       50001 |         50001 |                0 |                0 |          1 | select sleep(50) |
+----------------+-------------------------------------------------+-------------------------------------------------+-----------------------+-----------------------+------------+-----------------+
1 row in set (0.01 sec)
```

3. In the SQL statement details and slow SQL statement records of the ApsaraDB RDS for MySQL instance, you can query the execution information of this SQL statement on the ApsaraDB RDS for MySQL instance based on TRACE_ID.

   Slow query logs



Example 2

This example describes how to locate the original SQL statement in PolarDB-X based on the slow SQL statement located in ApsaraDB RDS for MySQL.

1. Based on the slow SQL query log in ApsaraDB RDS for MySQL, TRACE_ID of the slow SQL statement is ae0e55660c00000.
2. Based on the TRACE_ID obtained in Step 1, run `SHOW FULL PHYSICAL_SLOW` to obtain the physical execution information of this SQL statement.

```
mysql> show full physical_slow where trace_id = 'ae0e55660c00000';
+----------------+-------------------------------------------------+-------------------------------------------------+-----------------------+-----------------------+------------+-----------------+
| TRACE_ID       | GROUP_NAME                                      | DBKEY_NAME                                      | START_TIME            | EXECUTE_TIME | SQL_EXECUTE_TIME | GETLOCK_CONNECTION_TIME | CREATE_CONNECTION_TIME | AFFECT_ROW | SQL              |
+----------------+-------------------------------------------------+-------------------------------------------------+-----------------------+-----------------------+------------+-----------------+
| ae0e55660c00000 | PRIV_TEST_1489167306631PJAFPRIV_TEST_APKK_0000_RDS | rdso6g5b6206sdq832ow_priv_test_apkk_0000_nfup | 2017-03-29 19:27:37.308 |       10003 |         10001 |                0 |                0 |          1 | select sleep(10) |
+----------------+-------------------------------------------------+-------------------------------------------------+-----------------------+-----------------------+------------+-----------------+
1 row in set (0.02 sec)
```

11.14.9.2. Locate slow SQL statements

Generally, you can locate a slow SQL statement in two ways: Obtain historical information about slow SQL statements from slow SQL statement records, or run `SHOW PROCESSLIST` to display the real-time execution information about slow SQL statements.

You can troubleshoot slow SQL statements as follows:

1. Locate slow SQL statements.
2. Locate nodes with performance loss.
3. Troubleshoot the performance loss.

Note During troubleshooting, we recommend that you use the MySQL command line `mysql -hIP -PPORT -uUSER -pPASSWORD -c` to create the connection. Be sure to add `-c` to prevent the MySQL client from filtering out the comments (default operation) and therefore affecting the execution of HINT.

- View slow SQL statement records

  Run the following command to query top 10 slow SQL statements. This command can query logical SQL statements in PolarDB-X. One logical SQL statement corresponds to SQL statements of one or more databases or tables of the ApsaraDB RDS for MySQL instance. For more information, see Details about a low SQL statement.

```
mysql> SHOW SLOW limit 10;
+-----------------+-------------+------------------------+-------------+-----------+----------------------------------------------------------------+
| TRACE_ID        | HOST        | START_TIME             | EXECUTE_TIME | AFFECT_ROW | SQL                                                          |
+-----------------+-------------+------------------------+-------------+-----------+----------------------------------------------------------------+
| ac3133132801001 | xx.xxx.xx.97 | 2017-03-06 15:48:32.330 |      900392 |        -1 | select detail_url, sum(price) from t_item group by detail_url; |
......
+-----------------+-------------+------------------------+-------------+-----------+----------------------------------------------------------------+
10 rows in set (0.01 sec)
```

- View real-time SQL execution information

  If the execution of an SQL statement is slow in the current server, run **SHOW PROCESSLIST** to view the real-time SQL execution information in the current PolarDB-X database. The value in the TIME column indicates how long the current SQL statement has been run.

```
mysql> SHOW PROCESSLIST WHERE COMMAND != 'Sleep';
+--------------+----------+-------------------+------------+---------+----------------------------------------------------------------------+-----------------------------------------------------------------------------------------+-----------+--------------+-----------+
| ID           | USER     | DB                | COMMAND    | TIME    | STATE                                                                | INFO | ROWS_SENT | ROWS_EXAMINED | ROWS_READ |
+--------------+----------+-------------------+------------+---------+----------------------------------------------------------------------+-----------------------------------------------------------------------------------------+-----------+--------------+-----------+
| 0-0-352724126 | ifisibhk0 | test_123_wvvp_0000 | Query     |      13 | Sending data                                                     | /*DRDS /42.120.74.88/ac47e5a72801000/ */select `t_item`.`detail_url`,SUM(`t_item`.`price`) from `t_i |      NULL |         NULL |      NULL |
| 0-0-352864311 | cowxhthg0 | NULL              | Binlog Dump |      17 | Master has sent all binlog to slave; waiting for binlog to be updated | NULL                                                                                   |      NULL |         NULL |      NULL |
| 0-0-402714795 | ifisibhk0 | test_123_wvvp_0005 | Alter     |     114 | Sending data                                                     | /*DRDS /42.120.74.88/ac47e5a72801000/ */ALTER TABLE `Persons` ADD `Birthday` date        |      NULL |         NULL |      NULL |
......
+--------------+----------+-------------------+------------+---------+----------------------------------------------------------------------+-----------------------------------------------------------------------------------------+-----------+--------------+-----------+
12 rows in set (0.03 sec)
```

  The following describes each column:

  - ID: the ID of the connection.
  - USER: the user name of the database shard in which this SQL statement is run.
  - DB: the specified database. If no database is specified, the value is NULL.
  - COMMAND: the type of the command being executed. SLEEP indicates an idle connection. For more information about other commands, see MySQL thread information documentation.
  - TIME: the elapsed execution time of the SQL statement, in seconds.
  - STATE: the current execution status. For more information, see MySQL thread status documentation.
  - INFO: the SQL statement being executed. The SQL statement may be too long to be displayed completely. You can derive the complete SQL statement based on information such as service parameters.

  In the current example, the following slow SQL statement is identified:

```
ALTER TABLE `Persons` ADD `Birthday` date
```

11.14.9.3. Locate nodes with performance loss

When you locate a slow SQL statement in slow SQL statement records or real-time SQL execution information, you can run the TRACE command to trace the running time of the SQL statement in PolarDB-X and ApsaraDB RDS for MySQL to locate the bottleneck.

The TRACE command actually runs the SQL statement, records the time consumed on all nodes, and returns the execution result. For more information about TRACE and other control commands, see Help statements.

> **Note** The PolarDB-X TRACE command needs to maintain the context information of the connection. Some GUI clients may use connection pools, which results in command exceptions. Therefore, we recommend that you use the MySQL command line to run the TRACE command.

Run the following command for the identified slow SQL statement:

```
mysql> trace select detail_url, sum(distinct price) from t_item group by detail_url;
  +---------------+---------------+
  | detail_url    | sum(price)    |
  +---------------+---------------+
  | www.xxx.com   | 1084326800.00 |
  | www.xx1.com   | 1084326800.00 |
  | www.xx2.com   | 1084326800.00 |
  | www.xx3.com   | 1084326800.00 |
  | www.xx4.com   | 1084326800.00 |
  | www.xx5.com   | 1084326800.00 |
  ......
  +---------------+---------------+
  1 row in set (7 min 2.72 sec)
```

After the TRACE command is run, run SHOW TRACE to view the result. You can identify the bottleneck of the slow SQL statement based on the time consumption of each component.

```
mysql> SHOW TRACE;
+------+------------+-------------+-----------------------------------------------------------+-----------------------------------------+--------------
+-------------------------+------+-----------------------------------------------------------------------------------------------------------------------
---------------+--------+
| ID   | TIMESTAMP | TYPE      | GROUP_NAME                          | DBKEY_NAME                    | TIME_COST(MS) | CON
NECTION_TIME_COST(MS) | ROWS | STATEMENT                                                                                                                 | PARAMS |

11 rows in set (0.01 sec)
```

In the returned results of SHOW TRACE, you can determine which node has a long execution time based on the values (in milliseconds) in the TIME_COST column. You can also see the corresponding GROUP_NAME (that is, the PolarDB-X or ApsaraDB RDS for MySQL node) and the STATEMENT column information (that is, the SQL statement being executed). By checking whether the value of GROUP_NAME is PolarDB-X, you can determine whether the slow node exists in PolarDB-X or ApsaraDB RDS for MySQL.

According to the preceding results, the Merge Sorted action on the PolarDB-X node and the TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0005_RDS node of ApsaraDB RDS for MySQL take a lot of time.

11.14.9.4. Troubleshoot the performance loss

Slow nodes may exist on the PolarDB-X or ApsaraDB RDS for MySQL instance. Troubleshoot the fault accordingly after the cause is determined.

Solution for slow PolarDB-X nodes

When the `GROUP_NAME` of a slow node is in the PolarDB-X instance, check whether time-consuming computing operations such as Merge Sorted, Temp Table Merge, and Aggregate exist during SQL statement execution. If so, rectify it. For more information, see Overview.

Solution for slow ApsaraDB RDS for MySQL nodes

When the slow node is on the ApsaraDB RDS for MySQL instance, check the execution plan of this SQL statement on the ApsaraDB RDS for MySQL instance.

In PolarDB-X, you can run `/! TDDL:node={GROUP_NAME}*/ EXPLAIN` to check the SQL execution plan of an ApsaraDB RDS for MySQL instance. The execution plan displays the SQL execution process information, including inter-table association and index information.

The detailed process is as follows:

1. Based on `GROUP_NAME`, assemble the HINT: `/! TDDL:node='TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0005_RDS'*/`.
2. Combine the assembled HINT and the statement prefixed by EXPLAIN to form a new SQL statement and run it. The EXPLAIN command does not actually run. It only displays the execution plan of the SQL statement.

The following example describes how to query the execution plan of the identified slow node.

```
mysql> /! TDDL:node='TEST_123_1488766060743ACTJSANGUAN_TEST_123_WVVP_0005_RDS'*/ EXPLAIN select `t_item`.`detail_url`,SUM(distinct `t_item`.`price`) from `t_item` group by `t_item`.`detail_url` order by `t_item`.`detail_url` asc;
+----+-------------+--------+------+---------------+-----+---------+-----+---------+----------------------------------+
| id | select_type | table  | type | possible_keys | key | key_len | ref | rows    | Extra                            |
+----+-------------+--------+------+---------------+-----+---------+-----+---------+----------------------------------+
|  1 | SIMPLE      | t_item | ALL  | NULL          | NULL| NULL    | NULL| 1322263 | Using temporary; Using filesort |
+----+-------------+--------+------+---------------+-----+---------+-----+---------+----------------------------------+
1 row in set (0.01 sec)
```

When the preceding SQL statement is run in ApsaraDB RDS for MySQL, the message `Using temporary; Using filesort` is returned. It indicates that low SQL statement execution is caused by improper use of the index. In this case, you can correct the index and run the SQL statement again.

11.14.10. Handle DDL exceptions

When you run any data definition language (DDL) commands of PolarDB-X, PolarDB-X performs the corresponding DDL operation on all table shards.

Failures can be divided into two types:

1. A DDL statement fails to be executed in a database shard. DDL execution failure in any database shard may result in inconsistent table shard structures.
2. The system does not respond for a long time after a DDL statement is executed. When you perform a DDL statement on a large table, the system may make no response for a long time due to the long execution time of the DDL statement in a database shard.

Execution failures in database shards may occur for various reasons. For example, the table you want to create already exists, the column you want to add already exists, or the disk space is insufficient.

No response for a long time is generally caused by the long execution time of a DDL statement in a database shard. Taking ApsaraDB RDS for MySQL as an example, the DDL execution time depends mostly on whether the operation is an in-place (directly modifying the source table) or copy (copying data in the table) operation. An in-place operation only requires modification of metadata, while a copy operation reconstructs the whole table and also involves log and buffer operations.

To determine whether a DDL operation is an in-place or copy operation, you can view the returned value of "rows affected" after the operation is completed.

Example:

- Change the default value of a column (this operation is very fast and does not affect the table data at all):

```
Query OK, 0 rows affected (0.07 sec)
```

- Add an index (this operation takes some time, but "0 rows affected" indicates that the table data is not replicated):

```
Query OK, 0 rows affected (21.42 sec)
```

- Change the data type of column (this operation takes a long time and reconstructs all data rows in the table):

```
Query OK, 1671168 rows affected (1 min 35.54 sec)
```

Therefore, before executing a DDL operation on a large table, perform the following steps to determine whether the operation is a fast or slow operation:

1. Copy the table structure to generate a cloned table.
2. Insert some data.
3. Perform the DDL operation on the cloned table.
4. Check whether the value of "rows affected" is 0 after the operation is completed. A non-zero value means that this operation reconstructs the entire table. In this case, you need to perform this operation in off-peak hours.

Solution for failures

PolarDB-X DDL operations distribute all SQL statements to all database shards for parallel execution. Execution failure on any database shard does not affect the execution on other database shards. In addition, PolarDB-X provides the CHECK TABLE command to check the structure consistency of the table shards. Therefore, failed DDL operations can be performed again, and errors reported on database shards on which the operations have been executed do not affect the execution on other database shards. Make sure that all table shards ultimately have the same structure.

Procedure for handling DDL operation failures

1. Run the **CHECK TABLE** command to check the table structure. If the returned result contains only one row and the status is normal, **the table statuses are consistent**. In this case, go to Step 2. Otherwise, go to Step 3.
2. Run the **SHOW CREATE TABLE** command to check the table structure. If the displayed table structure is the same as the expected structure after the DDL statement is run, the DDL statement is run. Otherwise, go to Step 3.
3. Run the **SHOW PROCESSLIST** command to check the statuses of all SQL statements being executed. If any ongoing DDL operations are detected, wait until these operations are completed, and then perform Steps 1 and 2 to check the table structure. Otherwise, go to Step 4.
4. Perform the DDL operation again on PolarDB-X. If the **Lock conflict** error is reported, go to Step 5. Otherwise, go to Step 3.
5. Run the **RELEASE DBLOCK** command to release the DDL operation lock, and then go to Step 4.

The procedure is as follows:

1. Check the table structure consistency

   Run the CHECK TABLE command to check the table structure. When the returned result contains only one row and the displayed status is OK, **the table structures are consistent**.

   > **Notice** If no result is returned after you run CHECK TABLE, retry by using the CLI.

```
mysql> check table `xxxx`;
+----------------------------+-------+----------+----------+
| TABLE                      | OP    | MSG_TYPE | MSG_TEXT |
+----------------------------+-------+----------+----------+
| TDDL5_APP.xxxx             | check | status   | OK       |
+----------------------------+-------+----------+----------+
1 row in set (0.05 sec)
```

2. Check the table structure

   Run the SHOW CREATE TABLE command to check the table structure. If **table structures are consistent** and **correct**, the DDL statement has been run.

```
mysql> show create table `xxxx`;
+---------+-----------------------------------------------------------------------------------------------------------------------+
| Table   | Create Table                                                                                                          |
+---------+-----------------------------------------------------------------------------------------------------------------------+
| xxxx    | CREATE TABLE `xxxx` (
`id` int(11) NOT NULL DEFAULT '0',
`NAME` varchar(1024) NOT NULL DEFAULT '',
PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8 dbpartition by hash(`id`) tbpartition by hash(`id`) tbpartitions 3
|
+---------+-----------------------------------------------------------------------------------------------------------------------+
1 row in set (0.05 sec)
```

3. Check the SQL statements being executed.

   If some DDL statement executions are slow and no response is received for a long time, you can run the SHOW PROCESSLIST command to check the status of all SQL statements being executed.

```
mysql> SHOW PROCESSLIST WHERE COMMAND != 'Sleep';
+--------------+-----------+-------------------+-------------+---------+-------------------------------------------------------------------------------------------------------------+-----------+---------------+-----------+
| ID           | USER      | DB                | COMMAND     | TIME    | STATE                                                                                                       | INFO
| ROWS_SENT | ROWS_EXAMINED | ROWS_READ |
+--------------+-----------+-------------------+-------------+---------+-------------------------------------------------------------------------------------------------------------+-----------+---------------+-----------+
| 0-0-352724126 | ifisibhk0 | test_123_wvvp_0000 | Query     |    15 | Sending data                                                                                                | /*DRDS /x
x.xxx.xx.88/ac47e5a72801000/ */select `t_item`.`detail_url`,SUM(`t_item`.`price`) from `t_i |    NULL |      NULL |
NULL |
| 0-0-352864311 | cowxhthg0 | NULL              | Binlog Dump |    13 | Master has sent all binlog to slave; waiting for binlog
to be updated | NULL                                                                                                        |    NULL |      NULL |    NULL |
| 0-0-402714566 | ifisibhk0 | test_123_wvvp_0005 | Query     |    14 | Sending data                                                                                                | /*DRDS /x
x.xxx.xx.88/ac47e5a72801000/ */select `t_item`.`detail_url`,`t_item`.`price` from `t_i    |    NULL |      NULL |    N
ULL |
| 0-0-402714795 | ifisibhk0 | test_123_wvvp_0005 | Alter     |   114 | Sending data                                                                                                | /*DRDS /x
x.xxx.xx.88/ac47e5a72801000/ */ALTER TABLE `Persons` ADD `Birthday` date            |    NULL |      NULL |    NULL |
......
+--------------+-----------+-------------------+-------------+---------+-------------------------------------------------------------------------------------------------------------+-----------+---------------+-----------+
12 rows in set (0.03 sec)
```

   The value in the TIME column indicates the number of seconds that the command has been executed. If a command execution is too slow, as shown in the figure, you can run the **KILL '0-0-402714795'** command to cancel the slow command.

> **Notice** In PolarDB-X, one logical SQL statement corresponds to multiple statements on database shards. Therefore, you may need to kill multiple commands to stop a logical DDL statement. You can determine the logical SQL statement to which a command belongs based on the INFO column in the SHOW PROCESSLIST result set.

4. Handle the lock conflict error

   PolarDB-X adds a database lock before performing a DDL operation and releases the lock after the operation. The KILL DDL operation may not release the lock. If you perform the DDL operation again, the following error message will be returned:

   ```
   Lock conflict , maybe last DDL is still running
   ```

   In this case, run **RELEASE DBLOCK** to release the lock. After the command is canceled and the lock is released, run the DDL statement again during off-peak hours or when the service is stopped.

Other problems

Clients cannot display the modified table structures.

To enable some clients to obtain table structures from system tables (such as COLUMNS or TABLES), PolarDB-X creates a shadow database in database shard 0 on your ApsaraDB RDS for MySQL instance. The shadow database name must be the same as the name of your PolarDB-X logical database. It stores all table structures and other information in the user database.

The client obtains the PolarDB-X table structure from the system table of the shadow database. During the processing of DDL exceptions, the table structure may be modified normally in the user database but not in the shadow database due to some reasons. In this case, you need to connect to the shadow database and perform the DDL operation on the table again in the database.

> **Notice** The CHECK TABLE command does not check whether the table structure in the shadow database is consistent with that in the user database.

11.14.11. Efficiently scan DRDS data

Distributed Relational Database Service (DRDS) supports efficient data scanning and uses aggregate functions for statistical summary during full table scan.

The following describes common scanning scenarios:

- **Scan of table without database or table shards**: DRDS transmits the original SQL statement to the backend ApsaraDB RDS for MySQL database for execution. In this case, DRDS supports any aggregate functions.
- **Non-full table scan**: DRDS transmits the original SQL statement to each single ApsaraDB RDS for MySQL database for execution. For example, when the shard key in the WHERE clause is Equal, non-full table scan is performed. In this case, DRDS also supports any aggregate functions.
- **Full table scan**: Currently, the supported aggregate functions are COUNT, MAX, MIN, and SUM. In addition, LIKE, ORDER BY, LIMIT, and GROUP BY are also supported during full table scan.S
- **Parallel scan of all table shards**: If you need to export data from all databases, you can run the SHOW command to view the table topology and scan all table shards in parallel. For more information, see the following section.

Traverse tables by using a hint

1. Run the SHOW TOPOLOGY FROM TABLE_NAME command to obtain the table topology.

```
mysql:> SHOW TOPOLOGY FROM DRDS_USERS;
+------+------------------+-------------+
| ID  | GROUP_NAME     | TABLE_NAME  |
+------+------------------+-------------+
|  0 | DRDS_00_RDS    | drds_users  |
|  1 | DRDS_01_RDS    | drds_users  |
+------+------------------+-------------+
2 rows in set (0.06 sec)
```

By default, the non-partition table is stored in database shard 0.

2. Traverse each table for TOPOLOGY.
   i. Run the current SQL statement in database shard 0.

   ```
   /! TDDL:node='DRDS_00_RDS'*/ SELECT * FROM DRDS_USERS;
   ```

   ii. Run the current SQL statement in database shard 1.

   ```
   /! TDDL:node='DRDS_01_RDS'*/ SELECT * FROM DRDS_USERS;
   ```

> **Notice** We recommend that you run `SHOW TOPOLOGY FROM TABLE_NAME` to obtain the latest table topology before each scan.

Parallel scans

DRDS allows you to run mysqldump to export data. However, if you want to scan data faster, you can enable multiple sessions for each table shard to scan tables in parallel.

```
mysql> SHOW TOPOLOGY FROM LJLTEST;
+------+----------------+------------+
| ID  | GROUP_NAME    | TABLE_NAME |
+------+----------------+------------+
|  0 | TDDL5_00_GROUP | ljltest_00 |
|  1 | TDDL5_00_GROUP | ljltest_01 |
|  2 | TDDL5_00_GROUP | ljltest_02 |
|  3 | TDDL5_01_GROUP | ljltest_03 |
|  4 | TDDL5_01_GROUP | ljltest_04 |
|  5 | TDDL5_01_GROUP | ljltest_05 |
|  6 | TDDL5_02_GROUP | ljltest_06 |
|  7 | TDDL5_02_GROUP | ljltest_07 |
|  8 | TDDL5_02_GROUP | ljltest_08 |
|  9 | TDDL5_03_GROUP | ljltest_09 |
| 10 | TDDL5_03_GROUP | ljltest_10 |
| 11 | TDDL5_03_GROUP | ljltest_11 |
+------+----------------+------------+
12 rows in set (0.06 sec)
```

As shown above, the table has four database shards, and each database shard has three table shards. Run the following SQL statement to operate on the table shards of the TDDL5_00_GROUP database:

```
/! TDDL:node='TDDL5_00_GROUP'*/ select * from ljltest_00;
```

> **Note** TDDL5_00_GROUP in HINT corresponds to the GROUP_NAME column in the results of the SHOW TOPOLOGY command. In addition, the table name in the SQL statement is the table shard name.

At this time, you can enable up to 12 sessions (corresponding to 12 table shards respectively) to process data in parallel.

11.15. Appendix: PolarDB-X terms

This topic lists common terms of PolarDB-X for your reference.

Term	Description	Remarks
Cloud Native Distributed Database PolarDB-X	PolarDB-X is a distributed database service that was independently developed by Alibaba to solve the bottlenecks of single-instance database services. PolarDB-X is compatible with MySQL protocols and syntax. It supports automatic sharding, smooth scale-out, auto scaling, and transparent read/write splitting, and provides O&M capabilities for distributed databases throughout their entire lifecycle.	-
TDDL	Taobao Distributed Data Layer (TDDL) was developed by Alibaba and has become a preferred component for nearly 1,000 core applications of Alibaba.	-
PolarDB-X Console	PolarDB-X Console is designed for database administrators (DBAs) to isolate resources as required and perform operations, such as instance management, database and table management, read/write splitting configuration, smooth scale-out, monitoring data display, and IP address whitelist.	-
DRDS Manager	DRDS Manager is designed for global O&M personnel and DBAs to manage all PolarDB-X resources and monitor the system.	-
PolarDB-X Server	PolarDB-X Server is the service layer of PolarDB-X. Multiple server nodes make up a server cluster to provide distributed database services, including the read/write splitting, routed SQL execution, result merging, dynamic database configuration, and globally unique ID (GUID).	-
Load balancer	PolarDB-X server nodes are stateless, and therefore requests can be randomly routed to any PolarDB-X server node. The load balancer is used to complete this task. Server Load Balancer (SLB) is used for overall output by Apsara Stack. VIPServer is typically used for Alibaba middleware output.	-
Diamond	Diamond manages the configuration and storage of PolarDB-X. It provides the configuration functions for storage, query, and notification. In PolarDB-X, Diamond stores the source data of databases, and configuration data including the sharding rules, and switches.	-
Data Replication System	Data Replication System migrates and synchronizes data for PolarDB-X. Its core capabilities include full data migration and incremental data synchronization. Its derived features include smooth data import, smooth scale-out, and global secondary index. Data Replication System requires the support of ZooKeeper and PolarDB-X Rtools.	-
PolarDB-X instance (PolarDB-X instance)	A PolarDB-X instance consists of multiple PolarDB-X server nodes. A PolarDB-X instance can contain multiple PolarDB-X databases.	-
PolarDB-X instance ID (PolarDB-X instance ID)	An instance ID uniquely identifies an PolarDB-X instance.	-
Number of nodes on a PolarDB-X instance	The number of PolarDB-X server nodes in a PolarDB-X instance.	-

Term	Description	Remarks
VIP	The virtual IP addresses (VIPs) of the load balancer can be classified as: • 1. Public VIP, which is accessible from the Internet. It is used for testing. • 2. Private VIP, which is accessible only from the Alibaba Cloud internal network.	-
VPC	Virtual Private Cloud (VPC) is generally used on Alibaba Cloud.	-
Region	A region is a geographical location, such as East China. This concept is generally used for Alibaba Cloud.	-
Azone	A physical area with independent power grids and networks within one region, such as Hangzhou Zone A. This concept is generally used for Alibaba Cloud.	-
Logical SQL statement	A logical SQL statement is an SQL statement sent from an application to PolarDB-X.	-
Physical SQL statement	A physical SQL statement is an SQL statement obtained after PolarDB-X parses a logical SQL statement and sends it to ApsaraDB RDS for MySQL for execution.	Logical SQL statements and physical SQL statements may be the same or different. Logical and physical SQL statements may be in a one-to-one or one-to-many mapping.
QPS	The queries per second (QPS) is the average number of logical SQL statements executed by PolarDB-X per second in a statistical period,	instead of the number of transactions. Most control statements, such as COMMIT and SET, are not counted in QPS.
RT	The response time (RT) is the average response time (in milliseconds) of logical SQL statements executed by PolarDB-X in a statistical period. The RT of an SQL statement is calculated as follows: (Time when PolarDB-X writes the last packet of the result set) - (Time when PolarDB-X receives the SQL statement)	-
Physical QPS	The physical QPS is the average number of physical SQL statements that PolarDB-X executes on ApsaraDB RDS for MySQL per second in a statistical period.	-

Term	Description	Remarks
Physical RT	The physical RT is the average response time (in milliseconds) of physical SQL statements executed by PolarDB-X on ApsaraDB RDS for MySQL in a statistical period. The RT of a physical SQL statement is calculated as follows: (Time when PolarDB-X receives the result set returned by ApsaraDB RDS for MySQL) - (Time when PolarDB-X starts to obtain the connection to ApsaraDB RDS for MySQL)	This includes the time of establishing a connection to ApsaraDB RDS for MySQL or obtaining a connection from the connection pool, the network transmission time, and the time of executing the SQL statement by ApsaraDB RDS for MySQL.
Connections	The number of connections established between the application and PolarDB-X,	instead of the number of connections established between PolarDB-X and ApsaraDB RDS for MySQL.
Inbound traffic	The network traffic generated when the application sends SQL statements to PolarDB-X.	This traffic is irrelevant to the traffic used for interaction between PolarDB-X and ApsaraDB RDS for MySQL.
Outbound traffic	The network traffic generated when PolarDB-X sends the result set to the application.	This traffic is irrelevant to the traffic used for interaction between PolarDB-X and ApsaraDB RDS for MySQL.
Number of active threads (ThreadRunning)	The number of threads running on a PolarDB-X instance. This parameter can be used to indicate the load of the PolarDB-X instance.	-
Global	The total monitoring data of all databases on a PolarDB-X instance.	-
Memory usage	The Java Virtual Machine (JVM) memory usage of a PolarDB-X server process.	-
Total memory usage	The memory usage of the machine where the PolarDB-X server node is located.	This metric is available only when PolarDB-X servers are deployed on ECS instances. Generally, this metric is used for Alibaba Cloud.

Term	Description	Remarks
CPU utilization	The CPU utilization of the machine where a PolarDB-X server node is located.	This metric is available only when PolarDB-X servers are deployed on ECS instances. Generally, this metric is used for Alibaba Cloud.
System load	The load of the machine where a PolarDB-X server node is located.	This metric is available only when PolarDB-X servers are deployed on ECS instances. Generally, this metric is used for Alibaba Cloud.
Service port	The port used by PolarDB-X servers to provide MySQL-based services to external applications.	Generally, the port number is 3306. However, when multiple PolarDB-X nodes (mostly physical machines) are deployed on one machine, the port number will change accordingly.
Management port	The port used by PolarDB-X servers to provide management application program interfaces (APIs).	Generally, the port number is the service port number plus 100.
Start time	The time when PolarDB-X servers start.	-
Running time	The continuous running time of the PolarDB-X servers since the last startup time.	-
Total memory size	The maximum JVM memory size of a PolarDB-X server node.	-
Memory usage	The JVM memory that is already used by the PolarDB-X server nodes.	-
Number of nodes	Required. The number of machines. A PolarDB-X instance is essentially a PolarDB-X cluster, and the number of nodes refers to the number of machines in the cluster.	-
Instance type	Required. The type of the instance, including dedicated and shared instances. A dedicated instance works in the exclusive mode. A shared instance works in the multi-tenant mode, which is generally used in Alibaba Cloud.	-
Machine type	Required. The type of the machine where a PolarDB-X server node is deployed. Valid values are Auto-selected, PHY, and ECS. The PolarDB-X inventory is divided into physical machine inventory and virtual machine inventory according to the type of machines where the PolarDB-X servers are deployed. The two types cannot be mixed because their deployment and O&M methods are different.	-
AliUid	Required. The UID of the instance. In Apsara Stack, this ID is provided by the account system in the deployment environment.	-

Term	Description	Remarks
Backend port	The backend port of the VIP. For a PolarDB-X server node, this port is the service port of machine where the PolarDB-X server node is deployed.	-
Frontend port	The frontend port of the VIP for user access. Each VIP has a set of frontend ports and backend ports. The VIP forwards data from frontend ports to backend ports.	-
Private network/Internet	The network type of the VIP. Valid values: • Internet: the public VIP, which is accessible from the Internet. • Private network: the private VIP (including VPC VIP), which is accessible from private networks.	-
lbId	The ID of an SLB instance, which is the unique ID of VIP. A VIP is managed based on this ID.	-
Forwarding mode	The port forwarding mode of the VIP. The following modes are supported: • FNAT: This mode is recommended when the backend machine is a virtual machine or VPC needs to be supported. • NAT: This mode can be selected when the backend machine is a physical machine. Currently, this mode is only used on Alibaba Cloud. • Open FNAT: This mode is applicable only to Alibaba Cloud.	-
VPC ID	The ID of the destination VPC, that is, the VPC to be accessed.	-
VSwitch ID	The ID of the destination VSwitch, which determines the CIDR block where the VPC VIP of the instance is in.	-
APPName	The app name of the destination PolarDB-X database. Each PolarDB-X database has a corresponding app name for loading configurations.	-
UserName	The user name used to log on to the destination PolarDB-X database.	-
DBName	The name of the destination PolarDB-X database you want to log on to.	-
IP address whitelist	Only the IP addresses specified in the IP address whitelist can access the PolarDB-X instance.	-
Read-only instance	ApsaraDB RDS for MySQL instances where physical databases reside are divided into the following two types based on whether data can be written into the instances: • Primary instance: Both read and write requests are allowed on such an instance. In Apsara Stack, ApsaraDB RDS for MySQL is supported. In Alibaba Cloud, ApsaraDB for RDS is supported. • Read-only instance: Only read requests are allowed on such an instance. In Apsara Stack, ApsaraDB RDS for MySQL is supported. In Alibaba Cloud, ApsaraDB for RDS is supported.	-

Term	Description	Remarks
Read SQL statement	A type of SQL statements used to read data, such as the SELECT statement. PolarDB-X determines whether an SQL statement is a read-only SQL statement when it is not in a transaction. If the SQL statement is in a transaction, PolarDB-X treats it as a write SQL statement during read/write splitting.	-
Read/write splitting	If read-only ApsaraDB RDS for MySQL instances exist, you can configure in the PolarDB-X console to allocate read SQL statements to the primary and read-only instances proportionally. PolarDB-X automatically identifies the type of SQL statements and allocates them proportionally.	-
Smooth scale-out	On the basis of horizontal partitioning, the data distribution on ApsaraDB RDS for MySQL instances is dynamically adjusted for scale-out. Generally, scale-out is completed asynchronously without any modification to the business code.	-
Broadcast of small tables	You can synchronize the data in a single table in a database to all database shards in advance, to convert the cross-database JOIN query into a JOIN query that can be completed on physical databases.	-
Horizontal partitioning	Horizontal partitioning distributes the data rows originally stored in one table to multiple tables based on specified rules to achieve horizontal linear scaling.	-
Partition mode	This mode allows you to create multiple database shards on an ApsaraDB RDS for MySQL instance. These database shards make up a PolarDB-X database. In this mode, all PolarDB-X functions can be used.	-
Non-partition mode	In this mode, a database that has been created on an ApsaraDB RDS for MySQL instance is used as a PolarDB-X database. In this mode, only PolarDB-X read/write splitting is allowed, while other PolarDB-X features such as database sharding and table sharding are not allowed.	-
Imported database	An existing database on the ApsaraDB RDS for MySQL instance selected for creating a PolarDB-X database. This is a unique concept for the creation of a PolarDB-X database.	-
Read policy	The ratio of read SQL statements assigned by PolarDB-X to the primary and read-only ApsaraDB RDS for MySQL instances.	-
Full table scan	If no shard field is specified in a SQL statement, PolarDB-X runs the SQL statement on all table shards and summarizes the results. You can disable this function because of its high overheads.	-
Shard key	A column in a logical table. PolarDB-X routes data and SQL statements to a physical table based on this column.	-
Data import	The operation of importing data from an existing ApsaraDB RDS for MySQL instance to a PolarDB-X database.	-
Full data migration	The operation of migrating all existing records from a database to PolarDB-X. An offset is recorded before full migration starts.	-
Offset	In a MySQL binary log file, each row represents a data change operation. The position of a line in the binary log file is called an offset.	-

Term	Description	Remarks
Incremental data migration	The operation of reading all MySQL binary log records from the recorded offset, converting them into SQL statements, and then running them in PolarDB-X. Incremental migration continues before the switchover.	-
Switchover	A step of data import and smooth scale-out, which writes all the remaining incremental records from MySQL binary logs to PolarDB-X.	-
Cleanup	The last step of smooth scale-out, which cleans redundant data and configurations generated during smooth scale-out.	-
Heterogeneous indexing	For table shards of a PolarDB-X database, the WHERE condition of a SQL statement for query must contain the shard key whenever possible. In this way, PolarDB-X routes the query request to a specific database shard, improving the query efficiency. If the WHERE condition of the SQL statement does not contain the shard key, PolarDB-X performs a full table scan. PolarDB-X provides heterogeneous indexing to solve this problem. The data in a database shard or table shard of a PolarDB-X instance is fully or partially synchronized to another table based on different shard keys. The destination table to which the data is synchronized is called a heterogeneous index table.	-
PolarDB-X sequence	A PolarDB-X sequence (a 64-digit number of the BIGINT data type in MySQL) aims to ensure that the data (for example, PRIMARY KEY and UNIQUE KEY) in the defined unique field is globally unique and in ordered increments.	-
PolarDB-X hint	To facilitate PolarDB-X usage, PolarDB-X defines some hints to specify special actions.	-

12.AnalyticDB for PostgreSQL

12.1. What is AnalyticDB for PostgreSQL?

AnalyticDB for PostgreSQL is a distributed cloud database service that uses multiple compute nodes to provide massively parallel processing (MPP) data warehousing.

AnalyticDB for PostgreSQL is developed based on the open source Greenplum database project and enhanced by Alibaba Cloud. This service has the following features:

- Compatible with Greenplum and all tools that support Greenplum.
- Supports Object Storage Service (OSS), JSON, and HyperLogLog, a probabilistic algorithm for cardinality estimation.
- Supports SQL:2003-compliant syntax and Online Analytical Processing (OLAP) aggregate functions to provide flexible hybrid analysis.
- Supports both row store and column store to enhance analytics performance.
- Supports data compression to reduce storage costs.
- Provides online scaling and performance monitoring to enable Database Administrators (DBAs), developers, and data analysts to focus on improving enterprise productivity and creating core business value instead of managing and maintaining large numbers of MPP clusters.

12.2. Quick start

12.2.1. Overview

This topic describes all operations that you can perform on an AnalyticDB for PostgreSQL instance, from instance creation to database logon. It provides a quick start guide to the operations on the AnalyticDB for PostgreSQL instance.

- Log on to the AnalyticDB for PostgreSQL console

  You can log on to the AnalyticDB for PostgreSQL console.

- Create an instance

  Before you perform other operations, you must first create an AnalyticDB for PostgreSQL instance in the console.

- Configure a whitelist

  Before you use an AnalyticDB for PostgreSQL instance, add IP addresses or CIDR blocks needed to access your database to the whitelist of the instance to improve the security and stability of the database.

- Create an initial account

  After you create an instance, you must create an initial account to log on to the database.

- Connect to a database

  You can use a client that supports PostgreSQL or Greenplum to connect to a database.

12.2.2. Log on to the AnalyticDB for PostgreSQL console

This topic describes how to log on to the AnalyticDB for PostgreSQL console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.

- A browser is available. We recommend that you use the Google Chrome browser.

1. In the address bar of the browser, enter the URL of the Apsara Uni-manager Management Console and press the Enter key.
2. Enter your username and password.

   Obtain the username and password that are used to log on to the console from the operations administrator.

   > **Note** The first time you log on to the Apsara Uni-manager Management Console, you must change your password as prompted. For security reasons, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login** to go to the homepage of the Apsara Uni-manager Management Console.

12.2.3. Creates an instance

This topic describes how to create an AnalyticDB for PostgreSQL instance in the console. Before you perform other operations, you must first create an AnalyticDB for PostgreSQL instance.

1. Log on to the AnalyticDB for PostgreSQL console.
2. In the upper-right corner of the page, click **Create Instance**.
3. On the **Create AnalyticDB for PostgreSQL Instance** page, set the following parameters.

Section	Parameter	Description
Region	Organization	The organization to which the instance belongs.
	Resource Set	The resource set to which the instance belongs.
	Region	The region in which you want to create the AnalyticDB for PostgreSQL instance. **Note** If you want to access the AnalyticDB for PostgreSQL instance from an Elastic Compute Service (ECS) instance over a virtual private cloud (VPC), you must create the instance in the same region and zone as those of the ECS instance.
	Zone	The zone in which you want to create the AnalyticDB for PostgreSQL instance.
Basic Settings	Engine	Only the integrated computing and storage version is supported.
	Engine Version	The engine version of the AnalyticDB for PostgreSQL instance.
	Node Type	Specifications for each compute node. The storage space and compute capability of a compute node vary based on the specified specifications.

Section	Parameter	Description
	Nodes	The number of compute nodes. An instance must contain at least two compute nodes. The performance of an instance scales linearly with the number of compute nodes.
Network	Network Type	The network type of the AnalyticDB for PostgreSQL instance. Valid values: ○ *Classic Network*: Cloud services within the classic network are not isolated from each other. Unauthorized access to a cloud service can be blocked only by the security group or whitelist policy of the service. ○ *VPC*: A VPC helps you build an isolated network environment on Apsara Stack. You can customize route tables, CIDR blocks, and gateways in a VPC. We recommend that you select VPC for improved security. You can create a VPC in advance, or change the network type to VPC after the instance is created.
	VPC	The VPC in which you want to create the AnalyticDB for PostgreSQL instance. **Note** VPC: You can use a VPC to build an isolated network environment on Apsara Stack. You can customize route tables, CIDR blocks, and gateways in a VPC.
	vSwitch	The vSwitch to which the AnalyticDB for PostgreSQL instance is attached.
	IP Whitelist	The IP addresses that are allowed to access the instance.

4. After you set the preceding parameters, click **Submit**.

12.2.4. Configure a whitelist

To ensure a secure and stable database, you must add IP addresses or CIDR blocks that are allowed to access the database to a whitelist.

1. Log on to the AnalyticDB for PostgreSQL console.
2. Find the instance that you want to manage and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Security Controls**. The **Security Controls** page appears.
4. On the **Whitelist Settings** tab, click **Modify** corresponding to the *default* whitelist. The **Modify Group** page appears.

   Note You can also click Clear corresponding to the *default* whitelist to delete the IP addresses in the default whitelist. Then, click Add Group to create another whitelist.

5. Delete 127.0.0.1 from the *default* whitelist and enter your IP addresses in the whitelist. The following table describes the parameters.

Parameter	Description

Parameter	Description
Group Name	Specify the name of the whitelist. The name must be 2 to 32 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter and end with a letter or digit. The default whitelist cannot be modified or deleted.
IP Addresses	Enter the CIDR blocks or IP addresses that are allowed to access the database. Use commas (,) to separate multiple CIDR blocks or IP addresses. ◦ A whitelist can contain IP addresses such as 10.10.10.1 and CIDR blocks such as 10.10.10.0/24. This CIDR block indicates that all IP addresses in the 10.10.10.X format have access to the database. ◦ The percent sign (%) or 0.0.0.0/0 indicates that all IP addresses are allowed to access the database. **Notice** We recommend that you do not use this configuration because it reduces the security of the database. ◦ Default whitelists of new instances contain the loopback address 127.0.0.1. This configuration allows no access from external IP addresses. ◦ You can add up to 999 IP addresses or CIDR blocks to a whitelist.

6. Click **OK**.

What's next

- We recommend that you maintain the whitelist on a regular basis to ensure secure access for AnalyticDB for PostgreSQL.
- You can click **Modify** or **Delete** to modify or delete custom whitelists.

12.2.5. Create an initial account

After you create an instance, you must create an initial account to log on to the database.

1. Log on to the AnalyticDB for PostgreSQL console.
2. Find the instance that you want to manage and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Account Management**. The **Account Management** page appears.
4. In the upper-right corner of the page, click **Create Account**. The **Create Account** page appears.
5. Enter the database account and password, and click **OK**.

Parameter	Description
Account	The name of the account must be 2 to 16 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a letter and end with a letter or digit.
New Password	The password must be 8 to 32 characters in length. It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters.
Password	Enter the password again.

12.2.6. Obtain client tools

The interface protocol of AnalyticDB for PostgreSQL is compatible with Greenplum Community Edition and PostgreSQL 8.2. You can use the Greenplum or PostgreSQL client to connect to AnalyticDB for PostgreSQL.

> **Note**
>
> Apsara Stack is an isolated environment. You must deploy software installation packages to the internal environment.

Graphical client tools

AnalyticDB for PostgreSQL users can directly use client tools that support Greenplum, such as SQL Workbench, Navicat Premium, Navicat for PostgreSQL, and pgadmin III v1.6.3.

Command-line client psql (for RHEL 6, RHEL 7, CentOS 6, and CentOS 7)

For Red Hat Enterprise Linux (RHEL) 6, RHEL 7, CentOS 6, and CentOS 7, download the tools from the following links and decompress the packages to use them:

- For RHEL 6 or CentOS 6, click hybriddb_client_package_el6.
- For RHEL 7 or CentOS 7, click hybriddb_client_package_el7.

Command-line client psql (for other Linux systems)

For other Linux systems, perform the following operations to compile the client tools:

1. Obtain the source code by using one of the following methods:
   - Obtain the git directory. You must first install the git tool.

     ```
     git clone https://github.com/greenplum-db/gpdb.git
     cd gpdb
     git checkout 5d870156
     ```

   - Download the code.

     ```
     wget https://github.com/greenplum-db/gpdb/archive/5d87015609abd330c68a5402c1267fc86cbc9e1f.zip
     unzip 5d87015609abd330c68a5402c1267fc86cbc9e1f.zip
     cd gpdb-5d87015609abd330c68a5402c1267fc86cbc9e1f
     ```

2. Use GCC and other compilers.

   ```
   ./configure
   make -j32
   make install
   ```

3. Use psql and pg_dump. The two tools are located in the following paths:

   psql: */usr/local/pgsql/bin/psql*

   pg_dump: */usr/local/pgsql/bin/pg_dump*

Command-line client psql (for Windows and other systems)

For Windows and other systems, go to the Pivotal website to download HybridDB Client.

12.2.7. Connect to a database

Greenplum Database and AnalyticDB for PostgreSQL are both developed based on PostgreSQL 8.2 and fully compatible with its message protocol. AnalyticDB for PostgreSQL users can use tools that support the PostgreSQL 8.2 message protocol, such as libpq, Java Database Connectivity (JDBC), Open Database Connectivity (ODBC), psycopg2, and pgAdmin III.

Context

AnalyticDB for PostgreSQL provides psql, a binary program of Red Hat. For more information about the download link, see Obtain the client tool. The Greenplum official website provides an easy-to-install installation package that includes JDBC, ODBC, and libpq. For more information, see Greenplum official documentation.

> **Note**
> - Apsara Stack is an isolated environment. To access Apsara Stack, you must prepare the necessary software installation packages in advance.
> - By default, AnalyticDB for PostgreSQL instances can be accessed only by clients that are deployed on Elastic Compute Service (ECS) instances within the same region and zone.

psql

psql is a common tool used together with Greenplum, and provides a variety of command functions. Its binary files are located in the *bin* directory of Greenplum. To use psql, perform the following steps:

1. Use one of the following methods to connect to the database:
   - Connection string

     ```
     psql "host=yourgpdbaddress.gpdb.rds.aliyuncs.com port=3432 dbname=postgres user=gpdbaccount password=gpdbpassword"
     ```

   - Specified parameters

     ```
     psql -h yourgpdbaddress.gp.aliyun-inc.com -p 3432 -d postgres -U gpdbaccount
     ```

     The following section describes the parameters:

     - -h: the host address.
     - -p: the port used to connect to the database.
     - -d: the name of the database. The default value is postgres.
     - -U: the account used to connect to the database.

     You can run the `psql --help` command to view more options. You can also run the `\?` commandto view the commands supported in psql.
2. Enter the password to go to the psql shell interface.

   ```
   postgres=>
   ```

References

- For more information about the Greenplum psql usage, see psql.
- AnalyticDB for PostgreSQL also supports psql commands of PostgreSQL. Pay attention to the differences between Greenplum psql and PostgreSQL psql. For more information, see PostgreSQL 8.3.23 Documentation - psql.

pgAdmin III

pgAdmin III is a PostgreSQL graphical client that can be directly used to connect to AnalyticDB for PostgreSQL. For more information, click here. For more information about other graphical clients, see Obtain the client tool.

1. Download pgAdmin III 1.6.3 or earlier.

   You can download pgAdmin III 1.6.3 from the PostgreSQL website. pgAdmin III 1.6.3 supports various operating systems, such as Windows, macOS, and Linux.

> **Note** AnalyticDB for PostgreSQL is compatible with PostgreSQL 8.2. Therefore, you must use pgAdmin III 1.6.3 or earlier to connect to AnalyticDB for PostgreSQL. pgAdmin 4 and later are not supported.

2. Choose **File > Add Server**.
3. In the New Server Registration dialog box, set the parameters.
4. Click **OK** to connect to AnalyticDB for PostgreSQL.

JDBC

JDBC uses the interface provided by PostgreSQL. Use the following method to download the JDBC driver:

Click here to download the official JDBC of PostgreSQL. Then, add it to the environment variables.

Sample code:

```
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.sql.Statement;
public class gp_conn {
  public static void main(String[] args) {
    try {
      Class.forName("org.postgresql.Driver");
      Connection db = DriverManager.getConnection("jdbc:postgresql://mygpdbpub.gpdb.rds.aliyuncs.com:3432/postgres",
          "mygpdb", "mygpdb");
      Statement st = db.createStatement();
      ResultSet rs = st.executeQuery(
          "select * from gp_segment_configuration;");
      while (rs.next()) {
        System.out.print(rs.getString(1));
        System.out.print(" | ");
        System.out.print(rs.getString(2));
        System.out.print(" | ");
        System.out.print(rs.getString(3));
        System.out.print(" | ");
        System.out.print(rs.getString(4));
        System.out.print(" | ");
        System.out.print(rs.getString(5));
        System.out.print(" | ");
        System.out.print(rs.getString(6));
        System.out.print(" | ");
        System.out.print(rs.getString(7));
        System.out.print(" | ");
        System.out.print(rs.getString(8));
        System.out.print(" | ");
        System.out.print(rs.getString(9));
        System.out.print(" | ");
        System.out.print(rs.getString(10));
        System.out.print(" | ");
        System.out.println(rs.getString(11));
      }
      rs.close();
      st.close();
    } catch (ClassNotFoundException e) {
      e.printStackTrace();
    } catch (SQLException e) {
      e.printStackTrace();
    }
  }
}
```

Python

Python uses psycopg2 to connect to Greenplum and PostgreSQL. Perform the following operations:

1. Install psycopg2. Use one of the following methods to install psycopg2 in CentOS:
   - Method 1: Run the `yum -y install python-psycopg2` command.
   - Method 2: Run the `pip install psycopg2` command.
   - Method 3: Run the following source code:

```
yum install -y postgresql-devel*
wget http://initd.org/psycopg/tarballs/PSYCOPG-2-6/psycopg2-2.6.tar.gz
tar xf psycopg2-2.6.tar.gz
cd psycopg2-2.6
python setup.py build
sudo python setup.py install
```

2. Run the following commands to set PYTHONPATH and reference it:

```
import psycopg2
 sql = 'select * from gp_segment_configuration;'
 conn = psycopg2.connect(database='gpdb', user='mygpdb', password='mygpdb', host='mygpdbpub.gpdb.rds.aliyu
ncs.com', port=3432)
 conn.autocommit = True
 cursor = conn.cursor()
 cursor.execute(sql)
 rows = cursor.fetchall()
 for row in rows:
    print row
 conn.commit()
 conn.close()
```

An output similar to the following one is displayed:

```
(1, -1, 'p', 'p', 's', 'u', 3022, '192.168.2.158', '192.168.2.158', None, None)(6, -1, 'm', 'm', 's', 'u', 3019, '192.168.2.47', '192.
168.2.47', None, None)(2, 0, 'p', 'p', 's', 'u', 3025, '192.168.2.148', '192.168.2.148', 3525, None)(4, 0, 'm', 'm', 's', 'u', 3024
, '192.168.2.158', '192.168.2.158', 3524, None)(3, 1, 'p', 'p', 's', 'u', 3023, '192.168.2.158', '192.168.2.158', 3523, None)(5,
1, 'm', 'm', 's', 'u', 3026, '192.168.2.148', '192.168.2.148', 3526, None)
```

libpq

libpq is the C language interface to AnalyticDB for PostgreSQL. You can use the libpq library to access and manage PostgreSQL databases in a C program. You can find its static and dynamic libraries in the lib directory.

For more information about example programs, see Example Programs.

For more information about libpq, see PostgreSQL 9.4.17 Documentation - Chapter 31. libpq - C Library.

ODBC

PostgreSQL ODBC is an open source version based on the GNU Lesser General Public License (LGPL) protocol. You can download it from the PostgreSQL website.

1. Install the driver.

```
yum install -y unixODBC.x86_64
yum install -y postgresql-odbc.x86_64
```

2. View the driver configurations.

```
cat /etc/odbcinst.ini
# Example driver definitions
# Driver from the postgresql-odbc package
# Setup from the unixODBC package
[PostgreSQL]
Description = ODBC for PostgreSQL
Driver = /usr/lib/psqlodbcw.so
Setup = /usr/lib/libodbcpsqlS.so
Driver64 = /usr/lib64/psqlodbcw.so
Setup64 = /usr/lib64/libodbcpsqlS.so
FileUsage = 1
# Driver from the mysql-connector-odbc package
# Setup from the unixODBC package
[MySQL]
Description = ODBC for MySQL
Driver = /usr/lib/libmyodbc5.so
Setup = /usr/lib/libodbcmyS.so
Driver64 = /usr/lib64/libmyodbc5.so
Setup64 = /usr/lib64/libodbcmyS.so
FileUsage = 1
```

3. Configure the data source name (DSN). Replace `****` in the following code with the corresponding connection information.

```
[mygpdb]
Description = Test to gp
Driver = PostgreSQL
Database = ****
Servername = ****.gpdb.rds.aliyuncs.com
UserName = ****
Password = ****
Port = ****
ReadOnly = 0
```

4. Test the connectivity.

```
echo "select count(*) from pg_class" | isql mygpdb
+---------------------------------------+
| Connected!                            |
|                                       |
| sql-statement                         |
| help [tablename]                      |
| quit                                  |
|                                       |
+---------------------------------------+
SQL> select count(*) from pg_class
+----------------------+
| count                |
+----------------------+
| 388                  |
+----------------------+
SQLRowCount returns 1
1 rows fetched
```

5. After ODBC is connected to the instance, connect the application to ODBC. For more information, see psqlODBC - PostgreSQL ODBC driver and psqlODBC HOWTO - C#.

12.3. Instances

12.3.1. Reset the password

When you use AnalyticDB for PostgreSQL, you can reset the password of your database account in the AnalyticDB for PostgreSQL console if you forget your password.

> **Note** To ensure data security, we recommend that you change your password on a regular basis.

1. Log on to the AnalyticDB for PostgreSQL console.
2. Find the target instance and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Account Management**. The **Account Management** page appears.
4. Click **Reset Password** in the Actions column corresponding to an account. The **Reset Account Password** page appears.
5. After you enter and confirm the new password, click **OK**.

> **Note** The password must be 8 to 32 characters in length. It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. We recommend that you do not use a previously used password.

12.3.2. View monitoring information

You can go to the monitoring information page in the console to view the operation status of an instance.

1. Log on to the AnalyticDB for PostgreSQL console.
2. Find the instance that you want to manage and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Monitoring and Alarms**. The **Monitoring and Alarms** page appears.

   Specify a duration of time n up to seven days in length to view the metrics for that last n period.

12.3.3. Switch the network type of an instance

The default network type of an instance is Virtual Private Cloud (VPC). After an instance is created, you can switch its network type between classic network and VPC as needed.

Context

AnalyticDB for PostgreSQL supports two network types: classic network and VPC. Both network types use BGP connections, and are independent of the public network of your service provider. These network types only differ in functions, and you can choose a network type based on your requirements. The two network types are applicable to different scenarios:

- Classic network: IP addresses are allocated by Alibaba Cloud. Classic networks are easy to configure and use. This network type is suitable for users who do not need to perform complex operations, or who only require short deployment cycles.
- VPC: a logically isolated private network. You can customize the network topology and IP addresses and

connect through a leased line. This network type is suitable for advanced users.

Warning Switching the network type will cause the database service to stop. Proceed with caution.

1. Log on to the AnalyticDB for PostgreSQL console.
2. Find the target instance and click its ID. The **Basic Information** page appears.
3. In the left-side navigation pane, click **Database Connection**. The **Database Connection** page appears.
4. In the upper-right corner of the page, click **Switch to Classic Network** or **Switch to VPC**.
5. If you click **Switch to VPC**, you must select the destination **VPC** and **VSwitch**. Click **OK**.

   Note To switch the network type to VPC, a VPC and a VSwitch must exist or be created in the zone where the instance is located.

6. If you click **Switch to Classic Network**, click **OK** in the displayed message.

Note After you switch the network type, it takes 3 to 30 minutes for the instance to enter the running state.

12.3.4. Restart an instance

To better meet your requirements, AnalyticDB for PostgreSQL updates the minor kernel version on a regular basis. When you create an instance, the latest database kernel is used by default. After a new version is released, you can restart your instance to update the database kernel and use its extended features. This topic describes how to restart an instance.

Warning The database service may be interrupted when you restart an instance.

1. Log on to the AnalyticDB for PostgreSQL console.
2. Find the instance that you want to manage and click its ID. The **Basic Information** page appears.
3. In the upper-right corner of the page, click **Restart Instance**.

Note The restart process takes about 3 to 30 minutes. During the restart period, the instance cannot provide external services. We recommend that you take precautionary measures before you restart the instance. After the instance is restarted and enters the running state, you can access the database.

12.3.5. Import data

12.3.5.1. Import data from or export data to OSS in parallel

AnalyticDB for PostgreSQL allows you to import data from or export data to Object Storage Service (OSS) tables in parallel by using the OSS external table feature, gpossext. AnalyticDB for PostgreSQL also supports GZIP compression for OSS external tables to reduce file size and storage costs. gpossext can read from and write to TEXT and CSV files, even when they are compressed in GZIP packages.

- Create an OSS external table extension (oss_ext)

  To use an OSS external table, you must first create an OSS external table extension in AnalyticDB for PostgreSQL. You must create an extension for each database that you need to access.

  - To create the extension, execute the `CREATE EXTENSION IF NOT EXISTS oss_ext;` statement.
  - To delete the inextension, execute the `DROP EXTENSION IF EXISTS oss_ext;` statement.

- Import data in parallel
  i. Distribute data evenly into multiple files in OSS. We recommend that you set the number of OSS files to an integer that is the multiple of the number of compute nodes in AnalyticDB for PostgreSQL.
  ii. Create a READABLE external table in AnalyticDB for PostgreSQL.
  iii. Execute the following statement to import data in parallel:

```
INSERT INTO <Destination table> SELECT * FROM <External table>
```

  > **Note**
  > - The data import performance depends on the OSS performance and resources of AnalyticDB for PostgreSQL instances, such as CPU, I/O, memory, and network resources. To ensure the best import performance, we recommend that you use column store and compression when you create a table. For example, you can specify the following clause: `WITH (APPENDONLY=true, ORIENTATION=column, COMPRESSTYPE=zlib, COMPRESSLEVEL=5, BLOCKSIZE=1048576)`. For more information, see Greenplum Database official documentation on database table creation syntax.
  > - To ensure the best import performance, we recommend that you configure OSS and AnalyticDB for PostgreSQL instances within the same region.AnalyticDB for PostgreSQL

- Export data in parallel
  i. Create a WRITABLE external table in AnalyticDB for PostgreSQL.
  ii. Execute the following statement to export data to OSS in parallel:

```
INSERT INTO <External table> SELECT * FROM <Source table>
```

- Create OSS external tables

  > **Note** The syntax to create and use external tables is the same as that of Greenplum Database, except for the syntax of location-related parameters.

```
CREATE [READABLE] EXTERNAL TABLE tablename
( columnname datatype [, ...] | LIKE othertable )
LOCATION ('ossprotocol')
FORMAT 'TEXT'
        [( [HEADER]
          [DELIMITER [AS] 'delimiter' | 'OFF']
          [NULL [AS] 'null string']
          [ESCAPE [AS] 'escape' | 'OFF']
          [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
          [FILL MISSING FIELDS] )]
       | 'CSV'
        [( [HEADER]
          [QUOTE [AS] 'quote']
          [DELIMITER [AS] 'delimiter']
          [NULL [AS] 'null string']
          [FORCE NOT NULL column [, ...]]
          [ESCAPE [AS] 'escape']
          [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
          [FILL MISSING FIELDS] )]
[ ENCODING 'encoding' ]
[ [LOG ERRORS [INTO error_table]] SEGMENT REJECT LIMIT count
    [ROWS | PERCENT] ]
CREATE WRITABLE EXTERNAL TABLE table_name
( column_name data_type [, ...] | LIKE other_table )
LOCATION ('ossprotocol')
FORMAT 'TEXT'
          [( [DELIMITER [AS] 'delimiter']
          [NULL [AS] 'null string']
          [ESCAPE [AS] 'escape' | 'OFF'] )]
       | 'CSV'
          [([QUOTE [AS] 'quote']
          [DELIMITER [AS] 'delimiter']
          [NULL [AS] 'null string']
          [FORCE QUOTE column [, ...]] ]
          [ESCAPE [AS] 'escape'] )]
[ ENCODING 'encoding' ]
[ DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY ]
ossprotocol:

   id=userossid key=userosskey bucket=ossbucket compressiontype=[none|gzip] async=[true|false]
ossprotocol:
  oss://oss_endpoint dir=[folder/[folder/]...]/file_name
   id=userossid key=userosskey bucket=ossbucket compressiontype=[none|gzip] async=[true|false]
ossprotocol:
  oss://oss_endpoint filepath=[folder/[folder/]...]/file_name
   id=userossid key=userosskey bucket=ossbucket compressiontype=[none|gzip] async=[true|false]
```

Parameters

Common parameters

Parameter	Description

Parameter	Description
Protocol and endpoint	This parameter is in the `protocol name://oss_endpoint` format. The protocol name is oss. oss_endpoint is the domain name that is used to access OSS in a region. **Note** You can access the database from a virtual private cloud (VPC) host by using an internal endpoint that contains "internal" in the name to avoid generating public traffic.
id	The AccessKey ID of the OSS account.
key	The AccessKey secret of the OSS account.
bucket	The bucket where the data file is located. You must use OSS to create the bucket before you import data.

prefix	The prefix of the path name corresponding to the data file. Prefixes are directly matched and cannot be controlled by regular expressions. The prefix, filepath, and dir parameters are mutually exclusive. Only one of the parameters can be specified at a time.
	• If you create a READABLE external table for data import, all OSS files that contain the specified prefix are imported.
	  ◦ If you set prefix to test/filename, the following files are imported:
	  ▪ test/filename
	  ▪ test/filenamexxx
	  ▪ test/filename/aa
	  ▪ test/filenameyyy/aa
	  ▪ test/filenameyyy/bb/aa
	  ◦ If you set prefix to test/filename/, only the following file out of the preceding files is imported:
	  test/filename/aa
	• If you create a WRITABLE external table for data export, each exported file has a unique name based on this parameter.
	
	Note One or more files can be exported for each compute node. The names of exported files are in the `prefix_tablename_uuid.x` format. uuid indicates a timestamp in microseconds as an int64 value. x indicates the node ID. You can use an external table for multiple export operations. Each export operation is assigned a uuid value. The files exported during each operation share a uuid value.

Parameter	Description
dir	The virtual folder path in OSS. The prefix, filepath, and dir parameters are mutually exclusive. Only one of the parameters can be specified at a time. • A folder path must end with a forward slash (/). Example: `test/mydir/`. • If you use this parameter when you create an external table for data import, all files in the specified virtual directory (except for its subdirectories and contained files) are imported. Unlike filepath, dir does not require you to specify the names of files in the directory. • If you use this parameter when you create an external table for data export, all data is exported as multiple files within the specified directory. The names of exported files are in the `filename.x` format, where x is a number. The values of x may not be consecutive.
filepath	The file name that contains a path in OSS. The prefix, filepath, and dir parameters are mutually exclusive. Only one of the parameters can be specified at a time. You can specify only the filepath parameter when you create a READABLE external table for data import. • The file name includes the file path, but not the bucket name. • The file name that is specified for data import must be in the `filename` or `filename.x` format. The values of x must be consecutive numbers that start from 1. For example, if filepath is set to filename and OSS contains the following files, the imported files include filename, filename.1, and filename.2, but filename.4 is not imported because filename.3 does not exist. **filename** **filename.1** **filename.2** **filename.4**

Import mode parameters

Parameter	Description
async	Specifies whether to enable asynchronous data import. • By default, asynchronous data import is enabled. You can set async to false or f to disable asynchronous data import. • You can enable the worker thread to load data from OSS to accelerate the import performance. By default, asynchronous data import is used. • Asynchronous data import consumes more hardware resources than normal data import.
compressiontype	The compression format of the imported files. Valid values: • none: The import files are not compressed. This is the default value. • gzip: The imported files are compressed in the GZIP format. Only the GZIP format is supported.
compressionlevel	The compression level of the files that are written to OSS. Valid values: 1 to 9. Default value: 6.

Export mode parameters

Parameter	Description
oss_flush_block_size	The size of each data block that is written to OSS. Valid values: 1 to 128. Default value: 32. Unit: MB.
oss_file_max_size	The maximum size for each file that is written to OSS. If the limit is exceeded, subsequent data is written to another file. Valid values: 8 to 4000. Default value: 1024. Unit: MB.
num_parallel_worker	The number of parallel compression threads for data that is written to OSS. Valid values: 1 to 8. Default value: 3.

For data export, take note of the following items:

- WRITABLE is the keyword of the external table for data export. You must specify this keyword when you create an external table.
- Only the prefix and dir parameters are supported for data export. The filepath parameter is not supported.
- You can use the DISTRIBUTED BY clause to write data from compute nodes to OSS based on the specified distribution keys.

Other common parameters

The following table describes the fault-tolerance parameters that can be used for data import and export.

Fault-tolerance parameters

Parameter	Description
oss_connect_timeout	The connection timeout period. Default value: 10. Unit: seconds.
oss_dns_cache_timeout	The Alibaba Cloud DNS (DNS) timeout period. Default value: 60. Unit: seconds.
oss_speed_limit	The minimum rate tolerated. Default value: 1024 bit/s (1 Kbit/s).
oss_speed_time	The maximum amount of time tolerated. Default value: 15. Unit: seconds.

When the default values are used for the preceding parameters, a timeout occurs if the transmission rate is lower than 1 Kbit/s for 15 consecutive seconds. For more information, see **Troubleshooting** in *OSS SDK reference*.

The other parameters are compatible with the external table syntax of Greenplum Database. For more information about the syntax, see Greenplum Database official documentation on external table syntax. The following parameters are included:

- FORMAT: the supported file format, such as TEXT and CSV.
- ENCODING: the data encoding format of a file, such as UTF-8.
- LOG ERRORS refers to improperly imported data that can be ignored and is instead written to to error_table. You can also use the count parameter to specify the error reporting threshold.

Examples

```
# Create a READABLE external table of OSS.
create readable external table ossexample
    (date text, time text, open float, high float,
    low float, volume int)
    location('oss://oss-cn-hangzhou.aliyuncs.com
    prefix=osstest/example id=XXX
    key=XXX bucket=testbucket compressiontype=gzip')
    FORMAT 'csv' (QUOTE '"' DELIMITER E'\t')
    ENCODING 'utf8'
```

```
    LOG ERRORS INTO my_error_rows SEGMENT REJECT LIMIT 5;
create readable external table ossexample
    (date text, time text, open float, high float,
    low float, volume int)
    location('oss://oss-cn-hangzhou.aliyuncs.com
    dir=osstest/ id=XXX
    key=XXX bucket=testbucket')
    FORMAT 'csv'
    LOG ERRORS SEGMENT REJECT LIMIT 5;
create readable external table ossexample
    (date text, time text, open float, high float,
    low float, volume int)
    location('oss://oss-cn-hangzhou.aliyuncs.com
    filepath=osstest/example.csv id=XXX
    key=XXX bucket=testbucket')
    FORMAT 'csv'
    LOG ERRORS SEGMENT REJECT LIMIT 5;
# Create a WRITABLE external table of OSS.
create WRITABLE external table ossexample_exp
    (date text, time text, open float, high float,
    low float, volume int)
    location('oss://oss-cn-hangzhou.aliyuncs.com
    prefix=osstest/exp/outfromhdb id=XXX
    key=XXX bucket=testbucket') FORMAT 'csv'
    DISTRIBUTED BY (date);
create WRITABLE external table ossexample_exp
    (date text, time text, open float, high float,
    low float, volume int)
    location('oss://oss-cn-hangzhou.aliyuncs.com
    dir=osstest/exp/ id=XXX
    key=XXX bucket=testbucket') FORMAT 'csv'
    DISTRIBUTED BY (date);
# Create a heap table named example to which you want to import data.
create table example
    (date text, time text, open float,
     high float, low float, volume int)
     DISTRIBUTED BY (date);
# Import data to the example heap table from the ossexample table in parallel.
insert into example select * from ossexample;
# Export data from the example heap table to OSS in parallel.
insert into ossexample_exp select * from example;
# The following execution plan shows that all compute nodes are involved in the task.
# All compute nodes read data from OSS in parallel. AnalyticDB for PostgreSQL performs a redistribution motion operati
on to compute the data by using a hash algorithm, and then distributes the data to its compute nodes after computing.
After a compute node receives data, it performs an insert operation to add the data to AnalyticDB for PostgreSQL.
explain insert into example select * from ossexample;
                          QUERY PLAN
-------------------------------------------------------------------------------------------
 Insert (slice0; segments: 4)  (rows=250000 width=92)
   ->  Redistribute Motion 4:4  (slice1; segments: 4)  (cost=0.00..11000.00 rows=250000 width=92)
       Hash Key: ossexample.date
       ->  External Scan on ossexample  (cost=0.00..11000.00 rows=250000 width=92)
(4 rows)
# The following query plan shows that each compute node directly exports data to OSS without redistributing the data.
explain insert into ossexample_exp select * from example;
                  QUERY PLAN
-----------------------------------------------------------------
 Insert (slice0; segments: 3)  (rows=1 width=92)
   ->  Seq Scan on example  (cost=0.00..0.00 rows=1 width=92)
(2 rows)
```

TEXT and CSV format description

The following parameters specify the formats of files read from and written to OSS. You can specify the parameters in the external DDL parameters.

- \n: the line feed for TEXT and CSV files.
- DELIMITER: the delimiter of columns.
  - If the DELIMITER parameter is specified, the QUOTE parameter must also be specified.
  - Recommended column delimiters include commas (,), vertical bars (|), and special characters such as \t.
- QUOTE: encloses user data that contains special characters by column.
  - Strings that contain special characters must be enclosed by QUOTE to differentiate user data from control characters.
  - To optimize the efficiency, it is unnecessary to enclose data such as integers in QUOTE characters.
  - QUOTE cannot be the same string as specified in DELIMITER. The default value of QUOTE is double quotation marks (").
  - User data that contains QUOTE characters must also contain ESCAPE characters to differentiate user data from machine code.
- ESCAPE: the escape character.
  - Place an escape character before a special character that needs to be escaped to indicate that it is not a special character.
  - If ESCAPE is not specified, the default value is the same as QUOTE.
  - You can also use other characters such as backslashes (\) as ESCAPE characters, which is used by MySQL.

Default control characters for TEXT and CSV files

Default control characters for TEXT and CSV files

Control character	TEXT	CSV
DELIMITER	Tab (\t)	Comma (,)
QUOTE	double quotation mark (")	double quotation mark (")
ESCAPE	N/A	Same as QUOTE
NULL	Backslash plus N (\N)	Empty string without quotation marks

> **Note** All control characters must be single-byte characters.

SDK troubleshooting

The following Error log information table lists the error logs generated when an error occurs during the import or export process.

Error log information

Keyword	Description
code	The HTTP status code of the error request.
error_code	The error code returned by OSS.

Keyword	Description
error_msg	The error message returned by OSS.
req_id	The UUID used to identify the request. If you require assistance from OSS developers, you can submit a ticket that contains the req_id parameter of the failed request.

You can handle limitout-related errors by using parameters related to oss_ext.

12.3.5.2. Import data from MySQL

You can use the mysql2pgsql tool to migrate tables from MySQL to AnalyticDB for PostgreSQL, Greenplum Database, PostgreSQL, or Postgres Plus Advanced Server (PPAS).

Background information

mysql2pgsql connects to both the source MySQL database and the destination AnalyticDB for PostgreSQL database. The tool retrieves the data that you want to export from the source MySQL database, and uses a COPY statement to import the data to the destination database. This tool supports simultaneous data import over multiple threads. Each worker thread imports data from some database tables.

To download the binary installation package of mysql2pgsql, click here.

To view instructions on source code compilation of mysql2pgsql, click here.

Procedure

1. Modify the my.cfg configuration file to configure the connection information of source and destination databases.
   i. Modify the connection information of the source MySQL database.

   > **Note** You must have the read permissions on all user tables.

   ```
   [src.mysql]
   host = "192.168.1.1"
   port = "3306"
   user = "test"
   password = "test"
   db = "test"
   encodingdir = "share"
   encoding = "utf8"
   ```

   ii. Modify the connection information of the destination PostgreSQL, PPAS, or AnalyticDB for PostgreSQL database.

   > **Note** You must have the write permissions on the destination table.

   ```
   [desc.pgsql]
   connect_string = "host=192.168.1.2 dbname=test port=3432  user=test password=pgsql"
   ```

2. Use mysql2pgsql to import data.

```
./mysql2pgsql -l <tables_list_file> -d -n -j <number of threads> -s <schema of target able>
```

Parameters

Parameter	Description

-l	Optional. This parameter is used to specify a text file that contains tables to be synchronized. If you do not specify this parameter, all the tables in the database that is specified in the configuration file are synchronized. `<tables_list_file>` specifies the name of a file that contains a collection of tables to be synchronized and conditions for table queries. You can specify the file content in the following format:
	`table1 : select * from table_big where column1 < '2016-08-05'`
	`table2 :`
	`table3`
	`table4: select column1, column2 from tableX where column1 != 10`
	`table5: select * from table_big where column1 >= '2016-08-05'`

-d	Optional. This parameter indicates the table creation DDL statement that creates the destination table but does not synchronize data.
-n	Optional. This parameter must be used along with -d to specify that the table partition definition is not included in the DDL statement.
-j	Optional. This parameter is used to specify the number of threads that are used for data synchronization. If you do not specify this parameter, five concurrent threads are used.
-s	Optional. This parameter is used to specify the schema of the destination table. Only one schema at a time can be specified by the command. If you do not specify this parameter, the data is imported into the table under the public schema.

Typical usage

Full database migration

1. Run the following command to obtain the DDL statements of the corresponding destination table:

   ```
   ./mysql2pgsql -d
   ```

2. Create a table in the destination database based on these DDL statements with the distribution key information added.
3. Run the following command to synchronize all tables:

   ```
   ./mysql2pgsql
   ```

   This command migrates the data from all MySQL tables in the database that is specified in the configuration file to the destination database. By default, five concurrent threads are used to read and import data from involved tables.

Partial table migration

1. Create a file named tab_list.txt and enter the following content:

   ```
   t1
   t2 : select * from t2 where c1 > 138888
   ```

2. Run the following command to synchronize the specified t1 and t2 tables. For the t2 table, only data that meets the c1 > 138888 condition is migrated.

   ```
   ./mysql2pgsql -l tab_list.txt
   ```

12.3.5.3. Import data from PostgreSQL

You can use the pgsql2pgsql tool to migrate tables across AnalyticDB for PostgreSQL, Greenplum Database, PostgreSQL, and Postgres Plus Advanced Server (PPAS).

Context

pgsql2pgsql supports the following features:

- Full migration across PostgreSQL, PPAS, Greenplum Database, and AnalyticDB for PostgreSQL.
- Full migration and incremental migration from PostgreSQL or PPAS (version 9.4 or later) to AnalyticDB for PostgreSQL or ApsaraDB RDS for PPAS.

You can download the software packages from the dbsync project library.

- To download the binary installation package of pgsql2pgsql, click here.
- To view instructions on source code compilation of pgsql2pgsql, click here.

Procedure

1. Modify the my.cfg configuration file to configure the connection information of source and destination databases.
   i. Modify the connection information of the source PostgreSQL database.

   > **Note** In the connection information of the source PostgreSQL database, we recommend that you set the user to the owner of the source database.

   ```
   [src.pgsql]
   connect_string = "host=192.168.0.1 dbname=test port=3432  user=test password=pgsql"
   ```

   ii. Modify the connection information of the on-premises temporary PostgreSQL database.

   ```
   [local.pgsql]
   connect_string = "host=192.168.0.2 dbname=test port=3432  user=test2 password=pgsql"
   ```

   iii. Modify the connection information of the destination PostgreSQL database.

   > **Note** You must have the write permissions on the destination table.

   ```
   [desc.pgsql]
   connect_string = "host=192.168.0.2 dbname=test port=3432  user=test3 password=pgsql"
   ```

   > **Note**
   > - If you want to synchronize incremental data, you must have the permissions to create replication slots in the source database.
   > - PostgreSQL 9.4 and later support logic flow replication. Therefore, source databases of these versions support incremental data migration. A kernel supports logic flow replication only after you configure the following parameters:
   >
   >   wal_level = logical
   >
   >   max_wal_senders = 6
   >
   >   max_replication_slots = 6

2. Use pgsql2pgsql to perform full database migration.

`./pgsql2pgsql`

By default, the migration program migrates the table data of all users from the source PostgreSQL database to the destination PostgreSQL database.

3. View the status information.

   You can view the status information in a single migration process by connecting to the on-premises temporary database. The status information is stored in the db_sync_status table and includes the start and end time of full data migration, the start time of incremental data migration, and the status of incremental data synchronization.

12.3.5.4. Use the \COPY statement to import data

You can use the `\COPY` statement to import data from local text files to AnalyticDB for PostgreSQL instances. Local text must be properly formatted and include necessary delimiters such as commas (,), semicolons (;), or special characters.

Context

- Parallel writing of large amounts of data is unavailable because the `\COPY` statement writes data in series by using the coordinator node. If you need to import a large amount of data in parallel, you can use the data import method based on Object Storage Service (OSS).
- The `\COPY` statement is a psql instruction. If you use the database statement `COPY` instead of the `\COPY` statement, you must note that only stdin is supported. This COPY statement does not support files because the root user does not have the superuser permissions to perform operations on files.
- AnalyticDB for PostgreSQL also allows you to use JDBC to execute the COPY statement. The CopyIn method is encapsulated within JDBC. For more information, see Interface CopyIn.
- For more information about how to use the COPY statement, see COPY.

Procedure

1. Import data by using the following sample code:

```
\COPY table [(column [, ...])] FROM {'file' | STDIN}
   [ [WITH]
    [OIDS]
    [HEADER]
    [DELIMITER [ AS ] 'delimiter']
    [NULL [ AS ] 'null string']
    [ESCAPE [ AS ] 'escape' | 'OFF']
    [NEWLINE [ AS ] 'LF' | 'CR' | 'CRLF']
    [CSV [QUOTE [ AS ] 'quote']
       [FORCE NOT NULL column [, ...]]
    [FILL MISSING FIELDS]
    [[LOG ERRORS [INTO error_table] [KEEP]
    SEGMENT REJECT LIMIT count [ROWS | PERCENT] ]
\COPY {table [(column [, ...])] | (query)} TO {'file' | STDOUT}
   [ [WITH]
    [OIDS]
    [HEADER]
    [DELIMITER [ AS ] 'delimiter']
    [NULL [ AS ] 'null string']
    [ESCAPE [ AS ] 'escape' | 'OFF']
    [CSV [QUOTE [ AS ] 'quote']
       [FORCE QUOTE column [, ...]] ]
   [IGNORE EXTERNAL PARTITIONS ]
```

12.4. Databases

12.4.1. Overview

The operations based on Greenplum Database in AnalyticDB for PostgreSQL are the same as those in Greenplum Database, including their schemas, supported data types, and user permissions. Except for specific operations that are exclusive to Greenplum Database such as those on distribution keys and append-optimized (AO) tables, you can refer to PostgreSQL for other operations.

References

- Pivotal Greenplum Official Documentation
- GP 4.3 Best Practice

12.4.2. Create a database

After you log on to the AnalyticDB for PostgreSQL instance, you can execute SQL statements to create databases.

As in PostgreSQL, you can execute SQL statements to create databases in AnalyticDB for PostgreSQL. For example, after psql is connected to Greenplum, execute the following statements:

```
=> create database mygpdb;
CREATE DATABASE
=> \c mygpdb
psql (9.4.4, server 8.3devel)
You are now connected to database "mygpdb" as user "mygpdb".
```

12.4.3. Create a distribution key

AnalyticDB for PostgreSQL is a distributed database where data is distributed across all the data nodes. You must create distribution keys to distribute the data in AnalyticDB for PostgreSQL. Distribution keys are vital to query performance. Distribution keys are used to ensure **even data distribution**. Appropriate selection of keys can significantly improve query performance.

Specify a distribution key

In AnalyticDB for PostgreSQL, tables can be distributed across all compute nodes in hash or random mode. You must specify a distribution key when you create a table. Imported data is distributed to the specific compute node based on the hash value calculated by the distribution key.

```
=> create table vtbl(id serial, key integer, value text, shape cuboid, location geometry, comment text) distributed by (key
);
CREATE TABLE
```

If you do not specify the distribution key, AnalyticDB for PostgreSQL randomlv allocates the id field by using the round-robin algorithm. You can specify the distribution key by adding `distributed by (key)` to the table creation statement.

Rules for selecting the distribution key

- Select evenly distributed columns or multiple columns to prevent data skew.
- Select fields that are commonly used for connection operations, especially for highly concurrent statements.
- Select condition columns that feature high concurrency queries and high filterability.
- Do not use random distribution.

12.4.4. Construct data

In some test scenarios, you must construct data to fill the database.

1. Create a function that generates random strings.

```
CREATE OR REPLACE FUNCTION random_string(integer) RETURNS text AS $body$
SELECT array_to_string(array
            (SELECT substring('0123456789ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz'
                    FROM (ceil(random()*62))::int
                    FOR 1)
             FROM generate_series(1, $1)), '');
$body$
LANGUAGE SQL VOLATILE;
```

2. Create a partition key.

```
CREATE TABLE tbl(id serial, KEY integer, locate geometry, COMMENT text) distributed by (key);
```

3. Construct data.

```
INSERT INTO tbl(KEY, COMMENT, locate)
 SELECT
   KEY,
   COMMENT,
   ST_GeomFromText(locate) AS locate
 FROM
   (SELECT
     (a + 1) AS KEY,
     random_string(ceil(random() * 24)::integer) AS COMMENT,
     'POINT(' || ceil(random() * 36 + 99) || ' ' || ceil(random() * 24 + 50) || ')' AS locate
   FROM
     generate_series(0, 99999) AS a)
   AS t;
```

12.4.5. Query data

This topic describes the query statements and how to view the query plans.

Query statement sample

```
=> select * from tbl where key = 751;
| id  | key | value | shape      | locate                          | comment      |
+-----+-----+-------+------------+---------------------------------------------+--------------+
| 751 | 751 | red   | 0101000000000000000000C05B400000000000004A40 | B9hPhjeNWPqV |
(1 row)
Time: 513.101 ms
```

View a query plan

```
=> explain select * from tbl where key = 751;
Gather Motion 1:1  (slice1; segments: 1)  (cost=0.00..1519.28 rows=1 width=53)
  -> Seq Scan on tbl  (cost=0.00..1519.28 rows=1 width=53)
     Filter: key = 751
Settings:  effective_cache_size=8GB; gp_statistics_use_fkeys=on
Optimizer status: legacy query optimizer
```

12.4.6. Manage extensions

You can use extensions to expand database features. AnalyticDB for PostgreSQL enables you to manage extensions.

Supported extensions

AnalyticDB for PostgreSQL supports the following extensions:

- PostGIS: processes geographic data.
- MADlib: provides a machine learning function library.
- fuzzystrmatch: implements fuzzy match of strings.
- orafunc: provides compatibility with some Oracle functions.
- oss_ext: reads data from Object Storage Service (OSS).
- HyperLogLog: collects statistics.
- PL/Java: compiles user-defined functions (UDFs) in PL/Java.
- pgcrypto: provides cryptographic functions.
- IntArray: provides integer array-related functions, operators, and indexes.

Create an extension

Execute the following statements to create an extension:

```
CREATE EXTENSION <extension name>;
CREATE SCHEMA <schema name>;
CREATE EXTENSION IF NOT EXISTS <extension name> WITH SCHEMA <schema name>;
```

> **Note**
>
> Before you create a MADlib extension, you must create a plpythonu extension.
>
> ```
> CREATE EXTENSION plpythonu;
> CREATE EXTENSION madlib;
> ```

Delete an extension

Execute the following statements to delete an extension.

```
DROP EXTENSION <extension name>;
DROP EXTENSION IF EXISTS <extension name> CASCADE;
```

> **Note** If an object depends on an extension that you want to delete, you must add the CASCADE keyword to delete the object.

12.4.7. Manage users and permissions

This topic describes how to manage users and permissions in AnalyticDB for PostgreSQL.

Manage users

The system prompts you to specify an initial username and password when you create an instance. This initial user is the root user. After the instance is created, you can use the root user account to connect to the database. The system also creates superusers such as aurora and replicator for internal management.

You can run the `\du+` command to view the information of all the users after you connect to the database by using the client tool of PostgreSQL or Greenplum. Example:

```
postgres=> \du+
                             List of roles
 Role name  |        Attributes        | Member of | Description
------------+--------------------------+-----------+-------------
 root_user  |                          |           | rds_superuser
...
```

AnalyticDB for PostgreSQL does not provide superuser permissions, but offers a similar role, RDS_SUPERUSER, which is consistent with the permission system of ApsaraDB RDS for PostgreSQL. The root user, such as root_user in the preceding example, has the permissions of the RDS_SUPERUSER role. This permission attribute can only be identified by viewing the user description.

The root user has the following permissions:

- Create databases and users and perform actions such as LOGIN, excluding the SUPERUSER permissions.
- View and modify the data tables of other users and perform actions such as SELECT, UPDATE, DELETE, and changing owners.
- View the connection information of other users, cancel their SQL statements, and kill their connections.
- Create and delete extensions.
- Create other users with RDS_SUPERUSER permissions. Example:

```
CRATE ROLE root_user2 RDS_SUPERUSER LOGIN PASSWORD 'xyz' ;
```

Manage permissions

You can manage permissions at the database, schema, and table levels. For example, if you want to grant read permissions on a table to a user and revoke their write permissions, you can execute the following statements:

```
GRANT SELECT ON TABLE t1 TO normal_user1;
REVOKE UPDATE ON TABLE t1 FROM normal_user1;
REVOKE DELETE ON TABLE t1 FROM normal_user1;
```

12.4.8. Manage JSON data

JSON has become a basic data type in the Internet and Internet of things (IoT) fields. For more information about JSON, visit JSON official website. PostgreSQL provides full support for JSON. AnalyticDB for PostgreSQL is optimized by Alibaba Cloud to support the JSON type based on the PostgreSQL syntax.

Check whether the current version supports JSON

Execute the following statement to check whether the current version supports JSON:

```
=> SELECT '""'::json;
```

If the following output is displayed, the JSON type is supported and the instance is ready for use. If the operation fails, restart the instance.

```
 json
------
 ""
(1 row)
```

If the following output is displayed, the JSON type is not supported.

```
ERROR:  type "json" does not exist
LINE 1: SELECT '"'::json;
               ^
```

The preceding command converts data from the string type to the JSON type. PostgreSQL supports operations on JSON data based on this conversion.

JSON conversion in the database

Database operations include reading and writing. The written data is typically converted from the string type to the JSON type. The contents of a string must meet the JSON standard, such as strings, digits, arrays, and objects. Example:

String

```
=> SELECT '"hijson"'::json;
 json
-------
 "hijson"
(1 row)
```

`::` is used for explicit type conversion in PostgreSQL, Greenplum, and AnalyticDB for PostgreSQL. The database calls the input function of the JSON type during the conversion. Therefore, JSON format check is performed. Example:

```
=> SELECT '{hijson:1024}'::json;
ERROR:  invalid input syntax for type json
LINE 1: SELECT '{hijson:1024}'::json;
               ^
DETAIL:  Token "hijson" is invalid.
CONTEXT:  JSON data, line 1: {hijson...
=>
```

In the preceding example, `hijson` must be enclosed in double quotation marks (`"`) because JSON requires the KEY value to be a string. A syntax error is returned when `{hijson:1024}` is entered.

Apart from explicit type conversion, database records can also be converted to JSON.

Typically, JSON is not used for a string or a digit, but an object that contains one or more key-value pairs. AnalyticDB for PostgreSQL can support most JSON scenarios after data is converted from the string type to the object type. Example:

```
=> select row_to_json(row('{"a":"a"}', 'b'));
       row_to_json
---------------------------------
 {"f1":"{\"a\":\"a\"}","f2":"b"}
(1 row)
=> select row_to_json(row('{"a":"a"}'::json, 'b'));
     row_to_json
---------------------------
 {"f1":{"a":"a"},"f2":"b"}
(1 row)
```

You can see the differences between the string and JSON. The entire record is converted into the JSON type.

JSON data types

- Object

  The object is the most frequently used data type in JSON. Example:

```
=> select '{"key":"value"}'::json;
     json
-----------------
 {"key":"value"}
(1 row)
```

- Integer and floating point number

  JSON supports only three data types for numeric values: integer, floating-point number, and constant expression. AnalyticDB for PostgreSQL supports the three types.

```
=> SELECT '1024'::json;
 json
------
 1024
(1 row)
=> SELECT '0.1'::json;
 json
------
 0.1
(1 row)
```

  The following information is required in some special situations:

```
=> SELECT '1e100'::json;
 json
-------
 1e100
(1 row)
=> SELECT '{"f":1e100}'::json;
   json
-------------
 {"f":1e100}
(1 row)
```

  Extra-long numbers are also supported. Example:

```
=> SELECT '9223372036854775808'::json;
      json
---------------------
 9223372036854775808
(1 row)
```

- Array

```
=> SELECT '[[1,2], [3,4,5]]'::json;
      json
------------------
 [[1,2], [3,4,5]]
(1 row)
```

Operators

Operators supported by JSON

```
=> select oprname,oprcode from pg_operator where oprleft = 3114;
 oprname |       oprcode
---------+---------------------------
 ->      | json_object_field
 ->>     | json_object_field_text
 ->      | json_array_element
 ->>     | json_array_element_text
 #>      | json_extract_path_op
 #>>     | json_extract_path_text_op
(6 rows)
```

Basic usage

```
=> SELECT '{"f":"1e100"}'::json -> 'f';
 ?column?
----------
 "1e100"
(1 row)
=> SELECT '{"f":"1e100"}'::json ->> 'f';
 ?column?
----------
 1e100
(1 row)
=> select '{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}'::json#>array['f4','f6'];
 ?column?
-----------
 "stringy"
(1 row)
=> select '{"f2":{"f3":1},"f4":{"f5":99,"f6":"stringy"}}'::json#>'{f4,f6}';
 ?column?
-----------
 "stringy"
(1 row)
=> select '{"f2":["f3",1],"f4":{"f5":99,"f6":"stringy"}}'::json#>>'{f2,0}';
 ?column?
----------
 f3
(1 row)
```

JSON functions

Supported JSON functions

```
postgres=# \df *json*
                                                List of functions
  Schema   |        Name         | Result data type |                  Argument data types                   |  Type
-----------+---------------------+------------------+--------------------------------------------------------+--------
 pg_catalog | array_to_json       | json             | anyarray                                               | normal
 pg_catalog | array_to_json       | json             | anyarray, boolean                                      | normal
 pg_catalog | json_array_element  | json             | from_json json, element_index integer                  | normal
 pg_catalog | json_array_element_text | text         | from_json json, element_index integer                  | normal
 pg_catalog | json_array_elements | SETOF json       | from_json json, OUT value json                         | normal
 pg_catalog | json_array_length   | integer          | json                                                   | normal
 pg_catalog | json_each           | SETOF record     | from_json json, OUT key text, OUT value json           | normal
 pg_catalog | json_each_text      | SETOF record     | from_json json, OUT key text, OUT value text           | normal
 pg_catalog | json_extract_path   | json             | from_json json, VARIADIC path_elems text[]             | normal
 pg_catalog | json_extract_path_op | json            | from_json json, path_elems text[]                      | normal
 pg_catalog | json_extract_path_text | text          | from_json json, VARIADIC path_elems text[]             | normal
 pg_catalog | json_extract_path_text_op | text       | from_json json, path_elems text[]                      | normal
 pg_catalog | json_in             | json             | cstring                                                | normal
 pg_catalog | json_object_field   | json             | from_json json, field_name text                        | normal
 pg_catalog | json_object_field_text | text          | from_json json, field_name text                        | normal
 pg_catalog | json_object_keys    | SETOF text       | json                                                   | normal
 pg_catalog | json_out            | cstring          | json                                                   | normal
 pg_catalog | json_populate_record | anyelement      | base anyelement, from_json json, use_json_as_text boolean | no
rmal
 pg_catalog | json_populate_recordset | SETOF anyelement | base anyelement, from_json json, use_json_as_text boole
an | normal
 pg_catalog | json_recv           | json             | internal                                               | normal
 pg_catalog | json_send           | bytea            | json                                                   | normal
 pg_catalog | row_to_json         | json             | record                                                 | normal
 pg_catalog | row_to_json         | json             | record, boolean                                        | normal
 pg_catalog | to_json             | json             | anyelement                                             | normal
(24 rows)
```

Basic usage

```
=> SELECT array_to_json('{{1,5},{99,100}}'::int[]);
 array_to_json
---------------
 [[1,5],[99,100]]
(1 row)
=> SELECT row_to_json(row(1,'foo'));
   row_to_json
-----------------
 {"f1":1,"f2":"foo"}
(1 row)
=> SELECT json_array_length('[1,2,3,{"f1":1,"f2":[5,6]},4]');
 json_array_length
-------------------
                 5
(1 row)
=> select * from json_each('{"f1":[1,2,3],"f2":{"f3":1},"f4":null,"f5":99,"f6":"stringy"}') q;
 key |  value
-----+-----------
 f1  | [1,2,3]
 f2  | {"f3":1}
 f4  | null
 f5  | 99
 f6  | "stringy"
(5 rows)
=> select json_each_text('{"f1":[1,2,3],"f2":{"f3":1},"f4":null,"f5":"null"}');
 json_each_text
----------------
 (f1,"[1,2,3]")
 (f2,"{""f3"":1}")
 (f4,)
 (f5,null)
(4 rows)
=> select json_array_elements('[1,true,[1,[2,3]],null,{"f1":1,"f2":[7,8,9]},false]');
 json_array_elements
---------------------
 1
 true
 [1,[2,3]]
 null
 {"f1":1,"f2":[7,8,9]}
 false
(6 rows)
create type jpop as (a text, b int, c timestamp);
=> select * from json_populate_record(null::jpop,'{"a":"blurfl","x":43.2}', false) q;
  a   | b | c
--------+---+---
 blurfl |   |
(1 row)
=>    select * from json_populate_recordset(null::jpop,'[{"a":"blurfl","x":43.2},{"b":3,"c":"2012-01-20 10:42:53"}]',false) q;
  a   | b |         c
--------+---+--------------------------
 blurfl |   |
        | 3 | Fri Jan 20 10:42:53 2012
(2 rows)
```

Code examples

Create a table

```
create table tj(id serial, ary int[], obj json, num integer);
=> insert into tj(ary, obj, num) values('{1,5}'::int[], '{"obj":1}', 5);
INSERT 0 1
=> select row_to_json(q) from (select id, ary, obj, num from tj) as q;
           row_to_json
-------------------------------------------
 {"f1":1,"f2":[1,5],"f3":{"obj":1},"f4":5}
(1 row)
=> insert into tj(ary, obj, num) values('{2,5}'::int[], '{"obj":2}', 5);
INSERT 0 1
=> select row_to_json(q) from (select id, ary, obj, num from tj) as q;
           row_to_json
-------------------------------------------
 {"f1":1,"f2":[1,5],"f3":{"obj":1},"f4":5}
 {"f1":2,"f2":[2,5],"f3":{"obj":2},"f4":5}
(2 rows)
```

Join multiple tables

```
create table tj2(id serial, ary int[], obj json, num integer);
=> insert into tj2(ary, obj, num) values('{2,5}'::int[], '{"obj":2}', 5);
INSERT 0 1
=> select * from tj, tj2 where tj.obj->>'obj' = tj2.obj->>'obj';
 id | ary |   obj   | num | id | ary |   obj   | num
----+-------+-----------+-----+----+-------+-----------+-----
  2 | {2,5} | {"obj":2} |   5 |  1 | {2,5} | {"obj":2} |   5
(1 row)
=> select * from tj, tj2 where json_object_field_text(tj.obj, 'obj') = json_object_field_text(tj2.obj, 'obj');
 id | ary |   obj   | num | id | ary |   obj   | num
----+-------+-----------+-----+----+-------+-----------+-----
  2 | {2,5} | {"obj":2} |   5 |  1 | {2,5} | {"obj":2} |   5
(1 row)
```

Use the JSON function index

```
CREATE TEMP TABLE test_json (
    json_type text,
    obj json
);
=> insert into test_json values('aa', '{"f2":{"f3":1},"f4":{"f5":99,"f6":"foo"}}');
INSERT 0 1
=> insert into test_json values('cc', '{"f7":{"f3":1},"f8":{"f5":99,"f6":"foo"}}');
INSERT 0 1
=> select obj->'f2' from test_json where json_type = 'aa';
 ?column?
----------
 {"f3":1}
(1 row)
=> create index i on test_json (json_extract_path_text(obj, '{f4}'));
CREATE INDEX
=> select * from test_json where json_extract_path_text(obj, '{f4}') = '{"f5":99,"f6":"foo"}';
 json_type |            obj
-----------+-----------------------------------------------
 aa        | {"f2":{"f3":1},"f4":{"f5":99,"f6":"foo"}}
(1 row)
```

> **Note**
>
> JSON data cannot be used as the distribution key and does not support JSON aggregate functions.

The following example describes how to use Python to access the database:

```
#! /bin/env python
import time
import json
import psycopg2
def gpquery(sql):
  conn = None
  try:
    conn = psycopg2.connect("dbname=sanity1x2")
    conn.autocommit = True
    cur = conn.cursor()
    cur.execute(sql)
    return cur.fetchall()
  except Exception as e:
    if conn:
      try:
        conn.close()
      except:
        pass
      time.sleep(10)
    print e
  return None
def main():
  sql = "select obj from tj;"
  #rows = Connection(host, port, user, pwd, dbname).query(sql)
  rows = gpquery(sql)
  for row in rows:
    print json.loads(row[0])
if __name__ == "__main__":
  main()
```

12.4.9. Use HyperLogLog

AnalyticDB for PostgreSQL is highly optimized by Alibaba Cloud. It has the features of Greenplum Database and supports HyperLogLog. AnalyticDB for PostgreSQL is suited for industries such as Internet advertising and estimation analysis that require quick estimation of business metrics such as page views (PVs) and unique visitors (UVs).

Create a HyperLogLog extension

Execute the following statement to create a HyperLogLog extension:

```
CREATE EXTENSION hll;
```

Basic types

- Execute the following statement to create a table containing the hll field:

  ```
  create table agg (id int primary key,userids hll);
  ```

- Execute the following statement to convert int to hll_hashval:

  ```
  select 1::hll_hashval;
  ```

Basic operators

- The hll type supports =, !=,<>, ||, and #.

```
select hll_add_agg(1::hll_hashval) = hll_add_agg(2::hll_hashval);
select hll_add_agg(1::hll_hashval) || hll_add_agg(2::hll_hashval);
select #hll_add_agg(1::hll_hashval);
```

- The hll_hashval type supports =, !=,and <>.

```
select 1::hll_hashval = 2::hll_hashval;
select 1::hll_hashval <> 2::hll_hashval;
```

Basic functions

- Hash functions such as hll_hash_boolean, hll_hash_smallint, and hll_hash_bigint.

```
select hll_hash_boolean(true);
select hll_hash_integer(1);
```

- hll_add_agg: converts the int format to the hll format.

```
select hll_add_agg(1::hll_hashval);
```

- hll_union: aggregates the hll fields.

```
select hll_union(hll_add_agg(1::hll_hashval),hll_add_agg(2::hll_hashval));
```

- hll_set_defaults: sets the precision.

```
select hll_set_defaults(15,5,-1,1);
```

- hll_print: displays debugging information.

```
select hll_print(hll_add_agg(1::hll_hashval));
```

Examples

```
create table access_date (acc_date date unique, userids hll);
insert into access_date select current_date, hll_add_agg(hll_hash_integer(user_id)) from generate_series(1,10000) t(user_id);
insert into access_date select current_date-1, hll_add_agg(hll_hash_integer(user_id)) from generate_series(5000,20000) t(user_id);
insert into access_date select current_date-2, hll_add_agg(hll_hash_integer(user_id)) from generate_series(9000,40000) t(user_id);
postgres=# select #userids from access_date where acc_date=current_date;
   ?column?
------------------
 9725.85273370708
(1 row)
postgres=# select #userids from access_date where acc_date=current_date-1;
   ?column?
------------------
 14968.6596883279
(1 row)
postgres=# select #userids from access_date where acc_date=current_date-2;
   ?column?
------------------
 29361.5209149911
(1 row)
```

12.4.10. Use the CREATE LIBRARY statement

AnalyticDB for PostgreSQL introduces the CREATE LIBRARY and DROP LIBRARY statements to help you import custom software packages.

Syntax

```
CREATE LIBRARY library_name LANGUAGE [JAVA] FROM oss_location OWNER ownername
CREATE LIBRARY library_name LANGUAGE [JAVA] VALUES file_content_hex OWNER ownername
DROP LIBRARY library_name
```

Parameters

Parameter	Description
library_name	The name of the library that you want to install. If the library that you want to install has the same name as an existing library, you must delete the existing library before you install the new one.
LANGUAGE [JAVA]	The programming language that you want to use. Only PL/Java is supported.
oss_location	The location of the package. You can specify the Object Storage Service (OSS) bucket and object names. Only one object can be specified and the specified object cannot be a compressed file. Sample format: `oss://oss_endpoint filepath=[folder/[folder/]...]/file_name id=userossid key=userosskey bucket=ossbucket`
file_content_hex	The content of the file. The byte stream is in hexadecimal notation. For example, 73656c6563742031 indicates the hexadecimal byte stream of "select 1". You can use this syntax to import packages without the need to use OSS.
ownername	The user.
DROP LIBRARY	Deletes a library.

Examples

- Example 1: Install a JAR package named analytics.jar.

  ```
  create library example language java from 'oss://oss-cn-hangzhou.aliyuncs.com filepath=analytics.jar id=xxx key=yyy bucket=zzz';
  ```

- Example 2: Import the file content with the byte stream in hexadecimal notation.

  ```
  create library pglib LANGUAGE java VALUES '73656c6563742031' OWNER "myuser";
  ```

- Example 3: Delete a library.

  ```
  drop library example;
  ```

- Example 4: View installed libraries.

  ```
  select name, lanname from pg_library;
  ```

12.4.11. Create and use a PL/Java UDF

AnalyticDB for PostgreSQL allows you to compile and upload JAR software packages that are written in PL/Java language, and use these JAR packages to create user-defined functions (UDFs). AnalyticDB for PostgreSQL supports PL/Java 1.5.0 and JVM 1.8. This topic describes how to create a PL/Java UDF. For more information about PL/Java examples, see PL/Java code. For more information about the compiling method, see PL/Java documentation.

Procedure

1. In AnalyticDB for PostgreSQL, execute the following statement to create a PL/Java extension. You need only to execute the statement once for each database.

```
create extension pljava;
```

2. Compile the UDF based on your business requirements. For example, you can use the following code to compile the Test.java file:

```
public class Test
{
  public static String substring(String text, int beginIndex,
      int endIndex)
    {
      try {
        Process process = null;
        process = Runtime.getRuntime().exec("echo Test running");
      } catch (Exception e) {
        return "" + e;
      }
      return text.substring(beginIndex, endIndex);
    }
}
```

3. Compile the manifest.txt file:

```
Manifest-Version: 1.0
Main-Class: Test
Specification-Title: "Test"
Specification-Version: "1.0"
Created-By: 1.7.0_99
Build-Date: 01/20/2016 21:00 AM
```

4. Run the following commands to compile and package the program:

```
javac Test.java
jar cfm analytics.jar manifest.txt Test.class
```

5. Upload the analytics.jar file generated in Step 4 to Object Storage Service (OSS) by using the following OSS console command:

```
osscmd put analytics.jar oss://zzz
```

6. In AnalyticDB for PostgreSQL, execute the CREATE LIBRARY statement to import the file to AnalyticDB for PostgreSQL.

```
create library example language java from 'oss://oss-cn-hangzhou.aliyuncs.com filepath=analytics.jar id=xxx key=yyy bucket=zzz';
```

> **Note** You can only use the filepath variable in the CREATE LIBRARY statement to import files one at a time. The CREATE LIBRARY statement also supports byte streams to import files without the need to use OSS. For more information, see Use the CREATE LIBRARY statement.

7. In AnalyticDB for PostgreSQL, execute the following statements to create and use the UDF:

```
create table temp (a varchar) distributed randomly;
 insert into temp values ('my string');
 create or replace function java_substring(varchar, int, int) returns varchar as 'Test.substring' language java;
 select java_substring(a, 1, 5) from temp;
```

12.5. Table

12.5.1. Create a table

You can create tables within your databases.

Syntax

The following statement shows how to create a table. Not all clauses are required. Use the clauses that can fulfill your business needs.

```
CREATE [[GLOBAL | LOCAL] {TEMPORARY | TEMP}] TABLE table_name (
[ { column_namedata_type [ DEFAULT default_expr ]
  [column_constraint [ ... ]
[ ENCODING ( storage_directive [,...] ) ]
]
  | table_constraint
  | LIKE other_table [{INCLUDING | EXCLUDING}
                {DEFAULTS | CONSTRAINTS}] ...}
  [, ... ] ]
  )
  [ INHERITS ( parent_table [, ... ] ) ]
  [ WITH ( storage_parameter=value [, ... ] )
  [ ON COMMIT {PRESERVE ROWS | DELETE ROWS | DROP} ]
  [ TABLESPACE tablespace ]
  [ DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY ]
  [ PARTITION BY partition_type (column)
    [ SUBPARTITION BY partition_type (column) ]
      [ SUBPARTITION TEMPLATE ( template_spec ) ]
    [...]
  ( partition_spec )
    | [ SUBPARTITION BY partition_type (column) ]
      [...]
  ( partition_spec
   [ ( subpartition_spec
      [(...)]
     ) ]
  )
```

Definition of the column_constraint clause:

```
[CONSTRAINT constraint_name]
  NOT NULL | NULL
  | UNIQUE [USING INDEX TABLESPACE tablespace]
        [WITH ( FILLFACTOR = value )]
  | PRIMARY KEY [USING INDEX TABLESPACE tablespace]
          [WITH ( FILLFACTOR = value )]
  | CHECK ( expression )
  | REFERENCES table_name [ ( column_name [, ... ] ) ]
        [ key_match_type ]
        [ key_action ]
```

Definition of the storage_directive clause of columns:

```
COMPRESSTYPE={ZLIB | QUICKLZ | RLE_TYPE | NONE}
 [COMPRESSLEVEL={0-9} ]
 [BLOCKSIZE={8192-2097152} ]
```

Definition of the storage_parameter clause of tables:

```
APPENDONLY={TRUE|FALSE}
BLOCKSIZE={8192-2097152}
ORIENTATION={COLUMN|ROW}
CHECKSUM={TRUE|FALSE}
COMPRESSTYPE={ZLIB|QUICKLZ|RLE_TYPE|NONE}
COMPRESSLEVEL={0-9}
FILLFACTOR={10-100}
OIDS[=TRUE|FALSE]
```

Definition of the table_constraint clause:

```
[CONSTRAINT constraint_name]
UNIQUE ( column_name [, ... ] )
    [USING INDEX TABLESPACE tablespace]
    [WITH ( FILLFACTOR=value )]
| PRIMARY KEY ( column_name [, ... ] )
        [USING INDEX TABLESPACE tablespace]
        [WITH ( FILLFACTOR=value )]
| CHECK ( expression )
| FOREIGN KEY ( column_name [, ... ] )
      REFERENCES table_name [ ( column_name [, ... ] ) ]
      [ key_match_type ]
      [ key_action ]
      [ key_checking_mode ]
```

Valid values of key_match_type:

```
 MATCH FULL
| SIMPLE
```

Valid values of key_action:

```
 ON DELETE
| ON UPDATE
| NO ACTION
| RESTRICT
| CASCADE
| SET NULL
| SET DEFAULT
```

Valid values of key_checking_mode:

[ TABLESPACE tablespace ]
```

Definition of the storage_parameter clause:

```
  APPENDONLY={TRUE|FALSE}
  BLOCKSIZE={8192-2097152}
  ORIENTATION={COLUMN|ROW}
  CHECKSUM={TRUE|FALSE}
  COMPRESSTYPE={ZLIB|QUICKLZ|RLE_TYPE|NONE}
  COMPRESSLEVEL={1-9}
  FILLFACTOR={10-100}
  OIDS[=TRUE|FALSE]
```

Parameters

The Table creation parameters table describes the key parameters for creating a table.

Table creation parameters

Parameter	Description
TABLE_NAME	The name of the table that you want to create.
column_name	The name of a column that you want to create in the table.
data_type	The data type of the column. For columns that contain textual data, set the data type to VARCHAR or TEXT. We recommend that you do not use the CHAR type.
DEFAULT default_expr	Specifies a default value for the column. The system assigns this default value to all columns that do not have a value. The default value can be a variable-free expression. Subqueries or cross-references to other columns in the table are not allowed. The data type of the default expression must match the data type of the column. If a column does not have a default value, this parameter is left empty.
ENCODING storage_directive	Specifies the compression type and block size for the column data. This clause is valid only for append-optimized, column-oriented tables. Column compression settings are inherited from the table level to the partition level and then to the sub-partition level. The lowest-level settings have the highest priority.
INHERITS	Configures all columns in the new table to automatically inherit a parent table. You can use INHERITS to create a persistent relationship between the new child table and its parent table. Schema modifications to the parent table are applied to the child table as well. When the parent table is also scanned, the data of the child table is scanned as well.
LIKE other_table	Specifies a table from which the new table automatically copies all column names, data types, NOT NULL constraints, and distribution policies. Storage properties such as append-optimized or partition structure are not copied. Unlike INHERITS, the new table is completely decoupled from the original table after the new table is created.
CONSTRAINT constraint_name	Configures a column or table constraint. If a constraint is violated, the constraint name is displayed in the error message. Constraint names can be used to communicate helpful information to client applications.Constraint names that contain spaces must be enclosed by double quotation marks ('').
WITH (storage_option=value)	Configures storage options for the table or its indexes.
ON COMMIT	The operation that the system performs on the temporary tables at the end of a transaction. Valid values: • **PRESERVE ROWS**: No special action is taken. The data is retained after the transaction is complete. The data is released only when the session is disconnected. • **DELETE ROWS**: All rows in the temporary table are deleted. • **DROP**: The temporary table is deleted.
TABLESPACE tablespace	Specifies the name of the tablespace in which you want to create the new table. If this parameter is not specified, the default tablespace of the database is used.

Parameter	Description
DISTRIBUTED BY	Configures the distribution policy for the database. • DISTRIBUTED BY (column, [...]): specifies the distribution key. The system distributes data based on the distribution key. To evenly distribute data, you must set the distribution key to the primary key of the table or a unique column or a set of columns. • DISTRIBUTED RANDOMLY: randomly distributes data. Note We recommend that you do not use random distribution.
PARTITION BY	Configures a partition key to partition the table. Partitioning large tables improves data access efficiency. To partition a table is to create a top-level (parent) table and multiple lower-level (child) tables. After a partition table is created, its parent table is always empty. Data is stored in the lowest-level child tables. In a multi-level partition table, data is stored only in the lowest-level sub-partitions. Valid values: RANGE, LIST, and a combination of the two.
SUBPARTITION BY	Configures a multi-level partition table.
SUBPARTITION TEMPLATE	Specifies a sub-partition template to create sub-partitions (lower-level child tables). This ensures that all parent partitions have the same sub-partition structure.

Examples

Create a table and configure a distribution key. By default, a primary key is used as a distribution key in AnalyticDB for PostgreSQL.

```
CREATE TABLE films (
code      char(5) CONSTRAINT firstkey PRIMARY KEY,
title     varchar(40) NOT NULL,
did       integer NOT NULL,
date_prod  date,
kind      varchar(10),
len       interval hour to minute
);
CREATE TABLE distributors (
did   integer PRIMARY KEY DEFAULT nextval('serial'),
name  varchar(40) NOT NULL CHECK (name <> '')
);
```

Create a compressed table and configure a distribution key.

```
CREATE TABLE sales (txn_id int, qty int, date date)
WITH (appendonly=true, compresslevel=5)
DISTRIBUTED BY (txn_id);
```

Use sub-partition templates of each level and the default partition to create a three-level partition table.

```
CREATE TABLE sales (id int, year int, month int, day int,
region text)
DISTRIBUTED BY (id)
PARTITION BY RANGE (year)
 SUBPARTITION BY RANGE (month)
  SUBPARTITION TEMPLATE (
    START (1) END (13) EVERY (1),
    DEFAULT SUBPARTITION other_months )
 SUBPARTITION BY LIST (region)
  SUBPARTITION TEMPLATE (
    SUBPARTITION usa VALUES ('usa'),
    SUBPARTITION europe VALUES ('europe'),
    SUBPARTITION asia VALUES ('asia'),
    DEFAULT SUBPARTITION other_regions)
( START (2008) END (2016) EVERY (1),
 DEFAULT PARTITION outlying_years);
```

12.5.2. Principles and scenarios of row store, column store, heap tables, and AO tables

AnalyticDB for PostgreSQL supports row store, column store, heap tables, and append-optimized (AO) tables. This topic describes their principles and scenarios.

Row store and column store

Comparison

Dimension	Row store	Column store
Definition	Row store stores data in the form of rows. Each row is a tuple. To read a column, you must deform all of the columns that precede it. Therefore, the costs for accessing the first and the last columns are different.	Column store stores data as columns. Each column corresponds to a file or a batch of files. The cost of reading each column is the same. However, if you want to read multiple columns, you must access multiple files. The more columns you access, the higher the overheads are.
Compression ratio	Low.	High.
Cost of reading a column	The higher the column number, the higher the cost of reading the column.	Same.
Vector computing and JIT architecture	Not suitable. Not suitable for batch computing.	Suitable. More efficient when you access and collect statistics of a batch of data.

Dimension	Row store	Column store
Scenarios	If you need to perform a large number of update and delete operations due to online transaction processing (OLTP) requirements such as when you query table details where multiple columns are returned, you can use row store. You can use partition tables if you have complex requirements. For example, if you want to partition data based on time, you can use row store to query the details of recent data and use column store to obtain more statistics from historical data.	You can use column store if you need data statistics because of online analytical processing (OLAP) requirements. If you want a higher compression ratio, you can use column store.

Heap tables

A heap table is heap storage. All changes to the heap table generate redo logs that can be used to restore data by point in time. However, heap tables cannot implement logical incremental backup because all data blocks in the tables can be changed and it is inconvenient to record the position by using heap storage.

Commit and redo logs are used to ensure reliability when transactions are finished. You can also implement redundancy by using secondary nodes through redo logs.

AO tables

AO tables are used to append data for storage. When you delete the updated data, you can use another bitmap file to mark the row that you want to delete and then use the offset of the bit to determine whether the row was deleted.

When the transaction is finished, you must call the fsync() function to record the offset of the data block that performs the last write operation. Even if the data block contains only a single record, a new data block is appended for the next transaction. The data block is synchronized to the secondary node for data redundancy.

AO tables are not suitable for small transactions because the fsync() function is called at the end of each transaction. This data block is not reused even if space is left.

AO tables are suitable for OLAP scenarios, batch data writing, high compression ratio, and logical backup that supports incremental backup. During backup, you need only to record the offset from the backup and the bitmap deletion mark for each full backup.

Use scenarios of heap tables

- When multiple small transactions are handled, use a heap table.
- When you need to restore data by point in time, use a heap table.

Use scenarios of AO tables

- When you want to use column store, use an AO table.
- When data is written in batches, use an AO table.

12.5.3. Enable the column store and compression features

If you want to improve performance, speed up data import, or reduce costs for tables that have infrequent updates and multiple fields, we recommend that you use column store and compression. These features increase the compression ratio by up to threefold to ensure high performance and speed up data import.

To enable the column store and compression features, you must specify the column store and compression options when you create a table. For example, you can add the following clause to the CREATE statement to enable these features. For more information about the table creation syntax, see Create a table.

```
with (APPENDONLY=true, ORIENTATION=column, COMPRESSTYPE=zlib, COMPRESSLEVEL=5, BLOCKSIZE=1048576, OIDS=false)
```

> **Note** AnalyticDB for PostgreSQL supports only zlib and RLE_TYPE compression algorithms. If you specify the quicklz algorithm, it is automatically converted to zlib.

12.5.4. Add a field to a column store table and set the default value

This topic describes how to add a field to a column store table and set the default value for the field, and how to use the ANALYZE statement to view the impact of updated data on the size of the column store table.

Context

In a column store table, each column is stored as a file, and two columns in the same row correspond to each other by using the offset. For example, if you add two fields of the INT8 type, you can quickly locate column B from column A by using the offset.

When you add the field, AO tables are not rewritten. If an AO table contains the records of deleted data, the added field must be filled with the deleted records before using the offset.

Procedure

1. Create three AO column store tables.

```
postgres=# create table tbl1 (id int, info text) with (appendonly=true, blocksize=8192, compresstype=none, orientation=column);
NOTICE:  Table doesn't have 'DISTRIBUTED BY' clause -- Using column named 'id' as the Greenplum Database data distribution key for this table.
HINT:  The 'DISTRIBUTED BY' clause determines the distribution of data. Make sure column(s) chosen are the optimal data distribution key to minimize skew.
CREATE TABLE
postgres=# create table tbl2 (id int, info text) with (appendonly=true, blocksize=8192, compresstype=none, orientation=column);
NOTICE:  Table doesn't have 'DISTRIBUTED BY' clause -- Using column named 'id' as the Greenplum Database data distribution key for this table.
HINT:  The 'DISTRIBUTED BY' clause determines the distribution of data. Make sure column(s) chosen are the optimal data distribution key to minimize skew.
CREATE TABLE
postgres=# create table tbl3 (id int, info text) with (appendonly=true, blocksize=8192, compresstype=none, orientation=column);
NOTICE:  Table doesn't have 'DISTRIBUTED BY' clause -- Using column named 'id' as the Greenplum Database data distribution key for this table.
HINT:  The 'DISTRIBUTED BY' clause determines the distribution of data. Make sure column(s) chosen are the optimal data distribution key to minimize skew.
CREATE TABLE
```

2. Insert 10 million entries to the first two tables and 20 million entries to the third one.

```
postgres=# insert into tbl1 select generate_series(1,10000000),'test';
INSERT 0 10000000
postgres=# insert into tbl2 select generate_series(1,10000000),'test';
INSERT 0 10000000
postgres=# insert into tbl3 select generate_series(1,20000000),'test';
INSERT 0 20000000
```

3. Analyze the tables and display their sizes.

```
postgres=# analyze tbl1;
ANALYZE
postgres=# analyze tbl2;
ANALYZE
postgres=# analyze tbl3;
ANALYZE
postgres=# select pg_size_pretty(pg_relation_size('tbl1'));
 pg_size_pretty
----------------
 88 MB
(1 row)
postgres=# select pg_size_pretty(pg_relation_size('tbl2'));
 pg_size_pretty
----------------
 88 MB
(1 row)
postgres=# select pg_size_pretty(pg_relation_size('tbl3'));
 pg_size_pretty
----------------
 173 MB
(1 row)
```

4. Update all the data in the first table. Display the table size after the update. The size is twice as large as the size before the update.

```
postgres=# update tbl1 set info='test';
UPDATE 10000000
postgres=# analyze tbl1;
ANALYZE
postgres=# select pg_size_pretty(pg_relation_size('tbl1'));
 pg_size_pretty
----------------
 173 MB
(1 row)
```

5. Add fields to the three tables and set the default values.

```
postgres=# alter table tbl1 add column c1 int8 default 1;
ALTER TABLE
postgres=# alter table tbl2 add column c1 int8 default 1;
ALTER TABLE
postgres=# alter table tbl3 add column c1 int8 default 1;
ALTER TABLE
```

6. Analyze the tables and view the table sizes.

```
postgres=# analyze tbl1;
ANALYZE
postgres=# analyze tbl2;
ANALYZE
postgres=# analyze tbl3;
ANALYZE
postgres=# select pg_size_pretty(pg_relation_size('tbl1'));
 pg_size_pretty
----------------
 325 MB
(1 row)
postgres=# select pg_size_pretty(pg_relation_size('tbl2'));
 pg_size_pretty
----------------
 163 MB
(1 row)
postgres=# select pg_size_pretty(pg_relation_size('tbl3'));
 pg_size_pretty
----------------
 325 MB
(1 row)
```

When you add fields to the AO tables, the number of entries in the existing files will prevail. Even if all the entries are deleted, you must initialize the original data in the newly added fields.

12.5.5. Configure table partitions

For fact tables and large-sized tables in a database, we recommend that you configure table partitions.

Configure table partitions

You can use the table partitioning feature to add and remove data based on table partitions on a regular basis. You can use the `ALTER TABLE DROP PARTITION` statement to remove all the data in a partition, and use the `ALTER TABLE EXCHANGE PARTITION` statement to import data to a new data partition.

AnalyticDB for PostgreSQL supports range partitioning, list partitioning, and composite partitioning. Range partitioning supports only the numeric or datetime data types of fields.

The following example shows how to use range partitioning in a table:

```
CREATE TABLE LINEITEM (
L_ORDERKEY      BIGINT NOT NULL,
L_PARTKEY       BIGINT NOT NULL,
L_SUPPKEY       BIGINT NOT NULL,
L_LINENUMBER    INTEGER,
L_QUANTITY      FLOAT8,
L_EXTENDEDPRICE FLOAT8,
L_DISCOUNT      FLOAT8,
L_TAX           FLOAT8,
L_RETURNFLAG    CHAR(1),
L_LINESTATUS    CHAR(1),
L_SHIPDATE      DATE,
L_COMMITDATE    DATE,
L_RECEIPTDATE   DATE,
L_SHIPINSTRUCT  CHAR(25),
L_SHIPMODE      CHAR(10),
L_COMMENT       VARCHAR(44)
) WITH (APPENDONLY=true, ORIENTATION=column, COMPRESSTYPE=zlib, COMPRESSLEVEL=5, BLOCKSIZE=1048576, OIDS=false) DISTRIBUTED BY (l_orderkey)
PARTITION BY RANGE (L_SHIPDATE) (START (date '1992-01-01') INCLUSIVE END (date '2000-01-01') EXCLUSIVE EVERY (INTERVAL '1 month' ));
```

Principles of table partitioning

The purpose of partitioning is to minimize the amount of data to be scanned during a query. Therefore, partitions must be associated with the query conditions.

- Principle 1: Select the fields that are related to the query conditions to configure partitions and reduce the amount of data to be scanned.
- Principle 2: If multiple query conditions exist, configure sub-partitions to further reduce the amount of data to be scanned.

12.5.6. Configure the sort key

A sort key is an attribute of a table. Data on disks is stored in the order of the sort key.

Context

Sort keys have two major advantages:

- Speed up and optimize column-store operations. The min and max meta information the system collects seldom overlaps with each other, which features good filterability.
- Eliminate the need to perform ORDER BY and GROUP BY operations. The data directly read from the disk is ordered as required by the sorting conditions.

Create a table

```
Command:    CREATE TABLE
Description: define a new table
Syntax:
CREATE [[GLOBAL | LOCAL] {TEMPORARY | TEMP}] TABLE table_name (
[ { column_name data_type [ DEFAULT default_expr ]    [column_constraint [ ... ]
[ ENCODING ( storage_directive [,...] ) ]
]
  | table_constraint
  | LIKE other_table [{INCLUDING | EXCLUDING}
                {DEFAULTS | CONSTRAINTS}] ...}
  [, ... ] ]
  [column_reference_storage_directive [, ] ]
  )
  [ INHERITS ( parent_table [, ... ] ) ]
  [ WITH ( storage_parameter=value [, ... ] )
  [ ON COMMIT {PRESERVE ROWS | DELETE ROWS | DROP} ]
  [ TABLESPACE tablespace ]
  [ DISTRIBUTED BY (column, [ ... ] ) | DISTRIBUTED RANDOMLY ]
  [ SORTKEY (column, [ ... ] )]
  [ PARTITION BY partition_type (column)
     [ SUBPARTITION BY partition_type (column) ]
       [ SUBPARTITION TEMPLATE ( template_spec ) ]
     [...]
   ( partition_spec )
     | [ SUBPARTITION BY partition_type (column) ]
       [...]
   ( partition_spec
    [ ( subpartition_spec
       [(...)]
      ) ]
)
```

Examples:

```
create table test(date text, time text, open float, high float, low float, volume int) with(APPENDONLY=true,ORIENTATION
=column) sortkey (volume);
```

Sort the table

```
VACUUM SORT ONLY [tablename]
```

Modify the sort key

This statement only modifies the catalog and does not sort data. You must execute the `VACUUM SORT ONLY` statement to sort the table.

```
ALTER [[GLOBAL | LOCAL] {TEMPORARY | TEMP}] TABLE table_name SET SORTKEY (column, [ ... ] )
```

Examples:

```
alter table test set sortkey (high,low);
```

12.6. Best practices

12.6.1. Configure memory and load parameters

To improve database stability, you must configure memory and load parameters.

Background information

AnalyticDB for PostgreSQL is a massively parallel processing (MPP) database service with high computational and resource requirements. AnalyticDB for PostgreSQL consumes all of its resources. This allows AnalyticDB for PostgreSQL to reach high processing speeds but makes it very easy to reach its limits.

When CPU, network, or hard disk resources are exhausted, the worst that can occur is a hardware bottleneck. However, if all memory resources are completely consumed, the database may not respond.

How to avoid OOM errors

Out of memory (OOM) indicates that the system is unable to provide sufficient memory requested by a process. The following prompt appears when OOM errors occur:

```
Out of memory (seg27 host.example.com pid=47093) VM Protect failed to allocate 4096 bytes, 0 MB available
```

Causes

OOM errors occur due to the following causes:

- Database nodes do not have sufficient memory.
- Kernel parameters related to the memory of the operating system are incorrectly configured.
- Data skew has occurred. This causes a compute node to request a large amount of memory.
- Query skew has occurred. For example, if the grouping fields of some aggregate or window functions are not distribution keys, the data must be redistributed. After the data is redistributed, data is skewed on a specific computer node and results in the node requesting a large amount of memory.

Solutions

1. Modify the queries to request less memory.
2. Use a resource queue of AnalyticDB for PostgreSQL to limit the number of concurrent queries. Reduce the number of queries that are executed within the cluster at the same time to reduce the overall memory requested by the system.
3. Reduce the number of compute nodes deployed on a host. For example, you can deploy 8 compute nodes instead of 16 on a host that has 128 GB of memory to allow each compute node to utilize twice as much memory.
4. Increase the memory of a host.
5. Set the gp_vmem_protect_limit parameter to limit the maximum VMEM that can be used by a single compute node. The memory size of a single host and the number of compute nodes deployed on the host determine the maximum memory size that a single compute node can use on average.
6. For SQL statements that have unpredictable memory usage, you can set the statement_mem parameter in the session to limit the memory usage of a single SQL statement. This prevents a single SQL statement from consuming all available memory.
7. Set the statement_mem parameter at the database level to apply to all the sessions in the database.
8. Use the resource queue of AnalyticDB for PostgreSQL to limit the maximum memory usage of the resource group. Add database users to the resource group to limit the total memory used by these users.

Configure memory-related parameters

You can properly configure the operating system, database parameters, and resource queue to effectively reduce the probability of OOM.

When you calculate the average memory usage of a single compute node on a single host, you must consider both the primary and secondary compute nodes. If the cluster encounters a host failure, the system switches the service from primary compute nodes to the corresponding secondary compute nodes. At this time, the number of compute nodes on the host is greater than usual. Therefore, you must consider the amount of resources occupied by the secondary compute nodes during failover.

The following tables describe how to configure parameters for the operating system kernel and database to avoid OOM.

The following Operating system kernel parameters table describes the parameter configuration of the operating system kernel.

Operating system kernel parameters

Parameter	Description
huge page	Do not configure the huge page parameter of the system. AnalyticDB for PostgreSQL does not support the latest version of PostgreSQL and therefore does not support the huge page feature. The huge page parameter locks a part of the allocated memory. Database nodes are not able to use this part of the memory.
vm.overcommit_memory	If you use the swap space, set this parameter to 2. If you do not use the swap space, set this parameter to 0. Valid values: • 0: The requested memory space cannot exceed the difference between the total memory and the resident set size (RSS). An error is returned only when the memory has been exceeded. • 1: Most processes use the malloc function to request memory, but do not use all of the requested memory. When this parameter is set to 1, the memory requested by the malloc function is allocated in all circumstances unless the memory is not sufficient. • 2: The swap space is also considered when the system calculates the memory space that can be requested. You can request a large amount of memory even if the swap space is triggered.
overcommit_ratio	The larger the value is, the more memory the process can request. However, less space is reserved for the operating system. For more information about the formula that is used to calculate the memory parameters, see Examples to calculate the memory parameters. When this parameter is set to 2, the memory that can be requested cannot exceed swap + memory × overcommit_ratio.

The following Database parameters table describes the parameter configuration of the database.

Database parameters

Parameter	Description
gp_vmem_protect_limit	The maximum percentage of memory that all processes can request on each node. If the value is too large, it may result in a system OOM error or even more serious problems. If the value is too small, SQL statements may not be executed even when the system has enough memory.

Parameter	Description
runaway_detector_activation_percent	Default value: 90. Unit: %. When the amount of memory used by a compute node exceeds runaway_detector_activation_percent × gp_vmem_protect_limit/100, the query is terminated to prevent OOM. The node remains stopped until the memory usage reaches a value lower than runaway_detector_activation_percent × gp_vmem_protect_limit/100. You can use the gp_toolkit.session_level_memory_consumption view to observe the memory usage of each session and runaway information.
statement_mem	The maximum amount of memory that a single SQL statement can request. When the maximum memory is exceeded, spill files are created. Default value: 125. Unit: MB. We recommend that you set this parameter based on the following formula: `(gp_vmem_protect_limit * 0.9) / max_expected_concurrent_queries` **Note** • You can specify the statement_mem parameter in a session. If few concurrent queries exist and if the session needs to execute a query that requires a large amount of memory, you must specify this parameter in the session. • The statement_mem parameter is suitable for limiting memory usage in low concurrency scenarios. If you use statement_mem to limit the memory for high concurrency scenarios, each query is allocated with a very small amount of memory. As a result, the performance of a small number of queries with high memory requirements in high concurrency scenarios is affected. We recommend that you use the resource queue to limit the maximum memory usage in high concurrency scenarios.
gp_workfile_limit_files_per_query	The maximum number of spill files that can be created by each query. When the amount of memory requested by the query exceeds the statement_mem limit, spill files (also known as work files) are created. Spill files are similar to the swap space of the operating system. When the number of spill files used exceeds the limit, the query is terminated. The default value is 0, which indicates that an unlimited number of spill files can be created.
gp_workfile_compress_algorithm	The compression algorithm for spill files. Valid values: NONE and ZLIB. This parameter can optimize storage space or I/O by sacrificing CPU performance. You can set this parameter when the disk space is insufficient or when the spill files encounter a write bottleneck.

Examples to calculate the memory parameters

The following environment configurations are used in the examples:

- Host configuration:

```
Total RAM = 256GB
SWAP = 64GB
```

- Four hosts, each deployed with eight primary compute nodes and eight secondary compute nodes.

  When a host fails, the eight primary compute nodes are distributed to the remaining three hosts. A single host can be deployed with at most three extra primary compute nodes from the failed host. A single host can be deployed with at most 11 primary compute nodes.

1. Calculate the total memory allocated to AnalyticDB for PostgreSQL by the operating system.

   Reserve 7.5 GB and 5% of memory for the operating system and calculate the available memory for all applications. Then, divide the available memory by an empirical coefficient of 1.7.

   ```
   gp_vmem = ((SWAP + RAM) - (7.5 GB + 0.05 × RAM))/1.7
       = ((64 + 256) - (7.5 + 0.05 * 256)) / 1.7
       = 176
   ```

2. Use an empirical coefficient of 0.026 to calculate overcommit_ratio.

   ```
   vm.overcommit_ratio = (RAM - (0.026 * gp_vmem)) / RAM
               = (256 - (0.026 * 176)) / 256
               = .982
   Set vm.overcommit_ratio to 98.
   ```

3. Calculate the gp_vmem_protect_limit parameter by dividing gp_vmem by maximum_acting_primary_segments. The maximum_acting_primary_segments parameter indicates the number of primary compute nodes to be run on each other host after one host fails.

   ```
   gp_vmem_protect_limit calculation
   gp_vmem_protect_limit = gp_vmem / maximum_acting_primary_segments
                = 176 / 11
                = 16GB
                = 16384MB
   ```

Configure resource queues

You can use resource queues of AnalyticDB for PostgreSQL to limit the number of concurrent queries and the total memory usage. When a query is being executed, it is added to the corresponding queue and the resources used are recorded in the queue. The resource limit of the queue is applied to all sessions in the queue.

The resource queue in AnalyticDB for PostgreSQL is similar to cgroup in Linux.

The following syntax demonstrates how to create a resource queue:

```
Command:    CREATE RESOURCE QUEUE
Description: create a new resource queue for workload management
Syntax:
CREATE RESOURCE QUEUE name WITH (queue_attribute=value [, ... ])
where queue_attribute is:
  ACTIVE_STATEMENTS=integer
     [ MAX_COST=float [COST_OVERCOMMIT={TRUE|FALSE}] ]
     [ MIN_COST=float ]
     [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
     [ MEMORY_LIMIT='memory_units' ]
| MAX_COST=float [ COST_OVERCOMMIT={TRUE|FALSE} ]
     [ ACTIVE_STATEMENTS=integer ]
     [ MIN_COST=float ]
     [ PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX} ]
     [ MEMORY_LIMIT='memory_units' ]
```

The Resource queue creation parameters table describes the parameters for creating the resource queue.

Resource queue creation parameters

Parameter	Description
ACTIVE_STATEMENTS	The number of SQL statements that can be concurrently executed (in the active state). A value of -1 indicates that an unlimited number of SQL statements can be concurrently executed.

MEMORY_LIMIT 'memory_units kB, MB or GB'	The maximum memory usage allowed by all SQL statements in the resource queue. A value of -1 indicates unlimited memory usage. However, it is easy to trigger OOM errors because it is limited by the database or system parameters mentioned in the preceding sections.
	The memory usage of SQL statements is limited by resource queues and parameters.
	• When the gp_resqueue_memory_policy parameter is set to none, the limit is the same as that in Greenplum Database earlier than version 4.1.
	• When the gp_resqueue_memory_policy parameter is set to auto and you have specified the statement_mem parameter for a session or at the database level, the allowed memory of a single query exceeds the MEMORY_LIMIT value of the resource queue.
	Example:
	`=> SET statement_mem='2GB';`
	`=> SELECT * FROM my_big_table WHERE column='value' ORDER BY id;`
	`=> RESET statement_mem;`
	• The system parameter max_statement_mem can limit the maximum memory usage at the compute node level. The memory requested by a single query cannot exceed max_statement_mem.
	You can modify the statement_mem parameter at the session level, but do not modify the max_statement_mem parameter. We recommend that you specify max_statement_mem in the following formula:
	`(seghost_physical_memory) / (average_number_concurrent_queries)`
	• When the gp_resqueue_memory_policy parameter is set to eager_free, the database allocates the memory by stages. For example, if a query requests 1 GB of memory in total but needs only 100 MB during each stage, the database allocates 100 MB of memory to the query. You can use eager_free to reduce the possibility of insufficient memory for the query.

MAX_COST float	The maximum cost of the queries that can be concurrently executed by the resource group. The cost is the estimated total cost in the SQL execution plan. The value of the parameter can be specified as a floating-point number such as 100.0 or an exponent such as 1e+2. A value of -1 indicates that the cost is unlimited.
COST_OVERCOMMIT boolean	Specifies whether the limit of max_cost can be exceeded when the system is idle. A value of TRUE indicates that the limit can be exceeded.
MIN_COST float	When the resources requested exceed the limit, the queries are queued. However, if the cost of a query is lower than the min_cost value, the query can be executed without queuing.

Parameter	Description
PRIORITY={MIN|LOW|MEDIUM|HIGH|MAX}	The priority of the current resource queue. When resources are insufficient, CPU resources are allocated to the resource queue that has a higher priority. The SQL statements in the resource queue that has a higher priority can obtain CPU resources first. We recommend that you allocate users that initiate queries that have high real-time requirements to resource queues that have a higher priority. This parameter is similar to the time slice policy that is used in CPU resource groups in a Linux cgroup to schedule real-time and common tasks.

Example of modifying resource queue limits:

```
ALTER RESOURCE QUEUE myqueue WITH (MAX_COST=-1.0, MIN_COST= -1.0);
```

Example of putting a user in a resource queue:

```
ALTER ROLE sammy RESOURCE QUEUE poweruser;
```

The following table describes the parameters of resource queues.

Resource queue parameters

Parameter	Description
gp_resqueue_memory_policy	The memory management policy of the resource queue.
gp_resqueue_priority	Specifies whether to enable query prioritization. Valid values: • On • Off If this parameter is disabled, the existing priority settings are not evaluated.
gp_resqueue_priority_cpucores_per_segment	The number of CPU cores allocated to each compute node. For example, if an 8-core host is configured with two primary compute nodes, you can set the parameter to 4. If no other nodes exist on the primary node, set the parameter to 8. When the CPU is preempted, the SQL statements that are executed in a higher-priority resource group are allocated with CPU resources first.
gp_resqueue_priority_sweeper_interval	The interval at which CPU utilization is recalculated for all active statements. The share value is calculated when the SQL statement is executed. You can calculate the share value based on the priority and gp_resqueue_priority_cpucores_per_segment. The smaller the value and the more frequent the calculation, the better the result brought by the priority settings and the larger the overhead.

Tips for configuring resource queues:

- We recommend that you create a resource queue for each user.

  The default resource queue of AnalyticDB for PostgreSQL is pg_default. If no queue is created, all users are assigned to pg_default. This operation is not recommended. We recommend that you create a resource queue for each user. Typically, a database user corresponds to a business. Different database users may correspond to different businesses or users, such as business users, analysts, developers, and DBAs.

- We recommend that you do not use superusers to execute queries.

  Queries initiated by superusers are limited only by the preceding parameters and not by the resource queue. We recommend that you do not use superusers to execute queries if you want to use resource queues to limit the use of resources.

- ACTIVE_STATEMENTS indicates the SQL statements that can be concurrently executed within a resource queue. When the cost of a query is lower than the minimum cost specified by min_cost, the query can be executed without being queued.
- You can specify the MEMORY_LIMIT parameter to set the allowed maximum memory usage of all the SQL statements in a resource queue. The statement_mem parameter has a higher priority that can break through the limit of resource queues.

  > **Note** The memory of all resource queues cannot exceed gp_vmem_protect_limit.

- You can distinguish businesses by configuring the priorities of resource queues.

  For example, the report-related business has a top priority, while common businesses and analysts have lower priorities. In this case, you can create three resource queues that have the max, high, and medium priorities, respectively.

- If the number of resources requested at different periods of time varies, you can run the crontab command to periodically adjust the limits of resource queues based on usage patterns.

  For example, the queue of analysts has a top priority during the day, while the queue of the report-related business has a lower priority at night. AnalyticDB for PostgreSQL does not allow you to configure resource limits by period of time. Therefore, you can only externally deploy tasks by using the ALTER RESOURCE QUEUE statement.

- You can use the view provided by gp_toolkit to view the resource usage of the resource queues.

  ```
  gp_toolkit.gp_resq_activity
  gp_toolkit.gp_resq_activity_by_queue
  gp_toolkit.gp_resq_priority_backend
  gp_toolkit.gp_resq_priority_statement
  gp_toolkit.gp_resq_role
  gp_toolkit.gp_resqueue_status
  ```

13.KVStore for Redis

13.1. What is KVStore for Redis?

KVStore for Redis is a database service that is compatible with Redis-native protocols. KVStore for Redis provides a highly available hot standby architecture and can scale to meet the requirements of high-performance and low-latency read/write operations.

Features

- KVStore for Redis supports various data types, such as strings, lists, sets, sorted sets, hash tables, and streams. This service also supports advanced features, such as transactions, message subscription, and message publishing.
- KVStore for Redis Enhanced Edition (Tair), which is a key-value pair cloud caching service, is an advanced version of KVStore for Redis Community Edition.

Instance type

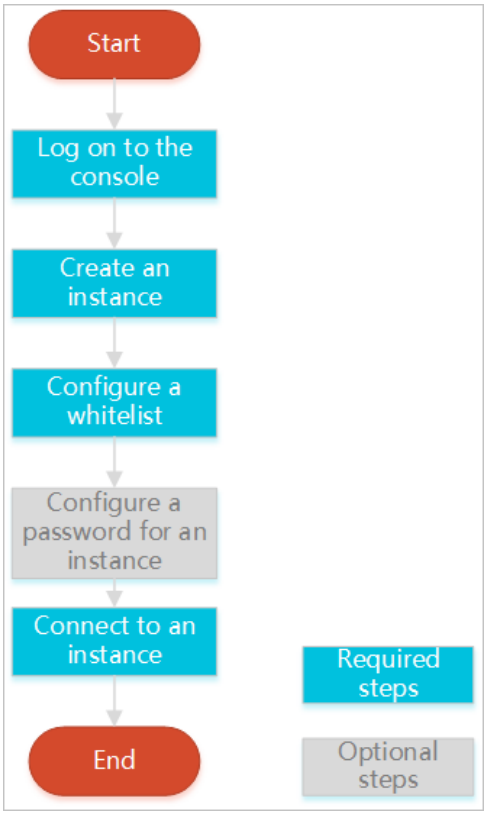
Instance type	Overview
Community Edition	KVStore for Redis Community Edition is compatible with the data caching service of Redis-native engines. This service supports master-replica instances and cluster instances.
Performance-enhanced instances of KVStore for Redis Enhanced Edition (Tair)	KVStore for Redis Enhanced Edition (Tair) provides a multi-threading model and integrates some features of Alibaba Tair. KVStore for Redis Enhanced Edition (Tair) supports multiple data structures of Tair and is suitable for diverse scenarios.

13.2. Quick Start

13.2.1. Get started with KVStore for Redis

This topic describes all operations that you can perform on an instance from instance creation to database logon. This topic helps you understand how to create and manage an instance.

The following figure shows how to manage a KVStore for Redis instance.



- Log on to the KVStore for Redis console

  This topic describes how to log on to the KVStore for Redis console.

- Create an instance

  KVStore for Redis supports classic networks and virtual private clouds (VPCs). You can create KVStore for Redis instances in these networks.

- Configure a whitelist

  Before you use a KVStore for Redis instance, add IP addresses or CIDR blocks that are used to access the database to the whitelist of the instance to improve the security and stability of the database.

- If you do not specify a password when you create the instance, specify a password on the **Instance Information** page.

- Connect to a KVStore for Redis instance

  To connect to the KVStore for Redis instance, you can use a client that supports Redis protocols or use the Redis command-line interface (redis-cli) tool.

13.2.2. Log on to the KVStore for Redis console

This topic describes how to log on to the KVStore for Redis console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

Obtain the username and password that you can use to log on to the console from the operations administrator.

> **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
>
> - Uppercase or lowercase letters
> - Digits
> - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, choose **Products > KVStore for Redis**.

13.2.3. Create a KVStore for Redis instance

This topic describes how to create a KVStore for Redis instance in the KVStore for Redis console.

Procedure

1. Log on to the KVStore for Redis console.
2. Click **Create Instance** in the upper-right corner of the page.
3. Set the following parameters.

   KVStore for Redis instance parameters

Section	Parameter	Description
Basic Settings	Organization	Select the organization to which the KVStore for Redis instance that you want to create belongs.
	Resource Set	Select the resource set to which the instance belongs. **Notice** After you select a resource set, the instance is accessible only to the members of the specified resource set.
Region	Region	Select the region to which the instance belongs.
	Zone	Select the zone to which the instance belongs.
Specifications	Engine Version	Select the engine version of the KVStore for Redis instance that you want to create.
	Architecture Type	Select the architecture type of the instance. KVStore for Redis provides cluster and standard architectures. The cluster architecture is applicable to scenarios that require a large capacity or high performance. Redis-native databases run in a single-threading model. If your database does not require high performance, we recommend that you use a standard instance. If your database requires high performance, select a cluster architecture.
	Node Type	**Master-replica** is automatically selected. The node type has one master node and one replica node.

Section	Parameter	Description
	Instance Type	Select the specification of the instance. The maximum number of connections and maximum internal bandwidth vary based on the instance specification. For more information, see *Instance specifications* in *Product Introduction*.
Network	**Network Type**	◦ Classic network: Cloud services in a classic network are not isolated. Unauthorized access to a cloud service is blocked by security groups or the service whitelist. ◦ VPC: A virtual private cloud (VPC) helps you build an isolated network environment on Apsara Stack. You can customize the route table, CIDR block, and gateway of a VPC. You can also migrate applications to the cloud without service interruption. You can use an Express Connect circuit or VPN to connect data centers to cloud resources in a VPC. **Note** Before you can select VPC, you must create a VPC. For more information, see *Create a VPC* and *Create a vSwitch* in *VPC User Guide*.
Password	**Instance Name**	Enter a name that can help you identify the instance. ◦ The name must be 2 to 128 characters in length. ◦ The name can contain letters, digits, underscores (_), and hyphens (-). The name must start with a letter.
	Password Setting	You can select **Set Now** or **Set after Purchase**.
	Logon Password	Enter a password to access the instance. The password must meet the following requirements: ◦ The password must be 8 to 30 characters in length. ◦ The password must contain uppercase letters, lowercase letters, and digits. The password must not contain special characters.
	Confirm Password	Enter the specified password again.

4. After you configure the parameters, click **Submit**.

13.2.4. Configure a whitelist

Before you use a KVStore for Redis instance, add IP addresses or CIDR blocks that are used to access the database to the whitelist of the instance to improve the security and stability of the database.

Context

Note A properly configured whitelist can ensure a higher level of security protection for your KVStore for Redis instance. We recommend that you maintain the whitelist on a regular basis.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.

3. In the left-side navigation pane, click **Whitelist Settings**.
4. Find the IP address whitelist that you want to manage and click **Modify**.

> **Note** You can also click **Add Whitelist** to create an IP address whitelist. The name of the IP address whitelist must be 2 to 32 characters in length and can contain lowercase letters, digits, and underscores (_). The name of the whitelist must start with a lowercase letter and end with a lowercase letter or digit.

5. In the dialog box that appears, perform one of the following operations:

Action	Procedure
Manually modify the IP address whitelist	Enter IP addresses or CIDR blocks. Manually modify the IP address whitelist  **Note** ◦ Separate multiple IP addresses with commas (,). You can add up to 1,000 unique IP addresses. Supported formats are specific IP addresses such as 10.23.12.24 and CIDR blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix. An IP address prefix can be 1 to 32 bits in length. ◦ If you set the prefix length to 0, for example, 0.0.0.0/0 or 127.0.0.1/0, all IP addresses are allowed to access the instance. In this case, the security risk of your instance is high. Proceed with caution.

Action	Procedure
Add private IP addresses of ECS instances to an IP address whitelist	i. Click **Load ECS Internal Network IP**. ii. Select IP addresses based on your business requirements. Add private IP addresses of ECS instances  **Note** To find the ECS instance to which a specific IP address is assigned, you can move the pointer over the IP address. Then, the system displays the ID and name of the ECS instance to which the IP address is assigned.
Remove IP addresses from the IP address whitelist	To remove all IP addresses from the IP address whitelist and retain the IP address whitelist, click **Delete**.

6. Then, click **OK**.

13.2.5. Connect to an instance

13.2.5.1. Use a Redis client

KVStore for Redis is compatible with open source Redis. You can connect to KVStore for Redis and open source Redis in a similar manner. Therefore, you can use a client that is compatible with the Redis protocols to connect to KVStore for Redis. You can connect to a KVStore for Redis instance by using clients of different programming languages.

Prerequisites

The private IP address of an Elastic Compute Service (ECS) instance or the public IP address of an on-premises machine is added to a whitelist of the instance. For more information, see Configure a whitelist.

Obtain connection information

When you use a client to connect to a KVStore for Redis instance, you must obtain the following information and specify the information in the code:

Information	Description

Information	Description
Endpoint	You can find the endpoint in the **Connection Information** section on the **Instance Information** page. **Note** KVStore for Redis instances support multiple types of endpoints. We recommend that you use endpoints in a VPC for higher security and lower network latency.
Port number	The default port number is 6379.
The account of the instance. This parameter is not required by some clients.	By default, a KVStore for Redis instance provides a database account that is named after the instance ID, such as, r-bp10noxlhcoim2****.
The password of the account.	If you forget your password, you can reset the password. For more information, see Change the password.

Commonly used clients

For the list of clients supported by Redis, see Redis clients.

- Jedis client
- PhpRedis client
- Redis-py client
- C or C++ client
- .NET client
- Node-redis client
- C# client StackExchange.Redis

Jedis client

1. Download and install the Jedis client. For more information, see Jedis.
2. Select a connection method to meet your business requirements.
   - JedisPool-based connection: This connection method is recommended.
     a. Launch the Eclipse client, create a project, and then configure the following pom file:

```
<dependency>
<groupId>redis.clients</groupId>
<artifactId>jedis</artifactId>
<version>2.7.2</version>
<type>jar</type>
<scope>compile</scope>
</dependency>
```

b. Enter the following code in the project to add the relevant applications:

```
import org.apache.commons.pool2.PooledObject;
import org.apache.commons.pool2.PooledObjectFactory;
import org.apache.commons.pool2.impl.DefaultPooledObject;
import org.apache.commons.pool2.impl.GenericObjectPoolConfig;
import redis.clients.jedis.HostAndPort;
import redis.clients.jedis.Jedis;
import redis.clients.jedis.JedisPool;
import redis.clients.jedis.JedisPoolConfig;
```

c. Enter the following code in the project based on the Jedis client version and modify the code based on the comments.

> **Note** For more information about how to obtain the connection endpoint and password of the KVStore for Redis instance, see Obtain connection information.

- Jedis 2.7.2

```
JedisPoolConfig config = new JedisPoolConfig();
//Maximum number of idle connections. You can configure this parameter. Make sure that the specified val
ue does not exceed the maximum number of connections that the KVStore for Redis instance supports.
config.setMaxIdle(200);
//Maximum number of connections. You can configure this parameter. Make sure that the specified value
does not exceed the maximum number of connections that the KVStore for Redis instance supports.
config.setMaxTotal(300);
config.setTestOnBorrow(false);
config.setTestOnReturn(false);
String host = "*.aliyuncs.com";
String password = "Password";
JedisPool pool = new JedisPool(config, host, 6379, 3000, password);
Jedis jedis = null;
try {
jedis = pool.getResource();
/// ... do stuff here ... for example
jedis.set("foo", "bar");
String foobar = jedis.get("foo");
jedis.zadd("sose", 0, "car");
jedis.zadd("sose", 0, "bike");
Set<String> sose = jedis.zrange("sose", 0, -1);
} finally {
if (jedis != null) {
jedis.close();
}
}
/// ... when closing your application:
pool.destroy();
```

- Jedis 2.6 or Jedis 2.5

```
JedisPoolConfig config = new JedisPoolConfig();
//Maximum number of idle connections. You can configure this parameter. Make sure that the specified value does not exceed the maximum number of connections that the KVStore for Redis instance supports.
config.setMaxIdle(200);
//Maximum number of connections. You can configure this parameter. Make sure that the specified value does not exceed the maximum number of connections that the KVStore for Redis instance supports.
config.setMaxTotal(300);
config.setTestOnBorrow(false);
config.setTestOnReturn(false);
String host = "*.aliyuncs.com";
String password = "Password";
JedisPool pool = new JedisPool(config, host, 6379, 3000, password);
Jedis jedis = null;
boolean broken = false;
try {
   jedis = pool.getResource();
   /// ... do stuff here ... for example
   jedis.set("foo", "bar");
   String foobar = jedis.get("foo");
   jedis.zadd("sose", 0, "car");
   jedis.zadd("sose", 0, "bike");
   Set<String> sose = jedis.zrange("sose", 0, -1);
}
catch(Exception e)
{
   broken = true;
} finally {
if (broken) {
   pool.returnBrokenResource(jedis);
} else if (jedis != null) {
   pool.returnResource(jedis);
 }
}
```

- Single Jedis connection: This connection method does not allow a client to automatically reconnect to the KVStore for Redis instance after a connection times out. Therefore, this connection is not recommended.

  Launch the Eclipse client, create a project, enter the following code, and then modify the code based on the comments.

  > **Note** For more information about how to obtain the connection endpoint and password of the KVStore for Redis instance, see Obtain connection information.

```
import redis.clients.jedis.Jedis;
public class jedistest {
public static void main(String[] args) {
try {
   String host = "xx.kvstore.aliyuncs.com";//You can find the connection address in the console.
   int port = 6379;
   Jedis jedis = new Jedis(host, port);
   //Authentication information.
   jedis.auth("password");//password
   String key = "redis";
   String value = "aliyun-redis";
   //Select a database. Default value: 0.
   jedis.select(1);
   //Specify a key.
   jedis.set(key, value);
   System.out.println("Set Key " + key + " Value: " + value);
   //Obtain the configured key and value.
   String getvalue = jedis.get(key);
   System.out.println("Get Key " + key + " ReturnValue: " + getvalue);
   jedis.quit();
   jedis.close();
}
catch (Exception e) {
 e.printStackTrace();
 }
}
}
```

3. Run the project. If Eclipse returns the following result, it indicates that the client is connected to the KVStore for Redis instance.

```
Set Key redis Value aliyun-redis
Get Key redis ReturnValue aliyun-redis
```

PhpRedis client

1. Download and install the PhpRedis client. For more information, see PhpRedis.
2. Enter the following code in a PHP editor and modify the code based on the comments.

> **Note** For more information about how to obtain the connection address, account, and password of the KVStore for Redis instance, see Obtain connection information.

```
<?php
 /* Replace the parameter values with the endpoint and port number of the instance. */
 $host = "r-bp10noxlhcoim2****.redis.rds.aliyuncs.com";
 $port = 6379;
 /* Replace the following parameter values with the ID and password of the instance. */
 $user = "test_username";
 $pwd = "test_password";
 $redis = new Redis();
 if ($redis->connect($host, $port) == false) {
     die($redis->getLastError());
  }
 if ($redis->auth($pwd) == false) {
     die($redis->getLastError());
 }
  /* You can manage the database after you pass the authentication. For more information, visit https://github.com/
phpRedis/phpredis. */
 if ($redis->set("foo", "bar") == false) {
     die($redis->getLastError());
 }
 $value = $redis->get("foo");
 echo $value;
 ?>
```

3. Run the preceding code to connect to the instance.

   For more information, see PhpRedis.

Redis-py client

1. Download and install the redis-py client. For more information, see redis-py.
2. Enter the following code in a Python editor and modify the code based on the comments.

   > **Note** For more information about how to obtain the connection endpoint and password of the KVStore for Redis instance, see Obtain connection information.

```
#!/usr/bin/env python
#-*- coding: utf-8 -*-
import redis
#Replace the value of the host parameter with the endpoint of the instance and replace the value of the port param
eter with the port number.
host = 'localhost'
port = 6379
#Replace the following parameter value with the password of the instance.
pwd = 'test_password'
r = redis.StrictRedis(host=host, port=port, password=pwd)
#You can perform database operations after you establish a connection. For more information, visit https://github.
com/andymccurdy/redis-py.
r.set('foo', 'bar');
print r.get('foo')
```

3. Run the preceding code to connect to the instance.

C or C++ client

1. Run the following commands to download, compile, and install the C client:

```
git clone https://github.com/redis/hiredis.git
cd hiredis
make
sudo make install
```

2. Enter the following code in a C or C ++ editor and modify the code based on the comments.

> **Note** For more information about how to obtain the connection endpoint and password of the KVStore for Redis instance, see Obtain connection information.

```
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <hiredis.h>
int main(int argc, char **argv) {
unsigned int j;
redisContext *c;
redisReply *reply;
if (argc < 4) {
    printf("Usage: example xxx.kvstore.aliyuncs.com 6379 instance_id password\n");
    exit(0);
}
const char *hostname = argv[1];
const int port = atoi(argv[2]);
const char *instance_id = argv[3];
const char *password = argv[4];
struct timeval timeout = { 1, 500000 }; // 1.5 seconds
c = redisConnectWithTimeout(hostname, port, timeout);
if (c == NULL || c->err) {
if (c) {
    printf("Connection error: %s\n", c->errstr);
    redisFree(c);
} else {
    printf("Connection error: can't allocate redis context\n");
}
exit(1);
}
/* AUTH */
reply = redisCommand(c, "AUTH %s", password);
printf("AUTH: %s\n", reply->str);
freeReplyObject(reply);
/* PING server */
reply = redisCommand(c,"PING");
printf("PING: %s\n", reply->str);
freeReplyObject(reply);
/* Set a key */
reply = redisCommand(c,"SET %s %s", "foo", "hello world");
printf("SET: %s\n", reply->str);
freeReplyObject(reply);
/* Set a key using binary safe API */
reply = redisCommand(c,"SET %b %b", "bar", (size_t) 3, "hello", (size_t) 5);
printf("SET (binary API): %s\n", reply->str);
freeReplyObject(reply);
/* Try a GET and two INCR */
reply = redisCommand(c,"GET foo");
printf("GET foo: %s\n", reply->str);
freeReplyObject(reply);
reply = redisCommand(c,"INCR counter");
printf("INCR counter: %lld\n", reply->integer);
```

```
freeReplyObject(reply);
/* again ... */
reply = redisCommand(c,"INCR counter");
printf("INCR counter: %lld\n", reply->integer);
freeReplyObject(reply);
/* Create a list of numbers, from 0 to 9 */
reply = redisCommand(c,"DEL mylist");
freeReplyObject(reply);
for (j = 0; j < 10; j++) {
    char buf[64];
    snprintf(buf,64,"%d",j);
    reply = redisCommand(c,"LPUSH mylist element-%s", buf);
    freeReplyObject(reply);
  }
/* Let's check what we have inside the list */
reply = redisCommand(c,"LRANGE mylist 0 -1");
if (reply->type == REDIS_REPLY_ARRAY) {
    for (j = 0; j < reply->elements; j++) {
    printf("%u) %s\n", j, reply->element[j]->str);
}
}
freeReplyObject(reply);
/* Disconnects and frees the context */
redisFree(c);
return 0;
}
```

3. Compile the code.

```
gcc -o example -g example.c -I /usr/local/include/hiredis -lhiredis
```

4. Perform a test run and connect to the instance.

```
example xxx.kvstore.aliyuncs.com 6379 instance_id password
```

.NET client

Warning If you need to switch or select a database from multiple databases in a cluster instance, you must set the cluster_compat_enable parameter to *0* and restart the client application. This disables the support for the cluster syntax of open source Redis. Otherwise, the system sends the following error message: `Multiple databases are not supported on this server; cannot switch to database` . For more information, see Parameter configuration.

1. Run the following command to download the .NET client.

```
git clone https://github.com/ServiceStack/ServiceStack.Redis
```

2. Create a .NET project on the .NET client.
3. Add a reference. The reference file is stored in the library file directory ServiceStack.Redis/lib/tests.
4. Enter the following code in the .NET project and modify the code based on the comments. For more information, see ServiceStack.Redis.

Note For more information about how to obtain the connection endpoint and password of the KVStore for Redis instance, see Obtain connection information.

```
using System;
 using System.Collections.Generic;
 using System.Linq;
```

```
using System.Text;
using System.Threading.Tasks;
using ServiceStack.Redis;
namespace ServiceStack.Redis.Tests
{
    class Program
{
public static void RedisClientTest()
{
    string host = "127.0.0.1";/*The endpoint of the host.*/
    string password = "password";/*The password*/
    RedisClient redisClient = new RedisClient(host, 6379, password);
    string key = "test-aliyun";
    string value = "test-aliyun-value";
    redisClient.Set(key, value);
    string listKey = "test-aliyun-list";
    System.Console.WriteLine("set key " + key + " value " + value);
    string getValue = System.Text.Encoding.Default.GetString(redisClient.Get(key));
    System.Console.WriteLine("get key " + getValue);
    System.Console.Read();
}
public static void RedisPoolClientTest()
{
    string[] testReadWriteHosts = new[] {
    "redis://password@127.0.0.1:6379"/* redis://password@endpoint:port */
};
RedisConfig.VerifyMasterConnections = false;//Required.
PooledRedisClientManager redisPoolManager = new PooledRedisClientManager(10/*Number of connection pools*/
, 10/*Connection pool timeout value*/, testReadWriteHosts);
for (int i = 0; i < 100; i++){
    IRedisClient redisClient = redisPoolManager.GetClient();//Obtain the connection.
    RedisNativeClient redisNativeClient = (RedisNativeClient)redisClient;
    redisNativeClient.Client = null;//KVStore for Redis does not support the CLIENT SETNAME command. Set Client t
o null.
try
{
    string key = "test-aliyun1111";
    string value = "test-aliyun-value1111";
    redisClient.Set(key, value);
    string listKey = "test-aliyun-list";
    redisClient.AddItemToList(listKey, value);
    System.Console.WriteLine("set key " + key + " value " + value);
    string getValue = redisClient.GetValue(key);
    System.Console.WriteLine("get key " + getValue);
    redisClient.Dispose();//
}catch (Exception e)
{
    System.Console.WriteLine(e.Message);
}
}
    System.Console.Read();
}
static void Main(string[] args)
{
    //Single-connection mode.
    RedisClientTest();
    //Connection-pool mode.
    RedisPoolClientTest();
}
}
```

```
}
```

Node-redis client

1. Download and install the node-redis client.

   ```
   npm install hiredis redis
   ```

2. Enter the following code in the node-redis client and modify the code based on the comments.

   > **Note** For more information about how to obtain the connection endpoint and password of the KVStore for Redis instance, see Obtain connection information.

   ```
   var redis = require("redis"),
   client = redis.createClient(<port>, <"host">, {detect_buffers: true});
   client.auth("password", redis.print)
   ```

   Parameters:

   - <port>: the service port number of the KVStore for Redis database. The default port number is 6379.
   - <"host">: the endpoint of the KVStore for Redis instance.

   Configuration examples:

   ```
   var redis = require("redis"),
   client = redis.createClient(6379, "r-abcdefg.redis.rds.aliyuncs.com", {detect_buffers: true});
   client.auth("password", redis.print)
   ```

3. Run the preceding code to connect to the KVStore for Redis instance.
4. Use KVStore for Redis.

   ```
   //Write data to the instance.
   client.set("key", "OK");
   //Query data on the instance. The returned data is of the STRING type.
   client.get("key", function (err, reply) {
   console.log(reply.toString()); // print `OK`
   });
   //If the input parameter is a buffer, the returned value is also a buffer.
   client.get(new Buffer("key"), function (err, reply) {
   console.log(reply.toString()); // print `<Buffer 4f 4b>`
   });
   client.quit();
   ```

C# client StackExchange.Redis

> **Warning** If you need to switch or select a database from multiple databases in a cluster instance, you must set the cluster_compat_enable parameter to *0* and restart the client application. This disables the support for the cluster syntax of open source Redis. Otherwise, the system sends the following error message: `RedisCommandException: Multiple databases are not supported on this server; cannot switch to database: 1`. For more information, see Parameter configuration.

1. Download and install the StackExchange.Redis client.
2. Add a reference.

   ```
   using StackExchange.Redis;
   ```

3. Initialize ConnectionMultiplexer.

ConnectionMultiplexer is the core of StackExchange.Redis and is shared and reused in the entire application. You must use ConnectionMultiplexer as a singleton. ConnectionMultiplexer is initialized in the following method:

> **Note**
> - For more information about how to obtain the connection endpoint and password of the KVStore for Redis instance, see .
> - ConfigurationOptions contains multiple options, such as keepAlive, connectRetry, and name. For more information, see ConfigurationOptions.

```
// redis config
private static ConfigurationOptions configurationOptions = ConfigurationOptions.Parse("127.0.0.1:6379,password
=xxx,connectTimeout=2000");
 //the lock for singleton
private static readonly object Locker = new object();
 //singleton
private static ConnectionMultiplexer redisConn;
//singleton
public static ConnectionMultiplexer getRedisConn()
{
  if (redisConn == null)
  {
    lock (Locker)
    {
      if (redisConn == null || !redisConn.IsConnected)
      {
        redisConn = ConnectionMultiplexer.Connect(configurationOptions);
      }
    }
  }
  return redisConn;
}
```

4. GetDatabase() returns a lightweight object. You can obtain this object from the object of ConnectionMultiplexer.

```
redisConn = getRedisConn();
var db = redisConn.GetDatabase();
```

5. You can use the client to perform database operations.

> **Note** The following examples describe the commands for common data types. These commands are slightly different from the Redis-native commands.

   - String

```
//set get
string strKey = "hello";
string strValue = "world";
bool setResult = db.StringSet(strKey, strValue);
Console.WriteLine("set " + strKey + " " + strValue + ", result is " + setResult);
//incr
string counterKey = "counter";
long counterValue = db.StringIncrement(counterKey);
Console.WriteLine("incr " + counterKey + ", result is " + counterValue);
//expire
db.KeyExpire(strKey, new TimeSpan(0, 0, 5));
Thread.Sleep(5 * 1000);
Console.WriteLine("expire " + strKey + ", after 5 seconds, value is " + db.StringGet(strKey));
//mset mget
KeyValuePair<RedisKey, RedisValue> kv1 = new KeyValuePair<RedisKey, RedisValue>("key1", "value1");
KeyValuePair<RedisKey, RedisValue> kv2 = new KeyValuePair<RedisKey, RedisValue>("key2", "value2");
db.StringSet(new KeyValuePair<RedisKey, RedisValue>[] {kv1,kv2});
RedisValue[] values = db.StringGet(new RedisKey[] {kv1.Key, kv2.Key});
Console.WriteLine("mget " + kv1.Key.ToString() + " " + kv2.Key.ToString() + ", result is " + values[0] + "&&" + value
s[1]);
```

- Hash

```
string hashKey = "myhash";
//hset
db.HashSet(hashKey,"f1","v1");
db.HashSet(hashKey,"f2", "v2");
HashEntry[] values = db.HashGetAll(hashKey);
//hgetall
Console.Write("hgetall " + hashKey + ", result is");
for (int i = 0; i < values.Length;i++)
{
 HashEntry hashEntry = values[i];
 Console.Write(" " + hashEntry.Name.ToString() + " " + hashEntry.Value.ToString());
}
Console.WriteLine();
```

- List

```
//list key
string listKey = "myList";
//rpush
db.ListRightPush(listKey, "a");
db.ListRightPush(listKey, "b");
db.ListRightPush(listKey, "c");
//lrange
RedisValue[] values = db.ListRange(listKey, 0, -1);
Console.Write("lrange " + listKey + " 0 -1, result is ");
for (int i = 0; i < values.Length; i++)
{
 Console.Write(values[i] + " ");
}
Console.WriteLine();
```

- Set

```
//set key
string setKey = "mySet";
//sadd
db.SetAdd(setKey, "a");
db.SetAdd(setKey, "b");
db.SetAdd(setKey, "c");
//sismember
bool isContains = db.SetContains(setKey, "a");
Console.WriteLine("set " + setKey + " contains a is " + isContains );
```

- Sorted Set

```
string sortedSetKey = "myZset";
//sadd
db.SortedSetAdd(sortedSetKey, "xiaoming", 85);
db.SortedSetAdd(sortedSetKey, "xiaohong", 100);
db.SortedSetAdd(sortedSetKey, "xiaofei", 62);
db.SortedSetAdd(sortedSetKey, "xiaotang", 73);
//zrevrangebyscore
RedisValue[] names = db.SortedSetRangeByRank(sortedSetKey, 0, 2, Order.Ascending);
Console.Write("zrevrangebyscore " + sortedSetKey + " 0 2, result is ");
for (int i = 0; i < names.Length; i++)
{
 Console.Write(names[i] + " ");
}
Console.WriteLine();
```

13.2.5.2. Use redis-cli

The redis-cli tool is a command-line interface (CLI) of Redis. You can use redis-cli to connect to a KVStore for Redis instance from an Elastic Compute Service (ECS) instance or on-premises machine and manage data.

Prerequisites

- The ECS instance and KVStore for Redis instance are deployed in the same classic network or virtual private cloud (VPC).
- The private IP address of the ECS instance is added to the whitelist of the KVStore for Redis instance. For more information, see Configure a whitelist.
- The ECS instance runs a Linux operating system and open source Redis is installed. For more information, see Redis official website.

Procedure

1. Log on to the CLI of the ECS instance and run the following command to connect to the Redis instance:

   ```
   src/redis-cli -h <hostname> -p <port>
   ```

   Parameters

Parameter	Description
<hostname>	The internal endpoint of the KVStore for Redis instance. You can find the endpoint in the **Connection Information** section on the **Instance Information** page.
<port>	The service port number of the KVStore for Redis instance. Default value: 6379.

   Example

   ```
   src/redis-cli -h r-bp1zxszhcgatnx****.redis.rds.aliyuncs.com -p 6379
   ```

2. Run the following command to verify the password:

```
AUTH <password>
```

<password>: the password that you specify when you create the instance. If you forget your password, you can reset the password. For more information, see Change the password.

Example:

```
AUTH testaccount:Rp829dlwa
```

If the password verification is successful, the following result is returned:

```
OK
```

13.3. Instance management

13.3.1. Change a password

If you forget your password, need to change your password, or have not set a password for an instance, you can set a new password for the instance.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the upper-right corner of the **Basic Information** page, click **Modify Password**.
4. In the dialog box that appears, enter the current password and a new password.

> **Note**
> - If you forget your password, you can click **Forgot password** in the Change Password dialog box and enter a new password.
> - The password must be 8 to 32 characters in length.
> - The password must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. Special characters include `!@#$%^&*()_+-=`.

5. Click **OK**.

13.3.2. Configure a whitelist

Before you use a KVStore for Redis instance, add IP addresses or CIDR blocks that are used to access the database to the whitelist of the instance to improve the security and stability of the database.

Context

> **Note** A properly configured whitelist can ensure a higher level of security protection for your KVStore for Redis instance. We recommend that you maintain the whitelist on a regular basis.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, click **Whitelist Settings**.

4. Find the IP address whitelist that you want to manage and click **Modify**.

> **Note** You can also click **Add Whitelist** to create an IP address whitelist. The name of the IP address whitelist must be 2 to 32 characters in length and can contain lowercase letters, digits, and underscores (_). The name of the whitelist must start with a lowercase letter and end with a lowercase letter or digit.

5. In the dialog box that appears, perform one of the following operations:

Action	Procedure
Manually modify the IP address whitelist	Enter IP addresses or CIDR blocks. Manually modify the IP address whitelist  **Note** ◦ Separate multiple IP addresses with commas (,). You can add up to 1,000 unique IP addresses. Supported formats are specific IP addresses such as 10.23.12.24 and CIDR blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix. An IP address prefix can be 1 to 32 bits in length. ◦ If you set the prefix length to 0, for example, 0.0.0.0/0 or 127.0.0.1/0, all IP addresses are allowed to access the instance. In this case, the security risk of your instance is high. Proceed with caution.

Action	Procedure
Add private IP addresses of ECS instances to an IP address whitelist	i. Click **Load ECS Internal Network IP**. ii. Select IP addresses based on your business requirements. Add private IP addresses of ECS instances  **Note** To find the ECS instance to which a specific IP address is assigned, you can move the pointer over the IP address. Then, the system displays the ID and name of the ECS instance to which the IP address is assigned.
Remove IP addresses from the IP address whitelist	To remove all IP addresses from the IP address whitelist and retain the IP address whitelist, click **Delete**.

6. Then, click **OK**.

13.3.3. Change specifications

This topic describes how to change the configuration of a KVStore for Redis instance.

Precautions

After configuration changes, the system migrates data and switches the instance. The instance is disconnected for a few seconds during this process. We recommend that you upgrade or downgrade the instance during off-peak hours.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. On the page that appears, configure the required parameters.

Parameter	Description

Parameter	Description
Architecture Type	Select the architecture type of the KVStore for Redis instance. KVStore for Redis supports cluster and standard architectures. The cluster architecture is suitable for scenarios that require large capacity or high performance. Redis-native databases run in a single-threading model. If your database does not require high performance, we recommend that you use a standard instance. If your database requires high performance, select a cluster architecture.
Instance Type	Select the specification of the instance. The maximum connections and maximum internal network bandwidth vary based on the instance type.

4. Click **Submit**.

13.3.4. Specify a maintenance window

You can modify the default maintenance window to perform maintenance on KVStore for Redis during off-peak hours.

Context

To ensure the stability of KVStore for Redis instances on the Alibaba Cloud platform, the backend system performs maintenance on instances and servers occasionally.

To guarantee the stability of the maintenance process, instances will enter the Maintaining Instance status before the preset maintenance window on the day of maintenance. While an instance is in this state, data in the database can still be accessed and query operations such as performance monitoring are still available. However, change operations such as configuration change are temporarily unavailable for this instance in the console.

> **Note** During the maintenance process, instances may be disconnected in the process of maintenance. We recommend that you set the maintenance window to a period during off-peak hours.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the **Basic Information** section, click **Settings** on the right of **Maintenance Window**.
4. Select a time period for maintenance and click **Save**.

> **Note** The time periods are in UTC+8.

13.3.5. Upgrade the minor version

Alibaba Cloud has continuously optimized the kernel of KVStore for Redis to fix security vulnerabilities and provide more stable services. You can upgrade the kernel version (minor version) of a KVStore for Redis instance with one click in the console.

Context

> **Note**
> - We recommend that you upgrade instance versions during off-peak hours and ensure that your application supports automatic reconnection.
> - The system automatically checks the kernel version of an instance. If the current version is the latest, the **Minor Version Upgrade** button in the upper-right corner of the **Basic Information** section for this instance will appear dimmed.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. On the **Instance Information** page, click **Minor Version Upgrade** in the upper-right corner of the **Basic Information** section.
4. In the **Minor Version Upgrade** dialog box that appears, click **Upgrade Now**.

   On the **Instance Information** page, the instance status will become Upgrading a minor version. When the instance status returns to Available, the upgrade has been completed.

13.3.6. Configure SSL encryption

The standard and cluster Instances of Redis 2.8 and the cluster instances of Redis 4.0 support secure sockets layer (SSL) encryption. You can enable SSL encryption to ensure more secure data transmission.

Context

> **Note** SSL encryption may increase the network response time of instances. We recommend that you enable this feature only when necessary.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, click **SSL Settings**.
4. In the upper-right corner of the **SSL Settings** page, click **Configure SSL**.
5. In the dialog box that appears, turn on **Enable SSL Certificate**.

   > **Note** If the version of the instance is not supported, upgrade the minor version. For more information, see Upgrade the minor version.

6. Click **OK**.

   > **Note**
   > - The result of the operation is displayed after a short period of time.
   > - In the upper-right corner of the SSL Settings page, you can also click **Update Validity** and **Download CA Certificate** to perform relevant operations.

13.3.7. Clear data

You can clear the data of a KVStore for Redis instance in the console.

Context

Warning This operation will delete all data contained on an instance. Deleted data cannot be restored. Proceed with caution.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the upper-right corner of the **Instance Information** page, click **Clear Data**.
4. In the **Clear Data** message that appears, click **OK**.

13.3.8. Release an instance

You can release a KVStore for Redis instance at any time based on your business needs. This topic describes how to release a KVStore for Redis instance.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instances** page, click the instance ID or choose > **Release** in the **Actions** column.

   Warning After an instance is released, the instance cannot be restored. Proceed with caution. We recommend that you back up your data before you release an instance.

3. In the **Release Instance** message that appears, click **OK**.

13.3.9. Manage database accounts

KVStore for Redis allows you to create up to 20 database accounts for an instance. You can grant permissions to these accounts and manage your instance to prevent user errors.

Prerequisites

The engine version of the instance is Redis 4.0 or later.

Note If the engine version of the instance is not Redis 4.0, only the default account that is created when you create the instance is available. For more information about how to change the password of the default account, see Change the password.

Context

You can create accounts, delete accounts, reset the password, and change the permissions. After an account is created, you can use this account to log on to the database and use the command-line tool to perform operations on the database with the account and granted permissions.

Create an account

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. On the **Instances** page, find the instance that you want to manage and click the instance ID. In the left-side navigation pane, click **Account Management**.

> **Note** If Account Management is unavailable for an instance of Redis 4.0 or later, you must upgrade the minor version of the instance. For more information, see Upgrade the minor version.

4. In the upper-right corner of the **Account Management** page, click **Create**.
5. In the dialog box that appears, configure the required parameters and click **OK**. The following table describes the parameters.

Parameter	Description
Account	The account name must be 1 to 16 characters in length. The name can contain lowercase letters, digits, and underscores (_) and must start with a letter.
Privilege	Specify the permissions that are granted to the account. Valid values: Read-only, Read/Write, and Replicate. If you select Replicate, you can run the SYNC and PSYNC commands after you connect to an instance by using your account. **Note** You can create accounts that have the replicate permissions only for standard instances of Redis 4.0 or later.
Password Settings	Specify a password for the account. The password must be 8 to 32 characters in length. The password must contain at least three of the following types of characters: uppercase letters, lowercase letters, digits, and special characters. The following special characters are supported: `!@#$%^&*()+-=_` .
Confirm Password	Enter the password again.
Description	The description of the account.

13.3.10. Restart an instance

You can restart an instance from the Instance List page of the console.

Procedure

1. Log on to the KVStore for Redis console.
2. In the **Actions** column, choose > **Restart**.

> **Warning** During the restart, the instance may be disconnected for a few seconds. We recommend that you restart instances during off-peak hours. You must also make sure that your application supports automatic reconnection.

3. In the dialog box that appears, specify the upgrade time and click **OK**.
   - Restart Immediately: restarts the instance immediately.
   - Restart Within Maintenance Window: restarts the instance within the preset maintenance window.

13.3.11. Export the list of instances

You can export the list of KVStore for Redis instances from the KVStore for Redis console for offline management.

Procedure

1. Log on to the KVStore for Redis console.

2. In the upper-right corner of the **Instance List** page, click the **Export Instances** icon.
3. In the **Export Instance List** dialog box that appears, select the columns to export and click **OK**.

> **Note** After you click **OK**, the browser begins to download the CSV file. You can use Excel or a text editor to view this file.

13.3.12. Use a Lua script

KVStore for Redis instances of all editions support Lua commands.

Support for Lua commands

Lua scripts improve the performance of KVStore for Redis. With support for the Lua environment, KVStore for Redis is able to perform check-and-set (CAS) operations, allowing you to combine and run multiple commands in an efficient manner.

> **Note** If the EVAL command cannot be executed, for example, the " `ERR command eval not support for normal user` " message appears, you can Upgrade the minor version. During the upgrade, the instance may be disconnected and become read-only for a few seconds. We recommend that you upgrade instance versions during off-peak hours.

Limits on Lua scripts

A Lua script, which is supported by the cluster instance of KVStore for Redis, has the following limits to ensure that all operations in the script are performed within the same hash slot:

- The Lua script uses the **redis.call/redis.pcall** function to run Redis commands. . For Redis commands, the keys must be passed by using the KEYS array, which cannot be replaced by Lua variables. If the KEYS array is not used, the following error message is returned:

  ```
  -ERR bad lua script for redis cluster, all the keys that the script uses should be passed using the KEYS array\r\n
  ```

- All keys that are used by the script must be allocated to the same hash slot. If the keys are allocated to different hash slots, the following error message is returned:

  ```
  -ERR eval/evalsha command keys must be in same slot\r\n
  ```

- Keys must be included in all commands that you want to run. If the keys are not included in all commands, the following error message is returned:

  ```
  -ERR for redis cluster, eval/evalsha number of keys can't be negative or zero\r\n
  ```

- The following Pub/Sub commands are not supported: **PSUBSCRIBE**, **PUBSUB**, **PUBLISH**, **PUNSUBSCRIBE**, **SUBSCRIBE**, and **UNSUBSCRIBE**.
- The UNPACK function is not supported.

> **Note** If you do not want to impose the preceding limits but can make sure that all operations are performed in the same hash slot in the code, you can set the script_check_enable parameter to 0 in the console to disable the backend script check.

13.4. Connection management

13.4.1. View endpoints

You can view the internal and public endpoints of instances in the KVStore for Redis console.

Context

> Note
> - The virtual IP address of a KVStore for Redis instance may change when you maintain or modify the instance. To ensure that the connection is available, we recommend that you use an endpoint to access the KVStore for Redis instance.
> - For more information about how to apply for a public endpoint, see Applies for a public connection string.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the **Connection Information** section, you can view the private and public endpoints of the instance.

> Note By default, only a private endpoint is provided by a KVStore for Redis instance. If you want to connect to a KVStore for Redis instance over the Internet, you must apply for a public endpoint. For more information, see Apply for a public endpoint.

13.4.2. Apply for a public endpoint

This topic describes how to apply for a public endpoint for a KVStore for Redis instance.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the **Connection Information** section, click **Apply for Public Endpoint**.
4. In the dialog box that appears, enter an endpoint and a port number and click **OK**.

> Note
> - The custom endpoint must be 8 to 64 characters in length and can contain lowercase letters and digits. The endpoint must start with a lowercase letter.
> - The custom port number ranges from 1024 to 65535. The default value is 6379.
> - After you apply for a public endpoint, you must add the public endpoint to the IP address whitelist of the instance. This way, you can connect to the instance over the Internet. For more information, see Configure a whitelist.

5. On the **Instance Information** page, view the **Public Endpoint** in the **Connection Information** section.

> Note If you no longer use the public endpoint, click **Release Public Endpoint** next to **Public Endpoint** to release the endpoint.

13.4.3. Modify the endpoint of an KVStore for Redis instance

KVStore for Redis allows you to modify internal and public endpoints for instances. When changing the KVStore for Redis instance, you can change the endpoint of the new instance to the endpoint of the original instance without modifying the application.

Prerequisites

The instance is in the Running state.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. On the **Instance Information** page, click **Modify Public Endpoint** in the **Connection Information** section.
4. In the **Modify Public Endpoint** dialog box, set the following parameters:

Parameter	Description
Connection type	Select **Internal Endpoint** or **Public Endpoint**.
Endpoint	Set the prefix of the endpoint. ○ The endpoint can contain lowercase letters and digits. ○ It must start with a lowercase letter. ○ The endpoint must be 8 to 64 characters in length.
Port	Specify a port number. Valid value: 1024 to 65535. **Note** It takes about 10 minutes for the modified port number of the public endpoint to take effect. You can refresh the page to view the latest port number information.

5. In the **Modify Public Endpoint** dialog box, modify **Connection Type**, **Endpoint**, and **Port**, and then click **OK**.

> **Note**
> - The custom endpoint prefix must be 8 to 64 characters in length and can contain lowercase letters and digits. It must start with a lowercase letter.
> - The custom port number ranges from 1024 to 65535. The default value is 6379.

13.5. Performance monitoring

13.5.1. Query monitoring data

You can query the monitoring data of a KVStore for Redis instance for a specified period within the last month.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, click **Performance Monitor**.
4. Select the start and end time and click **OK**.

> **Note** For more information about the metrics, see Understand metrics.

13.5.2. Select metrics

You can select the metrics to be displayed on the Historical Monitoring Data page of the KVStore for Redis console as needed.

Context

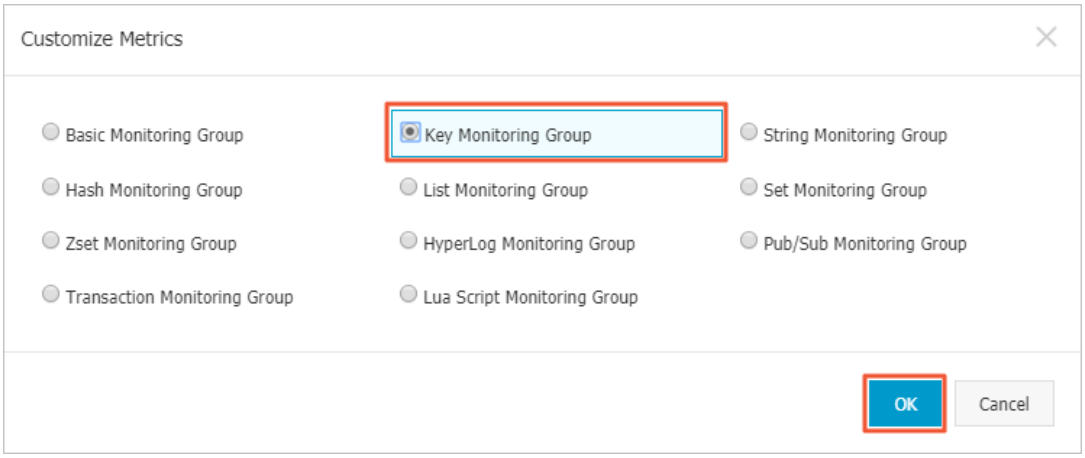
KVStore for Redis supports more than 10 monitoring groups. By default, the Performance Monitor page displays the metrics of the basic monitoring group. You can click **Customize Metrics** to switch to the metrics of other monitoring groups. The following table describes the monitoring groups.

Monitoring group	Description
Basic monitoring group	The basic monitoring information about an instance, such as the queries per second (QPS), bandwidth, and memory usage of the instance.
Key monitoring group	The monitoring information about the use of key-value related commands, such as the number of times that the DEL and EXITS commands are executed.
String monitoring group	The monitoring information about the use of string commands, such as the number of times that the APPEND and MGET commands are executed.
Hash monitoring group	The monitoring information about the use of hash commands, such as the number of times that the HGET and HDEL commands are executed.
List monitoring group	The monitoring information about the use of list commands, such as the number of times that the BLPOP and BRPOP commands are executed.
Set monitoring group	The monitoring information about the use of set commands, such as the number of times that the SADD and SCARD commands are executed.
Zset monitoring group	The monitoring information about the use of zset commands, such as the number of times that the ZADD and ZCARD commands are executed.
HyperLog monitoring group	The monitoring information about the use of HyperLogLog commands, such as the number of times that the PFADD and PFCOUNT commands are executed.
Pub/Sub monitoring group	The monitoring information about the use of publication and subscription commands, such as the number of times that the PUBLISH and SUBSCRIBE commands are executed.
Transaction monitoring group	The monitoring information about the use of transaction commands, such as the number of times that the WATCH, MULTI, and EXEC commands are executed.
Lua script monitoring group	The monitoring information about the use of Lua script commands, such as the number of times that the EVAL and SCRIPT commands are executed.

For more information about the definitions of the metrics in each monitoring group, see Metrics.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, click **Performance Monitor**.
4. On the **Historical Monitoring Data** page, click **Customize Metrics** in the **Data Index** section.
5. In the dialog box that appears, specify a monitoring group and click **OK**.



On the Historical Monitoring Data page, the metrics in the selected monitoring group appear.

13.5.3. Modify the data collection interval

KVStore for Redis console allows you to set the frequency at which monitoring data is collected.

Context

You can set the monitoring frequency to either 5 or 60 seconds to specify how often monitoring data to be collected by KVStore for Redis. The default monitoring time of 60 seconds is sufficient to meet common monitoring requirements. If you need to observe certain metrics at a higher frequency and lower latency, you can change the monitoring frequency to 5 seconds as described in the following section. Monitoring data does not occupy instance storage space, and collection of monitoring data does not affect normal running of the instance.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, click **Performance Monitor**.
4. In the upper-right corner of the **Historical Monitoring Data** page, click **Monitoring Frequency**.
5. In the **Monitoring Frequency** dialog box that appears, select the new monitoring frequency and click **OK**.

13.5.4. Understand metrics

KVStore for Redis updates more than 10 monitoring groups of metrics in real time. This allows you to monitor the status of KVStore for Redis instances. This topic describes the metrics of the monitoring groups.

Metrics of basic monitoring groups

Metric	Unit	Description	Statistical method
CpuUsage	%	The CPU utilization	Check the CPU utilization when the monitoring data is collected.
UsedMemory	Bytes	The amount of the used memory.	Check the memory usage when the monitoring data is collected.
TotalQps	Counts/s	The number of requests that are received by the instance per second.	Divide the number of requests in a monitoring cycle by the number of seconds in the monitoring cycle.

Metric	Unit	Description	Statistical method
ConnCount	Counts	The number of connections.	Check the number of connections when collecting monitoring data.
InFlow	KBps	The amount of data received by the instance per second.	Divide the amount of data that is received in a monitoring cycle by the number of seconds in the monitoring cycle.
OutFlow	KBps	The amount of data sent by the instance per second.	Divide the amount of data that is sent in a monitoring cycle by the number of seconds in the monitoring cycle.
FailedCount	Counts/s	The average number of abnormal requests per second.	Divide the total number of abnormal requests in a monitoring cycle by the number of seconds in the monitoring cycle.
AvgRt	us	The average response time of all requests. **Note** For more information, see Response time (RT) metrics.	Divide the processing time of all requests in a monitoring cycle by the number of requests in the monitoring cycle.
MaxRt	us	The maximum response time of requests. **Note** For more information, see Response time (RT) metrics.	The maximum time that is required to process a request in a monitoring cycle.
Keys	Counts	The total number of keys.	The number of keys when the monitoring data is collected.
Expires	Counts	The total number of keys for which an expiration time is configured.	The total number of keys for which an expiration time is set when the monitoring data is collected.
ExpiredKeys	Counts	The total number of expired keys.	The cumulative sum when the monitoring data is collected. After the instance is restarted, the cumulative sum is calculated again.
EvictedKeys	Counts	The total number of keys that are evicted because the memory is exhausted.	The cumulative sum when the monitoring data is collected. After the instance is restarted, the cumulative sum is calculated again.
request	Bytes	The total amount of request data received by KVStore for Redis nodes in a monitoring cycle.	See the description of this metric.
response	Bytes	The total amount of response data sent by KVStore for Redis nodes in a monitoring cycle.	See the description of this metric.

Metric	Unit	Description	Statistical method
request_max	Bytes	The maximum amount of data in a request in a monitoring cycle.	See the description of this metric.
response_max	Bytes	The maximum amount of data in a response in a monitoring cycle.	See the description of this metric.
traffic_control_input	Counts	The number of times that downstream throttling is triggered.	Monitor the cumulative sum in a monitoring cycle.
traffic_control_output	Counts	The number of times that uplink throttling is triggered.	Monitor the cumulative sum in a monitoring cycle.
traffic_control_input_status	Counts	Indicates whether downstream throttling was triggered in a monitoring cycle. A value of 0 indicates that throttling was not triggered. A value of 1 indicates that throttling was triggered.	See the description of this metric.
traffic_control_output_status	Counts	Indicates whether upstream throttling was triggered in a monitoring cycle. A value of 0 indicates that throttling was not triggered. A value of 1 indicates that throttling was triggered.	See the description of this metric.
hit_rate	%	The request hit rate, which is the probability that data exists in a KVStore for Redis instance for a data access request.	Calculate the percentage of the hit requests to the total number of requests in a monitoring cycle.
hit	Counts	The number of hit requests.	Check the number of hit requests in a monitoring cycle.
miss	Counts	The number of missed requests.	Check the number of missed requests in a monitoring cycle.
evicted_keys_per_sec	Counts/s	The number of keys that are evicted per second.	Divide the total number of keys that are evicted in a monitoring cycle by the number of seconds in the monitoring cycle.

Metrics in other monitoring groups

The system also uses other metrics to monitor specific types of data or specific features. The metrics are classified into:

- Metrics that indicate the number of times that commands are used. For example, the del, dump, and exists metrics that are used to monitor keys indicate the number of times that the DEL, DUMP, and EXISTS commands are executed.
- Response time (RT) metrics of commands. For example, the metrics that end with avg_rt, such as del_avg_rt dump_avg_rt, and exists_avg_rt, in the key monitoring group are used to monitor the average response time of the DEL, DUMP, and EXISTS commands in a monitoring cycle.

Response time (RT) metrics

All monitoring groups have RT metrics. RT metrics end with Rt or rt. For example, the AvgRt and MaxRt metrics are used in the basic monitoring group and the del_avg_rt and exists_avg_rt metrics are used to monitor keys.

The AvgRt and MaxRt metrics in the basic monitoring group are the most frequently used RT metrics. These metrics have different meanings for proxy nodes and data nodes.

- For a cluster instance or a read/write splitting instance, the AvgRt metric of a proxy node indicates the average time consumed by the proxy node to process all commands. The following process shows how a proxy node processes a command:
  i. The proxy node receives a command and forwards the command to a data node.
  ii. The data node processes the command and responds to the proxy node.
  iii. The proxy node returns the command processing result.

  The AvgRt metric of the proxy node includes the amount of time consumed by the data node to process a command and the time that is required to wait for the command to be processed. This metric also includes the amount of time consumed for network communication between the proxy node and the data node.
- For data nodes of a cluster instance or a read/write splitting instance or for a standard instance, the AvgRt metric indicates the average time consumed by a data node to process all commands. This metric records the period of time from the time when the data node receives the command to the time when the data node returns the result. This metric does not include the time consumed by the proxy node to process a command and the time that is required for network communication.
- The MaxRt metric indicates the maximum response time of requests. The statistical method of this metric is similar to the statistical method of the AvgRt metric for all KVStore for Redis instances.

13.6. Parameter configuration

KVStore for Redis allows you to customize certain instance parameters. This topic describes parameters and the common methods to modify them in the KVStore for Redis console.

Context

KVStore for Redis is completely compatible with the native database services of Redis. The method to set parameters for KVStore for Redis is similar to that of an on-premises Redis database. You can set the parameters described in this topic in the KVStore for Redis console.

Parameters

Parameters

Parameter	Description
#no_loose_check-whitelist-always	Specifies whether to check whether the client IP address is in the whitelist of the KVStore for Redis instance after password-free access is enabled in Virtual Private Cloud (VPC). Default value: no. If you set this parameter to yes, the whitelist will still take effect in password-free access mode for VPC. Valid values: • yes • no
#no_loose_disabled-commands	Specifies the disabled commands. Separate multiple commands with commas (,). You can disable the following commands: **FLUSHALL**, **FLUSHDB**, **KEYS**, **HGETALL**, **EVAL**, **EVALSHA**, and **SCRIPT**.
#no_loose_ssl-enabled	Specifies whether to enable SSL encryption. Default value: no. Valid values: • yes • no

Parameter	Description
#no_loose_sentinel-enabled	Specifies whether to enable Sentinel-compatible mode. Default value: no. Valid values: • yes • no
client-output-buffer-limit pubsub	Limits the size of output buffers for Pub/Sub clients. This parameter can contain options in the following format: **<hard limit> <soft limit> <soft seconds>** . • Hard limit: If the output buffer of a Pub/Sub client reaches or exceeds the number of bytes specified by hard limit, the client is immediately disconnected. • soft limit and soft seconds: If the output buffer of a Pub/Sub client reaches or exceeds the size in bytes specified by soft limit for a period of time in seconds specified by soft seconds, the client will be disconnected.
dynamic-hz	Specifies whether to enable dynamic frequency control for background tasks. Default value: yes. Valid values: • yes • no
hash-max-ziplist-entries	Specifies the maximum size of each key-value pair stored within a hash in bytes. A hash is encoded using ziplist when it meets the following conditions: 1. The maximum size of each key-value pair stored within the hash in bytes must be less than the value of the hash-max-ziplist-value parameter. 2. The number of key-value pairs stored within the hash must be less than the value of the hash-max-ziplist-entries parameter.
hash-max-ziplist-value	Specifies the maximum size of each key-value pair stored within a hash in bytes. A hash is encoded using ziplist when it meets the following conditions: 1. The maximum size of each key-value pair stored within the hash in bytes must be less than the value of the hash-max-ziplist-value parameter. 2. The number of key-value pairs stored within the hash must be less than the value of the hash-max-ziplist-entries parameter.
hz	Specifies the execution frequency for background tasks, such as tasks to evict expired keys. Valid values: 1 to 500. Default value: 10. The larger the value of the hz parameter, the more frequently background tasks are performed and the more precisely timeout events are handled, but the more CPU KVStore for Redis consumes. We recommend that you do not set the hz parameter to a value greater than 100.
lazyfree-lazy-eviction	Specifies whether to enable lazyfree for the eviction feature. Default value: no. Valid values: • yes • no

Parameter	Description
lazyfree-lazy-expire	Specifies whether to enable lazyfree to delete expired keys. Default value: yes. Valid values: • yes • no
lazyfree-lazy-server-del	Specifies whether to enable lazyfree to asynchronously delete data with the **DEL** command. Default value: yes. Valid values: • yes • no
list-compress-depth	Specifies the number of nodes that are not compressed at each side in a list. Default value: 0. Valid values: • 0: does not compress any nodes in the list. • 1: does not compress the first node from each side of the list, but compresses all nodes in between. • 2: does not compress the first two nodes from each side of the list, but compresses all nodes in between. • 3: does not compress the first three nodes from each side of the list, but compresses all nodes in between. • And so on up to 65535.
list-max-ziplist-size	• Specifies the maximum size of each ziplist in a quicklist. A positive number indicates the maximum number of elements in each ziplist of a quicklist. For example, if you set this parameter to 5, each ziplist of a quicklist can contain a maximum of five elements. • A negative number indicates the maximum number of bytes in each ziplist of a quicklist. Default value: -2. Valid values: ◦ -5: indicates that each ziplist of a quicklist cannot exceed 64 KB (1 KB = 1,024 bytes). ◦ -4: indicates that each ziplist of a quicklist cannot exceed 32 KB. ◦ -3: indicates that each ziplist of a quicklist cannot exceed 16 KB. ◦ -2: indicates that each ziplist of a quicklist cannot exceed 8 KB. ◦ -1: indicates that each ziplist of a quicklist cannot exceed 4 KB.
maxmemory-policy	Specifies the policy used to evict keys if the memory is fully occupied. Valid values: LRU means least recently used. LFU means least frequently used. LRU, LFU, and TTL are implemented by using approximated randomized algorithms. • volatile-lru: evicts the approximated least recently used (LRU) keys among keys with a preset expiration time. • allkeys-lru: evicts the approximated LRU keys. • volatile-lfu: evicts the approximated least frequently used (LFU) keys among keys with a preset expiration time. • allkeys-lfu: evicts the approximated LFU keys. • volatile-random: evicts random keys among keys with a preset expiration time. • allkeys-random: evicts random keys. • volatile-ttl: evicts keys with the nearest time to live (TTL) among keys with a preset expiration time. • noeviction: does not evict any keys, but returns an error on write operations.

Parameter	Description
notify-keyspace-events	Specifies the events that the Redis server can notify clients of. The value of this parameter is any combination of the following characters, each of which specifies a type of event to be notified: • K: keyspace events, published with the __keyspace@<db>__ prefix. • E: keyevent events, published with the __keyevent@<db>__ prefix. • g: generic commands that are non-type specific, such as DEL, EXPIRE, and RENAME. • l: list commands. • s: set commands. • h: hash commands. • z: sorted set commands. • x: expired key events. An expired key event is generated when a key expires. • e: evicted key events. An evicted key event is generated when a key is evicted due to the policy specified by the maxmemory-policy parameter. • A: the alias for g$lshzxe.
set-max-intset-entries	Specifies the maximum number of data entries in a set. A set is encoded by using intset when it meets the following conditions: 1. The set is composed of just strings. The number of strings is less than the value of this parameter. 2. All strings are integers in radix 10 in the range of 64-bit signed integers.
slowlog-log-slower-than	Specifies whether to log slow queries. • Negative number: does not log slow queries. • 0: logs all queries. • Positive number: logs queries that exceed an execution time specified by this positive number, in microseconds. Valid values: 0 to 10,000,000. Default value: 10,000.
slowlog-max-len	Specifies the maximum number of slow query log entries that can be stored. Valid values: 100 to 10,000. Default value: 1,024.
stream-node-max-bytes	Specifies the maximum memory that can be used by each macro node in streams. Valid values: 0 to 999,999,999,999,999. If you set the parameter to 0, each macro node can use an unlimited amount of memory.
stream-node-max-entries	Specifies the maximum number of stream entries that can be stored within each macro node. Valid values: 0 to 999,999,999,999,999. If you set the parameter to 0, each macro node can store unlimited stream entries.
timeout	Specifies a timeout period for client connections. Unit: seconds. Valid values: 0 to 100,000. 0 indicates that client connections never time out.

Parameter	Description
zset-max-ziplist-entries	Specifies the maximum size of each key-value pair stored within a sorted set in bytes. A sorted set is encoded using ziplist when it meets the following conditions: 1. The maximum size of each key-value pair stored within the sorted set in bytes must be less than the value of the zset-max-ziplist-value parameter. 2. The number of key-value pairs stored within the sorted set must be less than the value of the zset-max-ziplist-entries parameter.
zset-max-ziplist-value	Specifies the maximum size of each key-value pair stored within a sorted set in bytes. A sorted set is encoded using ziplist when it meets the following conditions: 1. The maximum size of each key-value pair stored within the sorted set in bytes must be less than the value of the zset-max-ziplist-value parameter. 2. The number of key-value pairs stored within the sorted set must be less than the value of the zset-max-ziplist-entries parameter.
list-max-ziplist-entries	Specifies the maximum size of each key-value pair stored within a list in bytes. A list is encoded using ziplist when it meets the following conditions: 1. The maximum size of each key-value pair stored within the list in bytes must be less than the value of the list-max-ziplist-value parameter. 2. The number of elements stored within the list is less than the value of the list-max-ziplist-entries parameter.
list-max-ziplist-value	Specifies the maximum size of each key-value pair stored within a list in bytes. A list is encoded using ziplist when it meets the following conditions: 1. The maximum size of each key-value pair stored within the list in bytes must be less than the value of the list-max-ziplist-value parameter. 2. The number of elements stored within the list is less than the value of the list-max-ziplist-entries parameter.
cluster_compat_enable	Specifies whether to enable compatibility with the syntax of Redis Cluster. Default value: 1. Valid values: • 0: no • 1: yes
script_check_enable	Specifies whether to confirm that all the keys used in a Lua script are in the same hash slot. Default value: 1. Valid values: • 0: no • 1: yes

Note The maxclients parameter, which is used to specify the maximum number of connections to Redis data nodes, is fixed to 10,000. You cannot modify the value of this parameter.

Configure parameters in the KVStore for Redis console

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane of the **Instance Information** page, click **System Parameters**.
4. Find the target parameter and click **Modify** in the **Action** column.
5. In the dialog box that appears, modify the parameter value and click **OK**.

13.7. Backup and recovery

13.7.1. Automatically back up data

An increasing number of applications use Redis for persistent storage. In this case, an automatic backup mechanism is required to back up data on a regular basis so that you can restore data if user errors occur. KVStore for Redis uses Redis database backup (RDB) snapshots to back up data on replica nodes. The backup process does not have negative impacts on the performance of your instance. You can configure a custom backup policy in the console.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, click **Backup and Recovery**.
4. Click the **Backup Settings** tab.
5. Click **Edit** and specify Backup Cycle and Backup Time.
   - **Retention Days**: The number of days for which backups are retained. This parameter is set to seven days and cannot be changed.
   - **Backup Cycle**: You can select one or more days in a week. By default, one backup is created per day.
   - **Backup Time**: You can specify a period of time in hours within a day. We recommend that you back up data during off-peak hours.
6. Click **OK**.

13.7.2. Back up an instance

You can initiate a manual backup task in the console at any time.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, click **Backup and Recovery**.
4. In the upper-right corner of the page, click **Create Backup**.
5. Click **OK**.

> **Note** On the **Data Backup** tab, you can select a time range to query existing backups. Backups are retained for seven days.

13.7.3. Download backup files

To archive backup files for a long period, you can copy the URLs in the console and download the database backup files to an on-premises machine.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, click **Backup and Recovery**.
4. Find the backup that you want to download and click in the **Actions** column.
5. In the dialog box that appears, perform one of the actions that are described in the following table.

Action	Procedure
Download the backup file over the Internet	i. Click **Get URL for Internet**. ii. Paste the URL into the address bar of a browser and press Enter. The browser automatically downloads the backup file.

Download the backup file over an internal network. For example, you can download the backup file on an Elastic Compute Service (ECS) instance.	i. Click **Get URL for Intranet**.
	ii. Select a downloading method based on the operating system of the client.
	■ Windows: Paste the URL into the address bar of a browser and press Enter. The browser automatically downloads the backup file.
	■ Linux: Run the following command in the specified format:
	`wget -c '<URL that is used to download the backup file over the internal network>' -O <Name of the downloaded backup file>.<The extension that is added to the name of the downloaded backup file>`
	Example:
	`wget -c 'http://rds****.oss-cn-hangzhou-internal.aliyuncs.com/custins416****/hins1****.rdb?...' -O backupfile.rdb`
	Note If you download the backup file on an ECS instance, the ECS instance and the KVStore for Redis instance can be deployed in different types of networks.

13.7.4. Restore data

KVStore for Redis allows you to restore data from a specified backup set to the current KVStore for Redis instance.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, click **Backup and Recovery**.
4. Perform one of the following operations based on the architecture of your KVStore for Redis instance:
   - Master-replica instance: Find the backup set that you want to restore and click **Restore Data** in the **Actions** column.
   - Cluster instance: Select the backup sets of all data shards that were generated at the same point in time and click **Restore Data** in the upper-right corner.

   Warning Risks may occur when you restore data. Proceed with caution. Verify the data that you want to restore before you restore the data.
5. In the message that appears, read the content and click **Continue**.

You can also restore backup data by cloning an instance. For more information, see Clone an instance.

13.7.5. Clone an instance

KVStore for Redis allows you to create an instance from a specified backup set. The data in the new instance is the same as the data in the backup set. This feature can be applied in scenarios such as data recovery, quick workload deployment, and data verification.

Prerequisites

The KVStore for Redis instance is of the master-replica type.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, click **Backup and Recovery**.
4. Find the backup set that you want to restore and click **Clone Instance** in the **Actions** column.
5. In the message that appears, click **OK**.
6. On the Restore Instance page, configure the parameters and click **Submit**.

> **Note** For more information about the configurations of the new instance, see Create an instance.

13.8. CloudDBA

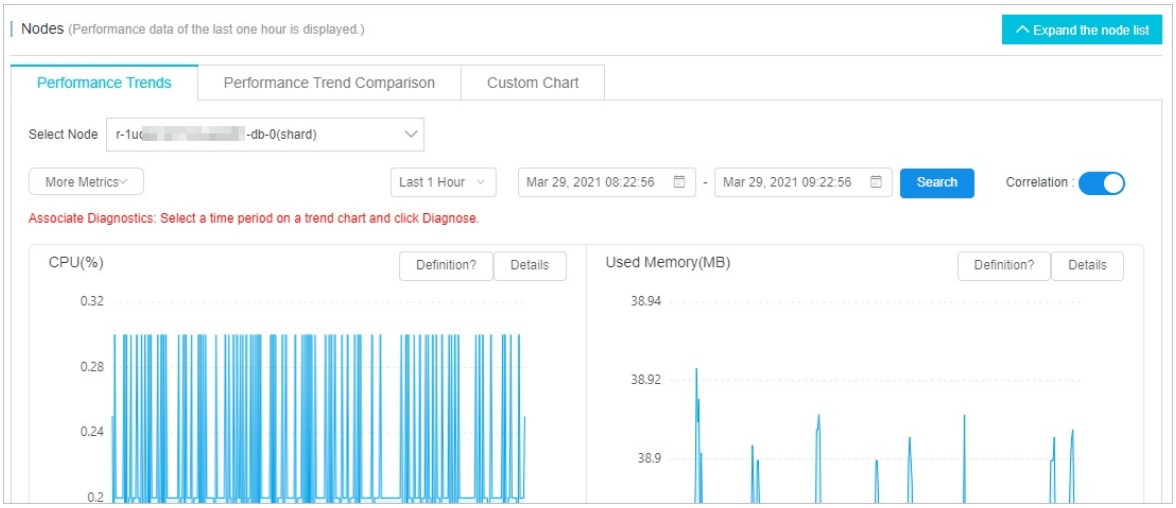
13.8.1. Performance trends

CloudDBA provides the performance trends feature that allows you to monitor the basic performance of a KVStore for Redis instance and the operational trends within a specified period of time. The performance trends include the CPU utilization, memory usage, queries per second (QPS), total connections, response time, data transfer, and key hit ratio.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, choose **CloudDBA > Performance Trends**.
4. You can use the following methods to view performance trends:

> **Note** If the KVStore for Redis instance uses a cluster architecture, the Performance Trends page displays the information about the nodes. The performance data during the last 1 hour is displayed. If you click the node ID, you can view the details of a specified node.



- **Performance trends**

  On the **Performance Trends** tab, specify a time range and click **Search**.

  > **Note**
  > - By default, **Correlation** is enabled. If you move the pointer over the CPU chart to view the CPU metric of the KVStore for Redis instance at 09:00, other charts also display other metrics of the instance at 09:00.
  > - To view the definition of the performance metric and the performance trend, click **Definition?** and **Details** in the upper-right corner of the chart.

- **Performance trend comparison**

  To compare the performance trends within two periods of time, click the **Performance Trend Comparison** tab, specify two periods of time, select more metrics, and then click **Search**.

- **Custom chart**

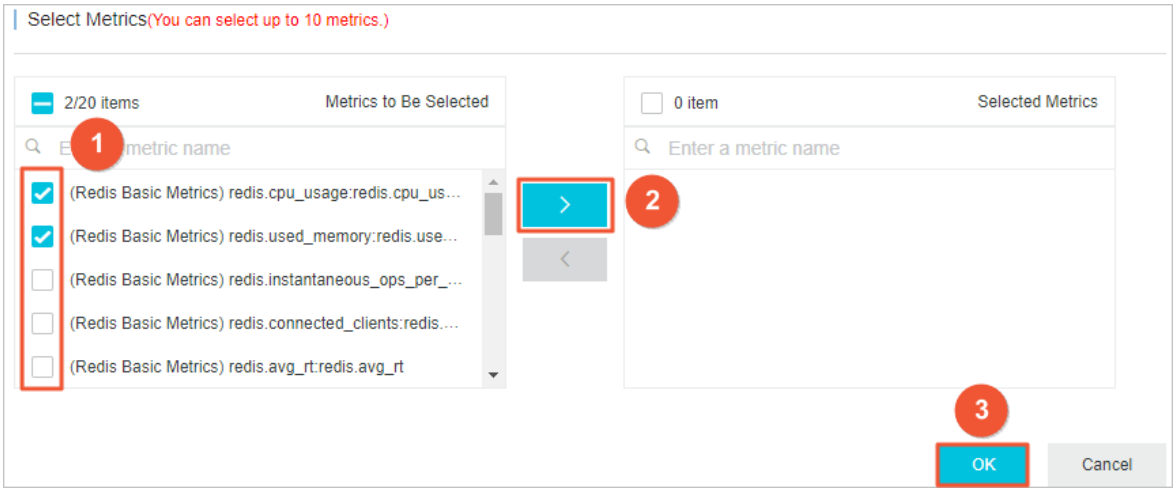
  The preceding two methods display the basic metrics of a KVStore for Redis instance. If you want to display only basic metrics, you can configure custom performance trend charts. For more information, see Add a performance trend chart.

13.8.2. Add a performance trend chart

The default performance trends tab displays the basic performance metrics of a KVStore for Redis instance. You can add a chart that contains only specified performance metrics to analyze the performance trends of your instances. This topic describes how to add a performance trend chart to a dashboard for KVStore for Redis instances.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, choose **CloudDBA > Performance Trends**.
4. Click the **Custom Chart** tab.
5. Click **Add Monitoring Dashboard**. In the Create Monitoring Dashboard dialog box, enter a dashboard name and click **OK**.
6. Click **+ Add Chart** or **Add Monitoring Chart**. Select the metrics that you want to add and click **OK**.



7. (Optional)You can view, modify, and delete monitoring dashboards.
   - View a monitoring dashboard

     Select the monitoring dashboard, specify a time range, and then click **Search**.
   - Modify a monitoring dashboard

     Click the following icons to modify or delete a chart in the monitoring dashboard.

   - Delete a monitoring dashboard

     Choose **Operate Dashboard > Delete Monitoring Dashboard**.

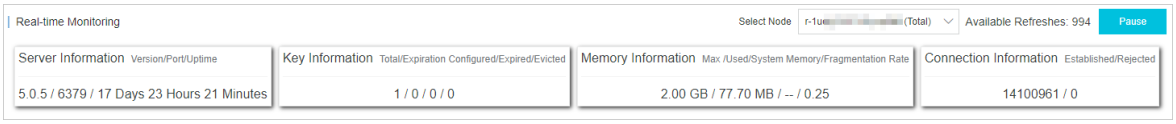
13.8.3. View performance metrics in real time

CloudDBA allows you to view the performance metrics of KVStore for Redis instances in real time. The performance metrics include information about CPU utilization, memory usage, queries per second (QPS), network traffic, servers, keys, clients, and connections.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, choose **CloudDBA > Real-time Performance**.
4. Select a view based on your business requirements.

In the upper part of the page, performance metrics are displayed in real time. The metrics include information about the server, keys, memory, clients, and connections. The details about the performance metrics are displayed in **Real-time Charts** and **Real-time Tables**.



Note The metrics are automatically updated every 5 minutes. Therefore, you can view real-time changes in performance. The remaining updating times are displayed in the upper-right corner. To stop updating the performance metrics, you can click **Pause**.

View	Description
Real-time Charts	Displays the real-time performance metrics of an instance in curve charts, such as key information, key hit information, key hit ratio, CPU utilization, memory information, QPS, and network traffic. Real-time Tables	Displays the information about keys, QPS, memory usage, CPU utilization, network traffic, clients, and connections. The table displays up to 999 records. A new record is added to the table every 5 seconds. 
13.8.4. Instance sessions

Instance sessions allow you to view the information about sessions between a KVStore for Redis instance and a client in real time, which includes the client information, commands that are run, and connection duration. You can also terminate abnormal sessions based on your business requirements.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, choose **CloudDBA > Instance Sessions**.
4. Perform the operations that are described in the following table based on your business requirements.

- View sessions: By default, the details of all sessions are displayed. You can move the pointer over a specific parameter name to view information.

  > **Note**
  > - You can enter keywords in the **search box** to filter session information.
  > - To refresh instance session information, click **Refresh** in the upper-left corner or enable **Auto Refresh** to automatically refresh the page every 30 seconds.

- Terminate sessions: Press the Shift key and select the specified session. To terminate the selected session, click **Kill Selected** in the upper-right corner. To terminate all sessions, click **Kill All**.

  > **Warning** To avoid unexpected results, we recommend that you do not terminate system-level sessions.

- View session statistics: Session statistics record the total number of clients, active clients, and source IP addresses of instance sessions.

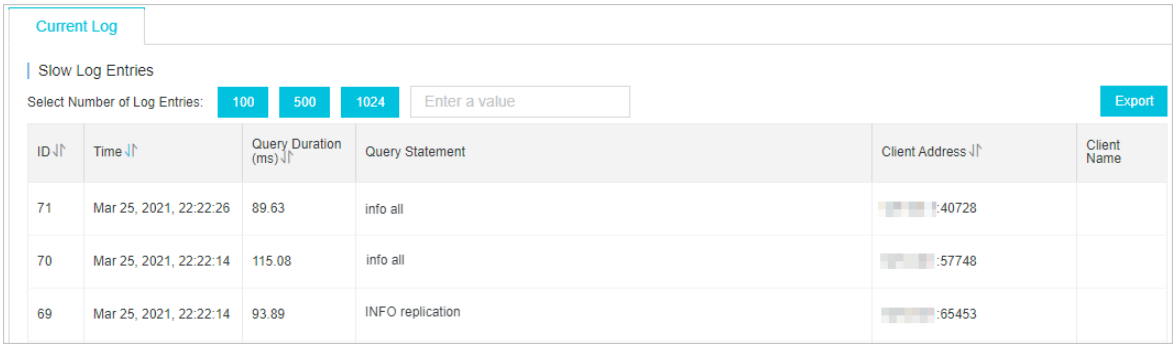
  > **Note** In the **Statistics by Source** table, click the icon on the right of the source IP address to modify the source alias. In the Total Sessions column, click a value to view the details about a source IP address.

13.8.5. Slow queries

Slow queries reduce the stability of KVStore for Redis instances. To monitor and analyze slow queries, you can view the details about slow query logs in CloudDBA.

Procedure

1. Log on to the KVStore for Redis console.
2. On the **Instance List** page, click the ID of the instance.
3. In the left-side navigation pane, choose **CloudDBA > Slow Queries**.
4. Query the details about the slow query logs.



> **Note** You can select the number of log entries to be displayed or enter keywords in the search box to filter log entries.

14.ApsaraDB for MongoDB

14.1. Usage notes

You must get familiar with the precautions and limits of ApsaraDB for MongoDB before you start.

To ensure the stability and security of ApsaraDB for MongoDB instances, take note of the limits, see Instance types in *ApsaraDB for MongoDB ApsaraDB for MongoDB limits*.

ApsaraDB for MongoDB limits

Item	Limit
Scale out nodes	You cannot scale out secondary nodes.
	• When a replica set instance is created, three nodes are added. • ApsaraDB for MongoDB provides a primary node, a secondary node, and a hidden node for each replica set instance. The hidden node is invisible to you. • You cannot scale out secondary nodes.
Restart an instance	You must restart an ApsaraDB for MongoDB instance in the ApsaraDB for MongoDB console or by calling the API operation.

14.2. Log on to the ApsaraDB for MongoDB console

This topic describes how to log on to the ApsaraDB for MongoDB console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

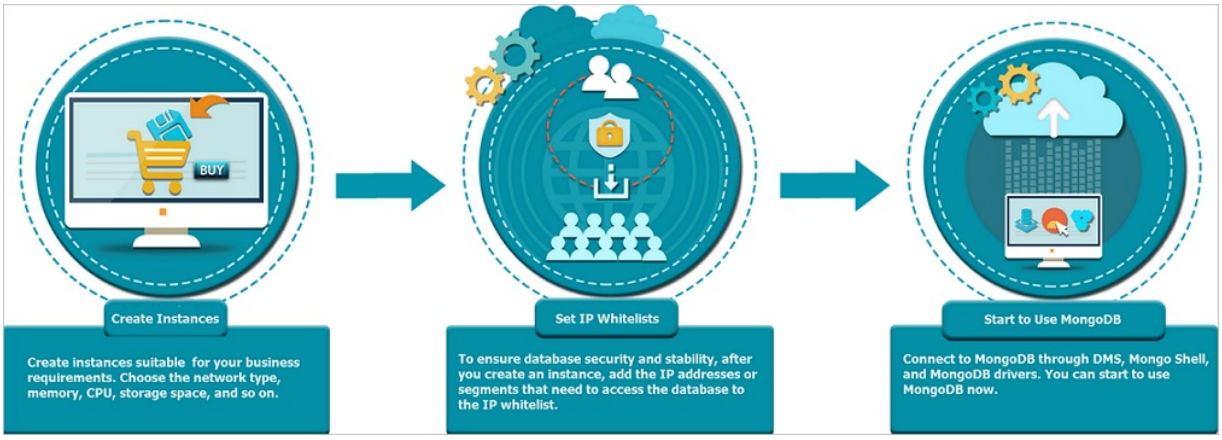
3. Click **Login**.

4. In the top navigation bar, choose **Products** > **Database Services** > **ApsaraDB for MongoDB**.

14.3. Quick start

14.3.1. Use ApsaraDB for MongoDB

This topic is a quick start guide to basic usage operations for ApsaraDB for MongoDB, such as creating an instance, configuring a whitelist, and connecting to an instance. Flowcharts are used to describe the basic procedures in ApsaraDB for MongoDB, and guide you to create an ApsaraDB for MongoDB instance.



- Create an ApsaraDB for MongoDB instance

  An instance is a virtual database server on which you can create and manage multiple databases.

- Configure a whitelist for an ApsaraDB for MongoDB instance

  After you create an ApsaraDB for MongoDB instance, you need to configure a whitelist for the instance to allow external devices to access the instance.

  A whitelist can enhance access security for ApsaraDB for MongoDB instances. We recommend that you update the whitelist on a regular basis. The normal services of the instance are not affected if you configure a whitelist.

- Connect to a replica set instance by using the mongo shell

  After you create an instance and configure a whitelist, you can use the mongo shell to connect to the instance.

14.3.2. Create an ApsaraDB for MongoDB instance

This topic describes how to create an instance in the ApsaraDB for MongoDB console.

Prerequisites

An account is obtained to log on to the ApsaraDB for MongoDB console.

Create a replica set instance

1. Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, click **Create Instance** in the upper-left corner. On the **Create ApsaraDB for MongoDB Instance** page, configure the parameters.

   The following table describes the required parameters.

   Parameters for creating a replica set instance

Section	Parameter	Description
Basic Settings	Organization	Select an organization for the new instance.
	Resource Set	Select a resource set for the new instance.
Region	Region	Select a region for the new instance.
	Zone	Select a zone for the new instance
Specifications	Database Engine	Select a database engine for the new instance. In this case, you can select only **MongoDB**.
	Engine Version	Select a database engine version for the new instance. Valid values: ○ 3.0 ○ 3.4 ○ 4.0 ○ 4.2
	Node Type	ApsaraDB for MongoDB supports the following options: ○ Three-node Replica Set: uses dedicated memory and I/O resources but shares CPU and storage resources with other general-purpose instances on the same server. ○ Dedicated Instance: uses dedicated CPU, memory, storage, and I/O resources to ensure long-term performance. In this case, an instance is not affected by other instances on the same server. ○ Dedicated Host: exclusively uses all resources of a server. This is the top configuration of exclusive specifications.
	Node Specifications	Select a node specification for the new instance. For more information, see descriptions in the ApsaraDB for MongoDB console.
	Storage Capacity (GB)	The storage space of the instance, which contains the space for data, system files, log files, and transaction files. For more information, see *Instance types* in *ApsaraDB for MongoDB Product Introduction*.
Network	Network Type	ApsaraDB for MongoDB supports the following options: ○ **Classic Network**: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. ○ **VPC**: Virtual Private Cloud (VPC) is an isolated network environment built in Apsara Stack. You can customize route tables, CIDR blocks, and gateways in a VPC. We recommend that you select VPC for improved security. **Note** If you select the **VPC** network type, you must configure the **VPC** and **vSwitch** parameters.
	VPC	Select a VPC. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.

Section	Parameter	Description
	vSwitch	Select a vSwitch. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
Password Settings	**Instance Name**	Set the name of the new instance. The name must be 2 to 256 characters in length, The name must start with a letter, and can contain digits, letters, underscores (_), and hyphens (-).
	Password Setting	Determine when to set the password for logging on to databases in the new instance. You can select **Set Now** to set the logon password immediately, or select **Set after Purchase** to set the logon password after you create the instance. For more information, see Reset the password for an ApsaraDB for MongoDB instance.
	Logon Password	Set a password. The password must meet the following requirements: ○ It must be 8 to 32 characters in length. ○ It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. ○ The name can contain special characters. Special characters include ! # $ % ^ & * ( ) _ + =
	Confirm Password	Enter the password again. The password you enter here must be the same as that in New Password.

3. Click **Submit** to create the instance.

Create a sharded cluster instance

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.
3. Click **Create Instance** in the upper-left corner to go to the **Create MongoDB Instance** page. Configure the parameters.

   The following table describes the required parameters.

   Parameters for creating a sharded cluster instance

Section	Parameter	MNS logs
Basic Settings	**Organization**	Select an organization for the new instance.
	Resource Set	Select a resource set for the new instance.
Region	**Region**	Select a region for the new instance.
	Zone	Select a zone for the new instance
	Database Engine	Select a database engine for the new instance. In this case, you can select only **MongoDB**.

Specifications	Parameter	MNS logs
	Engine Version	Select a database engine version for the new instance. Valid values: ○ 3.4 ○ 4.0 ○ 4.2
Network	**Network Type**	ApsaraDB for MongoDB supports the following options: ○ **Classic Network**: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. ○ **VPC**: Virtual Private Cloud (VPC) is an isolated network environment built in Apsara Stack. You can customize route tables, CIDR blocks, and gateways in a VPC. We recommend that you select VPC for improved security. **Note** If you select the **VPC** network type, you must configure the **VPC** and **vSwitch** parameters.
	VPC	Select a VPC. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
	vSwitch	Select a vSwitch. If no vSwitch exists, you can click **Create vSwitch** to create a vSwitch. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
Mongos Specifications	**Mongos Specifications**	The specifications of the mongos node. For more information, see descriptions in the ApsaraDB for MongoDB console.
	Quantity	The number of the mongos nodes. You can select 2 to 32 mongos nodes.
Shard Specifications	**Shard Specifications**	The specifications of the shard node. For more information, see descriptions in the ApsaraDB for MongoDB console.
	Storage Capacity (GB)	The storage space of the instance, which contains the space for data, system files, log files, and transaction files. For more information, see *Instance types* in *ApsaraDB for MongoDB Product Introduction*.
	Quantity	The number of the shard nodes. You can select 2 to 32 shard nodes.
Config Server Specifications	**Config Server Specifications**	The specifications of Configserver nodes. It is fixed at **1 vCPU, 2 GiB memory** and cannot be customized.
	Storage Capacity (GB)	The storage space of the Configserver node. It is fixed at 20 GB and cannot be customized.

Section	Parameter	MNS logs
Password Settings	Instance Name	Set the name of the new instance. The name must be 2 to 256 characters in length, and can contain digits, letters, underscores (_), and hyphens (-). It must start with a letter.
	Password Setting	Determine when to set the password for logging on to databases in the new instance. You can select **Set Now** to set the logon password immediately, or select **Set after Purchase** to set the logon password after you create the instance. For more information, see Reset the password for an ApsaraDB for MongoDB instance.
	Logon Password	Set a password. The password must meet the following requirements: ○ It must be 8 to 32 characters in length. ○ It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. ○ The name can contain special characters. Special characters include ! # $ % ^ & * ( ) _ + =
	Confirm Password	Enter the password again. The password you enter here must be the same as that in New Password.

4. Click **Submit** to create the instance.

14.3.3. Reset the password for an ApsaraDB for MongoDB instance

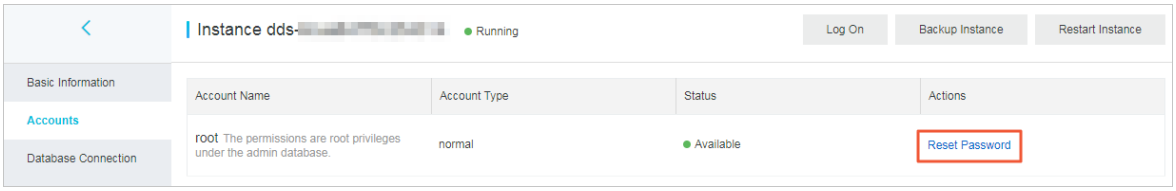
This topic describes how to reset your password in the ApsaraDB for MongoDB console.

Context

Notice We recommend that you change your password on a regular basis to ensure data security.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Accounts**.
5. Click **Reset Password** in the Actions column and configure the parameters in the Reset Password panel.



Parameters for resetting a password describes the parameters.

Parameters for resetting a password

Parameter	Description
New Password	◦ The password must be 8 to 32 characters in length and must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. Special characters include ! # $ % ^ & * ( ) _ + - = ! # $ % ^ & * ( ) _ + - = ◦
Confirm New Password	Enter the password again. The password you enter here must be the same as that in New Password.

6. Click **OK**.

14.3.4. Configure a whitelist for an ApsaraDB for MongoDB instance

This topic describes how to configure a whitelist for an ApsaraDB for MongoDB instance. Before you use an ApsaraDB for MongoDB instance, you must add the IP addresses or Classless Inter-Domain Routing (CIDR) blocks that you use for database access to a whitelist of this instance. This improves database security and stability. Proper configuration of whitelists can enhance access security of ApsaraDB for MongoDB. We recommend that you maintain the whitelists on a regular basis.

Context

The system creates a default whitelist for each instance. This whitelist can be modified or cleared, but it cannot be deleted. After an ApsaraDB for MongoDB instance is created, the system automatically adds the IP address 127.0.0.1 to the **default** whitelist of this instance. The IP address 0.0.0.0/0 indicates that all IP addresses are allowed to access this instance. You must add the IP addresses or CIDR blocks that you allow to access this ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **Data Security** > **Whitelist Settings**.
5. You can manually configure a whitelist or import ECS Internal IP addresses to the whitelist.

   Manually modify a whitelist

   i. Find the whitelist you want to modify and choose > **Manually Modify** in the **Actions** column.

ii. Enter IP addresses or CIDR blocks.

> **Note**
>
> - Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or CIDR blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix in the CIDR block. An IP address prefix can contain 1 to 32 bits.
> - If the IP whitelist is empty or only contains `0.0.0.0/0`, all devices are granted access. This is risky for your ApsaraDB for MongoDB instance. We recommend that you add only the IP addresses or CIDR blocks of your own web servers to the whitelist.

iii. Click **OK**.

Load IP addresses of ECS instances

i. Find the whitelist, and choose > **Import ECS Intranet IP** in the **Actions** column.

ii. From the displayed internal IP addresses of ECS instances that belong to the current account, select the IP addresses and click > to add them to the whitelist.

iii. Click **OK**.

14.3.5. Connect to an instance

14.3.5.1. Use DMS to log on to an ApsaraDB for MongoDB instance

You can use DMS to connect to an ApsaraDB for MongoDB instance.

Prerequisites

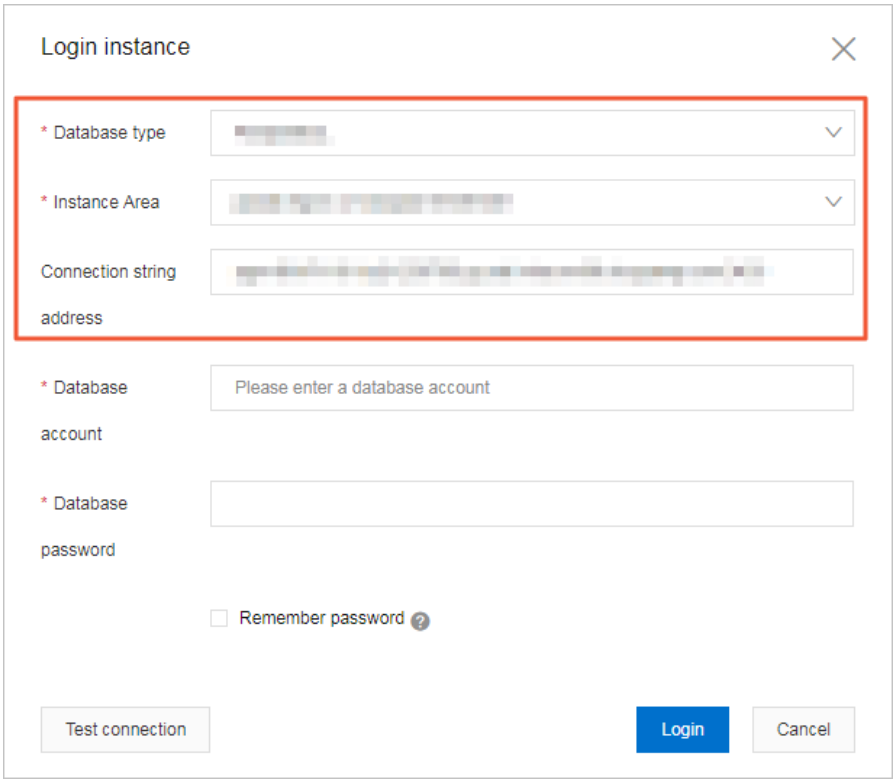
The IP address whitelist is configured. For more information about how to configure the IP address whitelist, see Configure a whitelist for an ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. Click **Log On** in the upper-right corner of the page.

   > **Note** For a sharded cluster instance, you must also select the Mongos node.

5. In the **Login instance** dialog box of the **DMS** console, check values of **Database type**, **Instance Area**, and **Connection string address**. If the information is correct, enter **Database account** and **Database password**, as shown in the following figure.



Parameter	Description
Database type	The engine of the database. By default, the engine of the database to be connected is displayed.
Instance Area	The region where the instance is deployed. By default, the region of the current instance is displayed.
Connection string address	The endpoint of the instance. By default, the endpoint of the current instance is displayed.
Database account	The account of the database to be connected.
Database password	The password of the account used to connect to the database.

6. Click **Login**.

> **Note** If you want your web browser to remember the password, select **Remember password** before you click **Login**.

14.3.5.2. Use the mongo shell to connect to an ApsaraDB for MongoDB instance

This topic describes how to use the mongo shell to connect to an ApsaraDB for MongoDB instance. The mongo shell is a database management tool provided by ApsaraDB for MongoDB. You can install it on your client or in an Elastic Compute Service (ECS) instance.

Prerequisites

- The version of the mongo shell is the same as your ApsaraDB for MongoDB instance. This ensures successful authentication. For more information about the installation procedure, see Install MongoDB. Choose the version

in the upper-left corner of the page based on your client version.

- The IP address of your client is added to a whitelist of the ApsaraDB for MongoDB instance. For more information, see Configure a whitelist for an ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Database Connections** to view connection strings.

   > **Note**
   > - Replica set instances: View the connection string or connection string URI of a node.
   > - Sharded cluster instances: View the connection string or connection string URI of a mongos node.
   >
   > For more information about connection strings, see Overview of replica set instance connections or Overview of sharded cluster instance connections.

5. Connect to the ApsaraDB for MongoDB instance from your client or ECS instance where the mongo shell is installed.

   Replica set instances:

   - Connection string of a node

     During routine tests, you can directly connect to a primary or secondary node. Note that if the primary node fails, the system automatically switches to the secondary node, and the roles of connected nodes change. This affects the read and write operations of your application.

     Command syntax:

     ```
     mongo --host <host> -u <username> -p --authenticationDatabase <database>
     ```

     > **Note**
     > - <host>: the connection string of the primary or secondary node.
     > - <username>: the username used to log on to a database of the instance. The initial username is **root**.
     > - <database>: the name of the database corresponding to the username if authentication is enabled. If the database username is root, enter admin as the database name.

     Example:

     ```
     mongo --host dds-bp**********.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase admin
     ```

     When `Enter password:` is displayed, enter the password of the database user and press the Enter key. If you forget the password of the root user, you can reset it. For more information, see Reset the password for an ApsaraDB for MongoDB instance.

     > **Note** The password characters are not displayed when you enter the password.

   - HA connection (recommended): You can use a connection string URI to connect to both the primary and secondary nodes of a replica set instance. This ensures that your application is always connected to the primary node and the read and write operations of your application are not affected even if the roles of the primary and secondary nodes are switched.

Command syntax:

```
mongo "<ConnectionStringURI>"
```

> **Note**
> - The connection string URI must be enclosed in a pair of double quotation marks ("").
> - <ConnectionStringURI>: the connection string URI of the instance.
>
> You must replace `****` in the connection string URI with the database password. For more information about how to set a database password, see Reset the password for an ApsaraDB for MongoDB instance.

Example:

```
mongo "mongodb://root:****@dds-**********.mongodb.rds.intra.env17e.shuguang.com:3717,dds-**********.mongodb.rds.intra.env17e.shuguang.com:3717/admin?replicaSet=mgset-*****"
```

Sharded cluster instances:

- Connection string of a mongos node

  Command syntax:

  ```
  mongo --host <mongos_host> -u <username> -p --authenticationDatabase <database>
  ```

  > **Note**
  > - <mongos_host>: the connection string of a mongos node in the sharded cluster instance.
  > - <username>: the username used to log on to a database of the instance. The initial username is **root**.
  > - <database>: the name of the database corresponding to the username if authentication is enabled. If the database username is root, enter admin as the database name.

  Example:

  ```
  mongo --host s-bp**********.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase admin
  ```

- HA connection (recommended): You can use a connection string URI to connect to a database. If one mongos node fails, another mongos node takes over business to ensure the high availability of the connection.

  Command syntax:

  ```
  mongo "<ConnectionStringURI>"
  ```

  > **Note**
  > - The connection string URI must be enclosed in a pair of double quotation marks ("").
  > - <ConnectionStringURI>: the **connection string URI** of the instance.
  >
  > You must replace `****` in the **connection string URI** with the database password. For more information about how to set a database password, see Reset the password for an ApsaraDB for MongoDB instance.

  Example:

```
mongo "mongodb://root:****@s-**********.mongodb.rds.intra.env17e.shuguang.com:3717,s-**********.mongodb.rds.intra.env17e.shuguang.com:3717/admin"
```

14.3.5.3. Introduction to connection strings and URIs

14.3.5.3.1. Overview of replica set instance connections

ApsaraDB for MongoDB supports both connection strings and connection string URIs. You can use a connection string to connect to the primary or secondary node, and use a connection string URI to connect to both of them. For high availability, we recommend that you use connection string URIs to connect your application to both primary and secondary nodes. This topic provides an overview of replica set instance connections.

Prerequisites

A whitelist is configured for the instance. For more information, see Configure a whitelist for an ApsaraDB for MongoDB instance.

View connection strings

1. Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, find the instance and then click the instance ID or choose **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
3. In the left-side navigation pane, click **Database Connections** to view connection strings.

Description of connection strings

Item	Description
Connection type	• Internal Connections - Classic Network: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. • Internal Connections - VPC: A virtual private cloud (VPC) is an isolated network with higher security and performance than the classic network. By default, ApsaraDB for MongoDB provides VPC endpoints.
Role	• Primary: the primary node in the replica set instance. If you connect to this node, you can perform read and write operations on the databases of the replica set instance. • Secondary: the secondary node in the replica set instance. If you connect to this node, you can perform only read operations on the databases of the replica set instance. • Connection String URI: ApsaraDB for MongoDB allows you to use a connection string URI to connect to a replica set instance to achieve load balancing and high availability.
Connection string	The connection string of a primary or secondary node is in the following format: `<host>:<port>` • <host>: the endpoint used to connect to the instance. • <port>: the port used to connect to the instance.

Item	Description
Connection string URI	A connection string URI is in the following format: **mongodb://[username:password@]host1[:port1][,host2[:port2],...[,hostN[:portN]]][/[database][?options]]** • mongodb://: the prefix of a connection string URI. • username:password@: the username and password used to log on to a database of the replica set instance. You must separate them with a colon (:). • hostX:portX: the endpoint and port of a node in the replica set instance. • /database: the name of the database corresponding to the username if authentication is enabled. • ?options: additional connection options. **Note** If your application is in a production environment, we recommend that you use a connection string URI to connect to the instance. This way, when a node fails, the read and write operations of your application are not affected as a result of the failover.

Related information

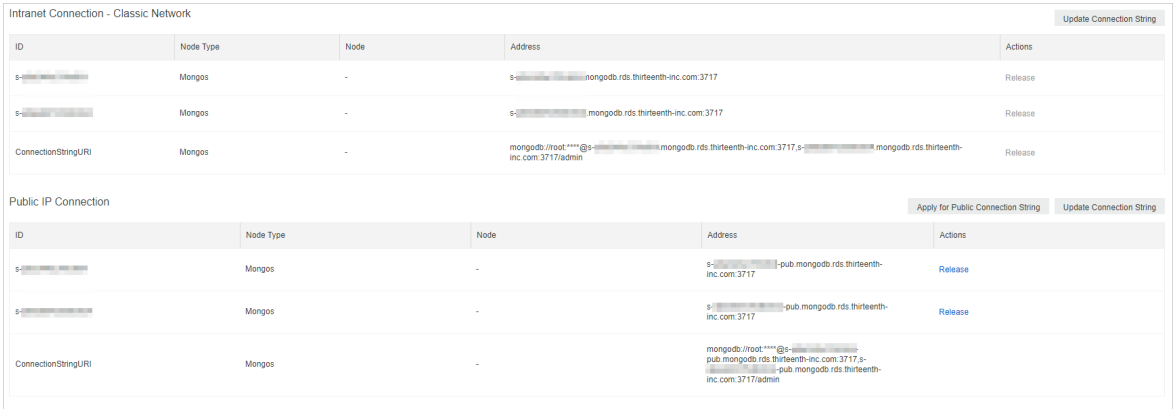
- Connect to a replica set instance by using the mongo shell

14.3.5.3.2. Overview of sharded cluster instance connections

ApsaraDB for MongoDB supports both connection strings and connection string URIs. You can use a connection string to connect to a single mongos node, and use a connection string URI to connect to multiple mongos nodes. For high availability, we recommend that you use connection string URIs to connect your application to multiple mongos nodes. This topic provides an overview of sharded cluster instance connections.

View connection strings

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Database Connections** to view connection strings.



Description of connection strings

Item	Description
Connection type	• Internal Connections - Classic Network: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. • Internal Connections - VPC: A virtual private cloud (VPC) is an isolated network with higher security and performance than the classic network. By default, ApsaraDB for MongoDB provides VPC endpoints. • Public Connections: Security risks may arise if you connect to a sharded cluster instance over the Internet. Therefore, ApsaraDB for MongoDB does not provide public endpoints. If you want to connect to an ApsaraDB for MongoDB instance from a device outside of Alibaba Cloud (such as an on-premises device), you must apply for a public endpoint. For more information, see Apply for a public endpoint for an ApsaraDB for MongoDB instance.
Mongos ID	The connection string of a mongos node is in the following format: `<host>:<port>` • <host>: the endpoint used to connect to the instance. • <port>: the port used to connect to the instance. **Note** During routine tests, you can use a connection string to directly connect to a mongos node.
Connection string URI	A connection string URI is in the following format: `mongodb://[username:password@]host1[:port1][,host2[:port2],...[,hostN[:portN]]][/[database][?options]]` • mongodb://: the prefix of a connection string URI. • username:password@: the username and password used to log on to a database of the sharded cluster instance. You must separate them with a colon (:). • hostX:portX: the endpoint and port of a mongos node in the sharded cluster instance. • /database: the name of the database corresponding to the username if authentication is enabled. • ?options: additional connection options. **Note** If your application is in a production environment, we recommend that you use a connection string URI to connect to the instance. Then, your client can automatically distribute your requests to multiple mongos nodes to balance loads. If a mongos node fails, your client automatically redirects requests to other mongos nodes in the normal state.

Log on to a database of an ApsaraDB for MongoDB instance

1. Obtain the connection string and the following information:
   - The username used to log on to the database. The initial username is root.
   - The password of the database user. If you forget the password of the root user, you can reset it. For more information, see Reset the password for an ApsaraDB for MongoDB instance.
   - The name of the database corresponding to the username if authentication is enabled. If the database username is root, enter admin as the database name.
2. Log on to the database.
   - Use DMS to log on to a replica set instance of ApsaraDB for MongoDB
   - Connect to a replica set instance by using the mongo shell

14.4. Instances

14.4.1. Create an ApsaraDB for MongoDB instance

This topic describes how to create an instance in the ApsaraDB for MongoDB console.

Prerequisites

An account is obtained to log on to the ApsaraDB for MongoDB console.

Create a replica set instance

1. Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, click **Create Instance** in the upper-left corner. On the **Create ApsaraDB for MongoDB Instance** page, configure the parameters.

   The following table describes the required parameters.

   Parameters for creating a replica set instance

Section	Parameter	Description
Basic Settings	Organization	Select an organization for the new instance.
	Resource Set	Select a resource set for the new instance.
Region	Region	Select a region for the new instance.
	Zone	Select a zone for the new instance
Specifications	Database Engine	Select a database engine for the new instance. In this case, you can select only **MongoDB**.
	Engine Version	Select a database engine version for the new instance. Valid values: ○ 3.0 ○ 3.4 ○ 4.0 ○ 4.2
	Node Type	ApsaraDB for MongoDB supports the following options: ○ Three-node Replica Set: uses dedicated memory and I/O resources but shares CPU and storage resources with other general-purpose instances on the same server. ○ Dedicated Instance: uses dedicated CPU, memory, storage, and I/O resources to ensure long-term performance. In this case, an instance is not affected by other instances on the same server. ○ Dedicated Host: exclusively uses all resources of a server. This is the top configuration of exclusive specifications.
	Node Specifications	Select a node specification for the new instance. For more information, see descriptions in the ApsaraDB for MongoDB console.

Section	Parameter	Description
	Storage Capacity (GB)	The storage space of the instance, which contains the space for data, system files, log files, and transaction files. For more information, see *Instance types* in *ApsaraDB for MongoDB Product Introduction*.
Network	**Network Type**	ApsaraDB for MongoDB supports the following options: ○ **Classic Network**: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. ○ **VPC**: Virtual Private Cloud (VPC) is an isolated network environment built in Apsara Stack. You can customize route tables, CIDR blocks, and gateways in a VPC. We recommend that you select VPC for improved security. **Note** If you select the **VPC** network type, you must configure the **VPC** and **vSwitch** parameters.
	VPC	Select a VPC. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
	vSwitch	Select a vSwitch. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
Password Settings	**Instance Name**	Set the name of the new instance. The name must be 2 to 256 characters in length, The name must start with a letter, and can contain digits, letters, underscores (_), and hyphens (-).
	Password Setting	Determine when to set the password for logging on to databases in the new instance. You can select **Set Now** to set the logon password immediately, or select **Set after Purchase** to set the logon password after you create the instance. For more information, see Reset the password for an ApsaraDB for MongoDB instance.
	Logon Password	Set a password. The password must meet the following requirements: ○ It must be 8 to 32 characters in length. ○ It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. ○ The name can contain special characters. Special characters include ! # $ % ^ & * ( ) _ + =
	Confirm Password	Enter the password again. The password you enter here must be the same as that in New Password.

3. Click **Submit** to create the instance.

Create a sharded cluster instance

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.
3. Click **Create Instance** in the upper-left corner to go to the **Create MongoDB Instance** page. Configure the

parameters.

The following table describes the required parameters.

Parameters for creating a sharded cluster instance

Section	Parameter	MNS logs
Basic Settings	**Organization**	Select an organization for the new instance.
	Resource Set	Select a resource set for the new instance.
Region	**Region**	Select a region for the new instance.
	Zone	Select a zone for the new instance
Specifications	**Database Engine**	Select a database engine for the new instance. In this case, you can select only **MongoDB**.
	Engine Version	Select a database engine version for the new instance. Valid values: ○ 3.4 ○ 4.0 ○ 4.2
Network	**Network Type**	ApsaraDB for MongoDB supports the following options: ○ **Classic Network**: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. ○ **VPC**: Virtual Private Cloud (VPC) is an isolated network environment built in Apsara Stack. You can customize route tables, CIDR blocks, and gateways in a VPC. We recommend that you select VPC for improved security. **Note** If you select the **VPC** network type, you must configure the **VPC** and **vSwitch** parameters.
	VPC	Select a VPC. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
	vSwitch	Select a vSwitch. If no vSwitch exists, you can click **Create vSwitch** to create a vSwitch. **Note** When **Network Type** is set to **VPC**, you must specify this parameter.
Mongos Specifications	**Mongos Specifications**	The specifications of the mongos node. For more information, see descriptions in the ApsaraDB for MongoDB console.
	Quantity	The number of the mongos nodes. You can select 2 to 32 mongos nodes.

Section	Parameter	MNS logs
Shard Specifications	Shard Specifications	The specifications of the shard node. For more information, see descriptions in the ApsaraDB for MongoDB console.
	Storage Capacity (GB)	The storage space of the instance, which contains the space for data, system files, log files, and transaction files. For more information, see *Instance types* in *ApsaraDB for MongoDB Product Introduction*.
	Quantity	The number of the shard nodes. You can select 2 to 32 shard nodes.
Config Server Specifications	Config Server Specifications	The specifications of Configserver nodes. It is fixed at **1 vCPU, 2 GiB memory** and cannot be customized.
	Storage Capacity (GB)	The storage space of the Configserver node. It is fixed at 20 GB and cannot be customized.
Password Settings	Instance Name	Set the name of the new instance. The name must be 2 to 256 characters in length, and can contain digits, letters, underscores (_), and hyphens (-). It must start with a letter.
	Password Setting	Determine when to set the password for logging on to databases in the new instance. You can select **Set Now** to set the logon password immediately, or select **Set after Purchase** to set the logon password after you create the instance. For more information, see Reset the password for an ApsaraDB for MongoDB instance.
	Logon Password	Set a password. The password must meet the following requirements: ○ It must be 8 to 32 characters in length. ○ It must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. ○ The name can contain special characters. Special characters include ! # $ % ^ & * ( ) _ + =
	Confirm Password	Enter the password again. The password you enter here must be the same as that in New Password.

4. Click **Submit** to create the instance.

14.4.2. View the details of an ApsaraDB for MongoDB instance

This topic describes how to view the details of an ApsaraDB for MongoDB instance, such as the basic information, internal network connection information, status, and configurations. This topic describes how to view the details of an ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Go to the instance details page. Either of the following methods can be used:
   - Find the instance and click its ID to go to the **Basic Information** page, where you can view the details of

the instance.

- In the Operations column corresponding to the instance, choose > **Manage** to go to the **Basic Information** page, where you can view the details of the instance.

14.4.3. Restart an ApsaraDB for MongoDB instance

You can manually restart an instance when the number of connections exceeds the threshold or any performance issue occurs on the instance. This topic describes how to restart an ApsaraDB for MongoDB instance.

Prerequisites

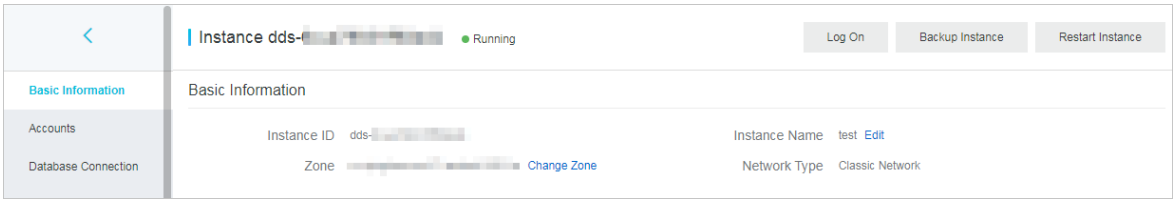
The instance is in the **Running** state.

Context

Note When an ApsaraDB for MongoDB instance is restarted, all its connections are terminated. Plan your operations in advance before you restart an ApsaraDB for MongoDB instance. Proceed with caution.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the upper-right corner of the page, click **Restart Instance**.



Note You can also choose > **Restart** in the **Actions** column corresponding to the instance.

5. In the **Restart Instance** message, click **OK**.

14.4.4. Change the specifications of an ApsaraDB for MongoDB instance

This topic describes how to change the specifications of an ApsaraDB for MongoDB instance. You can upgrade or downgrade an ApsaraDB for MongoDB instance to meet your business needs.

Prerequisites

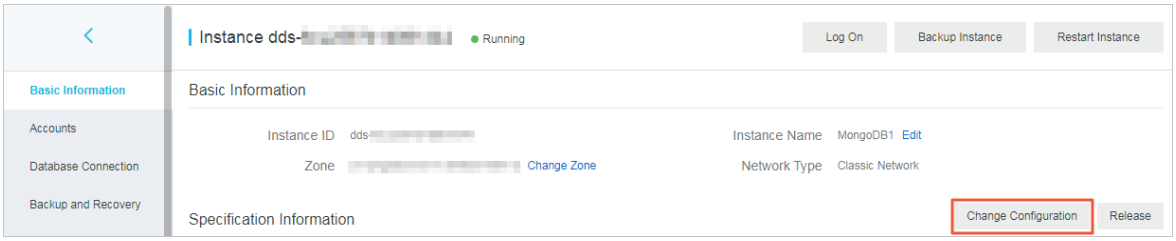
The instance must be an ApsaraDB for MongoDB replica set instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, find the instance and then click the instance ID or choose > **Manage** in

the **Actions** column. Then, the **Basic Information** page appears.

3. Click **Change Configuration** in the upper right corner of the Specification Information section to go to the **Modify Instance** page.



> **Note** To go to the **Modify Instance** page, you can also choose > **Change Configuration** in the **Actions** column corresponding to the instance on the **Replica Set Instances** page.

4. On the **Modify Instance** page, change the instance specifications.

   You can change values of the following parameters:

   - **Node Type**
   - **Node Specifications**
   - **Storage Capacity**

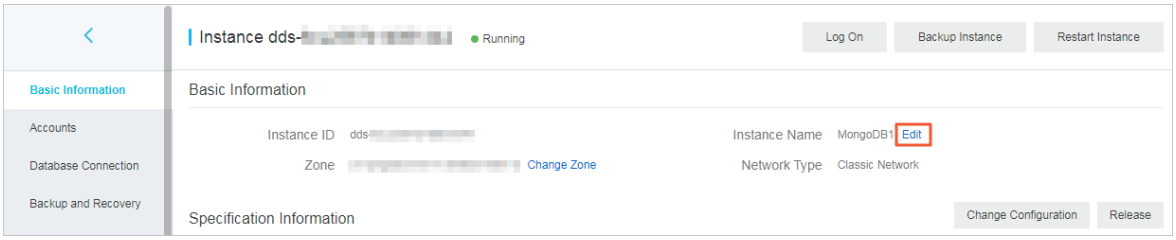
5. Click **Submit**.

14.4.5. Change the name of an ApsaraDB for MongoDB instance

This topic describes how to change the name of an ApsaraDB for MongoDB instance for better management.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. Click **Edit** next to **Instance Name**.



> **Note**
>
> - The instance name must start with an English letter. It cannot start with http:// or https://.
> - The instance name can contain letters, underscores (_), hyphens (-), and digits.
> - The instance name must be 2 to 128 characters in length.

5. Click **OK**.

14.4.6. Reset the password for an ApsaraDB for MongoDB instance

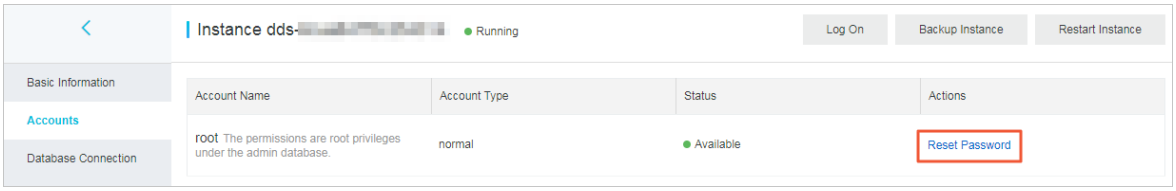
This topic describes how to reset your password in the ApsaraDB for MongoDB console.

Context

Notice We recommend that you change your password on a regular basis to ensure data security.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Accounts**.
5. Click **Reset Password** in the Actions column and configure the parameters in the Reset Password panel.



Parameters for resetting a password describes the parameters.

Parameters for resetting a password

Parameter	Description
New Password	○ The password must be 8 to 32 characters in length and must contain at least three of the following character types: uppercase letters, lowercase letters, digits, and special characters. Special characters include ! # $ % ^ & * ( ) _ + - = ! # $ % ^ & * ( ) _ + - = ○
Confirm New Password	Enter the password again. The password you enter here must be the same as that in New Password.

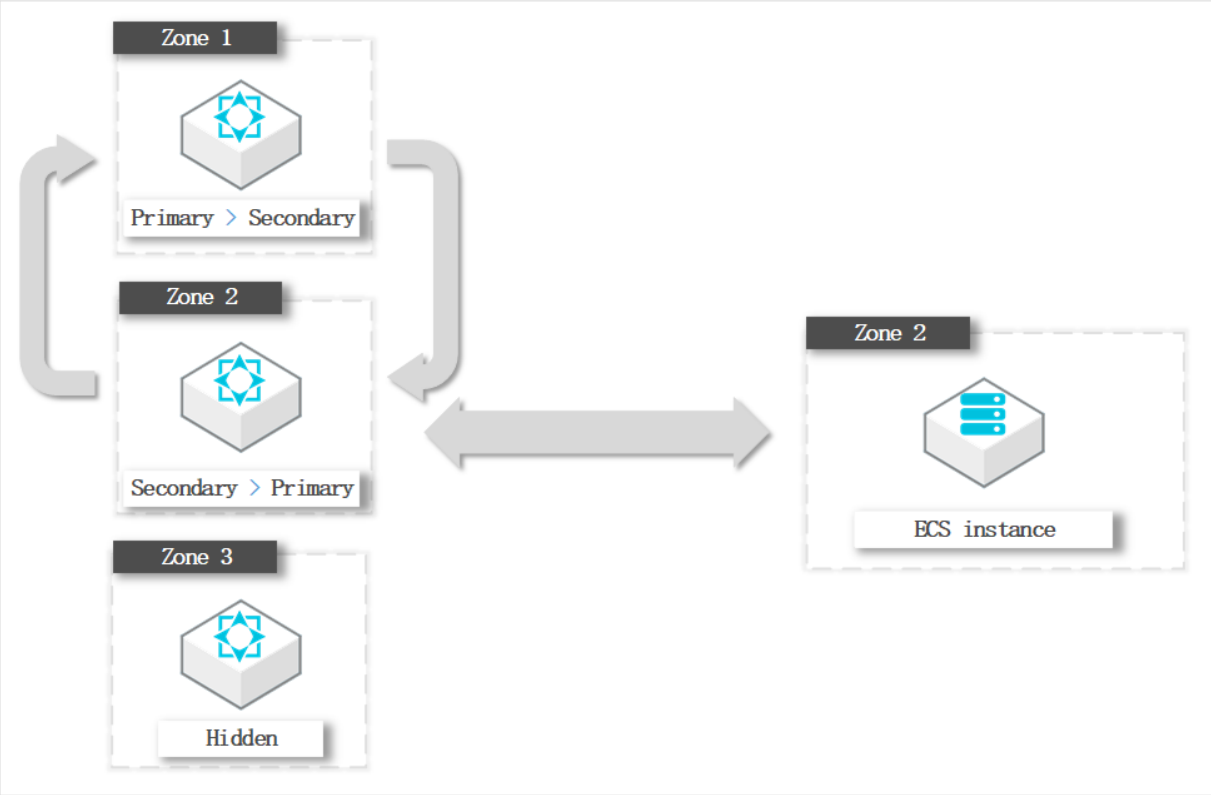
6. Click **OK**.

14.4.7. Switch node roles

You can switch the node roles of an ApsaraDB for MongoDB instance in the ApsaraDB for MongoDB console based on your business deployment.

Typical scenario

When an ECS instance and an ApsaraDB for MongoDB instance are in the same zone and connected over the internal network, the latency is minimal. If they are connected across different zones, the latency increases and the performance of ApsaraDB for MongoDB instances and your business will be affected.



In this example, the ECS instance to which the application belongs is in Zone 2. If the primary node of the ApsaraDB for MongoDB instance is in Zone 1, the ECS instance needs to connect to the primary node across zones.

To optimize the business deployment architecture, you can switch the roles of the primary and secondary nodes. In this example, you can change the role of the node in Zone 2 to primary and the role of the node in Zone 1 to secondary. Note that only the node roles are changed. ECS and ApsaraDB for MongoDB instances can be connected in the same zone without changing the actual zones and role IDs.

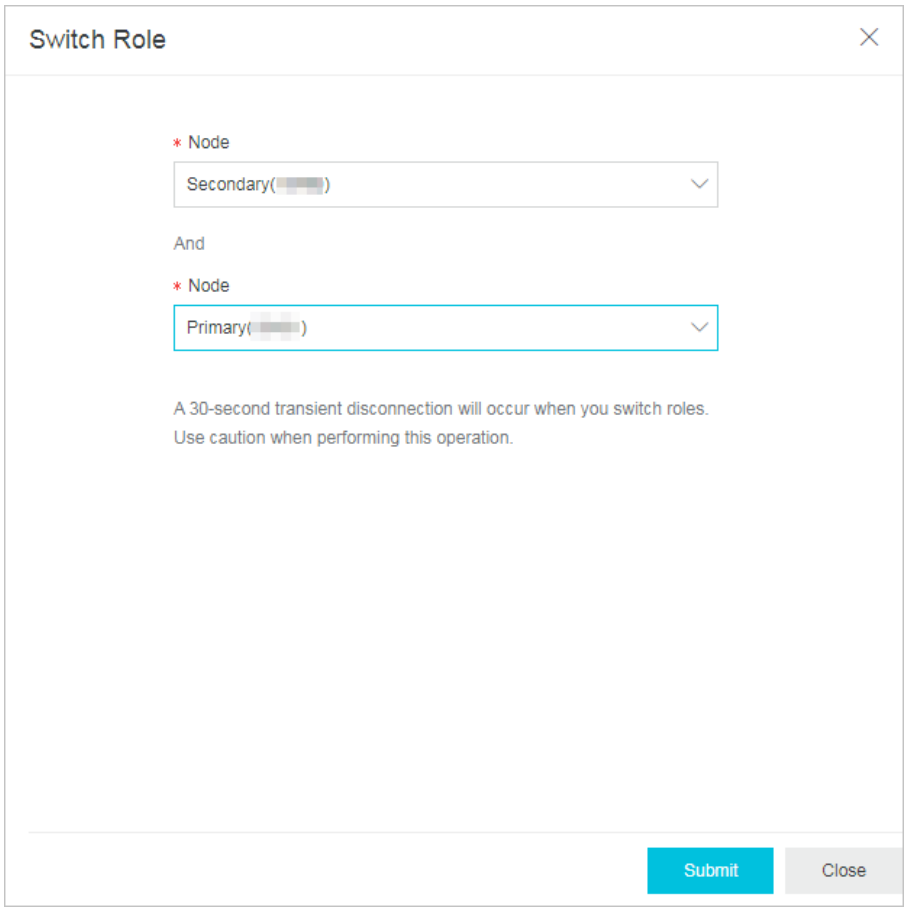
Precautions

- Switching node roles will cause a transient disconnection of up to 30 seconds. Perform this operation during off-peak hours or ensure that your application has a reconnection mechanism.
- Switching node roles only changes the roles of nodes, but not the zones and role IDs of nodes.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Service Availability**.
5. Subsequent steps on the **Service Availability** page vary depending on instance types.
   - Replica set instance
     a. Click **Switch Role** in the upper-right corner of the page.

b. In the **Switch Role** dialog box that appears, select the nodes.



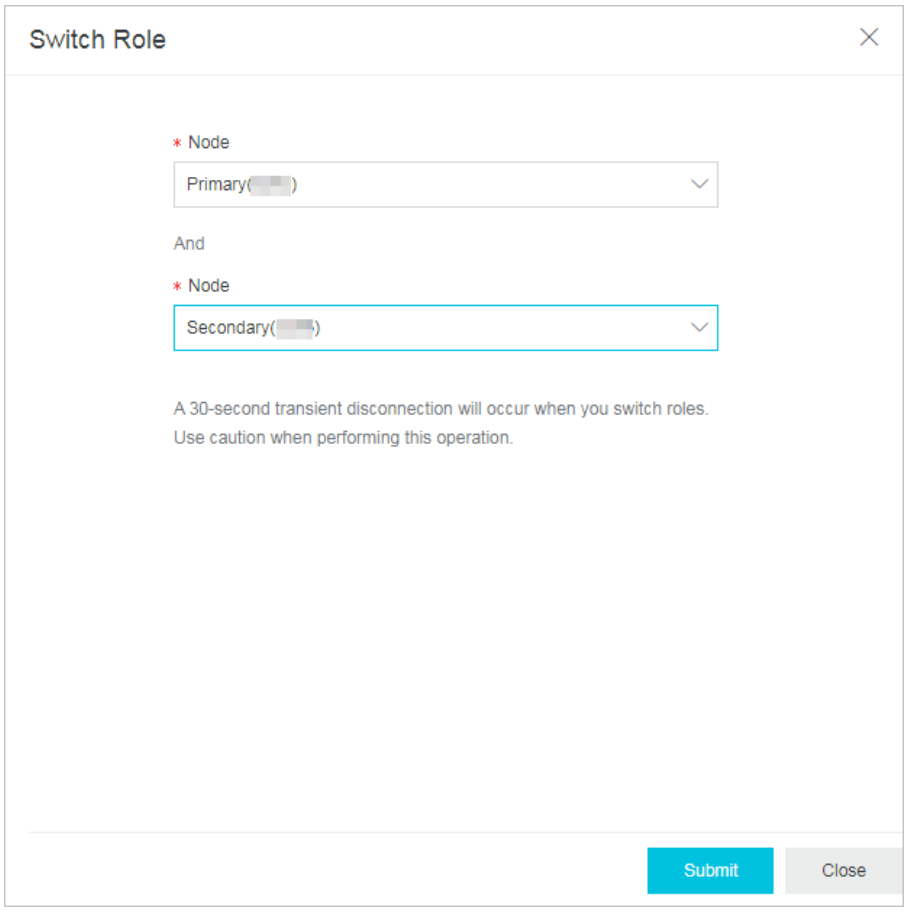
c. Click **OK**.

- Sharded cluster instance

> **Note** For sharded cluster instances, you can only manage the zone distribution of shard and Configserver nodes.

a. In the upper-right corner of the **Zone Distribution for Shards** or **Zone Distribution for Configservers** section, click **Switch Role**.

b. In the **Switch Role** dialog box that appears, select the nodes.



- Click **OK**.

14.4.8. Migrate an ApsaraDB for MongoDB instance across zones in the same region

This topic describes how to migrate an ApsaraDB for MongoDB instance across zones in the same region. After instances are migrated to other zones, the attributes, specifications, and connection strings of the instances remain unchanged.

Prerequisites

- The ApsaraDB for MongoDB instance is a replica set instance or sharded cluster instance that runs MongoDB 4.2 or later.
- Transparent data encryption (TDE) is not enabled for the ApsaraDB for MongoDB instance.
- The destination zone must be in the same region as the current zone of the instance.
- If the instance is in a VPC, make sure that a vSwitch is created in the destination zone before you start migration. For more information, see *Create a VPC* and *Create a vSwitch* in *VPC User Guide*.
- The instance does not have a public endpoint. If you have applied for a public endpoint, you must release it before migration. For more information, see Release a public connection string.

Precautions

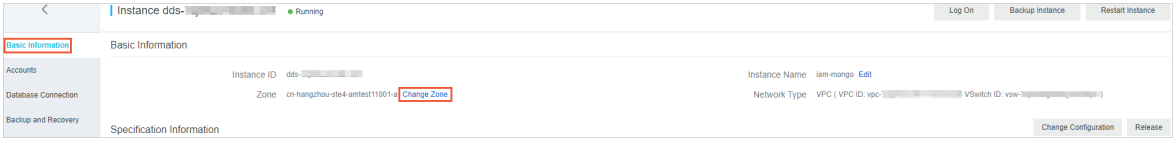
- If the instance is in a VPC, you cannot change the VPC when the instance is in the migration process.
- The time required varies based on factors such as the network conditions, task queue status, and data volume. We recommend that you migrate the instance across zones during off-peak hours.

- During the migration, a transient connection of 30 seconds occurs. Make sure that your application is configured to reconnect to the instance after it is disconnected.
- The virtual IP addresses (VIPs) of the instance, such as 172.16.88.60, are changed when the instance is migrated across zones. If your application uses the original VIP, the application cannot connect to the instance after the migration.

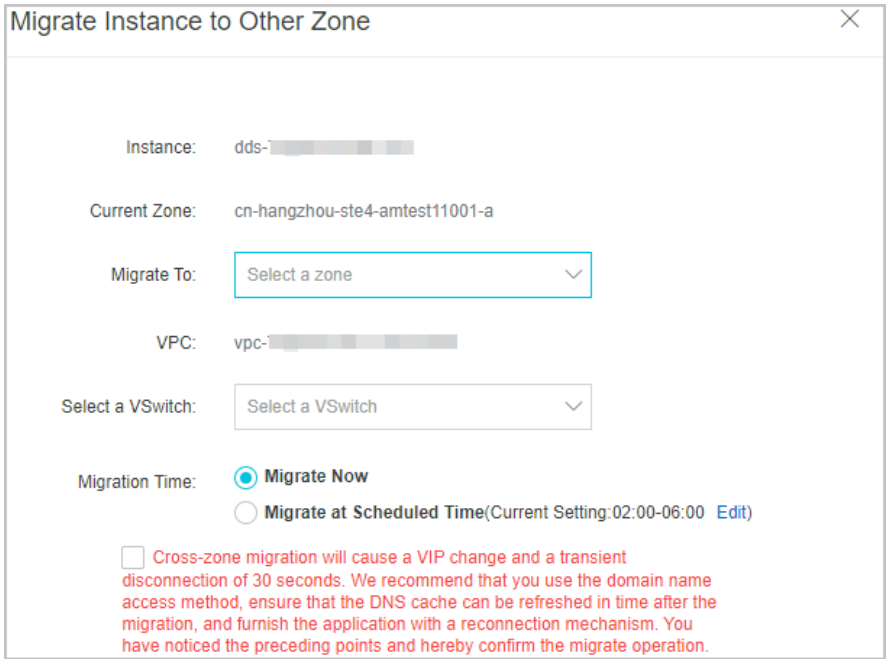
> **Note** We recommend that you use a connection string URI to connect to the instance, which ensures high availability. For more information, see Overview of replica set instance connections or Overview of sharded cluster instance connections.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the **Basic Information** section, click **Change Zone**.



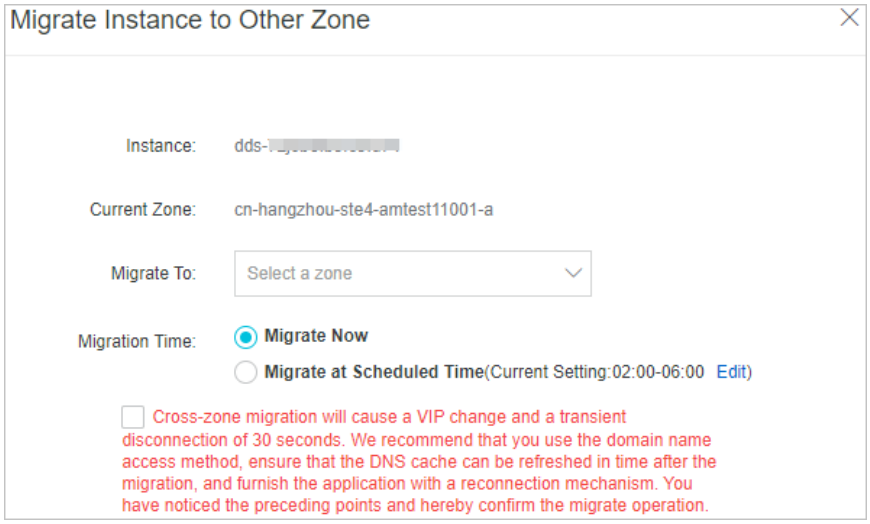
5. In the **Migrate Instance to Other Zone** panel, configure parameters based on the network type of the instance.
   - VPC



Parameter	Description
Migrate To	Select the destination zone.
Select a VSwitch	Select the destination vSwitch.

Parameter	Description
Migration Time	Select the time when you want to start the migration. ■ **Switch Immediately after Migration**: The migration immediately starts. When the instance status changes to Running, the migration is complete. ■ **Switch within Maintenance Window**: The migration starts during the specified period. You can click **Edit** next to **Switch within Maintenance Window** to change the period.

- Classic network



Parameter	Description
Migrate To	Select the destination zone.
Migration Time	Select the time when you want to start the migration. ■ **Switch Immediately after Migration**: The migration immediately starts. When the instance status changes to Running, the migration is complete. ■ **Switch within Maintenance Window**: The migration starts during the specified period. You can click **Edit** next to **Switch within Maintenance Window** to change the period.

6. Read the message that is displayed and select the check box next to the message.
7. Click **OK**.

14.4.9. Release an ApsaraDB for MongoDB instance

This topic describes how to manually release an ApsaraDB for MongoDB instance to meet your business needs. This topic describes how to manually release an ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.

4. In the lower-right corner of the **Basic Information** section, click **Release**.

   > **Note** You can also go to the Replica Set Instances page, find the instance, click the icon in the **Actions** column, and then choose **Release**.

5. In the **Release Instance** message, click **OK**.

   > **Warning** After you release an ApsaraDB for MongoDB instance, data in the instance can no longer be recovered. Proceed with caution.

14.4.10. Primary/secondary failover

14.4.10.1. Trigger a primary/secondary failover for a replica set instance

An ApsaraDB for MongoDB replica set instance consists of three nodes by default. ApsaraDB for MongoDB provides connection strings for you to connect to the primary node and a secondary node. The other secondary node is hidden as a backup to ensure high availability. If a node is faulty, the high availability system of ApsaraDB for MongoDB automatically triggers a primary/secondary failover to ensue the availability of the instance. You also can manually trigger a primary/secondary failover for an ApsaraDB for MongoDB instance in scenarios such as routine disaster recovery drills.

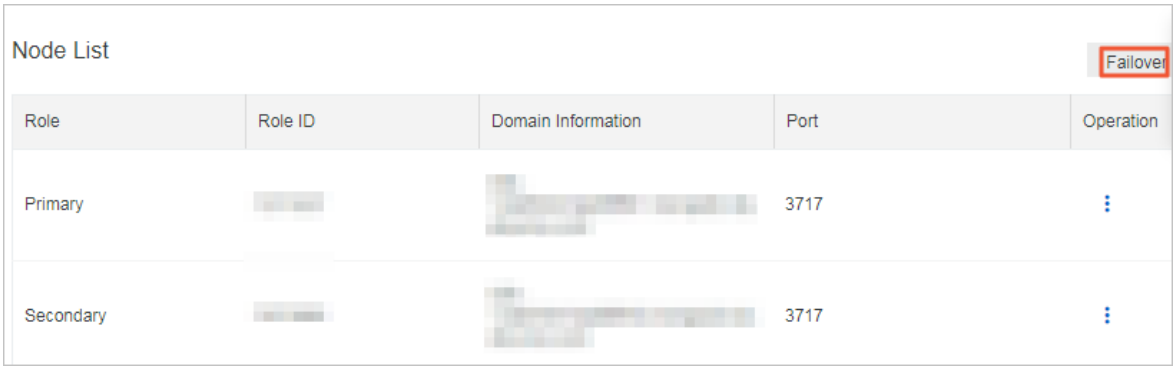
Context

After you log on to the ApsaraDB for MongoDB console or call the SwitchDBInstanceHA operation to trigger a primary/secondary failover for a replica set instance, ApsaraDB for MongoDB interchanges the roles of the primary and secondary nodes.

> **Note**
> - You can trigger a primary/secondary failover only for replica set and sharded cluster instances, but not for standalone instances due to their single-node architecture.
> - Each time you trigger a primary/secondary failover for an instance, the instance may have a transient connection error of about 30 seconds. Ensure that your applications can automatically re-establish a connection.
> - You can trigger a primary/secondary failover only for instances in the running state.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, find the instance and then click the instance ID or choose **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
3. In the **Node List** section, click **Failover**, as shown in the following figure.



4. In the dialog box that appears, click **OK**.
5. The instance status changes to **HA Switching**.The failover is successful when the instance status changes back to **Running**.

   The failover operation is complete in about one minute. Then the instance returns to normal.

> **Note** If you have connected to the connection string of the primary node for an instance, you are connecting to a secondary node after a failover and you have no write permissions on the instance. In this case, you must connect to the connection string of the new primary node and obtain read and write permissions. For more information, see Overview of replica set instance connections.

14.4.10.2. Trigger a primary/secondary failover for a sharded cluster instance

Each shard or Configserver of a sharded cluster instance consists of three nodes by default. If a node is faulty, the high availability system of ApsaraDB for MongoDB automatically triggers a primary/secondary failover to ensure the availability of the shard. You can also manually trigger a primary/secondary failover for an ApsaraDB for MongoDB instance in scenarios such as routine disaster recovery drills.

Precautions

ApsaraDB for MongoDB provides connection strings for you to connect to the primary and secondary nodes. The hidden node is invisible to you and only used to ensure high availability. After you log on to the ApsaraDB for MongoDB console or call the SwitchDBInstanceHA operation to trigger a primary/secondary failover for a shard of a sharded cluster instance, ApsaraDB for MongoDB switches the roles of the primary and secondary nodes.

> **Note**
> - You can trigger a primary/secondary failover only for the shard or Configserve node in the running state.
> - Each time you trigger a primary/secondary failover for an instance, the instance may have a transient connection error of about 30 seconds. We recommend that you perform this operation during off-peak hours and ensure that your applications can automatically re-establish a connection.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the **Shard List** or **ConfigServer List** section, find the node and choose > **Failover** in the Actions column.

> **Note** You can trigger a primary/secondary failover separately for each shard node. The failover operation takes effect only for the current shard node and does not affect other shard nodes of the same sharded cluster instance.

5. In the **Failover** message, click **OK**.

> **Note** The failover operation is complete in about one minute.

14.4.11. Monitoring

This topic describes the performance metrics provided by ApsaraDB for MongoDB to check the status of ApsaraDB for MongoDB instances. You can view these performance metrics in the ApsaraDB for MongoDB console.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Monitoring Info**.

   You can select a time range to query historical performance metrics. The following table describes metric details.

   Performance metrics

Performance metric	Description	Monitoring frequency
CPU Utilization Percentage	cpu_usage: the CPU utilization of the instance	Every 300 seconds
Memory Usage Percentage	mem_usage: the memory usage of the instance	Every 300 seconds
IOPS Usage	The input/output operations per second (IOPS) of the instance. The following items are included: ◦ data_iops: the IOPS of the data disk. ◦ log_iops: the IOPS of the log disk.	Every 300 seconds
IOPS Usage Percentage	iops_usage: the ratio of the IOPS used by the instance to the maximum IOPS allowed	Every 300 seconds
Disk Usage	The total disk space used by the instance. The following items are included: ◦ ins_size: the total space used. ◦ data_size: the space used on the data disk. ◦ log_size: the space used on the log disk.	Every 300 seconds

Performance metric	Description	Monitoring frequency
Disk Usage Percentage	disk_usage: the ratio of the total disk space used by the instance to the maximum disk space that can be used	Every 300 seconds
Operation QPS	The queries per second (QPS) of the instance. The following items are included: ◦ The number of insert operations. ◦ The number of query operations. ◦ The number of delete operations. ◦ The number of update operations. ◦ The number of getmore operations. ◦ The number of command operations.	Every 300 seconds
Connections	current_conn: the number of current connections to the instance	Every 300 seconds
Cursors	The number of cursors used by the instance. The following items are included: ◦ total_open: the number of cursors that are opened. ◦ timed_out: the number of cursors that timed out.	Every 300 seconds
Network Traffic	The network traffic of the instance. The following items are included: ◦ bytes_in: the inbound network traffic. ◦ bytes_out: the outbound network traffic. ◦ num_requests: the number of requests that are processed.	Every 300 seconds

Performance metric	Description	Monitoring frequency
Global Lock Waiting Queues	The length of the queues that are waiting for global locks for the instance. The following items are included: ◦ gl_cq_total: the length of the queue that is waiting for both global read and write locks. ◦ gl_cq_readers: the length of the queue that is waiting for global read locks. ◦ gl_cq_writers: the length of the queue that is waiting for global write locks.	Every 300 seconds
WiredTiger	The cache metrics of the WiredTiger engine used by the instance. The following items are included: ◦ bytes_read_into_cache: the amount of data that is read into the cache. ◦ bytes_written_from_cache: the amount of data that is written from the cache to the disk. ◦ maximum_bytes_configured: the size of the maximum available disk space that is configured.	Every 300 seconds
Primary/Secondary Replication Latency	repl_lag: the latency in data synchronization between the primary and secondary nodes of the instance	Every 300 seconds

14.5. Backup and restoration

14.5.1. Configure automatic backup for an ApsaraDB for MongoDB instance

This topic describes how to configure automatic backup for an ApsaraDB for MongoDB instance. ApsaraDB for MongoDB automatically backs up data based on the backup policy you specify.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Backup and Recovery**.
5. In the upper-left corner of the page, click **Backup Settings**. Configure the parameters in the Backup Settings panel.

The following table describes the parameters.

Backup policy parameters

Parameter	Description
Retention Days	The number of days for which you want to retain backup files. It can only be seven days.
Backup Time	The hour at which you want to perform the backup task.
Day of Week	The backup cycle. You can select one or more days in a week.

6. Click **OK**.

14.5.2. Manually back up an ApsaraDB for MongoDB instance

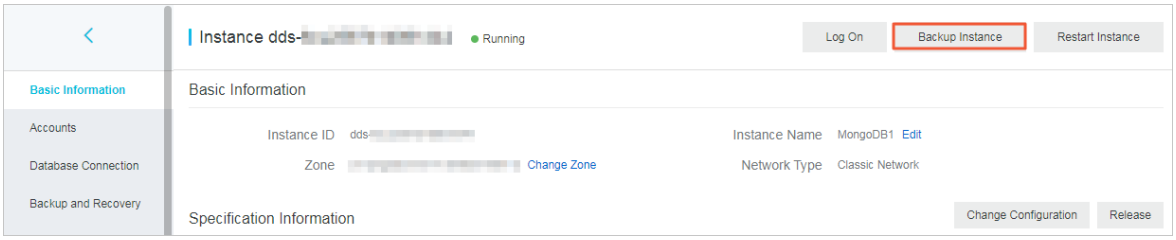
This topic describes how to manually back up an ApsaraDB for MongoDB instance.

Backup methods

- Physical backup: This method backs up physical database files of an ApsaraDB for MongoDB instance. Compared with logical backup, physical backup provides faster data backup and recovery.
- Logical backup: The mongodump tool is used to store operation records of databases to a logical backup file. Then, data can be restore data by using the mongorestore tool.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the upper-right corner of the page, click **Backup Instance**.



5. In the dialog box that appears, set **Backup Method** and click **OK**.

14.5.3. Restore data to the current ApsaraDB for MongoDB instance

This topic describes how to restore data to the current ApsaraDB for MongoDB instance. This helps minimize the data loss caused by incorrect operations.

Prerequisites

The instance is a replica set instance with three nodes.

Background information

- The time required to restore data to your current instance varies depending on factors such as the data volume, task queue status, and network conditions. When the status of the instance changes to **Running**, the restoration is complete.
- If you restore data to your current instance, all existing data is overwritten and cannot be restored.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, find the instance and then click the instance ID or choose **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
3. In the left-side navigation pane, click **Backup and Recovery**.
4. On the **Backup and Recovery** page that appears, find the backup set and choose **> Data Recovery** in the Actions column.

   > **Note** If you have upgraded the database version, you cannot use the backup files of the earlier database version to restore data.

5. In the **Roll Back Instance** message, click **OK**.

   > **Note** The instance status becomes **Restoring from Backup** after you click **OK**. You can click **Refresh** in the upper-right corner of the **Backup and Recovery** page to update the instance status. The restoration is complete when the instance status changes to **Running**.

14.6. Database connections

14.6.1. Modify a public or internal endpoint of an ApsaraDB for MongoDB instance

This topic describes how to modify a public or internal endpoint of an ApsaraDB for MongoDB instance in the ApsaraDB for MongoDB console.

Limits

Architecture	Limit
Replica set instance	You can modify the public and internal endpoints of both primary and secondary nodes.
Sharded cluster instance	You can modify only the public and internal endpoints of mongos nodes.

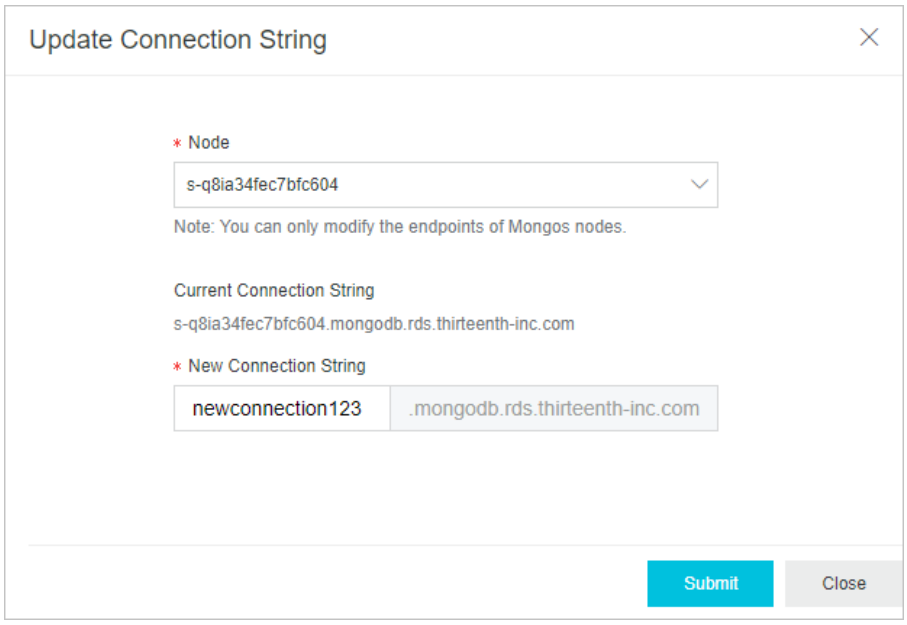
Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose **> Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Database Connections**.

5. In the upper-right corner of the **Internal Connections** or **Public Connections** section, click **Update Connection String**.
6. In the panel that appears, enter a new endpoint.

   Replica set instance

   Sharded cluster instance



> **Note**
> - You can modify only the prefix of the endpoint.
> - The endpoint must start with a lowercase letter and end with a lowercase letter or a digit. It must be 8 to 64 characters in length and can contain lowercase letters, digits, and hyphens (-).

7. Click **Submit**.

What's next

After you modify the public or internal endpoint, you must connect a client or an application to your ApsaraDB for MongoDB instance by using the new endpoint.

14.6.2. Use DMS to log on to an ApsaraDB for MongoDB instance

You can use DMS to connect to an ApsaraDB for MongoDB instance.

Prerequisites

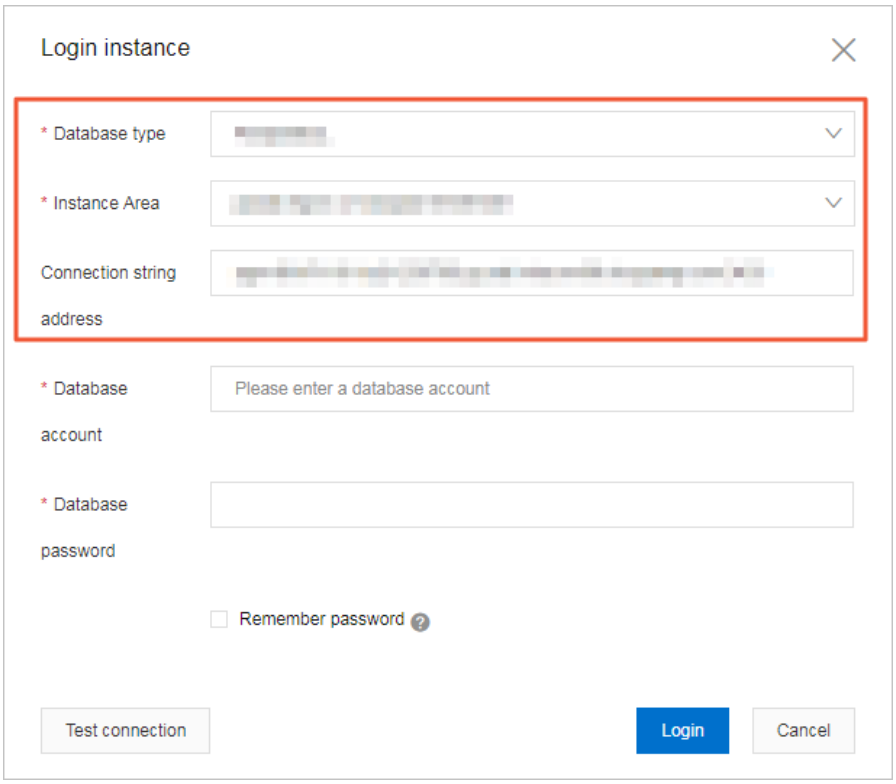
The IP address whitelist is configured. For more information about how to configure the IP address whitelist, see Configure a whitelist for an ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. Click **Log On** in the upper-right corner of the page.

   > **Note** For a sharded cluster instance, you must also select the Mongos node.

5. In the **Login instance** dialog box of the **DMS** console, check values of **Database type**, **Instance Area**, and **Connection string address**. If the information is correct, enter **Database account** and **Database password**, as shown in the following figure.



Parameter	Description
Database type	The engine of the database. By default, the engine of the database to be connected is displayed.
Instance Area	The region where the instance is deployed. By default, the region of the current instance is displayed.
Connection string address	The endpoint of the instance. By default, the endpoint of the current instance is displayed.
Database account	The account of the database to be connected.
Database password	The password of the account used to connect to the database.

6. Click **Login**.

> **Note** If you want your web browser to remember the password, select **Remember password** before you click **Login**.

14.6.3. Use the mongo shell to connect to an ApsaraDB for MongoDB instance

This topic describes how to use the mongo shell to connect to an ApsaraDB for MongoDB instance. The mongo shell is a database management tool provided by ApsaraDB for MongoDB. You can install it on your client or in an Elastic Compute Service (ECS) instance.

Prerequisites

- The version of the mongo shell is the same as your ApsaraDB for MongoDB instance. This ensures successful authentication. For more information about the installation procedure, see Install MongoDB. Choose the version in the upper-left corner of the page based on your client version.
- The IP address of your client is added to a whitelist of the ApsaraDB for MongoDB instance. For more information, see Configure a whitelist for an ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Database Connections** to view connection strings.

> **Note**
> - Replica set instances: View the connection string or connection string URI of a node.
> - Sharded cluster instances: View the connection string or connection string URI of a mongos node.
>
> For more information about connection strings, see Overview of replica set instance connections or Overview of sharded cluster instance connections.

5. Connect to the ApsaraDB for MongoDB instance from your client or ECS instance where the mongo shell is installed.

   Replica set instances:

- Connection string of a node

  During routine tests, you can directly connect to a primary or secondary node. Note that if the primary node fails, the system automatically switches to the secondary node, and the roles of connected nodes change. This affects the read and write operations of your application.

  Command syntax:

  ```
  mongo --host <host> -u <username> -p --authenticationDatabase <database>
  ```

  > **Note**
  > - <host>: the connection string of the primary or secondary node.
  > - <username>: the username used to log on to a database of the instance. The initial username is root.
  > - <database>: the name of the database corresponding to the username if authentication is enabled. If the database username is root, enter admin as the database name.

  Example:

  ```
  mongo --host dds-bp**********.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase admin
  ```

  When `Enter password:` is displayed, enter the password of the database user and press the Enter key. If you forget the password of the root user, you can reset it. For more information, see Reset the password for an ApsaraDB for MongoDB instance.

  > **Note** The password characters are not displayed when you enter the password.

- HA connection (recommended): You can use a connection string URI to connect to both the primary and secondary nodes of a replica set instance. This ensures that your application is always connected to the primary node and the read and write operations of your application are not affected even if the roles of the primary and secondary nodes are switched.

  Command syntax:

  ```
  mongo "<ConnectionStringURI>"
  ```

  > **Note**
  > - The connection string URI must be enclosed in a pair of double quotation marks ("").
  > - <ConnectionStringURI>: the connection string URI of the instance.
  >
  >   You must replace `****` in the connection string URI with the database password. For more information about how to set a database password, see Reset the password for an ApsaraDB for MongoDB instance.

  Example:

  ```
  mongo "mongodb://root:****@dds-**********.mongodb.rds.intra.env17e.shuguang.com:3717,dds-**********.mongodb.rds.intra.env17e.shuguang.com:3717/admin?replicaSet=mgset-*****"
  ```

Sharded cluster instances:

- Connection string of a mongos node

  Command syntax:

  ```
  mongo --host <mongos_host> -u <username> -p --authenticationDatabase <database>
  ```

> **Note**
> - <mongos_host>: the connection string of a mongos node in the sharded cluster instance.
> - <username>: the username used to log on to a database of the instance. The initial username is root.
> - <database>: the name of the database corresponding to the username if authentication is enabled. If the database username is root, enter admin as the database name.

Example:

```
mongo --host s-bp**********.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase admin
```

- HA connection (recommended): You can use a connection string URI to connect to a database. If one mongos node fails, another mongos node takes over business to ensure the high availability of the connection.

  Command syntax:

  ```
  mongo "<ConnectionStringURI>"
  ```

  > **Note**
  > - The connection string URI must be enclosed in a pair of double quotation marks ("").
  > - <ConnectionStringURI>: the **connection string URI** of the instance.
  >
  >   You must replace `****` in the **connection string URI** with the database password. For more information about how to set a database password, see Reset the password for an ApsaraDB for MongoDB instance.

  Example:

  ```
  mongo "mongodb://root:****@s-**********.mongodb.rds.intra.env17e.shuguang.com:3717,s-**********.mongodb.rds.intra.env17e.shuguang.com:3717/admin"
  ```

14.6.4. Apply for a public endpoint for an ApsaraDB for MongoDB instance

This topic describes how to apply for a public endpoint for an ApsaraDB for MongoDB instance when you want to connect to this instance over the Internet.

Context

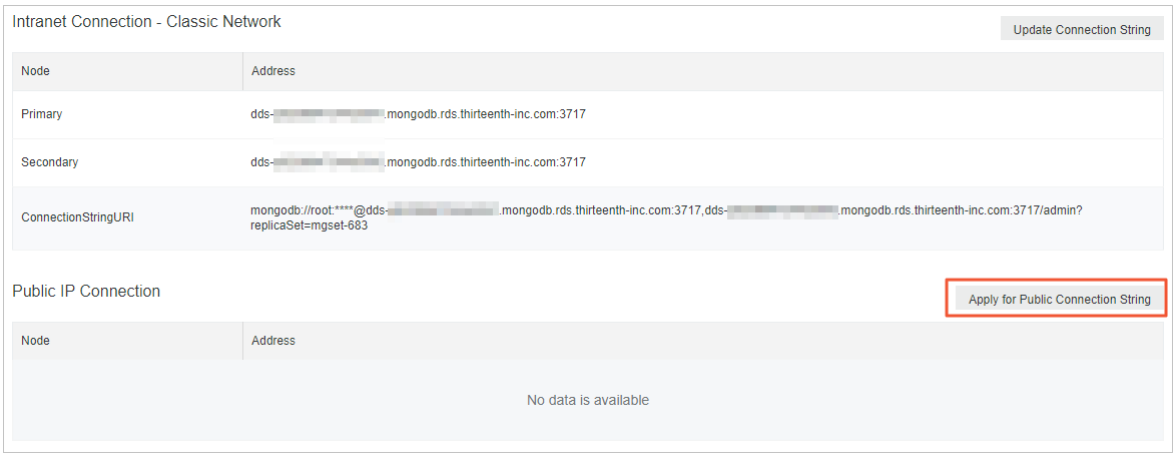
The following table describes the Virtual Private Cloud (VPC) and classic network endpoints supported by ApsaraDB for MongoDB.

Type	Description
VPC endpoint	• A VPC is an isolated network with higher security and performance than the classic network. • By default, ApsaraDB for MongoDB provides endpoints on a VPC.
Classic network endpoint	Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by using security groups or whitelists.

Type	Description
Public endpoint	• Security risks may arise if you connect to an ApsaraDB for MongoDB instance over the Internet. Therefore, ApsaraDB for MongoDB does not provide public endpoints. • If you want to connect to an ApsaraDB for MongoDB instance from a device outside of Alibaba Cloud (such as an on-premises device), you must apply for a public endpoint.

Apply for a public endpoint for a replica set instance

1. Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, find the instance and then click the instance ID or choose **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
3. In the left-side navigation pane, click **Database Connections**.
4. In the upper-right corner of the **Public Connections** section, click **Apply for Public Connection String**.



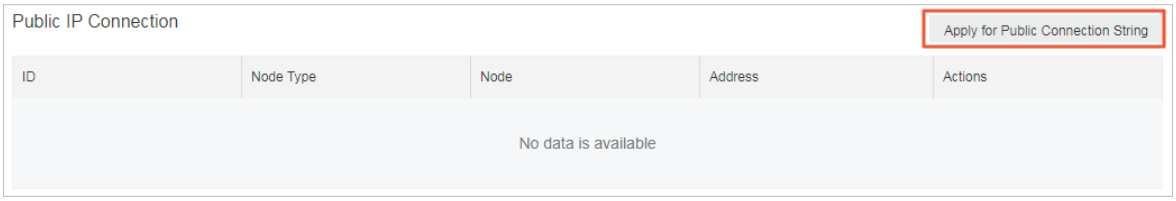
5. In the **Apply for Public Connection String** message, click **OK**.

> **Note** If you want to connect to an ApsaraDB for MongoDB instance by using a public endpoint, you must add the public IP address of your client to a whitelist of this instance. For more information, see Configure a whitelist for an ApsaraDB for MongoDB instance.

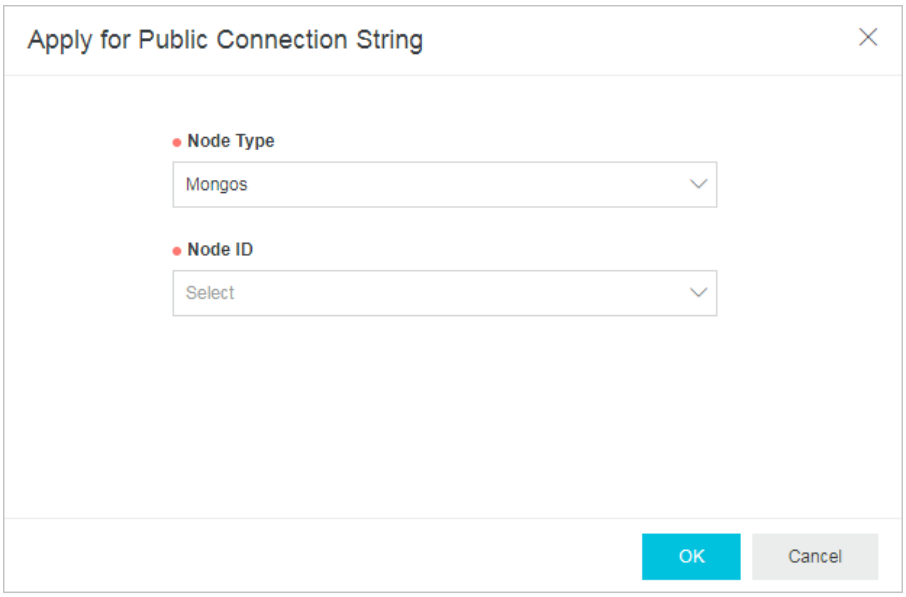
After the application is complete, the replica set instance generates new endpoints for both the primary and secondary nodes and the corresponding connection string URI. For more information, see Overview of replica set instance connections.

Apply for a public endpoint for a sharded cluster instance

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose **> Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Database Connections**.
5. In the upper-right corner of the **Public Connections** section, click **Apply for Public Connection String**.



6. In the panel that appears, specify **Node Type** and **Node ID**, and click **OK**.



Parameter	Value	Description
Node Type	**Mongos**	The mongos node. You can apply for public endpoints only for mongos nodes. Your applications are connected to mongos nodes in most cases.
Node ID	The ID of the component for which you want to apply for a public endpoint.	None

> **Note** You can repeat this step to apply for public endpoints for other mongos nodes as your needs change. You can apply for a new public endpoint only after the current one is created.

References

- To ensure data security, we recommend that you release a public endpoint if you no longer need it. For more information, see Release a public connection string.
- Before you connect to a replica set instance over the Internet, we recommend that you enable SSL encryption. For more information, see Use the mongo shell to connect to an ApsaraDB for MongoDB database in SSL encryption mode.

14.6.5. Release a public endpoint

To ensure data security, you can release a public endpoint that is no longer needed in the console.

Precautions

- You can release one or more public endpoints of the mongos nodes for a sharded cluster instance.
- After the public endpoint is released for an instance or node, you cannot connect to the instance or node by

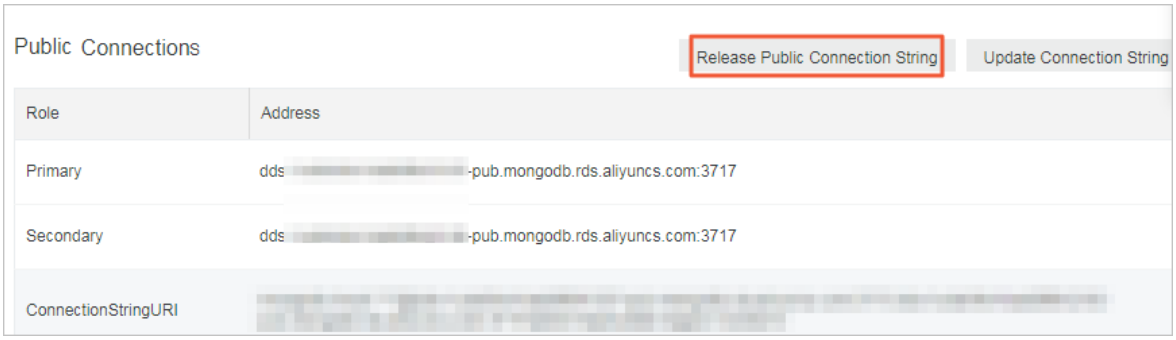
using the original public endpoint.

- After the public endpoint is released, we recommend that you delete the corresponding public IP address from the whitelist to ensure data security. For more information, see Configure a whitelist.

Release a public endpoint for a replica set instance

> **Note** After the public endpoint of a replica set instance is released, the public endpoints of the primary and secondary nodes are released.

1. Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, find the instance and then click the instance ID or choose **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
3. In the left-side navigation pane, click **Database Connections**.
4. In the upper-right corner of the **Public Connections** section, click **Release Public Connection String**.



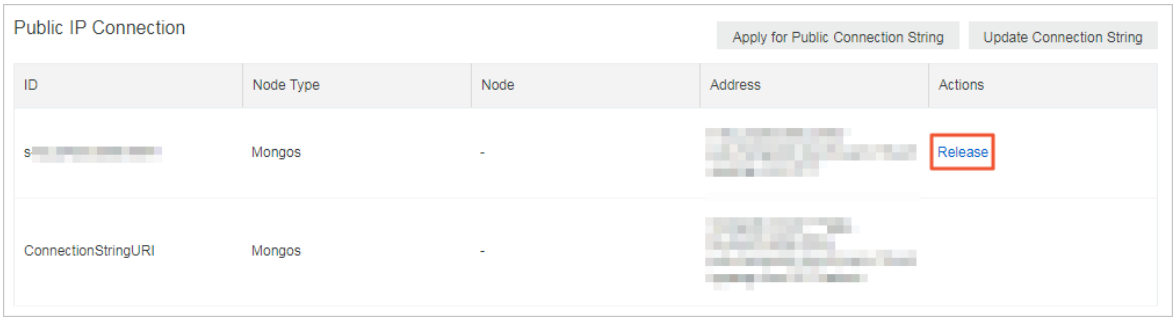
5. In the message that appears, click **OK**.

Release a public endpoint for a sharded cluster instance

You can release one or more public endpoints of the mongos, shard, and Configserver nodes for a sharded cluster instance.

> **Note** After the public endpoint of a shard or Configserver node is released, the public endpoints of the primary and secondary nodes are released.

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Database Connections**.
5. In the **Public Connections** section, find the mongos, shard, or Configserver node for which you want to release the public endpoint.
6. In the **Actions** column corresponding to the node, click **Release**.



> **Note** You can repeat this step to release the public endpoints of other nodes as your needs change. To release the public endpoint of the next node, you must wait until the public endpoint of the current node is released or the status of the current node becomes **Running**.

7. In the message that appears, click **OK**.

14.6.6. Overview of replica set instance connections

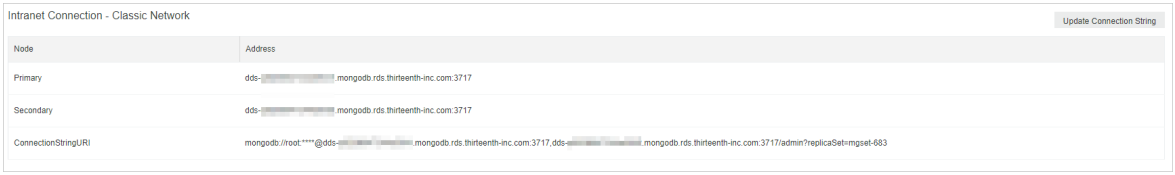
ApsaraDB for MongoDB supports both connection strings and connection string URIs. You can use a connection string to connect to the primary or secondary node, and use a connection string URI to connect to both of them. For high availability, we recommend that you use connection string URIs to connect your application to both primary and secondary nodes. This topic provides an overview of replica set instance connections.

Prerequisites

A whitelist is configured for the instance. For more information, see Configure a whitelist for an ApsaraDB for MongoDB instance.

View connection strings

1. Log on to the ApsaraDB for MongoDB console.
2. On the **Replica Set Instances** page, find the instance and then click the instance ID or choose **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
3. In the left-side navigation pane, click **Database Connections** to view connection strings.



Description of connection strings

Item	Description
Connection type	• Internal Connections - Classic Network: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. • Internal Connections - VPC: A virtual private cloud (VPC) is an isolated network with higher security and performance than the classic network. By default, ApsaraDB for MongoDB provides VPC endpoints.

Item	Description
Role	• Primary: the primary node in the replica set instance. If you connect to this node, you can perform read and write operations on the databases of the replica set instance. • Secondary: the secondary node in the replica set instance. If you connect to this node, you can perform only read operations on the databases of the replica set instance. • Connection String URI: ApsaraDB for MongoDB allows you to use a connection string URI to connect to a replica set instance to achieve load balancing and high availability.
Connection string	The connection string of a primary or secondary node is in the following format: `<host>:<port>` • <host>: the endpoint used to connect to the instance. • <port>: the port used to connect to the instance.
Connection string URI	A connection string URI is in the following format: `mongodb://[username:password@]host1[:port1][,host2[:port2],...[,hostN[:portN]]][/[database][?options]]` • mongodb://: the prefix of a connection string URI. • username:password@: the username and password used to log on to a database of the replica set instance. You must separate them with a colon (:). • hostX:portX: the endpoint and port of a node in the replica set instance. • /database: the name of the database corresponding to the username if authentication is enabled. • ?options: additional connection options. **Note** If your application is in a production environment, we recommend that you use a connection string URI to connect to the instance. This way, when a node fails, the read and write operations of your application are not affected as a result of the failover.

Related information

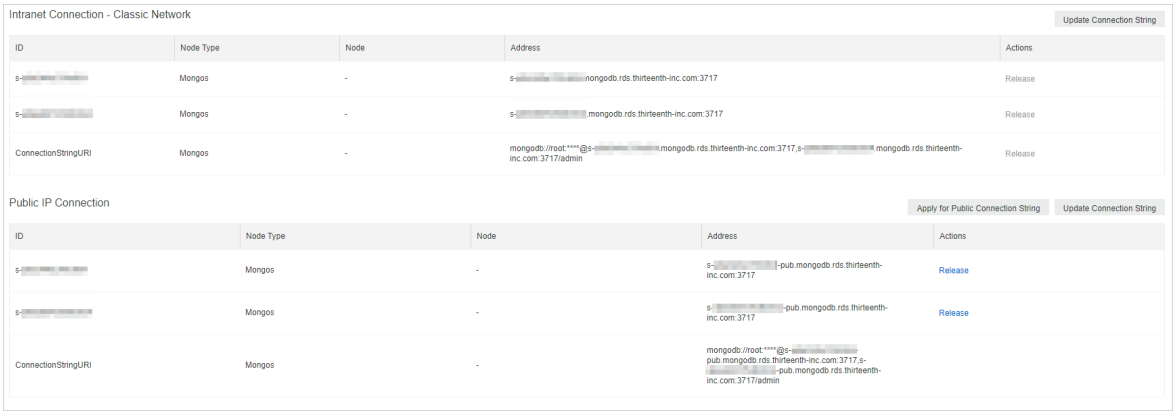
- Connect to a replica set instance by using the mongo shell

14.6.7. Overview of sharded cluster instance connections

ApsaraDB for MongoDB supports both connection strings and connection string URIs. You can use a connection string to connect to a single mongos node, and use a connection string URI to connect to multiple mongos nodes. For high availability, we recommend that you use connection string URIs to connect your application to multiple mongos nodes. This topic provides an overview of sharded cluster instance connections.

View connection strings

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, click **Database Connections** to view connection strings.



Description of connection strings

Item	Description
Connection type	• Internal Connections - Classic Network: Cloud services on the classic network are not isolated. Unauthorized access can be blocked only by security groups or whitelists. • Internal Connections - VPC: A virtual private cloud (VPC) is an isolated network with higher security and performance than the classic network. By default, ApsaraDB for MongoDB provides VPC endpoints. • Public Connections: Security risks may arise if you connect to a sharded cluster instance over the Internet. Therefore, ApsaraDB for MongoDB does not provide public endpoints. If you want to connect to an ApsaraDB for MongoDB instance from a device outside of Alibaba Cloud (such as an on-premises device), you must apply for a public endpoint. For more information, see Apply for a public endpoint for an ApsaraDB for MongoDB instance.
Mongos ID	The connection string of a mongos node is in the following format: `<host>:<port>` • <host>: the endpoint used to connect to the instance. • <port>: the port used to connect to the instance. **Note** During routine tests, you can use a connection string to directly connect to a mongos node.

Item	Description
Connection string URI	A connection string URI is in the following format: `mongodb://[username:password@]host1[:port1][,host2[:port2],...[,hostN[:portN]]][/[database][?options]]` • mongodb://: the prefix of a connection string URI. • username:password@: the username and password used to log on to a database of the sharded cluster instance. You must separate them with a colon (:). • hostX:portX: the endpoint and port of a mongos node in the sharded cluster instance. • /database: the name of the database corresponding to the username if authentication is enabled. • ?options: additional connection options. **Note** If your application is in a production environment, we recommend that you use a connection string URI to connect to the instance. Then, your client can automatically distribute your requests to multiple mongos nodes to balance loads. If a mongos node fails, your client automatically redirects requests to other mongos nodes in the normal state.

Log on to a database of an ApsaraDB for MongoDB instance

1. Obtain the connection string and the following information:
   - The username used to log on to the database. The initial username is root.
   - The password of the database user. If you forget the password of the root user, you can reset it. For more information, see Reset the password for an ApsaraDB for MongoDB instance.
   - The name of the database corresponding to the username if authentication is enabled. If the database username is root, enter admin as the database name.
2. Log on to the database.
   - Use DMS to log on to a replica set instance of ApsaraDB for MongoDB
   - Connect to a replica set instance by using the mongo shell

14.7. Data security

14.7.1. Configure a whitelist for an ApsaraDB for MongoDB instance

This topic describes how to configure a whitelist for an ApsaraDB for MongoDB instance. Before you use an ApsaraDB for MongoDB instance, you must add the IP addresses or Classless Inter-Domain Routing (CIDR) blocks that you use for database access to a whitelist of this instance. This improves database security and stability. Proper configuration of whitelists can enhance access security of ApsaraDB for MongoDB. We recommend that you maintain the whitelists on a regular basis.

Context

The system creates a default whitelist for each instance. This whitelist can be modified or cleared, but it cannot be deleted. After an ApsaraDB for MongoDB instance is created, the system automatically adds the IP address 127.0.0.1 to the **default** whitelist of this instance. The IP address 0.0.0.0/0 indicates that all IP addresses are allowed to access this instance. You must add the IP addresses or CIDR blocks that you allow to access this ApsaraDB for MongoDB instance.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **Data Security** > **Whitelist Settings**.
5. You can manually configure a whitelist or import ECS Internal IP addresses to the whitelist.

   Manually modify a whitelist

   i. Find the whitelist you want to modify and choose > **Manually Modify** in the **Actions** column.

   ii. Enter IP addresses or CIDR blocks.

   > Note
   > - Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. Supported formats are IP addresses such as 0.0.0.0/0 and 10.23.12.24, or CIDR blocks such as 10.23.12.24/24. /24 indicates the length of the IP address prefix in the CIDR block. An IP address prefix can contain 1 to 32 bits.
   > - If the IP whitelist is empty or only contains `0.0.0.0/0`, all devices are granted access. This is risky for your ApsaraDB for MongoDB instance. We recommend that you add only the IP addresses or CIDR blocks of your own web servers to the whitelist.

   iii. Click **OK**.

   Load IP addresses of ECS instances

   i. Find the whitelist, and choose > **Import ECS Intranet IP** in the **Actions** column.

   ii. From the displayed internal IP addresses of ECS instances that belong to the current account, select the IP addresses and click > to add them to the whitelist.

   iii. Click **OK**.

14.7.2. Create or delete a whitelist

This topic describes how to create or delete whitelists that consist of the IP addresses allowed to access specific databases.

Context

If your business involves multiple applications and you need to add a whitelist for each of them, you can sort the IP addresses into different whitelists.

Create a whitelist

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **Data Security** > **Whitelist Settings**.

5. Click **Create Whitelist** in the upper-left corner of the page.
6. In the panel that appears, set **Group Name** and **IP White List** and click **OK**.

> **Note**
> - **Group Name**: The name must be 2 to 32 characters in length and can contain lowercase letters, digits, and underscores (_). It must start with a lowercase letter and end with a lowercase letter or digit.
> - **IP White List**:
>   - Separate multiple IP addresses with commas (,). You can add a maximum of 1,000 different IP addresses to a whitelist. A whitelist can include IP addresses such as 0.0.0.0/0 and 10.23.12.24, or CIDR blocks such as 10.23.12.24/24. /24 indicates that the prefix of the CIDR block is 24-bit long. You can replace 24 with a value within the range of 1 to 32.
>   - If the whitelist is empty or contains only 0.0.0.0/0, all devices are granted access. This poses risks to your ApsaraDB for MongoDB instance. We recommend that you add only the IP addresses or CIDR blocks of your own web servers to the whitelist.

Delete a whitelist

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **Data Security** > **Whitelist Settings**.
5. Find the whitelist that you want to delete and choose > **Delete Whitelist Group** in the **Actions** column.

> **Note** You cannot delete the **default** whitelist.

6. In the Delete Whitelist Group message, click **OK**.

14.7.3. Audit logs

This topic describes audit logs provided in the ApsaraDB for MongoDB console. You can query the statement execution logs, operations logs, and error logs of an ApsaraDB for MongoDB instance to locate and analyze faults.

Context

The audit log feature records all operations that a client performs on a connected database. This feature provides references for you to perform fault analysis, behavior analysis, and security auditing because you can obtain the operation execution details from the audit logs. Audit logs are essential in the regulatory operations of Finance Cloud and other core business scenarios.

> **Note** Audit logs are stored for seven days, after which they are deleted.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the

Basic Information page appears.

4. In the left-side navigation pane, choose **Data Security > Audit Logs**.
5. Click **Enable Audit Log** in the upper-left corner. In the Enable Audit message, click **OK**.

Result

On the **Audit Log** page, specify the time range, database name, database user, and keyword to query audit logs. You can also perform the following operations:

- **Export File**: exports an audit log file.
- **File List**: displays a list of audit logs.
- **Disable Audit Log**: stops the collection of information on database operations and deletes the saved audit logs.

14.7.4. Configure SSL encryption for an ApsaraDB for MongoDB instance

This topic describes how to enhance link security by enabling Secure Sockets Layer (SSL) encryption and installing SSL CA certificates on your application services. The SSL encryption feature encrypts network connections at the transport layer to improve data security and ensure data integrity during communication.

Prerequisites

- The instance is a replica set instance.
- The MongoDB version of the instance is 3.4, 4.0, or 4.2.

Notes

When you enable or disable SSL encryption or update SSL CA certificates for an instance, the instance is restarted. Plan your operations in advance and make sure that your application is configured to reconnect to the instance after it is disconnected.

> **Note** When an instance is restarted, all its nodes are restarted in turn and each node has a transient connection error of about 30 seconds. If the instance contains more than 10,000 collections, the transient connection error last longer.

Precautions

- You can download SSL CA certificate files only from the ApsaraDB for MongoDB console.
- After you enable SSL encryption for an instance, the CPU utilization of the instance is significantly increased. We recommend that you enable SSL encryption only when necessary. For example, you can enable SSL encryption when you connect to an ApsaraDB for MongoDB instance over the Internet.

  > **Note** Internal network connections are more secure than Internet connections and do not need SSL encryption.

- After you enable SSL encryption for an instance, both SSL and non-SSL connections are supported.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.

4. In the left-side navigation pane, choose **Data Security > SSL**.
5. Perform one of the following operations.

> **Note** When you enable or disable SSL encryption or update SSL CA certificates for an instance, the instance is restarted. Plan your operations in advance and make sure that your applications can automatically re-establish a connection.

Operation	Prerequisite	Procedure
Enable SSL encryption	The SSL encryption status is **Disabled**.	Turn on **SSL Status**. In the message that appears, click **OK**.
Update an SSL CA certificate	The SSL encryption status is **Enabled**.	Click **Update Certificate**. In the message that appears, click **OK**.
Download an SSL CA certificate file	The SSL encryption status is **Enabled**.	Click **Download Certificate** to download an SSL CA certificate file to your computer.
Disable SSL encryption	The SSL encryption status is **Enabled**.	Turn off **SSL Status**. In the message that appears, click **OK**.

14.7.5. Configure TDE for an ApsaraDB for MongoDB instance

This topic describes how to configure Transparent Data Encryption (TDE) for an ApsaraDB for MongoDB instance. Before data files are written to disks, TDE encrypts the data files. When data files are loaded from disks to the memory, TDE decrypts the data files. TDE does not increase the sizes of data files. When you use TDE, you do not need to modify your application that uses the ApsaraDB for MongoDB instance. To enhance data security, you can enable the TDE feature for an instance in the ApsaraDB for MongoDB console.

Prerequisites

The MongoDB version of the instance is 4.0 or 4.2.

> **Note** Before you enable TDE, you can create a MongoDB 4.0 or 4.2 instance to test the compatibility between your application and the database version. You can release the instance after the test is complete.

Notes

- When you enable TDE, your instance is restarted, and your application is disconnected from the instance. We recommend that you enable TDE during off-peak hours and make sure that your application can reconnect to the instance after it is disconnected.
- TDE increases the CPU utilization of your instance.

Precautions

- You cannot disable TDE after it is enabled.
- You can enable TDE for an instance and disable encryption for a collection.

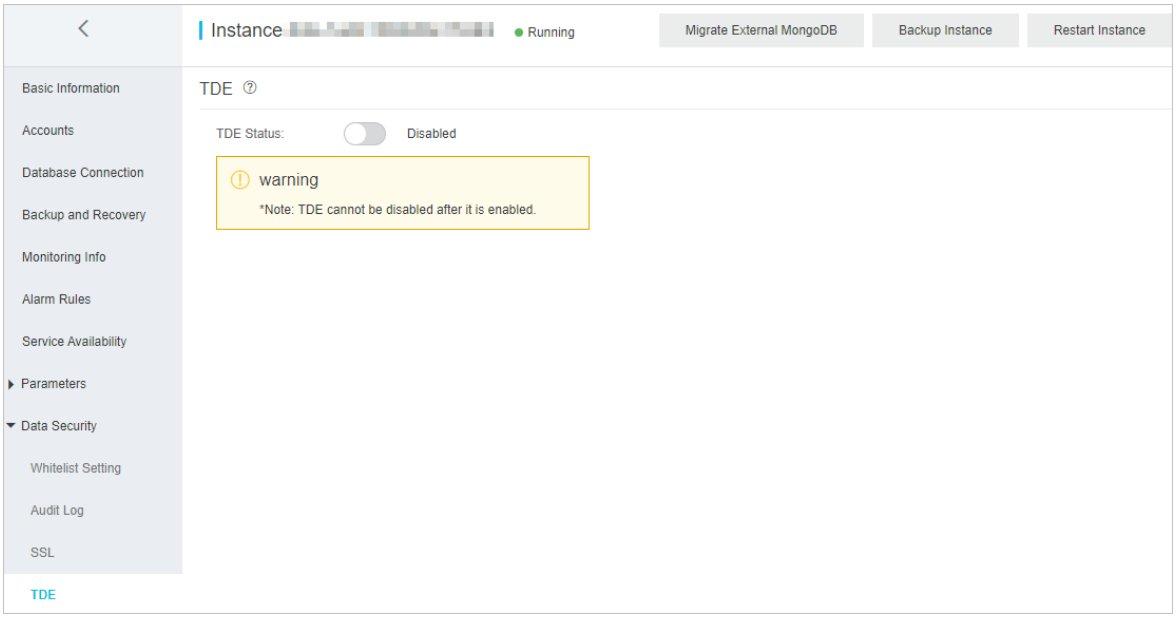
> **Note** In special business scenarios, you can choose not to encrypt a collection when you create it. For more information, see Disable encryption for a specified collection.

- After you enable TDE, only new collections are encrypted. Existing collections are not encrypted.
- Key Management Service (KMS) generates and manages the keys used by TDE. ApsaraDB for MongoDB does not

provide keys or certificates required for encryption.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **Data Security** > **TDE**.
5. Turn on **TDE Status** to enable TDE.



6. In the **Restart Instance** dialog box, click **OK**.
   The instance status changes to **Modifying TDE**. After the status changes to **Running**, TDE is enabled.

Disable encryption for a specified collection

After you enable TDE, all new collections are encrypted. When you create a collection, you can perform the following steps to disable encryption for the collection:

1. Connect to a replica set instance by using the mongo shell. For more information, see Connect to a replica set instance by using the mongo shell.
2. Run the following command to create a collection and disable the encryption feature:

```
db.createCollection("<collection_name>",{ storageEngine: { wiredTiger: { configString: "encryption=(name=none)" } } })
```

> **Note** <collection_name>: the name of the collection.

Example:

```
db.createCollection("customer",{ storageEngine: { wiredTiger: { configString: "encryption=(name=none)" } } })
```

14.7.6. Use the mongo shell to connect to an ApsaraDB for MongoDB database in SSL encryption mode

This topic describes how to use the mongo shell to connect to an ApsaraDB for MongoDB database in Secure Sockets Layer (SSL) encryption mode. SSL encryption can encrypt network connections at the transport layer to improve data security and ensure data integrity.

Prerequisites

- The instance is a replica set instance, and the database version of the instance is 3.4, 4.0, or 4.2.
- The mongo shell of the required version is installed on the local server or ECS instance from which you want to connect to the database. For more information about the installation procedure, visit MongoDB official documentation.
- SSL encryption is enabled for the instance. For more information, see Configure SSL encryption.
- The IP address of the local server or the ECS instance is added to a whitelist of the ApsaraDB for MongoDB instance. For more information, see Configure a whitelist for an ApsaraDB for MongoDB instance.

Precautions

After you enable SSL encryption for an instance, the CPU utilization of the instance is significantly increased. We recommend that you enable SSL encryption only when necessary.

Procedure

A local server with a Linux operating system is used in the following example.

1. Download an SSL CA certificate package. For more information, see Configure SSL encryption.
2. Decompress the package and upload the certificate files to the local server or the ECS instance where the mongo shell is installed.

   > **Note** In this example, the *.pem* file is uploaded to the */root/sslcafile/* directory of the local server.

3. On the local server or the ECS instance, run the following command to connect to a database of the ApsaraDB for MongoDB instance:

   ```
   mongo --host <host> -u <username> -p --authenticationDatabase <database> --ssl --sslCAFile <sslCAFile_path> --sslAllowInvalidHostnames
   ```

   > **Note**
   > - <host>: the connection string of the primary or secondary node for a replica set instance or of mongos node for a sharded cluster instance. For more information, see Overview of replica set instance connections or Overview of sharded cluster instance connections. If you want to connect to a database of the ApsaraDB for MongoDB instance over an internal network, make sure that the ApsaraDB for MongoDB instance has the same network type as the ECS instance. If the network type is VPC, make sure that the two instances are in the same VPC.
   > - <username>: the username you use to log on to a database of the ApsaraDB for MongoDB instance. The default username is root.
   > - <database>: the name of database corresponding to the username if authentication is enabled. If the database username is root, enter admin.
   > - <sslCAFile_path>: the path of the SSL CA certificate files.

Example:

```
mongo --host dds-bpxxxxxxxx-pub.mongodb.rds.aliyuncs.com:3717 -u root -p --authenticationDatabase admin --ssl --sslCAFile /root/sslcafile/ApsaraDB-CA-Chain.pem --sslAllowInvalidHostnames
```

4. When `Enter password:` is displayed, enter the password of the database user and press Enter.

> **Note**
> - The password characters are not displayed when you enter the password.
> - If you forget the password of the root user, you can reset it. For more information, see Reset the password for an ApsaraDB for MongoDB instance.

14.8. Zone-disaster recovery

14.8.1. Create a dual-zone replica set instance

This topic describes how to create a dual-zone replica set instance. ApsaraDB for MongoDB provides a zone-disaster recovery solution to ensure the reliability and availability of your replica set instance. This solution deploys the three nodes of a replica set instance across two different zones within one region. The components in these zones exchange data over an internal network. When one of the two zones becomes unavailable due to unexpected events such as a power or network failure, the high-availability (HA) system switches services over to another zone.

Deployment policies

The primary, secondary, and hidden nodes of a replica set instance are deployed in two different zones within one region.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances**.
3. On the **Replica Set Instances** page, click **Create Instance**.
4. On the **Create ApsaraDB for MongoDB Instance** page, configure parameters.

> **Note**
> - For the **Zone** parameter, you must select dual zones, such as the amtest17001-a and amtest17001-b zones of the cn-qingdao-env11e-MAZ1 region.
> - For more information, see Create a replica set instance.

5. Click **Submit**.

14.8.2. Create a dual-zone sharded cluster instance

This topic describes how to create a dual-zone sharded cluster instance. ApsaraDB for MongoDB provides a zone-disaster recovery solution to ensure the reliability and availability of your sharded cluster instance. This solution deploys the components of a sharded cluster instance across two different zones within one region. The components in these zones exchange data over an internal network. When one zone becomes unavailable due to unexpected events such as a power or network failure, the high availability (HA) system automatically switches business over to the other zone.

Deployment policies

The components of a sharded cluster instance are deployed across two different zones within one region.

- Mongos nodes are evenly deployed across all data centers. At least two mongos nodes are deployed at a time, with each in one zone. Each new mongos node added later is deployed to one of the zones in turn.
- The primary, secondary, and hidden nodes in each shard node are not deployed to the two zones in sequence. The deployment of these nodes may change when manual switchover or HA failover between primary and secondary nodes is triggered.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Sharded Cluster Instances**.
3. On the **Sharded Cluster Instances** page, click **Create Instance**.
4. On the **Create ApsaraDB for MongoDB Sharded Cluster Instance** page, configure parameters.

   > **Note**
   > - For the **Zone** parameter, you must select dual zones, such as the amtest17001-a and amtest17001-b zones of the cn-qingdao-env11e-MAZ1 region.
   > - For more information, see Create a sharded cluster instance.

5. Click **Submit**.

14.9. CloudDBA

14.9.1. Performance trends

This topic describes how to view performance trends in specific ranges, compare performance trends, and customize charts to view performance trends on your ApsaraDB for MongoDB instances.

Go to the Performance page

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose  > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **CloudDBA > Performance**.

> **Note** For more information about performance trends, see relevant topics in Database Autonomy Service (DAS) User Guide.

14.9.2. Real-time performance

This topic describes how to view real-time monitoring statistics of your ApsaraDB for MongoDB instances, such as read/write latency, queries per second (QPS), operations, connections, and network traffic.

Prerequisites

Database Autonomy Service (DAS) is authorized to manage ApsaraDB for MongoDB instances.

Procedure

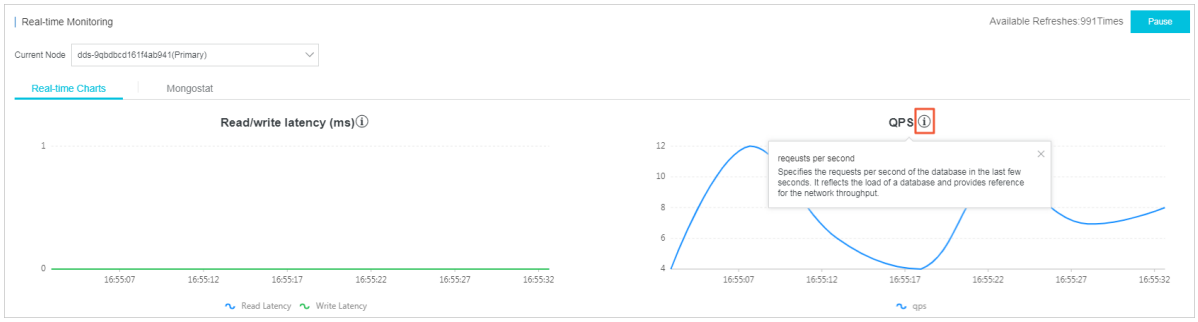
1. Log on to the ApsaraDB for MongoDB console.

2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **CloudDBA > Real-time Performance**.

Overview of the Real-time Monitoring page

On the Real-time Monitoring page, you can click the Real-time Charts or Mongostat tab to view monitoring statistics. When you refresh the **Real-time Monitoring** page, the information on the Real-time Charts and Mongostat tabs is refreshed, and **Available Refreshes** is reset in the upper-right corner.

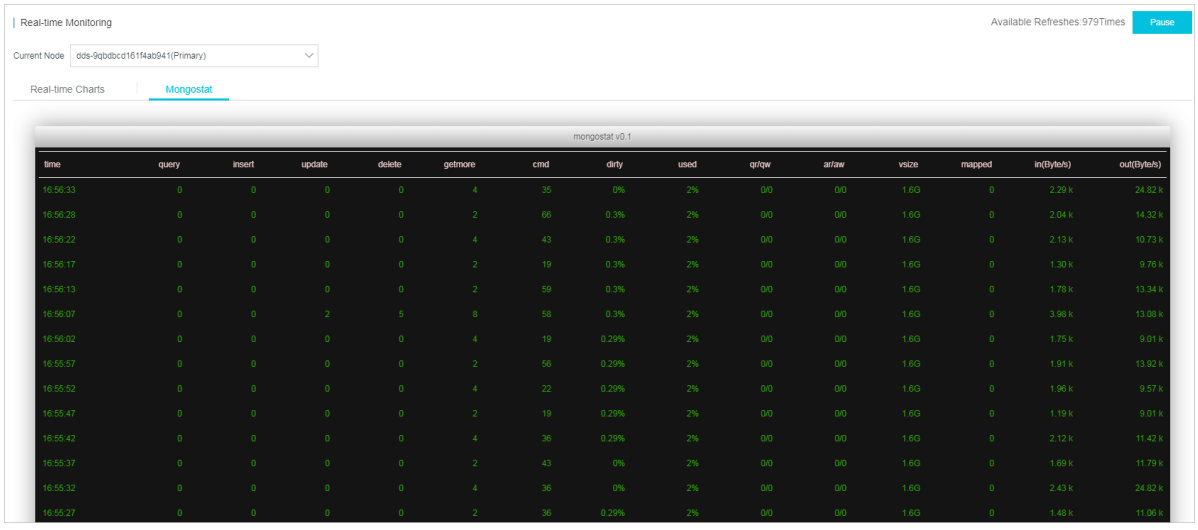
- Real-time charts



By default, content on the **Real-time Charts** tab is displayed when you go to the Real-time Monitoring page. Line charts on the tab are refreshed every 5 seconds.

> **Note** For more information about performance metrics, click the icon above each chart.

- mongostat



Click the **Mongostat** tab. On the tab, you can view Mongostat command outputs. A new line of monitoring data is added every 5 seconds. The tab can contain up to 999 lines of information.

> **Note** For more information about Mongostat command outputs, see MongoDB official documentation.

14.9.3. Instance sessions

This topic describes how to view real-time monitoring statistics of your ApsaraDB for MongoDB instances, such as read/write latency, queries per second (QPS), operations, connections, and network traffic.

Prerequisites

Database Autonomy Service (DAS) is authorized to manage your ApsaraDB for MongoDB instances.

View instance sessions

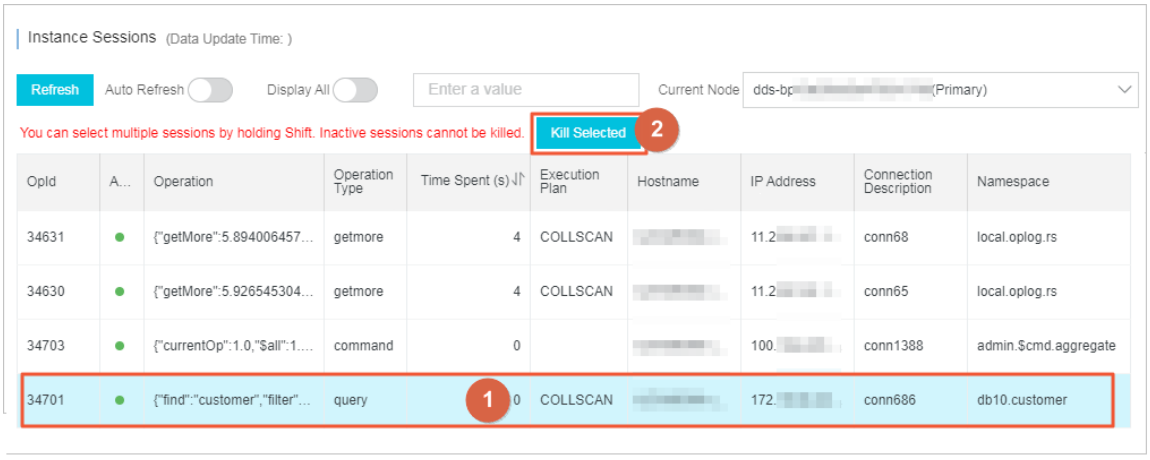
1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **CloudDBA > Sessions**.

> **Note**
> - If you turn on **Auto Refresh**, the system updates session data on the page every 5 seconds.
> - By default, the system displays only active sessions. You can turn on **Display All** to view both active and inactive sessions.
> - In the **Session Statistics** section, you can view information about sessions in the **Overview**, **Statistics by Client**, and **Statistics by Namespace** charts.

Terminate instance sessions

> **Warning** To avoid unexpected results, we recommend that you do not terminate system-level sessions.

1. In the **Instance Sessions** section, select the sessions that you want to terminate and click **Kill Selected**.



2. In the message that appears, click **OK**.

14.9.4. Storage analysis

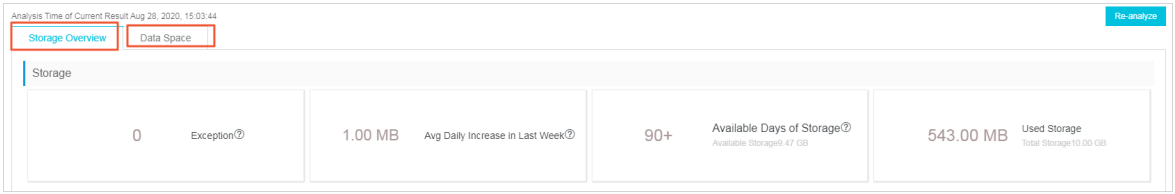
This topic describes how to view information about the storage analysis feature, including **Storage**, **Exceptions**, **Storage trend**, **Tablespaces**, and **Data space**. The information helps you identify and resolve exceptions in the database storage to ensure database stability.

Prerequisites

Database Autonomy Service (DAS) is authorized to manage ApsaraDB for MongoDB instances.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **CloudDBA > Storage analysis**.
5. In the upper-right corner, click **Re-analyze**. Then, wait until the analysis is complete.
6. On the **Storage Overview** or **Data Space** tab, view the analysis results.



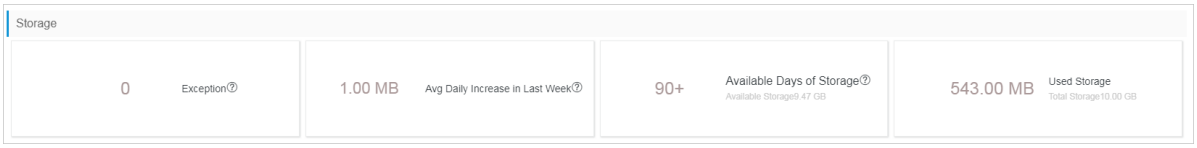
For more information about Storage Overview, see Storage Overview.

For more information about Data Space, see Data Space.

Storage Overview

On the Storage Overview tab, you can view information in the **Storage**, **Exceptions**, **Storage Trend**, and **Tablespaces** sections.

- **Storage**

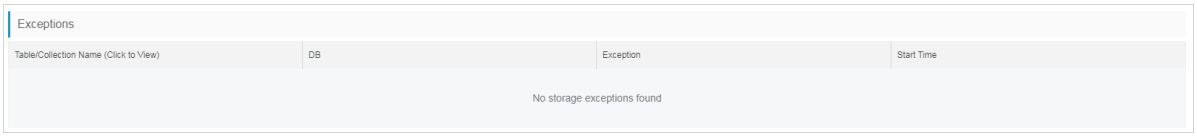


Item	Description
Exception	The number of detected storage exceptions. ApsaraDB for MongoDB can detect the following types of exceptions: ○ Over 90% of the storage capacity is used. ○ The total physical storage can become unavailable in seven days. ○ The number of indexes in a collection exceeds 10.

Item	Description
Avg Daily Increase in Last Week	The average daily increase of storage usage over the last seven days. Formula: (Storage usage at the time of collection - Storage usage seven days ago)/7. **Note** ◦ The increase speed is the average value during the seven days before the collection time. ◦ This parameter is used only as a reference for scenarios in which the traffic remains stable. Abrupt storage changes caused by batch imports, deletion of historical data, instance migration, or instance re-creation affect the accuracy of the data.
Available Days of Storage	The estimated number of days during which storage space is available. Formula: Size of available storage space/Average daily increase over the last week. **Note** ◦ 90+ indicates that the storage space is sufficient for more than 90 days of usage. ◦ This parameter is used only as a reference for scenarios in which the traffic remains stable. Abrupt storage changes caused by batch imports, deletion of historical data, instance migration, or instance re-creation affect the accuracy of the data.
Used Storage	The size of used storage space in contrast to the total size of storage space.

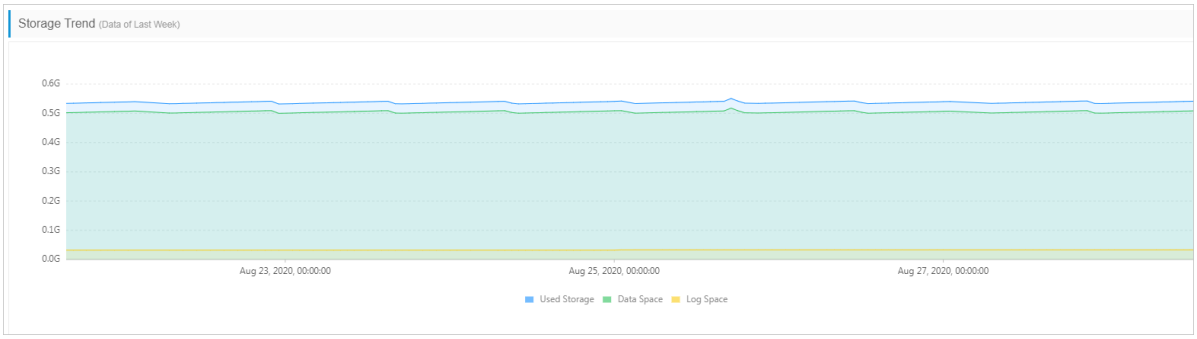
- **Exceptions**

  Information about detected storage exceptions. You can resolve the exceptions based on the information in this section.



- **Storage Trend**

  Changes in storage usage over the last week, such as changes in the **used storage**, **data space**, and **log space**.



- **Tablespaces**

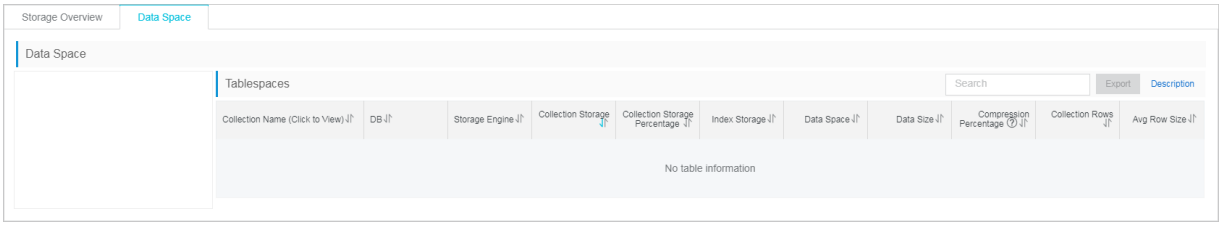
  Information about all tables, such as the database name, storage engine, and collection storage.

> **Note** You can click the name of a collection to view its indexes.

Data Space

The Data Space tab shows the total storage capacity and tablespace information of each database.

> **Note**
> - You can click the name of a data space to view its tablespace information.
> - You can click the name of a collection to view its indexes.



14.9.5. Slow query logs

This topic describes how to view slow query logs of ApsaraDB for MongoDB instances. You can identify, analyze, diagnose, and track slow query logs to create indexes. This improves the utilization of the instance resources.

Procedure

1. Log on to the ApsaraDB for MongoDB console.
2. In the left-side navigation pane, click **Replica Set Instances** or **Sharded Cluster Instances**.
3. Find the instance and then click the instance ID or choose > **Manage** in the **Actions** column. Then, the **Basic Information** page appears.
4. In the left-side navigation pane, choose **CloudDBA > Slow Query Logs**.

   > **Note** By default, slow query logs generated in the past 15 minutes are displayed in the trend chart. You can specify the time range and click **Search** to view slow query logs in specific periods of time. The maximum time range is one day.

5. View details of slow query logs by using one of the following methods:

   Method 1:

   i. Click the **Slow Log Details** tab in the lower part of the page.

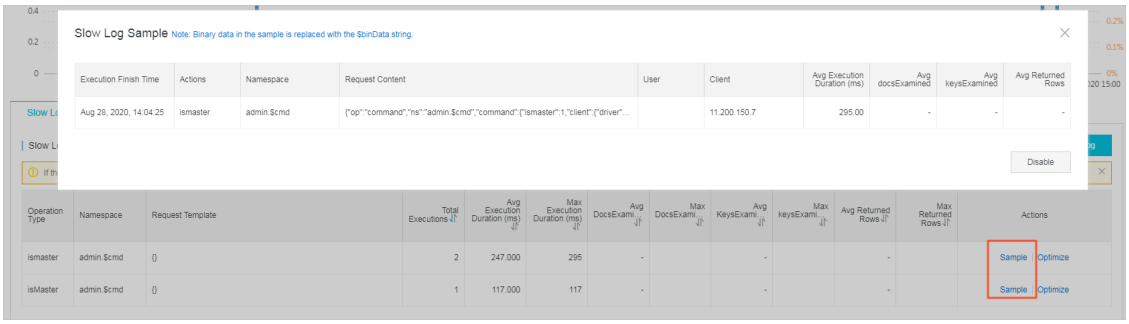
   ii. On the **Slow Log Details** tab, select the database that you want to query.

   > **Note** If the request content of the database is hidden, you can move the pointer over the corresponding content in the **Request Content** column and view the complete content.

   Method 2:

i. In the Slow Log Trend chart, click a point in time. Then, you can view the statistics of the slow query logs generated at the point in time on the **Slow Log Statistics** tab.

ii. On the **Slow Log Statistics** tab, click **Sample** in the **Actions** column corresponding to a slow query log. In the **Slow Log Sample** dialog box, you can view details of the slow query log.



> **Note** If the request content of the database is hidden, you can move the pointer over the corresponding content in the **Request Content** column and view the complete content.

Export slow query logs

You can click **Export Slow Log** on the **Slow Log Statistics** tab to save the slow query log information to your computer.

15.Data Management (DMS)

15.1. What is DMS?

Data Management (DMS) is a fully managed service that is provided by Alibaba Cloud. This service allows you to manage data, schema, development procedures, development specifications, users, and permissions. DMS also provides security control to ensure secure access to databases.

Supported databases

- Relational databases: MySQL, SQL Server, PostgreSQL, PolarDB-X (previously called DRDS), Oracle, and ApsaraDB for OceanBase.
- NoSQL databases: ApsaraDB for Redis and ApsaraDB for MongoDB.
- Analytical databases: AnalyticDB for MySQL and AnalyticDB for PostgreSQL.

Features

- DMS provides support for the database development process. The process includes the following stages: 1. Design table structures in an on-premises environment based on the predefined design specification. 2. Publish and produce SQL reviews that are included in code and schemas to a specified environment on demand. The SQL reviews are included in code in schemas. The SQL reviews in code are used to add, remove, modify, or query rows.
- DMS provides fine-grained access control at the database, table, or field level. You can perform the required operations on databases in the DMS console. The operations can be traced and audited.
- DMS allows you to configure the required operation specifications and approval processes for multiple modules. These modules include the schema design, data change, data export, and permission request.
- DMS integrates database development with database interaction. You can manage databases without the need to switch between database endpoints at a high frequency by using database accounts and passwords.
- DMS provides the task orchestration feature. This feature allows you to orchestrate and schedule SQL tasks for databases on a regular basis. You can use this feature to perform the required operations with ease. For example, you can dump historical data, analyze periodical reports, and generate analytical results.

15.2. Quick start

15.2.1. Log on to the DMS console

This topic uses Google Chrome to describe how to log on to the Data Management (DMS) console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

> **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
>
> - Uppercase or lowercase letters
> - Digits
> - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, move the pointer over **Products** and click **Data Management** under **Database Services**.
5. Set the **Organization** and **Region** parameters and click **DMS**.

> **Note** If you log on to the DMS console as a DMS administrator and your account is added to multiple tenants, you can move the pointer over the  icon in the upper-right corner and select **Switch tenant** to switch to another tenant.

15.2.2. Customize the top navigation bar

Data Management (DMS) allows you to customize the top navigation bar so that you can access the features that are commonly used in DMS with ease.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon.
3. Turn on the 

switch in the upper-right corner so that you can customize the top navigation bar.
   - on: You can customize the top navigation bar.
   - off: By default, all features are displayed. You cannot customize the top navigation bar.
4. Find a feature that you want to add to favorites and click the  icon. The feature is displayed in the top navigation bar.

> **Note** If a great many features are added to favorites, move the pointer over **More** in the top navigation bar to view the favorite features that are hided.

15.2.3. Add an instance

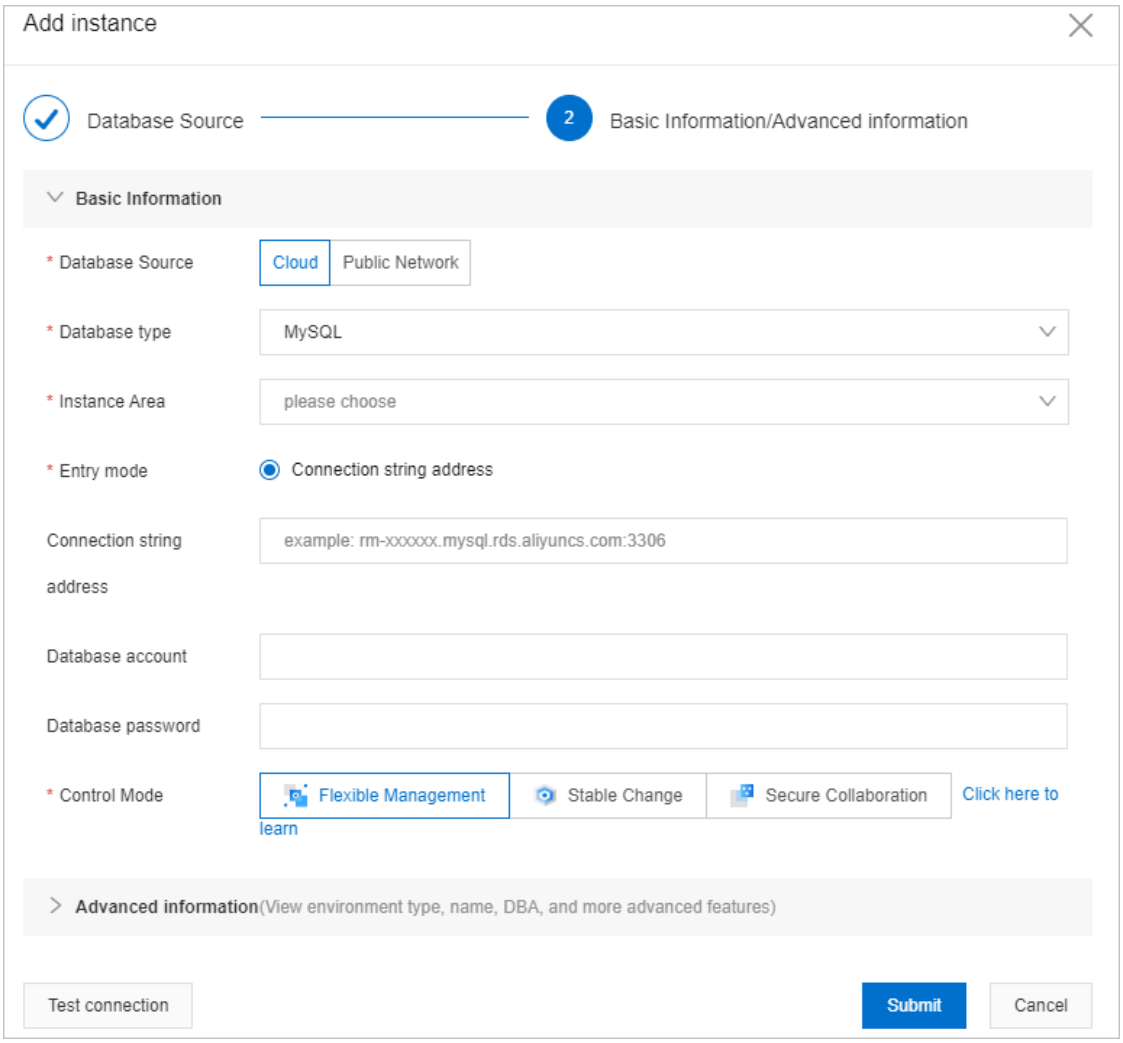
Before you can manage database instances in Data Management (DMS), you must add database instances to DMS. DMS allows you to add ApsaraDB instances and self-managed database instances for which public IP addresses are specified. This topic describes how to add an ApsaraDB RDS for MySQL instance to DMS.

Procedure

1. Log on to the DMS console.
2. In the left-side navigation pane, click **Add Instance**.

> **Note** You can also click the + icon in the left-side navigation pane to add an instance.

3. In the Add Instance dialog box, click the **Cloud** tab.
4. On the Cloud tab, select the type of the instance.
5. In the Basic Information section of the dialog box, set the required parameters. This example shows how to add an ApsaraDB RDS for MySQL instance.



Section	Parameter	Description
Basic Information	**Data Source**	The source of the database. In this example, select **Cloud**.
	Database Type	The type of the database. In this example, select **MySQL**.
	Instance Area	The area where the database instance resides. Select a region from the drop-down list.
	Entry mode	Valid value: **Connection string address**.
	Connection string address	The endpoint of the database instance. The endpoint contains a port number.
	Database account	The username of the account that is used to log on to the database of the instance.
	Database password	The password of the account.

Section	Parameter	Description
	Control Mode	The control mode that is used to manage the database. For more information, see Control modes. **Note** If you set this parameter to **Security Collaboration**, you must set the **Security Rules** parameter.
Advanced Information	**Environment type**	The type of the environment to which the database instance belongs.
	Instance Name	The name of the database instance.
	Enable DSQL	Specifies whether to enable the cross-database query feature. To enable the cross-database query feature, you must specify the name of a custom database link. For more information, see Cross-database query.
	Lock-free Schema Change	Specifies whether to enable the lock-free schema change feature.
	DBA	The database administrator (DBA) of the database instance. The DBA is used to handle approval processes, such as permission requests.
	query timeout(s)	The security policy. When the specified timeout period is reached, the execution of the SQL statement is terminated. This way, the security of the database is ensured.
	export timeout(s)	The security policy. When the specified timeout period is reached, the execution of the SQL export statement is terminated. This way, the security of the database is ensured.

6. After the preceding parameters are set, click **Basic Information** and click **Test connection** to verify the settings.

   Note If the connection test fails, check the specified parameters based on the error message that appears.

7. Click **Submit**.

Result

After the preceding steps are performed, the ApsaraDB instance is added to DMS. You can view and manage your database instance in the left-side navigation pane of the DMS console.

15.2.4. Add a user

Data Management (DMS) allows you to manage users. You can add users and assign the required roles to each user based on your business requirements.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **System > User**.

> **Note** On the User tab, you can perform the required operations on the existing users. For example, you can edit, disable, enable, or delete a user.

3. Click **New**.
4. In the Add User dialog box, set the required parameters. The following table describes the parameters.

Parameter	Description
Alibaba Cloud Account	The ID of an Apsara Stack tenant account. You can enter one of the following IDs: ○ The ID of an Apsara Stack tenant account. You can obtain the ID from the account owner. ○ The ID of a Resource Access Management (RAM) user. You can obtain the required ID from the Service-linked Roles page of the Apsara Uni-manager Management Console.
Role	The role that you want to assign to the user based on your business requirements. Valid values: ○ Regular User ○ DBA ○ Administrator ○ Security Administrator ○ Technical Support **Note** For more information about the features that are supported by each role, see Features that are supported by each role.

5. Click **OK**.

15.2.5. Use the sharing feature

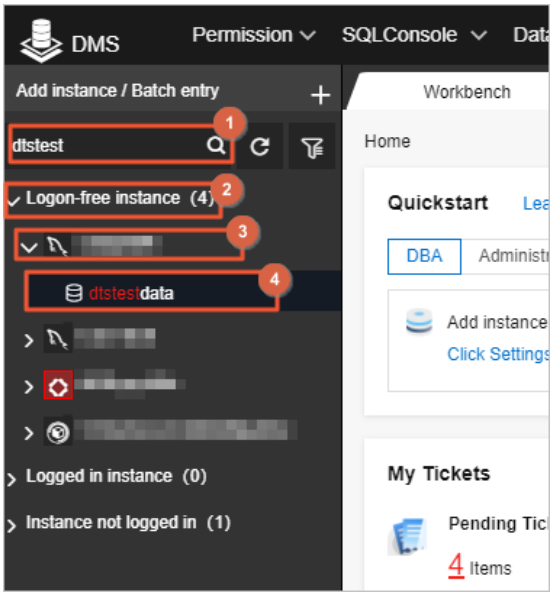
Data Management (DMS) provides the sharing feature for you to share an SQLConsole tab or a ticket. You can use a share link to access an SQLConsole tab or a ticket with ease. This improves efficiency. This topic describes how to use the sharing feature in DMS.

Scenarios

- You can share historical tickets. This improves the audit efficiency of security administrators.
- You can obtain the information about historical changes to databases based on the share links of historical data change tickets.
- You can query and update databases based on the share links of SQLConsole tabs.

Share an SQLConsole tab

1. Log on to the DMS console.
2. In the left-side navigation pane, enter the name of a database in the search box and press the Enter key. From the matched results, click the instance in which the database resides and double-click the database. The **SQLConsole** tab appears.



3. On the **SQLConsole** tab, click the icon in the upper-right corner.

> **Note** You can share the SQLConsole tab of a database only after you obtain the permissions on the database. Otherwise, the icon is not displayed.

4. In the dialog box that appears, click **Open sharing**.
5. Set the parameters as required.

Parameter	Description
Sharing form	The content to be shared. Valid values: **Console only** and **Console + SQL**. ○ **Console only**: the SQLConsole tab without SQL statements. ○ **Console + SQL**: the SQLConsole tab including the SQL statements that you entered.
Sharing period	The validity period of the share link. Valid values: **7 Days**, **30 Days**, **180 Days**, and **360 Days**.

6. Click **Generate and copy links**.

> **Note** After a share link is generated, you can turn off **Turn off sharing** if you no longer want to share the SQLConsole tab. Then, the generated share link becomes invalid.

Share a ticket

1. Log on to the DMS console.
2. On the Workbench tab of the DMS console, click **Submitted Tickets** in the **My Tickets** section. The **My Tickets** page appears.
3. On the **My Tickets** page, find the ticket that you want to share and click the ticket number to go to the **Ticket Details** page.

> **Note** Schema design tickets cannot be shared.

4. On the **Ticket Details** page, click the icon in the upper-right corner.
5. In the dialog box that appears, click **Open sharing**.
6. Set the parameters as required.

Parameter	Description
Share object	The recipients of the share link. You can specify one or more recipients. Valid values: **Everyone** and **Designated**. ○ **Everyone**: all the users of the current DMS tenant. ○ **Designated**: one or more specific users of the current DMS tenant.
Sharing period	The validity period of the share link. Valid values: **7 Days**, **30 Days**, **180 Days**, and **360 Days**.
Designated	The specific users to whom you want to send the share link. You can specify one or more users. **Note** This parameter is displayed only after you set the **Share object** parameter to **Designated**.

7. Click **Generate and copy links**.

> **Note** After a share link is generated, you can turn off **Turn off sharing** if you no longer want to share the ticket. Then, the generated share link becomes invalid.

15.3. Control modes

DMS provides three control modes for you to manage instances: Flexible Management, Stable Change, and Security Collaboration. You can specify a control mode for each instance.

Control mode	Description	Scenario	Logon method
Flexible management	This control mode allows you to manage the visualized data and schemas of multiple types of databases. It also provides a variety of data management solutions. This simplifies the use of databases and facilitates management.	• Database instances do not require strict control. • Database instances are used by a single user.	A database account and the related password.

Control mode	Description	Scenario	Logon method
Stable change	• This control mode provides multiple solutions to ensure database reliability. These solutions allow you to change data without the need to lock the related table or schema. • All features that are included in the flexible management control mode are available.	• Database instances require a high level of availability. This ensures that these database instances function as expected for an extended period of time. • Database instances are used by a small-sized group that includes multiple users.	A database account and the related password.
Security collaboration	• This control mode provides multiple solutions to ensure data security. These solutions include fine-grained access control at the database, table, or field level and sensitive data management. • This control mode allows you to produce enterprise-specific database DevOps solutions through custom design specifications and approval processes. • All features that are included in the flexible management and stable change control modes are available.	• Ensure the data security of database instances. • Implement strict access control over development or change workflows. • Manage compliance for enterprises.	Logon-free through authorization.

Note The instances that are managed in Stable Change mode consume the billing quota of the instances that are managed in Security Collaboration mode.

15.4. Features that are supported by each role

DMS provides the following roles: regular user, DBA, security administrator, and DMS administrator. This topic describes the features that are supported by each role.

Category	Feature	Regular user	DBA	Security administrator	DMS administrator	Description
Permission	Permission management	√	√	√	√	You can use this feature to apply for permissions on instances, databases, tables, and sensitive fields. You can also view permissions that you have.
	Data Changes	√	√	√	√	You can use this feature to initialize data for a newly published project, clean up historical data, fix bugs, or run a test.
	Data Import	√	√	√	√	You can use this feature to import a large amount of data to your databases at a time.

Category	Feature	Regular user	DBA	Security administrator	DMS administrator	Description
Data Plans	Data Export	√	√	√	√	You can use this feature to export a large amount of data for analysis or export the required data.
	Data Tracking	√	√	√	√	If specific data fails to meet your requirements due to reasons such as misoperation, you can use this feature to restore data to the normal state.
	Test Data Generate	√	√	√	√	Some business scenarios may require frequent data preparation. In this case, you can use this feature to generate test data to ensure data security and discreteness and improve production efficiency.
	Data Warehouse Development	√	√	√	√	DMS uses a database as a computing engine and integrates various tools and services, such as Data Transmission Service (DTS) and Data Lake Analytics (DLA), in the database ecosystem for data warehouse development. You can use this feature to develop and manage data warehouses in DMS with ease.
	Data Service	√	√	√	√	You can use this feature to export data at the field or row level, display data in a visualized manner, and publish API operations to the Alibaba Cloud Marketplace for sale.
	Database Clone	√	√	√	√	You can use this feature to clone MySQL databases.
Schemas	Schema Design	√	√	√	√	When you develop or optimize projects or process new business requirements, you can use this feature to change schemas. For example, you can use this feature to create a table or modify an existing table.
	Table Sync	√	√	√	√	You can use this feature to compare and synchronize the schemas of tables in different environments, such as online and offline environments. This feature helps ensure the consistency of schemas.
Optimization	SQL Review	√	√	√	√	You can use this feature to prevent SQL statements that do not use indexes or do not conform to database development standards. This feature helps protect against SQL injection attacks.

Category	Feature	Regular user	DBA	Security administrator	DMS administrator	Description
SQLConsole	Single Database query	√	√	√	√	You can write SQL statements to query data in a single database. This feature can be used to verify business code, analyze product effects, and identify issues in an online environment.
	Cross-database Query	√	√	√	√	You can use this feature to perform join queries across online heterogeneous databases that are deployed in different environments.
System Management	Instance management	×	√	×	√	You can use this feature to manage instances. For example, you can register, view, or edit instances.
	User management	×	×	×	√	You can use this feature to manage users. For example, you can add, view, or edit users as needed.
	Task management	×	√	×	√	You can use this feature to manage tasks. For example, you can create, start, or stop tasks.
	Configuration management	×	×	×	√	You can use this feature to view and modify system configurations, or view the historical modifications of the configurations.
Security management	Security Rules	×	√	×	√	You can use this feature to configure security rules. Only SQL statements that conform to the security rules can be executed.
	Approval Processes	×	√	×	√	Approval processes are associated with security rules. You can configure different approval processes for different types of tickets.
	Operation Logs	×	√	√	√	Operations logs record data changes. Each record contains information such as the user who performed the operation, operation details, and time at which the operation was performed. You can use this feature to track historical user operations at any time.
	Access IP Whitelists	×	×	×	√	After you configure an access IP whitelist, only the IP addresses or Classless Inter-Domain Routing (CIDR) blocks in the whitelist can access the resources within your DMS tenant. This effectively enhances data security.

Category	Feature	Regular user	DBA	Security administrator	DMS administrator	Description
	Sensitive Data	×	√	√	√	You can use this feature to manage sensitive data. For example, you can use algorithms to de-identify sensitive data or adjust the security levels of sensitive data.
Tickets	Ticket management	√	√	√	√	You can use this feature to configure notification methods. DMS can notify you of the approval or execution status of tickets by using DingTalk notifications or emails.

15.5. Apply for permissions

You can apply for the query, change, and export permissions on a database, table, or column. After the database owner approves your application, you can query, change, and export data.

Permissions

- Query permissions: the permissions to execute SQL statements in the SQLConsole to query the data of the object on which you want to apply for the permission.
- Change permissions: the permissions to submit tickets to change data or synchronize data in a database or table. You cannot change data without approval.
- Export permissions: the permissions to submit tickets to export data from the object on which you want to apply for the permission. You cannot export data without approval.

Permission categories that are supported by each control mode

Permission category	Permissions	Control mode		
		Flexible management	Stable change	Security collaboration
Instance logon	After you obtain the instance logon permission on an instance, you can use the preset database account and password to log on to the instance.	√	√	×
Database	Database permissions are classified into query, export, and change permissions. After you obtain the database permissions on a database, you can access the following resources of the database: 1. All the insensitive fields. 2. All the tables to which row-level control settings are not applied. 3. All new tables. • Query permission: You can execute SQL statements in the SQLConsole to query data. • Change permission: You can submit data change and data import tickets. • Export permission: You can submit data export tickets.	×	×	√

Permission category	Permissions	Control mode		
		Flexible management	Stable change	Security collaboration
Table	Table permissions are classified query, export, and change permissions. After you obtain the table permissions on a table, you have full access to all data in the table except sensitive fields. • Query permission: You can execute SQL statements in the SQLConsole to query data. • Change permission: You can submit data change and data import tickets. • Export permission: You can submit data export tickets.	×	×	√
Sensitive field	Sensitive field permissions are classified into query, export, and change permissions. After you obtain the sensitive field permissions on sensitive fields in a table, you have full access to all sensitive fields in the table. Before you apply for the sensitive field permissions, you must obtain the database and table permissions to which the sensitive fields belong. • Query permission: You can execute SQL statements in the SQLConsole to query data. • Change permission: You can submit data change and data import tickets. • Export permission: You can submit data export tickets.	×	×	√
Database owner	• The owner of a database can manage the permissions on the database. For example, the owner of a database can grant or revoke permissions on the database and tables in the database. • The owner of a database can query all data in the database except sensitive or confidential fields. The owner can also submit tickets to perform operations on the data and schemas in the database without the need to apply for permissions. • DMS automatically identifies and assigns database owners to owner nodes in approval processes.	√	√	√
Table owner	• The owner of a table can manage the permissions on the table. For example, the owner can grant or revoke permissions on the table. • The owner of a table can query all data in the table except sensitive or confidential fields.	√	√	√

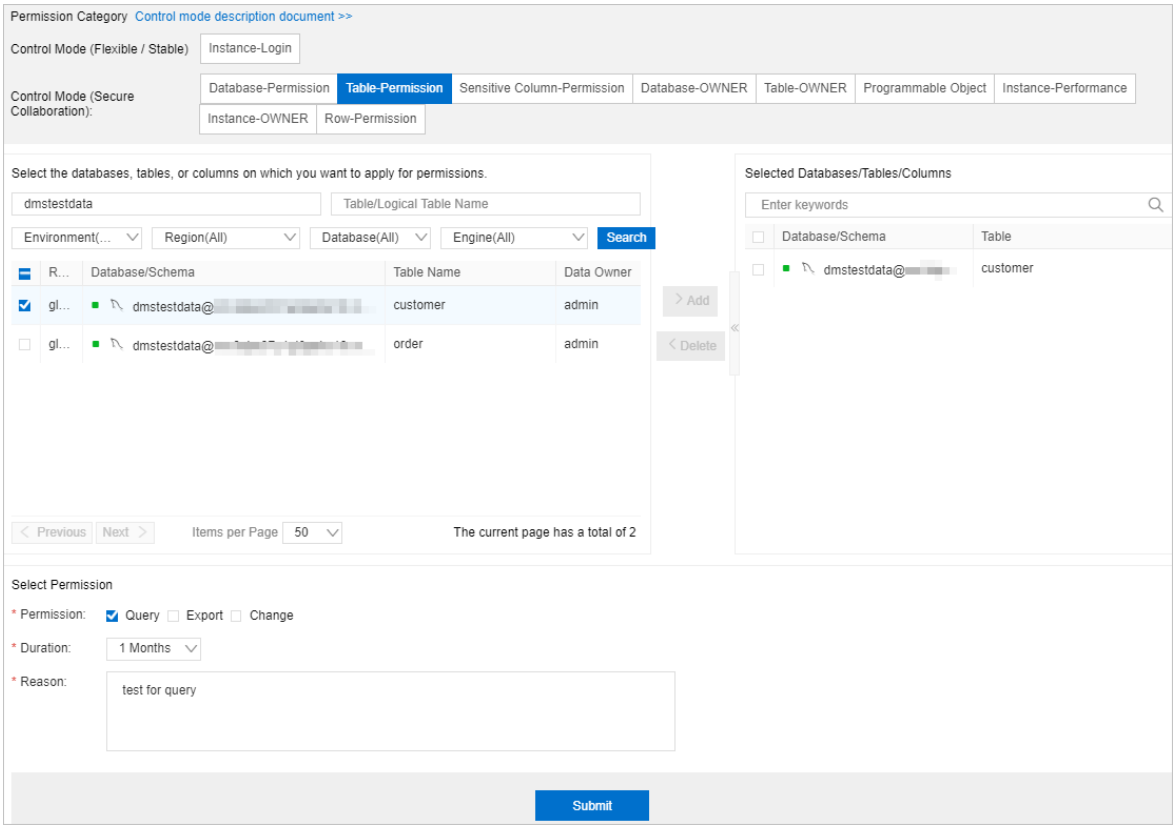
Permission category	Permissions	Control mode		
		Flexible management	Stable change	Security collaboration
Programmable object	Programmable object permissions are classified into query, export, and change permissions. • Query permission: You can execute SQL statements in the SQLConsole to query data. • Change permission: You can submit data change and data import tickets. • Export permission: You can submit data export tickets.	×	×	×
Instance performance	You can apply for permissions to view the performance of instances that are managed in security collaboration mode.	×	×	√
Instance owner	• The owner of an instance can manage the permissions on the instance. For example, the owner of an instance can grant or revoke permissions on the instance. • The owner of an instance can query all data in the databases of the instance except sensitive or confidential fields. The owner can also submit tickets to perform operations on the data and schemas of the instance without the need to apply for permissions.	√	√	√
Row	Row permissions are classified into query, export, and change permissions. You can apply for permissions on specific values of a managed field in a table. You can also apply for permissions on all values of a managed field in a table. • Query permission: You can execute SQL statements in the SQLConsole to query data. • Change permission: You can submit data change and data import tickets. • Export permission: You can submit data export tickets.	×	×	×

Apply for permissions

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Permissions** and select a permission category. For more information about permission categories, see Permission categories that are supported by each control mode.

   > **Note** In the top search box, you can search for databases or tables by name. In the search results, find the required database or table and click **Access apply** in the **Actions** column.

3. Set the required parameters of the permission for which you want to apply.



i. Select the category of the permission for which you want to apply.

ii. Select the databases, tables, or columns on which you want to apply for permissions.

> **Note** Enter keywords, specify filter conditions, and then click Search to search for databases or tables. The keywords that you enter can contain percent signs (%) as wildcards. In the search results, select the databases or tables on which you want to apply for permissions. Then, click Add.

iii. Select the type of permissions for which you want to apply and specify the duration for which you want to have the permission. Then, enter the reason for your application.

4. Click **Submit** and wait for approval.

> **Note** You can view the status of application ticket in the My Tickets section of the **Workbench** tab.

Manage permissions

Management type	Action	Description
Active management	Release permissions	On the Workbench tab, click **Effective Permissions** in the Permissions section. Select the object on which you want to release permissions and click **Release Permission**.
	Renew permissions	On the Workbench tab, click **Expiring Permissions** in the Permissions section to view and check the permissions that are about to expire. If you want to renew a permission, submit a ticket to apply for the renewal.
Passive management	N/A	The owner of a database can view and assess the rationality of permission assignments at any time and manage the permissions that are granted.

> **Note** All the operations that you perform to apply for, release, revoke, and grant permissions are recorded in operation logs. To view the operation logs, choose **System Management > Security > Operation Logs** in the top navigation bar.

15.6. SQLConsole

15.6.1. Single database query

The single database query feature allows you to execute various SQL statements in the SQLConsole of the Data Management (DMS) console with ease. You can use this feature to visualize the add, delete, modify, and query operations on the data in a database. This feature applies to scenarios, such as data queries and data development.

Prerequisites

You are granted the query permission on the database or table that you want to query.

Precautions

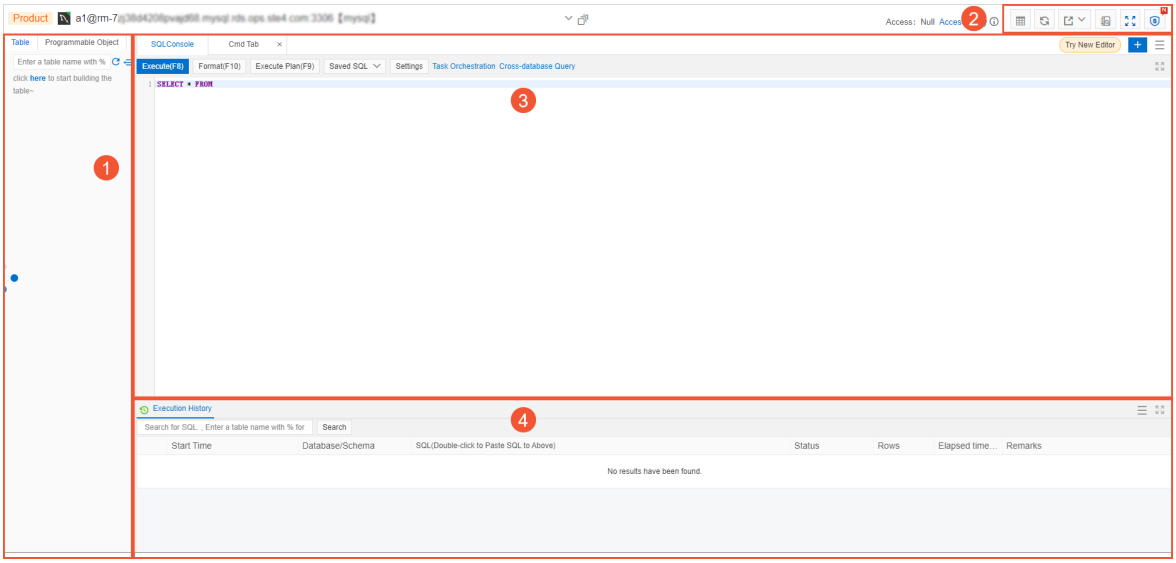
- A table may contain sensitive or confidential fields. You do not have permissions to access these fields. Therefore, the values of these fields are displayed as `******` in the query results. For more information, see Manage sensitive data.
- By default, a maximum of 200 data rows can be returned for each query. If you are an administrator, you can change this value based on your business requirements. To change this value, perform the following steps: 1. Log on to the Data Management (DMS) console. 2. In the top navigation bar, choose **System > Security > Security Rules**.
- A full scan can be performed on a table that does not exceed 10 GB in size. If you are an administrator, you can change this value based on your business requirements. To change this value, perform the following steps: 1. Log on to the DMS console. 2. In the top navigation bar, choose **System > Security > Security Rules**.
- By default, the timeout period to execute a single SQL statement is 60 seconds. If you are an administrator, you can change this value in the **Advanced information** section of the **Edit instance** dialog box.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > SQLConsole > Single Database Query**.

   > **Note** To go to the **SQLConsole** tab, you can also double-click the required database in the left-side instance list of the DMS console.

3. Select the database that you want to query from the drop-down list. You can also search for databases by keyword. After you find and select the required database, click **Confirm**.
4. Enter the SQL statement to be executed on the SQLConsole tab and click **Execute**.



GUI of the SQLConsole

No.	Section	Description
①	Visual operation section	In this section, you can visually manage your database. ○ **Tables** You can view all tables, fields, and indexes of the current database. You can also right-click a table in the database to modify the table schema, import data to the table, or export data from the table. ○ **Programmable objects** You can create, view, execute, and manage programmable objects, such as views, stored procedures, functions, triggers, and events. **Note** A maximum of 1,000 entries can be displayed. ○ Key-value pair information **Note** The key-value pair information can be displayed only for a NoSQL database.

No.	Section	Description
②	Extended feature section	In this section, shortcuts to extended features are provided. You can click the icons of the features to use the features. The following table describes the icons. ○  : the **Tables** icon. You can click the  icon to view the details about the table. Then, click the  icon to return to the SQLConsole tab. ○  : the **Sync Metadata** icon. After you click this icon, DMS collects most recent metadata information about the database, such as tables, fields, indexes, and programmable objects. This way, you can manage permissions on tables, fields, and programmable objects based on the security level. ○  : the Export icon. You can click this icon to export the data of the database, table schemas of the database, or table creation statements. ○  : the **Operation audit** icon. You can click this icon to view the information about all data query and data change records. For example, you can query the information about an operation, the operator, and the time when the operation is performed. For more information, see View operations logs.
③	Command running section	In this section, you can write and execute SQL statements to manage the current database. You can also format SQL statements, create execution plans, save commonly used SQL statements, and configure display settings. **Note** You can click the  icon to add multiple query tabs.
④	Execution result section	In this section, you can view the execution results after SQL statements are executed. You can also view the details about a single row and add, delete, or modify data. **Note** You can click the **Execution History** tab to view the historical execution records. For example, you can view the time at which the execution of an SQL statement started, the affected database, and the details about the SQL statement. You can also export the execution results as required.

15.6.2. Cmd Tab

Data Management (DMS) provides the Cmd Tab feature as a CLI for you to write and execute SQL statements. The executed SQL statements and execution results are displayed in the upper part of the Cmd Tab tab. This topic describes the GUI of the Cmd Tab tab and how to use the Cmd Tab tab.

Prerequisites

- The database to be queried is a relational database, such as a MySQL, an Oracle, or an SQL Server database.
- You are granted the query permissions on the database or table that you want to query.

Procedure

1. Log on to the DMS console.

2. In the top navigation bar, move the pointer over the **More** icon and choose **SQLConsole > Cmd Tab**.
3. Select the database that you want to query from the drop-down list or enter a keyword in the field to search for the database. After you select the database, click **Confirm**.
4. Enter the SQL statement to be executed in the lower part of the Cmd Tab tab and press `Ctrl+Enter` or click **Execute** to execute the SQL statement.

15.6.3. Super SQL mode

Data Management (DMS) provides the super SQL mode feature. After you enable this feature as a DMS administrator or a database administrator (DBA), all SQL statements that you execute on the SQLConsole tab are executed without being affected by security rules.

Prerequisites

- You are a DMS administrator or a DBA.
- An instance is managed in Security Collaboration mode.

Context

To enhance the stability and security of databases, DMS administrators and DBAs may configure security rules for the databases. For example, a security rule is configured to prevent unauthorized users from executing DML statements in a production database on the SQLConsole tab. They can execute those statements only by submitting a ticket. However, these security rules may cause inconvenience to privileged users, such as DMS administrators and DBAs.

In view of this, DMS provides the **super SQL mode** feature. If you enable this feature as a DMS administrator or a DBA, all SQL statements that you execute on the SQLConsole tab are executed without being affected by security rules.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon and choose **SQLConsole > Single Database query**.

   > **Note** To go to the **SQLConsole** tab, you can also double-click the database that you want to query in the left-side navigation pane of the DMS console.

3. Select the database that you want to query from the drop-down list or enter a keyword in the field to search for the database. After you select the database, click **Confirm**.
4. On the SQLConsole tab, click the  icon in the upper-right corner. In the message that appears, click **OK**.

   Then, the outside borders of the SQLConsole tab turn orange. This indicates that the **super SQL mode** feature is enabled. The SQL statements that you enter on the SQLConsole tab are directly executed.

   > **Notice** After you enable this feature as a DMS administrator or a DBA, all SQL statements that you execute on the SQLConsole tab are executed without being affected by security rules.

   To disable the **super SQL mode** feature, click the  icon in the upper-right corner.

15.6.4. Cross-database query

Data Management (DMS) provides the cross-database query feature that allows you to perform cross-database queries on online heterogeneous data sources that are deployed in different environments. The cross-database query feature allows you to perform cross-database queries on databases and tables in database instances that are added to DMS.

Prerequisites

- The type of the database instance that you want to query is MySQL, SQL Server, PostgreSQL, PolarDB-X, or Redis.
- The cross-database query feature is enabled for each database instance.

  > **Note** If the cross-database query feature is not enabled for a database instance, you can enable the feature in the Edit instance dialog box in the DMS console. Then, enter a database link name in the Advanced information section. The name of each database link must be unique.

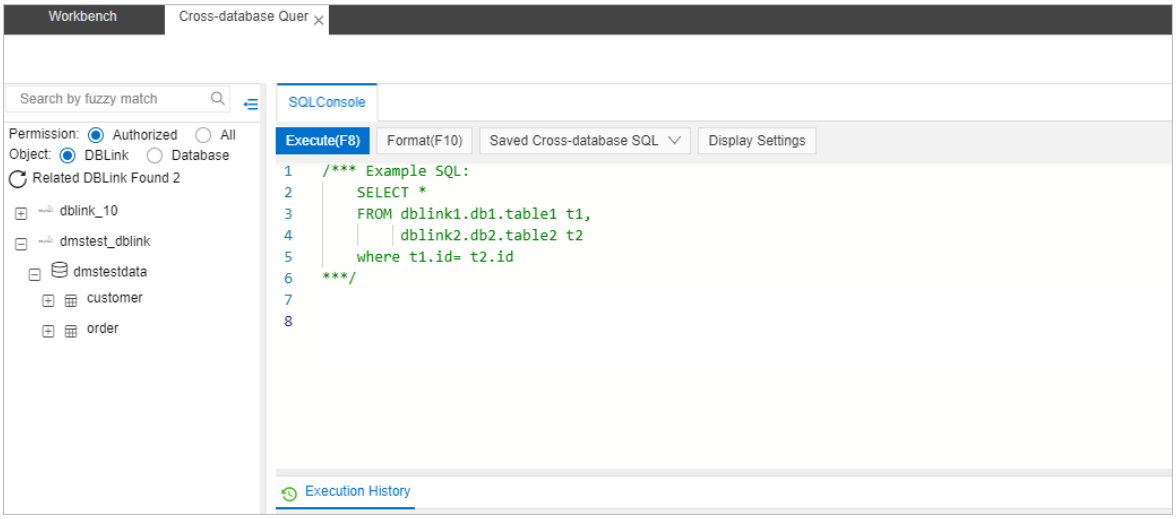
- You are granted the query permission on each database or table that you want to query.

Limits

You can perform cross-database queries only on physical databases. This feature is unavailable for logical databases.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > SQLConsole > Cross-database Query**.
3. In the left-side pane of the **Cross-database Query** tab, view the databases on which you have the query permission or all the databases.
4. On the **SQLConsole** tab, enter an SQL statement. You can perform cross-database queries on databases and tables on which you have the query permission in database instances.



> **Note**
> - You must specify the table that you want to query in the format of `<DBLinkName>.<databaseName>.<tableName>`, for example, `dmstest_dblink.dmstestdata.customer`.
> - In the left-side list, you can double-click a table on which you have the query permission or drag the table to the SQLConsole tab. An SQL statement that is used to query data in the table is automatically generated.

5. Click **Execute(F8)**. You can view the execution results and execution history in the Execution History section.

> **Note** DMS also provides the format, saved cross-database SQL, and display settings features. You can use these features based on your business requirements.

15.7. Data plans

15.7.1. Change data

DMS provides the data change feature that allows you to change data. This topic describes how to use the data change feature to change data.

Context

DMS allows you to submit data change tickets to initialize data for a newly published project, clear historical data, fix bugs, or run a test. The operations that you can perform to change data include insert, update, delete, or truncate operations.

Data change types

Type	Description

Normal data modify	You can use the normal data modify feature to perform the following data changes:
	• Perform normal data changes.
	• Perform lock-free schema changes. You can perform this type of operations to change character sets and collations for tables, adjust time zones, and change column data types. Compared with normal data change operations, lock-free schema changes can be performed to achieve the following benefits:
	  ◦ Ensures business continuity regardless of whether tables are locked due to database schema changes.
	  ◦ Ensures consistent synchronization between the primary and secondary databases regardless of whether the latency occurs due to native online data definition language (DDL) operations that are performed on the databases.
	  ◦ Reclaims tablespaces and reduces fragmentation rates without the need to lock tables. You no longer need to use the OPTIMIZE TABLE statement that results in table locks.
	Note You can use this feature only for MySQL databases. Before you use this feature, you must set the OnlineDDL parameter to Open(DMS OnlineDDL first) in the **Advanced information** section when you add or edit an instance. For more information, see Register database instances with DMS.

Lock-free data modify	You can use this feature to change a large amount of data. For example, you can use this feature to delete historical data and update all fields in a table. Multiple SQL statements for data changes are divided and executed at the same time based on the primary key or unique key. This limits the consumption of database performance and space. **Note** You can use this feature only for MySQL databases.
History data clean	You can use this feature to regularly clean historical data. This way, the stability of the production environment is not affected when you obtain historical data. **Note** You can use this feature only for MySQL databases.

Type	Description
Programmable object	Databases provide programmable objects such as stored functions and stored procedures. This feature allows you to use the programmable objects to standardize management processes and provide audit records.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Data Plans** and select a data change type.

   > **Note** This topic describes how to submit a ticket that is used to **modify normal data**.

3. Specify the required parameters for the data change ticket.

Parameter	Description
Reason Category	The reason for the data change. This helps you identify the ticket in the future.
Business Background	The purpose or objective of the data import. This reduces communication costs.
Change Stakeholder	The stakeholders of the data change. All specified stakeholders can view the details about the ticket and participate in the approval process. Unauthorized users, except for administrators and DBAs, cannot view the details about the ticket.
Execution Method	The method that is used to execute the ticket based on your business requirements.
Database	The database on which you have the change permission. If you have only query permissions on the database or the change permission on the tables of the database, you cannot submit a data change ticket.
Affected Rows	The estimated number of data rows that are affected by the data change. To obtain the actual number of affected rows, you can write an SQL statement that includes the COUNT function on the SQLConsole tab.
SQL Statements for Change	The executable SQL statements that are used to export data. You can upload a file to provide the SQL statements. DMS verifies the syntax of the SQL statements when you submit the ticket. If the syntax is invalid, DMS rejctes the ticket.
SQL Statements for Rollback	The executable SQL statements that are used to roll back the data import operation. You can write the SQL statements in the SQL Text field or upload an SQL that includes the required SQL statements.
Attachments	The images or files that are uploaded to add more information about the data change.

4. After you configure the settings, click **Submit**.
5. After your ticket passes the precheck, click **Submit for Approval**. In the message that appears, click **OK**.
6. After the ticket is approved, click **Execute Change**.
7. Set the Execute Immediately parameter and click **Confirm Execution**.

   > **Note** By default, the Execute Immediately switch is turned on. You can turn off the **Execute Immediately** switch and specify a point in time to run the ticket. The system automatically runs the ticket at the specified point in time.

8. Wait until the execution is completed.

15.7.2. Import data

Data Management (DMS) provides the data import feature that allows you to import large amounts of data to a database with ease. This saves manpower and resources.

Supported databases

- Self-managed MySQL databases and ApsaraDB RDS for MySQL databases
- PolarDB-X databases

Supported file formats for data import

- TXT format.
- SQL script. By default, you can use only the INSERT and REPLACE statements to import data to database instances that are managed in Security Collaboration mode. If you want to use other SQL statements to import data, modify the security rules for data import as a database administrator (DBA) or DMS administrator. To modify the security rules, click the **SQL Correct** tab on the **Security Rules** tab and set the Checkpoints parameter to **Batch Data import rules**.
- CSV format. Values in a CSV file must be separated by commas (,). The first row must be field names.

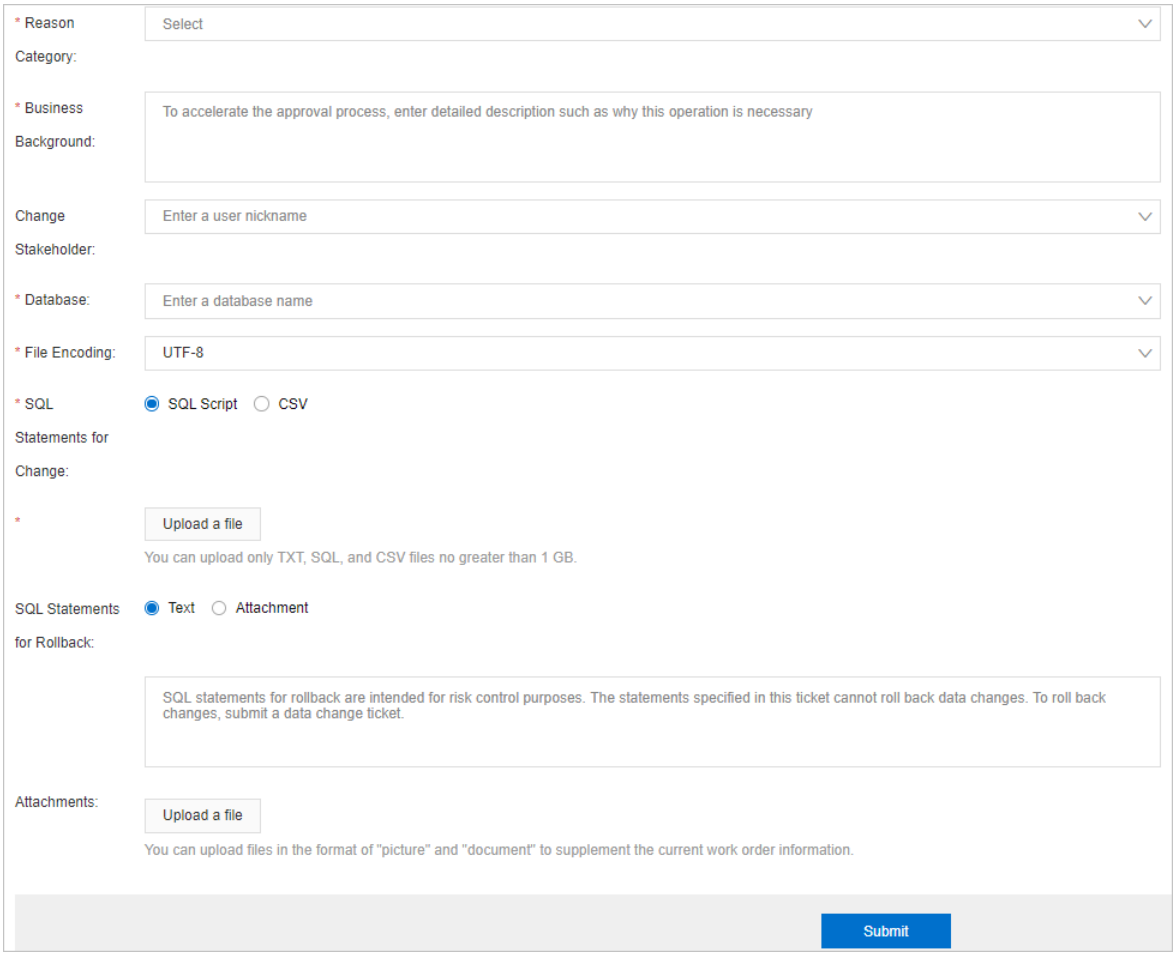
> **Note** The file size cannot exceed 5 GB.

Usage notes

- If you need to change only a small amount of data, we recommend that you submit a Normal Data Modify or Lockless change ticket to ensure stable data change. For more information, see Change data.
- If you submit a Large Data Import ticket to import a large amount of data to a table, the table will be locked even if you set the OnlineDDL parameter to Open (DMS OnlineDDL first) for the database instance.
- We recommend that you use SQL statements with better performance to import a large amount of data, such as the INSERT, UPDATE, and DELETE statements. Indexes of primary keys are used in the UPDATE and DELETE statements.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon and choose **Data Plans > Data Import**.
3. On the Large Data Import tab, set the parameters that are described in the following table.



Parameter	Description
Reason Category	The reason for the data import. This helps you identify the ticket in the future.
Business Background	The purpose or objective of the data import. This reduces unnecessary communication.
Change Stakeholder	The stakeholders involved in the data import. All the specified stakeholders can view the ticket details and assist in the approval process. Irrelevant users other than DMS administrators and DBAs are not allowed to view the ticket details.
Database	The database on which you have the change permissions. You cannot submit a data import ticket if you have only the permissions to query data in the database or change data in tables.
File Encoding	The encoding algorithm to be used by the database.
SQL Statements for Rollback	The executable SQL statements for rolling back the data import. You can write the SQL statements in the SQL Text field or upload an SQL script that includes the required SQL statements.
Attachments	The images or files that are uploaded to add more information about the data import.

4. After you configure the settings, click **Submit**.
5. After your ticket passes the precheck, click **Submit for Approval**. In the message that appears, click **OK**.

6. After the ticket is approved, click **Execute Change**.
7. Set the Execute Immediately parameter and click **Confirm Execution**.

> **Note** By default, the Execute Immediately switch is turned on. You can turn off the **Execute Immediately** switch and specify a point in time to run the ticket. The system automatically runs the ticket at the specified point in time.

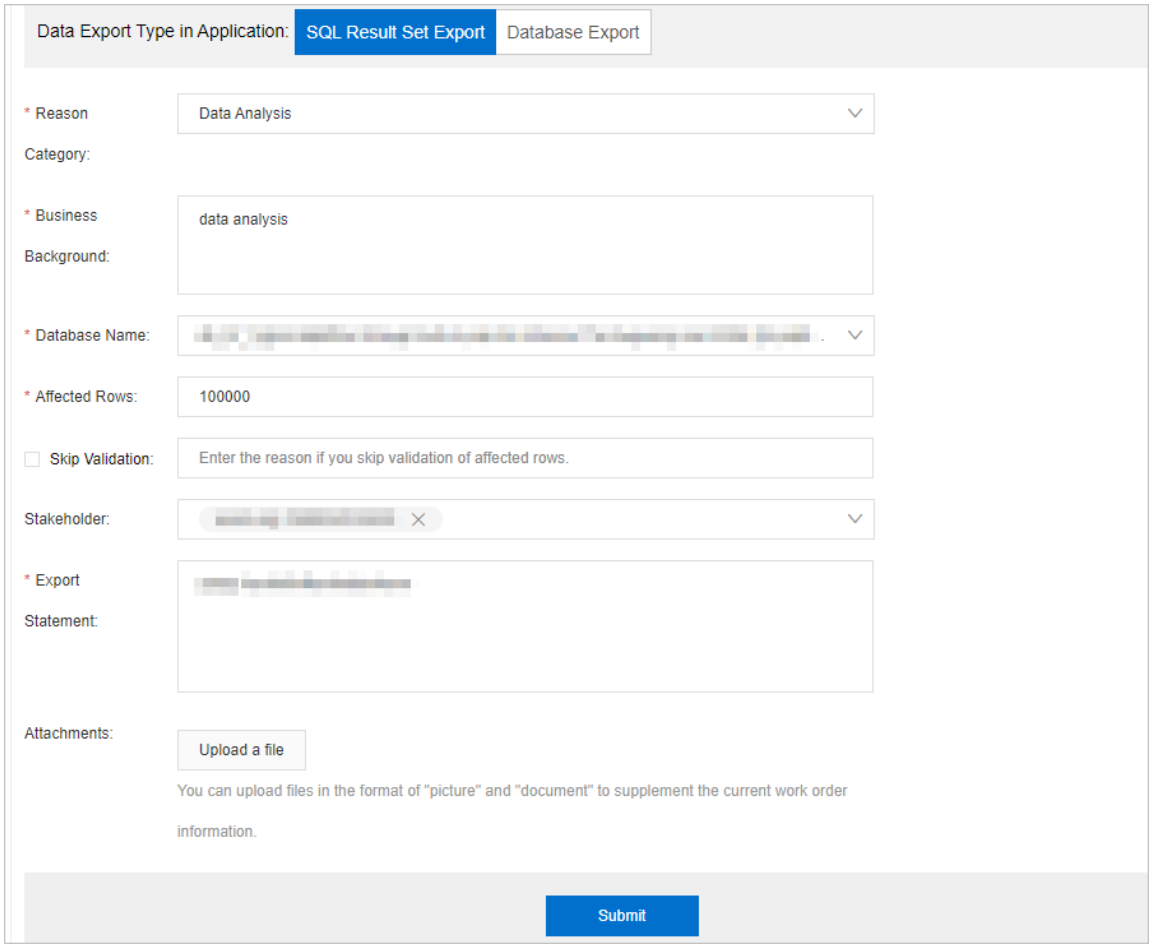
8. Wait until the execution is completed.

15.7.3. Data export

DMS provides the data export feature. You can use this feature to export a database or SQL result sets. Then, you can extract the required data for data analysis.

Procedure

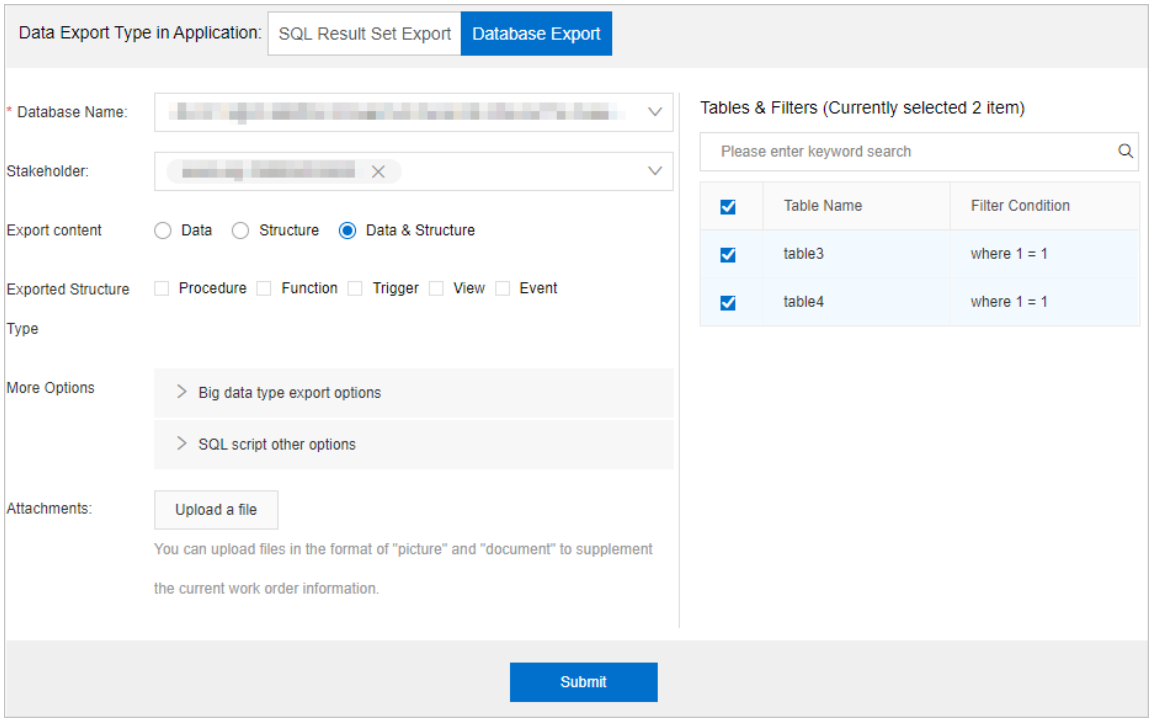
1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Data Plans** and select **SQL Result Set Export** or **Database Export**.
3. On the Data Export Ticket Application tab, set the required parameters.
   - Set the required parameters on the SQL Result Set Export tab



Parameter	Description

Parameter	Description
Reason Category	The reason for the data export. This helps you find the ticket in a timely manner in the future.
Business Background	The purpose or objective of the data export. This parameter reduces communication costs.
Database Name	The database on which you have the export permission.
Affected Rows	The estimated number of data rows that are affected by the data export. To obtain the actual number of affected rows, use the `COUNT` function in SQL statements on the SQL Editor tab.
Skip Validation	Specifies whether to skip validation. If you select **Skip Validation**, you must enter a reason in the field next to the check box. **Warning** If you select **Skip Validation**, DMS does not check the number of rows that are affected by the data export. If a large amount of data is exported, potential risks to your business increase. Proceed with caution.
Stakeholder	The stakeholders of the data export. All specified stakeholders can view the details about the ticket and are included in the approval process. Unauthorized users, except for administrators and DBAs, cannot view the details about the ticket.
Export Statement	The executable SQL statement that is used to export data. Example: `select * from testtable`. DMS verifies the syntax of the SQL statement when you submit the ticket. If the syntax is invalid, you cannot submit the ticket.
Attachments	The images or files that are uploaded to add more information about the data export.

- Configure a database export ticket



Parameter	Description
Database Name	The database on which you have the export permission. After you select the database, you must select the table to which you want to export data and configure filter conditions in the Tables & Filters section.
Reason Category	The reason for the data export. This helps you find the ticket in a timely manner in the future.
Business Background	The purpose or objective of the data export. This parameter reduces communication costs.
Stakeholder	The stakeholders of the data export. All specified stakeholders can view the details about the ticket and are included in the approval process. Unauthorized users, except for DMS administrators and DBAs, cannot view the details about the ticket.
Export content	The type of data that you want to export. Valid values: **Data**, **Structure**, and **Data & Structure**.
Exported Structure Type	The type of schema that you want to export.
More Options	The other objects that you want to export. Click **Big data type export options** or **SQL script other options** and select the required options.
Attachments	The images or files that are uploaded to add more information about the data export.

4. After you complete the configurations, click **Submit** and wait for approval.

   > **Note** When you export an SQL result set, DMS prechecks the SQL statements. After the SQL statements pass the precheck, click **Submit for Approval**. In the message that appears, click **OK**.

5. After your ticket is approved, go to the **Workbench** tab and click **Submitted Tickets** in the My Tickets section.
6. Find the data export ticket that is submitted and click the ticket number.
7. In the **Execute/Automatic Execution** section, click **Download Exported File**.

15.7.4. Generate test data

DMS provides the test data generation feature that allows you to generate data in a quick manner. You can generate test data for functional or performance tests.

Prerequisites

- A relational database is created to store test data that you generate. The relational database can be a self-managed MySQL, ApsaraDB RDS for MySQL, AnalyticDB for MySQL, or PolarDB-X database.
- A table is created. You can use the schema design feature to create a table. For more information, see Design a schema.

Context

Functional tests or performance tests often require test data. You can use one of the following methods to generate test data:

- Write test data. This method has low efficiency and is not applicable to scenarios in which a large amount of test data is required.
- Use scripts. This method requires high costs and the data that is generated by using this method cannot meet

discreteness requirements.

- Export data from a production environment as test data. This method is not secure and may cause data leak.

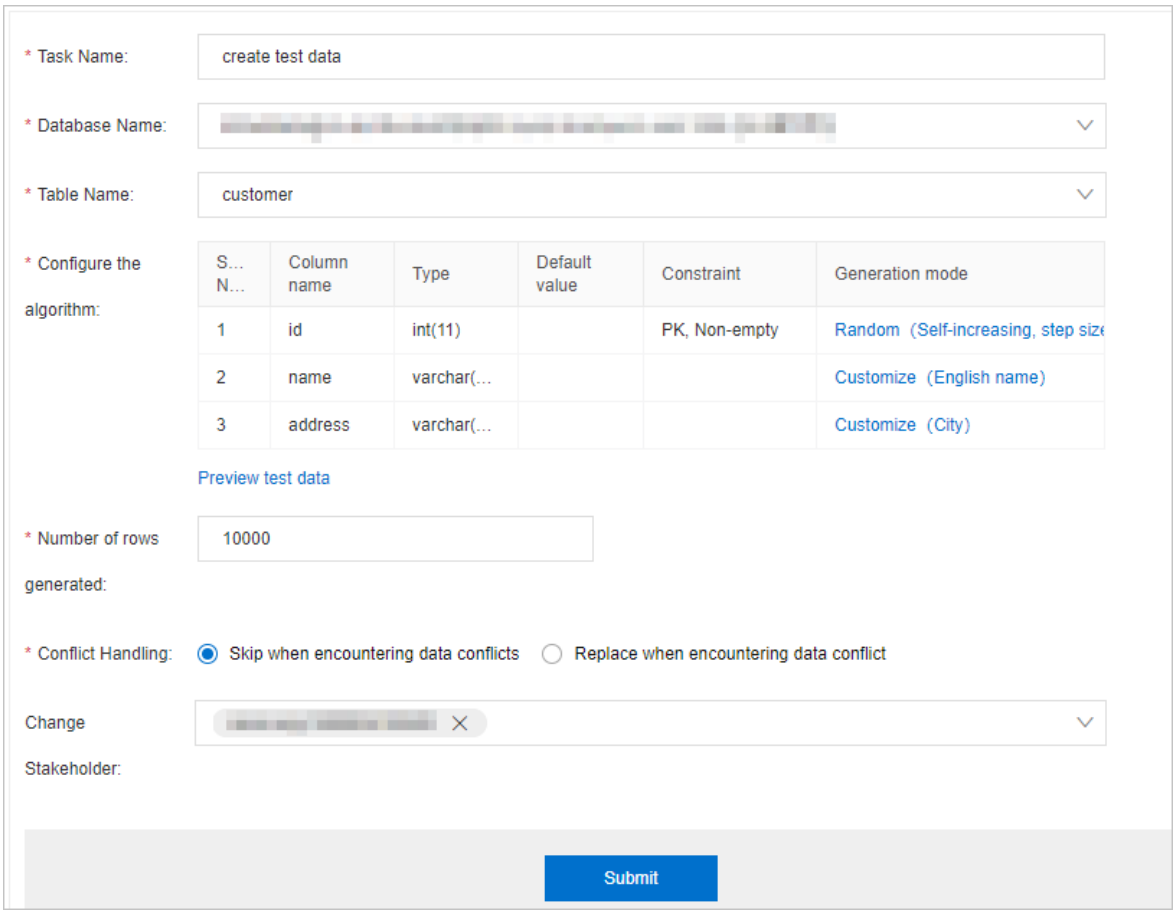
DMS provides the test data generation feature that allows you to generate test data in a quick, efficient, and secure manner. You can use this feature to control the discreteness of the data that is generated.

Precautions

- You can use this feature to generate test data in only one table at a time. To generate test data in multiple tables, submit a ticket.
- To prevent database overload due to the instantaneous generation of excessive data, DMS allows you to perform traffic throttling. Check the following examples for your reference.
  - About 1 minute is required to generate one million rows of data in a table that has four fields.
  - About 2 to 3 minutes are required to generate one million rows of data in a table that has 40 fields.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Data Plans > Test Data Generation**.
3. In the upper-right corner, click **Test Data Generation**.
4. In the Test data build ticket application dialog box, set the required parameters.



Parameter	Description
Task Name	The name of the task. The name can help you identify and manage the task in the future.

Parameter	Description
Database Name	The name of the database that includes the required table.
Table Name	The name of the table in which you want to generate test data. You can search for tables by keyword and then select a table from the matched results. After you select a table, the **Configure the algorithm** parameter that contains the field information of the table is displayed. **Note** You can use this feature to generate test data only in one table at a time. To generate test data in multiple tables, submit a ticket.
Configure the algorithm	The algorithms that are used to generate test data. Find the required field and click the value of the Generation mode parameter next to the field. Then, set the required parameters in Generation mode dialog box based on your business requirements. **Note** For example, you can use the random, customize, or enumeration algorithm to generate test data of the STRING type. The customize algorithm can be used to generate multiple industry-standard types of data.
Number of rows generated	The number of data rows that you want to generate.
Conflict Handling	The method that is used to handle conflicts based on your business requirements.
Change Stakeholder	The stakeholders of the ticket. All specified stakeholders can view the details about the ticket and are included in the approval process. Unauthorized users, except for DMS administrators and DBAs, cannot view the details about the ticket.

5. After you configure the settings, click **Submit**.
6. After your ticket is approved, DMS generates test data.

15.7.5. Clone databases

The database clone feature allows you to replicate data at the database level. This topic describes how to use the database clone feature.

Prerequisites

- A MySQL database is used.
- A database instance is managed in flexible management mode. You have logged on to the database instance in the Data Management (DMS) console.

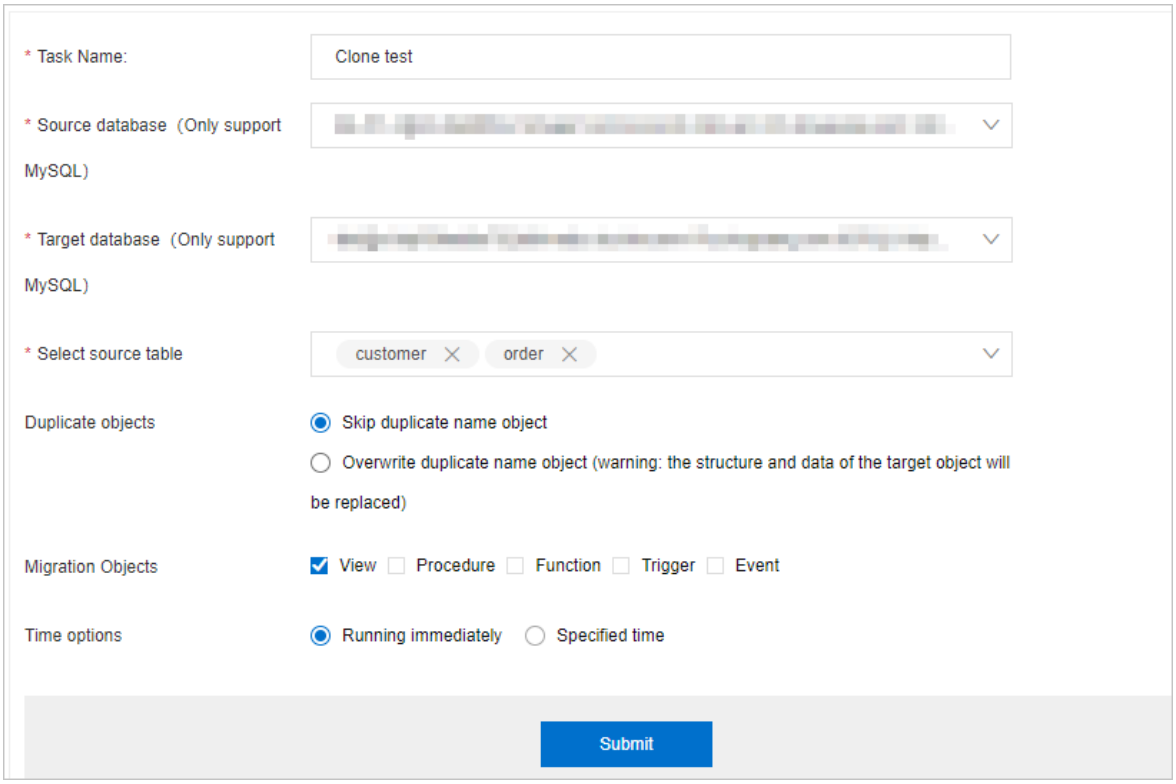
Scenarios

- Create a full database backup.
- Initialize databases that are deployed in different environments, such as development and test environments.
- Copy data from a database in an online environment to a database in an offline environment for data processing and analysis.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Data Plans > Database Clone**.
3. In the upper-right corner, click **Database Clone**.

4. In the Apply step, set the required parameters.



Parameter	Description
Task Name	The name of the task. The name is used to identify and manage the task.
Source database (Only support MySQL)	The source database that you want to clone. You can search for databases by keyword and then select a database from the matched results.
Target database (Only support MySQL)	The destination database to which you want to write the data that is cloned from the source database. You can search for databases by keyword and then select a database from the matched results. **Note** The destination database must be different from the source database.
Select source table	The tables that you want to clone from the source database. You can search for tables by keyword and then select a table from the matched results. **Note** To clone all tables, set this parameter to All Tables.
Duplicate objects	The method that is used to handle object conflicts based on your business requirements. ◦ **Skip duplicate name object**: The system skips objects that have a duplicate name. ◦ **Overwrite duplicate name object (warning: the structure and data of the target object will be replaced)**: If the two objects have the same name, the schema and data of the object in the destination database are overwritten by the schema and data of the object in the source database.

Parameter	Description
Migration Objects	The objects that you want to clone. In addition to tables, you can simultaneously clone other objects from the source database to the destination database. These objects include views, stored procedures, functions, triggers, and events.
Time options	Valid values: **Running immediately** and **Specified time**. If you set the Time options parameter to **Specified time**, you must specify a date and time to run the task. ○ **Running immediately**: The task is run immediately after the ticket is approved. ○ **Specified time**: DMS automatically runs the task to clone data at a specified point in time.

5. After you configure the settings, click **Submit**.
6. After the ticket is approved, the task is automatically run at a specified point in time.

15.8. Data factory

15.8.1. Task orchestration

The task orchestration feature runs based on a distributed scheduling engine that is developed by Alibaba Cloud. This feature allows you to create task flows and schedule these task flows. This feature also meets requirements for data processing based on powerful task flows that include various types of task nodes. For example, you can use this feature to archive data, integrate data, and transform data.

Scenarios

- Periodically archive and analyze business data.
- Synchronize online data to data warehouses for complex analysis.
- Periodically clean and transform offline data.
- Periodically schedule and orchestrate data definition language (DDL) or data manipulation language (DML) operations on databases.

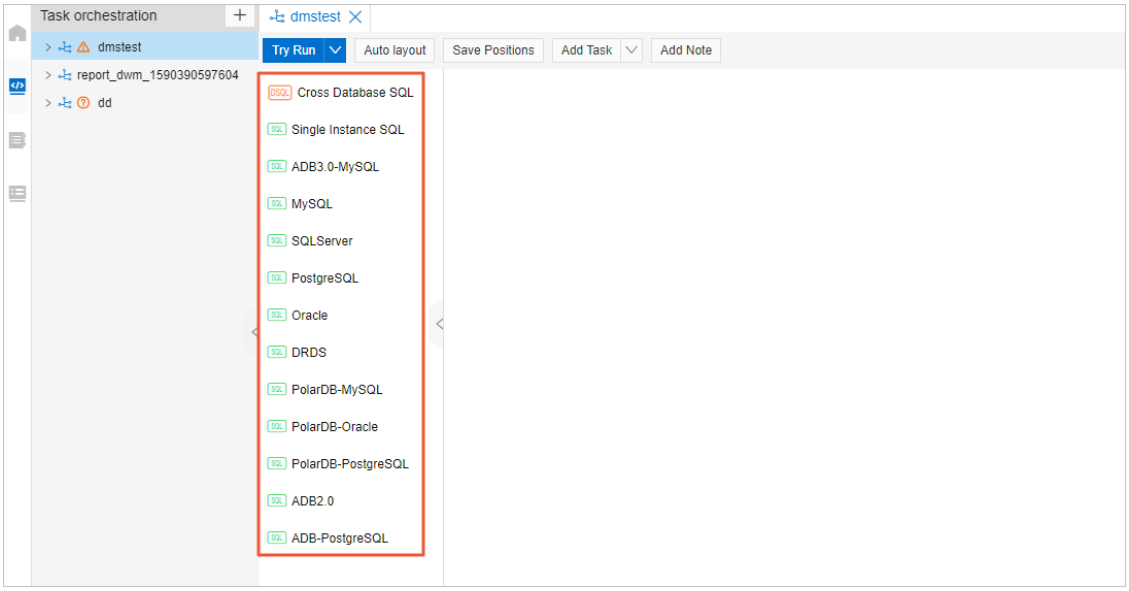
Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Data Factory > Task Orchestration**.
3. In the left-side navigation pane, click the  icon.
4. Configure a task flow.
   i. Click the icon next to **Task Orchestration**.
   ii. In the dialog box that appears, set the Task Flow Name and Description parameters.
   iii. Click **OK**.
5. Configure a task in the task flow.

   Note You can repeat this step to configure more tasks for the task flow.

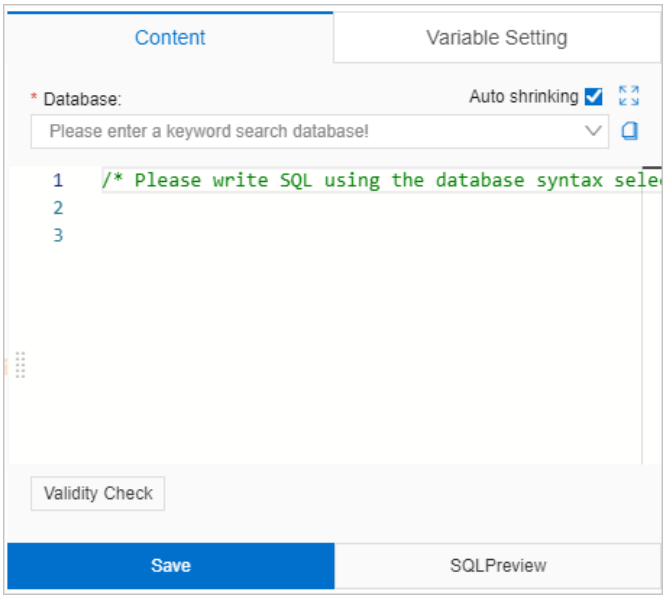
   i. In the left-side navigation pane of the Task Orchestration tab, find the new task flow and double-click the task flow name.

ii. On the Task Orchestration tab, drag a task node from the task node list to the canvas. On the canvas, you can create a directed acyclic graph (DAG) based on your business requirements.



iii. In the DAG, click the required task node.

iv. In the right-side pane, click a tab and set the required parameters.

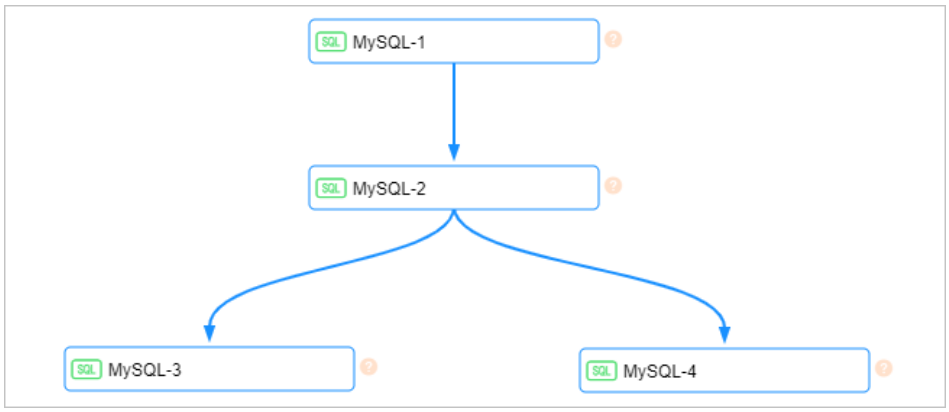


Tab	Parameter	Description

Tab	Parameter	Description
Metadata	Database	a. Select the database that you want to manage from the drop-down list. b. Enter the SQL statements to be executed in the field. c. Click **Save**. d. In the dialog box that appears, select **Existed table** or **New table** to store the query results. **Note** If you select **Existed table**, you must select a name for the required table from the drop-down list. If you select **New table**, you need to enter the name of a new table. e. Click **OK**.
Variable Setting	Variable Name	`bizdate` is the only default system variable. This variable indicates the day before the task is executed. The value of the bizdate variable is in the yyyy-MM-dd format. If the default system variable cannot meet your business requirements, you can create a custom variable and enter the variable name in the Variable Name field. **Note** To delete a variable that you set, click the icon.
	Variable Rule	To configure a variable rule, set the Time Format parameter. Then, set the required operator, integer value, and time unit, and click **Save**. To create more variables, you can click **Increase Variable**. **Note** After you configure a variable, you can reference the variable in the `${Variable name}` format in SQL statements on the **Content** tab. You can also click **SQLPreview** to check whether the variable is configured.

6. Configure node dependencies in the task flow.
   i. In the DAG, move the pointer over a task node and click and hold the circle, as shown in the following figure. Then, draw a line from the circle to the next node.

ii. Repeat the previous step to create dependencies between task nodes based on your business requirements. These dependencies indicate the execution order of each task.



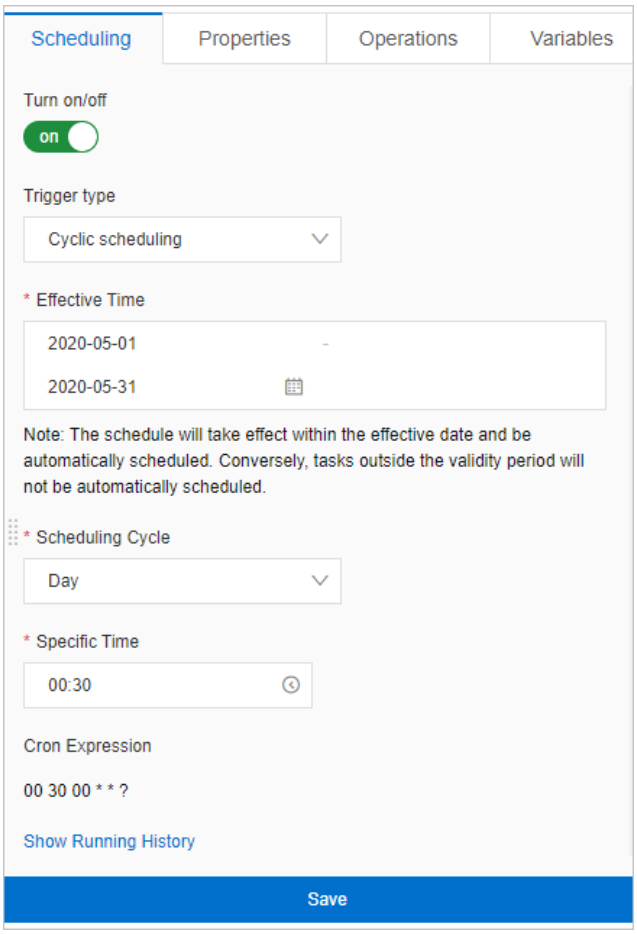
Note In the preceding figure, the MySQL-1 node is the first task to be execute and the MySQL-2 node is the second. After that, the MySQL-3 and MySQL-4 nodes are executed at the same time.

7. Specify scheduling information for the task flow.

i. Click the blank area on the canvas. In the right-side pane, click the **Scheduling** tab.

Note You can also click the **Properties** tab to configure the basic information of the task flow or click the **Operations** tab to view the historical operations that are performed on the task flow.

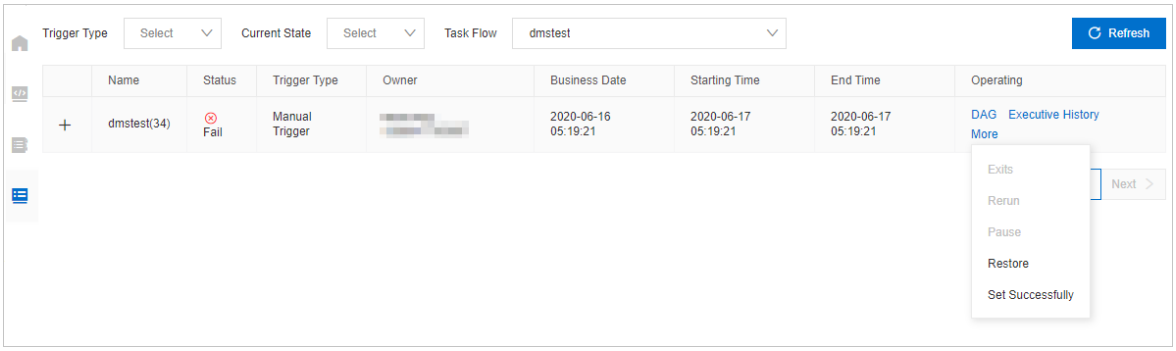
ii. Specify the scheduling information.



Parameter	Description
Turn on/off	Turn on the **Turn on/off** switch to enable scheduling.
Trigger type	Set this parameter based on your business requirements. ■ If you set this parameter to **Cyclic scheduling**, you must set the **Effective Time**, **Scheduling cycle**, and **Specific Time** parameters. ■ If you set this parameter to **Schedule once**, you need to set only the **Specific Time** parameter.

iii. Click **Save**.

8. After the preceding parameters are configured, click **Try Run** in the upper-left corner of the tab to check whether the task flow can be run as expected.
9. In the left-side navigation pane, click the icon, specify filter conditions, and then view the status of the task flow.



Note Click the icon next to the task flow name to view the status of each task.

You can perform the following operations on the task flow:

- **DAG**: View the DAG of the task flow.
- **Executive History**: View the details of the historical operations that are performed on the task flow.
- **More > Exits**: Stop a task flow that is in the running state.
- **More > Rerun**: Rerun a task flow that is executed or fails to be executed.
- **More > Pause**: Pause a task flow.
- **More > Restore**: Resume a paused task flow.
- **More > Set Successfully** : Set the status of a task flow that fails to be executed to Success.

15.8.2. Data warehouse development

15.8.2.1. Overview

Data Management (DMS) provides the data warehouse development feature. This feature uses databases as the computing engine and integrates a variety of tools and services in the database ecosystem. This allows you to develop and manage data warehouses with ease. This feature is designed to provide you with a one-stop development platform for data integration, processing, visualization, and value mining.

Benefits

- A variety of data warehouse engine types

  You can choose a data warehouse engine type based on your enterprise scale, data volume, and requirement for real-time performance. For example, you can choose AnalyticDB for MySQL or ApsaraDB RDS for MySQL as the data warehouse engine type.

- Two development modes

  The data warehouse development feature of DMS provides two development modes: task orchestration and professional development. The two modes meet different business requirements.

  - Task orchestration: This development mode allows you to develop a data warehouse by creating task flows and writing SQL scripts for task nodes. You do not need expertise in data warehouse development. You need only to focus on your business logic.
  - Professional development: This development mode meets the requirements of professional warehouse developers. It provides capabilities such as theme management, hierarchical management, production, release, multi-person collaboration, and data quality control. These capabilities empower professional warehouse development solutions for your enterprise.

    Note Some of the capabilities are planned to be supported soon.

- Support for offline and real-time data warehouses

  The data warehouse development feature supports offline data synchronization and task scheduling. This allows you to develop offline data warehouses with ease in DMS. In addition, DMS is integrated with Data Transmission Service (DTS) and cloud-native data warehouses. This allows you to build a real-time data warehouse system based on the real-time synchronization feature of DTS and cloud-native data warehouse engines. Then, you can develop data and consume data in real time in DMS.

- Unified management of online and offline data

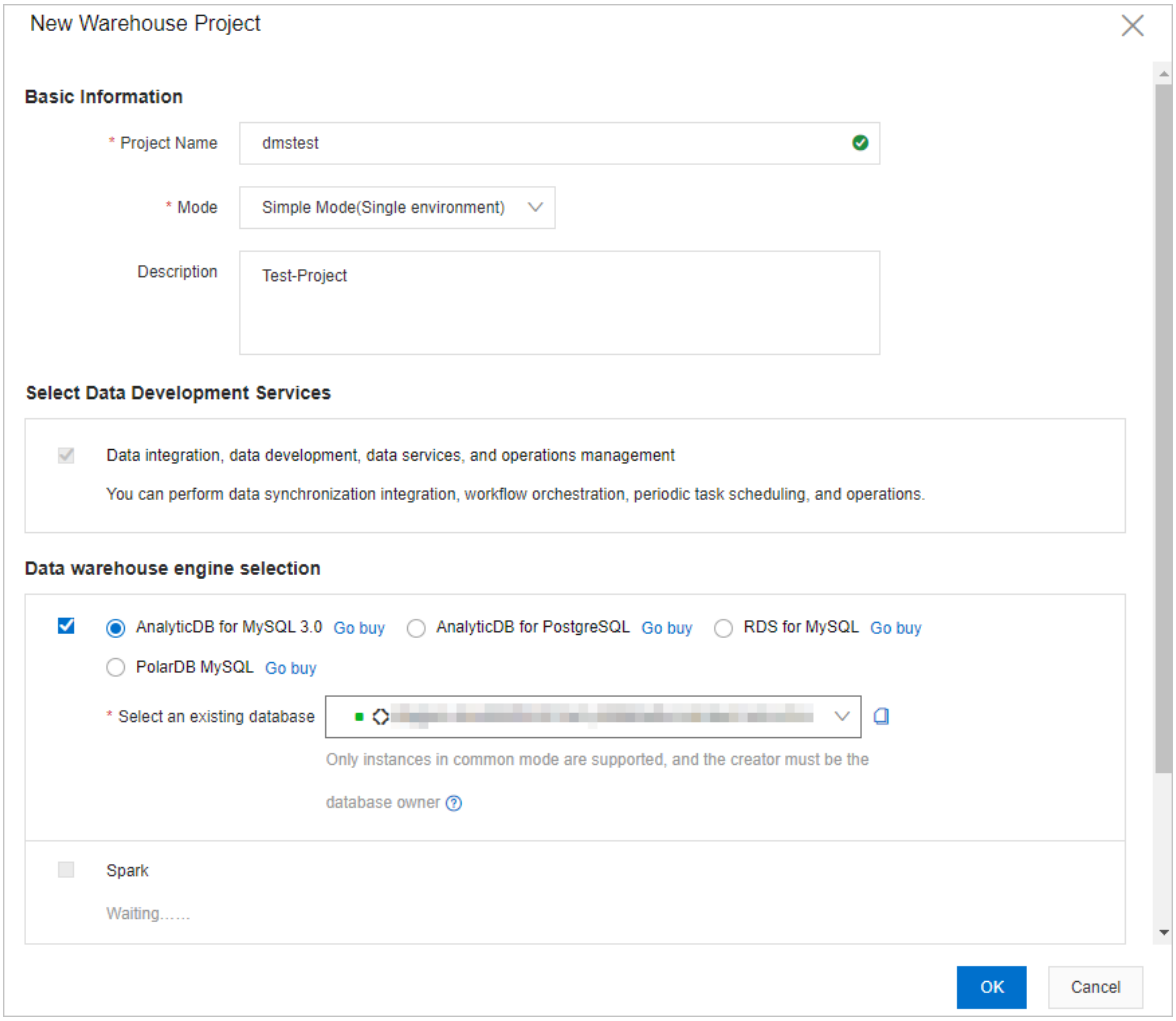
  DMS supports unified database management and permission management. You can manage your online transaction processing (OLTP) databases and online analytical processing (OLAP) databases in a centralized manner in DMS. This avoids security issues that are caused by the isolation between offline and online systems.

15.8.2.2. Create a data warehouse project

Before you can use the data warehouse development feature of Data Management (DMS), you must create a data warehouse project and select a data source for data warehouse development. This topic describes how to create a data warehouse project.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon and choose **Data Factory > Data Warehouse Development**.
3. On the left-side navigation submenu, click the  icon.
4. Click the  icon to the right of **Data warehouse**.
5. In the New Warehouse Project dialog box, set the parameters as required.



Section	Parameter	Description
Basic Information	**Project Name**	The name of the project. Specify a descriptive name for easy identification.
	Mode	The mode of the project. Set this parameter to **Simple Mode(Single environment)**. This way, you can use the same database in a development environment and a production environment.
	Description	The description of the project.
Select Data Development Services	N/A	DMS automatically completes the configuration in this section.
Data warehouse engine selection	Select a type of data warehouse engine.	After you select a data warehouse engine, such as **AnalyticDB for MySQL 3.0**, select a database from the **Select an existing database** drop-down list. **Note** Only the databases of the instances that are managed in Security Collaboration mode are available in the drop-down list. You must be the owner of the selected database.

6. Click **OK**.

What's next

Create or import an internal table

15.8.2.3. Create or import an internal table

After you create a data warehouse project in Data Management (DMS), you must create or import an internal table for the project. An internal table refers to a table that exists in the data warehouse engine. This topic describes how to create or import an internal table.

Prerequisites

You have the change permissions on the database for which you want to create or import an internal table. For information about how to apply for permissions, see Apply for permissions.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Factory > Data Warehouse Development**.
3. On the left-side navigation submenu, click the icon.
4. In the left-side navigation pane, expand a data warehouse project and then expand Warehouse table. Move the pointer over **Internal table** and then the More icon that appears. Then, select an option from the menu to perform one of the following operations.

   > **Note** You cannot configure external tables in DMS.

   
   - Create an internal table:
     a. Select **Add internal table**.
     b. On the tab that appears, enter an SQL statement to create a table.
     c. Click **Execute**.
   - Import an internal table:

     > **Note** The data warehouse development feature does not support real-time synchronization of tables that are created by using other means such as a command-line tool. You can import such tables to data warehouse projects in DMS.

     a. Select **Import internal tables**.

b. In the Import internal tables dialog box, select the table that you want to import from the **Choose table** drop-down list and enter a description in the Remarks field.
c. Click **OK**.

- Create a folder:

> **Note** If you have a large number of tables, you can use folders to organize and classify the tables.

a. Select **New folder**.
b. In the New folder dialog box, enter a folder name.
c. Click **OK**.

What's next

Manage task flows

15.8.2.4. Manage task flows

Data Management (DMS) supports task flows and timed scheduling. You can configure a variety of task nodes in task flows. This can meet your requirements for data archiving, integration, and processing.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Data Factory > Data Warehouse Development**.
3. On the left-side navigation submenu, click the icon.
4. In the left-side navigation pane, expand a data warehouse project. Move the pointer over **Task Flow** and then the

   icon that appears.
5. In the New Task Flow dialog box, enter a name and the description for the task flow.
6. Click **OK**.
7. On the tab that appears, configure task nodes for the task flow.

> **Note** The configurations of a task flow in professional development mode are basically the same as the configurations of a task flow in task orchestration mode. For more information, see Step 5 in the *Task orchestration* topic.

15.8.2.5. Use the data service feature

In Data Management (DMS), the data warehouse development feature is integrated with the data service feature. The data service feature allows you to export the data that is managed by DMS. This feature is applicable to scenarios in which you need to export data at the column or row level, visualize data, or perform complex analysis.

Limits

When you use the data service feature to create an API for a data warehouse, the data source of the API must be a table in the data warehouse project.

Procedure

1. Log on to the DMS console.

2. In the top navigation bar, choose **More > Data Factory > Data Warehouse Development**.

   > **Note** You can also choose **More > Data Factory > Data Service**.

3. On the left-side navigation submenu, click the icon.

4. In the left-side navigation pane, expand the required data warehouse project and double-click **Data Service**.

Configure an API

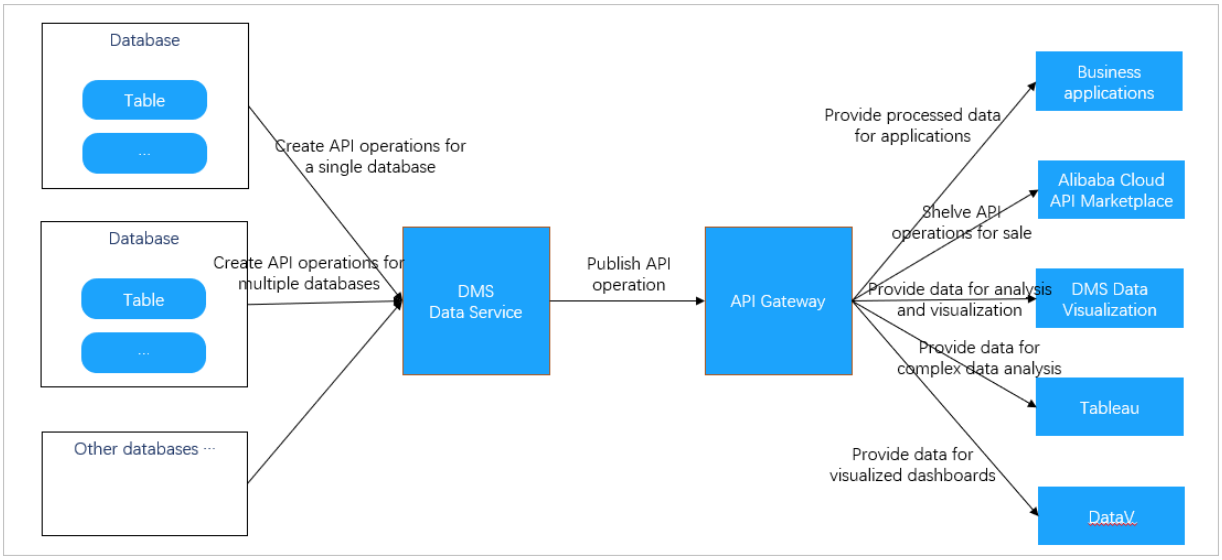
For information about how to configure an API, see Develop an API, Unpublish or test an API, Test an API, and Call an API.

15.8.3. Data service

15.8.3.1. Overview

Data Management (DMS) provides the data service feature, which allows you to export the data that is managed by DMS. This feature is applicable to scenarios where you need to export data at the column or row level, display data in a visualized manner, or perform complex analysis.

Features



- You can use the data service feature to create APIs that can be called to access the data that is managed by DMS. When you create the APIs, you can apply the security control features that are used for SQL execution in the SQLConsole, such as permission control and data de-identification.
- The data service feature works based on a serverless architecture. This feature frees you from the concern about the infrastructure of the runtime environment, such as servers and networks. You need to focus only on how to create APIs and design data query logic. This avoids operations and maintenance (O&M) overheads that are generated by using traditional architectures.
- The data service feature is fully integrated with API Gateway. You can use this feature to publish APIs to API Gateway. This way, you can use all the features that are provided by API Gateway, such as API permission control, IP address-based access control, throttling, metering and billing, and SDKs.

Scenarios

Scenario	Description
Minimize data exposure	Assume that you need to export the data that is managed by DMS to an external environment. In this case, APIs can be called to export the data of specific rows or columns to the external environment. To export the data of specific rows, specify a filter condition in the SQL statement. To export the data of specific columns, specify the columns in the SQL statement. Compared with data export of a whole table, this minimizes data exposure and ensures data security.
Connect visualization tools to databases	Most visualization tools can connect to databases by calling APIs. You can connect a visualization tool to your database by calling an API, instead of by using a username and a password. This method is easy to implement and avoids account exposure.
Sell APIs in the Alibaba Cloud Marketplace	If you want to provide paid or free data for other users, publish an API to the Alibaba Cloud Marketplace.
Provide processed data for applications	After data is processed and summarized by using the data warehouse development feature of DMS, APIs can be created and provided for applications to read the processed data from DMS to meet business needs. To modify the logic of data reading, you need only to modify the query logic of the required API without the need to republish the application.

15.8.3.2. Develop an API

The data service feature of Data Management (DMS) allows you to develop APIs with ease. This topic describes how to create and manage APIs.

Prerequisites

API Gateway is activated. For more information, see the documentation of *API Gateway*.

Context

The data service feature allows you to export the data that is managed by DMS. This feature is applicable to various scenarios. These scenarios include data export at the column or row level, data visualization, or complex data analysis. For more information, see Overview.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Data Factory > Data Service**.
3. In the left-side navigation pane, click the **API Development** tab.
4. On the APIManagement tab, click **New API** in the upper-right corner.
5. On the tab that appears, set the required parameters.

i. Set the required parameters on the AttributeConfiguration tab.

Parameter	Description
APIName	The name of the API. The name must be 4 to 100 characters in length, and can contain letters, digits, and underscores (_). The name must start with a letter.
Description	Optional. The description of the API. Enter an informative description, for example, a description of the data that you want the API to return or the scenarios in which the API can be called.
Path	The path of the API. The path must start with a forward slash (/) and can contain letters, digits, underscores (-), and hyphens (-). The specified path forms a part of the URL that is used to call the API. A URL that is used to call an API must be in the **https://{Domain name}{Path}** format. For example, if the domain name is **xxxx-cn-hangzhou.alicloudapi.com** and the path is **/item/monthly_data**, the URL that is used to call the API is **https://xxxx-cn-hangzhou.alicloudapi.com/item/monthly_data**.
ReturnFormat	The format in which you want the API to return data. Valid value: **JSON**.
RequestMode	The request method. Valid values: **POST** and **GET**.
TimeOut (MS)	The maximum period of time that the system can wait until an API request expires. Unit: milliseconds. If the execution time of an API exceeds the specified timeout period, the system returns a timeout error. Maximum value: 30000.
Returns the maximum number of records	The maximum number of entries that can be returned for an API request. This parameter limits the number of entries that can be returned for each API query. **Note** If the database instance is managed in security collaboration mode, the value of this parameter must be less than the maximum number of entries that is specified in the security rules.

ii. Click the **ExecuteConfiguration** tab and set the required parameters.

Parameter	Description
Instance query type	■ **Single InstanceQuery**: You can call the API to read data from only one database instance. ■ **Cross-instanceQuery**: You can write dynamic SQL statements for the API to query data across multiple database instances. **Note** If you set this parameter to **Cross-instanceQuery**, you need only to enter dynamic SQL statements in the **QuerySQL** field.
Data source	The database that is queried by the API. You can search for databases on which you have query permissions by keyword and then select a database.
ConfigurationMode	■ **Table boot mode**: You can configure data query by selecting a table and fields. ■ **Script mode**: You must configure a data query by specifying variables and writing SQL statements. **Note** After you set this parameter to **Script mode**, you need only to enter SQL statements in the **QuerySQL** field.
SelectTable	The table to be queried. You can search for tables by keyword.
FieldList	The fields in the selected table. You can specify the required fields as request parameters or response parameters.
Script mode	The mode in which an SQL script is written to define the data query logic. **Note** You can set the **ConfigurationMode** parameter to **Table boot mode** or Script mode.
QuerySQL	The SQL statement that is used to query the data in the table. After you enter an SQL statement, click **ParsingScript** to verify the syntax and to parse the request parameters and response parameters. **Note** ■ Custom variables are supported. Custom variables can be mapped as request parameters in API requests. The variables of an SQL statement must be specified in the `${Variable name}` format. For example, the `select item_id, item_name from ex_item where category=${category}` SQL statement include a variable named `category`. ■ If you set the **Instance query type** parameter to **Cross-instanceQuery**, you must use the syntax of cross-database query SQL statements. For more information, see Cross-database query.

iii. Click the **Request Parameters** tab and set the required parameters.

Parameter	Description
ParametersName	The name of the request parameter. ■ The name can contain letters, digits, hyphens (-), and underscores (_). ■ The name must start with a letter or an underscore (_). ■ The name must be 1 to 50 characters in length.
FieldName	The name of the field that is specified by the request parameter. The field name is specified on the **ExecuteConfiguration** tab and cannot be changed.
Cannot be empty	Specifies whether the request parameter is required.
Description	The description of the request parameter.
Data type	The data type of the request parameter. The data type is used to check whether the value of the request parameter in an API request is valid. Valid values: String, Integer, and Floating point. Default value: String. **Note** This parameter affects the SQL statement that is executed when the API is called.
Example value	The sample value of the request parameter. You can use the sample values that are provided in SDKs and documentation as references when you call API operations.
Default value	The default value of the request parameter. If the request parameter is optional and not specified in the API request, the default value is used.

iv. Click the **Return parameter** tab and set the required parameters.

Parameter	Description
ParametersName	The name of the response parameter. ■ The name can contain letters, digits, hyphens (-), and underscores (_). ■ The name must start with a letter or an underscore (_). ■ The name must be 1 to 50 characters in length.
FieldName	The name of the field that is returned. The name cannot be changed.
Description	The description of the response parameter.
Data type	The data type of the response parameter. Valid values: String, Integer, and Floating point. Default value: String. This parameter is used by DMS to convert the type of the data in API responses. This parameter affects the JSON data that is returned.
Example value	The sample value of the response parameter. You can use the sample values that are provided in SDKs and documentation as references to help you understand API responses.

6. Click **Save**.
7. In the left-side navigation pane, click the **API Development** tab.
8. Perform the following operations to manage the API based on your business requirements:

- Publish the API

  On the APIManagement tab, find the required API and click **Publish** in the **Operation** column of the API. In the message that appears, click **OK**.

- Modify the API

  On the APIManagement tab, find the required API and click **Modify** in the **Operation** column of the API. Modify the configurations of the API based on the descriptions in Step 5 and click **Save**.

- Delete the API:

  On the APIManagement tab, find the required API and click **Delete** in the **Operation** column of the API. In the message that appears, click **OK**.

15.8.3.3. Unpublish or test an API

This topic describes how to unpublish or test an API that has been published.

Prerequisites

An API is created. For more information, see Develop an API.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Data Factory > Data Service**.
3. Click the **API Publish** tab on the left side.
   The APIPublishList tab displays all the published APIs.
4. Find the API that you want to manage and perform the following operations based on your business requirements:
   - Unpublish the API:

     Click **Offline** in the **Operation** column. In the message that appears, click **OK**.

   - Test the API:

     Click **Test** in the **Operation** column. For more information, see Test an API.

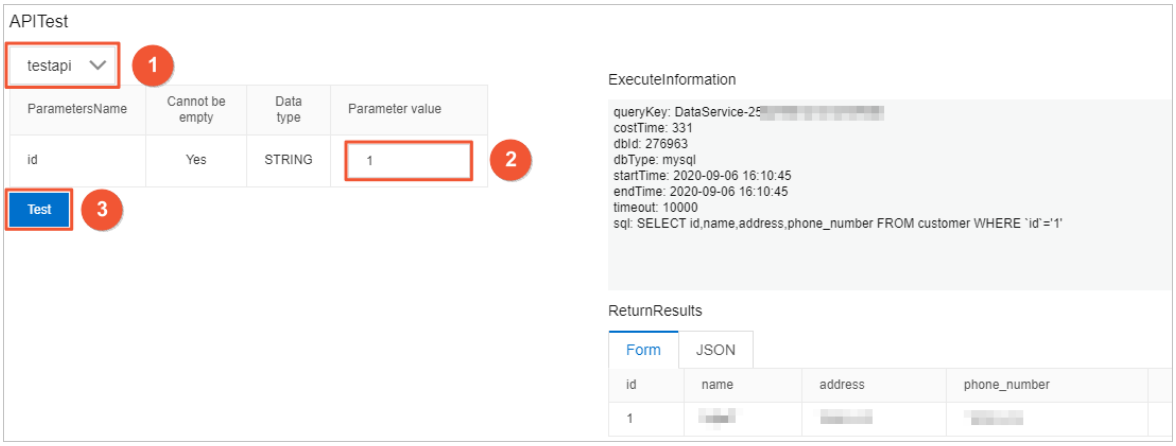
15.8.3.4. Test an API

After you create an API, you can test the API to verify whether the API meets your business requirements.

Prerequisites

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Data Factory > Data Service**.
3. Click the **API Test** tab on the left side.
4. On the APITest tab, test an API.



i. Select the API that you want to test from the drop-down list.

ii. Enter values in the Parameter value column.

iii. Click **Test**.
After the test is complete, the execution information and return results appear on the right side. You can evaluate whether the API meets your business requirements based on the information.

> **Note** You can click the **JSON** tab in the **ReturnResults** section so that the return results are displayed in the JSON format.

15.8.3.5. Call an API

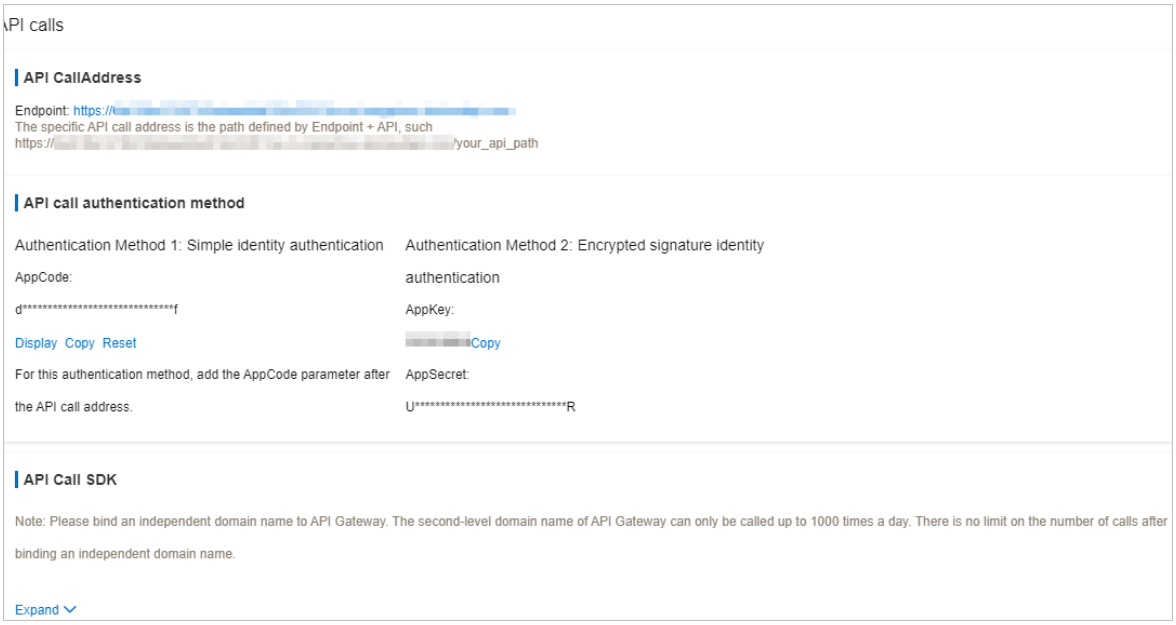
After you create, publish, and test an API, you can call the API in an application by using an SDK.

Prerequisites

- An API is created and published. For more information, see Develop an API.
- API Gateway is activated. For more information, see the documentation of *API Gateway*.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Data Factory > Data Service**.
3. Click the **API Call** tab on the left side.
4. View the API call address and the authentication information.



- **Simple identity authentication**: requires only an AppCode. This authentication method is suitable for calling APIs by using URLs. This authentication method has a low security level and is generally used in scenarios in which data visualization is involved, such as calling APIs in DataV.
- **Encrypted signature identity authentication**: requires an AppKey and an AppSecret, which are used to dynamically generate an encrypted signature for calling an API. This authentication method has a high security level.

5. Call the API in an application by using an SDK.

> **Note** For more information about how to call an API in an application by using an SDK, see the documentation of *API Gateway*.

15.9. Schemas

15.9.1. Schema design

Data Management (DMS) provides the schema design feature. This feature allows you to change schemas with ease. This topic describes how to change schemas.

Prerequisites

The destination database is a MySQL, a PolarDB-X, or an ApsaraDB for OceanBase database.

Context

When you create projects, process new business requirements, or optimize business operations, you may need to change schemas. These schema operations include creating and editing tables. For example, you may need to add or delete fields or indexes, adjust field attributes, or adjust the index composition. In these scenarios, you can use the schema design feature of DMS.

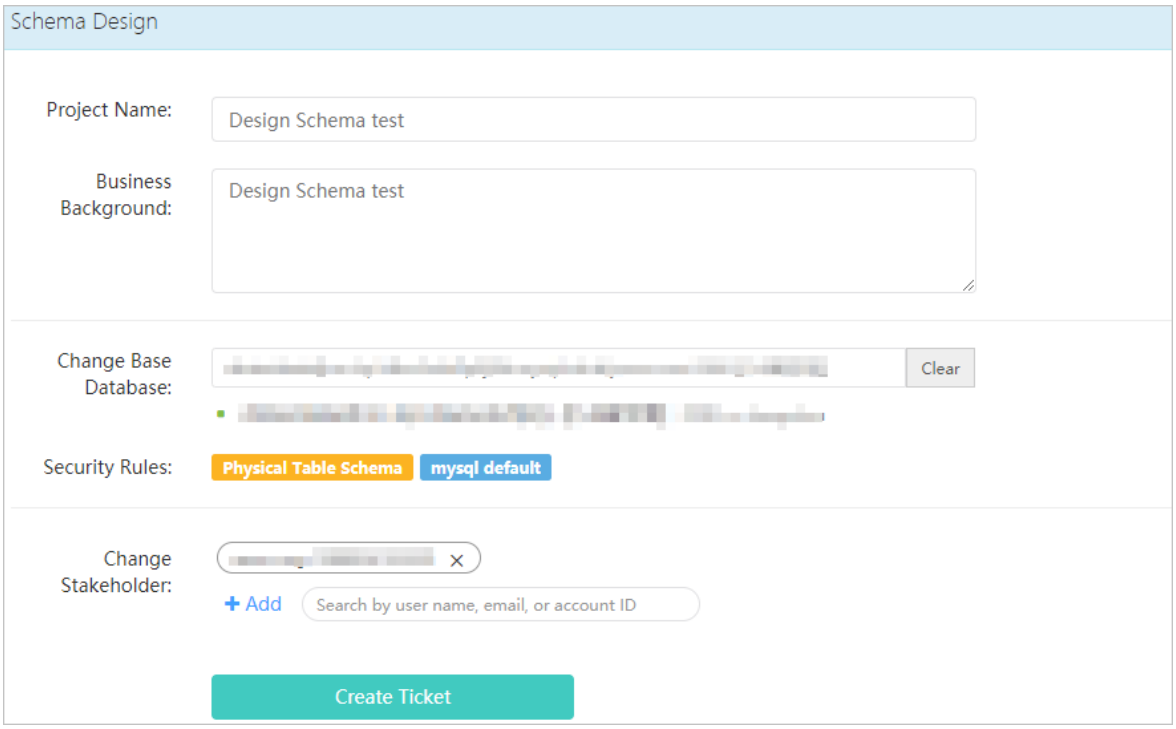
- This feature allows multiple users to simultaneously change a schema in the DMS console at the same time.
- This feature allows you to send verified scripts to other environments. This ensures consistency between schemas in different environments.

Precautions

When you submit a schema design ticket to delete a table, make sure that the table is created by using a schema design ticket.

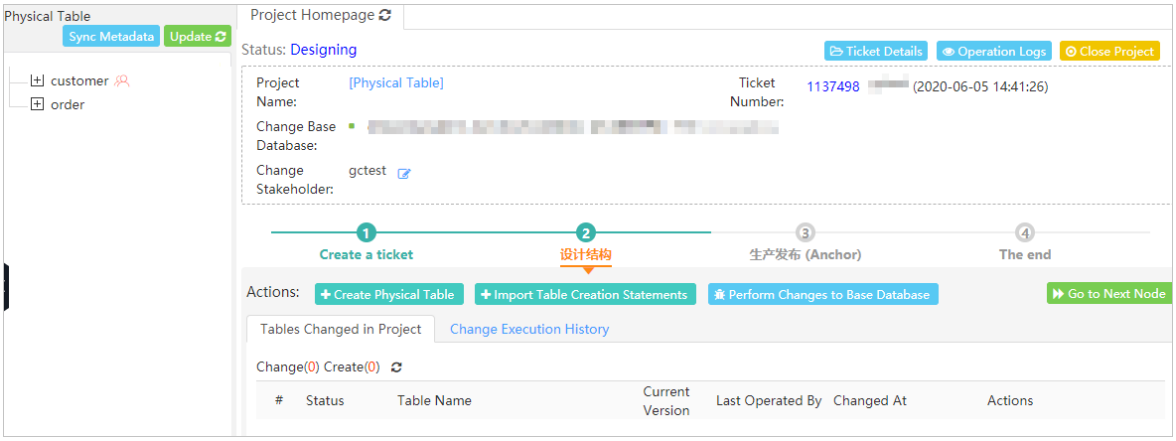
Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Schemas > Schema Design**.
3. In the upper-right corner of the Schema Design tab, click **Schema Design**.
4. On the Schema Design tab, specify the required parameters for a schema design ticket.



Parameter	Description
Project Name	The name of the project. Specify a name that can help you identify the project.
Project description	The background information about the project, such as the purpose or objective of the project. The description is used to reduce communication costs.
Change Base Database	The database whose schema you want to change. You can search for databases by keyword. Prefix match is applied. Only databases on which you have permissions in test or development environments are displayed. **Note** You must have at least the query, export, or change permissions on the database that you select.
Security Rules	No configurations are required. The default setting is specified.
Change Stakeholder	The stakeholders of the changes. The specified stakeholders can view the ticket details and are included in the approval process. Unauthorized users, except for administrators and database administrators (DBAs), cannot view the ticket details.

5. Click **Create Ticket**.
6. Change a schema based on your business requirements.



- Create a table:
  a. Click **Create Physical Table**.

     > **Note** If the destination database is a logical database, click **Create Logical Table**.

  b. On the Create Physical Table tab, set the required parameters. The parameters include the table name, character set, fields, and indexes.
  c. Click **Save**.

     > **Note** After you click Save, DMS verifies the specified information based on design specifications. If the information does not comply with the design specifications, a message appears.

  d. After the information passes the precheck, click **Confirm Changes and Submit to Save**.
- Change the schema of a table:
  a. In the left-side table list, right-click the name of the required table.
  b. On the menu that appears, select **Design Table**.
  c. Change the schema as required and click **Save**.

     > **Note** After you click Save, DMS verifies the specified information based on design specifications. If the information does not comply with the design specifications, a message appears.

  d. After the specified information passes the verification, click **Confirm Changes and Submit to Save**.

7. After the schema is changed, click **Perform Changes to Base Database**.
8. In the Perform Changes to Base Database dialog box, set the Execution Strategy parameter to **Execute Now** or **Schedule**.
9. Click **Submit for Execution** and wait until the ticket is approved.
10. After the ticket is approved, click **Go to Next Node**.

> **Note**
> - After the ticket is approved, DMS applies the changes at the specified point in time. If you do not specify the execution time, the changes are automatically applied after the ticket is approved at the last approval node. You can view the execution status and operation logs. After all changes are applied, you can repeat the preceding procedure to change the schema again. If no additional changes are required for the schema, click Go to Next Node.
> - After the ticket is submitted to the next node, whether you can go back to the previous node is subject to the predefined design specifications.

11. In the Go to Next Node message, click **Go to Next Node**.
12. On the Project Homepage tab, click **Perform Changes to Target Database**.
13. In the Perform Changes to Target Database dialog box, set the Target Database and Execution Strategy parameters and click **Submit for Execution**.

    > **Note** The required database must reside in a production environment.

14. Wait until the ticket is approved and the changes are applied.
15. Click **Go to Next Node**.
    The schema design process ends and the ticket is closed.

15.9.2. Schema synchronization

Data Management (DMS) provides the schema synchronization feature. You can use this feature to compare the schemas of two databases, generate a script to synchronize schemas, and then run the script on the destination database. This topic describes the schema synchronization feature and how to synchronize schemas.

Prerequisites

The source databases and destination databases are ApsaraDB for OceanBase or MySQL databases.

Precautions

- You cannot synchronize schemas to a destination database that resides in a production environment.
- The empty database initialization feature allows you to synchronize some or all tables from a physical or logical database.

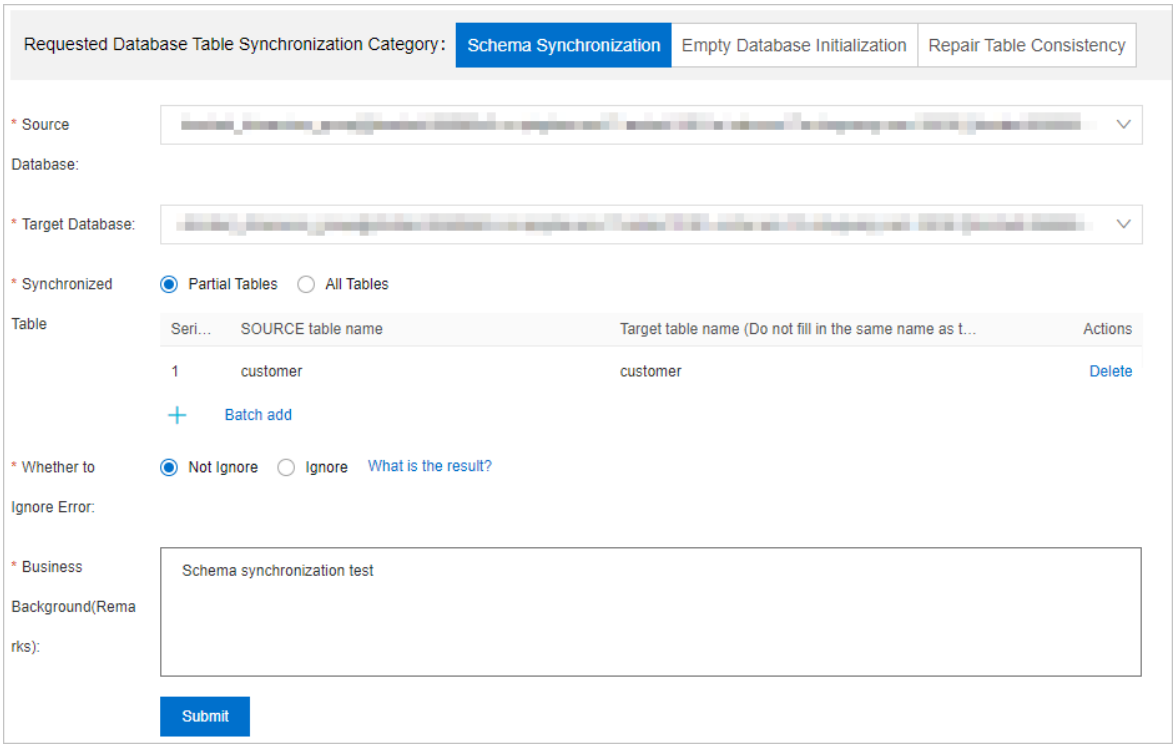
Scenarios

You can use the schema synchronization feature to synchronize schemas and ensure schema consistency in the following scenarios:

- Synchronize data between a database in a production environment and a database in a test environment.
- Synchronize data between different databases that are deployed in a test environment.
- Synchronize data between different databases that are deployed in a production environment.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Schemas > Schema Synchronization**.
3. Specify the required parameters for a schema synchronization ticket.



Parameter	Description
Source Database	The name of the source database from which you want to synchronize schemas. You must have the read permissions on the source database.
Target Database	The name of the destination database to which you want to synchronize schemas. You must have the change permissions on the destination database.
Synchronized Table	The tables that you want to synchronize. Valid values: ○ **Partial Tables**: Synchronize one or more tables in the source database. You can click **Batch Add** to add multiple tables. **Note** If you do not set this parameter, the names of the destination tables are the same as the names of the source tables. ○ **All Tables**: Synchronize all tables in the source database.
Whether to Ignore Error	○ **Not Ignore**: If an error occurs when SQL scripts are executed in serial mode, the system immediately stops executing the current and remaining SQL scripts. ○ **Ignore**: If an error occurs when SQL scripts are executed, DMS stops executing the current SQL script and continues to execute the next statement until all remaining SQL scripts are executed.

4. Click **Submit**. DMS starts to analyze the schemas.
5. Check the comparison results.

   Note If the schemas are changed when the system analyzes the schemas, click Re-analyze in the Schema Analysis step.

6. Verify the script that is used to synchronize schemas and click **Submit and Synchronize to Target Database**.

> **Note** If the schemas of the source database and destination database are the same, you do not need to submit the script, and the schema synchronization ticket is closed.

15.9.3. Synchronize shadow tables

Data Management (DMS) provides the shadow table synchronization feature to automatically create a shadow table based on the schema of a source table. DMS generates the name of the shadow table by attaching a prefix or suffix to the name of the source table. You can use this feature for end-to-end stress testing.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon and choose **Schemas > Shadow Table Synchronize**.
3. On the **Table/Database Synchronization Application** page, set the parameters that are described in the following table.

Parameter	Description
Source Database	The database whose data is to be synchronized.
Prefix / Suffix	The prefix or suffix that is used to create a shadow table name. The name can be in the **Prefix** + Source table name format or Source table name + **Suffix** format. You can use a custom prefix or suffix as needed. By default, the Prefix + Source table name format is used. Default shadow table name: `__test_Source table name` .
Synchronized Table	The tables whose schemas you want to synchronize. Valid values: ○ **Partial Tables** ○ **All Tables**
Synchronization Policy	The policy that is used for shadow table synchronization. Valid values: ○ **Synchronize Now**: DMS immediately synchronizes the tables after you submit the ticket. In this case, the tables are synchronized only once. ○ **Scheduled Synchronization**: DMS synchronizes the tables at the specified time on a regular basis. You can use a crontab expression to schedule synchronization based on your requirements. The minimum interval for synchronization is 1 hour. By default, the shadow tables start to be synchronized at 02:00 every day. For more information, see the Crontab expressions section of this topic.
Whether to Ignore Error	Specifies whether to skip errors that occur when SQL statements are being executed. Valid values: ○ **Not Ignore**: If an error occurs when SQL statements are being executed, DMS stops executing the current and subsequent SQL statements. ○ **Ignore**: If an error occurs when SQL statements are being executed, DMS skips the current SQL statement and continues to execute subsequent SQL statements until all remaining statements are executed.
Business Background(Remarks)	The business background of the project, such as the purposes and objectives of the project.

4. Click **Submit**. DMS starts to analyze the schemas.
5. Check the comparison results.

> **Note** If the schemas are changed when the system analyzes the schemas, click Re-analyze in the Schema Analysis step.

6. Verify the script that is used to synchronize schemas and click **Submit and Synchronize to Target Database**.

> **Note** If the schemas of the source database and destination database are the same, you do not need to submit the script, and the schema synchronization ticket is closed.

Crontab expressions

If you need to schedule the synchronization task to be run in a more precise manner, you can use a crontab expression. The interval for running the task can be specified by using a combination of minutes, hours, days, weeks, or months.

A crontab expression consists of five fields of the NUMERIC type. Valid values of each field:

- **Minutes**: `0 to 59`.
- **Hours**: `0 to 23`. A value of 0 indicates the midnight.
- **Days**: `1 to 31`. A value of this field indicates a specific day of a month.
- **Months**: `1 to 12`. A value of 1 indicates January, and a value of 2 indicates February. Similarly, the specific month that is indicated by a specific value can be obtained.
- **Weeks**: `1 to 7`. A value of 1 indicates Sunday, and a value of 2 indicates Monday. In other words, the seven week days from Sunday to Saturday are indicated by values 1 to 7.

Usage notes

- Specify the time for running a stress testing task by the day or week. You cannot specify the day and week at the same time. After you specify one of the preceding two values, you must set the other value to `?`. A value of ? indicates an unspecified value. For example, if you schedule the task to be run on the first and second days of each month, the **Weeks** field must be set to `?`.
- Limit the characters in a crontab expression to English special characters. The special characters can be wildcards such as asterisks (*) and question marks (?).
- Separate multiple values with commas (,).
- Use a hyphen (-) to indicate a value range. For example, if you set the **Days** field to `1-5`, the task is scheduled to be run on the first to fifth days of a month.
- Use a forward slash (/) to indicate an interval for running the task. For example, if you set the Days field to `*/2`, the task is scheduled to be run every two days.

Crontab expression examples

- To schedule the task to be run at 23:00 every Saturday and Sunday, use the following crontab expression: 0 23 ? * 7,1.
- To schedule the task to be run at 09:30 on the fifth, fifteenth, and twenty-fifth days of each month, use the following crontab expression: 30 9 5,15,25 * ?.
- To schedule the task to be run at 00:00 every two days, use the following crontab expression: 0 0 */2 * ?.

15.9.4. Initialize empty databases

DMS provides the empty database initialization feature. This feature allows you to compare the schemas of two databases, generate a script that is used to synchronize data from the source database to the destination database, and run the script on the destination database. To use this feature, the destination databases must be empty. This topic describes how to initialize empty databases.

Prerequisites

- The source databases and destination databases are MySQL or ApsaraDB for OceanBase databases.
- The destination databases are empty databases that do not contain tables.

Features

The empty database initialization feature allows you to synchronize some or all tables from a physical or logical database.

Scenario

Synchronize data between databases that are deployed in different regions or units. For example, this feature is applicable to the following scenarios:

- Synchronize data between a database that is deployed in a production environment and a database that is deployed in a test environment.
- Synchronize data between different databases that are deployed in the test environment.
- Synchronize data between different databases that are deployed in the production environment.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Schemas > Empty Database Initialization**.
3. On the Table/Database Synchronization Application tab, set the required parameters to create an empty database initialization ticket.

Parameter	Description
Source Database	The name of the source database from which data is synchronized. You must have the read permissions on the source database.
Target Database	The name of the destination database to which data is synchronized. You must have the write permissions on the destination database. **Note** The type of the destination database must be the same as the type of the source database.
Initialized Table	The tables that you want to synchronize. Valid values: ○ **Partial Tables**: Synchronize one or more tables in the source database. To add a table, click the **+** icon and specify a name for the source table. **Note** ■ You can also click **Batch Add**. In the Batch Add dialog box, select the required tables and click **Batch Add**. ■ If you do not set this parameter, the names of the destination tables are the same as the names of the source tables. ○ **All Tables**: Synchronize all tables in the source database.
Whether to Ignore Error	○ **Not Ignore**: If an error occurs when an SQL script is being executed in serial mode, the system immediately stops executing the current and remaining SQL scripts. ○ **Ignore**: If an error occurs when an SQL script is being executed, DMS stops executing the current SQL script and continue to execute the next statement until all remaining SQL scripts are executed.

4. Click **Submit**. DMS starts to analyze the schemas.

5. Check the comparison results.

   > **Note** If the schemas are changed when the system analyzes the schemas, click Re-analyze in the Schema Analysis step.

6. Verify the script that is used to synchronize schemas and click **Submit and Synchronize to Target Database**.

   > **Note** If the schemas of the source database and destination database are the same, you do not need to submit the script, and the schema synchronization ticket is closed.

15.9.5. Repair table consistency

DMS provides the table consistency repairing feature. This feature is used to compare schemas between tables in databases that are deployed in different environments, provides an efficient way to identify schema differences, and execute SQL statements that are specific to the required environment. This ensures schema consistency between different environments.

Prerequisites

The source databases and destination databases are MySQL or ApsaraDB for OceanBase databases.

Scenarios

- Ensure the schema consistency between physical tables that are deployed in the test environment and the production environment.
- Ensure the schema consistency between physical tables and logical tables in a physical database or a logical database.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > Schemas > Table Consistency Repairing**.
3. On the Table/Database Synchronization Application tab, set the required parameters to create a Repair Table Consistency ticket.

Parameter	Description
Base Database(Physical Database)	The source database based on which schema consistency is to be repaired. You must have the query permissions on the source database.
Target Database	The destination database whose data is to be modified. You must have the change permissions on the destination database.
Repaired Table	The tables between which schema consistency is to be repaired. To add tables, click the + icon and specify the required table names. **Note** If you do not specify the destination table name, the system names the destination table after the name of the specified source table.

Parameter	Description
Whether to Ignore Error	○ **Not Ignore**: If an error occurs when SQL statements are being executed in serial mode, the system immediately stops executing the current and remaining SQL statements. ○ **Ignore**: If an error occurs when DMS is executing an SQL statement, DMS stops executing the current SQL statement and continues to execute the remaining SQL statement.
Business Background	The business background of the ticket. This parameter reduces communication costs.

4. Click **Submit**. DMS starts to analyze the schemas.
5. Check the comparison results.

   > **Note** If the schemas are changed when the system analyzes the schemas, click Re-analyze in the Schema Analysis step.

6. Verify the script that is used to synchronize schemas and click **Submit and Synchronize to Target Database**.

   > **Note** If the schemas of the source database and destination database are the same, you do not need to submit the script, and the schema synchronization ticket is closed.

15.10. SQL review

DMS provides the SQL review feature to help you prevent SQL statements that do not use indexes or do not conform to database development standards. This reduces the risk of SQL injection attacks.

Prerequisites

The environment type of the database instance in which you want to use the SQL review feature is **Test** in the DMS console. This is because SQL review is performed before DMS publishes SQL statements to an online environment.

Context

When you develop a project, you need to execute SQL statements on databases to add, delete, modify, and query data so that you can implement business logic and display data. Before the project is published, you must review all SQL statements that are used. This prevents SQL statements that do not conform to database development standards from being published to an online environment and accordingly impeding the business.

If DBAs manually review all SQL statements one by one, excessive human resources are consumed and the R&D efficiency is low. The SQL review feature helps you review SQL statements and also provides optimization suggestions.

Usage notes

- Only XML or TXT files can be uploaded.
- Tables that are involved in SQL statements must exist in the database that you select. Otherwise, DMS cannot review these SQL statements.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **Optimization > SQL Review**.
3. On the tab that appears, click **New** in the upper-right corner.

4. Configure information about an SQL review ticket.

Parameter	Description
Project name	Enter a project name based on your business requirements so that the ticket can be distinguished from others in subsequent processing.
Data source	Select the database in the test environment that is used in your project. You must have the change permission on the database.
Business Description	Enter detailed information about the business scope of the project as required to help relevant users know about the project.
Relevant personnel	Enter an at sign (@) and select a user. **Note** You can repeat this operation to select multiple users.
Upload a file	Click **Add**, select files, and then click **Upload**. **Note** ○ The iBATIS and MyBatis files are in the XML format. ○ SQL statements are saved as TXT files. Multiple SQL statements are separated by semicolons (;). ○ To remove an added file, you can select the check box before the file name and click **Delete**.

5. Click **Submit application**.
6. View SQL review results.

Note
- If SQL statements in a file conform to database development standards and use indexes, DMS determines that these SQL statements pass the SQL review and offers no suggestion about indexes.
- If SQL statements in a file conform to database development standards but do not use indexes, DMS determines that these SQL statements pass the SQL review and offers suggestions about indexes.
- If SQL statements in a file do not conform to database development standards, DMS determines that these SQL statements fail the SQL review.

7. Find a failed SQL review result and click **View reason** to check the reason. You can also click **Details**, **Adjust SQL**, or **More** in the **Operation** column to perform other operations.

Note After you optimize SQL statements in a file and click **Confirm**, DMS reviews the SQL statements again. For dynamic SQL statements in XML files, you must optimize each SQL statement combination.

8. When all SQL statements pass the SQL review, click **Inspection results**.
9. In the dialog box that appears, click **Submit for approval** and wait for approval.

> **Note** The approval process of the ticket is based on the security rules that are configured for the current database instance.

15.11. System management

15.11.1. Manage instances

Data Management (DMS) allows you to manage database instances. For example, you can export the information about instance configurations.

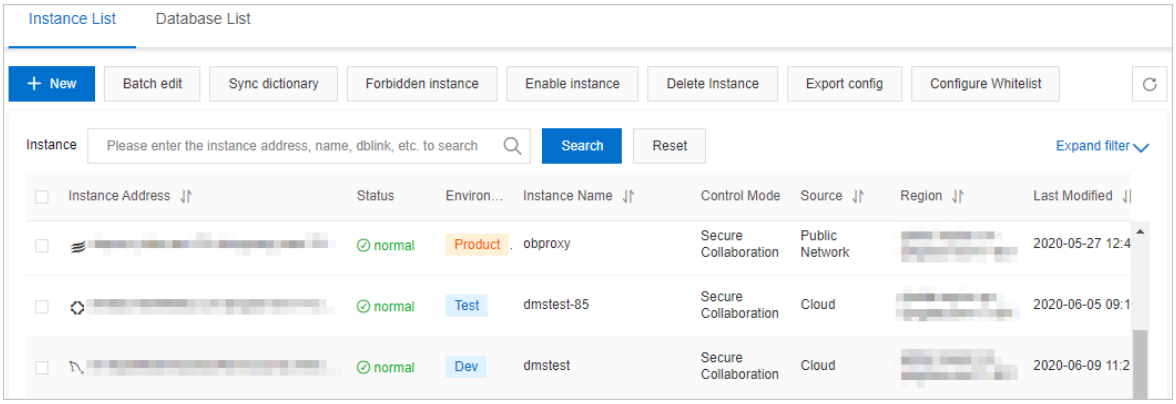
Prerequisites

You are a database administrator (DBA) or a DMS administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon and choose **System > Instance**.
3. On the **Instance List** tab, select one or more database instances that you want to manage. Then, you can perform the following operations based on your business requirements:

> **Note** You can click **Expand filter** to show more filter conditions.



- Add an instance

  Click **New** and register a database instance with DMS. For more information, see Register database instances with DMS.

- Edit multiple instances at a time

  Click **Batch edit**. In the dialog box that appears, modify the instance information and click **OK**.

  > **Note** The database instances that you select must be of the same database type, such as MySQL.

- Synchronize the data dictionary

  Click **Sync dictionary**. In the message that appears, click **OK**.

> **Note**
> - If you change schemas for a database instance by using DMS, DMS automatically synchronizes the data dictionary of the instance.
> - If you change schemas for a database instance by using a service other than DMS, you must manually synchronize the data dictionary of the instance.

- Disable or enable one or more instances

  Click **Forbidden instance** or **Enable instance**. In the message that appears, click **OK**.

  > **Note**
  > - After you disable a database instance, the instance is removed from the left-side instance list. DMS users can no longer find databases or tables in this instance in the DMS console.
  > - After you enable a database instance, the instance appears in the left-side instance list. Databases in this instance become available. Relevant permissions that have been granted to DMS users on this instance also become valid.

- Remove one or more instances

  Click **Delete Instance**. In the message that appears, click **OK**. After you remove a database instance, the instance is removed from the left-side instance list. DMS users can no longer use databases in this instance in the DMS console. Relevant permissions that have been granted to DMS users on this instance also become invalid and are revoked.

  > **Note** On the **Instance List** tab, you can find database instances in the Delete state and enable these instances to recover them.

- Export configuration information

  Click **Export config**. The browser automatically downloads a CSV file named *instances*. You can use Excel or a text editor to view this file.

- Configure a whitelist

  Click **Configure Whitelist**. In the message that appears, click **OK**. The IP addresses of DMS servers are automatically added to the whitelists of the specified database instances.

  > **Note** The destination database instances must be ApsaraDB instances.

- Other operations

  You can find a database instance and click Details in the Actions column to view the details about databases and tables in this instance. You can also move the pointer over More and perform other operations. For example, you can log on to the instance or edit the instance.

15.11.2. Database management

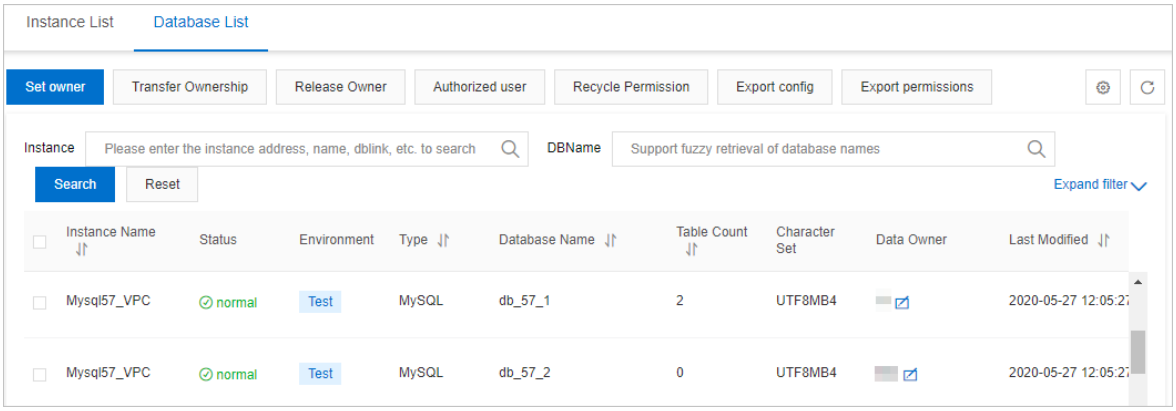
On the Database List tab, you can manage databases. For example, you can specify the database owner, transfer the ownership, revoke the owner permission, grant and revoke user permissions, and export the information about database configurations or permissions.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon and choose **System > Instance**.
3. In the top navigation bar, choose **System > Instance**.

4. Click the **Database List** tab.
5. Set filter conditions and select one or more databases that you want to manage. Then, you can perform the following operations based on your business requirements:

> **Note** You can click **Expand filter** to show more filter conditions.



- Specify an owner

  Specify an owner for the selected databases. You can specify multiple owners for multiple databases at a time.

- Transfer the ownership

  Transfer the ownership of the selected databases to a user. If you transfer the ownership of multiple databases at a time, you can select only a user that assumes the ownership of all of the databases as the original owner.

- Revoke owner permissions

  Revoke the owner permission from the owners of the selected databases.

- Grant permissions

  Grant the query, export, or change permission on the selected databases to one or more users. You can also specify an expiration time for the permission.

- Revoke permissions

  Revoke the query, export, or change permission on the selected databases from one or more users. If a user does not have the related permissions, the following message appears: **No corresponding permissions. You do not need to recycle or release permissions** .

- Export configurations

  Export the configurations of the selected databases to an Excel file. The configurations include the instance status, environment, DBA, and owner.

- Export permission information

  Export the permission information about the selected databases to an Excel file. The permission information includes the database information, users, permissions, and users who grant the permissions.

- Other operations

  You can click Tables in the Actions column of a database to view the details about tables in the database. You can also move the pointer over More and select the required operation that you want to perform. For example, you can query data in the database, manage permissions, view the details about the instance to which the database belongs, and find the instance on the Instance List tab.

15.11.3. Manage users

Data Management (DMS) allows you to manage users. For example, you can manage user permissions and roles.

Prerequisites

You are a DMS administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon and choose **System > User**.
3. Select the user that you want to manage. Then, you can perform the following operations based on your business requirements:
   - Add a user

     Click **New** and set parameters to add a user. For more information, see Add a user.
   - Edit a user

     Click **Change** in the **Actions** column. In the dialog box that appears, modify the user configurations and click **Confirm Change**.
   - Disable or enable a user

     Move the pointer over **More** in the **Actions** column and select **Disable** or **Enable**.
   - Remove a user

     Move the pointer over **More** in the **Actions** column and select **Delete**. In the message that appears, click **OK**.
   - Grant permissions

     Move the pointer over **Authorize** in the **Actions** column and select the object on which you want to grant permissions to the user. For example, you can select **Authorize instance**, **Authorize database**, **Authorize table**, **Authorize Line**, or **Authorize sensitive column**. In the dialog box that appears, enter a keyword to filter objects, set the Permission and Expire Date parameters, and then click **OK**.
   - Release permissions

     Move the pointer over **More** in the **Actions** column and select **Permission Details**. You can set conditions to filter the permissions that are granted to the user, select the permission type that you want to manage, and then click **Release Permission** to release the permissions.

15.11.4. Enable metadata access control

Data Management (DMS) provides the metadata access control feature. You can use this feature to allow users to view the information about and access a database or database instance on which they have permissions. Before this feature is enabled, regular users can query all databases and database instances within the current tenant account. After this feature is enabled, you can allow specific users to view the information about and access the databases or database instances on which they have permissions. This further enhances the data security of your enterprise.

Background information

As a centralized data management service, DMS provides different roles that are assigned different permissions. This helps you manage data in your enterprise in a secure manner. After you enable metadata access control for a database instance or database, only users who have permissions on the instance or database can view the information about and access the instance or database. This way, users can view the information about and access only databases on which they have permissions. This further enhances data security.

> **Note** In DMS, permissions on a database include the query, export, and change permissions. If you have one of these permissions on a database, you can view the following information about the database:
>
> - Information about the database. You can search for the database in the search box in the upper part of the left-side navigation pane or in the top navigation bar of the DMS console. Alternatively, you can search for the database in the search box of the Select the databases, tables, or columns on which you want to apply for permissions field on the Permission Application Ticket page. Whether you can query the data in the database depends on whether you have the query permissions on the database.
> - Information about the instance to which the database belongs. Whether you can view the information about other databases in this instance depends on whether you have permissions on the other databases.

You can enable metadata control access for the following objects:

- A user: The user can view the information about and access only databases on which the user has permissions.
- A database: Only users who have permissions on the database can view the information about and access the database.
- A database instance: Only users who have permissions on the database instance can view the information about and access the database instance. If a user has permissions on a database in this database instance, the user can view the information about and access this database.

Enable metadata access control for a user

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon and choose **System > User**.

   > **Note** You are a DMS administrator.

3. Find the user for whom you want to enable metadata access control, move the pointer over **More** in the **Actions** column, and then select **Access control**.
4. In the User access control dialog box, turn on **Metadata access control** and click **OK**.

Enable metadata access control for a database instance

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon and choose **System > Instance**.

   > **Note** You are a database administrator (DBA) or a DMS administrator.

3. On the **Instance List** tab, find the instance for which you want to enable metadata access control. Then, select the instance and click **Access control** in the upper part of this tab.

   > **Note** You can also enable metadata access control for multiple instances at a time. Select multiple instances and click **Access control** in the upper part of this tab.

4. In the dialog box that appears, turn on **Metadata access control** and click **OK**.

Enable metadata access control for a database

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon and choose **System > Instance**.

   > **Note** You are a DBA or a DMS administrator.

3. On the **Database List** tab, find the database for which you want to enable metadata access control. Move

the pointer over **More** in the **Actions** column and select **Access control**.

> **Note** You can also enable metadata access control for multiple databases at a time. Select multiple databases and click **Access control** in the upper part of this tab.

4. In the dialog box that appears, turn on **Metadata access control** and click **OK**.

15.11.5. Manage tasks

The task management feature allows you to manage various tasks that are created by using tickets. You can also use this feature to directly create or manage tasks.

Prerequisites

You are a database administrator (DBA) or an administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > System > Task**.
3. On the **Task** tab, view and manage tasks that are created by using tickets.
4. Find a task and perform one of the following operations based on your business requirements: For example, you can **pause**, **retry**, or**delete** a task.
   - Pause a task

     Click **Pause** to pause a task.
   - Retry a task

     If a task is in the **Failure** state, click **Retry** to run the task again.
   - Delete a task

     Click **Delete** to delete a task. After a task is deleted, the status of the task changes to **Delete** and the task cannot be run.
   - Create a task

     Click **Add SQL task**. In the Add SQL task dialog box, enter the task description, the database that you want to manage, and the SQL statements that you want to execute. Then, click **Submit Task**.

15.11.6. Configuration management

DMS allows you to manage system configurations. To implement flexible management, you must log on to the DMS console as an administrator to modify the required system configurations.

Prerequisites

An administrator account is required to perform the operation.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > System > Configuration**.
3. Find the required parameter and click **Change** in the **Actions** column of the parameter.

> **Note** You can click **Change History** to view the change history of the parameter.

4. In the Change Parameter Configuration dialog box, enter the required value.

5. Click **Confirm Change**.

Types of data changes

key	value	Description
config_correct	Modify Config	Modifies configurations.
project_init_data	Init Project Data	Initializes the data for a project.
program_bug	Program Bug	Fixes a bug.
require_deal_without_backend_function	Requirements Without Backend Function	Manages the data of an application that does not support backend management.
history_data_clear	History Data Clean	Clears historical data.
test	Test	Runs a test.
mis_operation	Mis Operation	Restores data after a misoperation.
others	Others	Changes data for other reasons.

15.11.7. Database grouping

This topic describes how to create a database group in Data Management (DMS). You can use this feature to apply a data change or a schema change to all of the databases in a database group with ease.

Prerequisites

The databases that you want to add to a database group meet the following conditions:

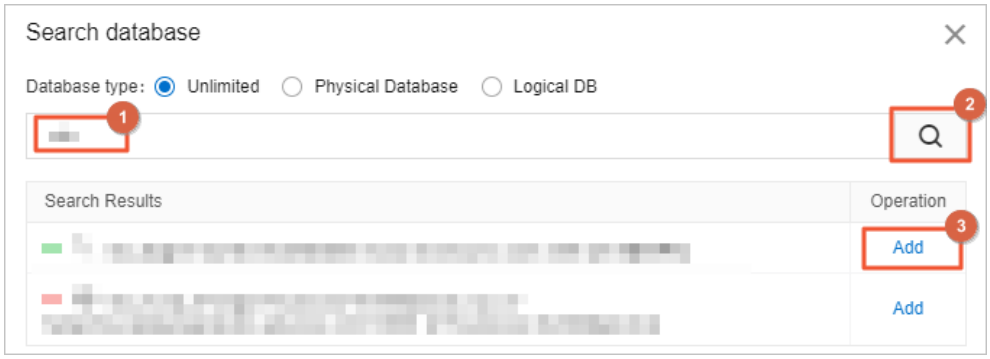
- All of the instances to which the databases belong are managed in Security Collaboration mode.
- All of the databases are physical databases or logical databases.
- All of the databases are deployed in the same environment, such as the development environment.
- The engines of the databases are of the same type. For example, all of the databases are MySQL databases.

Create a database group

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon and choose **System > Database grouping**.
3. Click **New Group**.
4. In the **NewGrouping** dialog box, perform the following steps:
   i. Enter a group name in the **Group name** field.
   ii. Set the **Grouping type** parameter to **General grouping**.

> **Note** You cannot set this parameter to **Remote live**. This feature will be available soon.

iii. Click **Add database**. In the **Search database** dialog box, enter a prefix in the search box to search for databases. Select one or more databases to be grouped from the matched results and click **Add** in the Operation column.



iv. After you add all the databases to be grouped, click the icon in the upper-right corner to close the Search database dialog box.

5. After you complete the configurations, click **Save**.

Scenarios

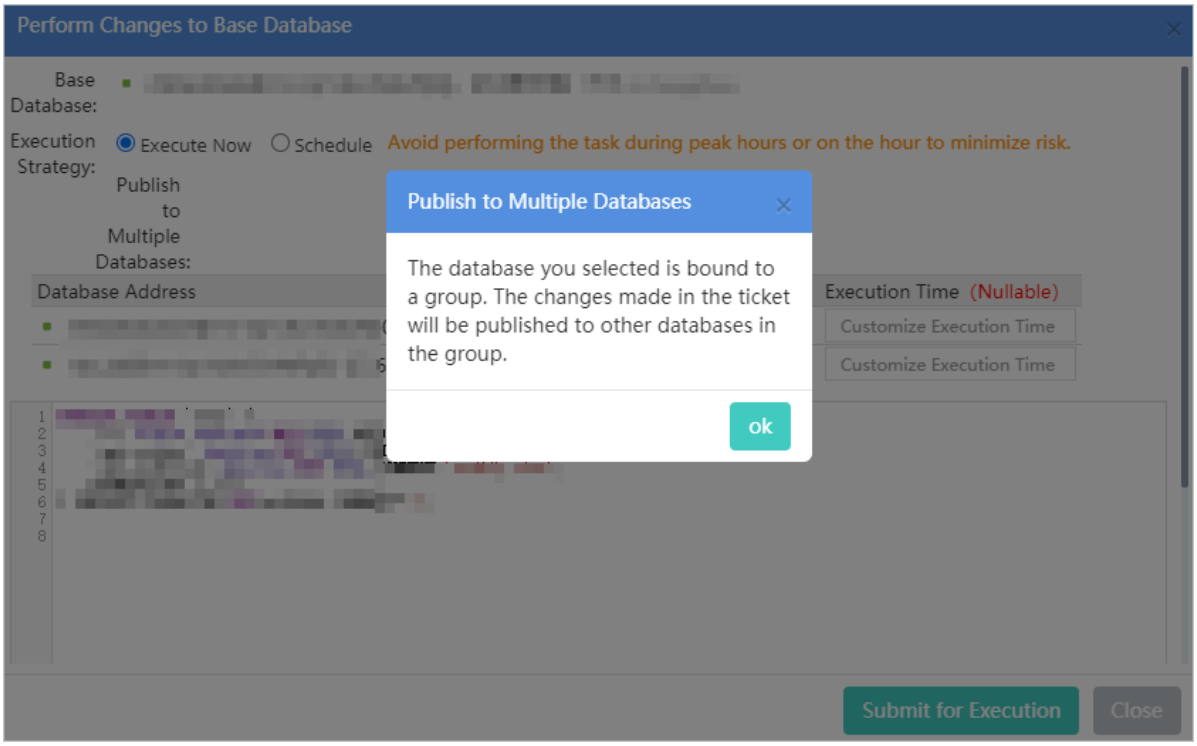
- Data change

  For example, you want to create a ticket to perform a data change on a database, and the database belongs to a database group. After you select the database, DMS displays a message to remind you that the selected database belongs to a database group. If you click **OK**, DMS adds all the other databases in the group as the databases on which the data change will be performed. This saves your effort in selecting databases one by one. If you click **Cancel**, the other databases in the group will not be selected. The following figure shows the message.

  This feature applies to the data change and data import tickets that are supported by DMS. For more information about how to create a ticket, see Change data and Import data.

- Schema design

For example, you want to create a schema design ticket and select a database that belongs to a database group as a base database. After you click **Perform Changes to Base Database**, DMS displays a message. This message is used to remind you that the base database belongs to a database group and the current operation will apply to all the other databases in the group. The following figure shows the message.



For more information about how to use the schema design feature, see Design a schema.

15.11.8. Security management

15.11.8.1. Manage security rules

Security rules are implemented by using a collection of domain-specific languages (DSLs) to control user access to databases based on several factors. These factors include the type of databases, the syntax of database operations, and the number of affected rows. You can use security rules to standardize database operations, development processes, and approval processes as required. This topic describes how to manage security rules.

Prerequisites

You are a database administrator (DBA) or an administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > System > Security Rules**.
3. Perform one of the following operations based on your business requirements:
   - Create a rule set

     Click **Create Rule Set**. In the Create Rule Set dialog box, set the Engine Type, Rule Set Name, and Remarks parameters, and click **Submit**.
   - Edit a rule set
     a. Find the required rule set and click **Edit** in the **Actions** column of the rule set.

b. In the left-side pane, click the required rule subset, for example, **SQLConsole**. In the right-side pane, select a checkpoint.
c. Find the required rule and click **Edit** next to the rule. For more information about the related syntax, see DSL syntax for security rules.

> **Note** You can disable or delete a rule.

- Create a similar rule set
  a. Find the required rule set and click **Create As** in the **Actions** column of the rule set.
  b. In the dialog box that appears, enter a name and a description for the new rule set.
  c. Click **Submit**. The system copies the configurations of the original rule set to the new rule set.
- Delete a rule set

  Find the required rule set and click **Delete** in the **Actions** column of the rule set. In the message that appears, click **OK**.

  > **Note**
  > - A deleted rule set cannot be recovered. Proceed with caution.
  > - You can delete only custom rule sets. You cannot delete built-in rule sets.
- Set a rule set as the default rule set

  Find the required rule set and click **Set as Default** next to the rule set. In the message that appears, click **OK**. The rule set is used as the default rule set for the related database engine.

15.11.8.2. DSL syntax for security rules

DMS provides a domain-specific language (DSL) to describe security rules. You can use the DSL syntax to define security rules. This allows you to define database development standards based on your business requirements.

Overview

The DSL syntax can include one or more conditions and related actions that are specified by an IF-ELSE statement.

> **Note** The if clause is required. Zero or more elseif clauses can be specified. Zero or one else clause can be specified.

Example 1: If Condition 1 is met, DMS performs Action 1.

```
if
  Condition 1
then
  Action 1
end
```

Example 2: If Condition 1 is met, DMS performs Action 1. If Condition 2 is met, DMS performs Action 2. If Condition 1 and Condition 2 are not met, DMS performs Action 3.

> **Note** If the `else Action 3` clause is removed and Condition 1 and Condition 2 are not met, DMS performs no action.

```
if
  Condition 1
then
  Action 1
elseif
  Condition 2
then
  Action 2
[else Action 3]
end
```

DSL syntax

- Conditional clauses

  DMS uses conditional clauses to evaluate whether to perform actions. The result of a conditional clause is true or false. A conditional clause consists of one or more connectors, operators, and factors. Connectors include AND and OR. Factors are predefined system variables. The following examples are valid conditional clauses:

  ```
  1. true          // This is the simplest conditional clause. The result is true.
  2. 1 > 0
  3. 1 > 0 and 2 > 1
  4. 1 <= 0 or 1 == 1
  ```

- Connectors

  Connectors include AND and OR. The AND connector has higher priority than the OR connector. The two connectors have lower priority than operators. For example, a conditional clause is `1 <= 0 or 1 == 1`. DMS evaluates the result of the `1 <= 0` expression and the result of the `1 == 1` expression. Then, DMS evaluates the result of the OR expression based on the preceding results.

- Operators

  Operators are used to connect factors and constants to perform logical operations. The following table describes the operators that are supported by DMS.

Operator	Description	Examples
==	Evaluates whether a value is equal to another value.	1 == 1
!=	Evaluates whether a value is not equal to another value.	1 != 2
>	Evaluates whether a value is greater than another value.	1 > 2
>=	Evaluates whether a value is greater than or equal to another value.	1 >= 2
<	Evaluates whether a value is less than another value.	1 < 2
<=	Evaluates whether a value is less than or equal to another value.	1 <= 2
in	Evaluates whether a value belongs to an array of values.	'a' in ['a', 'b', 'c']
not in	Evaluates whether a value does not belong to an array of values.	'a' not in ['a', 'b', 'c']

Operator	Description	Examples
matchs	Evaluates whether a string matches a regular expression.	'idxaa' matchs 'idx\w+'
not matchs	Evaluates whether a string does not match a regular expression.	'idxaa' not matchs 'idx\w+'
isBlank	Evaluates whether a value is empty.	'' isBlank
isNotBlank	Evaluates whether a value is not empty.	'' isNotBlank

> **Note**
> - If you need to use a backslash (\) in a regular expression, you must add another backslash (\) as an escape character before the backslash that you want to use. For example, if you want to write the `idx_\w+` expression, you must enter `idx_\\w+`.
> - If a conditional clause includes nested expressions, we recommend that you enclose the required expressions in parentheses (). For example, a conditional clause is `1 <= 2 == true`. To specify the priority, you can change the clause to `(1 <= 2) == true`. DMS first evaluates the result of the `1 <= 2` expression in the parentheses.

- Factors

  A factor is a predefined variable in DMS. You can use factors to obtain the context to be validated by security rules. The context includes command categories and the number of affected rows. A factor name is prefixed by `@fac.`. Each tab of the Security Rules tab includes different factors for different checkpoints. The following table describes the factors that are supported by DMS.

Factor	Description
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.sql_type	The type of the SQL statement, for example, UPDATE or INSERT. For more information, see the SQL subcategories that are described in the "SQLConsole for relational databases" topic.
@fac.detail_type	The type of the data change. Valid values: ○ COMMON: a normal data modify ticket ○ CHUNK_DML: a lock-free data modify ticket ○ PROCEDURE: a programmable object ticket ○ CRON_CLEAR_DATA: a history data clean ticket ○ BIG_FILE: a large data import ticket
@fac.is_logic	A Boolean value that indicates whether the affected database is a logical database.
@fac.extra_info	Other information about the ticket. This factor is not in use.
@fac.is_ignore_affect_rows	A Boolean value that indicates whether to skip the validation.
@fac.insert_rows	The number of data rows to be inserted.

Factor	Description
@fac.update_delete_rows	The number of data rows to be updated.
@fac.max_alter_table_size	The size of the largest tablespace in which the table to be modified is stored.
@fac.is_has_security_column	A Boolean value that indicates whether sensitive fields are specified in the SQL statement to be executed.
@fac.security_column_list	The sensitive fields that are specified in the SQL statement to be executed.
@fac.risk_level	The risk level that is identified.
@fac.risk_reason	The reason based on which the operation is identified as this risk level.

Note You can use factors in conditional clauses. For example, you can write `@fac.sql_type == 'DML'` to evaluate whether an SQL statement is a DML statement.

- Action clauses

  An action indicates an operation that is performed when the if clause evaluates to true. For example, DMS can disable the submission of a ticket, select an approval process, approve a ticket, or reject a ticket. An action indicates the usage of a security rule. An action name is prefixed by `@act.` .Each tab of the Security Rules tab includes different actions for different checkpoints. The following table describes the actions that are supported by DMS.

Action	Description
@act.allow_submit	Requires the submission of SQL statements to be executed in a ticket.
@act.allow_execute_direct	Allows the execution of SQL statements in the SQLConsole.
@act.forbid_execute	Disables the execution of SQL statements.
@act.mark_risk	Marks the risk level of a data change. Example: `@act.mark_risk 'medium-level risk: online environment'` .
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	
@act.choose_approve_template_with_reason	

- Predefined functions

  DMS provides predefined functions that can be used in conditional clauses and action clauses. A function name is prefixed by `@fun.` .

Function	Description	Format

Function	Description	Format
@fun.concat	Connects strings to form a single string. Output: a string. Input: multiple strings.	@fun.concat('d', 'm', 's') // The output is the string 'dms'. @fun.concat('[Development standards] The [', @fac.column_name, '] You must enter remarks.') // The output is a prompt that reminds the user who submits the ticket to enter a value in the field.
@fun.char_length	Calculates the length of a string. Output: an integer. Input: a string.	@fun.char_length('dms') // The output is 3. @fun.char_length(@fac.table_name) // The output is the length of the table name.
@fun.is_char_lower	Evaluates whether all the letters in a string are lowercase letters. Output: true or false. Input: a string.	@fun.is_char_lower('dms') // The output is true. @fun.is_char_lower(@fac.table_name) // If the output is true, it indicates that all the letters in the table name are lowercase.
@fun.is_char_upper	Evaluates whether all the letters in a string are uppercase letters. Output: true or false. Input: a string.	@fun.is_char_upper('dms') // The output is false. @fun.is_char_upper(@fac.table_name) // If all the letters in the table name are uppercase letters, the output is true.
@fun.array_size	Counts the number of values in an array. Output: an integer. Input: an array of values.	@fun.array_size([1, 2, 3]) // The output is 3. @fun.array_size(@fac.table_index_array) // The output is the number of indexes of the table.
@fun.add	Adds multiple numeric values. Output: a numeric value. Input: multiple numeric values.	@fun.add(1, 2, 3) // 6
@fun.sub	Deducts a numeric value from another numeric value. Output: a numeric value. Input: two numeric values.	@fun.sub(6, 1) // 5
@fun.between	Evaluates whether a value belongs to a specific closed range. The supported data types are NUMERIC, DATE, and TIME. Output: true or false. Input: three values. The first value is the value to be evaluated. The second value indicates the lower limit. The third value indicates the upper limit.	@fun.between(1, 1, 3) // The output is true because the value 1 belongs to [1, 3]. @fun.between(2, 1, 3) // The output is true because the value 2 belongs to [1, 3]. @fun.between(7, 1, 3) // The output is false because the value 7 does not belong to [1, 3]. @fun.between(@fac.export_rows, 2001, 100000) // If the number of exported rows belongs to [2001, 100000], the output is true. @fun.between(@fun.current_datetime(), '2019-10-31 00:00:00', '2019-11-04 00:00:00') // If the current date and time belong to [2019-10-31 00:00:00, 2019-11-04 00:00:00], the output is true. @fun.between(@fun.current_date(), '2019-10-31', '2019-11-04') // If the current date belongs to [2019-10-31, 2019-11-04], the output is true. @fun.between(@fun.current_time(), '13:30:00', '23:59:59') // If the current time belongs to [13:30:00, 23:59:59], the output is true.
@fun.current_datetime	Returns the current date and time, in the format of yyyy-MM-dd HH:mm:ss. Output: a string. Input: none.	@fun.current_datetime() // For example, the output is 2019-10-31 00:00:00.
@fun.current_date	Returns the current date, in the format of yyyy-MM-dd. Output: a string. Input: none.	@fun.current_date() // For example, the output is 2020-01-13.

Function	Description	Format
@fun.current_time	Returns the current time, in the format of HH:mm:ss. Output: a string. Input: none.	@fun.current_time() // For example, the output is 19:43:20.

DSL configuration examples

Limit the number of SQL statements in a ticket: If the number of SQL statements in a ticket exceeds 1,000, DMS rejects the ticket and returns the related message.

```
if
  @fac.sql_count > 1000
then
  @act.reject_execute 'The number of SQL statements in a ticket cannot exceed 1,000.'
else
  @act.allow_execute
end
```

Allows the submission of only data manipulation language (DML) statements: If the SQL statements in a ticket are DML statements such as the UPDATE, DELETE, and INSERT statements, DMS allows the execution of the statements.

```
if
  @fac.sql_type in ['UPDATE','DELETE','INSERT','INSERT_SELECT']
then
  @act.allow_submit
end
```

15.11.8.3. Configure security rules for a database instance

This topic describes how to configure security rules for a database instance.

Prerequisites

- You are a database administrator (DBA) or an administrator.
- The control mode of the database instance is **security collaboration**.

Procedure

1. Log on to the DMS console.
2. In the left-side navigation pane, right-click the required database instance.
3. In the shortcut menu that appears, choose **Control Mode > Security Collaboration** and select the required security rule set.

   > **Note** You can also change the security rule set of the database instance on the Instance tab. For more information, see Instance management.

15.11.8.4. Customize approval processes

Data Management (DMS) allows you to configure instance-level security rules so that you can customize different approval processes for different database instances or database operations. However, instance-level security rules have some limits in the production environment. This topic describes how to customize an approval process.

Prerequisites

You are a database administrator (DBA) or an administrator.

Context

- Each database instance has only one DBA. However, multiple DBAs are included in an approval process to ensure business continuity regardless of whether one of the DBAs is unavailable.
- If multiple business units share the same database in a database instance, each business unit must approve the tickets for their respective business operations in an approval process.

To resolve the issues in the preceding scenarios, you can customize approval processes.

Precautions

- Do not assign only one approver to an approval node. We recommend that you assign at least two approvers to each approval node and at least two data owners to a database.
- You can assign a maximum of three data owners to a database. If multiple business units share the same database, you can specify these business units in an approval process by performing the following steps: Create an approval node and add the data owners of the business units as approvers. Then, add the new node instead of the system node Owner to an approval template.

Procedure

This topic describes how to customize an approval process and specify multiple DBAs in the approval process. You can perform similar steps to customize an approval process in other scenarios.

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > System > Approval Processes**.
3. Create an approval node.
   i. Click the **Approval Node** tab. Then, click **Create Approval Node**.
   ii. The following table describes the parameters that you can specify for the approval node.

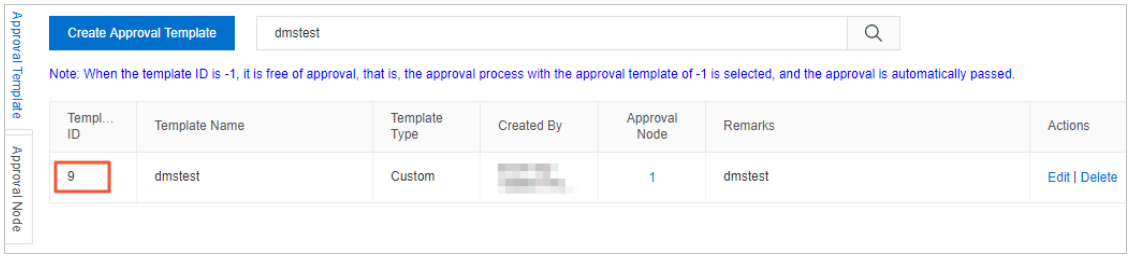
Parameter	Description
Node Name	The name of the approval node. The name must be globally unique.
Remarks	The description of the approval node. This parameter distinguishes the approval node from other approval nodes.
Approver	The Apsara Stack tenant accounts of the approvers for the approval node. You can search for approvers by keyword. Prefix match is used. **Note** In this example, three approvers are selected.

   iii. Click **Submit**.
4. Create an approval template.
   i. Click the **Approval Template** tab. Then, click **Create Approval Template**.

ii. The following table describes the parameters that you can specify for the approval template.

Parameter	Description
Template Name	The name of the approval template. The name must be globally unique.
Remarks	The description of the approval template. This parameter distinguishes the approval template from other approval templates.
Approval Node	Click Add Node and select the required approval nodes. In this example, the system node Owner and the approval node that is created in Step 3 are selected to allow multiple DBAs to participate in the approval process. **Note** The approval process is implemented based on the values of the Approval Order parameter in ascending order.

iii. Click **Submit**.
After the approval template is created, you can view the template ID. In this example, the template ID is 9.



5. Apply a new approval process.

This example shows how to edit a rule that is applied to medium-level risk approval processes under the **Risk Approval Rules** checkpoint. You can perform similar steps to apply a rule to other scenarios.

i. In the top navigation bar, choose **System > Security > Security Rules**.
ii. Find the required rule set that you want to edit and click **Edit** in the **Actions** column of the rule set.
iii. In the left-side navigation pane, click the **SQL Correct** tab.
iv. Select **Risk Approval Rules** as the checkpoint.
v. Find the rule that is related to the medium-level risk approval process and click **Edit**.
vi. In the **Rule DSL** field, change the template ID.

Note In this example, change `3` to `9`, as shown in the preceding figure. The ID 9 is the ID of the approval template that is created in Step 4.

vii. Click **Submit**.

Result

If the data change tickets that you submit match the rule, all specified DBAs receive ticket approval notifications and can participate in the approval process.

15.11.8.5. Operation audit

Data Management (DMS) provides the operation audit feature in addition to the basic features of operation log management. You can use this feature to troubleshoot database issues with ease and audit the operations that are performed on databases. You can also use this feature to view and manage the SQL statements that are used in the SQLConsole, tickets, logon information, and operation logs.

Features

The following table describes the two modules of the operation audit feature in DMS: Operation Logs and Operation audit.

Module	Description	Item
Operation Logs	Displays the logs of all the operations that are performed in DMS.	Includes the logs of management and configuration operations, SQL statements that are used in the SQLConsole, tickets, and logon information.
Operation audit	Displays all the operations that are performed on databases in DMS. **Note** This module provides a user interface (UI) for you to audit operations in a centralized manner. This also helps you troubleshoot database issues with ease.	Includes SQL statements that are used in the SQLConsole, tickets, and logon information. **Note** Only a DMS administrator, a database administrator (DBA), a ticket submitter, and stakeholders involved in the ticket approval process are allowed to view the ticket details.

Log data is permanently retained in DMS. You can access and view the log data of the instances that are managed in **Stable Change** or **Security Collaboration** mode at any time.

Note You can view the log data of the instances that are managed in **Flexible Management** mode only for the last seven days. To view all log data, change the control mode of the instances.

Links and supported roles

The following table describes the roles that you can assume to use the operation audit feature. It also shows you how to go to the Operation audit tab in the DMS console.

Auditing dimension	Limit	Link to operation audit	Supported role

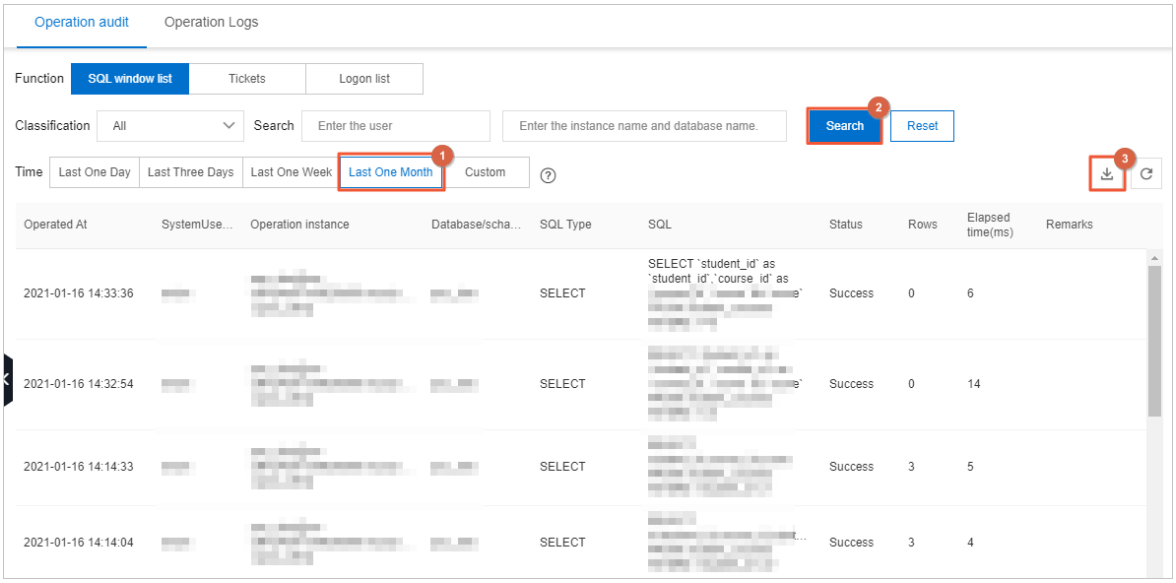
Auditing dimension	Limit	Link to operation audit	Supported role
Database	You can view and audit only the operations that are performed on the current database.	• On the SQLConsole tab of the database that you want to audit, click the icon in the upper-right corner. • In the left-side navigation pane of the DMS console, click the instance in which the database you want to audit resides, right-click the database, and then select **Operation audit**.	You can be a DMS administrator, a security administrator, a DBA, an instance owner, or a regular user. **Note** If you are a regular user, you can view and audit only the operations that you performed on the current database.
Instance	You can view and audit only the operations that are performed on the current instance.	In the left-side navigation pane of the DMS console, right-click the instance that you want to audit and select **Operation audit**.	You can be a DMS administrator, a security administrator, a DBA, an instance owner, or a regular user. **Note** If you are a regular user, you can view and audit only the operations that you performed on the current instance.
Global	You can view and audit all the operations that are performed in DMS.	In the top navigation bar, move the pointer over the **More** icon and choose **System > Operation audit**.	You can be a DMS administrator, a security administrator, or a DBA.

View and download operation records

This example shows you how to view and download all the SQL statements that are used in the SQLConsole in the last month.

1. Log on to the DMS console.
2. In the top navigation bar, move the pointer over the **More** icon and choose **System > Operation audit**.
   By default, a list of SQL statements appears.
3. Set the Time parameter to **Last One Month** and click **Search**.
   Then, DMS returns the search results.
4. Click the icon to download the results.

   Then, DMS exports an XLSX file that contains the search results on the current page.



> **Note** To preview and export more results, you can set the **Items per page** parameter to **100**.

15.11.8.6. Configure IP whitelists

DMS allows you to configure IP whitelists to control the service scope of DMS. You can allow user access to DMS only from specific trusted network environments.

Prerequisites

You are an administrator.

Procedure

1. Log on to the DMS console.
2. In the top navigation, choose **More > System > Access IP Whitelists**.
3. Perform the following operations based on your business requirements:
   - Enable or disable the whitelist control feature

     Click **Click to Open** or **Click to Close** to enable or disable the whitelist control feature.
   - Create a whitelist
     a. Click **Create Whitelist**.
     b. In the dialog box that appears, enter the IP addresses and description.

     > **Note**
     > - Separate IP addresses with semicolons (;). Make sure that each IP address in a whitelist is unique.
     > - You can specify IP addresses such as 10.23.12.24 or CIDR blocks such as 10.23.12.24/24, where /24 indicates the length of the IP address prefix in the CIDR block. The IP address prefix can be 1 to 32 bits in size.
     > - The 0.0.0.0/0 value indicates that all IP addresses are allowed.

     c. Click **Submit**.
   - Edit a whitelist
     a. Find the required IP address whitelist and click **Edit** in the **Actions** column of the IP address.

b. In the dialog box that appears, modify the IP address information.

c. Click **Submit**.

- Delete a whitelist

a. Find the required IP address whitelist and click **Delete** in the **Actions** column of the IP address.

b. In the message that appears, click **OK**.

> **Note** You cannot delete all IP address whitelists. At least one IP address whitelist must be retained.

15.11.8.7. Row-level control

In some cases, different users may access different rows in the same table, which can be achieved by using views. Data Management (DMS) provides an alternative solution that is called the row-level control feature to control access at the row level.

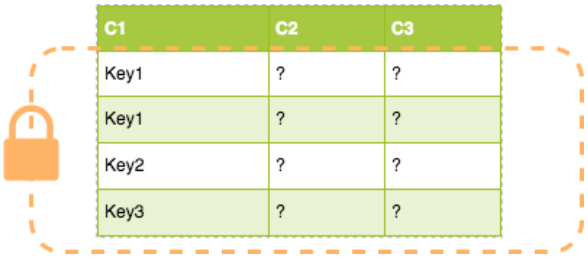
Prerequisites

You are a security administrator, a database administrator (DBA), or an administrator.

Context

Row-level control is used to provide horizontal data protection for tables. All the rows in a table are distinguished by one or more specified values. These values are called control values. To access a row that corresponds to a control value in the DMS console, you must have permissions on the row.

> **Note** A control value may correspond to multiple rows. If a user has permissions on a control value that corresponds to multiple rows, the user has permissions on all the rows that correspond to the control value.



Limits

- The sensitive data management feature applies only to relational databases, such as MySQL. However, this feature is unavailable for NoSQL databases.
- You can use the row-level control feature only on database instances managed in security collaboration mode.
- This feature applies only to physical databases. However, this feature is unavailable for logical databases.
- When you execute SQL statements to query, modify, or delete the data of a row-level control table, the following limits are set on filter conditions.
  i. The control field must be specified in SQL statements to filter data.
  ii. The system controls access to all the rows of a row-level control table. Users who do not have permissions on all rows can use only the `=` and `IN` operators to specify a control field. The control value that is specified in an SQL statement must be one of the control values for the table.
  iii. Users who do not have permissions on all rows cannot use some operators, such as OR, XOR, and logical NOT.

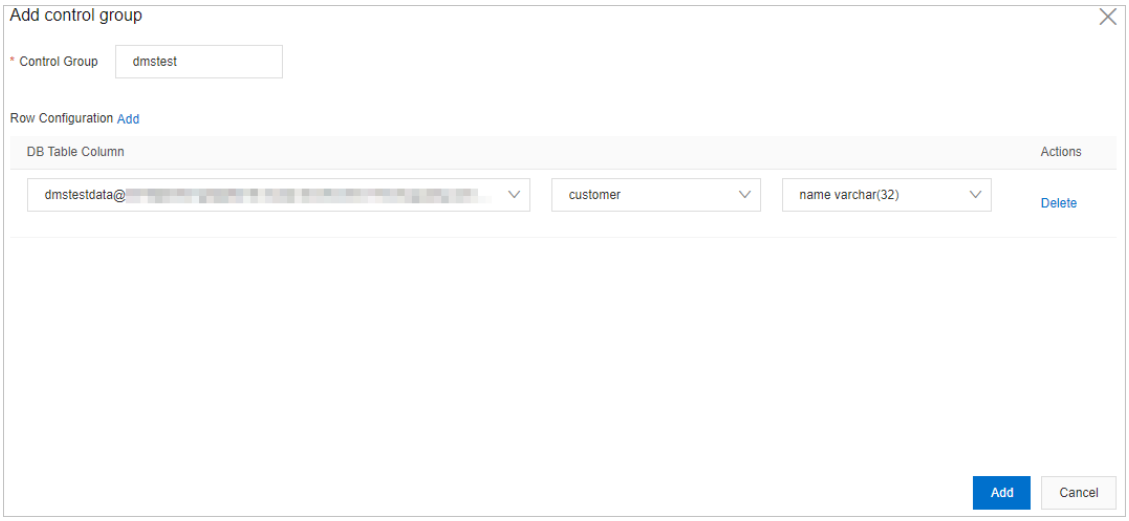
Terms

Term	Description
row permission	You can apply for permissions on a control value to access rows that correspond to the control value. Permissions on the rows of a table are defined as row permissions and are incorporated into the existing permissions of DMS. Permissions that can be controlled in security collaboration mode include permissions on databases, tables, columns (fields), and rows.
single control value	When a user applies for permissions on the rows of a row-level control table, the user can select **Single** to apply for permissions on a single control value. **Note** A control value may correspond to multiple rows. If a user has permissions on a control value that corresponds to multiple rows, the user has permissions on all the rows that correspond to this control value.
all control values	When a user applies for permissions on the rows of a row-level control table, the user can select **ALL** to apply for permissions on all control values. After the application is approved, the user has permissions on all the rows of the table. In this case, the user can access the entire row-level control table without limits. Even if the control values are changed or more control values are added, the user still has permissions on all the rows of the table.
row-level control table	A table that requires row-level control is called a row-level control table.
control field	A control field is a field to which the control values of a row-level control table are added.
control group	A control group is a group of row-level control tables that have the same control values. For example, if Table A and Table B have the same control values, you can add the two tables to a control group. This way, you can manage the two tables at the same time by using one set of control values.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > System > Sensitive Data**.
3. Click the **Row Level Security** tab.
4. Add a control group.
   i. Click **Add control group**.

ii. In the Add control group dialog box, set the required parameters.



Parameter	Description
Control Group	Enter a name for the control group.
Row Configuration	Click **Add** to add a row configuration in which you can specify a database, table, and field. **Note** You can repeat this step to add multiple row configurations.
DB Table Column	Search for databases by keyword and select a database. Then, select a table and a field from the drop-down lists. **Note** The selected field is the control field.

iii. Click **Add**.

5. Add control values.
   i. Find the new control group and click **Details** in the **Actions** column of the control group.
   ii. Click **Add Row Value**.
   iii. In the Import Row Value dialog box, specify whether to append row values and enter the required row values.

   Note Separate multiple row values with commas (,).

   iv. Click **Import**.

What to do next

After you configure row-level control settings for a table, a user may still have no permission on a control value that corresponds to one or more rows in the table. In this case, an error appears when the user queries row data. The error indicates that the user does not have permissions to access the row. The user can apply for permissions on the control value to access the rows. For more information, see Apply for permissions.

15.11.8.8. Manage sensitive data

Data Management (DMS) allows you to manage all classified sensitive and confidential fields in a unified manner. You can configure encryption algorithms for sensitive and confidential fields. This improves the control over the data masking feature.

Prerequisites

You are a security administrator, a database administrator (DBA), or an administrator.

Context

When you query a table that contains sensitive or confidential fields on which and you do not have permissions on the fields, the values of the fields are displayed as `******` in the query results. In this case, sensitive data is fully masked. In some scenarios, developers or test engineers may need to view a part of sensitive data for troubleshooting. To meet this requirement, you can configure masking algorithms to show some sensitive data.

Limits

- The sensitive data management feature applies only to relational databases such as MySQL. However, this feature is unavailable for NoSQL databases.
- To use this feature, the required database instance must be managed in security collaboration mode.

Procedure

1. Log on to the DMS console.
2. Specify security levels for fields in the required table.

   > **Note** If security levels are specified for the fields, skip this step.

   i. In the left-side database instance list, click the icon next to the required database instance to show the databases in the instance.

   ii. Find the required database, right-click the database, and then select **Tables**.

   iii. Click the + icon next to the table name to show the table details.

   iv. Click **Adjust**.

   v. In the Adjust Security Level dialog box, change the security levels of fields.

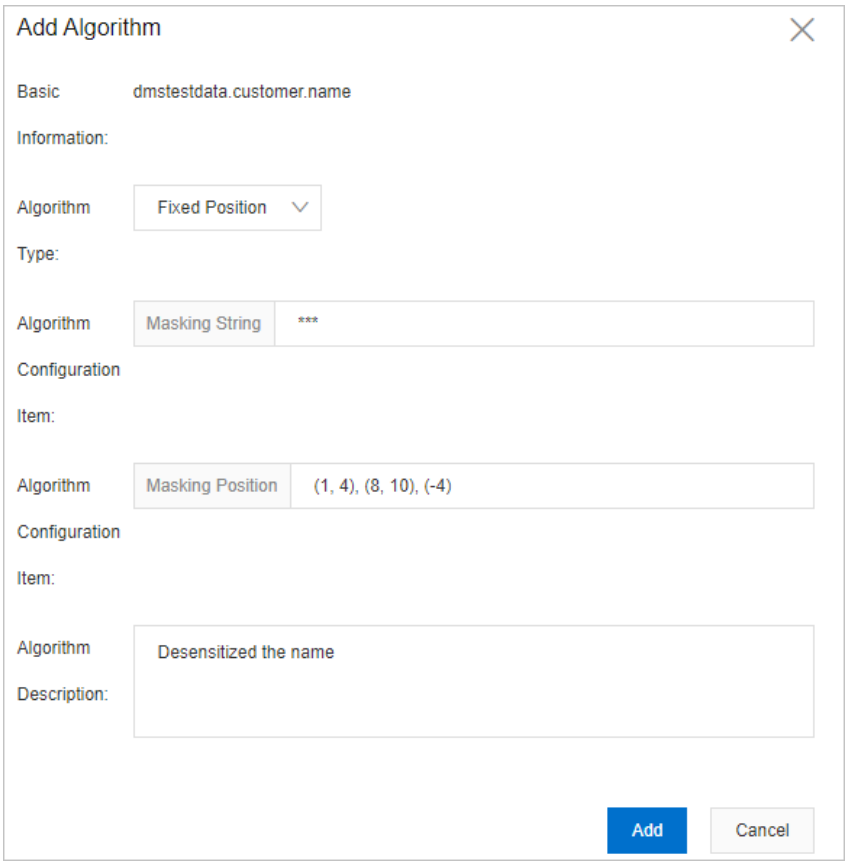
   
   vi. Click **Submit for Security Department Approval**.

   > **Note** The application to increase the security level of a field is automatically approved. The application to decrease the security level of a field is approved based on the approval process specified by an administrator or DBA.

   vii. In the message that appears, click **OK**.

3. In the top navigation bar, choose **More > System > Sensitive Data**.

4. Find the required field and click **Add Algorithm** in the **Actions** column of the field.
5. In the dialog box that appears, configure a masking algorithm.



Parameter	Description
Algorithm Type	The type of the algorithm. You can select an algorithm type based on your business requirements.

Parameter	Description
Algorithm Configuration Item	The algorithm configuration items vary based on the specified algorithm type. ○ **Fixed Position** algorithm type You must set the Masking String and Masking Position parameters. For example, you can set the Masking String parameter to ***. The Masking Position parameter specifies the positions of the characters to be masked in the field values. The positions are in the format of coordinates. Examples: ■ (1, 4): masks the first four characters. You can also enter (4) to simplify the format. ■ (-4): masks the last four characters. **Note** You can specify a maximum of three positions. For example, (1, 4), (8, 10), (-4) indicates to mask the first four characters, the eighth to tenth characters, and the last four characters. ○ **Fixed Character** algorithm type You must set the Masking String and Character to Be Replaced parameters. **Note** The Character to Be Replaced parameter specifies the characters that you want to mask in the format of a string. You can specify a maximum of three strings. ○ **Full Masking** algorithm type You need to set only the Masking String parameter.
Algorithm Description	Enter a description that can help you identify the algorithm.

6. Click **Add**.

15.11.8.9. Data protection

Data Management (DMS) provides the data protection feature. This topic describes how to use the data protection feature.

Context

Data protection is one of the greatest challenges in the process of data application. Data is the core of an enterprise. Most critical and sensitive information is stored as structured data. The information includes ID numbers, bank account numbers, phone numbers, customer records, medical records, transaction records, and salary records. Security events may cause enormous economic loss and damage the reputation of enterprises. These security events include data tampering, data theft, and data misuse.

To ensure data security, you need to understand how to protect your data from these security risks. The data protection feature helps the security management team achieve the following goals:

- Intelligently recognizes and classifies sensitive data. Then, you can group the data based on the security level of fields for DMS.
- Audits databases and prevents against data loss.
- Provides an efficient method to identify data application mode. Then, you can use the user and entity behavior analytics identification model and big data security expert rules of Ant Financial to identify and manage risks.
- Provides unified masking SDKs to protect sensitive information. These SDKs are used to intelligently identify sensitive data that exists in the system content that is displayed and mask the data. These operations are performed based on the definition of sensitive information and masking policies that are specified in the data

protection feature. These SDKs are also used to provide a unified method to manage masking rules within an enterprise, and increase the efficiency of security management.

Control access

Data protection is a tool that is provided by DMS to data security administrators. To enable and use the data protection feature, you must log on to the DMS console with security administrator permissions.

1. Log on to the DMS console.

   > **Note** You must use an account with administrator permissions to log on to the DMS console.

2. In the top navigation bar, choose **More > System > User**.
3. Click **Change**.
4. Select **Security Administrator** and click **Confirm Change**.
5. Use the account to re-log on to the Log on to the DMS console again.
6. In the top navigation bar, choose **More > Security > Data Protection**.

   > **Note** To enable a user to use the data protection feature, you must log on to the DMS console with security administrator permission to enable the feature and authorize the user to use the feature.

Data classification

The data protection feature classifies fields based on the custom automatic classification setting that is specified in the metadata of these fields. The classification results are used to update the levels of these DMS fields. This feature facilitates the access control over DMS fields.

1. Log on to the DMS console.

   > **Note** You must use an account with security administrator permissions to log on to the DMS console.

2. In the top navigation bar, choose **More > Security > Data Protection**.
3. In the left-side navigation pane, choose **Rule Configuration > Data Identification Rules**.
4. In the upper-right corner, click **Create Rule**. Then, set the **Data Type**, **Data Name**, **Owner** and **Remarks** parameters.
5. Click **Next**.
6. Set the Level parameter. Valid values: Internal, Sensitive, and Confidential. Select Field Scanning in the Data Recognition Rules field.
7. Click **Next**. After the rule is configured, click **Save and Enable**.

   > **Note**
   > - You can view all rules on the **Data Identification Rules** page. You can also modify, disable, or enable a rule on this page.
   > - After a rule is applied, the system identifies and classifies data based on metadata every hour on the hour. The security level of a field in DMS Enterprise is updated based on the classification result. This enables field-level access control over DMS operations.

Manually correct data

The Manual Data Correction page shows all identified fields. This way, you can verify these fields. If some fields are incorrectly identified, you can remove these fields or change the related types. After data is corrected, the results are immediately synchronized to the DMS Enterprise console.

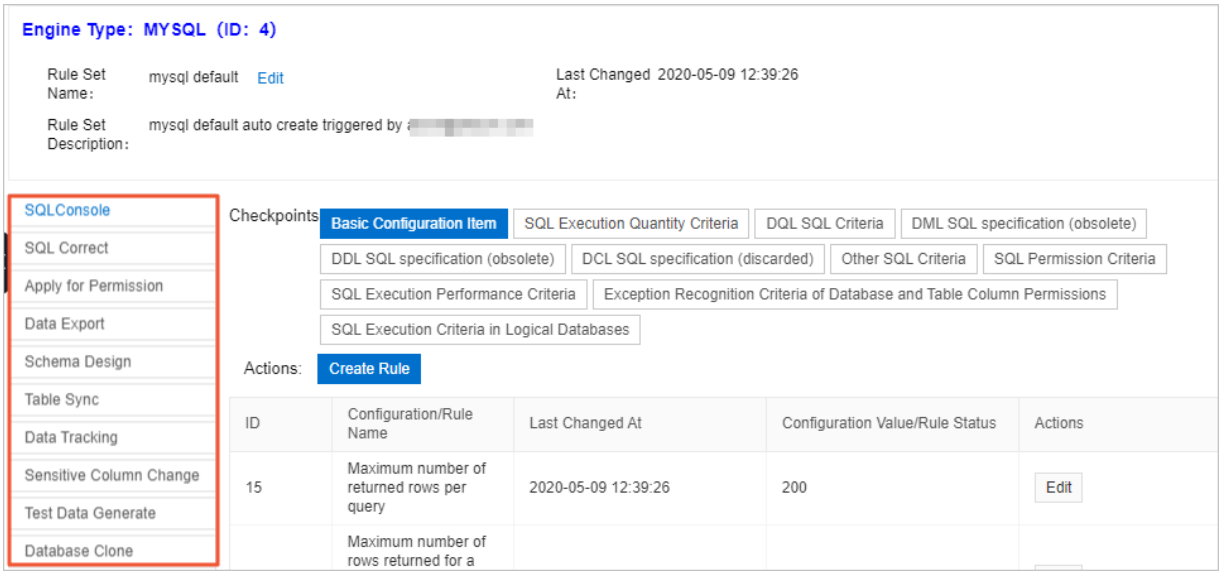
Data detection

The data detection feature is used to collect statistics based on the results of data identification from multiple dimensions and show the details of fields that are identified in the field details list. These dimensions include the security level and related instance.

15.11.9. Security rules

15.11.9.1. Overview of security rule sets

Security rule sets are implemented by using a collection of domain-specific languages (DSLs) to control user access to databases based on several factors. These factors include the type of databases, the syntax of database operations, and the number of affected rows. You can use security rule sets to standardize database operations, development processes, and approval processes as required.



This topic describes the features that are supported by security rule sets. You can click the link of a feature to view the information about the feature. The information includes the basic configuration items, checkpoints, factors, actions, and supported statements or commands.

- SQLConsole for relational databases
- SQLConsole for MongoDB
- SQLConsole for Redis
- Data change
- Permission application
- Data export
- Schema design
- Database and table synchronization
- Sensitive field change
- Test data generation
- Database cloning

15.11.9.2. Manage security rules under checkpoints

This topic describes how to configure a security rule under the SQL Execution Quantity Criteria checkpoint on the SQL Editor tab. You can configure security rules under other checkpoints by using a method similar to that described in this topic.

Procedure

1. Log on to the DMS console.
2. In the top navigation bar, choose **More > System > Security Rules**.
3. Find the required security rule set and click **Edit** in the **Actions** column of the security rule.

   > **Note** In this example, the security rule that is configured for MySQL databases is used.

4. Click a tab and then click a checkpoint based on your business requirements. In this example, click the **SQL Editor** tab and then click the **SQL Execution Quantity Criteria** checkpoint.

   > **Note**
   > - For more information about the tabs and checkpoints, see Overview of security rule sets.
   > - You can click **Create Rule** to create a security rule. For more information about the syntax, see DSL syntax for security rules.

5. Find the required security rule and click **Edit** in the **Actions** column of the security rule.

   > **Note** You can click **Disable** to disable a security rule or click **Delete** to delete a security rule.

6. In the Change Rule - SQL Editor dialog box, modify the DSL statements of the security rule based on your business requirements. For more information about the syntax, see DSL syntax for security rules. In this example, change the maximum number of SQL statements that can be executed at a time from 1,000 to 500.

   > **Note**
   > - A large number of security rule templates are provided for each checkpoint. You can click **Load from Template Database** to use a template.
   > - For more information about factors and actions, see Overview of security rule sets.

7. Click **Submit**.

15.11.9.3. SQLConsole for relational databases

DMS allows you to manage relational and non-relational databases on the SQLConsole tab. The definition and classification of security rules are different for relational and non-relational databases. This topic describes the security rules for relational databases on the SQLConsole tab, such as MySQL databases.

Default security rules

- Constraints on SQL statement categories: No constraints are imposed on data query language (DQL) statements. By default, DML statements, DDL statements, data control language (DCL) statements, and SQL statements that

cannot be identified by DMS are all blocked. To execute DML, DDL, or DCL statements on the SQLConsole tab, you must configure and enable corresponding security rules.

- Constraints on permissions on databases, tables, and fields: By default, users can perform operations on databases, tables, and fields without permission validation. To enable permission validation, you must configure and enable security rules under the **SQL Permission Criteria** checkpoint. For more information, see Supported checkpoints.

Basic configuration items

Configuration item	Description
Maximum number of returned rows per query	The maximum number of rows that can be returned for a query.
Maximum number of rows returned for a single query with sensitive column conditions	The maximum number of rows that can be returned for a query that contains query conditions for sensitive fields.
Limit the maximum allowed SQL full table scan (MB)	The maximum size of data that can be scanned. Before an SQL statement is executed, DMS checks the execution plan. If the size of the data to be scanned exceeds the specified threshold, the SQL statement fails to be executed. **Note** This item can be configured only for MySQL and Oracle databases.
Turn off the execution of change SQL validation affects the number of rows and prompts	Specifies whether to check the number of rows to be affected and display a prompt before DMS executes an SQL statement to change data. By default, this item is disabled.
How many rows does result set page support	The maximum number of rows that can be returned in the query result set on the SQLConsole tab.
Does the result set support paging	Specifies whether the query result set can be displayed on multiple pages on the SQLConsole tab.
Does the result set support editing	Specifies whether the query result set can be edited on the SQLConsole tab.

Supported checkpoints

Note Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description
SQL Execution Quantity Criteria	Allows you to limit the number of SQL statements that can be submitted at a time.
DQL SQL Criteria	Allows you to set constraints on DQL statements.

Checkpoint	Description
Other SQL Criteria	Allows you to set constraints on multiple categories of SQL statements. Different enterprises may define different high-risk SQL statements, which may include specific subcategories of DML, DCL, and DDL statements. **Note** You can also set constraints on SQL statements that cannot be identified by DMS.
SQL Permission Criteria	Allows you to set constraints on the execution of SQL statements from the aspect of permissions. For example, DMS checks whether a user has the required permissions on the corresponding databases, tables, and fields.
SQL Execution Performance Criteria	Allows you to set constraints on the execution of SQL statements from the aspect of performance. For example, you can specify that a DML statement is not executed if the number of rows to be affected by the statement exceeds the specified threshold, or that a DDL statement is not executed if the size of the table involved exceeds the specified threshold.
Exception Recognition Criteria of Database and Table Column Permissions	After a user submits SQL statements on the SQLConsole tab, DMS parses the SQL statements and checks whether the user has the required permissions on the corresponding databases, tables, and fields. You can configure security rules under this checkpoint to ensure that if exceptions occur when DMS parses complex SQL statements, these statements can be executed. **Note** If you configure and enable security rules under the **Exception Recognition Criteria of Database and Table Column Permissions** checkpoint, security rules under the SQL Permission Criteria, DQL SQL Criteria, Other SQL Criteria, and SQL Execution Performance Criteria checkpoints are automatically disabled.
SQL Execution Criteria in Logical Databases	This checkpoint is reserved for logical databases and not suitable for physical databases.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`. The following table describes the supported factors for relational databases on the SQLConsole tab.

Factor	Description
@fac.sql_count	The number of SQL statements that are submitted at a time.
@fac.select_sql_count	The number of DQL statements among the SQL statements that are submitted at a time.
@fac.dml_sql_count	The number of DML statements among the SQL statements that are submitted at a time.
@fac.sql_type	The category and subcategory of the SQL statement. For more information, see Supported SQL statements.
@fac.sql_sub_type	
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.

Factor	Description
@fac.fulltable_delete	A Boolean value that indicates whether the current SQL statement deletes a full table. Valid values: *true* and *false*.
@fac.fulltable_update	A Boolean value that indicates whether the current SQL statement updates a full table. Valid values: *true* and *false*.
@fac.current_sql	The current SQL statement.
@fac.user_is_admin	A Boolean value that indicates whether the current user is a DMS administrator. Valid values: *true* and *false*.
@fac.user_is_dba	A Boolean value that indicates whether the current user is a DBA. Valid values: *true* and *false*.
@fac.user_is_inst_dba	A Boolean value that indicates whether the current user is the DBA of the current instance. Valid values: *true* and *false*.
@fac.user_is_sec_admin	A Boolean value that indicates whether the current user is a security administrator. Valid values: *true* and *false*.
@fac.sql_affected_rows	The number of rows to be affected by the current SQL statement. **Warning** This factor triggers COUNT operations, which may affect the database performance. Use this factor with caution.
@fac.sql_relate_table_store_size	The estimated total size of the table to be accessed by the current SQL statement. Unit: MB. **Note** This value is estimated based on the metadata that is obtained by DMS. It is not an actual value.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`. The following table describes the supported actions for relational databases on the SQLConsole tab.

Action	Description
@act.reject_execute	Rejects the request to execute the current SQL statement.
@act.allow_execute	Allows the current SQL statement to be executed.
@act.reject_sql_type_execute	Rejects the request to execute a specific subcategory of SQL statements. You must specify an SQL statement subcategory after the action name. Example: `@act.reject_sql_type_execute 'UPDATE'`.
@act.allow_sql_type_execute	Allows a specific subcategory of SQL statements to be executed. You must specify an SQL statement subcategory after the action name. Example: `@act.allow_sql_type_execute 'UPDATE'`.

Action	Description
@act.check_dml_sec_column_permission	Checks whether a user has the required permissions on sensitive fields. If the user does not have the permissions, the DML statement for data change is not executed.
@act.uncheck_dml_sec_column_permission	Does not check whether a user has the required permissions on sensitive fields.
@act.check_sql_access_permission	Checks whether a user has the required permissions, such as query and change permissions, on the databases, tables, and fields that are involved in the SQL statements to be executed.
@act.uncheck_sql_access_permission	Does not check whether a user has the required permissions on the objects that are involved in the SQL statements to be executed.
@act.enable_sec_column_mask	De-identifies sensitive fields in query result sets that are returned for SQL statements that are submitted by users who do not have permissions on the sensitive fields.
@act.disable_sec_column_mask	Does not de-identify sensitive fields in query result sets that are returned for SQL statements that are submitted by users who do not have permissions on the sensitive fields.

Supported SQL statements

Category	Subcategory
DQL	• SELECT • DESC • EXPLAIN • SHOW
DML	• INSERT • INSERT_SELECT • REPLACE • REPLACE_INTO • UPDATE • DELETE • MERGE

Category	Subcategory
DDL	• DATABASE_OP • CREATE • CREATE_INDEX • CREATE_VIEW • CREATE_SEQUENCE • CREATE_TABLE • CREATE_SELECT • TRUNCATE • DROP_INDEX • DROP_VIEW • DROP_TABLE • RENAME • ALTER • ALTER_INDEX • ALTER_VIEW • ALTER_TABLE • ALTER_SEQUENCE • CREATE_FUNCTION • CREATE_PROCEDURE • ALTER_FUNCTION • ALTER_PROCEDURE • DROP_FUNCTION • DROP_PROCEDURE
DCL	• GRANT • DECLARE • SET • ANALYZE • FLUSH • OPTIMIZE • KILL

15.11.9.4. SQLConsole for MongoDB

DMS allows you to manage relational and non-relational databases on the SQLConsole tab. The definition and classification of security rules are different for relational and non-relational databases. This topic describes the security rules for MongoDB databases on the SQLConsole tab.

Basic configuration items

Maximum number of returned rows per query: the maximum number of rows that can be returned for a query.

Supported checkpoints

> **Note** Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description
User Permission Validation	Allows you to specify whether to check the permissions of specific users when they submit commands.
Collection Statement Criteria	Allows you to specify whether to allow DMS to run a specific category of commands.
DB Statement Criteria	
Cache Query Statement Criteria	
User Management Statement Criteria	
Role Management Statement Criteria	
Replication Set Statement Criteria	
Sharding Statement Criteria	

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as command categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`. The following table describes the supported factors for MongoDB databases on the SQLConsole tab.

Factor	Description
@fac.sql_sub_type	The subcategory of the current command. For more information about the supported commands, see Supported MongoDB commands.
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as `DEV` or `PRODUCT`.
@fac.current_sql	The current command.
@fac.user_is_admin	A Boolean value that indicates whether the current user is a DMS administrator. Valid values: *true* and *false*.
@fac.user_is_dba	A Boolean value that indicates whether the current user is a DBA. Valid values: *true* and *false*.
@fac.user_is_inst_dba	A Boolean value that indicates whether the current user is the DBA of the current instance. Valid values: *true* and *false*.
@fac.user_is_sec_admin	A Boolean value that indicates whether the current user is a security administrator. Valid values: *true* and *false*.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`. The following table describes the supported actions for MongoDB databases on the SQLConsole tab.

Action	Description
@act.reject_execute	Rejects the request to run the current command.
@act.allow_execute	Allows the current command to be run.
@act.reject_sql_type_execute	Rejects the request to run a specific subcategory of commands. You must specify a subcategory after the action name. Example: `@act.reject_sql_type_execute 'UPDATE'`.
@act.allow_sql_type_execute	Allows a specific subcategory of commands to be run. You must specify a subcategory after the action name.

Supported MongoDB commands

Category	Subcategory	Command
Collection commands	Query commands	• aggregate • find • findOne • count • distinct • getIndexes • getShardDistribution • isCapped • stats • dataSize • storageSize • totalIndexSize • totalSize
	Data update commands	• insert • save • findAndModify • remove • update
	Collection modification commands	• drop • renameCollection
	Index modification commands	• createIndex • createIndexes • dropIndexes • reIndex
	Other commands	validate

Category	Subcategory	Command
Database commands	Database query commands	• commandHelp • currentOp • getCollectionInfos • getCollectionNames • getLastError • getLastErrorObj • getLogComponents • getPrevError • getProfilingStatus • getReplicationInfo • getSiblingDB • help • isMaster • listCommands • printCollectionStats • printReplicationInfo • version • serverBuildInfo • serverStatus,stats
	Collection creation commands	createCollection
	High-risk commands	• dropDatabase • fsyncLock • fsyncUnlock • killOp • repairDatabase • resetError • runCommand
Commands related to the query plan cache	Read commands	• getPlanCache • getPlansByQuery • listQueryShapes
	Write commands	clearPlansByQuery
User management commands	User query commands	• getUser • getUsers
	User modification commands	• createUser • changeUserPassword • dropUser • dropAllUsers • grantRolesToUser • revokeRolesFromUser • updateUser

Category	Subcategory	Command
Role management commands	Role query commands	• getRole • getRoles
	Role modification commands	• createRole • dropRole • dropAllRoles • grantPrivilegesToRole • revokePrivilegesFromRole • revokeRolesFromRole • updateRole
Replica set commands	N/A	• help • printReplicationInfo • status • conf
Sharding commands	N/A	• getBalancerState • isBalancerRunning

15.11.9.5. SQLConsole for Redis

DMS allows you to manage relational and non-relational databases on the SQLConsole tab. The definition and classification of security rules are different for relational and non-relational databases. This topic describes the security rules for Redis databases on the SQLConsole tab.

Supported checkpoints

Note Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description
Permission Execution Statement Criteria	Allows you to set constraints on the permissions for command execution.
Statement Criteria: Keys	Allows you to specify whether to check the permissions of specific users when they submit commands.
Statement Criteria: String	Allows you to specify whether to allow the execution of various Redis commands.
Statement Criteria: List	
Statement Criteria: SET	
Statement Criteria: SortedSet	
Statement Criteria: Hash	

Checkpoint	Description
Statement Criteria: Other	

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`. The following table describes the supported factors for Redis databases on the SQLConsole tab.

Factor	Description
@fac.cmd_type	The type of the Redis command. For more information about valid values, see Supported Redis commands.
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as `DEV` or `PRODUCT`.
@fac.is_read	A Boolean value that indicates whether the current command is a read command. Valid values: *true* and *false*.
@fac.is_write	A Boolean value that indicates whether the current command is a write command. Valid values: *true* and *false*.
@fac.current_sql	The current command.
@fac.user_is_admin	A Boolean value that indicates whether the current user is a DMS administrator. Valid values: *true* and *false*.
@fac.user_is_dba	A Boolean value that indicates whether the current user is a DBA. Valid values: *true* and *false*.
@fac.user_is_inst_dba	A Boolean value that indicates whether the current user is the DBA of the current instance. Valid values: *true* and *false*.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`. The following table describes the supported actions for Redis databases on the SQLConsole tab.

Action	Description
@act.reject_execute	Rejects the request to run the current command.
@act.allow_execute	Allows the current command to be run.

Supported Redis commands

Category	Subcategory	Command

Category	Subcategory	Command
Key-related commands	Key-related read commands	• EXISTS • TTL • PTTL • RANDOMKEY • TYPE • SCAN • OBJECTS
	Key-related write commands	• DEL • DUMP • EXPIRE • EXPIREART • MOVE • PERSIST • PEXPIRE • PEXPIREAT • RENAME • RENAMENX • RESTORE • SORT • TOUCH • UNLIMK • WAIT • MIGRATE
String-related commands	String-related read commands	• GET • GETRANGE • BITCOUNT • GETBIT • MGET • STRLEN • BITOPS

Category	Subcategory	Command
	String-related write commands	• APPEND • BITFIELD • BITOP • DECR • DECRBY • GETSET • INCR • INCRBY • INCRBYFLOAT • MSET • MSETNX • PSETEX • SET • SETNX
List-related commands	List-related read commands	• LINDEX • LLEN • LRANGE
	List-related write commands	• BLPOP • BRPOP • BRPOPLPUSH • LINSERT • LPOP • LPUSH • LPUSHX • LREM • LSET • LTRIM • RTOP • RPOPLPUSH • RPUSH • RPUSHX
Set-related commands	Set-related read commands	• SCARD • SISMEMBER • SRANDMEMBER • SSCAN
	Set-related write commands	• SADD • SMOVE • SPOP • SREM

Category	Subcategory	Command
Sorted set-related commands	Sorted set-related read commands	• ZCARD • ZCOUNT • ZLEXCOUNT • ZRANGE • ZRANGEBYLEX • ZRANGEBYSCORE • ZRANK • ZREVRNGE • ZREVRANGEBYLEX • ZREVRANGEBYSCORE • ZREVRANK • ZSCAN • ZSCORE
	Sorted set-related write commands	• ZADD • ZINCRBY • ZINTERSTORE • ZPOPMAX • ZPOPMIN • ZREM • ZUNIONSTORE • BZPOPMIN • BZPOPMAX
Hash-related commands	Hash-related read commands	• HEXISTS • HGET • HLEN • HMGET • HSCAN • HSTRLEN
	Hash-related write commands	• HDEL • HINCRBY • HINCRBYFLOAT • HMESET • HSET • HSETNX

15.11.9.6. Data change

In DMS, you can execute SQL statements for data changes. However, the execution requires a high level of security. DMS allows you to configure security rules on the SQL Correct tab to validate the submission and approval of tickets for data changes. Only the SQL statements that are validated by the security rules can be executed.

Background information

Based on a DSL, new security rules are flexible to use. You can apply new security rules to define risk levels for tickets so that a ticket can be submitted to the approval process that is designed for the specified risk level. For more information, see DSL syntax for security rules.

Basic configuration items

Configuration item	Description
Data change default approval Template	By default, this approval template takes effect if you do not configure different approval rules for data changes at different risk levels under the Risk Approval Rules checkpoint. In the Switch Approval Template dialog box, you can change the approval process of the default approval template. For more information, see Customize approval processes.
Data Change risk level list	This risk level list defines risk levels that are used in the **Risk Identification Rules** and **Risk Approval Rules** checkpoints to identify and classify risks in data changes. You can set risk levels based on the type and scenario of data changes. Data changes at different risk levels are submitted to different approval processes. DMS allows you to set the following four risk levels: • *low*: a low risk level. • *middle*: a medium risk level. • *high*: a high risk level. • *highest*: a critical risk level.

Supported checkpoints

Note Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description

SQL execution rules	SQL execution rules are used to limit the SQL statements that can be submitted for execution. If you do not enable SQL execution rules, all SQL statements that are used for data changes cannot be executed. Assume that you want to use DML statements to change the data of a database in an online environment. You can create the following SQL execution rule:
	Example:
	`if`
	`  @fac.env_type not in ['product']`
	`  and`
	`  @fac.sql_type in [ 'UPDATE','DELETE','INSERT']`
	`then`
	`  @act.allow_submit`
	`end`
	Note:
	The preceding rule specifies that you can only submit data change tickets to execute UPDATE, DELETE, and INSERT statements on a database that is deployed in an online environment.

Checkpoint	Description
Risk Identification Rules	If a ticket conforms to the preset SQL execution rules, DMS continues to validate the ticket based on the risk identification rules. Risk identification rules are used to identify and classify risks in data changes. You can create risk identification rules based on your database environment, the number of rows in which data is affected, and the categories and subcategories of SQL statements. **Note** Different risk identification rules apply to different check items. DMS automatically identifies the highest risk level for a data change. For example, if the risk level of a data change is identified as high, medium, and low by one, three, and five risk identification rules, DMS assumes that the data change is at high risk. Example: `if @fac.env_type not in ['product','pre'] then @act.mark_risk 'low 'Low risk level: offline environment' end` Note: The preceding rule specifies that if the destination database is deployed in an offline environment, data changes are at low risk.
Risk Approval Rules	After the risk level of a data change is identified by the risk identification rules, DMS processes the ticket based on the risk approval rules. You can customize risk approval rules under the **Risk Approval Rules** checkpoint. **Note** • If a data change does not hit risk approval rules, DMS uses the default approval template that is specified under the Basic Configuration Item checkpoint to process the ticket. • By default, an offline environment is identified as a factor at low risk and requires no approval.
Batch Data import rules	These rules apply only to the validation of data import tickets. You can use the default rules that are provided in templates, or configure rules based on your actual needs.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.` .The following table describes the supported factors on the SQL Correct tab.

Factor	Description
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.sql_type	The type of the SQL statement. The value is the subcategory of the SQL statement, such as UPDATE or INSERT. For more information, see Supported SQL statements.

Factor	Description
@fac.detail_type	The type of the data change. Valid values: • *COMMON*: a Normal Data Modify ticket. • *CHUNK_DML*: a Lock-Free Data Modify ticket. • *PROCEDURE*: a Programmable Object ticket. • *CRON_CLEAR_DATA*: a History Data Clean ticket. • *BIG_FILE*: a Large Data Import ticket.
@fac.is_logic	A Boolean value that indicates whether the database to be affected is a logical database.
@fac.extra_info	The additional information about the data change. This factor is not in use.
@fac.is_ignore_affect_rows	A Boolean value that indicates whether to skip the validation.
@fac.insert_rows	The number of rows of data to be inserted.
@fac.update_delete_rows	The number of rows of data to be updated.
@fac.max_alter_table_size	The size of the largest tablespace where the table to be modified is stored.
@fac.is_has_security_column	A Boolean value that indicates whether the SQL statement to be executed involves sensitive fields.
@fac.security_column_list	A list of sensitive fields that the SQL statement to be executed involves.
@fac.risk_level	The risk level of the operation that is to be performed by the SQL statement.
@fac.risk_reason	The reason for identifying the operation to be performed as at the risk level.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.` .The following table describes the supported action on the SQL Correct tab.

Action	Description
@act.allow_submit	Requires the submission of SQL statements to be executed in a ticket.
@act.allow_execute_direct	Allows the execution of SQL statements in the SQLConsole.
@act.forbid_execute	Forbids the execution of SQL statements.
@act.mark_risk	Marks the risk level of a data change. Example: `@act.mark_risk 'Medium risk level: online environment'` .
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	
@act.choose_approve_template_with_reason	

15.11.9.7. Permission application

DMS allows you to configure security rules on the Access apply tab to validate applications for permissions, including permissions on instances, databases, and tables.

Background information

In DMS, security rules are flexible to use. You can apply security rules to define risk levels for tickets so that a ticket can be submitted to the approval process that is designed for the specified risk level. For more information about the DSL syntax, see DSL syntax for security rules.

Basic configuration items

The following table describes the basic configuration items that are supported on the Access apply tab.

Configuration item	Description
[Instance-permission application] default approval Template	By default, this approval template takes effect if you do not set different approval processes for instance permission applications at different risk levels under the **Validation for Instance Permission Application** checkpoint. **Note** In the Switch Approval Template dialog box, you can change the approval process of the default approval template.
[DB-permission application] default approval Template	By default, this approval template takes effect if you do not set different approval processes for database permission applications at different risk levels under the **Database Permission Application Validation** checkpoint.
Table-permission request default approval Template	By default, this approval template takes effect if you do not set different approval processes for table permission applications at different risk levels under the **Table Permission Application Validation** checkpoint.
[Programmable object-permission application] default approval Template	By default, this approval template takes effect if you do not set different approval processes for programmable object permission applications at different risk levels under the **Programmable object verification** checkpoint.
[Field-permission application] default approval Template	By default, this approval template takes effect if you do not set different approval processes for sensitive field permission applications at different risk levels under the **Sensitive Field Application Validation** checkpoint.
Line-permission application default approval Template	By default, this approval template takes effect if you do not set different approval processes for row permission applications at different risk levels under the **Line permission application verification** checkpoint.
[Owner-application] default approval template (when the resource has no Owner)	By default, this approval template takes effect if you do not set different approval processes for data ownership applications at different risk levels under the **Owner Application Validation** checkpoint and the data that is involved in the application has no owner.
[Owner-application] default approval template (when the resource has an Owner)	By default, this approval template takes effect if you do not set different approval processes for data ownership applications at different risk levels under the **Owner Application Validation** checkpoint and the data that is involved in the application has one or more owners.

Supported checkpoints

When a user submits a ticket to apply for permissions, DMS checks whether the ticket conforms to rules that are specified under checkpoints. The ticket can be submitted only after DMS determines that the ticket conforms to all rules that are specified under checkpoints.

> **Note** Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description
Owner Application Validation	Allows you to set approval processes or constraints for **Instance-OWNER**, **Table-OWNER**, and **Database-OWNER** tickets.
Validation for Instance Permission Application	Allows you to set approval processes or constraints for **Instance-Performance** and **Instance-Login** tickets.
Database Permission Application Validation	Allows you to set approval processes or constraints for **Database-Permission** tickets.
Table Permission Application Validation	Allows you to set approval processes or constraints for **Table-Permission** tickets.
Programmable object verification	Allows you to set approval processes or constraints for **Programmable Object** tickets.
Sensitive Field Application Validation	Allows you to set approval processes or constraints for **Sensitive Column-Permission** tickets.
Line permission application verification	Allows you to set approval processes or constraints for **Row-Permission** tickets.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and database names. A factor name starts with the prefix `@fac.`. The following table describes the supported factors on the Access apply tab.

Factor	Description
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.schema_name	The name of the database.
@fac.perm_apply_duration	The period of time during which the applicant needs the permission. Unit: hours.
@fac.column_security_level	The security level of the field. Valid values: • *sensitive* • *confidential* • *inner*

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`. The following table describes the supported action on the Access apply tab.

Action	Description
@act.forbid_submit_order	Forbids a ticket from being submitted.
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	
@act.choose_approve_template_with_reason	

15.11.9.8. Data export

DMS allows you to manage security rules on the Data Export tab to validate the permissions of applicants on involved databases, tables, sensitive fields, and rows during the submission and approval of data export tickets. This helps ensure data security.

Basic configuration items

Data export default approval Template: the default approval template that takes effect if you do not set different approval processes for data export tickets at different risk levels under the Approval Rule Validation checkpoint. In the Switch Approval Template dialog box, you can change the approval process of the default approval template. For more information, see Customize approval processes.

Supported checkpoints

Note Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description
Pre-check Validation	Allows you to specify whether to validate the permissions of applicants on involved databases, tables, sensitive fields, and rows by configuring security rules.
Approval Rule Validation	Allows you to submit data export tickets to different approval processes by configuring security rules. For example, you can submit tickets for exporting more than a specific number of rows to an approval process and other tickets to another approval process.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`. The following table describes the supported factors on the Data Export tab.

Factor	Description
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.is_ignore_export_rows_check	A Boolean value that indicates whether to skip the check on the number of rows to be affected.
@fac.export_rows	The number of rows to be exported.
@fac.include_sec_columns	A Boolean value that indicates whether the data to be exported contains sensitive fields.

Factor	Description
@fac.sec_columns_list	The sensitive fields that require or do not require approval before data is exported. The sensitive fields are displayed in the format of `Table name.Field name,[Table name.Field name, ...]`.
@fac.user_is_admin	A Boolean value that indicates whether the applicant is a DMS administrator.
@fac.user_is_dba	A Boolean value that indicates whether the applicant is a DBA.
@fac.user_is_inst_dba	A Boolean value that indicates whether the applicant is the DBA of the current instance.
@fac.user_is_sec_admin	A Boolean value that indicates whether the applicant is a security administrator.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`. The following table describes the supported actions on the Data Export tab.

Action	Description
@act.do_not_approve	Allows a ticket to be processed without approval.
@act.choose_approve_template	Specifies an approval template.
@act.choose_approve_template_with_reason	Specifies an approval template with a reason provided.
@act.forbid_submit_order	Forbids a ticket from being submitted.
@act.enable_check_permission	Validates the permissions of an applicant on involved databases and tables.
@act.disable_check_permission	Does not validate the permissions of an applicant on involved databases and tables.
@act.enable_check_sec_column	Validates the permissions of an applicant on involved sensitive fields.
@act.disable_check_sec_column	Does not validate the permissions of an applicant on involved sensitive fields.

15.11.9.9. Schema design

DMS allows you to configure security rules on the Schema Design tab to check the design rules and risk identification rules that apply to schema design tickets. This helps ensure data security.

Basic configuration items

Configuration item	Description
Enable non-peer Publishing	Specifies whether to enable non-peer publishing. By default, data changes to a table can be published only to a table with the same name in another database. After you enable non-peer publishing, you can perform data changes on all tables. **Warning** This feature may bring high risks. We recommend that you proceed with caution and enable this feature only for special requirements.
R & D process	The whole process of a schema design ticket. It is the most important configuration item on the Schema Design tab. For more information about the parameters of the configuration item, see Parameters involved in the R&D process.
Field type configuration	The supported data types of fields to be added.
Index type configuration	The supported data types of indexes to be added.
It is forbidden to modify the original field data type	Specifies whether to prohibit the data types of the original fields from being modified when the original table is to be modified.
Prohibit deleting original fields	Specifies whether to prohibit the existing fields from being deleted when the original table is to be modified. **Note** We recommend that you enable this feature because deleting existing fields may bring high risks.
Prohibit renaming original fields	Specifies whether to prohibit the existing fields from being renamed when the original table is to be modified. **Note** We recommend that you enable this feature because reaming existing fields may bring high risks.
Table character set license configuration	The range of character sets that are allowed to be used when you create a table. For example, you can specify utf8 and utf8mb4.
Default approval template for Structural design	The default approval template that is used for a schema design ticket if you do not configure the Approval Rule Validation checkpoint. In the Switch Approval Template dialog box, you can change the approval process of the default approval template.
When published, the ticket will automatically advance to the end state	The point that is used to stop the schema change process. If you enable this feature, after the node that is set as the anchor in the R&D process is run, DMS automatically turns the ticket to the Finished state. **Note** To use this feature, you must set the last node in the R&D process as the anchor.

Supported checkpoints

> **Note** Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

The Schema Design tab contains the following two processes:

- Process of saving changes: DMS provides the following three checkpoints for this process. The checkpoints validate the table headings, fields, and indexes.
  - **Save Changes and Validate Header**
  - **Save Changes and Validate Field**
  - **Save Changes and Validate Index**
- Process of applying changes: DMS provides the following five checkpoints for this process. The first four checkpoints identify the risks that arise from changing schemas without locking tables, and the last checkpoint assigns an approval process to each type of risk.
  - **Table Creation Risk Control**
  - **Field Change Risk Control**
  - **Index Change Risk Control**
  - **SQL Execution Risk Control**
  - **Approval Rule Validation**

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`. The following table describes the supported factors on the Schema Design tab.

Factor	Description
@fac.table_kind	The type of the table whose schema is to be changed. Valid values: • *new*: a newly created table. • *old*: an existing table.
@fac.column_kind	The type of the field to be changed. Valid values: • *new*: a newly created field. • *old*: an existing field.
@fac.xxxx_old	The value of an existing field or index that is used for comparison.
@fac.column_is_primary	A Boolean value that indicates whether the current field serves as a primary key. Valid values: *true* and *false*.
@fac.column_type_support_default	A Boolean value that indicates whether the data type of the current field supports a default value. Valid values: *true* and *false*. **Note** For example, a field of the CHAR type supports a default value, whereas a field of the TEXT type does not.
@fac.index_kind	The type of the index to be changed. Valid values: • *new*: a newly created index. • *old*: an existing index.
@fac.index_column_count	The number of fields in the index.

Factor	Description
@fac.change_type	The type of the schema change to be performed by DDL statements. Valid values: • *add*: adds one or more fields or indexes. • *modify*: modifies one or more fields or indexes. • *delete*: deletes one or more fields or indexes.
@fac.altered_table_size	The size of the table whose schema is to be changed. Unit: MB.
@fac.online_execute	A Boolean value that indicates whether the schema change can be performed in an online environment. Valid values: *true* and *false*.
@fac.change_risk_level	The risk level of the schema change. Valid values: • *high*: a high risk level. • *middle*: a medium risk level. • *low*: a low risk level.
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`.The following table describes the supported actions on the Schema Design tab.

Action	Description	Format
@act.block_submit	Blocks the submission of the schema change and displays the error message. This action can be used in the process of saving changes.	@act.block_submit 'Reason for blocking the submission'
@act.show_warning	Displays the error message without blocking the submission of the schema change. This action can be used in the process of saving changes.	@act.show_warning 'Error message'
@act.mark_middle_risk	Specifies that the schema change is at medium risk. This action can be used in the process of identifying the risk level.	@act.mark_middle_risk 'Reason for the identification'
@act.mark_high_risk	Specifies that the schema change is at high risk. This action can be used in the process of identifying the risk level.	@act.mark_high_risk 'Reason for the identification'
@act.forbid_submit_publish	Rejects the ticket. This action can be used in the process of setting the approval process.	@act.forbid_submit_publish 'Reason for the rejection'
@act.do_not_approve		
@act.choose_approve_template	Specifies the ID of an approval	

Action	Description	Format
@act.choose_approve_template_with_reason	Specifies the ID of an approval template.	N/A

Parameters involved in the R&D process

Parameter	Description
Step	• The type of the node. Valid values: • **Design**: The design node in the R&D process is generated by default and cannot be removed. It determines the environment where the schema change is designed. • **Publish**: A publish node in the R&D process is used to publish the schema change after the change is designed. You can set multiple publish nodes.
Node Name	The name of the node. The node name can be up to 10 characters in length.
Database Environment	The environment where the node is run.
Execution Strategy	• The way in which the node is run. Valid values: • **Immediately**: The node is run immediately after it is approved. • **Periodically**: The node is run at the time that you specify. **Note** If a node is approved before the specified point in time, it is run as scheduled. Otherwise, the node is interrupted and not run.
Can Go Back	Specifies whether a publish node can be rolled back to the design node.
Can Skip	Specifies whether the current node can be skipped.
Anchor	The point that is used to stop the schema change process. If you set a node as the anchor, after the node is published, the nodes that follow the anchor cannot be run and the schema change process ends. At this time, the ticket enters the Published state.
Actions	The operation that you can perform on a publish node. You can remove a publish node as required.

15.11.9.10. Database and table synchronization

DMS allows you to configure security rules on the Table Sync tab to validate operations that are related to schema synchronization, empty database initialization, and table consistency repair.

Basic configuration items

Configuration item	Description
Enable execution capability	Specifies whether to enable SQL-based synchronization. If this configuration item is set to OFF, applicants can compare table schemas but cannot execute SQL statements to synchronize databases and tables. Other configuration items and security rules you set under checkpoints on the Table Sync tab also become invalid.
Database table synchronization default approval Template	The default approval template for database and table synchronization applications. You can use the default approval template or click Switch Approval Template and select another template. For more information, see Customize approval processes.

Configuration item	Description
Analysis phase script Expiration Time (unit: hours)	The timeout period of the analysis phase. You can set an appropriate timeout period in which synchronization can be canceled if schemas are changed in the destination database.

Supported checkpoints

The Table Sync tab contains three checkpoints that are corresponding to the three features that are supported by the tab. The three checkpoints are unrelated to each other. For example, when you submit a Schema Synchronization ticket, only the basic configuration items and the security rules that are specified under the Schema Synchronization Validation checkpoint are used to validate the ticket.

Note Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Checkpoint	Description
Schema Synchronization Validation	Allows you to set approval processes or constraints for Schema Synchronization tickets.
Empty Database Initialization Validation	Allows you to set approval processes or constraints for Empty Database Initialization tickets.
Table Consistency Repair Validation	Allows you to set approval processes or constraints for Repair Table Consistency tickets.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`. The following table describes the supported factors on the Table Sync tab.

Factor	Description
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.schema_name	The name of the schema.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`. The following table describes the supported actions on the Table Sync tab.

Action	Description
@act.forbid_submit_order	Forbids a ticket from being submitted. The statement is in the following format: `@act.forbid_submit_order 'Reason for forbidding the submission of the ticket'`.
@act.do_not_approve	
@act.choose_approve_template	Specifies the ID of an approval template.

Action	Description
@act.choose_approve_template_with_reason	

15.11.9.11. Sensitive field change

The topic describes the security rules on the Sensitive Column Change tab.

Basic configuration items

Sensitive column default approval Template: the default approval template that takes effect if you do not set approval processes for tickets that apply to change the security levels of sensitive fields under the Approval Rule Validation checkpoint. In the Switch Approval Template dialog box, you can change the approval process of the default approval template.

Supported checkpoints

Approval Rule Validation: When a user submits a ticket to change the security level of a sensitive field, DMS checks whether the ticket conforms to the rules that are specified under the Approval Rule Validation checkpoint.

> **Note** Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.` .The following table describes the supported factors on the Sensitive Column Change tab.

Factor	Description

@fac.column_level_change_type	The type of security level change that the applicant wants to perform on a sensitive field. Valid values:
	• *upper*: raises the current security level, including the following three cases:
	  ◦ From inner to sensitive
	  ◦ From inner to confidential
	  ◦ From sensitive to confidential
	• *sensitive_to_inner*: lowers the security level from sensitive to inner.
	• *confidential_to_sensitive*: lowers the security level from confidential to sensitive.
	• *confidential_to_inner*: lowers the security level from confidential to inner.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.` .The following table describes the supported actions on the Sensitive Column Change tab.

Action	Description
@act.forbid_submit_order	Forbids a ticket from being submitted. The statement is in the following format: `@act.forbid_submit_order 'Reason for forbidding the submission of the ticket'` .

Action	Description
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	
@act.choose_approve_template_with_reason	

15.11.9.12. Test data generation

This topic describes the security rules on the Test Data Generate tab.

Supported checkpoints

Approval rule validation: When a user submits a ticket to generate test data, DMS checks whether the ticket conforms to the rules that are specified under the Approval rule validation checkpoint.

> **Note** Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Supported factors

A factor is a built-in variable in DMS. You can use factors to obtain the context to be validated by security rules, such as SQL statement categories and the number of rows to be affected. A factor name starts with the prefix `@fac.`. The following table describes the supported factors on the Test Data Generate tab.

Factor	Description
@fac.env_type	The type of the environment. The value is the display name of the environment type, such as DEV or PRODUCT.
@fac.schema_name	The name of the schema.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.`. The following table describes the supported actions on the Test Data Generate tab.

Action	Description
@act.forbid_submit_order	Forbids a ticket from being submitted. The statement is in the following format: `@act.forbid_submit_order 'Reason for forbidding the submission of the ticket'`.
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	
@act.choose_approve_template_with_reason	

15.11.9.13. Database cloning

This topic describes the security rules on the Database Clone tab.

Basic configuration items

Database clone default approval Template: the default approval template that takes effect if you do not set approval processes for database clone tickets under the Approval rule validation checkpoint. In the Switch Approval Template dialog box, you can change the approval process of the default approval template.

Supported checkpoints

Approval rule validation: When a user submits a database clone ticket, DMS checks whether the ticket conforms to the rules that are specified under the Approval rule validation checkpoint.

> **Note** Various security rule templates are built in each checkpoint. You can configure security rules based on these templates or create custom security rules as needed.

Supported actions

An action in a security rule is an operation that DMS performs when the if condition in the rule is met. For example, DMS can forbid the submission of a ticket, approve a ticket, or reject a ticket. An action in a security rule denotes the purpose of the security rule. An action name starts with the prefix `@act.` .The following table describes the supported actions on the Database Clone tab.

Action	Description
@act.forbid_submit_order	Forbids a ticket from being submitted. The statement is in the following format: `@act.forbid_submit_order 'Reason for forbidding the submission of the ticket'` .
@act.do_not_approve	Specifies the ID of an approval template.
@act.choose_approve_template	
@act.choose_approve_template_with_reason	

16.Server Load Balancer (SLB)

16.1. What is SLB?

This topic provides an overview of Server Load Balancer (SLB). SLB distributes inbound network traffic across multiple Elastic Compute Service (ECS) instances that act as backend servers based on forwarding rules. You can use SLB to improve the responsiveness and availability of your applications.

Overview

After you add ECS instances that are deployed in the same region to a SLB instance, SLB uses virtual IP addresses (VIPs) to virtualize these ECS instances into backend servers in a high-performance server pool that ensures high availability. Client requests are distributed to the ECS instances based on forwarding rules.

SLB checks the health status of the ECS instances and automatically removes unhealthy ones from the server pool to eliminate single points of failure (SPOFs). This enhances the resilience of your applications.

Components

SLB consists of three components:

- SLB instances

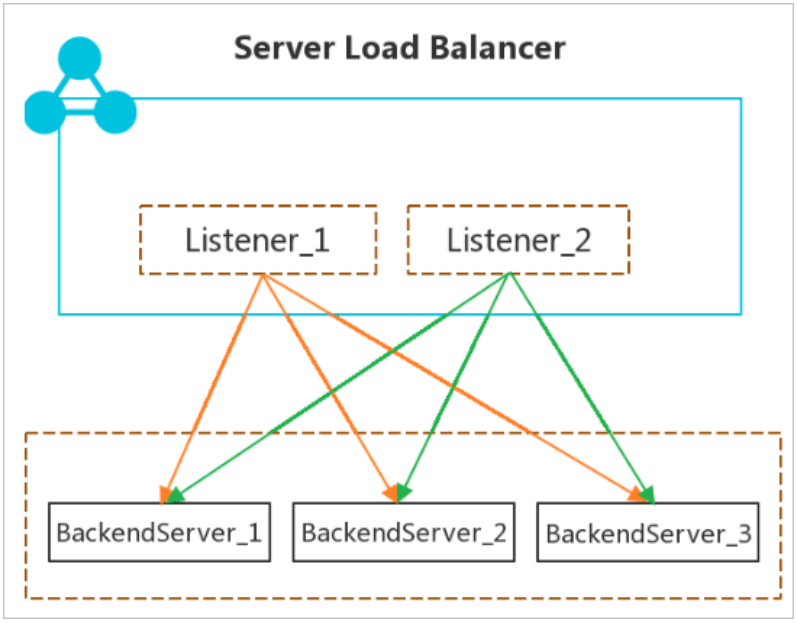
  A SLB instance is a running SLB service entity that receives traffic and distributes traffic to backend servers. To get started with SLB, you must create a SLB instance and add at least one listener and two ECS instances to the SLB instance.

- Listeners

  A listener checks client requests and forwards them to backend servers. It also performs health checks on backend servers.

- Backend servers

  ECS instances are used as backend servers to receive distributed requests. You can separately add ECS instances to the server pool, or use vServer groups or primary/secondary server groups to add and manage ECS instances in batches.



Benefits

- High availability

SLB is designed with full redundancy that avoids SPOFs and supports zone-disaster recovery.

SLB can be scaled based on application loads and can provide continuous service during traffic fluctuations.

- High scalability

  You can increase or decrease the number of backend servers to adjust the load balancing capability of your applications.

- Cost-effectiveness

  SLB can save 60% of load balancing costs compared with using traditional hardware solutions.

- Security

  You can use SLB with Apsara Stack Security to defend your applications against up to 5 Gbit/s DDoS attacks.

- High concurrency

  A SLB cluster supports hundreds of millions of concurrent connections and a single SLB instance supports tens of millions of concurrent connections.

16.2. Log on to the SLB console

This topic describes how to go to the Server Load Balancer (SLB) console after you log on to the Apsara Uni-manager Management Console by using the Chrome browser.

Prerequisites

- The domain name of the Apsara Uni-manager Management Console is obtained from the engineer that deploys the service before you log on to the Apsara Uni-manager Management Console.
- We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, choose **Products > Networking > Server Load Balancer**.

16.3. Quick start

16.3.1. Overview

This topic describes how to create an Internet SLB instance and forward client requests to two ECS instances that act as backend servers.

> **Note** Before you create an SLB instance, you must plan its configurations such as the instance type, region, and billing method. For more information, see Make preparations.

Perform the following operations:

1. Create a CLB instance

   Create an SLB instance. An SLB instance is an entity running the SLB service.

2. Add listeners and backend servers

   After you create an SLB instance, you must add listeners and backend servers.

3. Release an SLB instance

   If an SLB instance is no longer needed, delete the instance to avoid extra fees.

16.3.2. Make preparations

This topic describes the considerations for configuring a Server Load Balancer (SLB) instance. Before you create an SLB instance, you must determine the listener type and network type of the SLB instance.

Select the region of the SLB instance

When you select a region, take note of the following issues:

- To reduce latency and increase the download speed, we recommend that you select a region that is closest to your customers.
- To provide more stable and reliable load balancing services, SLB supports primary/secondary zone deployment in most regions. This implements disaster recovery across data centers in the same region. We recommend that you select a region that supports primary/secondary zone deployment.
- SLB does not support cross-region deployment. Therefore, you must deploy the SLB instance and backend Elastic Compute Service (ECS) instances in the same region.

Select the network type of the SLB instance (Internet-facing or internal-facing)

SLB provides load balancing services for the public network and internal network:

- If you want to use SLB to distribute requests from the Internet, create an Internet-facing SLB instance.

  An Internet-facing SLB instance is assigned a public IP address to receive requests from the Internet.

- If you want to use SLB to distribute requests from the internal network, create an internal-facing SLB instance.

  An internal-facing SLB instance is assigned a private IP address and is only accessible from the internal network.

Select an instance type

Apsara Stack released guaranteed-performance SLB instances on April 1, 2018. When you create an SLB instance, you can choose a guaranteed-performance instance that provides exclusive resources and higher service availability. SLB provides six types of instances:

- For a pay-as-you-go instance, we recommend that you select the instance type that provides the highest specifications. This guarantees flexible load balancing services at no extra costs. However, if the capacity of Super I (slb.s3.large), the highest-performance instance type, far exceeds the demand of your business, you can select a more appropriate type such as Higher II (slb.s3.medium).

Select a listener protocol

SLB supports Layer 4 (TCP and UDP) and Layer 7 (HTTP and HTTPS) load balancing:

- A Layer 4 listener directly distributes requests to backend servers without modifying packet headers. After a client request reaches a Layer 4 listener, SLB uses the backend port that is configured for the listener to establish

a TCP connection with a backend ECS instance.

- A Layer 7 listener functions as a reverse proxy. After a client request reaches a Layer 7 listener, SLB establishes a new TCP connection over HTTP with a backend server, instead of directly forwarding the request to the backend server (ECS instance).

  Compared with Layer 4 listeners, Layer 7 listeners require an additional step of Tengine processing. Therefore, Layer 4 listeners provide better performance than Layer 7 listeners. In addition, the performance of Layer 7 listeners may be affected by factors such as insufficient client ports or excessive backend server connections. We recommend that you use Layer 4 listeners for high performance purposes.

Create backend servers

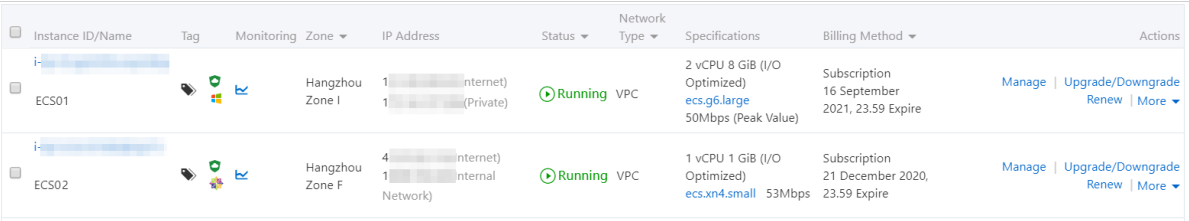
Before you use the SLB service, you must create ECS instances, deploy applications on the ECS instances, and then add the ECS instances to your SLB instance to process client requests.

When you create and configure an ECS instance, take note of the following issues:

- Region and zones of the ECS instance

  Make sure that the ECS instance is deployed in the same region as the SLB instance. We recommend that you deploy ECS instances in different zones to improve availability.

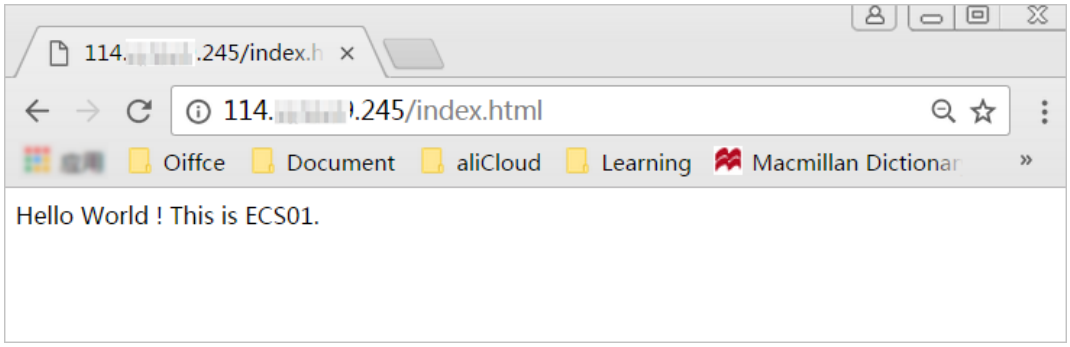
  In this example, two ECS instances named ECS01 and ECS02 are created in the **China (Hangzhou)** region. The following figure shows their basic configurations.



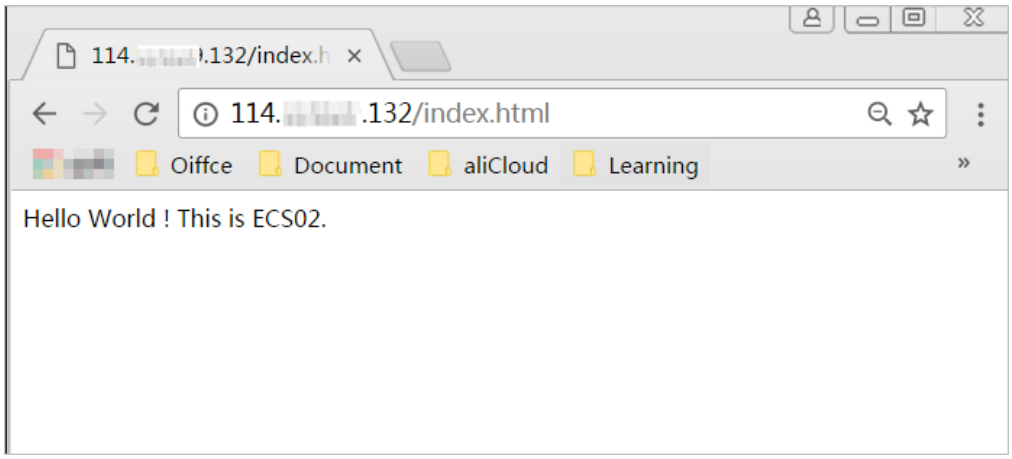
- Configurations

  In this example, two static web pages are hosted on ECS01 and ECS02 by using Apache.

  - Enter the elastic IP address (EIP) that is associated with ECS01 in the address bar of your browser.



- Enter the EIP that is associated with ECS02 in the address bar of your browser.



No additional configurations are required after you deploy applications on the ECS instances. However, if you want to use a Layer 4 (TCP or UDP) listener and the ECS instances run Linux, make sure that the following parameters in the *net.ipv4.conf* file under */etc/sysctl.conf* are set to 0:

```
net.ipv4.conf.default.rp_filter = 0
net.ipv4.conf.all.rp_filter = 0
net.ipv4.conf.eth0.rp_filter = 0
```

16.3.3. Create an SLB instance

This topic describes how to create a Server Load Balancer (SLB) instance. An SLB instance is a running entity of the SLB service. You can add multiple listeners and backend servers to an SLB instance.

Prerequisites

- Elastic Compute Service (ECS) instances are created and applications are deployed on the ECS instances.
- The ECS instances and the SLB instance belong to the same organization. In addition, the security group rules configured for the ECS instances allow access from port 80 (HTTP) and port 443 (HTTPS).

Procedure

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Instances**.
3. On the **Instances** page, click **Create Instance**.
4. Configure the SLB instance and click **Submit**.

Parameter	Description
Organization	Select the organization to which the SLB instance belongs. **Note** Make sure that the SLB instance and its backend servers belong to the same organization.
Resource Set	Select the resource group to which the SLB instance belongs.
Region	Select the region where you want to deploy the SLB instance.
Zone	Select the zone where you want to deploy the SLB instance.

Parameter	Description
Quantity	Select the number of SLB instances that you want to purchase.
Instance Name	Enter a name for the SLB instance. If you set Quantity to a value greater than 1, the system automatically assigns names to the SLB instances.
Instance Edition	Select one of the following options: ○ **Shared-resource**: Shared-resource SLB instances share resources with each other. The performance of shared-resource SLB instances is not guaranteed. ○ **High-performance**: High-performance SLB instances use exclusive resources. The performance of high-performance SLB instances varies by specification.
Instance Type	Select the type of network traffic that you want to distribute. Valid values: Internal Network and Internet. Internal Network is selected in this example.
Network Type	Select the network type of the SLB instance. Valid values: Classic Network and VPC. VPC is selected in this example.
IP Version	Select an IP version.
VPC	Select a virtual private cloud (VPC).
vSwitch	Select a vSwitch.
Billing Method	Set the billing method.

What's next

Configure an SLB instance

16.3.4. Configure an SLB instance

This topic describes how to configure a Server Load Balancer (SLB) instance. Before an SLB instance can forward traffic, you must add at least one listener and one group of backend servers to the SLB instance. The following example shows how to add a TCP listener and Elastic Compute Service (ECS) instances to an SLB instance. The ECS instances are ECS 01 and ECS 02. These ECS instances function as backend servers that host static web pages.

Procedure

1. Log on to the SLB console.
2. On the **Instances** page, find the SLB instance that you want to manage and click **Configure Listener** in the Actions column.
3. On the **Protocol and Listener** wizard page, set the following parameters to configure the listener. Use the default settings for other parameters. Click **Next**.
   - **Select Listener Protocol**: Select a listener protocol. **TCP** is selected in this example.
   - **Listening Port**: Specify a frontend port to receive and distribute requests to backend servers. In this example, the port is set to **80**.

     The SLB instance uses this port to provide external services. In most cases, port 80 is set for HTTP listeners and port 443 is set for HTTPS listeners.

   Advanced:

- **Enable Peak Bandwidth Limit**: Applications that run on backend ECS instances provide external services. You can set bandwidth caps to limit service capabilities of applications.
- **Scheduling Algorithm**: SLB supports the following scheduling algorithms. **Round-Robin (RR)** is selected in this example.
  - **Weighted Round-Robin (WRR)**: Requests are distributed to backend servers in sequence. Backend servers that have higher weights receive more requests.
  - **Round-Robin (RR)**: Requests are distributed to backend servers in sequence.
  - **Consistent Hash (CH)**: Only high-performance SLB instances support the CH algorithm.
    - **Source IP**: specifies consistent hashing that is based on source IP addresses. Requests from the same source IP address are distributed to the same backend server.
    - **Tuple**: specifies consistent hashing that is based on four factors: source IP address, destination IP address, source port number, and destination port number. Requests that contain the same information based on the four factors are distributed to the same backend server.

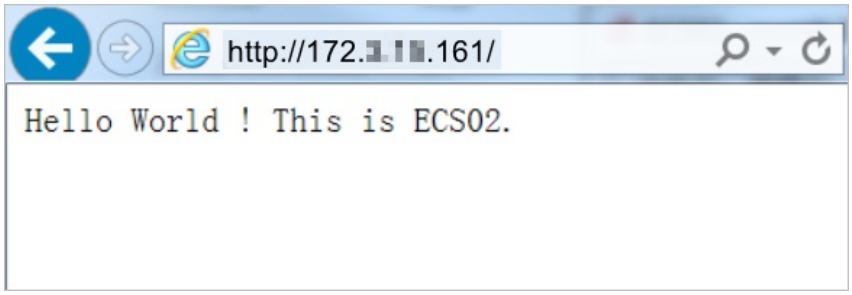
4. On the **Backend Servers** wizard page, select **Default Server Group** and click **Add More** to add backend servers.
   i. In the **Available Servers** panel, select ECS 01 and ECS 02 and click **Next**.
   ii. A backend server that has a higher weight receives more requests. The default value is 100. We recommend that you use the default value.
   iii. Click **Add**.
   iv. On the **Default Server Group** tab, specify backend ports that are available to receive requests. The ports are used by backend ECS instances to receive requests. You can specify the same port for multiple backend servers that are added to the same SLB instance. The port is set to 80 in this example.
5. Click **Next** to configure the health check feature. The default health check settings are used in this example.

   After you enable health checks for the SLB instance, the SLB instance periodically checks whether the backend ECS instances are healthy. When the SLB instance detects an unhealthy ECS instance, the SLB instance distributes the requests to other healthy ECS instances. When the unhealthy ECS instance recovers, the SLB instance starts to distribute requests to the ECS instance again.
6. Click **Next**. On the **Confirm** wizard page, check the configurations and click **Submit**.
7. Click **OK** to go back to the **Instances** page and click  to refresh the page.

   If the health check state of a backend ECS instance is **Active**, this indicates that the backend server works as expected and can process requests.
8. Enter the IP address of the SLB instance into the address bar of the browser to test load balancing services of the instance.

   ECS01

   
   ECS02



16.3.5. Release an SLB instance

If an SLB instance is no longer needed, you can release the instance to save costs. The backend ECS instances will not be deleted or affected after you delete an SLB instance.

Procedure

1. Log on to the SLB console.
2. On the **Instances** page, find the instance and click > **Release** in the Actions column, or select the instance and click **Release** at the lower part of the page.
3. In the **Release** dialog box, select **Release Now**.

   > **Note** The system performs release operations at 30-minute and hour marks. However, billing for the SLB instance is stopped at the specified release time.

4. Click **Next**.
5. Click **OK** to release the SLB instance.

   > **Note** Pay-as-you-go SLB instances cannot be restored once deleted. We recommend that you exercise caution when you release SLB instances.

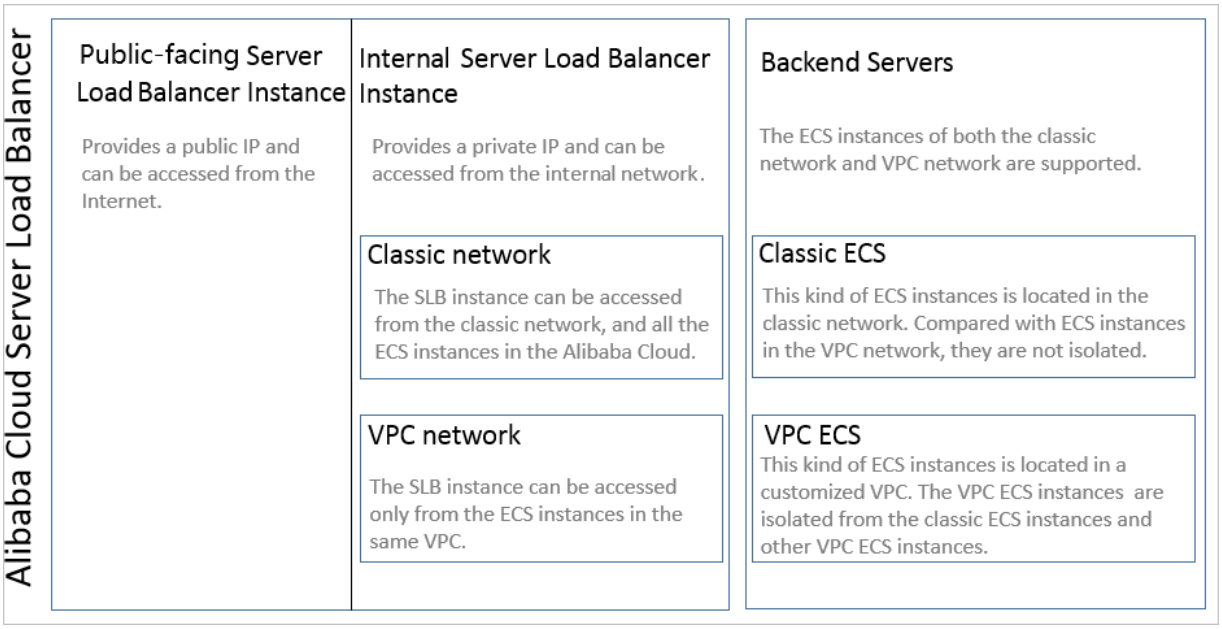
16.4. SLB instances

16.4.1. SLB instance overview

A Server Load Balancer (SLB) instance is a running entity of the SLB service. To use the SLB service, you must create an SLB instance and add listeners and backend servers to the instance.

Instance network types

Apsara Stack provides Internet-facing and internal-facing SLB instances. You can create Internet-facing SLB instances or internal-facing SLB instances based on your business requirements. If you create an Internet-facing SLB instance, a public IP address is allocated. If you create an internal-facing SLB instance, a private IP address is allocated.



- Internet-facing SLB instances

  An Internet-facing SLB instance distributes client requests over the Internet to backend servers based on configured forwarding rules. An internal-facing SLB instance in a virtual private cloud (VPC) can process requests sent over the Internet only when the instance is associated with an elastic IP address (EIP). The following table provides more detailed information.

Type	Feature
Internet-facing SLB instances After you create an Internet-facing SLB instance, the system allocates a public IP address to the instance. You can bind a domain name to the public IP address to provide external services.	◦ The public IP address is allocated to the SLB instance and cannot be unbound from the instance. ◦ Internet-facing SLB instances support only pay-by-data-transfer and pay-by-bandwidth billing methods.
Internal-facing SLB instances that are associated with EIPs An internal-facing SLB instance that is associated with an EIP can process requests sent over the Internet.	◦ A public IP address is allocated to the EIP. You can associate the EIP with the SLB instance and disassociate the EIP from the SLB instance based on your requirements. ◦ An EIP that is associated with an EIP bandwidth plan supports the 95th percentile bandwidth billing method.

- Internal-facing SLB instances

  Internal-facing SLB instances can be used only inside Apsara Stack and can forward only requests from clients that can access SLB instances over the internal network.

  You can select one of the following network types for an internal-facing SLB instance:

- Classic network

  If you choose classic network for an internal-facing SLB instance, the IP address of the SLB instance is allocated and maintained by Apsara Stack. This instance can be accessed only by Elastic Compute Service (ECS) instances in the classic network.

- VPC

  If you choose VPC for an internal-facing SLB instance, the IP address of the SLB instance is allocated from the CIDR block of the vSwitch that is attached to the VPC. This SLB instance can be accessed only by ECS instances in the VPC.

Instance types and specifications

Alibaba Cloud provides shared-performance SLB instances and guaranteed-performance SLB instances. Guaranteed-performance SLB instances provide reliable performance metrics.

- Shared-performance SLB instances

  All shared-performance SLB instances share SLB resources. This indicates that the instance performance cannot be guaranteed.

- Guaranteed-performance SLB instances

  The following content describes three key metrics of guaranteed-performance SLB instances:

  - Max Connection

    The maximum number of concurrent connections that an SLB instance supports. When the number of concurrent connections reaches the specified limit, new connection requests are dropped.

  - Connections Per Second (CPS)

    The number of new connections that are established per second. When the CPS value reaches the specified limit, new connection requests are dropped.

  - Queries Per Second (QPS)

    The number of HTTP or HTTPS queries (requests) that can be processed per second. This metric is specific to Layer 7 listeners. When the QPS value reaches the specified limit, new connection requests are dropped.

Apsara Stack provides four types of guaranteed-performance SLB instances.

Type	Specification	Max connection	CPS	QPS	Purchase method
Type 1	Small I (slb.s1.small)	5,000	3,000	1,000	Available for purchase from the official website of Apsara Stack.
Type 2	Standard I (slb.s2.small)	50,000	5,000	5,000	Available for purchase from the official website of Apsara Stack.
Type 3	Standard II (slb.s2.medium)	100,000	10,000	10,000	Available for purchase from the official website of Apsara Stack.

Type	Specification	Max connection	CPS	QPS	Purchase method
Type 4	Higher I (slb.s3.small)	200,000	20,000	20,000	Available for purchase from the official website of Apsara Stack.

The following table describes the differences between shared-performance SLB instances and guaranteed-performance SLB instances.

Feature	Shared-performance SLB instance	Guaranteed-performance SLB instance
Resource allocation	Shared resources	Exclusive resources
Service level agreement for guaranteed availability	Not supported	99.95%
IPv6	×	√
Server Name Indication (SNI) certificates	×	√
Support for blacklists and whitelists	×	√
Elastic network interface (ENI) mounting	×	√
Assignment of secondary IP addresses to ENIs that are bound to ECS instances	×	√
HTTP-to-HTTPS redirection	×	√
Consistent hashing	×	√
TLS security policies	×	√
HTTP2	×	√
Websocket(S)	×	√

16.4.2. Create an SLB instance

This topic describes how to create a Server Load Balancer (SLB) instance. An SLB instance is a running entity of the SLB service. You can add multiple listeners and backend servers to an SLB instance.

Prerequisites

- Elastic Compute Service (ECS) instances are created and applications are deployed on the ECS instances.
- The ECS instances and the SLB instance belong to the same organization. In addition, the security group rules of the ECS instances allow access from port 80 (HTTP) and port 443 (HTTPS).

Procedure

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Instances**.

3. On the **Instances** page, click **Create Instance**.
   - **Organization**: Select an organization for the SLB instance from the drop-down list.

     > **Note** Make sure that the organization of the SLB instance is the same as the organization of its backend servers.

   - **Resource Set**: Select a resource set for the SLB instance from the drop-down list.
   - **Region**: Select the region where you want to deploy the SLB instance.
   - **Zone**: Select a zone for the SLB instance from the drop-down list.
   - **Instance Name**: Enter a name for the SLB instance in the Instance Name field.

     The name must be 2 to 128 characters in length, and can contain letters, digits, full-width characters, hyphens (-), colons (:), periods (.), and underscores (_). Line breaks and spaces are supported. It must start with a letter and cannot start with `http://` or `https://`.
   - **Instance Edition**: Select one of the following options: shared-performance and guaranteed-performance. Shared-performance SLB instances share resources with each other. The performance of shared-performance SLB instances is not guaranteed. The performance of guaranteed-performance SLB instances varies by type.
   - **Instance Type**: Select the type of network traffic that you want to distribute. Valid values: Internal Network and Internet.
   - **Network Type**: Select the network type of the SLB instance. Valid values: Classic Network and VPC.
   - **IP Version**: Select an IP version.
   - **IP Address**: Enter a service IP address for the SLB instance. Make sure that the service IP address is valid. Otherwise, the SLB instance cannot be created. If you do not set this parameter, the system automatically allocates an IP address to the SLB instance.

     > **Note** The private IP address that you specify must belong to the destination CIDR block of the vSwitch.

4. Click **Submit**.

What's next

Configure a CLB instance

16.4.3. Start and stop an SLB instance

This topic describes how to start and stop an SLB instance. SLB instances can be started or stopped at any time. A stopped SLB instance does not receive or forward client traffic.

Procedure

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. Find the target SLB instance. In the **Actions** column, choose  **> Start** or  **> Stop**.
4. To start or stop multiple instances at a time, select the instances and click **Start** or **Stop** at the bottom of the page.

16.4.4. Tags

16.4.4.1. Tag overview

This topic provides an overview of tags in SLB. SLB provides the tag management feature that allows you to classify SLB instances by using tags.

Each tag consists of a key and a value. Before you use tags, note the following limits:

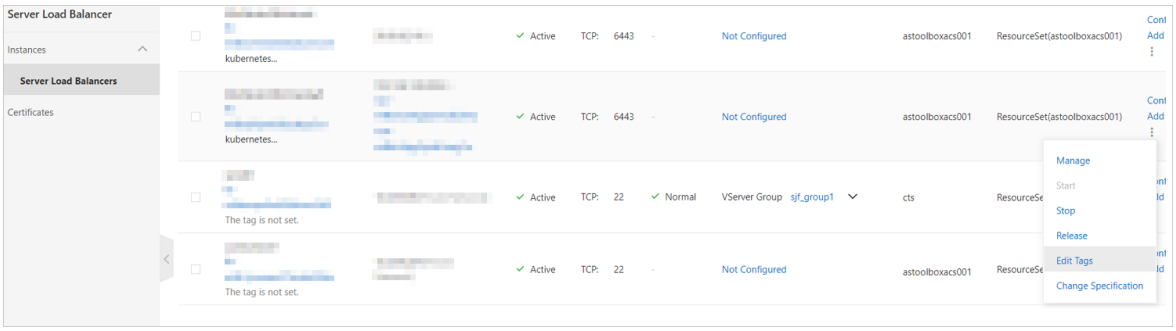
- Tags must be added to SLB instances.
- Each SLB instance can have a maximum of ten tags. You can add or remove a maximum of 5 tags at a time.
- The key of each tag added to an SLB instance must be unique. If a tag with the same key already exists, the tag is overwritten with the new value.

16.4.4.2. Add tags

This topic describes how to add tags to an SLB instance.

Procedure

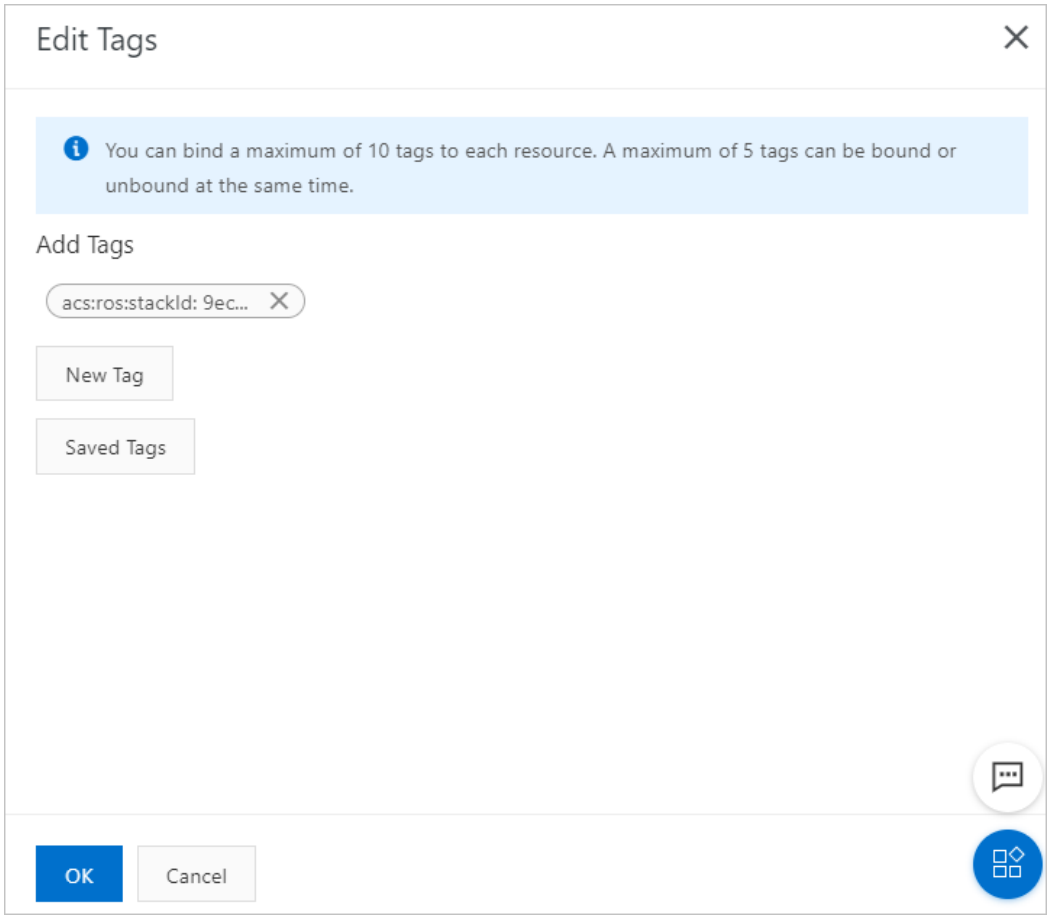
1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. In the **Actions** column, choose > **Edit Tags**.



4. Edit tags in the **Edit Tags** dialog box.

   To add a tag, perform the following operations:

   - To add an existing tag, click **Saved Tags** and then select a tag.
   - To create and add a new tag, click **New Tag** in the **Edit Tags** dialog box, enter the key and value of the new tag, and then click **OK** next to the value.



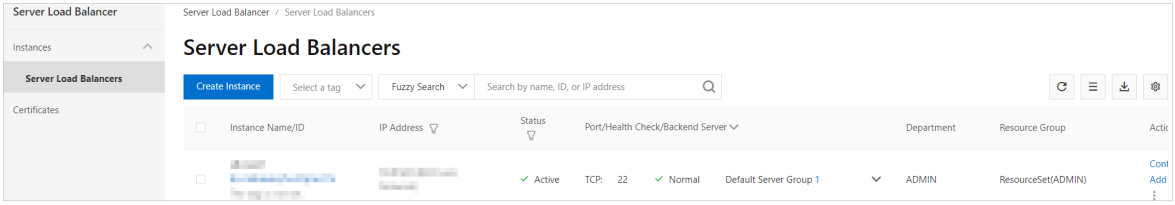
5. Click **OK**.

16.4.4.3. Query SLB instances by tag

This topic describes how to use tags to query SLB instances.

Procedure

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. Select a data from the **Select a tag** drip-down list to filter instances.



Note To clear the search condition, move the pointer over the selected tag and click the displayed deletion icon next to it.

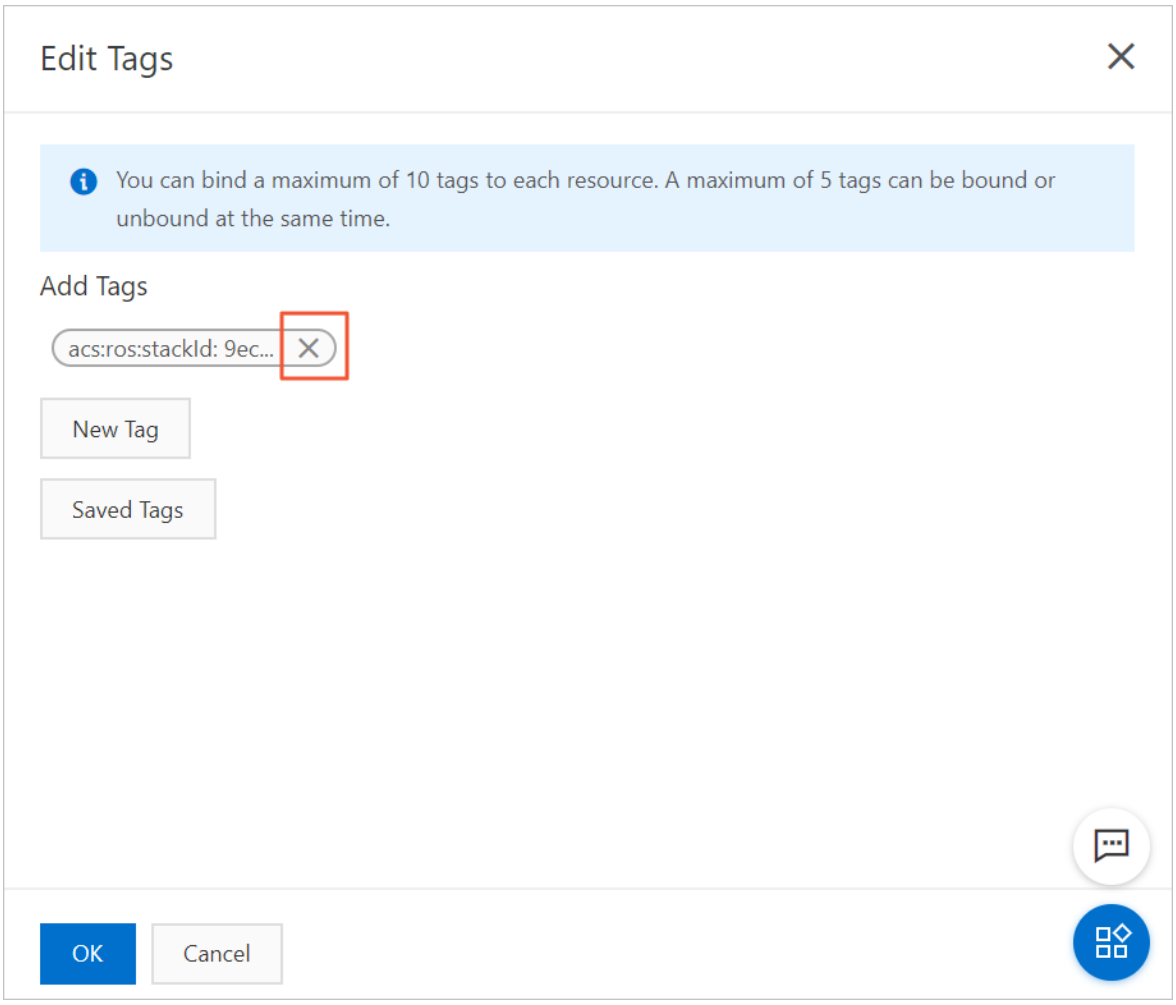
16.4.4.4. Remove a tag

This topic describes how to remove tags from a CLB instance. You can only remove tags for one CLB instance at a time.

Procedure

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. In the **Actions** column, choose ⋮ > **Edit Tags**.
4. In the **Edit Tags** dialog box, click the deletion icon next to the tags to be removed, and then click **OK**.

> **Note** If a tag is removed from a CLB instance and is not added to other instances, the tag is deleted from the system.



16.4.5. Release an SLB instance

This topic describes how to release an SLB instance. You can release SLB instances immediately.

Procedure

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Server Load Balancers**.
3. Find the target SLB instance and choose ⋮ > **Release**.
4. In the **Release** dialog box, select **Release Now**.
5. Click **Next**.

6. Confirm the displayed information and click **OK** to release the instance.

16.5. Listeners

16.5.1. Listener overview

This topic provides an overview of listeners. After you create a Server Load Balancer (SLB) instance, you must configure one or more listeners for it. A listener checks for connection requests and then distributes the requests to backend servers based on the forwarding rules that are defined by a specified scheduling algorithm.

SLB provides Layer 4 (TCP and UDP) and Layer 7 (HTTP and HTTPS) listeners. The following table lists the features and use cases of these listeners.

Protocol	Feature	Use case
TCP	• A connection-oriented protocol. A logical connection must be established before data can be sent and received. • Source IP address-based session persistence. • Source IP addresses readable at the network layer. • Fast data transmission	• Applicable to scenarios that require high reliability and data accuracy but can tolerate low speeds, such as file transmission, sending or receiving emails, and remote logons. • Web applications that do not have special requirements. For more information, see Add a TCP listener.
UDP	• A connectionless protocol. UDP transmits data packets directly instead of making a three-way handshake with the other party before UDP sends data. UDP does not provide error recovery or data re-transmission. • Fast data transmission but relatively low reliability.	Applicable to scenarios where real-time transmission is more important than reliability, such as video chats and real-time financial market pushes. For more information, see Add a UDP listener.
HTTP	• An application-layer protocol that is used to package data. • Cookie-based session persistence. • Use X-Forward-For to obtain source IP addresses.	Applicable to scenarios that require data content to be identified, such as web applications and small mobile games. For more information, see Add an HTTP listener.
HTTPS	• Encrypted data transmission that prevents unauthorized access. • Centralized certificate management service. You can upload certificates to SLB. The decryption operations are directly completed on SLB.	Applicable to scenarios that require encrypted transmission. For more information, see Add an HTTPS listener.

16.5.2. Add a TCP listener

This topic describes how to add a Transmission Control Protocol (TCP) listener to a Server Load Balancer (SLB) instance. TCP provides reliable and accurate data delivery at relatively low connection speeds. Therefore, TCP applies to file transmission, email sending or receiving, and remote logons. You can add a TCP listener to forward TCP requests.

Step 1: Open the listener configuration wizard

To open the listener configuration wizard, perform the following operations:

1. Log on to the SLB console.
2. In the left-side navigation pane, choose **Instances > Instances**.
3. Use one of the following methods to open the listener configuration wizard:
   - On the **Instances** page, find the SLB instance and click **Configure Listener** in the **Actions** column.
   - On the **Instances** page, click the ID of the SLB instance. On the **Listener** tab, click **Add Listener**.

Step 2: Configure the TCP listener

To configure the TCP listener, perform the following operations:

1. Set the following parameters and click **Next**.

Parameter	Description
Select Listener Protocol	Select the protocol of the listener. In this example, **TCP** is selected.
Listening Port	Specify the listening port that is used to receive requests and forward them to backend servers. Valid values: 1 to 65535.
Advanced	
Scheduling Algorithm	SLB supports the following scheduling algorithms: ○ **Weighted Round-Robin (WRR)**: Backend servers that have higher weights receive more requests than backend servers that have lower weights. ○ **Round-Robin (RR)**: Requests are distributed to backend servers in sequence. ○ **Consistent Hash (CH)**: ■ **Source IP**: specifies consistent hashing that is based on source IP addresses. Requests from the same source IP address are distributed to the same backend server. ■ **Tuple**: specifies consistent hashing that is based on four factors: source IP address, destination IP address, source port, and destination port. Requests that contain the same information based on the four factors are distributed to the same backend server. **Note** Only high-performance SLB instances support the CH algorithm.
Enable Session Persistence	Specify whether to enable session persistence. After session persistence is enabled, SLB forwards all requests from a client to the same backend server. For TCP listeners, session persistence is implemented based on IP addresses. Requests from the same IP address are forwarded to the same backend server.

Parameter	Description
Enable Peak Bandwidth Limit	Specify whether to set a bandwidth limit for the listener. If an SLB instance is billed based on bandwidth usage, you can set different bandwidth limit values for different listeners. This limits the amount of network traffic that flows through each listener. The sum of the bandwidth limit values of all listeners that are added to an SLB instance cannot exceed the bandwidth limit of this SLB instance. By default, this feature is disabled and all listeners share the bandwidth of the SLB instance.
Idle Timeout	Specify the timeout of idle TCP connections. Unit: seconds. Valid values: 10 to 900.
Obtain Client Source IP Address	Backend servers associated with Layer 4 listeners can obtain client IP addresses without additional configurations.
Automatically Enable Listener After Creation	Specify whether to immediately enable the listener after it is created. By default, this feature is enabled.

Step 3: Add backend servers

After you configure the listener, you must add backend servers to process client requests. You can use the default server group that is configured for the SLB instance, or create a vServer group or a primary/secondary server group. For more information, see Overview.

Backend servers are added to the default server group in this example.

1. On the **Backend Servers** wizard page, select **Default Server Group** and click **Add More**.
2. In the **My Servers** panel, select the ECS instances that you want to add as backend servers and click **Next**.
3. On the **Configure Ports and Weights** wizard page, specify the weights of the backend servers that you want to add. A backend server with a higher weight receives more requests.

   > **Note** If the weight of a backend server is set to 0, no request is distributed to the backend server.

4. Click **Add**. On the Default Server Group tab, specify the ports that you want to open on the backend servers to receive requests. The backend servers are the ECS instances that you selected. Valid values: 1 to 65535.

   You can specify the same port on different backend servers that are added to an SLB instance.

5. Click **Next**.

Step 4: Configure health checks

SLB performs health checks to check the availability of the ECS instances that serve as backend servers. The health check feature improves overall service availability and reduces the impact of backend server failures. Click **Modify** to configure advanced health check settings and click Next. For more information, see Health check overview.

Step 5: Submit the configurations

To submit the configurations, perform the following operations:

1. On the **Confirm** wizard page, check the configurations. You can click **Modify** to modify the configurations.
2. After you confirm the configurations, click **Submit**.
3. In the **Configuration Successful** message, click **OK**.

   After you configure the listener, you can view the listener on the Listener tab.

16.5.3. Add a UDP listener

This topic describes how to add a User Datagram Protocol (UDP) listener to a Server Load Balancer (SLB) instance. UDP applies to services that prioritize real-time content delivery over reliability, such as video conferencing and real-time quote services. You can add a UDP listener to forward UDP packets.

Context

Before you configure a UDP listener, take note of the following items:

- You are not allowed to specify ports 250, 4789, or 4790 for UDP listeners. They are system reserved ports.
- Fragmentation is not supported.
- You cannot view source IP addresses by using the UDP listeners of an SLB instance in the classic network.
- The following operations take effect 5 minutes after they are performed on a UDP listener:
  - Remove backend servers.
  - Set the weight of a backend server to 0 after it is detected unhealthy.

Step 2: Configure the UDP listener

To configure the listener, perform the following operations:

1. On the **Protocol and Listener** wizard page, set the following parameters and click **Next**.

Parameter	Description
Listener Protocol	Select a protocol for the listener. In this example, **UDP** is selected.
Listening Port	Set the listening port that is used to receive requests and forward them to backend servers. Valid values: 1 to 65535.
Advanced	

Parameter	Description
Scheduling Algorithm	SLB supports the following scheduling algorithms: ◦ **Weighted Round-Robin (WRR)**: Backend servers that have higher weights receive more requests than backend servers that have lower weights. ◦ **Round-Robin (RR)**: Requests are distributed to backend servers in sequence. ◦ **Consistent Hash (CH)**: ▪ **Source IP**: specifies consistent hashing that is based on source IP addresses. Requests from the same source IP address are distributed to the same backend server. ▪ **Tuple**: specifies consistent hashing that is based on four factors: source IP address, destination IP address, source port, and destination port. Requests that contain the same information based on the four factors are distributed to the same backend server. ▪ **QUIC ID**: specifies consistent hashing that is based on Quick UDP Internet Connections (QUIC) IDs. Requests that contain the same QUIC ID are distributed to the same backend server. **Notice** QUIC is implemented based on draft-ietf-quic-transport-10 and is rapidly evolving. Therefore, compatibility is not guaranteed for all QUIC versions. We recommend that you perform tests before you apply the protocol to a production environment.
Enable Session Persistence	Specify whether to enable session persistence. SLB maintains the persistence of UDP sessions by using consistent hashing that is based on source IP addresses.
Enable Peak Bandwidth Limit	Specify whether to set a bandwidth limit for the listener. If an SLB instance is billed based on bandwidth usage, you can specify different bandwidth limit values for different listeners. This limits the amount of network traffic that flows through each listener. The sum of the bandwidth limit values of all listeners that are added to an SLB instance cannot exceed the bandwidth limit of this SLB instance. By default, this feature is disabled and all listeners share the bandwidth of the SLB instance.
Obtain Client Source IP Address	Backend servers associated with UDP listeners can obtain client IP addresses without additional configurations. **Note** You cannot view source IP addresses by using the UDP listeners of an SLB instance in the classic network.
Automatically Enable Listener After Creation	Specify whether to immediately enable the listener after it is created. By default, this feature is enabled.

Step 3: Add backend servers

After you configure the listener, you must add backend servers to process client requests. You can use the default server group that is configured for the SLB instance, or create a vServer group or a primary/secondary server group. For more information, see Overview.

Backend servers are added to the default server group in this example.

1. On the **Backend Servers** wizard page, select **Default Server Group**. Then, click **Add More**.
2. In the **Available Servers** panel, select the Elastic Compute Service (ECS) instances that you want to add as backend servers and click **Next**.
3. Set weights for the backend servers that you add.

   An ECS instance with a higher weight receives more requests.

   > **Note** If the weight of a backend server is set to 0, no request is distributed to the backend server.

4. Click **Add**. On the Default Server Group tab, specify the ports that you want to open on the backend servers to receive requests. The backend servers are the ECS instances that you selected. Valid values: 1 to 65535.

   You can specify the same port on different backend servers that are added to an SLB instance.

5. Click **Next**.

Step 4: Configure health checks

SLB performs health checks to check the availability of the ECS instances that serve as backend servers. The health check feature improves overall service availability and reduces the impact of backend server failures. Click **Modify** to configure advanced health check settings and click Next. For more information, see Health check overview.

Step 5: Submit the configurations

To submit the configurations, perform the following operations:

1. On the **Confirm** wizard page, check the configurations. You can click **Modify** to modify the configurations.
2. After you confirm the configurations, click **Submit**.
3. In the **Configuration Successful** message, click **OK**.

   After you configure the listener, you can view the listener on the Listener tab.

16.5.4. Add an HTTP listener

This topic describes how to add an HTTP listener to a Server Load Balancer (SLB) instance. HTTP is applicable to applications that must identify data from different users, such as web applications and mobile games. You can add HTTP listeners to forward HTTP requests.

Step 1: Configure an HTTP listener

1. Log on to the SLB console.
2. Use one of the following methods to open the listener configuration wizard:
   - On the **Instances** page, find the SLB instance that you want to manage and click **Configure Listener** in the **Actions** column.
   - On the **Instances** page, click the ID of the SLB instance that you want to manage. On the **Listener** tab, click **Add Listener**.
3. Set the following parameters to configure the listener.

Parameter	Description
Listener Protocol	Select a protocol for the listener. In this example, **HTTP** is selected.

Parameter	Description
Listening Port	Specify the listening port that is used to receive requests and forward them to backend servers. Valid values: 1 to 65535.
Advanced	Click **Modify** to configure advanced settings.
Scheduling Algorithm	Select a scheduling algorithm. ○ **Weighted Round-Robin (WRR)**: Backend servers that have higher weights receive more requests than backend servers that have lower weights. ○ **Round-Robin (RR)**: Requests are distributed to backend servers in sequence.
Redirection	Specify whether to redirect traffic from the HTTP listener to an HTTPS listener. **Note** Before you enable redirection, make sure that an HTTPS listener is created.
Enable Session Persistence	Specify whether to enable session persistence. After session persistence is enabled, SLB forwards all requests from a client to the same backend server. HTTP session persistence is implemented through cookies. You can use one of the following methods to handle cookies: ○ **Insert cookie**: If you select this option, you need only to specify the timeout period of the cookie. SLB inserts a cookie (SERVERID) into the first HTTP or HTTPS response that is sent to a client. The next request from the client contains the cookie. Then, the listener distributes the request to the recorded backend server. ○ **Rewrite cookie**: If you select this option, you can specify the cookie that you want to insert into an HTTP or HTTPS response. You must specify the timeout period and the lifetime of a cookie on a backend server. When SLB detects a user-defined cookie, SLB rewrites the original cookie with the user-defined cookie. The next request from the client contains the user-defined cookie. Then, the listener forwards the request to the recorded backend server.
Enable Peak Bandwidth Limit	Specify whether to set a bandwidth limit for the listener. Unit: Mbit/s. Valid values: 0 to 5120. If an SLB instance is billed based on bandwidth usage, you can set different bandwidth limit values for different listeners. This limits the amount of network traffic that flows through each listener. The sum of the bandwidth limit values of all listeners that are added to an SLB instance cannot exceed the bandwidth limit of this SLB instance. By default, this feature is disabled and all listeners share the bandwidth of the SLB instance.

Parameter	Description
Idle Timeout	Specify the timeout period of idle connections. Unit: seconds. Valid values: 1 to 60. If no request is received within the specified timeout period, SLB closes the connection. SLB recreates the connection when a new connection request is received.
Request Timeout	Specify the request timeout period. Unit: seconds. Valid values: 1 to 180. If no response is received from the backend server within the request timeout period, SLB returns an HTTP 504 error to the client.
Enable Gzip Compression	Specify whether to enable Gzip compression to compress specific types of files. Gzip supports the following file types: text/xml, text/plain, text/css, application/javascript, application/x-javascript, application/rss+xml, application/atom+xml, and application/xml.
Add HTTP Header Fields	You can add the following HTTP headers: ○ Use the `X-Forwarded-For` header to retrieve the real IP addresses of clients. ○ Use the `SLB-ID` header to retrieve the ID of the SLB instance. ○ Use the `SLB-IP` header to retrieve the public IP address of the SLB instance. ○ Use the `X-Forwarded-Proto` header to retrieve the listener protocol used by the SLB instance.
Obtain Client Source IP Address	Specify whether to retrieve the real IP address of the client. By default, this feature is enabled.
Automatically Enable Listener After Creation	Specify whether to immediately enable the listener after it is created. By default, this feature is enabled.

4. Click **Next**.

Step 2: Add backend servers

After you configure the listener, you must add backend servers to process client requests. You can use the default server group that is configured for the SLB instance. You can also create a vServer group or a primary/secondary server group. For more information, see Overview.

The default server group is selected in this example.

1. On the **Backend Servers** wizard page, select **Default Server Group**. Then, click **Add More**.
2. In the **My Servers** panel, select the Elastic Compute Service (ECS) instances that you want to add as backend servers and click **Next**.
3. On the **Configure Ports and Weights** wizard page, specify the weights of the backend servers that you want to add. A backend server with a higher weight receives more requests.

   > **Note** If the weight of a backend server is set to 0, no request is distributed to the backend server.

4. Click **Add**. On the Default Server Group tab, specify the ports that you want to open on the backend servers to receive requests. The backend servers are the ECS instances that you selected. Valid values: 1 to 65535.

   You can specify the same port on different backend servers that are added to an SLB instance.

5. Click **Next**.

Step 4: Configure health checks

SLB performs health checks to check the availability of the ECS instances that serve as backend servers. The health check feature improves overall service availability and reduces the impact of backend server failures. Click **Modify** to configure advanced health check settings and click Next. For more information, see Health check overview.

Step 5: Submit the configurations

To submit the configurations, perform the following operations:

1. On the **Confirm** wizard page, check the configurations. You can click **Modify** to modify the configurations.
2. After you confirm the configurations, click **Submit**.
3. In the **Configuration Successful** message, click **OK**.

   After you configure the listener, you can view the listener on the Listener tab.

16.5.5. Add an HTTPS listener

This topic describes how to add an HTTPS listener to a Server Load Balancer (SLB) instance. HTTPS is intended for applications that require encrypted data transmission. You can add an HTTPS listener to forward HTTPS requests.

Step 1: Configure an HTTPS listener

1. Log on to the SLB console.
2. Use one of the following methods to open the listener configuration wizard:
   - On the **Instances** page, find the SLB instance that you want to manage and click **Configure Listener** in the Actions column.
   - On the **Instances** page, click the ID of the SLB instance that you want to manage. On the **Listener** tab, click **Add Listener**.
3. Set the following parameters and click **Next**.

Parameter	Description
Listener Protocol	Select the protocol type of the listener. In this example, **HTTPS** is selected.
Listening Port	Specify the listening port that is used to receive requests and forward them to backend servers. Valid values: 1 to 65535.
Advanced	Click **Modify** to configure advanced settings.
Scheduling Algorithm	Select a scheduling algorithm. ○ **Weighted Round-Robin (WRR)**: Backend servers that have higher weights receive more requests than backend servers that have lower weights. ○ **Round-Robin (RR)**: Requests are distributed to backend servers in sequence.

Parameter	Description
Enable Session Persistence	Specify whether to enable session persistence. After session persistence is enabled, SLB forwards all requests from a client to the same backend server. SLB maintains the persistence of HTTP sessions based on cookies. SLB allows you to use the following methods to process cookies: ◦ **Insert cookie**: If you select this option, you need only to specify the timeout period of the cookie. SLB inserts a cookie (SERVERID) into the first HTTP or HTTPS response that is sent to a client. The next request from the client contains the cookie. Then, the listener distributes the request to the recorded backend server. ◦ **Rewrite cookie**: If you select this option, you can specify the cookie that you want to insert into an HTTP or HTTPS response. You must specify the timeout period and the lifetime of a cookie on a backend server. After you specify a cookie, SLB overwrites the original cookie with the specified cookie. The next time SLB receives a client request that carries the specified cookie, the listener distributes the request to the recorded backend server.
Enable HTTP/2	Select whether to enable HTTP/2.0 for the frontend protocol of the SLB instance.
Enable Peak Bandwidth Limit	Specify whether to set a bandwidth limit for the listener. If an SLB instance is billed based on bandwidth usage, you can set different bandwidth limit values for different listeners. This limits the amount of traffic that flows through each listener. The sum of the bandwidth limit values of all listeners that are added to an SLB instance cannot exceed the bandwidth limit of this SLB instance. By default, this feature is disabled and all listeners share the bandwidth of the SLB instance.
Idle Timeout	Specify the timeout period of idle connections. Unit: seconds. Valid values: 1 to 60. If no request is received within the specified timeout period, SLB closes the connection. SLB recreates the connection when a new connection request is received.
Request Timeout	Specify the request timeout period. Unit: seconds. Valid values: 1 to 180. If no response is received from the backend server within the request timeout period, SLB returns an HTTP 504 error to the client.
Enable Gzip Compression	Specify whether to enable Gzip compression to compress specific types of files. Gzip supports the following file types: text/xml, text/plain, text/css, application/javascript, application/x-javascript, application/rss+xml, application/atom+xml, and application/xml.
Add HTTP Header Fields	You can add the following HTTP headers: ◦ Use the `X-Forwarded-For` header to retrieve the real IP addresses of clients. ◦ Use the `SLB-ID` header to retrieve the ID of the SLB instance. ◦ Use the `SLB-IP` header to retrieve the public IP address of the SLB instance. ◦ Use the `X-Forwarded-Proto` header to retrieve the listener protocol used by the SLB instance.

Parameter	Description
Obtain Client Source IP Address	Specify whether to retrieve the real IP address of the client. By default, this feature is enabled.
Automatically Enable Listener After Creation	Specify whether to immediately enable the listener after it is created. By default, this feature is enabled.

Step 2: Configure an SSL certificate

When you add an HTTPS listener, you must upload a server certificate or certification authority (CA) certificate , as shown in the following table.

Item	Description	Required for one-way authentication	Required for mutual authentication
Server certificate	The certificate that is used to identify the server. Your browser uses the server certificate to verify whether the certificate sent by the server is signed and issued by a trusted CA.	Yes You must upload the server certificate to the certificate management system of SLB.	Yes You must upload the server certificate to the certificate management system of SLB.
Client certificate	The certificate that is used to identify the client. The server identifies the client by checking the certificate sent by the client. You can sign a client certificate with a self-signed CA certificate.	No	Yes You must install the client certificate on the client.
CA certificate	The server uses a CA certificate to verify the signature on the client certificate. If the signature is invalid, the connection request is denied.	No	Yes You must upload the CA certificate to the certificate management system of SLB.

Before you upload a certificate, take note of the following items:

- SLB supports the following public key algorithms: RSA 1024, RSA 2048, RSA 4096, ECDSA P-256, ECDSA P-384, and ECDSA P-521.
- The certificate that you want to upload must be in the PEM format.
- After you upload a certificate to SLB, SLB can manage the certificate. You do not need to bind the certificate to backend servers.
- It may take a few minutes to upload, load, and verify the certificate. Therefore, an HTTPS listener is not enabled immediately after it is created. It requires about 1 to 3 minutes to enable an HTTPS listener.
- The ECDHE cipher suite used by HTTPS listeners supports forward secrecy. It does not support the security enhancement parameters that are required by the DHE cipher suite. Therefore, you cannot upload certificates (PEM files) that contain the `BEGIN DH PARAMETERS` field. For more information, see Certificate requirements.
- HTTPS listeners do not support Server Name Indication (SNI). You can choose TCP listeners and configure SNI on backend servers.
- By default, the timeout period of session tickets for HTTPS listeners is 300 seconds.
- The actual amount of data transfer on an HTTPS listener is larger than the billed amount because a portion of data is used for handshaking.
- If a large number of connections are established, a large amount of data is used for handshaking.

1. On the **SSL Certificates** wizard page, select the server certificate that you uploaded. You can also click

Create Server Certificate to upload a server certificate.

2. To enable mutual authentication or configure a TLS security policy, click **Modify** next to **Advanced**.
3. Enable mutual authentication, and select an uploaded CA certificate. You can also upload a CA certificate.

Step 3: Add backend servers

After you configure the listener, you must add backend servers to process client requests. You can use the default server group that is configured for the SLB instance. You can also create a vServer group or a primary/secondary server group. For more information, see Overview.

The default server group is selected in this example.

1. On the **Backend Servers** wizard page, select **Default Server Group**. Then, click **Add More**.
2. In the **My Servers** panel, select the Elastic Compute Service (ECS) instances that you want to add as backend servers and click **Next**.
3. On the **Configure Ports and Weights** wizard page, specify the weights of the backend servers that you want to add. A backend server with a higher weight receives more requests.

   > **Note** If the weight of a backend server is set to 0, no request is distributed to the backend server.

4. Click **Add**. On the Default Server Group tab, specify the ports that you want to open on the backend servers to receive requests. The backend servers are the ECS instances that you selected. Valid values: 1 to 65535.

   You can specify the same port on different backend servers that are added to an SLB instance.

5. Click **Next**.

Step 4: Configure health checks

SLB performs health checks to check the availability of the ECS instances that serve as backend servers. The health check feature improves overall service availability and reduces the impact of backend server failures. Click **Modify** to configure advanced health check settings and click Next. For more information, see Health check overview.

Step 5: Submit the configurations

1. On the **Confirm** wizard page, check the configurations. You can click **Modify** to modify the configurations.
2. After you confirm the configurations, click **Submit**.
3. In the **Configuration Successful** message, click **OK**.

   After you configure the listener, you can view the listener on the Listener tab.

16.5.6. Configure forwarding rules

This topic describes how to configure forwarding rules for a Server Load Balancer (SLB) instance. You can configure domain name-based or URL-based forwarding rules for an SLB instance that uses Layer 7 listeners. Layer 7 listeners distribute requests destined for different domain names or URLs to different Elastic Compute Service (ECS) instances.

Context

You can add multiple forwarding rules to a listener. Each forwarding rule is associated with a unique server group. Each server group contains one or more ECS instances. For example, you can configure a listener to forward read requests to one server group and write requests to another server group. This allows you to optimize load balancing among your server resources.

SLB forwards requests based on the following rules:

- If a request matches a domain name-based or URL-based forwarding rule of a listener, the request is forwarded to the corresponding server group based on the forwarding rule.
- If a request does not match the domain name-based or URL-based forwarding rules of a listener but the listener

is associated with a server group, the request is forwarded to the server group.

- If none of the preceding conditions are met, requests are forwarded to the ECS instances in the default server group of the SLB instance.

Procedure

1. Log on to the SLB console.
2. Click the ID of the SLB instance that you want to manage. On the **Listener** tab, find the listener that you want to manage.

   You can configure domain name-based or URL-based forwarding rules only for HTTP and HTTPS listeners.
3. Click **Configure Forwarding Rule** in the **Actions** column.
4. Configure forwarding rules based on the following information:
   - Configure a domain name-based forwarding rule
     - When you configure a domain name-based forwarding rule, leave the URL field empty. You do not need to enter a forward slash (/) in this field. The domain name can contain only letters, digits, hyphens (-), and periods (.).
     - Domain-based forwarding rules support both exact matching and wildcard matching. For example, www.aliyun.com is an exact domain name, whereas *.aliyun.com and *.market.aliyun.com are wildcard domain names. When a request matches multiple domain name-based forwarding rules, an exact match prevails over wildcard matches, as described in the following table. Domain name matching rule

Type	Request URL	Domain name matching rule (√ indicates that the domain name is matched whereas x indicates that the domain name is not matched.)		
		www.aliyun.com	*.aliyun.com	*.market.aliyun.com
Exact match	www.aliyun.com	√	x	x
Wildcard match	market.aliyun.com	x	x	x
	info.market.aliyun.com	x	x	√

   - Configure a URL-based forwarding rule
     - When you configure a URL-based forwarding rule, leave the Domain Name field empty.
     - The URL can contain only letters, digits, and hyphens `(-)./%?#&`
     - The URL must start with a forward slash (/).

       > **Note** If you enter only a forward slash (/) in the URL field, the URL-based forwarding rule is invalid.

     - URL-based forwarding rules support string matching and adopt sequential matching. Examples: `/admin`, `/bbs_`, and `/ino_test`.
   - Configure both domain name-based and URL-based forwarding rules

     You can configure both domain name-based and URL-based forwarding rules to forward traffic destined for different URLs of the same domain name. We recommend that you configure a default forwarding rule with the URL field left empty in case errors are returned when the URLs of requests are not matched.

     For example, the domain name of a website is `www.aaa.com`. You are required to forward requests destined for `www.aaa.com/index.html` to Server Group 1 and forward requests destined for other URLs of the domain name to Server Group 2. To meet the preceding requirements, you must configure two forwarding rules, as shown in the following figure. Otherwise, a 404 error code is returned when a request destined for the `www.aaa.com` domain name does not match all forwarding rules.

5. Click **Save**.

16.5.7. Enable access control

This topic describes how to enable access control for a listener. You can enable access control for each listener of a Classic Load Balancer (CLB). You can set whitelists for different listeners to regulate network access control.

Procedure

1. Log on to the SLB console.
2. Click the ID of the CLB instance.
3. Click the **Listener** tab, find the listener that you want to manage, and then choose ⋮ > **Set Access Control** in the **Actions** column.
4. Set the following parameters and click **OK**.

Parameter	Description
Enable Access Control	Enable access control.
Access Control Method	**Whitelist**: After you set a whitelist for a listener, the listener forwards only requests from IP addresses or CIDR blocks that are added to the whitelist. However, your business may be adversely affected if the whitelist is not set properly. After you set a whitelist for a CLB listener, only requests from IP addresses or CIDR blocks that are added to the whitelist are distributed by the listener. After you enable the whitelist, if no IP address is added to the whitelist, the listener does not forward requests.
Access Control List	Select a network ACL. IPv6 instances can be associated only with IPv6 network ACLs, and IPv4 instances can be associated only with IPv4 network ACLs. **Note** Separate multiple IP entries with commas (,). You can add up to 300 IP entries to each network ACL. IP entries must be unique within each network ACL.

16.5.8. Disable access control

This topic describes how to disable access control for a listener.

Procedure

1. Log on to the SLB console.
2. Find an SLB instance and click its instance ID.
3. Click the **Listener** tab next to the **Instance Details** tab.
4. Find the listener for which you want to disable access control, and choose ⋮ > **Set Access Control** in the Actions column.
5. In the **Access Control Settings** panel, disable access control and then click **OK**.

16.6. Backend servers

16.6.1. Backend server overview

Before you use the Server Load Balancer (SLB) service, you must add Elastic Compute Service (ECS) instances as backend servers to an SLB instance to process client requests.

Backend server overview

You can set virtual IP addresses for an SLB instance. This way, the added ECS instances in the same region can be virtualized into an application service pool that provides high performance and availability. You can manage backend servers by using vServer groups. A listener of an SLB instance can be associated with a specific vServer group so that different listeners can forward requests to their associated backend servers that use different ports.

> **Note** If you associate a vServer group with a listener, the listener distributes requests to backend servers in the associated vServer group instead of those in the default server group.

Limits

You can increase or decrease the number of backend ECS instances at any time and switch ECS instances to receive client requests. When you perform the operations, make sure that the health check feature is enabled and at least one ECS instance is running as expected to maintain service stability.

When you add backend ECS instances, take note of the following items:

- You can add ECS instances of different operating systems to an SLB instance. However, the applications deployed on the ECS instances must be the same and have consistent data. We recommend that you use ECS instances of the same operating system to facilitate management and maintenance.
- Up to 50 listeners can be added to a single SLB instance. Each listener corresponds to an application deployed on backend ECS instances. Listening ports of an SLB instance correspond to application service ports that are opened on backend ECS instances.
- You can specify a weight for each ECS instance in the application service pool. An ECS instance with a higher weight receives more requests.
- If session persistence is enabled, requests may not be evenly distributed to backend ECS instances. To solve this problem, we recommend that you disable session persistence and check whether the problem persists.

  If requests are not evenly distributed, troubleshoot the issue in the following way:

  i. Collect statistics on the access logs of the web service on backend ECS instances for a specified period.
  ii. Check whether the numbers of access logs of backend ECS instances match SLB configurations. If session persistence is enabled, you must differentiate the access logs for the same IP address. If different weights are configured for backend ECS instances, you must check whether the percentage of access logs is normal based on the percentage of weights.
- When an ECS instance is undergoing hot migration, persistent connections to SLB may be interrupted. You can solve this problem by reestablishing the connections.

Default server groups

A default server group contains ECS instances that are used to receive requests. If a listener is not associated with a vServer group or a primary/secondary server group, the listener forwards requests to ECS instances in the default server group.

Before you use the SLB service, you must add at least one default backend server to receive client requests forwarded by SLB. For more information, see Add a default backend server.

vServer groups

You can use a vServer group if you want to distribute different requests to different backend servers or configure forwarding rules based on domain names and URLs. For more information, see Create a vServer group.

Primary/secondary server groups

A primary/secondary server group contains only two ECS instances. One ECS instance acts as the primary server and the other acts as the secondary server. Health checks are not performed on the secondary server. If the primary server is detected unhealthy, traffic is redirected to the secondary server. After the primary server recovers and is considered healthy, traffic is switched back to the primary server. For more information, see Create a primary/secondary server group.

> **Note** You can add primary/secondary server groups only for TCP and UDP listeners.

Related information

- Add a default backend server
- Create a vServer group
- Create a primary/secondary server group

16.6.2. Default server groups

16.6.2.1. Add a default backend server

This topic describes how to add a default backend server. Before you use the Classic Load Balancer (CLB) service, you must add at least one default backend server to receive client requests.

Prerequisites

Before you add an Elastic Compute Service (ECS) instance to the default server group, make sure that the following requirements are met:

- A CLB instance is created. For more information, see Create an SLB instance.
- ECS instances are created and applications are deployed on the ECS instances to receive requests.

Procedure

1. Log on to the SLB console.
2. Find the CLB instance that you want to manage and click its ID.
3. Click the **Default Server Group** tab.
4. Click **Add**.
5. In the **My Servers** panel, for **Select Servers**, select one or more ECS instances that you want to add to the default server group.
6. Click **Next**.
7. For **Configure Ports and Weights**, specify the weight of each ECS instance.

   An ECS instance that has a higher weight receives more requests.

   You can change the weight of a server and then move the pointer over  to change the weights of other servers:

   - If you click **Replicate to Below**, the weights of all servers below the current server are set to the weight of the current server.
   - If you click **Replicate to Above**, the weights of all servers above the current server are set to the weight of the current server.
   - If you click **Replicate to All**, the weights of all servers in the default server group are set to the weight of

the current server.

- If you click **Reset**, when you clear the weight of the current server, the weights of all servers in the default server group are cleared.

> **Notice**
>
> - Valid values of weights: 0 to 100. If you set the weight of a server to 0, the server does not receive requests.
> - If two servers have the same weight, only one server receives requests.

8. Click **Add**.
9. Click **OK**.

16.6.2.2. Add IDC servers to the default server group

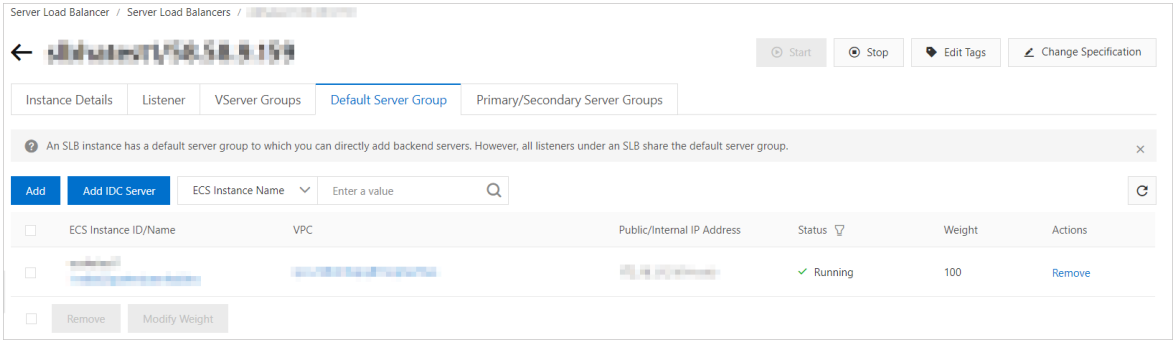
This topic describes how to add servers in on-premises Internet Data Centers (IDCs) as default backend servers to the default server group of an SLB instance. Before you use the SLB service, you must add at least one default backend server to receive client requests forwarded by SLB.

Prerequisites

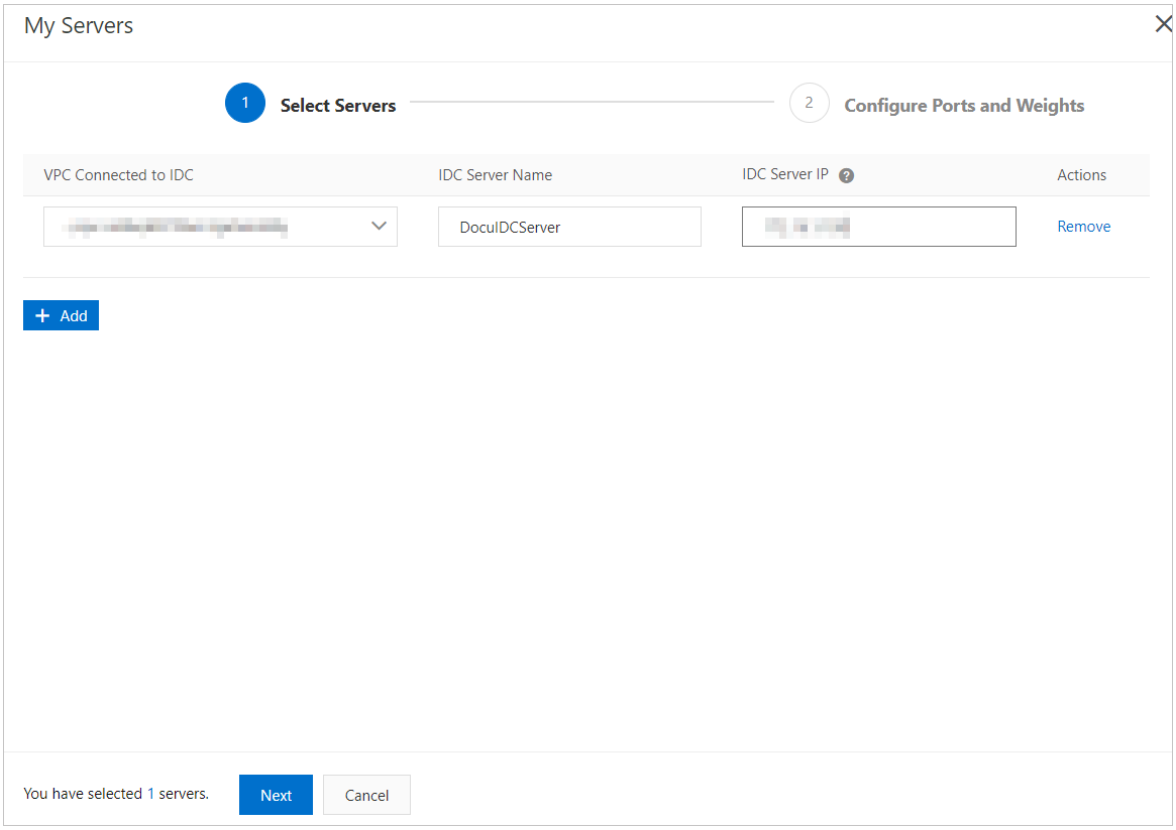
Applications are deployed on the IDC servers, and the IDC servers are ready to receive distributed requests.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **Default Server Group** tab.
4. Click **Add IDC Server**.



5. In the **My Servers** dialog box, click **Add**.
6. Select a VPC from the VPC Connected to IDC drop-down list, enter a name for the IDC server, and specify the IP address of the IDC server.



7. Click **Next**.
8. In the **Configure Ports and Weights** step, specify the weight of each added IDC server.

   An IDC server with a higher weight receives more requests.

   You can change the weight of a server and then move the pointer over to change the weights of multiple servers:

   - Click **Replicate to Below**: The weights of all servers below the current server are set to the weight of the current server.
   - Click **Replicate to Above**: The weights of all servers above the current server are set to the weight of the current server.
   - Click **Replicate to All**: The weights of all servers in the default server group are set to the weight of the current server.
   - Click **Reset**: The weight fields of all servers in the default server group are cleared.

   > **Notice** If the weight of a backend server is set to 0, this backend server no longer receives new requests.

9. Click **Add**.
10. Click **OK**.

16.6.2.3. Change the weight of a backend server

This topic describes how to change the weight of a backend server to adjust the proportion of requests sent to the backend server.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **Default Server Group** tab.
4. Move the pointer over the weight value of the target backend server and click the  icon.
5. Change the weight and then click **OK**.

   A backend server (ECS instance or IDC server) with a higher weight receives more requests.

   > **Notice** The weight value ranges from 0 to 100. If the weight of a backend server is set to 0, no requests are sent to the backend server.

16.6.2.4. Remove a backend server

This topic describes how to remove a backend server that is no longer needed.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **Default Server Group** tab.
4. Find the target backend server and click **Remove** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

16.6.3. VServer groups

16.6.3.1. Add ECS instances to a VServer group

This topic describes how to create a VServer group and then add ECS instances as backend servers to the VServer group. If you associate a VServer group with a listener, the listener distributes requests only to the backend servers in the VServer group instead of other backend servers.

Prerequisites

Before you create a VServer group, make sure that the following conditions are met:

- An SLB instance is created. For more information, see Create an SLB instance.
- You have created ECS instances and deployed applications on these ECS instances to process requests.

Context

Note the following items before you create a VServer group:

- An ECS instance can be added to multiple VServer groups.
- A VServer group can be associated with multiple listeners of an SLB instance.
- The settings of the VServer group include the settings of ECS instances and application ports.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **VServer Groups** tab.
4. On the **VServer Groups** tab, click **Create VServer Group**.

5. On the **Create VServer Group** page, configure the VServer group.
   i. In the **VServer Group Name** field, enter a name for the VServer group.
   ii. Click **Add**. In the **My Servers** dialog box, select ECS instances that you want to add.
   iii. Click **Next**.
   iv. Specify a port and a weight for each ECS instance and then click **Add**.

   Set the ports and weights based on the following information:

   - **Port**: The backend port opened on an ECS instance to receive requests.

     You can set the same port number for multiple backend servers of the same SLB instance. In addition, you can click **Add Port** to add multiple ports for a backend server.
   - **Weight**: An ECS instance with a higher weight receives more requests.

     > **Notice** If the weight of an ECS instance is set to 0, the ECS instance no longer receives new requests.

   You can change the weight of a server and then move the pointer over to change the weights of multiple servers:

   - Click **Replicate to Below**: The weights of all servers below the current server are set to the weight of the current server.
   - Click **Replicate to Above**: The weights of all servers above the current server are set to the weight of the current server.
   - Click **Replicate to All**: The weights of all servers in the VServer group are set to the weight of the current server.
   - Click **Reset**: The weight fields of all servers in the VServer group are cleared.

   > **Notice** If the weight of a backend server is set to 0, this backend server no longer receives new requests.

   v. Click **Add**.
6. Click **Create**.

16.6.3.2. Add IDC servers to a VServer group

This topic describes how to create a VServer group and then add IDC servers to the VServer group. You can add ECS instances and IDC servers as backend servers to a VServer group. If you associate a VServer group with a listener, the listener distributes requests only to the backend servers in the VServer group instead of other backend servers.

Prerequisites

Before you create a VServer group, make sure that applications are deployed on the IDC servers and the IDC servers are ready to receive distributed requests.

Context

Note the following items before you create a VServer group:

- An IDC server can be added to multiple VServer groups.
- A VServer group can be associated with multiple listeners of an SLB instance.
- The settings of the VServer group include the settings of IDC servers and application ports.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **VServer Groups** tab.
4. On the **VServer Groups** tab, click **Create VServer Group**.
5. On the **Create VServer Group** page, configure the VServer group.
   i. In the **VServer Group Name** field, enter a name for the VServer group.
   ii. Click **Add IDC Server**.
   iii. In the **My Servers** dialog box, click **Add**.
   iv. Select a VPC from the VPC Connected to IDC drop-down list, enter a name for the IDC server, and specify the IP address of the IDC server.

   The IP address of the IDC server must be accessible to the VPC.
   v. Click **Next**.
   vi. Specify a port and weight for each IDC server, and then click **Add**.

   Set the ports and weights based on the following information:

   - **Port**: The backend port opened on an IDC server to receive requests. Multiple ports can be added to an IDC server.

     You can set the same port number for multiple backend servers of the same SLB instance.
   - **Weight**: An IDC server with a higher weight receives more requests.

     > **Notice** If the weight of an IDC server is set to 0, the IDC server no longer receives new requests.

   You can change the weight of a server and then move the pointer over  to change the weights of multiple servers:

   - Click **Replicate to Below**: The weights of all servers below the current server are set to the weight of the current server.
   - Click **Replicate to Above**: The weights of all servers above the current server are set to the weight of the current server.
   - Click **Replicate to All**: The weights of all servers in the VServer group are set to the weight of the current server.
   - Click **Reset**: The weight fields of all servers in the VServer group are cleared.

     > **Notice** If the weight of a backend server is set to 0, this backend server no longer receives new requests.
   vii. Click **Add**.
6. Click **Create**.

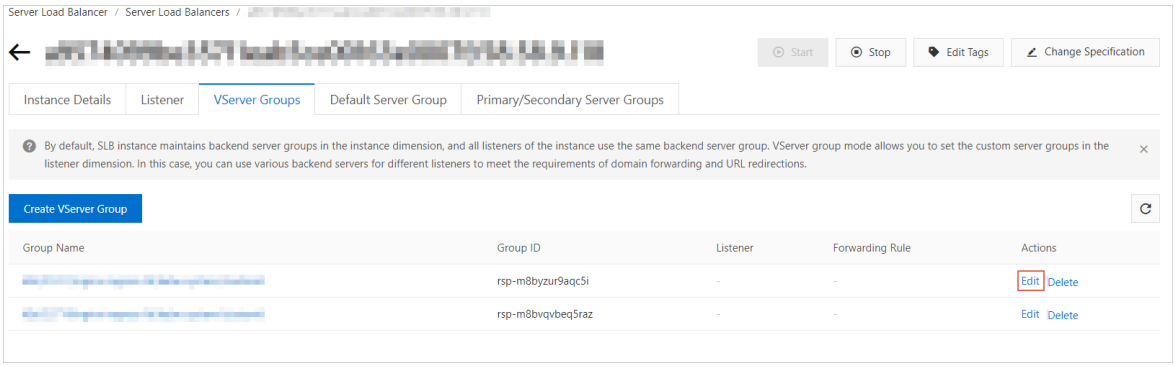
16.6.3.3. Modify a VServer group

This topic describes how to modify the settings of ECS instances or IDC servers in a VServer group.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **VServer Groups** tab.

4. Find the target VServer group and then click **Edit** in the Actions column.



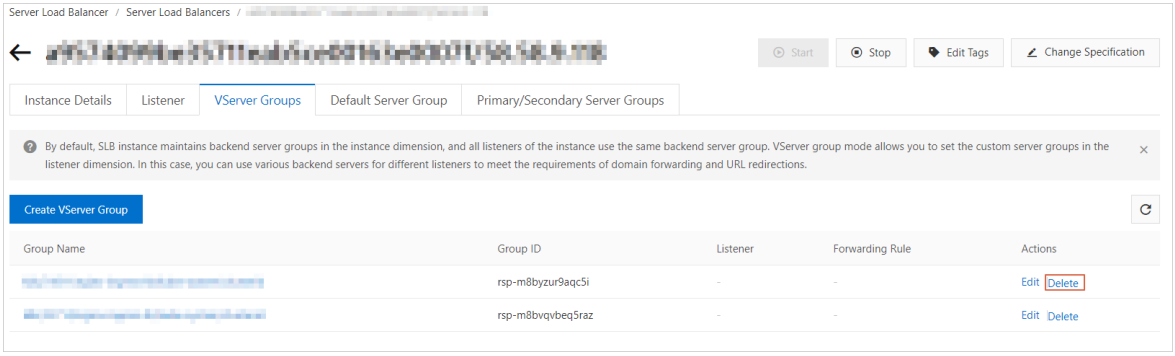
5. Modify the ports and weights of ECS instances or IDC servers, and then click **Save**.

16.6.3.4. Delete a VServer group

This topic describes how to delete a VServer group that is no longer needed for traffic distribution.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **VServer Groups** tab.
4. Find the target VServer group, and then click **Delete** in the Actions column.



5. In the dialog box that appears, click **OK**.

16.6.4. Active/standby server groups

16.6.4.1. Add ECS instances to a primary/secondary server group

This topic describes how to create a primary/secondary server group and then add ECS instances to the primary/secondary server group. You can use a primary/secondary server group to implement failover between a primary server and a secondary server. By default, the primary server handles all distributed requests. When the primary server fails, traffic is redirected to the secondary server.

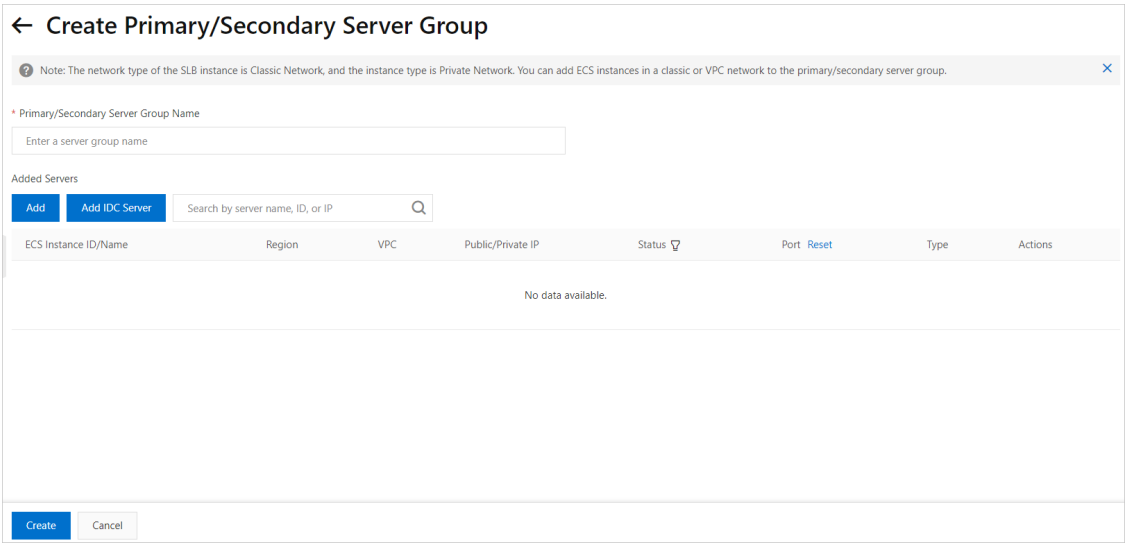
Prerequisites

Before you create a primary/secondary server group, make sure that the following conditions are met:

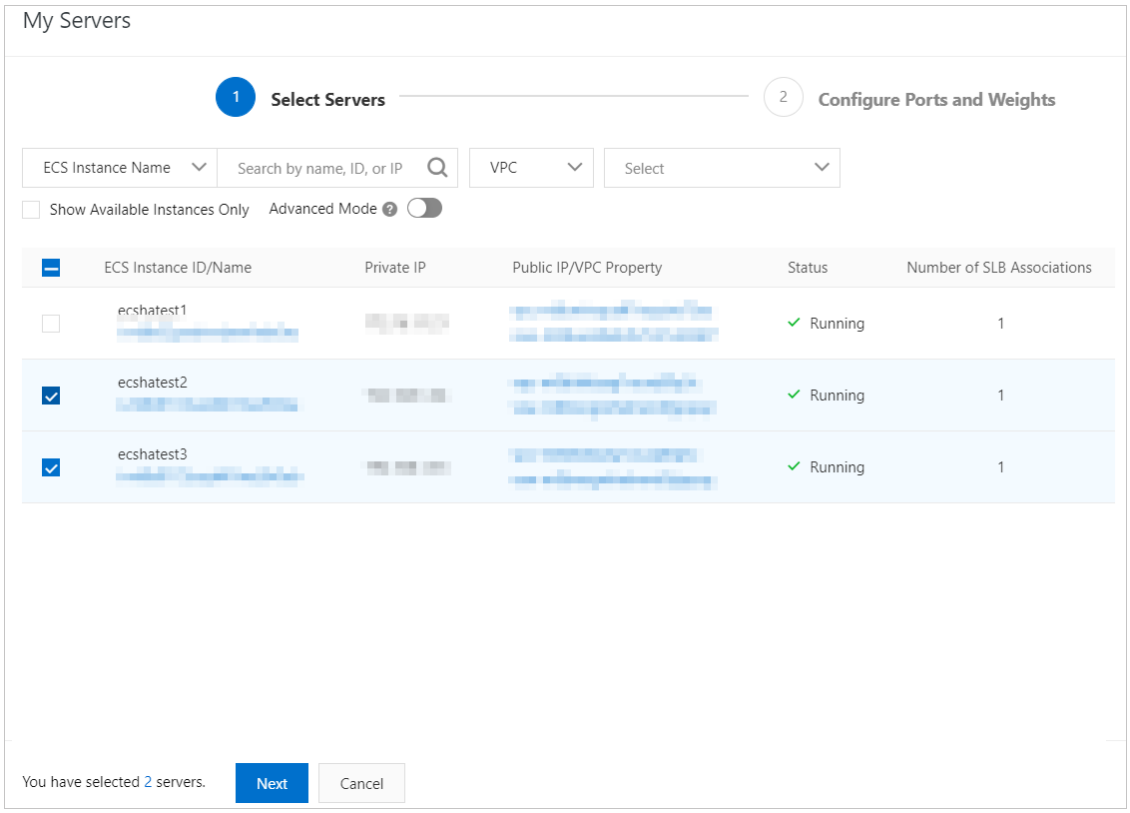
- An SLB instance is created. For more information, see Create an SLB instance.
- You have created ECS instances and deployed applications on these ECS instances to process requests.

Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **Primary/Secondary Server Groups** tab.
4. On the **Primary/Secondary Server Groups** tab, click **Create Primary/Secondary Server Group**.
5. On the **Create Primary/Secondary Server Group** page, configure the primary/secondary server group.
   i. In the **Primary/Secondary Server Group Name** field, enter a name for the primary/secondary server group.



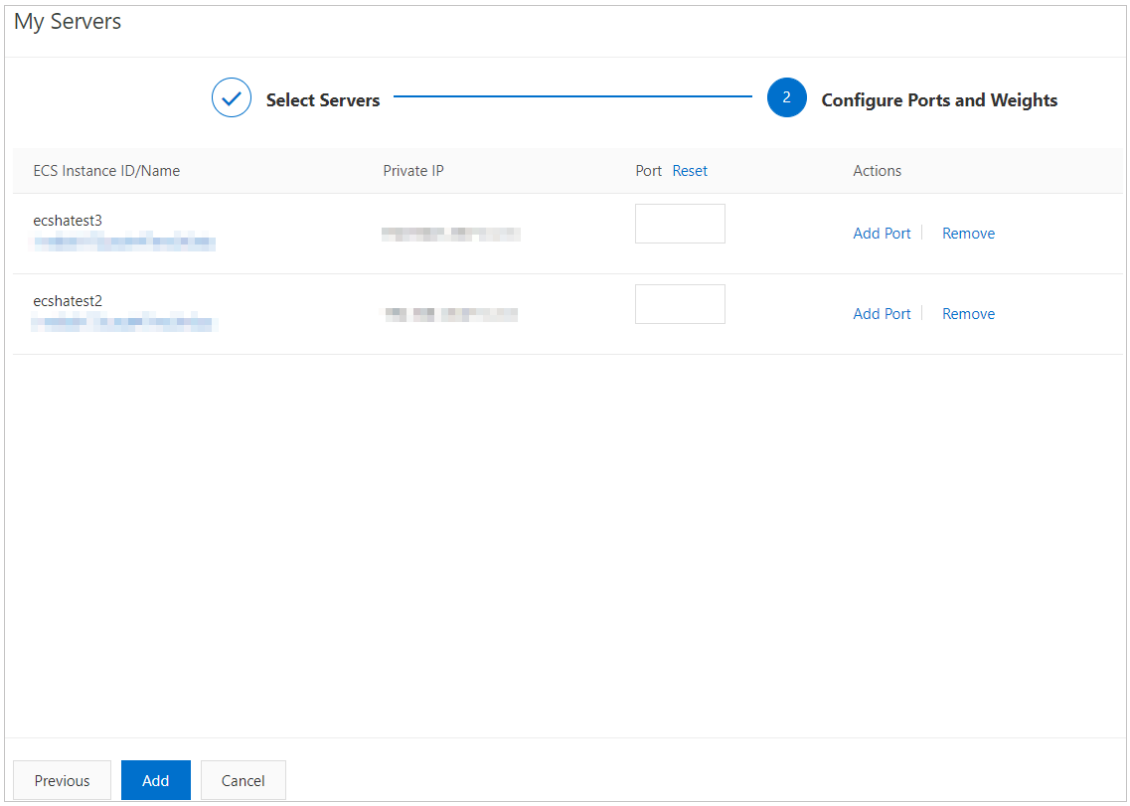
ii. Click **Add**. In the **My Servers** dialog box, select ECS instances that you want to add in the **Select Servers** step.



You can add up to two ECS instances to a primary/secondary server group.

iii. Click **Next**.

iv. Configure the backend ports opened on ECS instances to receive requests, and then click **Add**.



You can set multiple ports for an ECS instance.

v. Set an ECS instance as the primary server.

vi. Click **Create**.

16.6.4.2. Add IDC servers to a primary/secondary server group

This topic describes how to create a primary/secondary server group and then add IDC servers to the primary/secondary server group. You can use a primary/secondary server group to implement failover between a primary server and a secondary server. By default, the primary server handles all distributed requests. When the primary server fails, traffic is redirected to the secondary server.

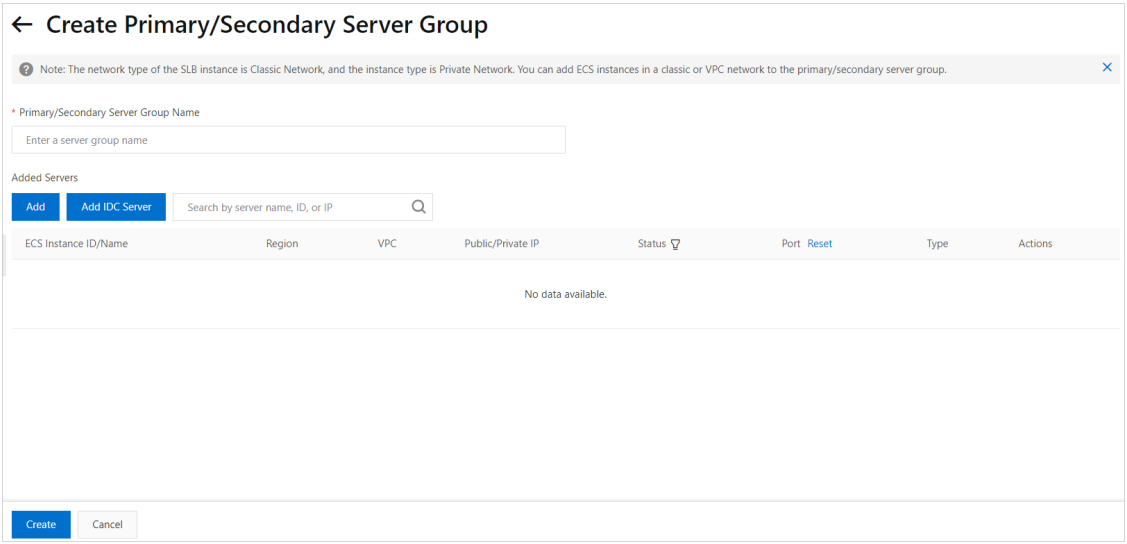
Prerequisites

The IDC servers are created, configured to deploy applications, and ready to receive distributed requests.

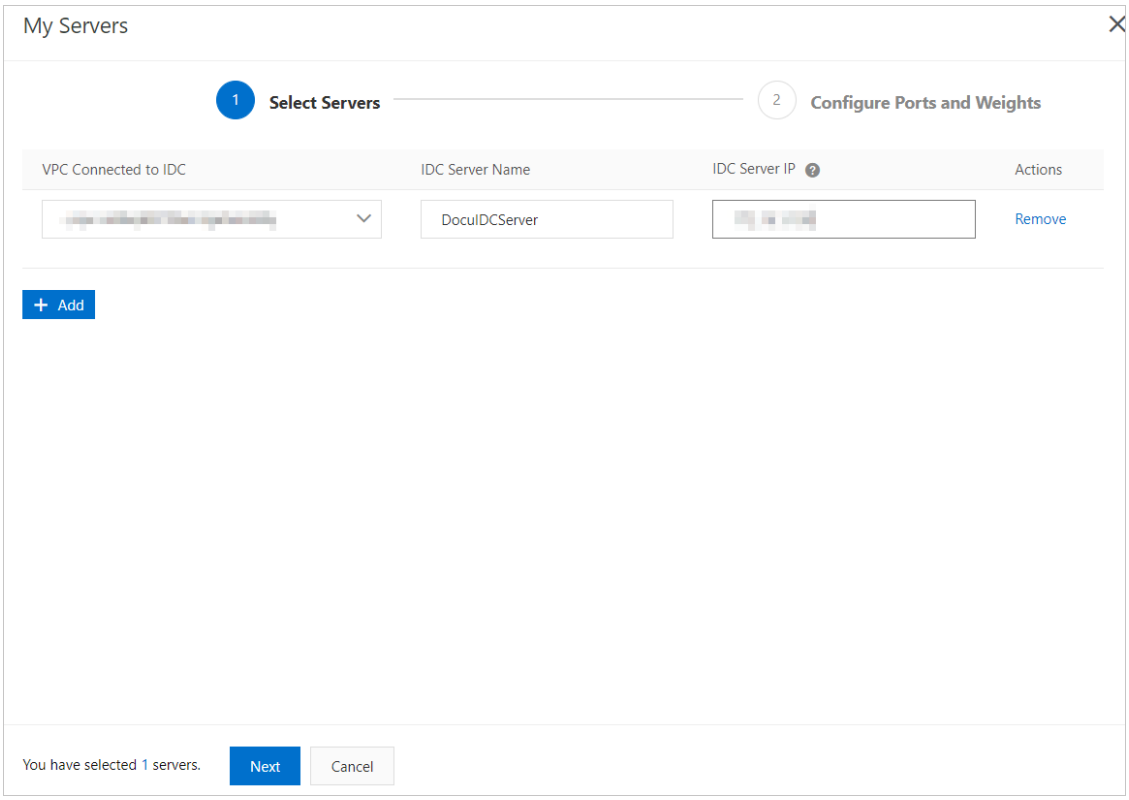
Procedure

1. Log on to the SLB console.
2. Find the target SLB instance and click its instance ID.
3. Click the **Primary/Secondary Server Groups** tab.
4. On the **Primary/Secondary Server Groups** tab, click **Create Primary/Secondary Server Group**.
5. On the **Create Primary/Secondary Server Group** page, configure the primary/secondary server group.

i. In the **Primary/Secondary Server Group Name** field, enter a name for the primary/secondary server group, and then click **Add IDC Server**.



ii. In the **My Servers** dialog box, click **Add**.

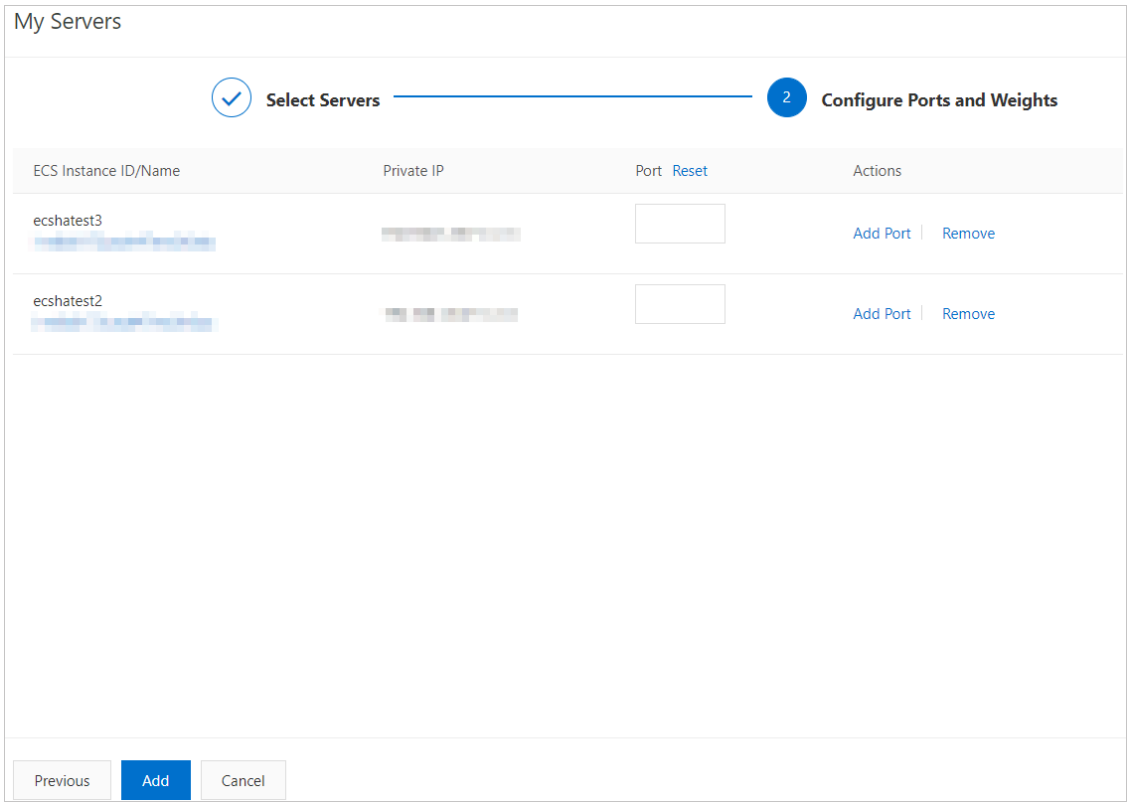


iii. Select a VPC from the VPC Connected to IDC drop-down list, enter a name for the IDC server, and specify the IP address of the IDC server.

The IP address of the IDC server must be accessible to the VPC.

iv. Click **Next**.

v. Configure the backend ports opened on ECS instances to receive requests, and then click **Add**.



You can set multiple ports for an IDC server.

vi. Set a backend server as the primary server.

vii. Click **Create**.

16.6.4.3. Delete a primary/secondary server group

This topic describes how to delete a primary/secondary server group of a Server Load Balancer (SLB) instance. If a primary/secondary server group is no longer needed to forward traffic, you can delete the primary/secondary server group.

Procedure

1. Log on to the SLB console.
2. Find the SLB instance and click its instance ID.
3. Click the **Primary/Secondary Server Groups** tab.
4. On the **Primary/Secondary Server Groups** tab, find the primary/secondary server group that you want to delete and click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

16.7. Health check

16.7.1. Health check overview

This topic describes the health check feature of Server Load Balancer (SLB). SLB checks the availability of Elastic Compute Service (ECS) instances that act as backend servers by performing health checks. The health check feature improves the overall availability of your frontend business and mitigates the impacts of exceptions that occur on backend ECS instances.

After you enable the health check feature, SLB stops distributing requests to ECS instances that are declared unhealthy and distributes new requests to healthy ECS instances. When the unhealthy ECS instances have recovered, SLB starts forwarding requests to these ECS instances again.

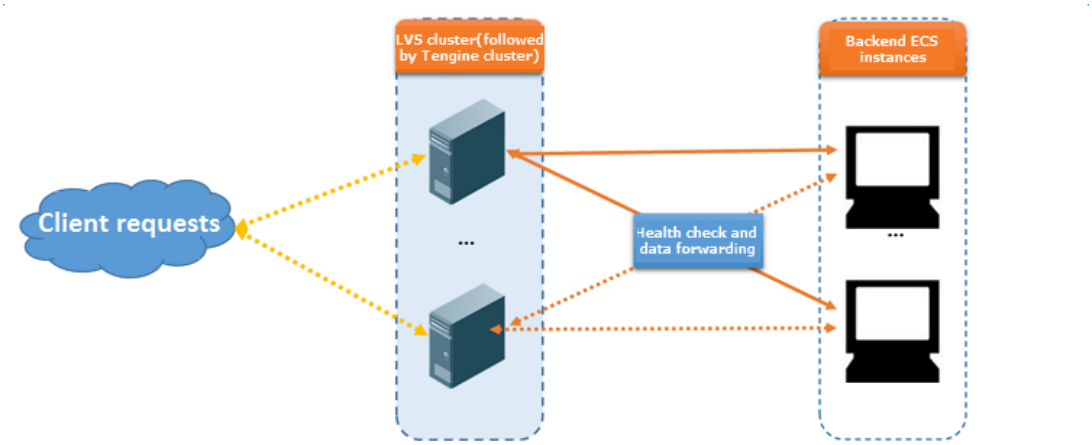
If your business is highly sensitive to traffic loads, frequent health checks may impact the availability of normal business. To reduce the impacts of health checks on your business, you can reduce the health check frequency, increase the health check interval, or change Layer 7 health checks to Layer 4 health checks. We recommend that you do not disable the health check feature to ensure business continuity.

Health check process

SLB is deployed in clusters. Node servers in the LVS or Tengine cluster forward data and perform health checks.

The node servers in the LVS cluster forward data and perform health checks independently and in parallel based on configured load balancing policies. If an LVS node server detects that a backend ECS instance is unhealthy, this node server no longer sends new client requests to this ECS instance. This operation is synchronized among all node servers in the LVS cluster.

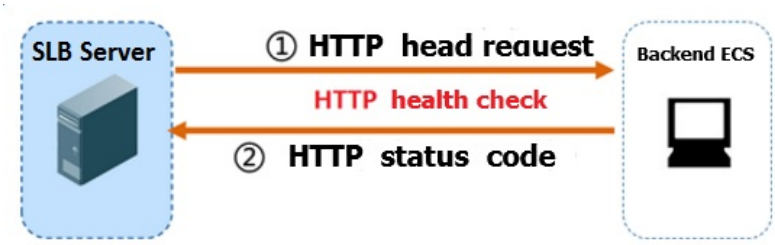
SLB uses the CIDR block of 100.64.0.0/10 for health checks. Make sure that backend ECS instances do not block this CIDR block. You do not need to configure a security group rule to allow access from this CIDR block. However, if you have configured security rules such as iptables, you must allow access from this CIDR block. 100.64.0.0/10 is reserved by Alibaba Cloud. Other users cannot use any IP addresses within this CIDR block, and therefore no relevant security risks exist.



Health checks of HTTP or HTTPS listeners

For Layer 7 (HTTP or HTTPS) listeners, SLB checks the status of backend ECS instances by sending HTTP HEAD requests. The following figure shows the process.

For HTTPS listeners, certificates are managed in SLB. To improve system performance, HTTPS is not used for data exchange (including health check data and business interaction data) between SLB and backend ECS instances.



The following section describes the health check process of a Layer 7 listener:

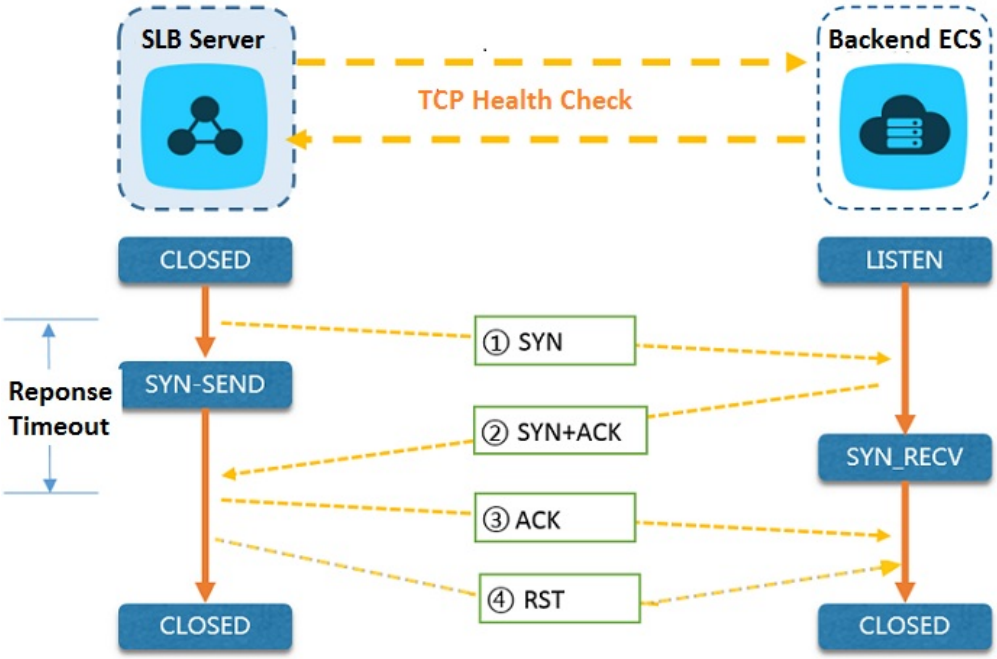
1. A Tengine node server sends an HTTP HEAD request that contains the configured domain name to the internal IP address, health check port, and health check path of a backend ECS instance based on health check settings.
2. After the backend ECS instance receives the request, the ECS instance returns an HTTP status code based on

the running status.

3. If the Tengine node server does not receive a response from the backend ECS instance within the specified response timeout period, the backend server is declared unhealthy.
4. If the Tengine node server receives a response from the backend ECS instance within the specified response timeout period, the node server compares the response with the configured status code. If the response contains the status code that indicates a healthy server, the backend server is declared healthy. Otherwise, the backend server is declared unhealthy.

Health checks of TCP listeners

For TCP listeners, SLB checks the status of backend servers by establishing TCP connections to improve health check efficiency. The following figure shows the process.



The following section describes the health check process of a TCP listener:

1. An LVS node server sends a TCP SYN packet to the internal IP address and health check port of a backend ECS instance.
2. After the backend ECS instance receives the request, the ECS instance returns an SYN-ACK packet if the corresponding port is listening normally.
3. If the LVS node server does not receive a packet from the backend ECS instance within the specified response timeout period, the backend ECS instance is declared unhealthy. Then, the node server sends an RST packet to the backend ECS instance to terminate the TCP connection.
4. If the LVS node server receives a packet from the backend ECS instance within the specified response timeout period, the node server determines that the service runs properly and the health check succeeds. Then, the node server sends an RST packet to the backend ECS instance to terminate the TCP connection.

Note A TCP three-way handshake is conducted to establish a TCP connection. After the LVS node server receives the SYN+ACK packet from the backend ECS instance, the node server sends an ACK packet, and then immediately sends an RST packet to terminate the TCP connection.

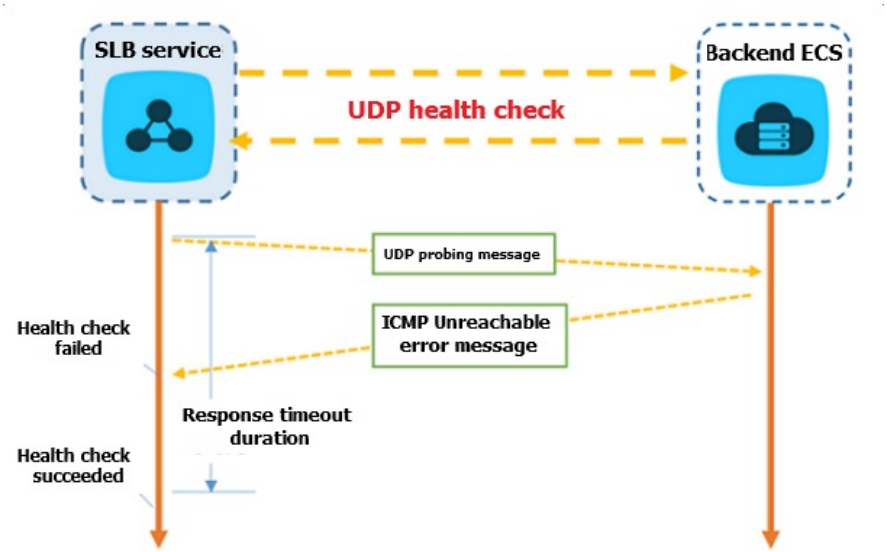
This process may cause backend ECS instances to think that an error such as an abnormal exit occurred in the TCP connection. Then, these instances may report a corresponding error message, such as `Connection reset by peer`, in logs such as Java connection pool logs.

Solution:

- You can implement HTTP health checks.
- If you have enabled the feature of obtaining actual client IP addresses on backend ECS instances, you can ignore connection errors caused by the access of the SLB CIDR block.

Health checks of UDP listeners

For UDP listeners, SLB checks the status of backend ECS instances by sending UDP packets. The following figure shows the process.



The following section describes the health check process of a UDP listener:

1. An LVS node server sends a UDP packet to the internal IP address and health check port of an ECS instance based on health check configurations.
2. If the corresponding port of the ECS instance is not listening normally, the system returns an ICMP error message, such as `port XX unreachable`. Otherwise, no message is returned.
3. If the LVS node server receives the ICMP error message within the response timeout period, the backend ECS instance is declared unhealthy.
4. If the LVS node server does not receive any messages from the backend ECS instance within the response timeout period, the ECS instance is declared healthy.

> **Note** For UDP health checks, the health check result may not reflect the real status of a backend ECS instance in the following situation:
>
> If the backend ECS instance uses a Linux operating system, the speed at which ICMP messages in high concurrency scenarios are sent is limited due to the ICMP attack prevention feature of Linux. In this case, even if a service exception occurs, SLB may declare the backend ECS instance healthy because the error message `port XX unreachable` is not returned. Consequently, the health check result deviates from the actual service status.
>
> Solution:
>
> You can specify a request and a response for UDP health checks. The ECS instance is considered healthy only when the specified response is returned. However, the client must be configured accordingly to return responses.

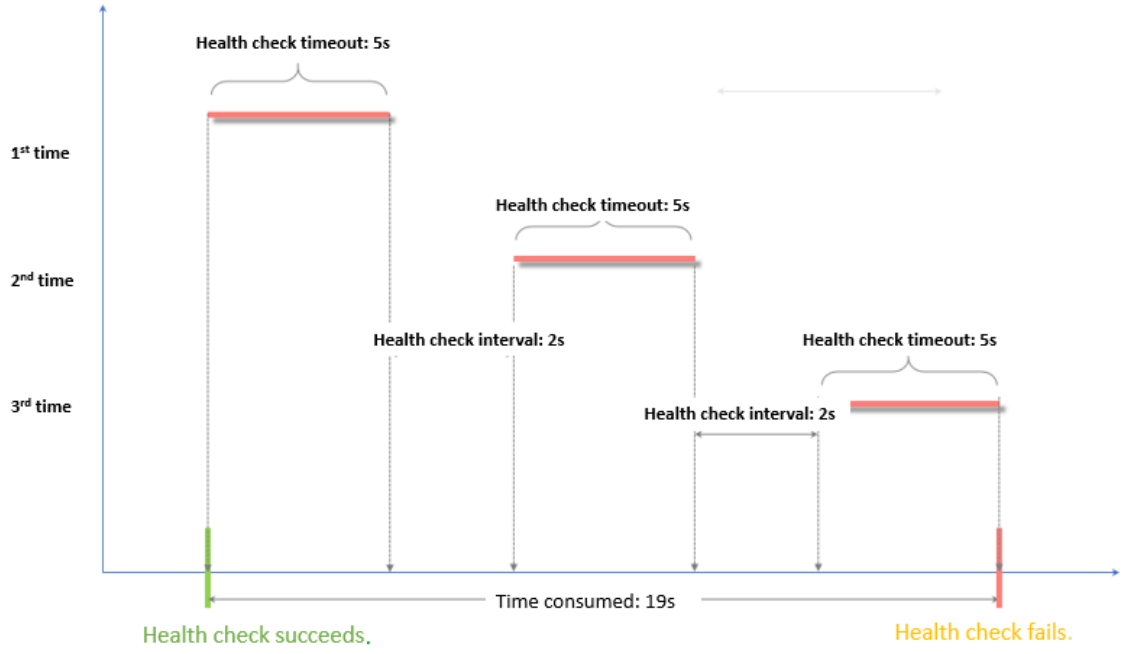
Health check time window

The health check feature effectively improves the availability of your services. However, to avoid impacts on system availability caused by frequent switching after failed health checks, the health check status switches only when health checks successively succeed or fail for a specified number of times within a certain time window. The health check time window is determined by the following factors:

- Health check interval: how often health checks are performed
- Response timeout: the length of time to wait for a response
- Health check threshold: the number of consecutive successes or failures of health checks

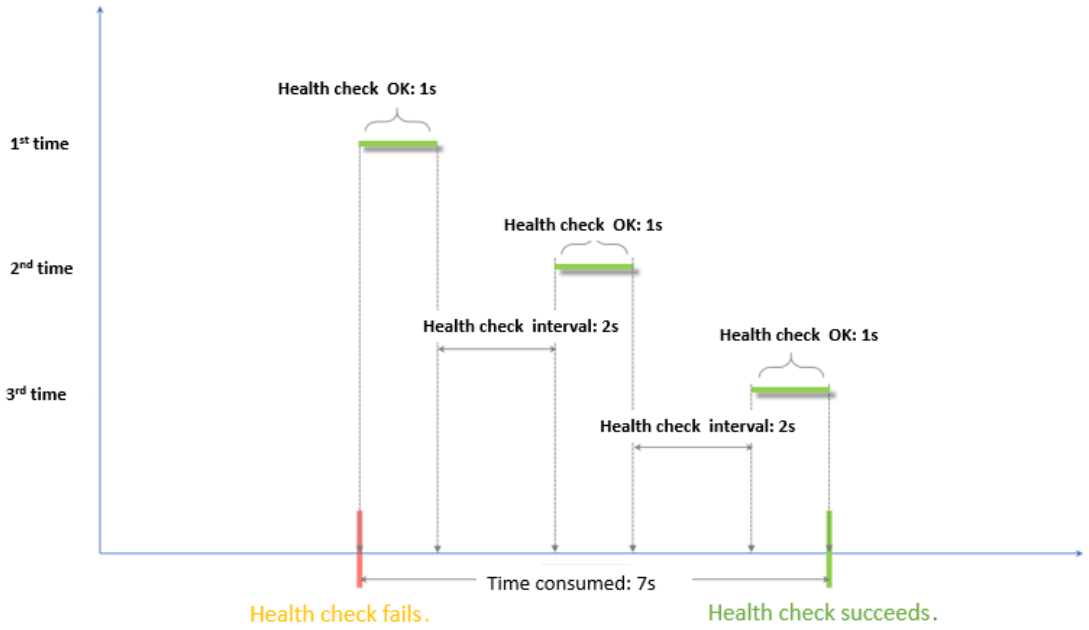
The health check time window is calculated based on the following formula:

- Time window for health check failures = Response timeout × Unhealthy threshold + Health check interval × (Unhealthy threshold - 1)



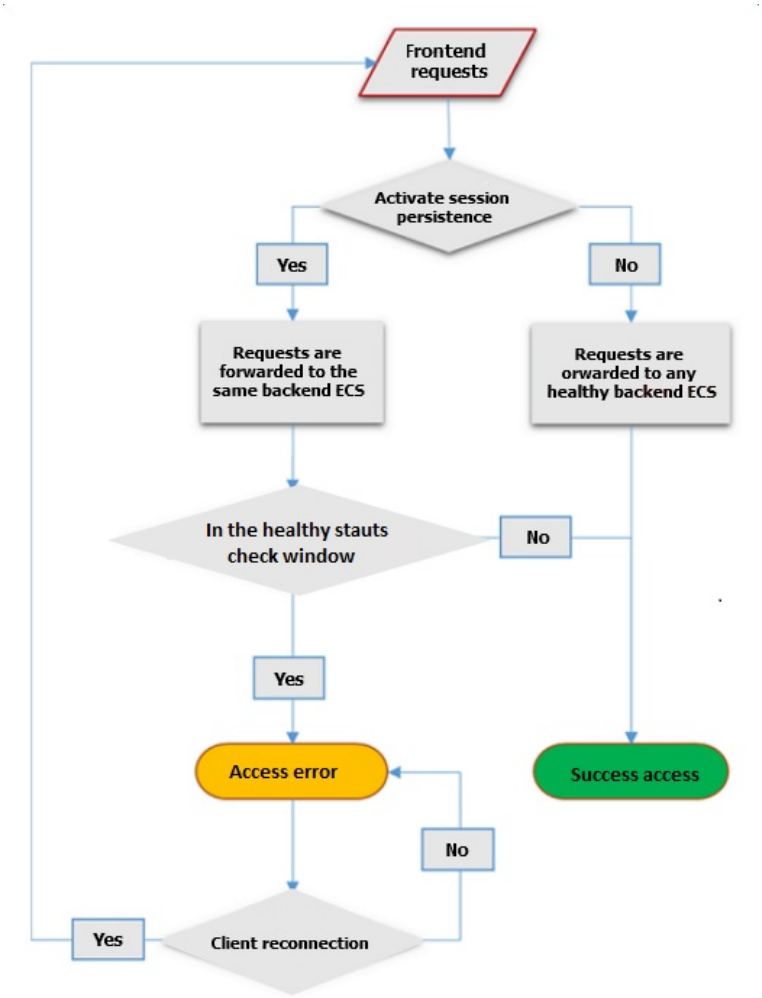
- Time window for health check successes = Response time of a successful health check × Healthy threshold + Health check interval × (Healthy threshold - 1)

> **Note** The response time of a successful health check is the duration from the time when the health check request is sent to the time when the response is received. When TCP health checks are used, the response time is short and almost negligible because only whether the specific port is alive is checked. For HTTP health checks, the response time depends on the performance and load of the application server and is typically within a few seconds.



The health check result has the following impacts on request forwarding:

- If the health check of the backend ECS instance fails, new requests are distributed to other backend ECS instances. This does not affect client access.
- If the health check of the backend ECS instance succeeds, new requests are distributed to this instance. The client access is normal.
- If an exception occurs on the backend ECS instance and a request arrives during a time window for health check failures, the request is still sent to the backend ECS instance. This is because the number of failed health checks has not reached the unhealthy threshold (3 times by default). In this case, the client access fails.



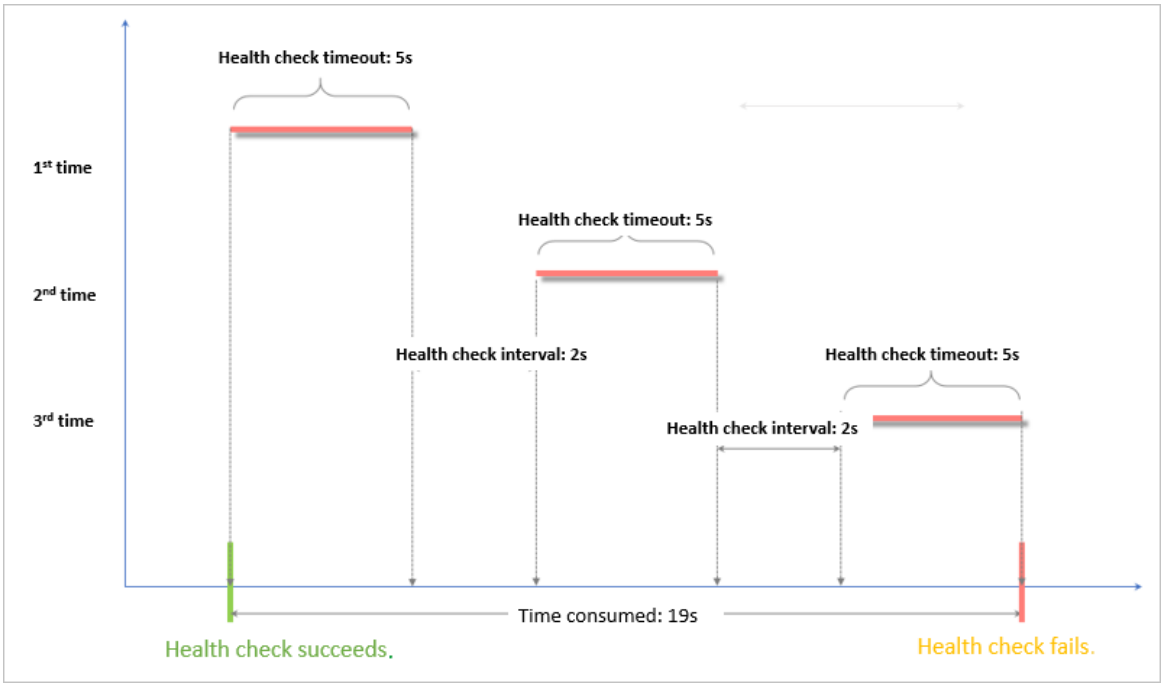
Examples of health check response timeout and health check interval

The following health check settings are used in these examples:

- **Response Timeout Period: 5 Seconds**
- **Health Check Interval: 2 Seconds**
- **Healthy Threshold: 3 Times**
- **Unhealthy Threshold: 3 Times**

Time window for health check failures = Response timeout × Unhealthy threshold + Health check interval × (Unhealthy threshold - 1). That is, 5 × 3 + 2 × (3 - 1) = 19 seconds. If the response time of a health check exceeds 19 seconds, the health check fails.

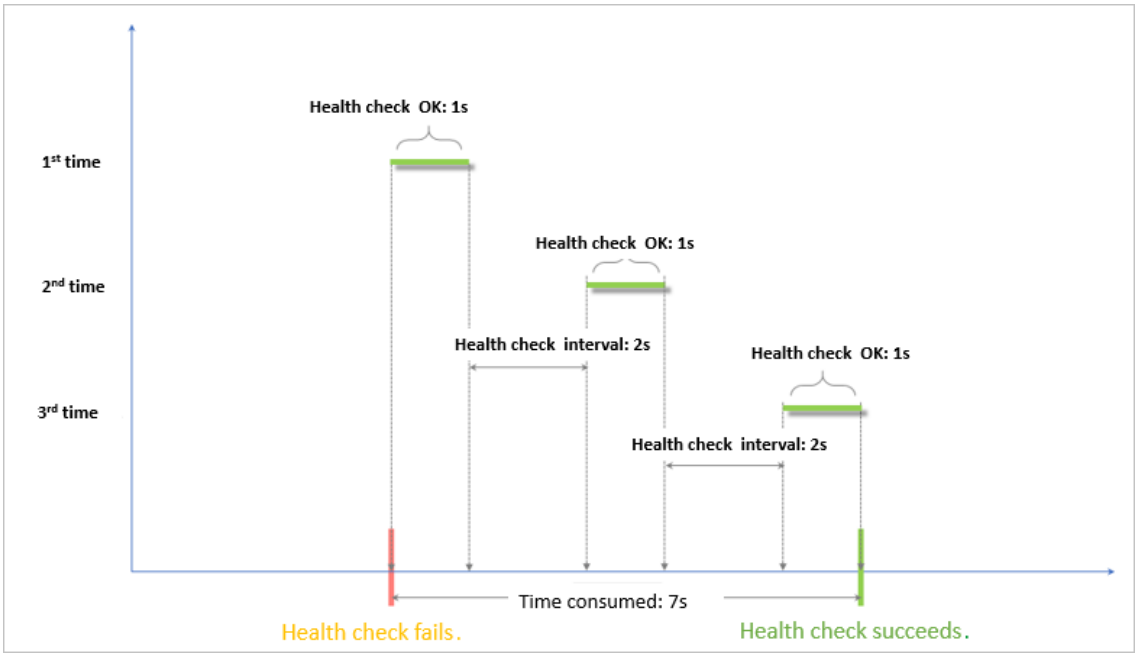
The following figure shows the time window from a healthy status to an unhealthy status.



Time window for health check successes = Response time of a successful health check × Healthy threshold + Health check interval × (Healthy threshold - 1). That is, (1 × 3) + 2 × (3 - 1) = 7 seconds. If the response time of a successful health check is less than seven seconds, the health check succeeds.

> **Note** The response time of a successful health check is the duration from the time when the health check request is sent to the time when the response is received. When TCP health checks are used, the response time is short and almost negligible because only whether the specific port is alive is checked. For HTTP health checks, the response time depends on the performance and load of the application server and is typically within a few seconds.

The following figure shows the time window from an unhealthy status to a healthy status (assume that it takes 1 second for the server to respond to a health check request).



Domain name setting in HTTP health checks

When HTTP health checks are used, you can set a domain name for health checks. The setting is optional. Some application servers verify the host field in requests. In this case, the request header must contain the host field. If a domain name is configured in health check setting, SLB adds the domain name to the host field when SLB forwards a request to an application server. If no domain name is configured, the health check request is denied by the application server because it does not contain a host field and the health check may fail. If your application server verifies the host field in requests, you must configure a domain name to make sure that the health check feature works.

16.7.2. Configure health checks

This topic describes how to configure health checks. You can configure health checks when you create a listener or for an existing listener. The default health check settings can meet your requirements in most cases.

Procedure

1. Log on to the SLB console.
2. Find an SLB instance and click the instance ID.
3. On the page that appears, click the **Listener** tab.
4. Click **Add Listener**, or find an existing listener and click **Modify Listener** in the **Actions** column.
5. Click **Next** to go to the **Health Check** step and configure the health check.

   We recommend that you use the default settings when you configure health checks.

   Health check parameters

Parameter	Description
Health Check Protocol	Select the protocol that the SLB instance uses when it performs health checks. For TCP listeners, both TCP health checks and HTTP health checks are supported. ○ A TCP health check implements detection at the network layer by sending SYN packets to check whether a port is open. ○ An HTTP health check verifies the health of a backend server by sending HEAD or GET requests to simulate browser access.
Health Check Method (for the HTTP and HTTPS health checks only)	Health checks of Layer 7 (HTTP or HTTPS) listeners support both the HEAD and GET methods. The HEAD method is used by default. If your backend application server does not support the HEAD method or if the HEAD method is disabled, the health check may fail. To solve this issue, you can use the GET method instead. If the GET method is used and the response size exceeds 8 KB, the response is truncated. However, the health check result is not affected.

Parameter	Description
Health Check Path and **Health Check Domain Name (Optional)** (for the HTTP health checks only)	By default, SLB sends HTTP HEAD requests to the default homepage configured on the application server through the internal IP address of the backend ECS instance to perform health checks. If you do not use the default homepage of the application server for health checks, you must specify the path for health checks. Some application servers verify the host field in requests. In this case, the request header must contain the host field. If a domain name is configured in health check settings, SLB adds this domain name to the host field when SLB forwards a health check request to one of the preceding application servers. If no domain name is configured, SLB does not include the host field in requests and the requests are rejected by the application server, which may cause health checks to fail. If your application server verifies the host field in requests, you must configure a domain name in health check settings to ensure that the health check feature functions properly.
Normal Status Code (for the HTTP health checks only)	Select the HTTP status code that indicates successful health checks. Default values: http_2xx and http_3xx.
Health Check Port	The detection port used by the health check feature to access backend servers. By default, the backend port configured for the listener is used. **Note** If a VServer group or a primary/secondary server group is configured for the listener, and the ECS instances in the group use different ports, leave this parameter empty. SLB uses the backend port of each ECS instance to perform health checks.
Response Timeout	The length of time to wait for a health check response. If the backend ECS instance does not send an expected response within the specified period of time, the health check fails. Valid values: 1 to 300. Unit: seconds. Default value for UDP listeners: 10. Default value for HTTP, HTTPS, and TCP listeners: 5.
Health Check Interval	The interval between two consecutive health checks. All nodes in the LVS cluster perform health checks independently and in parallel on backend ECS instances at the specified interval. The health check statistics of a single ECS instance cannot reflect the health check interval because the nodes perform health checks at different times. Valid values: 1 to 50. Unit: seconds. Default value for UDP listeners: 5. Default value for HTTP, HTTPS, and TCP listeners: 2.

Parameter	Description
Unhealthy Threshold	The number of consecutive failed health checks that must occur on a backend ECS instance before this ECS instance is declared unhealthy. Valid values: 2 to 10. Default value: 3.

6. Click **Next**.

16.7.3. Disable the health check feature

This topic describes how to disable the health check feature. If you disable the health check feature, requests may be distributed to unhealthy ECS instances and cause impacts on your business. We recommend that you enable the health check feature.

Context

Note You can only disable the health check feature for HTTP and HTTPS listeners. The health check feature for UDP and TCP listeners cannot be disabled.

Procedure

1. Log on to the SLB console.
2. On the **Server Load Balancer** page, find the target SLB instance and click its instance ID.
3. On the **Listeners** tab, find the target listener and click **Configure** in the **Actions** column.
4. On the **Configure Listener** page, click **Next** until the **Health Check** step appears.
5. Turn off **Enable Health Check**.
6. Click **Next**.
7. Click **Submit**, and then click **OK**.

16.8. Certificate management

16.8.1. Certificate overview

This topic provides an overview of the certificates that can be deployed on SLB instances. To use an HTTPS listener, you must upload the required third-party server certificate and digital identification issued by a certificate authority (CA) to SLB. You do not need to configure certificates on backend servers after uploading the certificates to SLB.

To upload a third-party certificate, you must have the files that contain the public key and private key of the certificate.

HTTPS server certificates and client CA certificates are supported.

You can create a maximum of 100 certificates per account.

16.8.2. Certificate requirements

Server Load Balancer (SLB) supports only certificates in the PEM format. Before you upload a certificate, make sure that the certificate content, certificate chain, and private key meet the corresponding format requirements.

Certificates issued by a root CA

If the certificate was issued by a root certification authority (CA), the received certificate is the only one that needs to be uploaded to SLB. In this case, the website that is configured with this certificate is regarded as a trusted website and does not require additional certificates.

The certificate must meet the following format requirements:

- The certificate must start with `-----BEGIN CERTIFICATE-----` and end with -----END CERTIFICATE-----.
- Each line (except the last line) must contain 64 characters. The last line can contain 64 or fewer characters.
- The certificate content cannot contain spaces.

Certificates issued by an intermediate CA

If the certificate was issued by an intermediate CA, the received certificate file contains multiple certificates. You must upload both the server certificate and the required intermediate certificates to SLB.

The format of the certificate chain must meet the following requirements:

- The server certificate must be put first and the content of the one or more required intermediate certificates must be put underneath without blank lines between the certificates.
- The certificate content cannot contain spaces.
- Blank lines are not allowed between the certificates. Each line must contain 64 characters. For more information, see RFC1421.
- Certificates must meet the corresponding format requirements. In most cases, the intermediate CA provides instructions about the certificate format when certificates are issued. The certificates must meet the format requirements.

The following section provides a sample certificate chain:

```
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
```

Public keys of certificates

SLB supports the following public key algorithms:

- RSA 1024
- RSA 2048
- RSA 4096
- ECDSA P-256
- ECDSA P-384
- ECDSA P-521

RSA private keys

When you upload a server certificate, you must upload the private key of the certificate.

An RSA private key must meet the following format requirements:

- The private key must start with `-----BEGIN RSA PRIVATE KEY-----` and end with -----END RSA PRIVATE KEY-----, and these parts must also be uploaded.
- Blank lines are not allowed in the content. Each line (except the last line) must contain 64 characters. The last line can contain 64 or fewer characters. For more information, see RFC1421.

You may use an encrypted private key. For example, the private key starts with `----BEGIN PRIVATE KEY-----` and ends with -----END PRIVATE KEY-----, or starts with `-----BEGIN ENCRYPTED PRIVATE KEY-----` and ends with -----END ENCRYPTED PRIVATE KEY-----. The private key may also contain `Proc-Type: 4,ENCRYPTED`. In this case, you must first run the following command to convert the private key:

```
openssl rsa -in old_server_key.pem -out new_server_key.pem
```

16.8.3. Upload certificates

This topic describes how to create and upload certificates to Server Load Balancer (SLB). Before you create an HTTPS listener, you must upload the required server certificate and CA certificate to SLB. You do not need to configure certificates on backend servers after you upload the certificates to SLB.

Prerequisites

- A server certificate is purchased.
- A CA certificate and a client certificate are generated.

Context

Note that you can create up to 100 certificates with each account.

Procedure

1. In the left-side navigation pane, click **Certificates**.
2. On the Certificates page, click **Create Certificate**.
3. In the **Create Certificate** panel, set the required parameters and click **Create**.

Parameter	Description
Certificate Name	Enter a name for the certificate. The name must be 1 to 80 characters in length, and can contain only letters, digits, hyphens (-), forward slashes (/), periods (.), underscores (_), and asterisks (*).
Organization	The organization to which the certificate belongs.
Resource Group	The resource set to which the certificate belongs.
Certificate Standard	Select the type of certificate. You can select **International Standard Certificate** or **National Standard Certificate**.
Public Key Certificate	The content of the server certificate. Paste the content into the editor. Click **Example** to view the valid certificate formats. For more information, see Certificate requirements.
Private Key	The private key of the server certificate. Paste the private key into the editor. Click **Example** to view the valid certificate formats. For more information, see Certificate requirements. **Notice** A private key is required only when you upload a server certificate.
Region	The region where you want to deploy the certificate.

4. Click **Create**.

16.8.4. Generate a CA certificate

When you configure an HTTPS listener, you can use a self-signed CA certificate. This topic describes how to generate a CA certificate and use the CA certificate to sign a client certificate.

Generate a CA certificate by using Open SSL

1. Run the following commands to create a *ca* folder in the */root* directory and then create four subfolders under the *ca* folder.

   ```
   sudo mkdir ca
   cd ca
   sudo mkdir newcerts private conf server
   ```

   - *newcerts* is used to store the digital certificate signed by the CA certificate.
   - *private* is used to store the private Key of the CA certificate.
   - *conf* is used to store the configuration files used for simplifying parameters.
   - *server* is used to store the server certificate.

2. Create an *openssl.conf* file that contains the following information in the *conf* directory.

   ```
   [ ca ]
   default_ca = foo
   [ foo ]
   dir = /root/ca
   database = /root/ca/index.txt
   new_certs_dir = /root/ca/newcerts
   certificate = /root/ca/private/ca.crt
   serial = /root/ca/serial
   private_key = /root/ca/private/ca.key
   RANDFILE = /root/ca/private/.rand
   default_days = 365
   default_crl_days= 30
   default_md = md5
   unique_subject = no
   policy = policy_any
   [ policy_any ]
   countryName = match
   stateOrProvinceName = match
   organizationName = match
   organizationalUnitName = match
   localityName = optional
   commonName     = supplied
   emailAddress   = optional
   ```

3. Run the following command to generate a private Key.

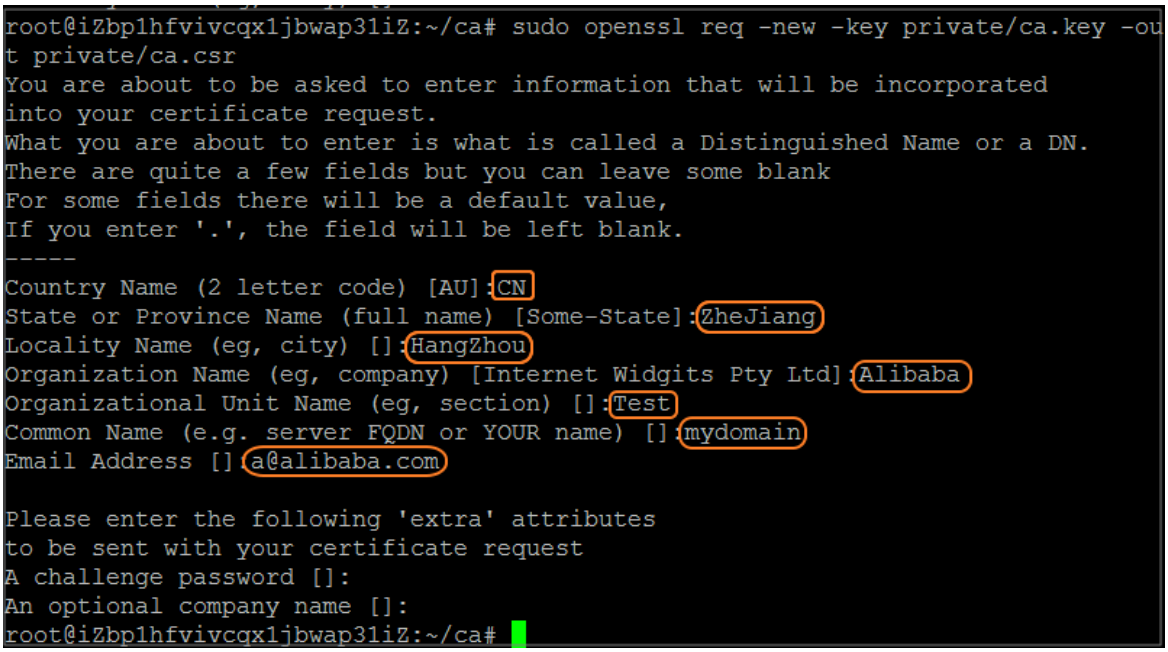
   ```
   cd /root/ca
   sudo openssl genrsa -out private/ca.key
   ```

   The following figure is an example of the key generation.

   ```
   root@iZbp1hfvivcqx1jbwap31iZ:~/ca/conf# cd /root/ca
   root@iZbp1hfvivcqx1jbwap31iZ:~/ca# sudo openssl genrsa -out private/ca.key
   Generating RSA private key, 2048 bit long modulus
   ..........................................................................
   .....+++
   ..+++
   e is 65537 (0x10001)
   ```

4. Run the following command and input the required information according to the prompts. Press Enter to generate a *csr* file.

```
sudo openssl req -new -key private/ca.key -out private/ca.csr
```



> **Note**
>
> Common Name is the domain name of the SLB instance.

5. Run the following command to generate a *crt* file:

```
sudo openssl x509 -req -days 365 -in private/ca.csr -signkey private/ca.key -out private/ca.crt
```

6. Run the following command to set the start sequence number for the private Key, which can be any four characters.

```
sudo echo FACE > serial
```

7. Run the following command to create a CA Key library:

```
sudo touch index.txt
```

8. Run the following command to create a certificate revocation list for removing the client certificate:

```
sudo openssl ca -gencrl -out /root/ca/private/ca.crl -crldays 7 -config "/root/ca/conf/openssl.conf"
```

The output is:

```
Using configuration from /root/ca/conf/openssl.conf
```

Sign the client certificate

1. Run the following command to generate a *users* folder under the *ca* directory to store the client Key.

```
sudo mkdir users
```

2. Run the following command to create a Key for the client certificate:

```
sudo openssl genrsa -des3 -out /root/ca/users/client.key 1024
```

> **Note**
>
> Enter a pass phrase when creating the Key. It is the password to protect the private Key from unauthorized access. Enter the same password twice.

3. Run the following command to create a *csr* file for the client Key.

```
sudo openssl req -new -key /root/ca/users/client.key -out /root/ca/users/client.csr
```

Enter the pass phrase set in the previous step and other required information when prompted.

> **Note**
>
> A challenge password is the password of the client certificate. Note that it is not the password of the client Key.

4. Run the following command to sign the client Key.

```
sudo openssl ca -in /root/ca/users/client.csr -cert /root/ca/private/ca.crt -keyfile /root/ca/private/ca.key -out /root/ca/users/client.crt -config "/root/ca/conf/openssl.conf"
```

Enter *y* twice when prompted to confirm the operation.

```
root@iZbp1hfvivcqx1jbwap31iZ:~/ca# sudo openssl ca -in /root/ca/users/client.csr
 -cert /root/ca/private/ca.crt -keyfile /root/ca/private/ca.key -out /root/ca/us
ers/client.crt -config "/root/ca/conf/openssl.conf"
Using configuration from /root/ca/conf/openssl.conf
Check that the request matches the signature
Signature ok
The Subject's Distinguished Name is as follows
countryName           :PRINTABLE:'CN'
stateOrProvinceName   :ASN.1 12:'ZheJiang'
localityName          :ASN.1 12:'HangZhou'
organizationName      :ASN.1 12:'Alibaba'
organizationalUnitName:ASN.1 12:'Test'
commonName            :ASN.1 12:'mydomain'
emailAddress          :IA5STRING:'a@alibaba.com'
Certificate is to be certified until Jun  4 15:28:55 2018 GMT (365 days)
Sign the certificate? [y/n]:y

1 out of 1 certificate requests certified, commit? [y/n]y
Write out database with 1 new entries
Data Base Updated
root@iZbp1hfvivcqx1jbwap31iZ:~/ca#
```

5. Run the following command to convert the certificate to a *PKCS12* file.

```
sudo openssl pkcs12 -export -clcerts -in /root/ca/users/client.crt -inkey /root/ca/users/client.key -out /root/ca/users/client.p12
```

Follow the prompts to enter the pass phrase of client Key. Then enter the password used for exporting the client certificate. This password is used to protect the client certificate, which is required when you install the client certificate.

6. Run the following commands to view the generated client certificate:

```
cd users
ls
```

16.8.5. Convert the certificate format

Server Load Balancer (SLB) supports PEM certificates only. Certificates in other formats must be converted to the PEM format before they can be uploaded to SLB. We recommend that you use Open SSL for conversion.

Convert DER to PEM

DER: This format is usually used on a Java platform. The certificate file suffix is generally *. der*, *. cer*, or *. crt*.

- Run the following command to convert the certificate format:

```
openssl x509 -inform der -in certificate.cer -out certificate.pem
```

- Run the following command to convert the private key:

```
openssl rsa -inform DER -outform PEM -in privatekey.der -out privatekey.pem
```

Convert P7B to PEM

P7B: This format is usually used in a Windows server and Tomcat.

Run the following command to convert the certificate format:

```
openssl pkcs7 -print_certs -in incertificate.p7b -out outcertificate.cer
```

Convert PFX to PEM

PFX: This format is usually used in a Windows server.

- Run the following command to extract the certificate:

```
openssl pkcs12 -in certname.pfx -nokeys -out cert.pem
```

- Run the following command to extract the private key:

```
openssl pkcs12 -in certname.pfx -nocerts -out key.pem -nodes
```

16.8.6. Replace a certificate

This topic describes how to replace a certificate with a new certificate. We recommend that you replace certificates before they expire to avoid impacts on your service.

Procedure

1. Create and upload a new certificate.

   For more information, see Certificate overview.
2. Configure the certificate for the target HTTPS listener.

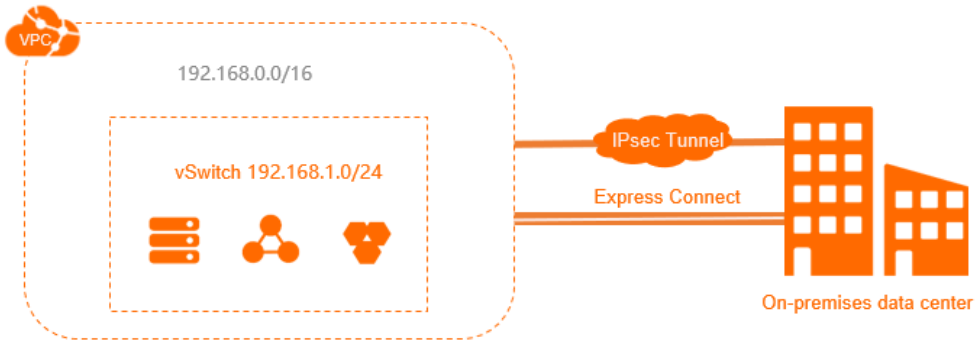
   For more information, see Add an HTTPS listener.
3. On the **Certificates** page, find the certificate to be replaced and click **Delete** in the Actions column.
4. In the dialog box that appears, click **OK**.

17.Virtual Private Cloud (VPC)

17.1. What is a VPC?

A virtual private cloud (VPC) is a private network dedicated for your use. You have full control over your VPC. For example, you can specify the CIDR block and configure route tables and gateways. In a VPC, you can deploy Apsara Stack resources, such as Elastic Compute Service (ECS) instances, ApsaraDB RDS instances, and Server Load Balancer (SLB) instances.

Furthermore, you can connect your VPC to other VPCs or on-premises networks to create a custom network environment. This way, you can migrate applications to the cloud and extend data centers.



Components

Each Virtual Private Cloud consists of at least one private network segment, one router, and at least one switch.

- Private CIDR blocks

  When you create a VPC and a vSwitch, you must specify the private IP address range for the VPC in CIDR notation.

  You can use the standard private CIDR blocks listed in the following table and their subsets as CIDR blocks for your VPCs. For more information, see 网络规划. For more information, see The network planning section in *User Guide*.

CIDR blocks	Number of available private IP addresses (system reserved ones excluded)
192.168.0.0/16	65,532
172.16.0.0/12	1,048,572
10.0.0.0/8	16,777,212

- VRouter

  A VRouter is a hub that connects all VSwitches in a VPC and serves as a gateway between the VPC and other networks. After a VPC is created, the system creates a VRouter for the VPC. Each vRouter is associated with a route table.

  For more information, see Overview.

  For more information, see the Route table overview topic in *User Guide*.

- vSwitches

  A vSwitch is a basic network component that connects different cloud resources in a VPC. After you create a VPC, you can create a vSwitch to divide your VPC into multiple subnets. vSwitches deployed in a VPC can communicate with each other over the private network. You can deploy your applications in vSwitches that belong to different zones to improve service availability.

For more information, see Switch .

For more information, see the Create a vSwitch topic in *User Guide*.

17.2. Log on to the VPC console

This topic describes how to log on to the Virtual Private Cloud (VPC) console of Apsara Uni-manager by using the Google Chrome browser.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, choose **Products > Networking > Virtual Private Cloud**.

17.3. Quick start

17.3.1. Plan and design a VPC

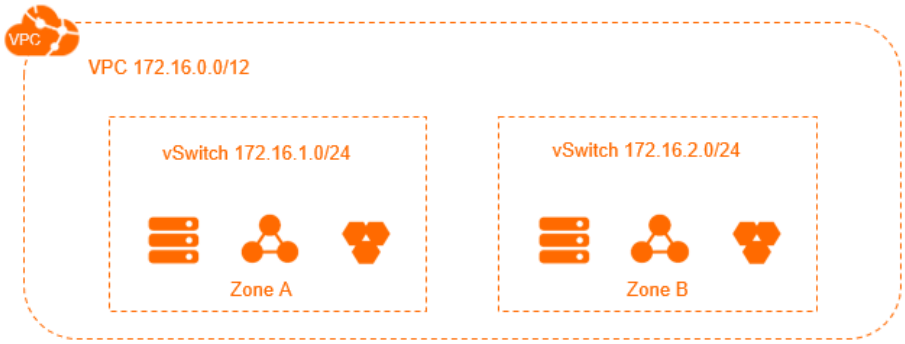
Before you create virtual private clouds (VPCs) and VSwitches, you need to plan the quantity and Classless Inter-domain Routing (CIDR) blocks of VPCs and VSwitches.

- How many VPCs are required?
- How many VSwitches are required?
- How do I specify CIDR blocks?
- How do I specify CIDR blocks if I want to connect a VPC to other VPCs or on-premises data centers?

How many VPCs are required?

- One VPC

  We recommend that you create one VPC if you do not need to deploy systems in multiple regions or separate VPCs.



- Multiple VPCs

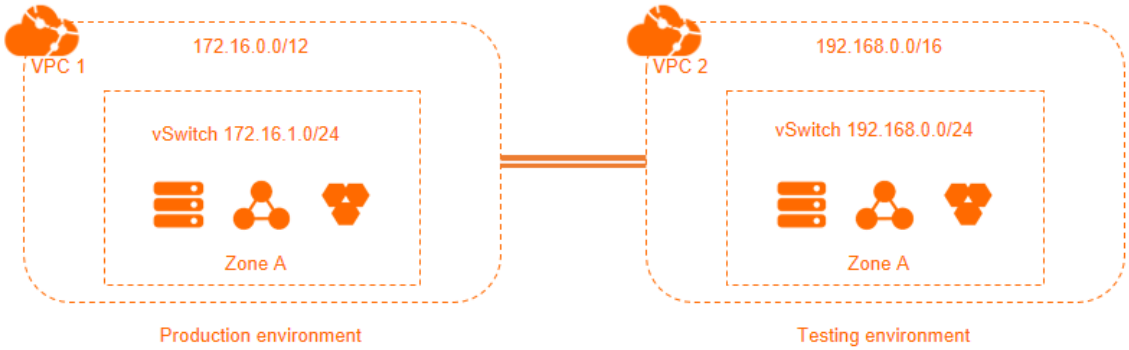
  We recommend that you create multiple VPCs if you need to:

  - Deploy application systems across regions.

    A VPC cannot be deployed across regions. If you want to deploy your application systems in different regions, you must create multiple VPCs. You can use Express Connect and VPN Gateway to connect VPCs.

  - Separate IT systems

    To separate IT systems, you must create multiple VPCs. The following figure shows an example of isolating a production environment from a test environment by deploying them in separate VPCs.



How many VSwitches are required?

We recommend that you create at least two VSwitches for each VPC and deploy these VSwitches in different zones to achieve zone-disaster recovery.

After you deploy your applications in different zones within a region, you must measure the network latency between these applications. This is because the cross-zone network latency may be higher than expected due to complex data processing or cross-zone calls. An ideal approach is to optimize and adjust your systems to strike a balance between availability and latency.

In addition, the sizes and designs of your IT systems must also be taken into consideration when you create VSwitches. If you allow traffic from the Internet to be routed to and from the frontend systems, you can deploy the front-end systems in different VSwitches and the backend systems in other VSwitches to create a robust disaster recovery strategy.

How do I specify CIDR blocks?

When you create VPCs and VSwitches, you must specify their private IP address ranges in the form of CIDR blocks.

- VPC CIDR blocks

  You can use 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or their subsets as the CIDR blocks of your VPCs. To specify CIDR blocks for VPCs, follow these rules:

  - If you have only one VPC and this VPC does not need to communicate with any on-premises data center, you can use one of the preceding CIDR blocks or one of their subsets as the CIDR block of the VPC.
  - If you have multiple VPCs, or you need to build a hybrid cloud to integrate VPCs and on-premises data centers, we recommend that you use the subsets of the preceding CIDR blocks for your VPCs. In this case, the mask cannot be longer than 16 bits.

- VSwitch CIDR blocks

  The CIDR block of a VSwitch must be a subset of the CIDR block of the VPC this VSwitch resides in. For example, if the CIDR block of a VPC is 192.168.0.0/16, the CIDR block of a VSwitch in the VPC must be a segment from 192.168.0.0/17 to 192.168.0.0/29.

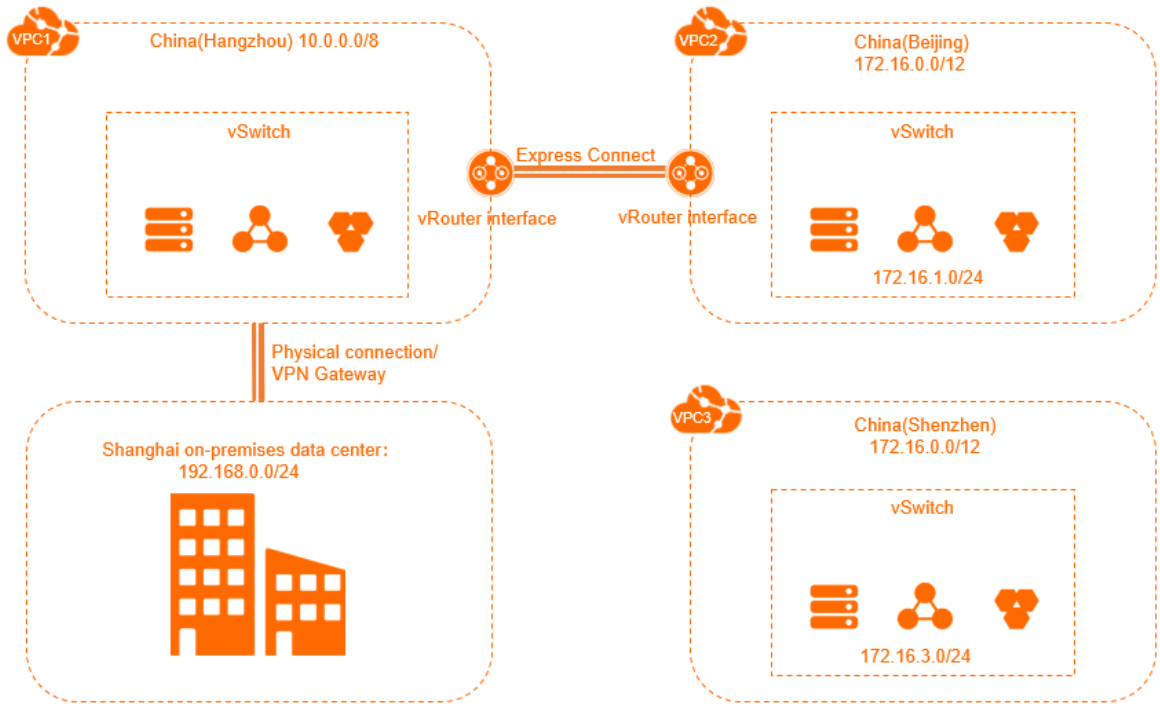
  To specify CIDR blocks for VSwitches, follow these rules:

  - The CIDR block size for a VSwitch is between a 16-bit mask and a 29-bit mask. It means that 8 to 65,536 IP addresses can be provided. This range is set because a 16-bit host address space provides addressing for 65,534 ECS instances, which can meet your needs in most cases, while a mask smaller than 29 bits can only allow very few usable host addresses.
  - The first and the last three IP addresses in each VSwitch CIDR block are reserved by the system. For example, if the CIDR block of a VSwitch is 192.168.1.0/24, the IP addresses 192.168.1.0, 192.168.1.253, 192.168.1.254, and 192.168.1.255 are reserved.
  - You must check the number of ECS instances in the VSwitch before you specify the CIDR block of a VSwitch.

How do I specify CIDR blocks if I want to connect a VPC to other VPCs or on-premises data centers?

Before you connect your VPC to another VPC or an on-premises data center, you must make sure that the CIDR block of your VPC does not conflict with that of the peer network.

For example, assume you have three VPCs: VPC1 in China (Hangzhou), VPC2 in China (Beijing), and VPC3 in China (Shenzhen), as shown in the following figure. Express Connect circuit is used for VPC1 and VPC2 to communicate with each other. VPC3 does not communicate with other VPCs, but may need to communicate with VPC2 in the future. Additionally, you have an on-premises data center in Shanghai, and you need to connect it to VPC1 by using an Express Connect circuit.



In this example, the CIDR block of VPC2 is different from the CIDR block of VPC1, but is the same with the CIDR block of VPC3. However, considering that VPC2 and VPC3 may need to communicate with each other later in the private network, the VSwitches in these VPCs are assigned with different CIDR blocks. This example demonstrates that VPCs communicating with each other can have identical CIDR blocks, but their VSwitches must have different CIDR blocks.

When you specify CIDR blocks for multiple VPCs that need to communicate with each other, follow these rules:

- The preferred practice is to specify different CIDR blocks for different VPCs. You can use the subsets of the standard CIDR blocks to increase the number of available CIDR blocks.
- If you cannot assign different CIDR blocks for VPCs, try to specify different CIDR blocks for the VSwitches in these VPCs.
- If you cannot assign different CIDR blocks for all VSwitches in these VPCs, make sure that different CIDR blocks are configured for the VSwitches communicating with each other.

17.3.2. Create an IPv4 VPC

This topic describes how to create a virtual private cloud (VPC) with an IPv4 CIDR block and create an Elastic Compute Service (ECS) instance in the VPC.

Prerequisites

To deploy cloud resources in a VPC, you must first prepare network subnetting. For more information, see Plan and design a VPC.

Step 1: Create a VPC

Perform the following steps to create a VPC:

1. Log on to the VPC console.
2. On the **VPCs** page, click **Create VPC**.
3. On the **Create VPC** page, set the following parameters and click **Submit**.

Parameter	Description
Organization	Select the organization to which the VPC belongs.
Resource Set	Select the resource set to which the VPC belongs.
Region	Select the region where you want to deploy the VPC.
Sharing Scope	Select the participants that can use the VPC to create resources. ○ **Current Resource Set**: Only the administrator of the current resource set can create resources for the shared VPC. ○ **Current Organization and Subordinate Organization**: Only the administrators of the current organization and its subordinate organization can create resources for the shared VPC. ○ **Current Organization**: Only the administrator of the current organization can create resources for the shared VPC. **Current Resource Set** is selected in this example.
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`. **VPCtest** is used in this example.
IPv4 CIDR Block	Select an IPv4 CIDR block for the VPC. The following settings are supported: ○ **Recommended CIDR Block**: You can use one of the following standard IPv4 CIDR blocks: 192.168.0.0/16 and 172.16.0.0/16. ○ **Custom CIDR Block**: You can use 192.168.0.0/16, 172.16.0.0/16, or a subset of the preceding CIDR blocks. The subnet mask must be 8 to 28 bits in length. For example, enter 192.168.0.0/16. In this example, 192.168.0.0/16 is used as the IPv4 CIDR block of the VPC. **Note** After you create a VPC, you cannot change its IPv4 CIDR block.
IPv6 CIDR Block	Specify whether to assign an IPv6 CIDR block. ○ **Do Not Assign**: The system does not assign an IPv6 CIDR block to the VPC. ○ **Assign**: The system automatically assigns an IPv6 CIDR block to the VPC. **Do Not Assign** is selected in this example.
Description	Enter a description for the VPC. The description must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

4. Click **Back to Console**. On the **VPCs** page, you can view the VPCs that are created.

Step 2: Create a vSwitch

Perform the following steps to create a vSwitch in a VPC:

1. In the left-side navigation pane, click **vSwitches**.
2. On the **vSwitches** page, click **Create vSwitch**.
3. On the **vSwitch** page, set the following parameters and click **Submit**.

Parameter	Description
Organization	Select the organization to which the vSwitch belongs.
Resource Set	Select the resource set to which the vSwitch belongs.
Region	Select the region where the vSwitch is deployed.
Zone	Select the zone to which the vSwitch belongs. In a VPC, each vSwitch can be deployed in only one zone. You cannot deploy a vSwitch across zones. However, you can deploy cloud resources in vSwitches that belong to different zones to achieve cross-zone disaster recovery. **Note** An instance can be deployed in only one vSwitch.
Sharing Scope	Select the participants that can use the vSwitch to create resources. ○ **Current Resource Set**: Only the administrator of the current resource set can create resources in the vSwitch. ○ **Current Organization and Subordinate Organization**: Only the administrators of the current organization and its subordinate organizations can create resources in the vSwitch. ○ **Current Organization**: Only the administrator of the current organization can create resources in the vSwitch. **Current Resource Set** is selected in this example.
VPC	The VPC in which you want to create the vSwitch. VPCtest is selected in this example.
Dedicated for Out-of-cloud Physical Machines	Specify whether the vSwitch is dedicated for bare-metal servers. For more information about bare-metal servers, see the **Bare-metal servers in VPCs** topic in *Bare-metal Server Management Service User Guide*. **No** is selected in this example.
vSwitch Name	Enter a name for the vSwitch. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.
IPv4 CIDR Block	Specify an IPv4 CIDR block for the vSwitch. The default IPv4 CIDR block is used in this example.

Parameter	Description
IPv6 CIDR Block	Specify an IPv6 CIDR block for the vSwitch. **Do Not Assign** is selected in this example.
Description	Enter a description for the vSwitch. The description must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

Step 3: Create a security group

Perform the following steps to create a security group:

1. In the top navigation bar, choose **Products > Elastic Computing > Elastic Compute Service**.
2. Choose **Networks and Security > Security Groups**.
3. On the **Security Groups** page, click **Create Security Group**.
4. On the **Create Security Group** page, set the following parameters and click **Submit**.

Parameter	Description
Organization	Select the organization to which the security group belongs.
Resource Set	Select the resource set to which the security group belongs.
Region	Select the region to which the security group belongs. Make sure that the security group and the VPC belong to the same region.
Zone	Select the zone to which the security group belongs.
Sharing Scope	Select the participants that can use the security group to create resources. ○ **Current Resource Set**: Only the administrator of the current resource set can create resources for the security group. ○ **Current Organization and Subordinate Organization**: Only the administrators of the current organization and its subordinate organization can create resources for the security group. ○ **Current Organization**: Only the administrator of the current organization can create resources for the security group. **Current Resource Set** is selected in this example.
VPC	The VPC to which the security group belongs.
Security Group Name	Enter a name for the security group. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

Parameter	Description
Description	Enter a description for the security group. The description must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

Step 4: Create an ECS instance

Perform the following steps to create an ECS instance in the VPC:

1. In the top navigation bar, choose **Products > Networking > Virtual Private Cloud**.
2. In the left-side navigation pane, click **vSwitches**.
3. In the top navigation bar, select the region where the vSwitch is deployed.
4. On the **vSwitches** page, find the vSwitch that you want to manage, and choose **Create > ECS Instance** in the **Actions** column.
5. On the **Create ECS Instance** page, set the parameters and click **Submit**.

   For more information about how to configure ECS instances, see Create an instance**Create an instance** in **Quick start** of *ECS user guide*.

17.3.3. Create an IPv6 VPC

This topic describes how to create a virtual private cloud (VPC) that supports IPv6 CIDR blocks and then create an Elastic Compute Service (ECS) instance that is assigned an IPv6 address in the VPC to access IPv6 services.

Step 1: Create a VPC and a vSwitch

Before you deploy cloud resources in a VPC, you must create a VPC and a vSwitch.

Perform the following steps to create a VPC and a vSwitch:

1. Log on to the VPC consoleLog on to the VPC console.
2. On the **VPCs** page, click **Create VPC**.
3. On the **Create VPC** page, set the following parameters to configure the VPC and click **OK**.

Parameter	Description
Organization	Select the organization to which the VPC belongs.
Resource Set	Select the resource set to which the VPC belongs.
Region	Select the region where you want to deploy the VPC.

Parameter	Description
Sharing Scope	Specify the scope of entities that are allowed to use the VPC. ○ **Current Resource Set**: If you select this option, the administrator of the current resource set can create resources in the VPC. ○ **Current Organization and Subordinate Organizations**: If you select this option, administrators that belong to the current organization and subordinate organizations can create resources in the VPC. ○ **Current Organization**: If you select this option, administrators that belong to the current organization can create resources in the VPC. In this example, **Current Resource Set** is selected.
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character and cannot start with **http://** or **https://**. In this example, **VPCtest** is entered.
IPv4 CIDR Block	Specify the IPv4 CIDR block of the VPC. You can specify an IPv4 CIDR block in one of the following ways: ○ **Recommended CIDR Block**: You can use one of the following standard IPv4 CIDR blocks: 192.168.0.0/16, 172.16.0.0/12, and 10.0.0.0/8. ○ **Custom CIDR Block**: Enter 192.168.0.0/16, 172.16.0.0/12, 10.0.0.0/8, or a subset of these CIDR blocks. The subnet mask must be 8 to 28 bits in length. For example, you can enter 192.168.0.0/16. In this example, Recommended CIDR Block is selected and 192.168.0.0/16 is selected as the IPv4 CIDR block of the VPC. **Note** After you create a VPC, you cannot change its IPv4 CIDR block.
IPv6 CIDR Block	Specify whether to assign an IPv6 CIDR block. ○ **Do Not Assign**: If you select this option, the system does not assign an IPv6 CIDR block to the VPC. ○ **Assign**: If you select this option, the system automatically assigns an IPv6 CIDR block to the VPC. In this example, **Assign** is selected.
Description	Enter a description for the VPC. The description must be 2 to 256 characters in length and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with **http://** or **https://**.

4. Click **Back to Console**. In the left-side navigation pane, click **VSwitches**.
5. On the **VSwitches** page, click **Create VSwitch**.
6. On the **vSwitch** page, set the following parameter to configure the vSwitch and click **Submit**.

Parameter	Description
Organization	Select the organization to which the vSwitch belongs.
Resource Set	Select the resource set to which the vSwitch belongs.

Parameter	Description
Region	Select the region where you want to deploy the vSwitch.
Zone	Select the zone where you want to deploy the vSwitch. In a VPC, each vSwitch can be deployed in only one zone. You cannot deploy a vSwitch across zones. However, you can deploy cloud resources in vSwitches that belong to different zones to achieve zone-disaster recovery. **Note** Each cloud resource can be added to only one vSwitch.
Sharing Scope	Specify the scope of entities that are allowed to use the vSwitch. ○ **Current Resource Set**: If you select this option, the administrator of the current resource set can create resources in the vSwitch. ○ **Current Organization and Subordinate Organizations**: If you select this option, administrators that belong to the current organization and subordinate organizations can create resources in the vSwitch. ○ **Current Organization**: If you select this option, administrators that belong to the current organization can can create resources in the vSwitch. In this example, **Current Resource Set** is selected.
VPC	Select the VPC where you want to deploy the vSwitch. In this example, VPCtest is selected.
Dedicated for Out-of-cloud Physical Machines	Specify whether the vSwitch to be created is dedicated to bare-metal servers. For more information about bare-metal servers, see the **Bare-metal servers in VPCs** topic in *Bare-metal Server Management Service User Guide*. In this example, **No** is selected.
vSwitch Name	Enter a name for the vSwitch. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.
IPv4 CIDR Block	Enter an IPv4 CIDR block for the vSwitch. In this example, the default IPv4 CIDR block is used.
IPv6 CIDR Block	Enter an IPv6 CIDR block for the vSwitch. In this example, the default IPv6 CIDR block is used.
Description	Enter a description for the vSwitch. The description must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.

Step 2: Create a security group

Perform the following steps to create a security group:

1. In the top navigation bar, choose **Products > Elastic Computing > Elastic Compute Service**.

2. Choose **Networks and Security > Security Groups**.
3. On the **Security Groups** page, click **Create Security Group**.
4. On the **Create Security Group** page, set the following parameters to configure the security group and click **Submit**.

Parameter	Description
Organization	Select the organization to which the security group belongs.
Resource Set	Select the resource set to which the security group belongs.
Region	Select the region to which the security group belongs. Make sure that the security group and the VPC belong to the same region.
Zone	Select the zone to which the security group belongs.
VPC	Select the VPC to which the security group belongs.
Security Group Name	Enter a name for the security group. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.
Description	Enter a description for the security group. The description must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character. It cannot start with `http://` or `https://`.

Step 3: Create and configure an ECS instance

After you create a VPC and a vSwitch, you must create an ECS instance and assign an IPv6 address to the ECS instance. You must associate this IPv6 address with the network interface controller (NIC) of the ECS instance.

Perform the following steps to create and configure an ECS instance:

1. In the top navigation bar, choose **Products > Networking > Virtual Private Cloud**.
2. In the left-side navigation pane, click **VSwitches**.
3. Select the region where the vSwitch is created.
4. On the **VSwitches** page, find the vSwitch that you want to manage and choose **Create > ECS Instance** in the **Actions** column.
5. On the **Create ECS Instance** page, configure the ECS instance and click **Submit**.

   In this example, **Assign** is selected. Therefore, an IPv6 IP address is assigned to the ECS instance. For more information about other parameters that you are required to specify when you create an ECS instance, see Create an instance**Create an ECS instance** in **Quick Start** of *Elastic Compute Service User Guide*.
6. Return to the **Instances** page and click the instance ID to view the IPv6 address that is assigned to the ECS instance.
7. Configure a static IPv6 address.
   - If the image of your ECS instance supports DHCPv6, you do not need to manually configure a static IPv6 address. DHCPv6 enables automatic configuration of IPv6 addresses. Therefore, if your ECS instance image supports DHCPv6, the ECS instance can use the assigned IPv6 address to communicate within the private network.

     The following images support DHCPv6:

- Linux images:
  - CentOS 7.6 IPV6 64Bit
  - CentOS 6.10 64Bit
  - SUSE Linux Enterprise Server 12 SP4 64Bit
- Windows Server images

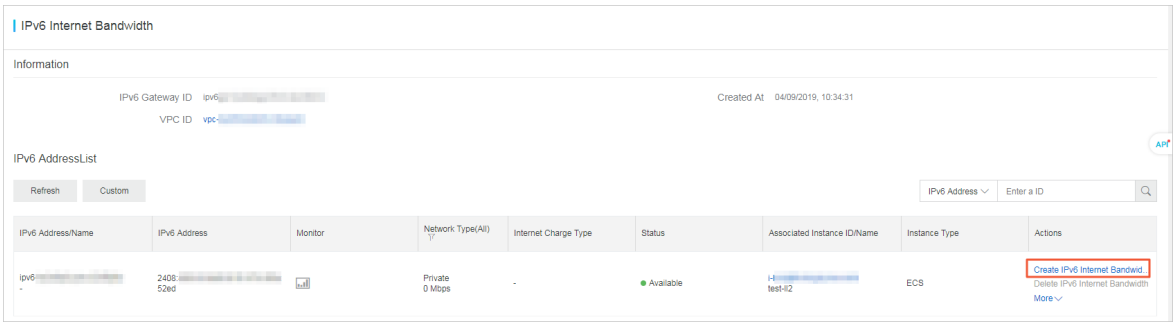
- If the image of your ECS instance does not support DHCPv6, you must manually configure an IPv6 address for the ECS instance. We recommend that you refer to the related documentation for each image for configuration guidance.

Step 4: Purchase an IPv6 Internet bandwidth plan

By default, IPv6 addresses are only used for communication within private networks. If you want to allow an instance that is assigned an IPv6 address to access the Internet or receive requests from IPv6 clients over the Internet, you must purchase an Internet bandwidth plan for the IPv6 address.

Perform the following steps to purchase an Internet bandwidth plan for the IPv6 address:

1. In the top navigation bar, choose **Products > Networking > IPv6 Gateway**.
2. Select the region where the IPv6 gateway is created.
3. On the **IPv6 Gateway** page, find the IPv6 gateway that you want to manage and click **Manage** in the **Actions** column.
4. In the left-side navigation pane, click **IPv6 Internet Bandwidth**.
5. On the **IPv6 Internet Bandwidth** page, find the IPv6 address that you want to manage and click **Enable IPv6 Internet Bandwidth** in the **Actions** column.



6. Select a bandwidth plan and click **OK**.

   The maximum IPv6 Internet bandwidth for an IPv6 gateway of the Free, Enterprise, or Enhanced Edition is 2 Gbit/s.

Step 5: Configure security group rules

IPv4 and IPv6 addresses are independent of each other. If the current security group rules do not apply to your IPv6 services, you must configure security group rules for the ECS instances to regulate communication with IPv6 addresses.

For more information about how to configure security rules, see Add a security group rule the **Add security group rules** chapter in **Security Groups** of *Elastic Compute Service User Guide*.

Step 6: Test the network connectivity

Log on to an ECS instance and **ping** an IPv6 service to test the network connectivity.

```
[root@iZhp3aehva                    ~]# ping6 ipv6.baidu.com
PING ipv6.baidu.com(2400:da00:2::29 (2400:        2::29)) 56 data bytes
64 bytes from 2400:       2::29 (2400:        2::29): icmp_seq=1 ttl=45 time=77.1 ms
64 bytes from 2400:       2::29 (2400:        2::29): icmp_seq=2 ttl=45 time=77.1 ms
64 bytes from 2400:da00.2::29 (2400:        2::29): icmp_seq=3 ttl=45 time=77.0 ms
^C
--- ipv6.baidu.com ping statistics ---
3 packets transmitted, 3 received, 0% packet loss, time 2002ms
rtt min/avg/max/mdev = 77.070/77.101/77.127/0.227 ms
[root@iZhp3ae                       ~]#
```

17.4. VPCs and VSwitches

17.4.1. Overview

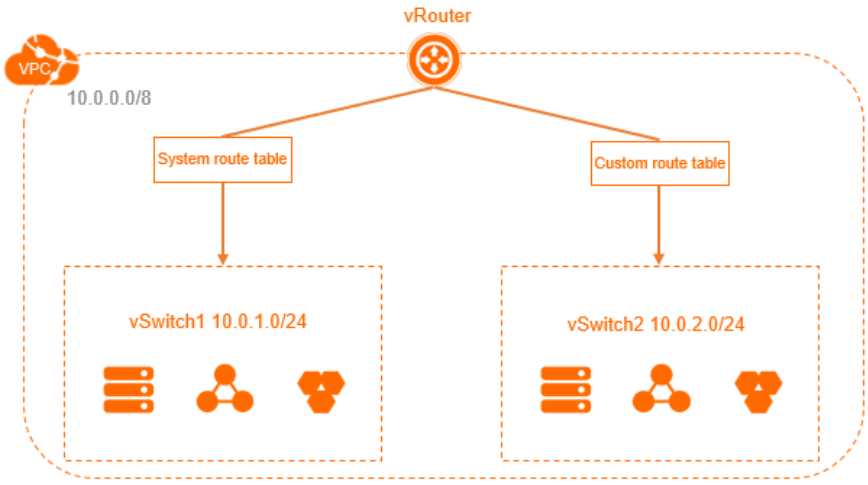
Before you can use cloud resources in a virtual private cloud (VPC), you must create a VPC and a vSwitch. You can create more than one vSwitch to divide a VPC into multiple subnets. By default, the subnets in a VPC can communicate with each other.

VPCs and vSwitches

A VPC is a private network dedicated for your use.

> **Note** You cannot directly deploy cloud resources in a VPC. You must deploy cloud resources in vSwitches of a VPC.

vSwitches are basic components of VPCs and are used to connect different cloud resources. You can deploy a VPC only in one region and cannot deploy a VPC across regions. However, a VPC contains all zones of the region to which the VPC belongs. You can create one or more vSwitches in a zone to divide a VPC into multiple subnets.



CIDR blocks and IP addresses

VPCs support both IPv4 and IPv6. By default, VPCs use IPv4. You can enable IPv6 based on your business requirements.

VPCs support the dual-stack mode. In dual-stack mode, resources in a VPC can communicate through both IPv4 and IPv6 addresses. IPv4 and IPv6 addresses are independent of each other. Therefore, you must configure routes and security groups for both IPv4 and IPv6 addresses.

The following table lists the differences between IPv4 and IPv6 addresses.

IPv4 VPC	IPv6 VPC
An IPv4 address is 32 bits in length and contains four groups. Each group consists of at most three decimal digits.	An IPv6 address is 128 bits in length and contains eight groups. Each group consists of four hexadecimal digits.
By default, IPv4 is enabled.	You can enable IPv6.
The subnet mask of a VPC CIDR block can range from /8 to /24.	The subnet mask of a VPC CIDR block is /61.
The subnet mask of a vSwitch CIDR block can range from /16 to /29.	The subnet mask of a vSwitch CIDR block is /64.
You can specify an IPv4 CIDR block.	You cannot specify an IPv6 CIDR block. The system automatically assigns an IPv6 CIDR block to your VPC from the IPv6 address pool.
Supported by all instance types.	Not supported by specific instance types. For more information, see **Instance types** under **What is ECS?** in the *Elastic Compute Service User Guide*.
IPv4 elastic IP addresses (EIPs) are supported.	IPv6 EIPs are not supported.
VPN gateways and NAT gateways are supported.	VPN gateways and NAT gateways are not supported.

By default, IPv4 and IPv6 addresses provided for VPCs support only communication over private networks. Cloud resources deployed in different vSwitches that belong to the same VPC can communicate with each other over private networks. To connect a VPC to another VPC or a data center, you can use Express Connect, or VPN Gateway.

To enable cloud resources in a VPC to communicate with the Internet, perform the following operations:

- Through IPv4 addresses

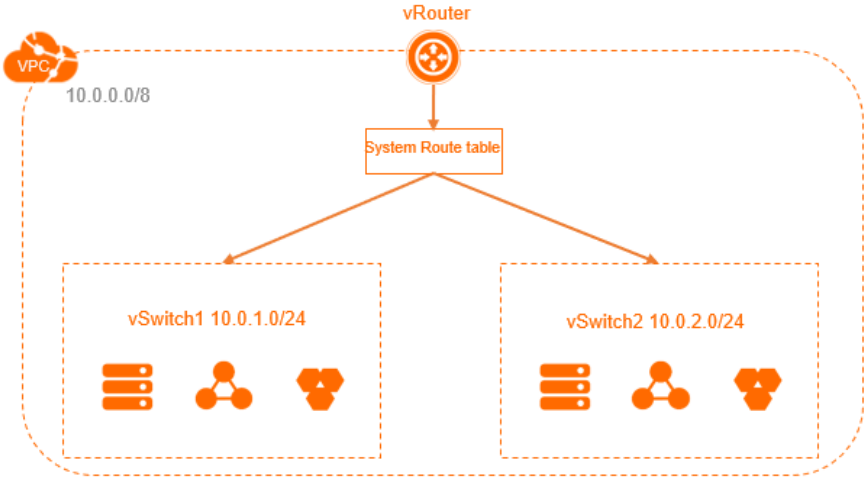
  You can configure NAT gateways or associate EIPs with Elastic Compute Service (ECS) instances in a VPC. This way, these ECS instances can communicate with the Internet through IPv4 addresses.

- Through IPv6 addresses

  To enable cloud resources in a VPC to communicate with the Internet through IPv6 addresses, you must purchase an IPv6 Internet bandwidth plan. You can configure egress-only rules for IPv6 addresses. This allows cloud resources in the VPC to access the Internet through IPv6 addresses. However IPv6 clients cannot access the cloud resources over the Internet.

Routes

The system automatically creates a system route table and adds system route entries to control the traffic of the VPC. A VPC has only one system route table. You cannot create or delete a system route table.



If multiple route entries match the destination CIDR block, the route entry with the largest prefix prevails and determines the next hop. This ensures that the traffic is routed to the most precise destination. You can also add a custom route entry to route traffic to a specified destination.

17.4.2. VPC management

17.4.2.1. Create a VPC

A virtual private cloud (VPC) is a private network dedicated for your use. You have full control over your VPC. For example, you can specify CIDR blocks, and configure route tables and gateways for your VPC. You can create a VPC, and then use Alibaba Cloud resources, such as Elastic Compute Service (ECS), ApsaraDB RDS, and Server Load Balancer (SLB) instances in the VPC. This topic describes how to create a VPC.

Prerequisites

Before you create a VPC, you must plan your networks. For more information, see 网络规划.

Procedure

1. Log on to the VPC console.
2. In the top navigation bar, select the region where you want to deploy the VPC.

   > **Note** The VPC must be deployed in the same region as that of the cloud resources that you want to deploy in this VPC.

3. On the **VPC** page, click **Create VPC**.
4. On the **Create VPC** page, configure the VPC and click **OK**. The following table describes the parameters.

Parameter	Description
Organization	Select the organization to which the VPC belongs.
Resource Set	Select the resource set to which the VPC belongs.
Region	Select the region where you want to deploy the VPC.

Parameter	Description
Sharing Scope	Select the participants that can use the VPC to create resources. ○ **Current Resource Set**: Only the administrator of the current resource set can create resources for the shared VPC. ○ **Current Organization and Subordinate Organization**: Only the administrators of the current organization and its subordinate organization can create resources for the shared VPC. ○ **Current Organization**: Only the administrator of the current organization can use create resources for the shared VPC.
VPC Name	Enter a name for the VPC. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.
IPv4 CIDR Block	Select an IPv4 CIDR block for the VPC. The following settings are supported: ○ **Recommended CIDR Block**: You can use one of the following standard IPv4 CIDR blocks: 192.168.0.0/16 and 172.16.0.0/16. ○ **Custom CIDR Block**: You can use 192.168.0.0/16, 172.16.0.0/16, or a subset of these CIDR blocks. The subnet mask must be 8 to 28 bits in length. For example, enter 192.168.0.0/24. **Note** After you create a VPC, you cannot change its IPv4 CIDR block.
IPv6 CIDR Block	Specify whether to assign an IPv6 CIDR block. ○ **Do Not Assign**: The system does not assign an IPv6 CIDR block to the VPC. ○ **Assign**: The system automatically assigns an IPv6 CIDR block to the VPC. If you set this parameter to Assign, the system automatically creates a free IPv6 gateway for this VPC, and assigns an IPv6 CIDR block with the subnet mask /56, such as 2XX1:db8::/56. By default, IPv6 addresses can be used for communication within only private networks. If you want to use the IPv6 address to access the Internet or to be accessed by IPv6 clients over the Internet, you must purchase an Internet bandwidth plan for the IPv6 address. For more information, see Enable Internet connectivity for an IPv6 addressthe **Activate IPv6 Internet bandwidth** section of the **Manage IPv6 Internet bandwidth** topic of the *IPv6 gateway user guide*.
Description	Enter a description for the VPC. The description must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

17.4.2.2. Add a secondary IPv4 CIDR block

This topic describes how to expand a virtual private cloud (VPC) by adding a secondary IPv4 CIDR block to the VPC.

Prerequisites

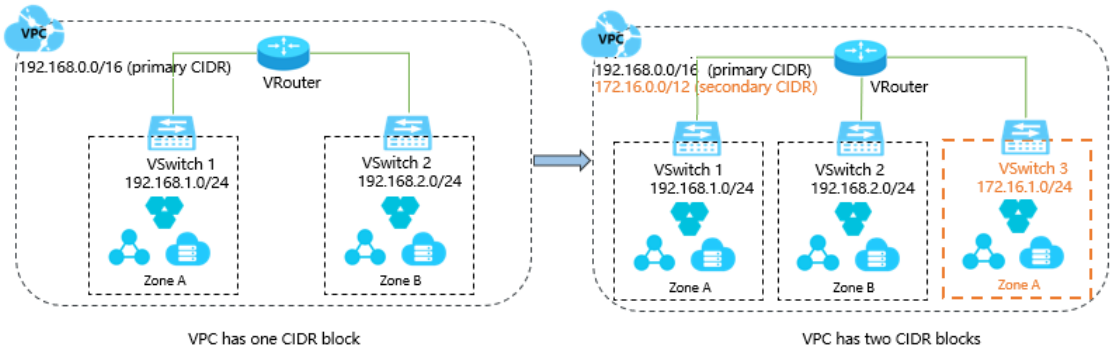
A VPC is created. For more information, see Work with VPCs.

Context

When you create a VPC, the IPv4 CIDR block that you specified is the primary CIDR block. After the VPC is created, the primary IPv4 CIDR block of the VPC cannot be modified. However, you can add a secondary IPv4 CIDR block to expand the VPC. After you add the secondary IPv4 CIDR block, both the primary and secondary IPv4 CIDR blocks

take effect. You can create a vSwitch with the primary or secondary IPv4 CIDR block. However, each vSwitch belongs to only one VPC CIDR block.

The system automatically adds a vSwitch route to the VPC route table when you create a vSwitch with the primary or secondary IPv4 CIDR block. The destination CIDR block of a vSwitch route is the CIDR block with which the vSwitch is created. The CIDR block range cannot be the same as or larger than those of other routes in the route table of the VPC.



Note You can add only one secondary IPv4 CIDR block to a VPC and cannot increase the quota.

Procedure

1. Log on to the VPC console.
2. In the top navigation bar, select the region where the VPC is deployed.
3. On the **VPC** page, find the VPC and click **Manage** in the **Actions** column.
4. On the **CIDRs** tab, click **Add IPv4 CIDR**.
5. In the **Add Secondary CIDR** panel, set the following parameters and click **OK**.

Parameter	Description
VPC	The VPC to which you want to add the secondary IPv4 CIDR block.
Secondary CIDR	Select a method to configure the secondary IPv4 CIDR block: ○ **Default CIDR Block**: You can specify one of the following standard IPv4 CIDR blocks as the secondary IPv4 CIDR block: 192.168.0.0/16 and 172.16.0.0/12. ○ **Custom CIDR Block**: You can specify one of the following standard IPv4 CIDR blocks and their subnets as the secondary IPv4 CIDR block: 192.168.0.0/16 and 172.16.0.0/12. When you add a secondary IPv4 CIDR block, take note of the following limits: ○ The CIDR block cannot start with 0. The subnet mask must be 8 to 24 bits in length. ○ The secondary IPv4 CIDR block cannot overlap with the primary IPv4 CIDR block or an existing secondary IPv4 CIDR block. For example, if the primary IPv4 CIDR block of a VPC is 192.168.0.0/16, you cannot specify one of the following CIDR blocks as the secondary IPv4 CIDR block: ■ A CIDR block that is larger than 192.168.0.0/16, such as 192.168.0.0/8. ■ 192.168.0.0/16. ■ A CIDR block that is smaller than 192.168.0.0/16, such as 192.168.0.0/24.

What's next

Work with vSwitches

17.4.2.3. Delete a secondary IPv4 CIDR block

This topic describes how to delete a secondary IPv4 CIDR block of a virtual private cloud (VPC). However, you cannot delete the primary IPv4 CIDR block of a VPC.

Prerequisites

Before you delete a secondary IPv4 CIDR block, make sure that you have deleted the vSwitch that is created within the secondary IPv4 CIDR block. For more information, see Delete a VSwitch.

Procedure

1. Log on to the VPC console.
2. In the top navigation bar, select the region where the VPC is deployed.
3. On the **VPCs** page, find the VPC that you want to manage and click **Manage** in the **Actions** column.
4. On the **CIDRs** tab, find the secondary IPv4 CIDR block that you want to delete and click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

17.4.2.4. Modify the name and description of a VPC

This topic describes how to modify the name and description of a virtual private cloud (VPC).

Procedure

1. Log on to the VPC console.
2. In the top navigation bar, select the region where your VPC is deployed.
3. On the **VPCs** page, find the target VPC network and click **Manage** in the **Actions** column.
4. In the **VPC Details** section, click **Edit** next to **Name**. In the dialog box that appears, enter a new name for the VPC and click **OK**.

   The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), and hyphens (-). It must start with a letter or a Chinese character.
5. Click **Edit** next to **Description**. In the dialog box that appears, enter a new description, and click **OK**.

   The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.

17.4.2.5. Delete a VPC

This topic describes how to delete a virtual private cloud (VPC). After you delete a VPC, the vRouters and route tables associated with the VPC are also deleted.

Prerequisites

Before you delete a VPC, make sure that the following requirements are met:

- No vSwitch exists in the VPC. If a vSwitch exists in the VPC, delete the vSwitch first. For more information, see Delete a VSwitch.
- No IPv6 gateway exists in the VPC. If an IPv6 gateway exists in the VPC, delete the IPv6 gateway first.

Procedure

1. Log on to the VPC console.
2. In the top navigation bar, select the region where the VPC is deployed.

3. On the **VPCs** page, find the VPC that you want to delete, and click **Delete** in the **Actions** column.
4. In the **Delete VPC** message, click **OK**.

17.4.3. VSwitch management

17.4.3.1. Create a vSwitch

A vSwitch is a basic network component that connects different cloud resources in a virtual private cloud (VPC).

Context

After you create a VPC, you can create vSwitches to divide the VPC into one or more subnets. vSwitches within the same VPC can communicate with each other. Cloud resources must be deployed in vSwitches. You can deploy applications in vSwitches that belong to different zones to improve service availability.

> **Note** vSwitches do not support multicasting or broadcasting.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **vSwitches**.
3. Select the region of the VPC in which you want to create a vSwitch.
4. On the **vSwitches** page, click **Create vSwitch**.
5. On the **vSwitch** page, set the following parameters and click **Submit**.

Parameter	Description
Organization	Select the organization to which the vSwitch belongs.
Resource Set	Select the resource set to which the vSwitch belongs.
Region	Select the region where you want to deploy the vSwitch.
Zone	Select the zone to which the vSwitch belongs. In a VPC, each vSwitch can be deployed in only one zone. You cannot deploy a vSwitch across zones. However, you can deploy cloud resources in vSwitches that belong to different zones to achieve cross-zone disaster recovery. **Note** A cloud instance can be deployed in only one vSwitch.
Sharing Scope	Select the participants that can use the vSwitch to create resources. ○ **Current Resource Set**: Only the administrator of the current resource set can create resources in the vSwitch. ○ **Current Organization and Subordinate Organization**: Only the administrators of the current organization and its subordinate organizations can create resources in the vSwitch. ○ **Current Organization**: Only the administrator of the current organization can create resources in the vSwitch.
VPC	Select the VPC for which you want to create the vSwitch.

Parameter	Description
Dedicated for Out-of-cloud Physical Machines	Specify whether the vSwitch is dedicated for bare-metal servers. For more information about bare-metal servers, see the **Bare-metal servers in VPCs** topic in *Bare-metal Server Management Service User Guide*.
vSwitch Name	Enter a name for the vSwitch. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.
IPv4 CIDR Block	Enter an IPv4 CIDR block for the vSwitch. ○ You must specify the IP address range of the vSwitch in CIDR notation. The subnet mask must be 16 to 29 bits in length. It means that 8 to 65,536 IP addresses can be provided. ○ The CIDR block of a vSwitch must be a proper subset of the CIDR block of the VPC to which the vSwitch belongs. ○ The first IP address and last three IP addresses of a vSwitch are reserved. For example, if the CIDR block of a vSwitch is 192.168.1.0/24, the IP addresses 192.168.1.0, 192.168.1.253, 192.168.1.254, and 192.168.1.255 are reserved. ○ The CIDR block of a vSwitch cannot be the same as the destination CIDR block in a route entry of the VPC to which the vSwitch belongs. However, the CIDR block of the vSwitch can be a proper subset of the destination CIDR block of the route entry. ○ After a vSwitch is created, you cannot modify its CIDR block.
IPv6 CIDR Block	Enter an IPv6 CIDR block for the vSwitch. ○ You must check whether IPv6 is enabled for the specified VPC. If IPv6 is disabled, you cannot assign an IPv6 CIDR block to the vSwitch. ○ If IPv6 is enabled, you can enter a decimal number ranging from 0 to 255 to define the last 8 bits of the IPv6 CIDR block of the vSwitch. For example, if the IPv6 CIDR block of the VPC is 2xx1:db8::/64, specify 255 to define the last 8 bits of the IPv6 CIDR block. In this case, the IPv6 CIDR block of the vSwitch is 2XX1:db8:ff::/64. ff is the hexadecimal value of 255.
Description	Enter a description for the vSwitch. The description must be 2 to 256 characters in length, and can contain digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter and cannot start with `http://` or `https://`.

17.4.3.2. Create cloud resources in a vSwitch

You cannot directly deploy cloud resources in a virtual private cloud (VPC). You can deploy cloud resources only in a vSwitch that belongs to a VPC. This topic describes how to create cloud resources in a vSwitch.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **vSwitches**.
3. Select the region of the VPC to which the vSwitch belongs.
4. On the **vSwitches** page, find the vSwitch, click **Create** in the **Actions** column, and select the cloud resource that you want to create.

   You can create Elastic Compute Service (ECS) instances, ApsaraDB RDS instances, and Server Load Balancer

(SLB) instances in a vSwitch.

5. On the page that appears, set the parameters.

17.4.3.3. Modify a vSwitch

This topic describes how to modify the name and description of a vSwitch.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **vSwitches**.
3. Select the region of the VPC to which the vSwitch belongs.
4. On the **vSwitches** page, find the vSwitch that you want to manage and click **Manage** in the **Actions** column.
5. In the **vSwitch Basic Information** section, click **Edit** next to **Name** to modify the name of the vSwitch.

   The name must be 2 to 128 characters in length, and can contain letters, digits, underscores (_), and hyphens (-). The name must start with a letter.
6. Click **Edit** next to **Description** to modify the description of the vSwitch.

   The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.

17.4.3.4. Delete a vSwitch

This topic describes how to delete a vSwitch. After you delete a vSwitch, you cannot deploy cloud resources in it.

Prerequisites

Before you delete a vSwitch, make sure that the following requirements are met:

- All instances deployed in the vSwitch are deleted, such as Elastic Compute Service (ECS) instances, Server Load Balancer (SLB) instances, and ApsaraDB RDS instances.
- All resources associated with the vSwitch are deleted, such as high-availability virtual IP addresses (HAVIPs) and Source Network Address Translation (SNAT) entries.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **vSwitches**.
3. Select the region of the VPC to which the vSwitch belongs.
4. On the **vSwitch** page, find the vSwitch that you want to delete and click **Delete** in the **Actions** column.
5. In the **Delete vSwitch** message, click **OK**.

17.5. Route tables

17.5.1. Overview

After you create a virtual private cloud (VPC), the system creates a system route table for the VPC and adds system routes to the route table. The system routes are used to route traffic within the VPC. You cannot create or delete system routes. However, you can create custom routes to route traffic from specific CIDR blocks to a specified destination.

Route tables

After you create a VPC, the system creates a system route table to manage routes of the VPC. By default, vSwitches in the VPC use this route table. You cannot create or delete the system route table of a VPC.

Each entry in a route table is a *route entry*. A route entry specifies the destination of traffic and consists of the destination CIDR block, next hop type, and next hop. Route entries include system route entries and custom route entries.

Regions that support custom route tables

The following table describes the regions that support custom route tables by default.

Area	Supported region
Asia Pacific	China (Qingdao), China (Zhangjiakou), China (Hohhot), China (Ulanqab), China (Shanghai), China (Heyuan), China (Guangzhou), China (Chengdu), China (Hong Kong), Japan (Tokyo), Singapore (Singapore), Australia (Sydney), Malaysia (Kuala Lumpur), and Indonesia (Jakarta)
Europe & Americas	US (Silicon Valley), US (Virginia), Germany (Frankfurt), and UK (London)
Middle East and India	India (Mumbai) and UAE (Dubai)

The custom route table feature is in public preview in the following regions. You can apply for participating in the public review.

Area	Supported region
Asia Pacific	China (Beijing), China (Shanghai), and China (Shenzhen)

System routes

After you create a VPC, the system automatically adds the following system routes to the route table:

- A route entry with a destination CIDR block of 100.64.0.0/10. This route is used for communication among cloud resources within the VPC.
- Route entries whose destination CIDR blocks are the same as the CIDR blocks of the vSwitches in the VPC. These routes are used for communication among cloud resources within the vSwitches.

For example, if you create a VPC whose CIDR block is 192.168.0.0/16 and two vSwitches whose CIDR blocks are 192.168.1.0/24 and 192.168.0.0/24, three system routes are automatically added to the route table of the VPC. The following table describes the system routes.

Destination CIDR block	Next hop	Route entry type
100.64.0.0/10	-	System route
192.168.1.0/24	-	System route
192.168.0.0/24	-	System route

Custom routes

You can add custom routes to replace system routes or route traffic to a specified destination. You can specify the following types of next hops when you create a custom route:

- Elastic Compute Service (ECS) instance: Traffic that is destined for the destination CIDR block is routed to a specified ECS instance in the VPC.

  You can select this type if you want to access the Internet or other applications through the applications deployed on the ECS instance.

- VPN gateway: Traffic destined for the destination CIDR block is routed to a specified VPN gateway.

  You can select this type if you want to connect a VPC to another VPC or an on-premises network through the VPN gateway.

- NAT gateway: Traffic destined for the destination CIDR block is routed to a specified NAT gateway.

  You can select this type if you want to connect a VPC to the Internet through the NAT gateway.
- Router interface (to VPC): Traffic that is destined for the destination CIDR block is routed to a specified VPC.

  You can select this type if you want to connect two VPCs through Express Connect circuits.
- Router interface (to VBR): Traffic that is destined for the destination CIDR block is routed to a specified virtual border router (VBR).

  You can select this type if you want to connect a VPC to an on-premises network through Express Connect circuits.
- Secondary ENI: Traffic that is destined for the destination CIDR block is routed to a specified secondary elastic network interface (ENI).

IPv6 routes

If IPv6 is enabled for your VPC, the following route entries are automatically added to the system route table of the VPC:

- A custom route entry whose destination CIDR block is ::/0 and whose next hop is the IPv6 gateway. Cloud resources deployed in the VPC use this route to access the Internet through IPv6 addresses.
- A system route entry of which the destination CIDR block is the IPv6 CIDR block of a vSwitch. This route is used for communication within the vSwitch.

Routing rules

If multiple route entries match the destination CIDR block, the route entry with the largest prefix prevails and determines the next hop. This ensures that the traffic is routed to the most precise destination.

For example, the following table describes the route table of a VPC.

Destination CIDR block	Next hop type	Next hop	Route entry type
100.64.0.0/10	-	-	System route
192.168.0.0/24	-	-	System route
0.0.0.0/0	Instance	i-12345678	Custom route
10.0.0.0/24	Instance	i-87654321	Custom route

The route entries that are destined for `100.64.0.0/10` and `192.168.0.0/24` are system route entries. The route entries that are destined for `0.0.0.0/0` and `10.0.0.0/24` are custom route entries. Traffic that is destined for `0.0.0.0/0` is routed to the ECS instance `i-12345678`, whereas traffic that is destined for `10.0.0.0/24` is routed to the ECS instance `i-87654321`. Based on the preceding rule, traffic that is destined for `10.0.0.1` is routed to the ECS instance `i-87654321`, whereas traffic that is destined for `10.0.1.1` is routed to the ECS instance `i-12345678`.

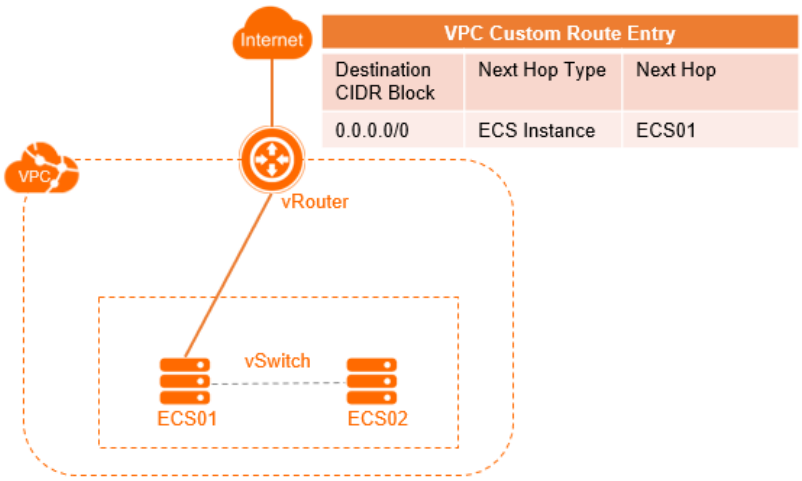
Routing examples

You can add custom route entries to a route table to control inbound and outbound traffic that are transmitted over the VPC.

- Routes within a VPC

  The following figure shows a NAT gateway that is deployed on an ECS instance (ECS 01) in a VPC. To enable the cloud resources in the VPC to access the Internet through the ECS instance, you must add the following route entry to the route table.

Destination CIDR block	Next hop type	Next hop
0.0.0.0/0	ECS instance	ECS01



- Connect two VPCs through Express Connect

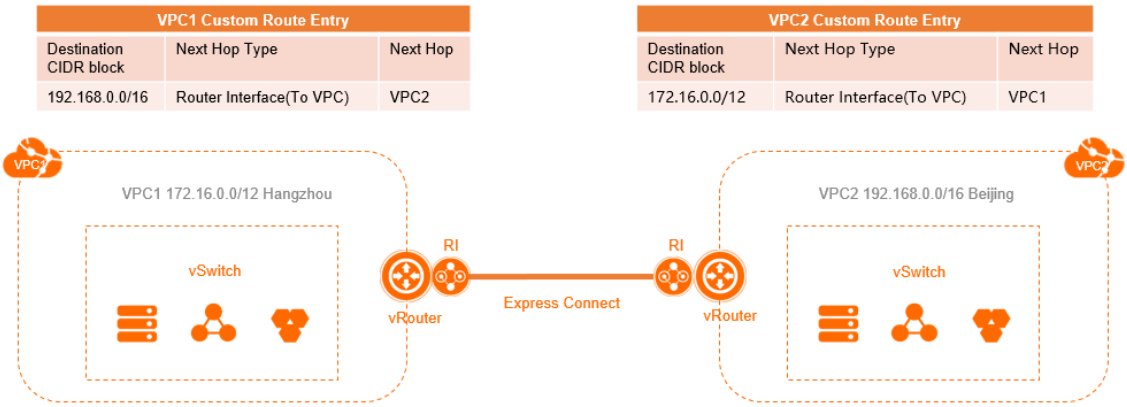
  The following figure shows that VPC 1 (172.16.0.0/12) is connected to VPC 2 (192.168.0.0/16) through Express Connect. After you create router interfaces, you must add the following route entries to the VPCs:

  - Add the following route entry to VPC 1

Destination CIDR block	Next hop type	Next hop
192.168.0.0/16	Router interface (to VPC)	VPC2

  - Add the following route entry to VPC 2

Destination CIDR block	Next hop type	Next hop
172.16.0.0/12	Router interface (to VPC)	VPC1



- Connect two VPCs through a VPN gateway

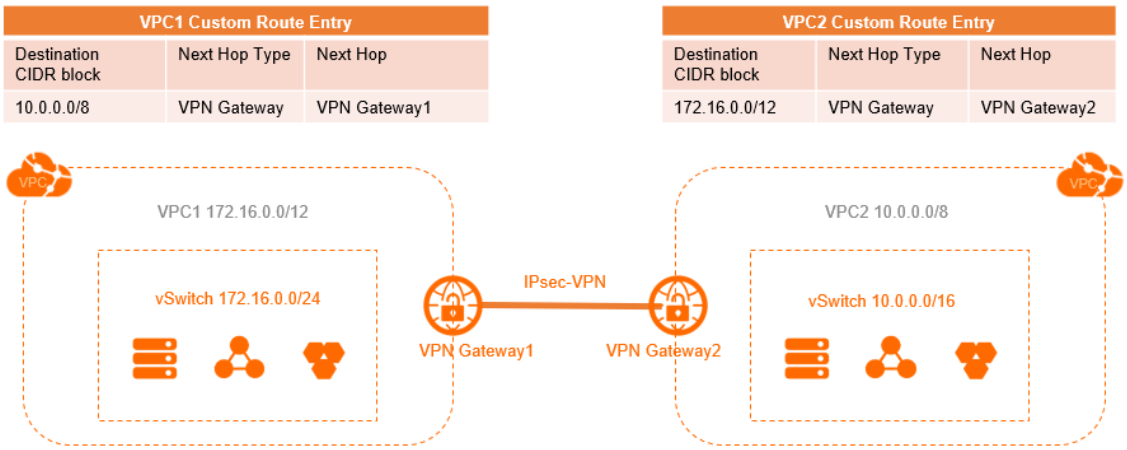
  The following figure shows that VPC 1 (172.16.0.0/12) is connected to VPC 2 (10.0.0.0/8) through a VPN gateway. After you configure the VPN gateway, you must add the following route entries to the VPCs.

- Add the following route entry to VPC 1

Destination CIDR block	Next hop type	Next hop
10.0.0.0/8	VPN gateway	VPN gateway 1

- Add the following route entry to VPC 2

Destination CIDR block	Next hop type	Next hop
172.16.0.0/12	VPN gateway	VPN gateway 2



- Connect a VPC to a data center through Express Connect

  The following figure shows that a VPC is connected to an on-premises network through Express Connect. After you configure a connection over an Express Connect circuit and a virtual border router (VBR), you must add the following route entries:

  - Add the following route entry to the VPC

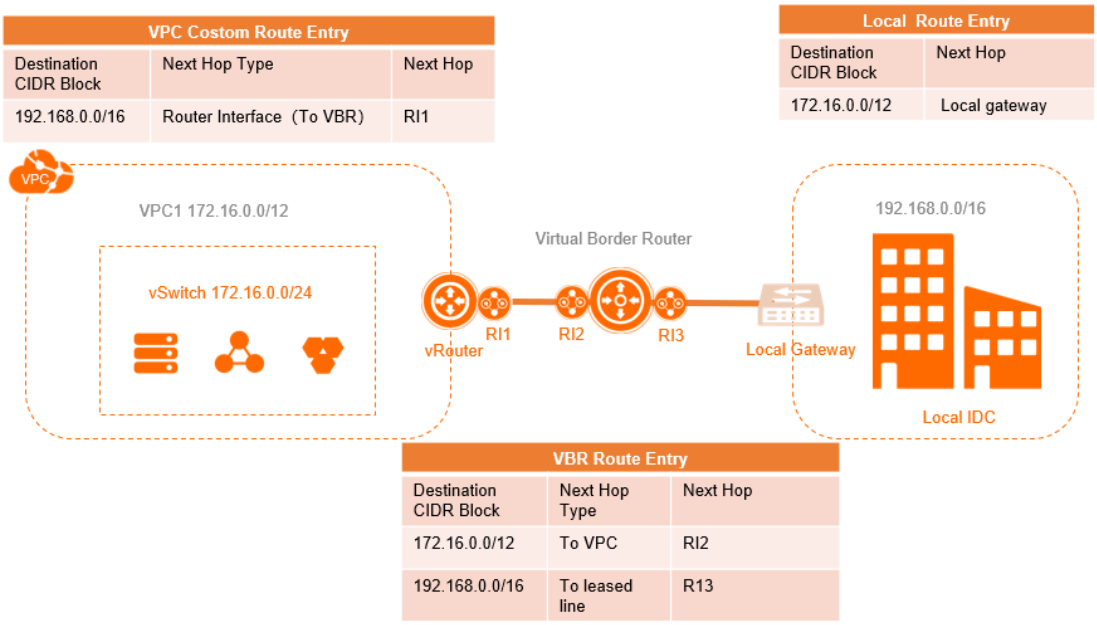
Destination CIDR block	Next hop type	Next hop
192.168.0.0/16	Router interfaces (general routing)	Router interface RI 1

  - Add the following route entry to the VBR

Destination CIDR block	Next hop type	Next hop
192.168.0.0/16	Express Connect circuit	Router interface RI 3
172.16.0.0/12	VPC	Router interface RI 2

- Add the following route entry to the on-premises network

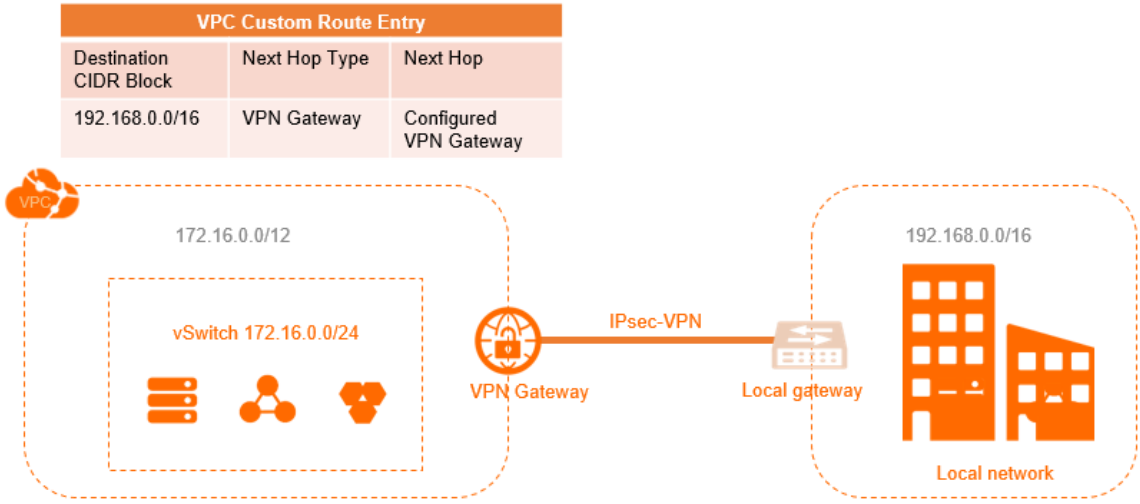
Destination CIDR block	Next hop type	Next hop
172.16.0.0/12	-	On-premises gateway device



- Connect a VPC to a data center through a VPN gateway

  The following figure shows that a VPC (172.16.0.0/12) is connected to a data center (192.168.0.0/16) through a VPN gateway. After you configure the VPN gateway, you must add the following route entry to the VPC.

Destination CIDR block	Next hop type	Next hop
192.168.0.0/16	VPN gateway	The VPN gateway that you created



17.5.2. Add a custom route entry

This topic describes how to add a custom route entry. After you create a virtual private cloud (VPC), the system creates a system route table and adds system route entries to the route table. The system route entries are used to route traffic within the VPC. You cannot create or delete system route entries. However, you can create custom route entries to route traffic from source CIDR blocks to specific destinations.

Context

Each item in the route table is a route entry. A route entry, which consists of the destination CIDR block, type of next hop, and next hop, specifies the destination for network traffic. Route entries include system route entries and custom route entries.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route table belongs.
4. On the **Route Tables** page, find the route table and click **Manage** in the **Actions** column.
5. In the **Route Table Details** section, click **Add Route Entry**.
6. In the **Add Route Entry** panel, set the following parameters and click **OK**:

Parameter	Description
Destination CIDR block	Enter a destination CIDR block for the route entry.

Parameter	Description
Next Hop Type	Select the type of next hop. Valid values: ○ **ECS Instance**: Traffic destined for the specified CIDR block is routed to the specified Elastic Compute Service (ECS) instance. Select this type if you want to route traffic to an ECS instance for centralized traffic forwarding and management. For example, you can configure an ECS instance as the Internet-facing gateway to route traffic from other ECS instances to the Internet. ○ **HaVip Address**: Traffic destined for the specified CIDR block is routed to the high-availability virtual IP address (HAVIP) that you select. ○ **VPN Gateway**: Traffic destined for the specified CIDR block is routed to the specified VPN gateway. ○ **NAT Gateway**: Traffic destined for the specified CIDR block is routed to the specified NAT gateway. ○ **Secondary ENI**: Traffic destined for the specified CIDR block is routed to the secondary elastic network interface (ENI) that you select. ○ **Router Interface (To VPC)**: Traffic destined for the specified CIDR block is routed to the specified VPC. Select this type if you want to connect VPCs through Express Connect circuits. ○ **Router Interface (To VBR)**: Traffic destined for the specified CIDR block is routed to the router interface that is associated with a virtual border router (VBR). Select this type if you want to connect the VPC to a data center through an Express Connect circuit. If you specify Router Interface (To VBR), you must select a routing mode: ■ **General Routing**: Select an associated router interface. ■ **Active/Standby Routing**: Select two instances as the next hop. The active route has a weight of 100 and the standby route has a weight of 0. The standby route takes effect when the active route fails the health check. ■ **Load Balancing**: Select two to four router interfaces as the next hop. The peer router of each router interface must be a VBR. Valid values of the instance weight: 1 to 255. The value must be an integer and the default value is 100. The weight of each instance must be the same. This way, traffic can be evenly distributed to the next-hop instances.
ECS Instance/VPN Gateway/NAT Gateway/Secondary ENI/HAVIP/VPC	Select an instance as the next hop.

17.5.3. Export route entries

This topic describes how to export route entries from a route table for backup.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route table belongs.

4. On the **Route Tables** page, find the route table and click **Manage** in the **Actions** column.
5. In the **Route Table Details** section, click the **Route Entry List** tab, and then click **Export**.

   The route entries are exported to a *.csv* file in your local computer.

17.5.4. Modify a route table

This topic describes how to modify the name and description of a route table.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route table belongs.
4. On the **Route Tables** page, find the route table and click its ID.
5. In the **Route Table Details** section, click **Edit** next to **Name**. In the dialog box that appears, enter a new name for the route table and click **OK**.

   The name must be 2 to 128 characters in length and can contain letters, Chinese characters, digits, underscores (_), and hyphens (-). It must start with a letter or a Chinese character.
6. Click **Edit** next to **Description**. In the dialog box that appears, enter a new description of the route table, and click **OK**.

   The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.

17.5.5. Delete a custom route entry

This topic describes how to delete a custom route entry. A route table consists of one or more route entries that determine which way to forward traffic. Note that system route entries cannot be deleted.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Route Tables**.
3. In the top navigation bar, select the region to which the route table belongs.
4. On the **Route Tables** page, find the route table and click its ID.
5. On the **Route Entry List** tab, find the target route entry and then click **Delete** in the **Actions** column.
6. In the **Delete Route Entry** dialog box, click **OK**.

17.6. HAVIPs

17.6.1. Overview

High-availability virtual IP addresses (HAVIPs) are private IP addresses that can be created and released as independent resources. You can use HAVIPs with high-availability (HA) software such as Keepalived to provide active/standby services. This improves the availability of your services.

Overview

Each Elastic Compute Service (ECS) instance is assigned a private IP address as the primary IP address. You can associate HAVIPs with an ECS instance to increase the number of private IP address available for the ECS instance. Both the primary IP address and HAVIPs of an ECS instance can be used to access networks. In addition, you can use HAVIPs with HA software such as Keepalived to provide active/standby services. This improves the availability of your services. You can associate an HAVIP with ECS instances by using the following methods:

- Directly associate an HAVIP with ECS instances.

Each HAVIP can be associated with two ECS instances. After an HAVIP is associated with ECS instances, the ECS instances can send Address Resolution Protocol (ARP) messages to advertise the HAVIP. After the ECS instances advertise the HAVIP, one of the ECS instances serves as the primary instance, and the other ECS instance serves as the secondary instance. If the primary ECS instance is down, the secondary ECS instance takes over to provide services.

- Attach secondary elastic network interfaces (ENIs) to ECS instances. Then, associate the HAVIP with the secondary ENIs.

  Each HAVIP can be associated with ENIs of two ECS instances. After the HAVIP is associated with the ENIs, the ECS instances can send ARP messages to advertise the HAVIP. After the ECS instances advertise the HAVIP, one of the ECS instances serves as the primary instance, and the other ECS instance serves as the secondary instance. If the primary ECS instance is down, the secondary ECS instance takes over to provide services.

  > **Note** Before you associate an HAVIP with secondary ENIs, make sure that the secondary ENIs are attached to two ECS instances.

HAVIPs have the following features:

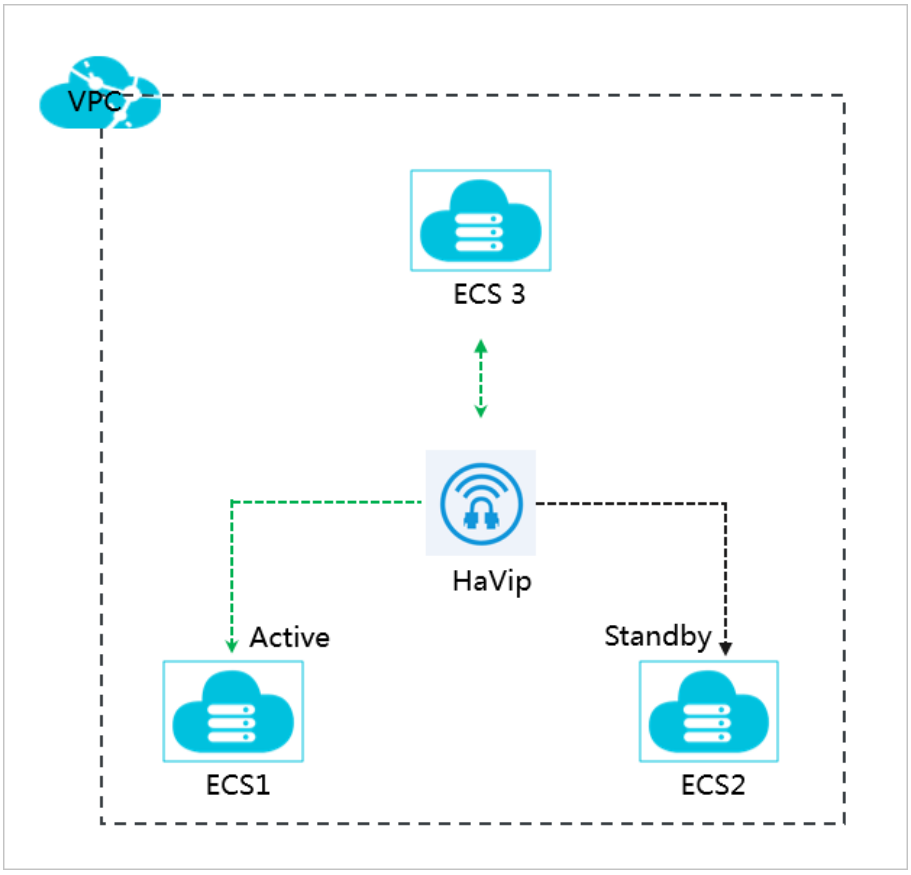
- HAVIPs are floating private IP addresses and are not statically assigned to specified ECS instances. HAVIPs can be associated with or disassociated from ECS instances through ARP announcements.
- An HAVIP can be associated with only ECS instances or ENIs that belong to the same vSwitch.
- You can associate each HAVIP with two ECS instances or two secondary ENIs. However, you cannot associate an HAVIP with an ECS instance and a secondary ENI at the same time.

Scenarios

HAVIPs support flexible configurations in the following scenarios:

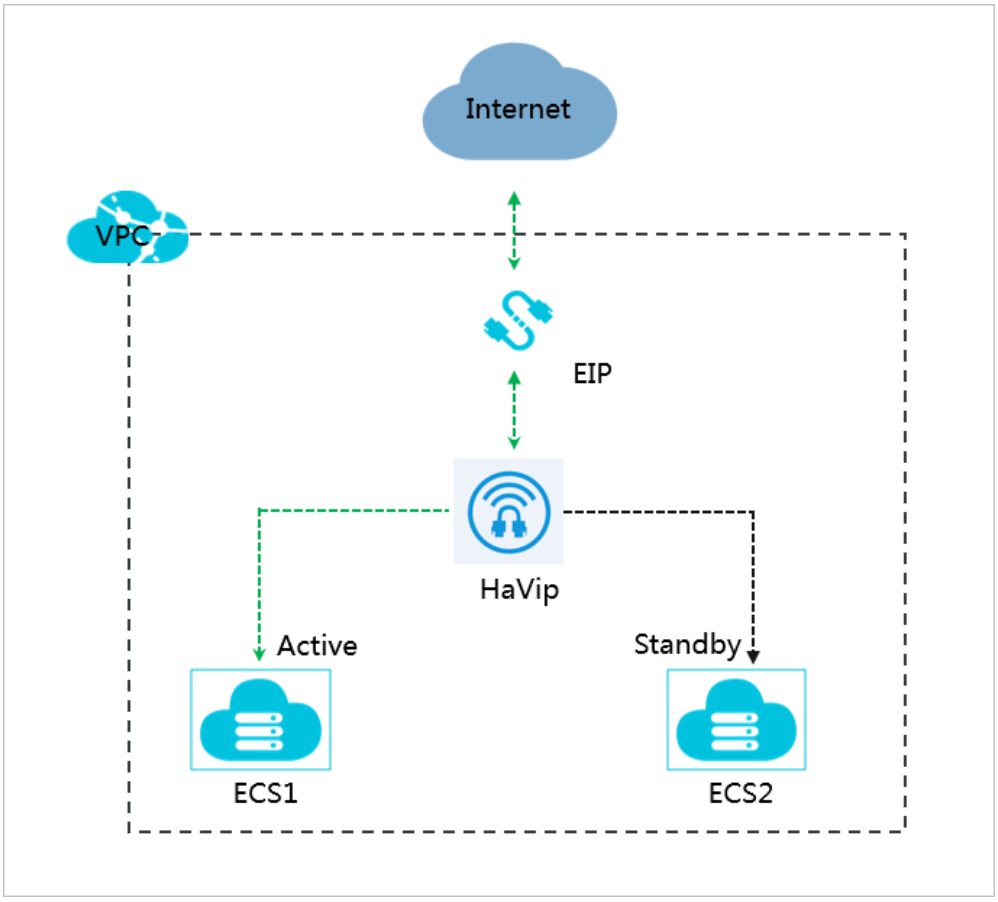
- Scenario 1: Internal-facing HA services

  In the following figure, two ECS instances are assigned the same HAVIP. Keepalived is configured for the ECS instances to provide an internal-facing HA service. Other instances in the same virtual private cloud (VPC) can access this service. The HAVIP serves as the service address. If the primary ECS instance is down, the secondary ECS instance takes over. This improves the availability of your services.



- Scenario 2: Internet-facing HA services

  In the following figure, two ECS instances are assigned the same HAVIP. Keepalived is configured and the HAVIP is associated with an elastic IP address (EIP) for the ECS instances to provide an Internet-facing HA service. The EIP that is associated with the HAVIP serves as the service address. If the primary ECS instance is down, the secondary ECS instance takes over. This improves the availability of your services.



Limits

Before you use HAVIPs, take note of the following limits.

Item	Default
Number of HAVIPs that can be created in each VPC	5
Number of HAVIPs that can be associated with each ECS instance	5
Number of HAVIPs that can be associated with each secondary ENI	5
Number of ECS instances that can be associated with each HAVIP	2
Number of secondary ENIs that can be associated with each HAVIP	2
Number of route entries that point to an HAVIP in each VPC	5

Item	Default
Whether HAVIPs support broadcast or multicast communication	Not supported **Note** HAVIPs support only unicasting. To implement high availability through third-party software such as Keepalived, you must modify the configuration file to change the communication method to unicasting.

17.6.2. Create HAVIPs

High-availability virtual IP addresses (HAVIPs) are private IP addresses that can be created and released as independent resources. This topic describes how to create HAVIPs in the console.

Prerequisites

A VPC and vSwitches are created. For more information, see Create a VPC and Work with vSwitches.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top menu bar, select the region where you want to create the HAVIP.
4. On the **HaVip** page, click **Create HaVip**.
5. On the **Create a high-availability virtual IP address** page, set the following parameters and click **Submitted** to create an HAVIP.

Parameter	Description
Tissue	Select the organization to which the HAVIP belongs.
Resource Set	Select the resource set to which the HAVIP belongs.
Region	Select the region where you want to create the HAVIP.
Proprietary Network vpc	Select the VPC to which the HAVIP that you want to create belongs.
vswitch	Select the vSwitch to which the HAVIP that you want to create belongs.
Private IP Address	Specify a private IP address for the HAVIP. **Note** You must specify an idle private IP address that falls within the CIDR block of the vSwitch.

17.6.3. Associate HAVIPs with backend cloud resources

17.6.3.1. Associate an HAVIP with an ECS instance

This topic describes how to associate a high-availability virtual IP address (HAVIP) with an Elastic Compute Service (ECS) instance that is deployed in a virtual private clouds (VPC). After you associate an HAVIP with an ECS instance, the ECS instance can send Address Resolution Protocol (ARP) messages to advertise the HAVIP. This way, the ECS instance can use more than one private IP address. Each HAVIP can be associated with at most two ECS instances.

Prerequisites

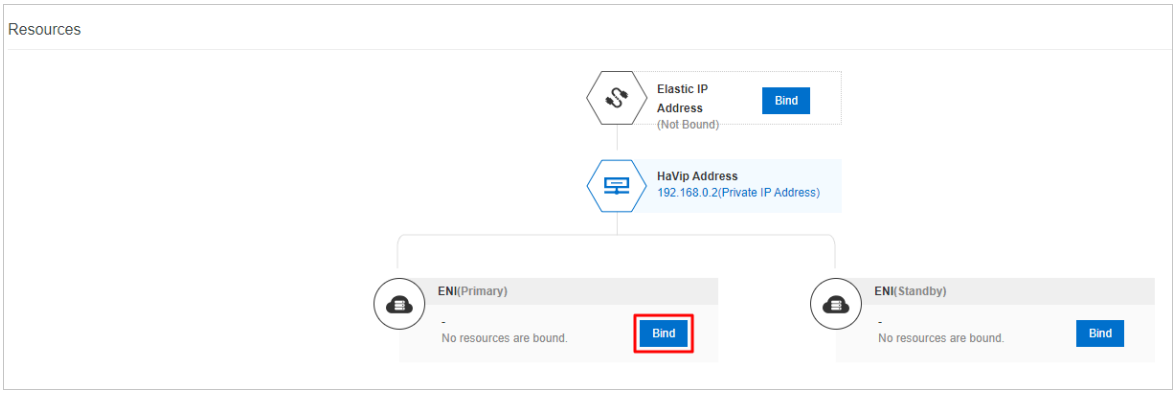
An ECS instance is created. For more information, see in the **Create an ECS instance** topic in **Quick Start** of *Elastic Compute Service User Guide*.

Context

You can associate an HAVIP with two ECS instances or two secondary elastic network interfaces (ENIs). However, you cannot associate an HAVIP with an ECS instance and a secondary ENI at the same time.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top navigation bar, select the region where the HAVIP is created.
4. On the **HaVip Addresses** page, find the HAVIP that you want to manage and click **Manage** in the **Actions** column.
5. In the **Resources** section, find **ENI (Primary)** or **ENI (Standby)** and click **Bind**.



6. In the dialog box that appears, set the following parameters to associate the HAVIP with an ECS instance.

Parameter	Description
Resource Type	Select the type of resource with which you want to associate the HAVIP. Valid values: ○ **ECS Instances** ○ **ENI** In this example, **ECS Instances** is selected.
Bind Resource	Select the ECS instance with which you want to associate the HAVIP. The ECS instance that you select must meet the following requirements: ○ The ECS instance is deployed in a VPC. ○ The ECS instance and the HAVIP belong to the same vSwitch.

7. Click **OK**.

17.6.3.2. Associate an HAVIP with an ENI

This topic describes how to associate a high-availability virtual IP address (HAVIP) with ENIs that are attached to Elastic Compute Service (ECS) instances. Then, the ECS instances can send Address Resolution Protocol (ARP) messages to advertise the HAVIP. This way, the ECS instances can use more than one private IP address.

Prerequisites

An ENI is created. For more information, see the **Create an Elastic Network Interface** topic in the **Elastic Network Interface** chapter of *Elastic Compute Service User Guide*.

Context

You can associate each HAVIP with two ECS instances or two ENIs. However, you cannot associate an HAVIP with an ECS instance and an ENI at the same time.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top navigation bar, select the region where the HAVIP is created.
4. On the **HaVip Addresses** page, find the HAVIP that you want to associate and click its ID.
5. In the **Resources** section, find **ENI (Primary)** or **ENI (Standby)** and click **Bind**.
6. In the dialog box that appears, set the following parameters and click **OK**.

Parameter	Description
Resource Type	Select the type of resource with which you want to associate the HAVIP. Valid values: ○ **ECS Instance** ○ **ENI** In this example, **ENI** is selected.
Bind Resource	Select the ENI with which you want to associate the HAVIP. The ENI and the HAVIP must belong to the same vSwitch.

17.6.4. Associate HAVIPs with EIPs

This topic describes how to associate high-availability virtual IP addresses (HAVIPs) with elastic IP addresses (EIPs). After you associate an HAVIP with an EIP, the HAVIP can use the EIP to provide services over the Internet.

Prerequisites

An EIP is created. For more information, see **Create an EIP** in **Quick Start** of the *Elastic IP Address User Guide*.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top menu bar, select the region where the HAVIP is created.
4. On the **HaVip Addresses** page, find the HAVIP that you want to manage, and choose **More > Bind EIP Address** in the **Actions** column.
5. In the dialog box that appears, select the EIP with which you want to associate the HAVIP and click **OK**.

The EIP with which you want to associate the HAVIP must meet the following requirements:

- The EIP and HAVIP are created in the same region.
- The EIP must be in the Available state.

17.6.5. Disassociate HAVIPs from backend cloud resources

17.6.5.1. Disassociate an HAVIP from an ECS instance

This topic describes how to disassociate a high-availability virtual private IP address (HAVIP) from an Elastic Compute Service (ECS) instance. After you disassociate an HAVIP from an ECS instance, the ECS instance cannot send Address Resolution Protocol (ARP) messages to advertise the HAVIP.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top navigation bar, select the region where the HAVIP is created.
4. On the **HaVip** page, find the HAVIP that you want to manage and click **Manage** in the **Actions** column.
5. In the **Resources** section, find the ECS instance that you want to manage and click **Unbind**.
6. In the message that appears, click **OK**.

17.6.5.2. Disassociate an HAVIP from an ENI

This topic describes how to disassociate a high-availability virtual IP address (HAVIP) from an elastic network interface (ENI). After you disassociate an HAVIP from an ENI, the Elastic Compute Service (ECS) instance with which the ENI is associated cannot send Address Resolution Protocol (ARP) messages to advertise the HAVIP.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top navigation bar, select the region where the HAVIP is created.
4. On the **HaVip** page, find the HAVIP that you want to disassociate and click **Manage** in the **Actions** column.
5. In the **Resources** section, find the ENI that you want to manage and click **Unbind**.
6. In the message that appears, click **OK**.

17.6.6. Disassociate an HAVIP from an EIP

This topic describes how to disassociate a high-availability virtual IP address (HAVIP) from an elastic IP address (EIP).

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip Addresses**.
3. Select the region to which the HAVIP belongs.
4. On the **HaVip Addresses** page, find the HAVIP that you want to manage and choose **More > Unbind with EIP** in the **Actions** column.
5. In the message that appears, click **OK**.

17.6.7. Delete an HAVIP

This topic describes how to delete a high-availability virtual IP address (HAVIP).

Prerequisites

- The HAVIP that you want to delete is not associated with an elastic IP address (EIP). If the HAVIP is associated with an EIP, disassociate the HAVIP from the EIP first. For more information, see Disassociate HAVIPs from EIPs.
- The HAVIP is not associated with an Elastic Compute Service (ECS) instance. If the HAVIP is associated with an ECS instance, disassociate the HAVIP from the ECS instance. For more information, see Disassociate an HAVIP from an ECS instance.
- The HAVIP is not associated with a secondary elastic network interface (ENI). If the HAVIP is associated with a secondary ENI, disassociate the HAVIP from the secondary ENI first. For more information, see Disassociate HAVIPs from secondary ENIs.

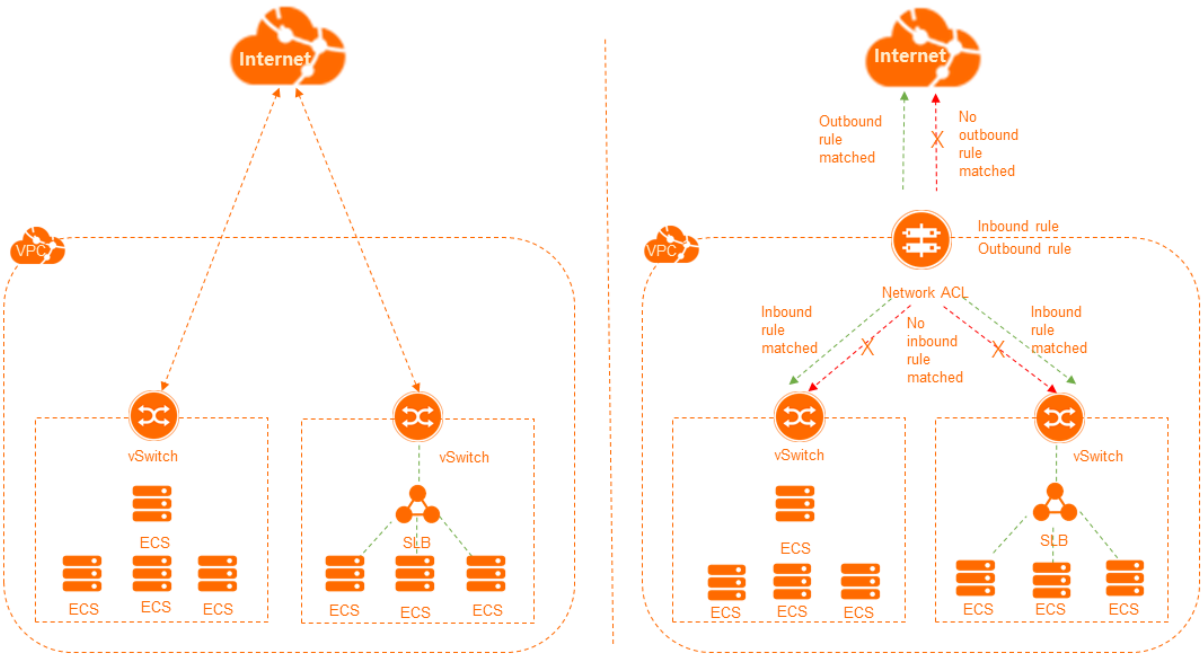
Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **HaVip**.
3. In the top navigation bar, select the region where the HAVIP is created.
4. On the **HaVip** page, find the HAVIP that you want to manage and choose **More > Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

17.7. Network ACLs

17.7.1. Overview

Network access control lists (ACLs) allow you to regulate access control for a virtual private cloud (VPC). You can create network ACL rules and associate a network ACL with a vSwitch. This allows you to control inbound and outbound traffic of Elastic Compute Service (ECS) instances that are associated with the vSwitch.



Features

Network ACLs have the following features:

- A network ACL is used to filter inbound and outbound network traffic of ECS instances that are associated with a vSwitch in a VPC. The network traffic forwarded to ECS instances by Server Load Balancer (SLB) instances is also filtered.
- Network ACLs are stateless. You must set both inbound and outbound rules. Otherwise, the system may fail to respond to requests.
- If you create a network ACL that does not contain a rule, all inbound and outbound access are denied.
- If a network ACL is associated with a vSwitch, the network ACL does not filter the traffic forwarded between ECS instances that are associated with the vSwitch.

Network ACL rules

You can add rules to or delete rules from a network ACL. Changes to the rules are automatically synchronized to the associated vSwitch. By default, an inbound and an outbound rule are automatically added to a newly created network ACL. These rules allow all inbound and outbound network traffic transmitted through the associated vSwitch. You can delete the default rules. The following table lists the default inbound and outbound rules.

- Default inbound rule

Priority	Protocol	Source CIDR block	Destination port range	Action	Type
1	all	0.0.0.0/0	-1/-1	Allow	Custom

- Default outbound rule

Priority	Protocol	Destination CIDR block	Destination port range	Action	Type
1	all	0.0.0.0/0	-1/-1	Allow	Custom

A network ACL contains the following parameters:

- Priority: A smaller value indicates a higher priority. The system attempts to match traffic requests with rules in descending order of priority that starts from the rule whose priority is 1. If a request matches a rule, the system applies the rule to the request and ignores the other rules.

  For example, the following rules are added and requests destined for IP address 172.16.0.1 are sent from an ECS instance. In the following table, the requests match Rules 2 and 3. Rule 2 has a higher priority than Rule 3. Therefore, the system applies Rule 2. Based on the action of Rule 2, the requests are denied.

Priority	Protocol	Destination CIDR block	Destination port range	Action	Type
1	all	10.0.0.0/8	-1/-1	Allow	Custom
2	all	172.16.0.0/12	-1/-1	Block	Custom
3	all	172.16.0.0/12	-1/-1	Allow	Custom

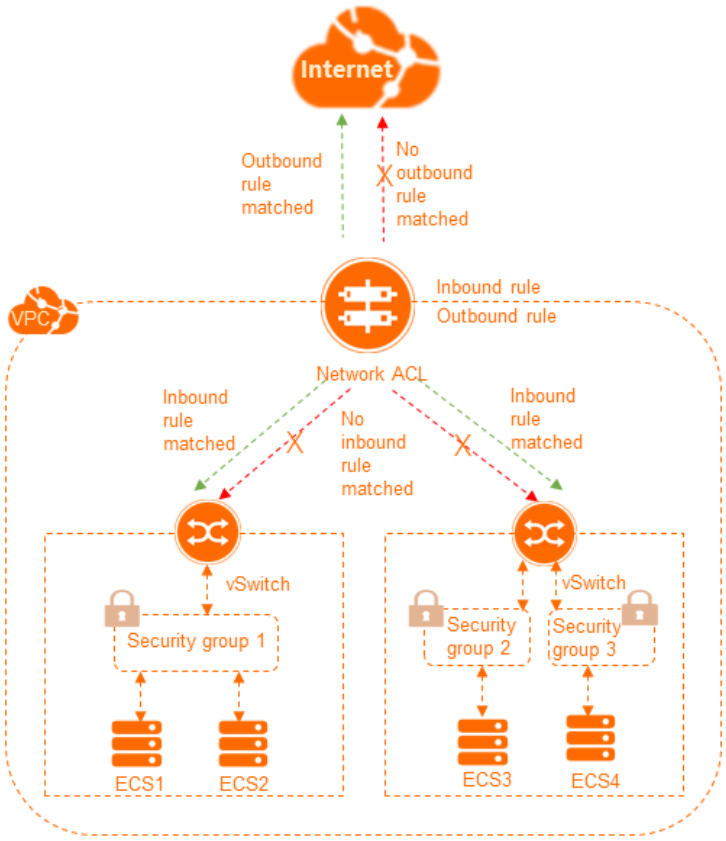
- Policy: specifies whether to allow or block specific traffic.
- Protocol: the protocol type. Available options include All, ICMP, GRE, TCP, and UDP.
- Source CIDR block: the source CIDR block from which inbound traffic is transmitted.
- Destination CIDR block: the destination CIDR block to which outbound traffic is transmitted.
- Destination port range: the range of destination ports to which the inbound rule applies.
- Destination port range: the range of destination ports to which the outbound rule applies.

Comparison between network ACLs and security groups

Network ACLs control data transmitted through associated vSwitches while security groups control data transmitted through associated ECS instances. The following table lists the differences between network ACLs and security groups.

Network ACL	Security group
Applied to vSwitches.	Applied to instances.
Stateless: Returned traffic must be allowed by inbound rules.	Stateful: Returned traffic is automatically allowed and not affected by rules.
The system attempts to match requests with rules in descending order of priority. Not all rules are matched.	The system matches a request against all rules before a rule is applied.
Each vSwitch can be associated with only one network ACL.	Each ECS instance can be added to more than one security group.

The following figure shows how network ACLs and security groups are applied to ensure network security.



Limits

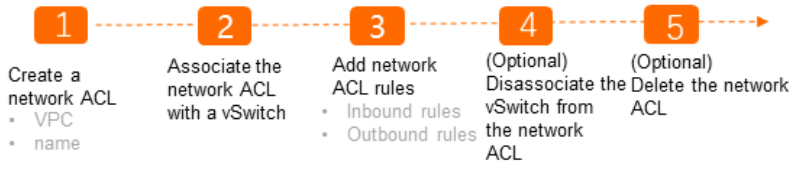
Before you use network ACLs, take note of the following limits.

Item	Default
Number of network ACLs that can be created in each VPC	200
Number of network ACLs that can be associated with each vSwitch	1

Item	Default
Number of rules that can be added to a network ACL	• Inbound rules: 20 • Outbound rules: 20

Procedure

The following flowchart shows how to use a network ACL.



17.7.2. Scenarios

If you are familiar with the ports that are commonly used by ECS instances, you can specify them in access control list (ACL) rules to facilitate precise network traffic filtering. This topic describes the ports that are commonly used by ECS instances and the application scenarios of these ports.

Ports

The following table lists the ports and the services that use these ports.

Port	Service	Description
21	FTP	The FTP port. It is used to upload and download files.
22	SSH	The SSH port. It is used to log on to Linux instances in the command line method by using username and password pairs.
23	Telnet	The Telnet port. It is used to remotely log on to ECS instances.
25	SMTP	The SMTP port. It is used to send emails.
80	HTTP	The HTTP port. It is used to access services such as IIS, Apache, and NGINX.
110	POP3	The POP3 port. It is used to send and receive emails.
143	IMAP	The Internet Message Access Protocol (IMAP) port. It is used to receive emails.
443	HTTPS	The HTTPS port. It is used to access services. The HTTPS protocol can implement encrypted and secure data transmission.
1433	SQL Server	The TCP port of SQL Server. It is used for SQL Server to provide external services.
1434	SQL Server	The UDP port of SQL Server. It is used to return the TCP/IP port occupied by SQL Server.
1521	Oracle	The Oracle communication port. ECS instances that run Oracle SQL must have this port open.

Port	Service	Description
3306	MySQL	The MySQL port. It is used for MySQL databases to provide external services.
3389	Windows Server Remote Desktop Services	The Windows Server Remote Desktop Services port. It is used to log on to a Windows instance.
8080	Proxy port	An alternative to port 80. It is commonly used for WWW proxy services.

Custom network ACLs

Inbound rules and Outbound rules describe a network ACL example for VPCs that support IPv4 addresses only.

- The inbound rules in effective order 1, 2, 3, and 4 respectively allow HTTP, HTTPS, SSH, and RDP traffic to the VSwitch. Outbound response rules are those in effective order 3.
- The outbound rules in effective order 1 and 2 respectively allow HTTP and HTTPS traffic from the VSwitch. Outbound response rules are those in effective order 5.
- The inbound rule in effective order 6 denies all inbound IPv4 traffic. This rule ensures that packets that do not match any other rules are denied.
- The outbound rule in effective order 4 denies all outbound IPv4 traffic. This rule ensures that packets that do not match any other rules are denied.

> **Note** An inbound or outbound rule must correspond to an inbound or outbound rule that allows response traffic.

Inbound rules

Effective order	Protocol	Source IP addresses	Destination port range	Action	Description
1	TCP	0.0.0.0/0	80/80	Accept	Allows inbound HTTP traffic from any IPv4 addresses.
2	TCP	0.0.0.0/0	443/443	Accept	Allows inbound HTTPS traffic from any IPv4 addresses.
3	TCP	0.0.0.0/0	22/22	Accept	Allows inbound SSH traffic from any IPv4 addresses.
4	TCP	0.0.0.0/0	3389/3389	Accept	Allows inbound RDP traffic from any IPv4 addresses.
5	TCP	0.0.0.0/0	32768/65535	Accept	Allows inbound IPv4 traffic from the Internet. This port range is for reference only. For more information on how to select appropriate ephemeral ports, see Ephemeral ports.
6	All	0.0.0.0/0	-1/-1	Drop	Denies all inbound IPv4 traffic.

Outbound rules

Effective order	Protocol	Destination IP addresses	Destination port range	Action	Description
1	TCP	0.0.0.0/0	80/80	Accept	Allows outbound IPv4 HTTP traffic from the VSwitch to the Internet.
2	TCP	0.0.0.0/0	443/443	Accept	Allows outbound IPv4 HTTPS traffic from the VSwitch to the Internet.
3	TCP	0.0.0.0/0	32768/65535	Accept	Allows outbound IPv4 traffic from the VSwitch to the Internet. This port range is for reference only. For more information on how to select appropriate ephemeral ports, see Ephemeral ports.
4	All	0.0.0.0/0	-1/-1	Drop	Denies all outbound IPv4 traffic.

Network ACLs for SLB

If the ECS instance in the VSwitch acts as the backend server of an SLB instance, you must add the following network ACL rules.

- Inbound rules

Effective order	Protocol	Source IP addresses	Destination port range	Action	Description
1	SLB listener protocol	Client IP addresses allowed to access the SLB instance	SLB listener port	Accept	Allows inbound traffic from specified client IP addresses.
2	Health check protocol	100.64.0.0/10	Health check port	Accept	Allows inbound traffic from health check IP addresses.

- Outbound rules

Effective order	Protocol	Destination IP addresses	Destination port range	Action	Description
1	All	Client IP addresses allowed to access the SLB instance	-1/-1	Accept	Allows all outbound traffic to specified client IP addresses.
2	All	100.64.0.0/10	-1/-1	Accept	Allows outbound traffic to health check IP addresses.

Ephemeral ports

Clients use different ports to initiate requests. You can select different port ranges for network ACL rules based on the client type. The following table lists ephemeral port ranges for common clients.

Client	Port range
Linux	32768/61000
Windows Server 2003	1025/5000
Windows Server 2008 and later	49152/65535
NAT gateway	1024/65535

17.7.3. Create a network ACL

A network access control list (ACL) allows you to manage network access in a virtual private cloud (VPC). This topic describes how to create a network ACL in a VPC.

Prerequisites

A VPC is created. For more information, see Create a VPC.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where you want to create the network ACL.
4. On the **Network ACL** page, click **Create Network ACL**.
5. In the **Create Network ACL** dialog box, set the following parameters, and click **OK**.

Parameter	Description
Organization	Select the organization to which the network ACL belongs.
Resource Set	Select the resource set to which the network ACL belongs.
Region	Select the region where you want to deploy the network ACL.
Name	Enter a name for the network ACL. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter.
Description	Enter a description for the network ACL. The description must be 2 to 256 characters in length, and can contain letters, digits, underscores (_), colons (:), and hyphens (-). It must start with a letter and cannot start with `http://` or `https://`.
VPC	Select the VPC for which you want to create the network ACL. **Note** The VPC and network ACL must be deployed in the same region.

What's next

- Associate a network ACL with a VSwitch
- Add an inbound rule
- Add an outbound rule

17.7.4. Associate a network ACL with a vSwitch

After you create a network access control list (ACL), you can associate the network ACL with a vSwitch. This way, you can use the network ACL to manage the traffic of the Elastic Compute Service (ECS) instances in the vSwitch.

Prerequisites

Before you associate a network ACL with a vSwitch, make sure that the following requirements are met:

- A network ACL is created. For more information, see Work with network ACLs.
- A vSwitch is created. The vSwitch and network ACL belong to the same virtual private cloud (VPC). For more information, see Work with vSwitches.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL that you want to manage and click **Manage** in the **Actions** column.
5. On the **Resources** tab, click **Bind Resource**.
6. In the **Associate vSwitch** panel, select the vSwitch and click **OK**.

> **Note** The network ACL and vSwitch must belong to the same VPC. A vSwitch can be associated with only one network ACL.

What's next

- Add an inbound rule
- Add an outbound rule

17.7.5. Add network ACL rules

17.7.5.1. Add an inbound rule

This topic describes how to add an inbound rule to a network access control list (ACL). You can use inbound rules to control Internet or internal network traffic destined for Elastic Compute Service (ECS) instances connected to a vSwitch.

Prerequisites

A network ACL is created. For more information, see Work with network ACLs.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL that you want to manage and click **Inbound Rule** in the **Actions** column.

5. On the **Inbound Rule** tab, click **Create Inbound Rule**.
6. In the **Create Inbound Rule** panel, set the following parameters and click **OK**.

Parameter	Description
Name	Enter a name for the inbound rule. The name must be 2 to 128 characters in length, and can contain letters, digits, underscores (_), and hyphens (-). The name must start with a letter. It cannot start with `http://` or `https://`.
Effective order	The order in which the inbound rule takes effect. Valid values: 1 to 20. A smaller number indicates a higher priority.
Action	Select an action for the inbound rule. Valid values: ○ **Accept**: accepts network traffic that is destined for the ECS instances connected to the vSwitch. ○ **Drop**: denies network traffic that is destined for the ECS instances connected to the vSwitch.
Protocol Type	Select a transport layer protocol. Valid values: ○ **ALL** ○ **ICMP** ○ **GRE** ○ **TCP** ○ **UDP**
Source IP Addresses	The source CIDR block from which data is transmitted. Default value: 0.0.0.0/32.
Destination Port Range	Enter the destination port range. Valid values: 1 to 65535. Use a forward slash (/) to separate the highest and lowest values in a port range, for example, 1/200 or 80/80. -1/-1 indicates that all ports are available. You cannot set the value to -1/-1.

17.7.5.2. Add an outbound rule

This topic describes how to add an outbound rule to a network access control list (ACL). You can use outbound rules to control how Elastic Compute Service (ECS) instances connected to a vSwitch access the Internet or other internal networks.

Prerequisites

A network ACL is created. For more information, see Work with network ACLs.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL and click **Outbound Rule** in the **Actions** column.

5. On the **Outbound Rule** tab, click **Create Outbound Rule**.
6. In the **Create Outbound Rule** panel, set the following parameters and click **OK**.

Parameter	Description
Name	Enter a name for the outbound rule. The name must be 2 to 128 characters in length, and can contain letters, digits, underscores (_), and hyphens (-). The name must start with a letter. It cannot start with `http://` or `https://`.
Effective order	The order in which the outbound rule takes effect. Valid values: 1 to 20. A smaller number indicates a higher priority.
Policy	Select an action for the outbound rule. Valid values: ○ **Accept**: allows ECS instances connected to the vSwitch to access the Internet or other internal networks. ○ **Drop**: forbids ECS instances connected to the vSwitch to access the Internet or other internal networks.
Protocol Type	Select a transport layer protocol. Valid values: ○ **ALL** ○ **ICMP** ○ **GRE** ○ **TCP** ○ **UDP**
Destination IP Addresses	The destination CIDR block to which data is transmitted. Default value: 0.0.0.0/32.
Destination Port Range	Enter the destination port range. Valid values: 1 to 65535. Use a forward slash (/) to separate the highest and lowest values in a port range, for example, 1/200 or 80/80. -1/-1 indicates that all ports are available. You cannot set the value to -1/-1.

17.7.5.3. Change the priority of a network ACL rule

Rules added to network access control lists (ACLs) take effect in descending order of priority. A smaller value indicates a higher priority. You can change the priority of a network ACL rule to meet your business requirements.

Change the priority of an inbound rule

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL that you want to manage and click **Manage** in the **Actions** column.
5. Click the **Inbound Rule** tab and click **Sort**.
6. In the **Sort** panel, change the priority of the rule by dragging and dropping the rule. Then, click **OK**.

> **Note** Rules are listed in descending order of priority.

Change the priority of an outbound rule

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL and click **Manage** in the **Actions** column.
5. Click the **Outbound Rule** tab and click **Sort**.
6. In the **Sort** panel, change the priority of the rule by dragging and dropping the rule. Then, click **OK**.

> **Note** Rules are listed in descending order of priority.

17.7.6. Disassociate a network ACL from a vSwitch

This topic describes how to disassociate a network access control list (ACL) from a vSwitch. After you disassociate a network ACL from a vSwitch, the network ACL no longer controls the traffic of Elastic Compute Service (ECS) instances that belong to the vSwitch.

Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL and click **Manage** in the **Actions** column.
5. On the **Resources** tab, find the vSwitch and click **Unbind** in the **Actions** column.
6. In the **Unbind Network ACL** message, click **OK**.

17.7.7. Delete a network ACL

This topic describes how to delete a network access control list (ACL).

Prerequisites

Make sure that the network ACL is not associated with a vSwitch. If the network ACL is associated with a vSwitch, disassociate the network ACL from the vSwitch first. For more information, see Disassociate a VSwitch from a network ACL.

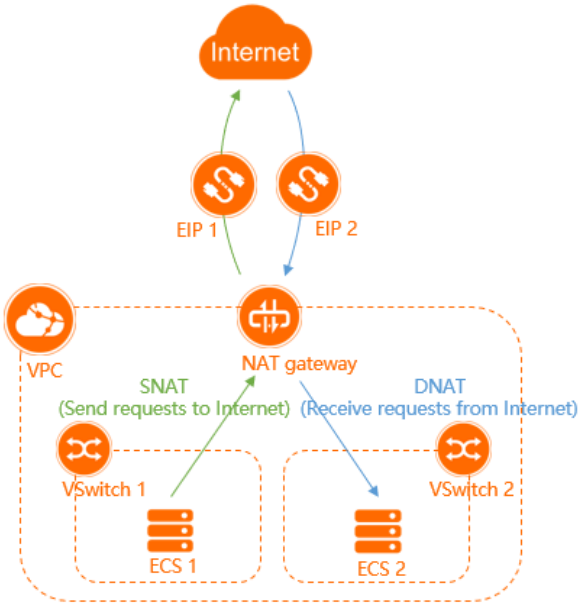
Procedure

1. Log on to the VPC console.
2. In the left-side navigation pane, click **Network ACL**.
3. In the top navigation bar, select the region where the network ACL is created.
4. On the **Network ACL** page, find the network ACL that you want to delete and click **Delete** in the **Actions** column.
5. In the **Delete Network ACL** message, click **OK**.

18.NAT Gateway

18.1. What is NAT Gateway?

NAT gateways are enterprise-class gateways that provide the Source Network Address Translation (SNAT) and Destination Network Address Translation (DNAT) features. Each NAT gateway provides a throughput capacity of up to 100 Gbit/s. NAT gateways also support cross-zone disaster recovery.



Features

You must associate public IP addresses with NAT gateways so that the NAT gateways can function as expected. After you create a NAT gateway, you can associate elastic IP addresses (EIPs) with the NAT gateway.

NAT gateways provide the SNAT and DNAT features.

Feature	Description
SNAT	SNAT allows ECS instances that are deployed in a VPC to access the Internet when no public IP address is associated with these ECS instances.
DNAT	DNAT maps the EIPs of a NAT gateway to ECS instances. This way, the ECS instances can receive requests from the Internet.

18.2. Log on to the NAT Gateway console

This topic describes how to log on to the Apsara Uni-manager Management Console to manage your NAT gateways. The Google Chrome browser is used as an example.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top menu bar, choose **Products > Networking > Virtual Private Cloud**.
5. In the left-side navigation pane, choose **Internet Access > NAT Gateway**.

18.3. Quick Start

18.3.1. Overview

This topic describes how to configure Source Network Address Translation (SNAT) and Destination Network Address Translation (DNAT). You can configure SNAT and DNAT to enable ECS instances in a Virtual Private Cloud (VPC) network to communicate with the Internet through a NAT gateway.

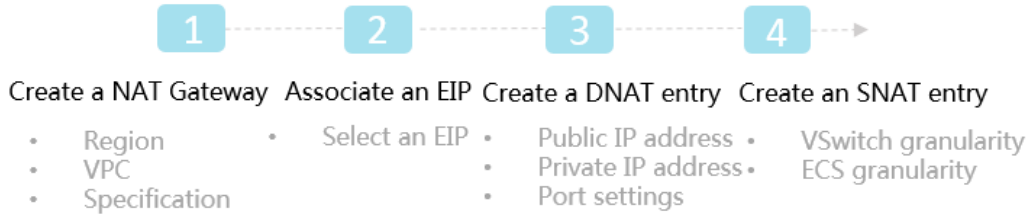
Prerequisites

Before you start, make sure that the following conditions are met:

- A VPC network is created. For more information, see *VPC User Guide* **Create a VPC network** in the **Quick Start** chapter in the VPC User Guide.
- An ECS instance is created in the VPC network. For more information, see *ECS User Guide* **Create an instance** in the **Quick Start** chapter in the ECS User Guide.
- An elastic IP address (EIP) is created. For more information, see *EIP User Guide* **Create an EIP** in the **Quick Start** chapter in the EIP User Guide.

Procedure

In this topic, an ECS instance that is not associated with any public IP addresses in a VPC network is used as an example. The following flowchart shows how to associate an EIP with a NAT gateway:



1. Create a NAT gateway

   A NAT gateway is an enterprise-class gateway that provides NAT proxy services. Before you configure SNAT and DNAT entries, you must create a NAT gateway.

   For more information, see Create a NAT gateway.

2. Associate an EIP to a NAT gateway

   A NAT gateway functions as expected only after it is associated with a public IP address. After you create a NAT gateway, you can associate it with an EIP.

   For more information, see Associate an EIP with a NAT Gateway.

3. Create a DNAT entry

   This topic describes how to create a Destination Network Address Translation (DNAT) entry. DNAT maps public IP addresses to Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network. This way, the ECS instances can receive requests sent over the Internet. DNAT supports port mapping and IP mapping.

   For more information, see Create a DNAT entry.

4. Create an SNAT entry

   This topic describes how to create a Source Network Address Translation (SNAT) entry. SNAT allows Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network to access the Internet without using public IP addresses.

   For more information, see Create a SNAT entry.

18.3.2. Create a NAT gateway

A NAT gateway is an enterprise-class gateway that provides NAT proxy services. Before you configure SNAT and DNAT entries, you must create a NAT gateway.

Prerequisites

A VPC network is created. For more information, see *VPC User Guide*Create a VPC network in the Quick Start chapter in the VPC User Guide.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateway** page, click **Create NAT Gateway**.
3. Set the parameters for the NAT gateway based on the following information, and then click **Submit**.

Parameter	Description
Organization	The organization to which the NAT gateway belongs.
Resource set	The resource set to which the NAT gateway belongs.
Region	The region where the NAT gateway is deployed.
VPC	The VPC network to which the NAT gateway belongs. If you cannot find the target VPC network in the list, perform the following operations: ○ Check whether the VPC network is already associated with a NAT gateway. Each VPC network can be associated with only one NAT gateway. ○ Check whether the VPC network has a custom route entry with the destination CIDR block set to 0.0.0.0/0. If such a custom route entry exists, delete it. ○ Check whether the RAM user is authorized to access the VPC network. If the RAM user is not authorized, contact your Alibaba Cloud account owner to grant permissions.

Parameter	Description
Specification	Select the size of the NAT gateway. Valid values: ○ **Small**: supports up to 10,000 SNAT connections. ○ **Medium**: supports up to 50,000 SNAT connections. ○ **Large**: supports up to 200,000 SNAT connections. ○ **Super Large**: supports up to 1,000,000 SNAT connections. **Note** The size of a NAT gateway determines the maximum number of SNAT connections, but it does not affect the maximum number of DNAT connections.
Parameter	Enter a name for the NAT gateway. The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character but cannot start with `http://` or `https://`.

18.3.3. Associate an EIP with a NAT gateway

A NAT gateway works as expected only after you associate an elastic IP address (EIP) with it. This topic describes how to associate an EIP with a NAT gateway.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway with which you want to associate an EIP, and choose ⋮ > **Bind Elastic IP Address** in the **Actions** column.
4. In the **Associate EIP** dialog box, set the following parameters, and click **OK**.

Parameter	Description
Usable EIP List	Select the EIP that is used to communicate with the Internet.
vSwitch	Select the vSwitch to which you want to add SNAT entries. After you select a vSwitch, the system automatically adds SNAT entries to the vSwitch. Then, cloud services in the vSwitch can access the Internet. You can skip this step and manually add SNAT entries after you associate an EIP with the NAT gateway. For more information, see Create a SNAT entry.

18.3.4. Create a DNAT entry

This topic describes how to create a DNAT entry. DNAT can map public IP addresses of NAT gateways to Elastic Compute Service (ECS) instances. This way, ECS instances can provide services over the Internet. DNAT supports port mapping and IP mapping.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.

3. On the **NAT Gateway** page, find the NAT gateway that you want to manage, and click **Configure DNAT** in the **Actions** column.
4. On the **DNAT Table** page, click **Create DNAT Entry**.
5. In the **Create DNAT Entry** panel, set the following parameters and click **OK**.

Parameter	Description
Public IP Address	Select an available public IP address. **Note** If a public IP address is already used to create an SNAT entry, the public IP address cannot be used to create a DNAT entry.
Private IP Address	Specify the ECS instance that uses the DNAT entry to communicate with the Internet. You can specify the private IP address of the ECS instance in the following ways: ○ **Auto Fill**: Select the ECS instance from the drop-down list. ○ **Manually Input**: Enter the private IP address of the ECS instance. **Note** This private IP address must fall within the CIDR block of the virtual private cloud (VPC). You can also enter the private IP address of an existing ECS instance.
Port Settings	Select a DNAT mapping method: ○ **All**: This method uses IP mapping. All requests destined for the elastic IP address (EIP) are forwarded to the ECS instance. ○ **Specific Port**: This method uses port mapping. The NAT gateway forwards requests that use the specified protocol and port to the specified port of the ECS instance. After you select Specific Port, specify the **Public Port** (the external port), **Private Port** (the internal port), and **IP Protocol** (the protocol over which data is transferred).
Entry Name	Enter a name for the DNAT entry. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter.

18.3.5. Create an SNAT entry

This topic describes how to create an SNAT entry. SNAT can provide the proxy service for Elastic Compute Service (ECS) instances. ECS instances that have no IP address assigned in virtual private clouds (VPCs) can access the Internet by using SNAT.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway and click **Configure SNAT** in the **Actions** column.
4. On the **SNAT Table** page, click **Create SNAT Entry**.
5. In the **Create SNAT Entry** panel, set the following parameters and click **OK**.

Parameter	Description
VSwitch Granularity	
VSwitch	Select a vSwitch in the VPC. All ECS instances in the vSwitch can access the Internet by using SNAT. **Note** SNAT entries do not take effect on ECS instances that are assigned public IP addresses. For example, an ECS instance may be assigned a static public IP address, associated with an elastic IP address (EIP), or configured with DNAT IP mapping. Such an ECS instance uses the public IP address instead of the SNAT entry to access the Internet.
VSwitch CIDR Block	The CIDR block of the selected vSwitch.
Public IP Address	Select the EIP that is used to access the Internet. You can select one or more EIPs. You can use multiple EIPs to create an SNAT IP address pool. **Note** An EIP that is already used in a DNAT entry cannot be used in an SNAT entry.
ECS Granularity	
Available ECS Instances	Select an ECS instance in the VPC. The ECS instance can access the Internet by using the specified EIP. Make sure that the following requirements are met: ○ The ECS instance is in the Running state. ○ The ECS instance is not assigned an EIP or a static public IP address.
ECS CIDR Block	The CIDR block of the ECS instance.
Public IP Address	Select the EIP that is used to access the Internet. You can select one or more EIPs. You can use multiple EIPs to create an SNAT IP address pool. The maximum bandwidth supported by each EIP in an SNAT IP address pool is 200 Mbit/s. To make full use of your EIP bandwidth plan and avoid port conflicts caused by insufficient EIPs, we recommend that you add EIPs to the SNAT address pool based on the following rules: ○ If the maximum bandwidth value of the EIP bandwidth plan is 1,024 Mbit/s, specify at least five EIPs in each SNAT entry. ○ If the maximum bandwidth value of the EIP bandwidth plan exceeds 1,024 Mbit/s, specify at least one additional EIP in each SNAT entry for every incremental 200 Mbit/s. **Note** An EIP that is already used in a DNAT entry cannot be used in an SNAT entry.

18.4. Manage a NAT gateway

18.4.1. Overview

NAT gateways are enterprise-class gateways that support SNAT and DNAT features. Each NAT gateway provides a forwarding capacity of 10 Gbit/s. NAT gateways support cross-zone disaster recovery.

Sizes of NAT gateways

NAT gateways are available in multiple sizes, including small, middle, large, and super large-1. The size of a NAT gateway determines the SNAT performance, which includes the maximum number of connections and the number of new connections per second. However, the size of a NAT gateway does not affect the DNAT performance. The following table describes available sizes of NAT gateways.

Size	Maximum number of SNAT connections	Number of new SNAT connections per second
Small	10,000	1,000
Medium	50,000	5,000
Large	200,000	10,000
Super Large-1	1,000,000	50,000

When you specify the size of a NAT gateway, take note of the following limits:

- CloudMonitor monitors only the maximum number of SNAT connections for NAT gateways. CloudMonitor does not monitor the number of new SNAT connections per second.
- The timeout period of SNAT connections on NAT gateways is 900 seconds.
- To avoid timeouts of SNAT connections caused by network congestion or Internet jitter, make sure that your applications support automatic reconnection.
- NAT gateways do not support packet fragmentation.
- If you use the same destination public IP address and port, the maximum number of concurrent connections is based on the number of elastic IP addresses (EIPs) that are associated with the NAT gateway. Each EIP that is associated with the NAT gateway supports up to 55,000 concurrent connections. If N EIPs are associated with the NAT gateway, the maximum number of concurrent connections that the NAT gateway supports is N × 55,000.

18.4.2. Create a NAT gateway

A NAT gateway is an enterprise-class gateway that provides NAT proxy services. Before you configure SNAT and DNAT entries, you must create a NAT gateway.

Prerequisites

A VPC network is created. For more information, see *VPC User Guide*Create a VPC network in the Quick Start chapter in the VPC User Guide.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateway** page, click **Create NAT Gateway**.
3. Set the parameters for the NAT gateway based on the following information, and then click **Submit**.

Parameter	Description
Organization	The organization to which the NAT gateway belongs.

Parameter	Description
Resource set	The resource set to which the NAT gateway belongs.
Region	The region where the NAT gateway is deployed.
VPC	The VPC network to which the NAT gateway belongs. If you cannot find the target VPC network in the list, perform the following operations: ○ Check whether the VPC network is already associated with a NAT gateway. Each VPC network can be associated with only one NAT gateway. ○ Check whether the VPC network has a custom route entry with the destination CIDR block set to 0.0.0.0/0. If such a custom route entry exists, delete it. ○ Check whether the RAM user is authorized to access the VPC network. If the RAM user is not authorized, contact your Alibaba Cloud account owner to grant permissions.
Specification	Select the size of the NAT gateway. Valid values: ○ **Small**: supports up to 10,000 SNAT connections. ○ **Medium**: supports up to 50,000 SNAT connections. ○ **Large**: supports up to 200,000 SNAT connections. ○ **Super Large**: supports up to 1,000,000 SNAT connections. **Note** The size of a NAT gateway determines the maximum number of SNAT connections, but it does not affect the maximum number of DNAT connections.
Parameter	Enter a name for the NAT gateway. The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), hyphens (-), periods (.), colons (:), and commas (,). It must start with a letter or Chinese character but cannot start with `http://` or `https://`.

18.4.3. Modify a NAT gateway

This topic describes how to modify the name and description of a NAT gateway.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway that you want to manage, and then click **Manage** in the **Actions** column.
4. On the **NAT Gateway Details** tab, click **Edit** next to the name. In the dialog box that appears, enter a new name for the NAT gateway, and then click **OK**.

   The name must be 2 to128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.
5. Click **Edit** next to the description. In the dialog box that appears, enter a new description, and then click **OK**.

   The description must be 2 to 256 characters in length. It cannot start with `http://` or `https://`.

18.4.4. Delete a NAT gateway

You can delete NAT gateways that are billed on a pay-as-you-go basis. You cannot delete subscription NAT gateways.

Prerequisites

Before you delete a NAT gateway, make sure that the following conditions are met:

- The NAT gateway is not associated with an EIP. If the NAT gateway is associated with an EIP, disassociate the EIP first. For more information, see Disassociate EIPs from a NAT gateway.
- The DNAT table is empty. If the DNAT table contains DNAT entries, delete these entries first. For more information, see Delete a DNAT entry.
- The SNAT table is empty. If the DNAT table contains SNAT entries, delete these entries first. For more information, see Delete a SNAT entry.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateways** page, find the target NAT gateway, and click ⋮ > **Delete** in the **Actions** column.
4. In the dialog box that appears, click **OK**.

> **Note** If you select **Delete (Delete NAT gateway and resources)**, the DNAT and SNAT entries of the NAT gateway are deleted automatically. The EIP associated with the NAT gateway is also disassociated.

18.5. Manage EIPs

18.5.1. Associate an EIP with a NAT gateway

A NAT gateway works as expected only after it is associated with an elastic IP address (EIP). This topic describes how to associate an EIP with a NAT gateway.

Prerequisites

Before you associate an EIP with a NAT gateway, make sure that the following requirements are met:

- A NAT gateway is created. For more information, see Create a NAT gateway.
- An EIP is purchased. For more information, see the *Create an EIP* topic in **Quick Start** of **Elastic IP Address User Guide**.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway with which you want to associate an EIP, and choose ⋮ > **Bind Elastic IP Address** in the **Actions** column.
4. In the **Associate EIP** dialog box, set the following parameters, and click **OK**.

Parameter	Description
Usable EIP list	Select the EIP that is used to communicate with the Internet.

Parameter	Description
vSwitch	Select the vSwitch to which you want to add SNAT entries. After you select a vSwitch, the system automatically adds SNAT entries to the vSwitch. Then, cloud services in the vSwitch can access the Internet. You can skip this step and manually add SNAT entries after you associate an EIP with the NAT gateway.

18.5.2. Disassociate an EIP from a NAT gateway

This topic describes how to disassociate an elastic IP address (EIP) from a NAT gateway. After an EIP is disassociated from a NAT gateway, the NAT gateway can no longer communicate with the Internet by using the EIP.

Prerequisites

Make sure that the EIP to be disassociated is not used in an SNAT entry or a DNAT entry. If the EIP is used in an SNAT or a DNAT entry, delete the SNAT or DNAT entry first. For more information, see Delete a SNAT entry and Delete a DNAT entry.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway, and choose ⋮ > **Unbind Elastic IP Address** in the **Actions** column.
4. In the **Unbind Elastic IP Address** panel, select the EIP that you want to disassociate, and click **OK**.

18.6. Manage a DNAT table

18.6.1. DNAT overview

NAT Gateway supports the Destination Network Address Translation (DNAT) feature. You can create DNAT entries to map public IP addresses to ECS instances in a Virtual Private Cloud (VPC) network. This way, the ECS instances can receive requests from the Internet.

DNAT entries

You can configure port mapping when you create a DNAT entry. After the DNAT entry is created, requests destined for the specified public IP address are forwarded to the ECS instances within a VPC network based on the port mapping rule.

Each DNAT entry consists of the following elements:

- **Public IP** : the Elastic IP Address (EIP) bound to the NAT gateway.
- **Private IP** : the private IP address of the ECS instance in the Virtual Private Cloud.
- **Public port** : the external port for port forwarding.
- **Private Network Port** : the internal port for port forwarding.
- **Protocol type** : the protocol type of the forwarding port.

Port mapping and IP mapping

The DNAT feature supports port mapping and IP mapping:

- Port Mapping

After port mapping is configured, a NAT gateway forwards requests destined for a public IP address to the specified ECS instance based on the specified protocol and ports. The following DNAT entries are used as examples:

- Entry 1: The NAT gateway forwards requests destined for TCP port 80 of ECS instance 1.1.XX.XX to TCP port 80 of ECS instance 192.168.1.1.
- Entry 2: The NAT gateway forwards requests destined for UDP port 8080 of ECS instance 2.2.XX.XX to UDP port 8000 of ECS instance 192.168.1.2.

DNAT entry	Public IP address	External port	Private IP address	Internal port	TLS version
Entry 1	1.1.XX.XX	80	192.168.1.1	80	TCP
Entry 2	2.2.XX.XX	8080	192.168.1.2	8000	UDP

- IP mapping

  After IP mapping is configured, a NAT gateway forwards all requests destined for a public IP address to the specified ECS instance. The following entry is used as an example:

  Entry 3: The NAT gateway forwards requests destined for ECS instance 3.3.XX.XX to ECS instance 192.168.1.3.

DNAT entry	Public IP address	External port	Private IP address	Internal port	TLS version
Entry 3	3.3.XX.XX	Any	192.168.1.3	Any	Any

18.6.2. Create a DNAT entry

This topic describes how to create a Destination Network Address Translation (DNAT) entry. DNAT maps a public IP address to an Elastic Compute Service (ECS) instance in a Virtual Private Cloud (VPC) network. This allows the ECS instance to receive requests sent over the Internet. DNAT supports port mapping and IP mapping.

Prerequisites

A NAT gateway is created and associated with an elastic IP address (EIP). For more information, see Create a NAT gateway and Associate an EIP with a NAT Gateway.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway that you want to manage, and click **Configure DNAT** in the **Actions** column.
4. On the **DNAT Table** page, click **Create DNAT Entry**.
5. In the **Create DNAT Entry** panel, set the following parameters and click **OK**.

Parameter	Description
Public IP Address	Select an available public IP address. **Note** If a public IP address is already used to create an SNAT entry, the public IP address cannot be used to create a DNAT entry.

Parameter	Description
Private IP Address	Specify the ECS instance that uses the DNAT entry to communicate with the Internet. You can specify the private IP address of the ECS instance in the following ways: ○ **Auto Fill**: Select the ECS instance from the drop-down list. ○ **Manually Input**: Enter the private IP address of the ECS instance. **Note** This private IP address must fall within the CIDR block of the virtual private cloud (VPC). You can also enter the private IP address of an existing ECS instance.
Port Settings	Select a DNAT mapping method: ○ **All**: This method uses IP mapping. All requests destined for the elastic IP address (EIP) are forwarded to the ECS instance. ○ **Specific Port**: This method uses port mapping. The NAT gateway forwards requests that use the specified protocol and port to the specified port of the ECS instance. After you select Specific Port, specify the **Public Port** (the external port), **Private Port** (the internal port), and **IP Protocol** (the protocol over which data is transferred).
Entry Name	Enter a name for the DNAT entry. The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter.

18.6.3. Modify a DNAT entry

This topic describes how to modify the public IP address, private IP address, or port of a DNAT entry.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway that you want to manage, and click **Configure DNAT** in the **Actions** column.
4. On the **DNAT Table** page, find the DNAT entry, and click **Edit** in the **Actions** column.
5. In the **Edit DNAT Entry** panel, modify the public IP address, private IP address, or port, and then click **OK**.

18.6.4. Delete a DNAT entry

This topic describes how to delete a Destination Network Address Translation (DNAT) entry. If you no longer need an Elastic Compute Service (ECS) instance to receive requests sent over the Internet, you can delete the DNAT entry of the ECS instance.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway that you want to manage, and click **Configure DNAT** in the **Actions** column.

4. On the **DNAT table** page, find the target DNAT entry, and click **Remove** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

18.7. Manage an SNAT table

18.7.1. SNAT table overview

NAT Gateway supports Source Network Address Translation (SNAT). SNAT allows Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network to access the Internet without using public IP addresses.

SNAT entries

You can create SNAT entries in an SNAT table to allow ECS instances to access the Internet.

An SNAT entry consists of the following elements:

- **VSwitch or ECS instance**: the VSwitch or ECS instance that requires the SNAT proxy service.
- **Public IP address**: the public IP address used to access the Internet.

VSwitch granularity and ECS granularity

SNAT entries can be created based on the following granularity to enable ECS instances in a VPC network to access the Internet.

- VSwitch granularity

  You can select the VSwitch granularity to create an SNAT entry. The NAT gateway provides proxy service for an ECS instance attached to the specified VSwitch by using a specified public IP address when the instance sends requests to the Internet. By default, all ECS instances attached to the VSwitch can use the specified public IP address to access the Internet.

  > **Note** SNAT entries do not take effect on ECS instances that are assigned public IP addresses. For example, an ECS instance may be assigned static public IP address, associated with an elastic IP address (EIP) or has a Destination Network Address Translation (DNAT) IP mapping configured. These ECS instances use the public IP addresses instead of the SNAT entries to access the Internet.

- ECS granularity

  If you select the ECS granularity to create an SNAT entry, the specified ECS instance uses the specified public IP address to access the Internet. The NAT gateway provides proxy service (SNAT) for a specified ECS instance by using a specified public IP address when the instance sends requests to the Internet.

18.7.2. Create an SNAT entry

This topic describes how to create a Source Network Address Translation (SNAT) entry. SNAT allows Elastic Compute Service (ECS) instances in a Virtual Private Cloud (VPC) network to access the Internet without using public IP addresses.

Prerequisites

Before you create an SNAT entry, make sure that the following requirements are met:

- A NAT gateway is created and associated with an elastic IP address (EIP). For more information, see Create a NAT gateway and Associate an EIP with a NAT Gateway.
- To create an SNAT entry with VSwitch granularity, make sure that the VSwitch is created and associated with the NAT gateway in a VPC network.
- To create an SNAT entry with ECS granularity, make sure that the ECS instance is created and associated with the NAT gateway in a VPC network.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway and click **Configure SNAT** in the **Actions** column.
4. On the **SNAT Table** page, click **Create SNAT Entry**.
5. In the **Create SNAT Entry** panel, set the following parameters and click **OK**.

Parameter	Description
VSwitch Granularity	
VSwitch	Select a vSwitch in the VPC. All ECS instances in the vSwitch can access the Internet by using SNAT. **Note** SNAT entries do not take effect on ECS instances that are assigned public IP addresses. For example, an ECS instance may be assigned a static public IP address, associated with an elastic IP address (EIP), or configured with DNAT IP mapping. Such an ECS instance uses the public IP address instead of the SNAT entry to access the Internet.
VSwitch CIDR Block	The CIDR block of the selected vSwitch.
Public IP Address	Select the EIP that is used to access the Internet. You can select one or more EIPs. You can use multiple EIPs to create an SNAT IP address pool. **Note** An EIP that is already used in a DNAT entry cannot be used in an SNAT entry.
ECS Granularity	
Available ECS Instances	Select an ECS instance in the VPC. The ECS instance can access the Internet by using the specified EIP. Make sure that the following requirements are met: ◦ The ECS instance is in the Running state. ◦ The ECS instance is not assigned an EIP or a static public IP address.
ECS CIDR Block	The CIDR block of the ECS instance.

Parameter	Description
Public IP Address	Select the EIP that is used to access the Internet. You can select one or more EIPs. You can use multiple EIPs to create an SNAT IP address pool. The maximum bandwidth supported by each EIP in an SNAT IP address pool is 200 Mbit/s. To make full use of your EIP bandwidth plan and avoid port conflicts caused by insufficient EIPs, we recommend that you add EIPs to the SNAT address pool based on the following rules: ◦ If the maximum bandwidth value of the EIP bandwidth plan is 1,024 Mbit/s, specify at least five EIPs in each SNAT entry. ◦ If the maximum bandwidth value of the EIP bandwidth plan exceeds 1,024 Mbit/s, specify at least one additional EIP in each SNAT entry for every incremental 200 Mbit/s. **Note** An EIP that is already used in a DNAT entry cannot be used in an SNAT entry.

18.7.3. Modify an SNAT entry

This topic describes how to modify the public IP address in an SNAT entry.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway and click **Configure SNAT** in the **Actions** column.
4. On the **SNAT Table** page, find the SNAT entry, and click **Edit** in the **Actions** column.
5. In the **Edit SNAT Entry** panel, change the public IP address and click **OK**.

18.7.4. Delete a SNAT entry

This topic describes how to delete a Source Network Address Translation (SNAT) entry. You can delete the SNAT entry if the Elastic Compute Service (ECS) instances without public IP addresses in a Virtual Private Cloud (VPC) network no longer need the SNAT service to access the Internet.

Procedure

1. Log on to the NAT Gateway console.
2. In the top navigation bar, select the region where the NAT gateway is deployed.
3. On the **NAT Gateway** page, find the NAT gateway and click **Configure SNAT** in the **Actions** column.
4. On the **SNAT table** page, find the target SNAT entry, and click **Remove** in the **Actions** column.
5. In the dialog box that appears, click **OK**.

18.8. NAT service plan

18.8.1. Create a NAT service plan

You can associate an elastic IP address (EIP) or a NAT service plan to a NAT gateway. However, you can choose only one of them for the NAT gateway. If you want to associate a NAT service plan with the NAT gateway, you must create a NAT service plan first. Then, you can configure SNAT or DNAT for the NAT gateway. A NAT service plan consists of public IP addresses and Internet bandwidth.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateways** page, find the target NAT gateway and choose **Purchase NAT Bandwidth Package** in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, click **Purchase**.
4. On the **NAT Bandwidth Package** page, set the following parameters, and click **Submit**.

Parameter	Description
Region	Indicates the region for which the NAT service plan is purchased.
Billing methods	Select the billing method of the NAT service plan. Only **By Bandwidth** is supported.
Bandwidth (Mbit/s)	Enter a bandwidth value for the NAT service plan that you want to purchase. The maximum value is 5000 Mbit/s.
Name	Enter a name for the NAT service plan. The name must be 2 to 128 characters in length and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.
Description	Enter a description for the NAT service plan. The description must be 2 to 256 characters in length and cannot start with `http://` or `https://`.
Quantity	Enter the number of NAT bandwidth plans that you want to purchase.

18.8.2. Modify the bandwidth of a NAT service plan

This topic describes how to modify the bandwidth of a NAT bandwidth plan. The modification takes effect immediately.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateways** page, find the target NAT gateway and click the ID of the NAT service plan in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, click the target NAT service plan, and then choose **Modify Bandwidth**.
4. On the **Modify Bandwidth** page, modify the bandwidth, and then click **Submit**.

   Each NAT bandwidth plan supports a maximum of 5,000 Mbit/s in bandwidth.

18.8.3. Add an IP address

This topic describes how to add IP addresses to a NAT service plan. The added IP addresses can be used to create Source Network Address Translation (SNAT) and Destination Network Address Translation (DNAT) rules.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateways** page, find the target NAT gateway and click the ID of the NAT service plan in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, click the target NAT service plan, and then choose **Add IP Address**.
4. On the **Modify IP Addresses** page, enter the number of IP addresses to be added, and then click **Submit**.

18.8.4. Release an IP address

This topic describes how to release IP addresses in a NAT service plan. The NAT service plan must contain at least one IP address.

Prerequisites

Before you release an IP address in the NAT service plan, make sure that the IP address is not used in Source Network Address Translation (SNAT) and Destination Network Address Translation (DNAT) entries. If the IP address is used in an SNAT or DNAT entry, delete the SNAT or DNAT entry first. For more information, see Delete a DNAT entry and Delete a SNAT entry.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateways** page, find the target NAT gateway and click the ID of the NAT service plan in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, click the target NAT service plan.
4. In the **Public IP List** section, find the target IP address, and click **Release** in the **Actions** column.
5. In the **Release IP** dialog box, click **OK**.

18.8.5. Delete a NAT service plan

This topic describes how to delete a service plan.

Prerequisites

Before you start, make sure that the following requirements are met:

- Delete the IP addresses that are used in Destination Network Address Translation (DNAT) entries. For more information, see Delete a DNAT entry.
- Delete the IP addresses that are used for Source Network Address Translation (SNAT) entries. For more information, see Delete a SNAT entry.

Procedure

1. Log on to the NAT Gateway console.
2. On the **NAT Gateways** page, find the target NAT gateway and click the ID of the NAT service plan in the **Internet Shared Bandwidth** column.
3. On the **Bandwidth Package Details** page, find the target NAT service plan and click **Delete**.
4. In the **Delete Shared Internet Shared Bandwidth** dialog box, click **OK**.

18.9. Anti-DDoS Origin Basic

A distributed denial-of-service (DDoS) attack is a malicious network attack against one or more systems, which can crash the targeted network. Alibaba Cloud provides up to 5 Gbit/s of basic anti-DDoS protection for a NAT gateway free of charge. Anti-DDoS Origin Basic can effectively prevent DDoS attacks.

How Anti-DDoS Origin Basic works

After you enable Anti-DDoS Origin Basic, traffic from the Internet must pass through Alibaba Cloud Security before the traffic arrives at the NAT gateway. Anti-DDoS Origin Basic scrubs and filters common DDoS attacks at Alibaba Cloud Security. Anti-DDoS Origin Basic protects your services against attacks such as SYN floods, UDP floods, ACK floods, ICMP floods, and DNS Query floods.

Anti-DDoS Origin Basic specifies the traffic scrubbing and blackhole triggering thresholds based on the bandwidth limit of the elastic IP address (EIP) that is associated with the NAT gateway. When the inbound traffic reaches the threshold, traffic scrubbing or blackhole is triggered:

- Traffic scrubbing: When the attack traffic from the Internet exceeds the scrubbing threshold or matches the attack traffic pattern, Alibaba Cloud Security starts to scrub the attack traffic. Traffic scrubbing includes packet filtering, bandwidth capping, and traffic throttling.
- Blackhole: When the attack traffic from the Internet exceeds the blackhole triggering threshold, blackhole is triggered and all inbound traffic is dropped.

Traffic scrubbing and blackhole triggering thresholds

The following table describes the methods that are used to calculate the traffic scrubbing and blackhole triggering thresholds on NAT gateways.

Bandwidth limit of the EIP	Traffic scrubbing threshold (bit/s)	Traffic scrubbing threshold (pps)	Default blackhole triggering threshold
Lower than or equal to 800 Mbit/s	800 Mbit/s	120,000	1.5 Gbit/s
Higher than 800 Mbit/s	Predefined bandwidth	Predefined bandwidth × 150	Predefined bandwidth × 2

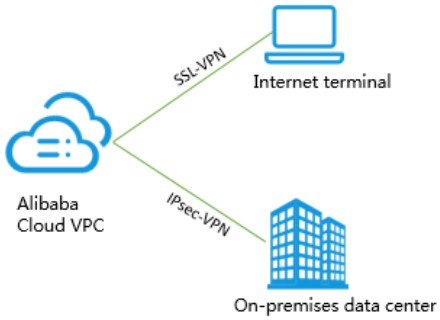
If the bandwidth limit of the EIP is 1,000 Mbit/s, the traffic scrubbing threshold (bit/s) is 1,000 Mbit/s, the traffic scrubbing threshold (pps) is 150,000, and the default blackhole triggering threshold is 2 Gbit/s.

19.VPN Gateway

19.1. What is VPN Gateway?

VPN Gateway is an Internet-based service that allows you to connect enterprise data centers, office networks, or Internet-facing terminals to Alibaba Cloud Virtual Private Cloud (VPC) networks through secure and reliable connections. VPN Gateway supports both IPsec-VPN connections and SSL-VPN connections.

> **Note** The Alibaba Cloud VPN Gateway service complies with the local regulations and policies. VPN Gateway does not provide Internet access services.



Features

VPN Gateway supports the following features:

- IPsec-VPN

  Route-based IPsec-VPN allows you to route network traffic in multiple ways, and also facilitates the configuration and maintenance of VPN policies.

  You can use IPsec-VPN to connect an on-premises data center to a VPC network or connect two VPC networks. IPsec-VPN supports the IKEv1 and IKEv2 protocols. Any devices that support these two protocols can connect to Alibaba Cloud VPN Gateway, such as devices manufactured by Huawei, H3C, Hillstone, Sangfor, Cisco ASA, Juniper, SonicWall, Nokia, IBM, and Ixia.

- SSL-VPN

  SSL-VPN is implemented based on the OpenVPN framework. You can create an SSL-VPN connection to connect a remote client to applications and services deployed in a VPC network. After you deploy your applications or services, you only need to import the certificate to the client to initiate a connection.

Benefits

VPN Gateway offers the following benefits:

- High security: You can use the IKE and IPsec protocols to encrypt data for secure and reliable data transmission.
- High availability: VPN Gateway adopts the hot-standby architecture to achieve failover within a few seconds, session persistence, and zero service downtime.
- Cost-effectiveness: The encrypted Internet connections provided by VPN Gateway are more cost-effective than leased lines.
- Ease of use: VPN Gateway is a ready-to-use service. VPN gateways start to work immediately after they are deployed.

19.2. Log on to the VPN Gateway console

This topic describes how to log on to the Apsara Uni-manager Management Console. You can manage your VPN gateways in the console. The Google Chrome browser is used as an example.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top menu bar, choose **Products > Networking > Virtual Private Cloud**.
5. In the left-side navigation pane, choose **Cross-Network Connections > VPN**.

19.3. Get started with IPsec-VPN

19.3.1. Connect a data center to a VPC

This topic describes how to connect a data center to a virtual private cloud (VPC) by using an IPsec-VPN connection.

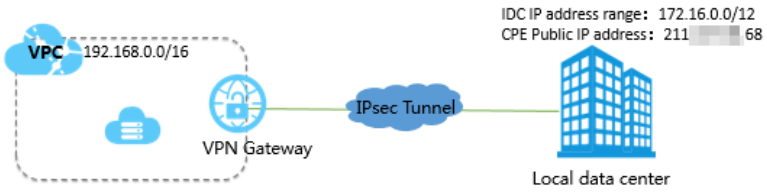
Prerequisites

Before you start, make sure that the following requirements are met:

- The gateway device in the data center is checked. VPN Gateway supports the standard IKEv1 and IKEv2 protocols. Gateway devices that support these two protocols can connect to VPN gateways on Alibaba Cloud, such as gateway devices that are manufactured by H3C, 华为、Hillstone, Sangfor, Cisco ASA, Juniper, SonicWall, Nokia, IBM, or Ixia.
- A static public IP address is assigned to the gateway device in the data center.
- The CIDR block of the data center does not overlap with that of the VPC.

Context

An enterprise has created a VPC on Alibaba Cloud. The CIDR block of the VPC is 192.168.0.0/16. The CIDR block of the data center is 172.16.0.0/12. The static public IP address for the gateway device in the data center is 211.XX.XX.68. To meet business requirements, the enterprise needs to connect the data center to the VPC.



As shown in the preceding figure, you can establish an IPsec-VPN connection between the data center and the VPC.

Step 1: Create a VPN gateway

Take the following steps to create a VPN gateway:

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways** .
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN Gateway** page, set the following parameters for the VPN gateway, and then click **Submit**.
   - **Organization**: Select the organization to which the VPN gateway belongs.
   - **Resource Set**: Select the resource set to which the VPN gateway belongs.
   - **Region**: Select the region where you want to deploy the VPN gateway.

     > **Note** Make sure that the VPN gateway and the VPC are deployed in the same region.

   - **Name**: Enter a name for the VPN gateway.

     The name must be 2 to 128 characters in length, and can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter, and cannot start with `http://` or `https://` .
   - **VPC**: Select the VPC to be associated with the VPN gateway.
   - **vSwitch**: Select the vSwitch to which you want to attach the VPN gateway.
   - **Bandwidth**: Select a maximum bandwidth value for the VPN gateway. The bandwidth is used for data transfer over the Internet.
   - **IPsec-VPN**: Specify whether to enable IPsec-VPN for the VPN gateway. In this example, **Enable** is selected.

     After IPsec-VPN is enabled, you can create a secure IPsec tunnel to connect a data center to a VPC, or connect two VPCs.
   - **SSL-VPN**: Specify whether to enable SSL-VPN. In this example, **Disable** is selected.

     SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without the need to configure a customer gateway.
   - **SSL Connections**: Select the maximum number of concurrent SSL connections that the VPN gateway supports.

     > **Note** This parameter is available only after SSL-VPN is enabled.

5. Go to the VPN Gateways page to view the newly created VPN gateway.

   The newly created VPN gateway is in the **Preparing** state. The VPN gateway changes to the **Normal** state after about 2 minutes. The **Normal** state indicates that the VPN gateway is initialized and ready for use.

> **Note** It takes about 1 to 5 minutes to create a VPN gateway.

Step 2: Create a customer gateway

Perform the following operations to create a customer gateway.

1. In the left-side navigation pane, choose **VPN > Customer Gateways**.
2. Select the region where you want to create the customer gateway.
3. On the **Customer Gateways** page, click **Create Customer Gateway**.
4. On the **Create Customer Gateway** page, set the following parameters, and click **Submit**.
   - **Organization**: Select the organization to which the customer gateway belongs.
   - **Resource Set**: Select the resource set to which the customer gateway belongs.
   - **Region**: Select the region where you want to deploy the customer gateway.

     > **Note** Make sure that the customer gateway and the VPN gateway to be connected are deployed in the same region.

   - **Zone**: Select the zone where you want to deploy the customer gateway.
   - **Name**: Enter a name for the customer gateway.

     The name must be 2 to 128 characters in length, and can contain digits, hyphens (-), and underscores (_). It must start with a letter and cannot start with `http://` or `https://`.
   - **IP Address**: Enter the public IP address of the gateway device in the data center that you want to connect to the VPC. In this example, **211.XX.XX.68** is entered.
   - **Description**: Enter a description for the customer gateway.

     The description must be 2 to 256 characters in length, and can contain digits, hyphens (-), underscores (_), full width periods (。), full width commas (，), and full width colons (：). The description must start with a letter and cannot start with `http://` or `https://`.

Step 3: Create an IPsec-VPN connection

Perform the following operations to create an IPsec-VPN connection:

1. In the left-side navigation pane, choose **VPN > IPsec Connections**.
2. Select the region where you want to create an IPsec-VPN connection.
3. On the **IPsec Connections** page, click **Create IPsec Connection**.
4. On the **Create IPsec Connection** page, set the following parameters for the IPsec-VPN connection, and click **Submit**.
   - **Organization**: Select the organization to which the IPsec-VPN connection belongs.
   - **Resource Set**: Select the resource set to which the IPsec-VPN connection belongs.
   - **Region**: Select the region to which the IPsec-VPN connection belongs.
   - **Zone**: Select the zone to which the IPsec-VPN connection belongs.
   - **Name**: Enter a name for the IPsec-VPN connection.
   - **VPN Gateway**: Select the VPN gateway you created.
   - **Customer Gateway**: Select the customer gateway to be connected through the IPsec-VPN connection.
   - **Source CIDR Block**: Enter the CIDR block of the VPC with which the selected VPN gateway is associated. In this example, **192.168.0.0/16** is entered.
   - **Destination CIDR Block**: Enter the CIDR block of the data center. In this example, **172.16.0.0/12** is entered.

- **Immediate Effect**: Specify whether to start connection negotiations immediately.
  - **Yes**: immediately starts negotiations after you complete the configuration.
  - **No**: starts negotiations when traffic is detected.
- **Advanced Configuration**: Use **default** advanced configurations.

  A pre-shared key is automatically generated by default.

Step 4: Load the configurations of the IPsec-VPN connection to the on-premises gateway device

Perform the following operations to load the configurations of the IPsec-VPN connection to the on-premises gateway device:

1. In the left-side navigation pane, choose **VPN > IPsec Connections**.
2. Select the region where the IPsec-VPN connection is created.
3. On the **IPsec Connections** page, find the IPsec-VPN connection you want to manage, and then choose **More > Download Configuration** in the **Actions** column.
4. Load the configurations of the IPsec-VPN connection to the on-premises gateway device based on the configuration requirements of the gateway device. For more information, consult the vendor of the gateway device.

   RemoteSubnet and LocalSubnet in the downloaded configurations are opposite to RemoteSubnet and LocalSubnet that you specify when you create an IPsec-VPN connection. For a VPN gateway, RemotSubnet refers to the CIDR block of the data center and LocalSubnet refers to the CIDR block of the VPC. For a customer gateway, LocalSubnet refers to the CIDR block of the data center and RemoteSubnet refers to the CIDR block of the VPC.

Step 5: Configure routes for the VPN gateway

Take the following steps to configure routes for the VPN gateway:

1. In the left-side navigation pane, choose **VPN > VPN Gateways**.
2. Select the region where the VPN gateway is deployed.
3. On the **VPN Gateways** page, find the VPN gateway for which you want to configure routes, and click its ID in the **Instance ID/Name** column.
4. In the **Destination-based routing** tab, click **Add Route Entry**.
5. In the **Add Route Entry** dialog box, set the following parameters, and click **OK**.
   - **Destination CIDR Block**: Enter the CIDR block of the data center. In this example, **172.16.0.0/12** is entered.
   - **Next Hop Type**: Select **IPsec Connection**.
   - **Next Hop**: Select an IPsec-VPN connection.
   - **Publish to VPC**: Specify whether to automatically advertise new route entries to the VPC route table. In this example, **Yes** is selected.
   - **Weight**: Select a weight. In this example, **100** is selected.

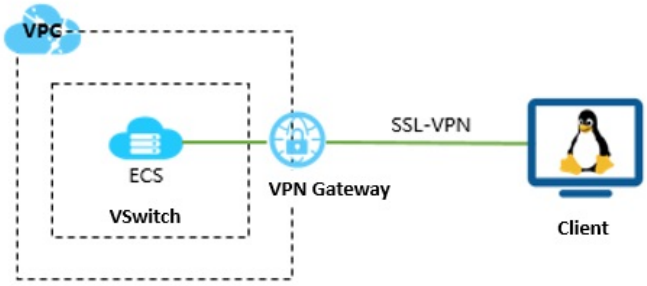
Step 6: Test the connectivity

Log on to an Elastic Compute Service (ECS) instance that is not assigned a public IP address in the VPC. Run the **ping** command to **ping** the private IP address of a server in the data center to test the connectivity.

19.4. Get started with SSL-VPN

19.4.1. Connect a Linux client to a VPC

This topic describes how to connect a Linux client to a virtual private cloud (VPC) through SSL-VPN connections.



Prerequisites

Before you start, make sure that the following requirements are met:

- A VPC is created.
- The CIDR block of the VPC must be different from that of the on-premises device.
- Your client can access the Internet.

Step 1: Create a VPN gateway

Perform the following operations to create a VPN gateway:

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN Gateway** page, set the following parameters for the VPN gateway, and then click **Submit**.
   - **Organization**: Select the organization to which the VPN gateway belongs.
   - **Resource Set**: Select the resource set to which the VPN gateway belongs.
   - **Region**: Select the region where you want to deploy the VPN gateway.

     > **Note** Make sure that the VPC and the VPN gateway for the VPC are deployed in the same region.

   - **Instance Name**: Enter a name for the VPN gateway.

     The name must be 2 to 128 characters in length and can contain letters, digits, periods (.), colons (:), underscores (_), and hyphens (-). It must start with a letter and cannot start with `http://` or `https://`.
   - **VPC**: Select the VPC network to be associated with the VPN gateway.
   - **vSwitch**: Select the vSwitch to which you want to attach the VPN gateway.
   - **Bandwidth**: Specify the maximum bandwidth of the VPN gateway. The bandwidth is used for data transfer over the Internet.
   - **IPsec-VPN**: Specify whether to enable IPsec-VPN for the VPN gateway. In this example, **Disable** is selected.
   - **SSL-VPN**: Specify whether to enable SSL-VPN for the VPN gateway. In this example, **Enable** is selected.

     SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without configuring a gateway for the client.
   - **SSL Connections**: Specify the maximum number of concurrent SSL connections that the VPN gateway supports.
5. Return to the **VPN Gateways** page to view the VPN gateway.

The newly created VPN gateway is in the **Preparing** state. The VPN gateway changes to the **Normal** state after about 2 minutes. The **Normal** state indicates that the VPN gateway is initialized and ready for use.

> **Note** It takes about 1 to 5 minutes to create a VPN gateway.

Step 2: Create an SSL server

Perform the following steps to create an SSL server:

1. In the left-side navigation pane, choose **VPN > SSL Servers**.
2. In the top navigation bar, select the region where you want to create the SSL server.
3. On the **SSL Servers** page, click **Create SSL Server**.
4. On the **Create SSL Server** page, set the following parameters for the SSL server, and then click **Submit**.
   - **Organization**: Select the organization to which the SSL server belongs.
   - **Resource Set**: Select the resource set to which the SSL server belongs.
   - **Region**: Select the region where you want to deploy the SSL server.
   - **Zone**: Select the zone where you want to deploy the SSL server.
   - **Name**: Enter a name for the SSL server.
   - **VPN Gateway**: Select a VPN gateway from the drop-down list.
   - **Local Network**: Enter the CIDR block of the network to which you want to connect. Click ⊕ to add more CIDR blocks. You can add the CIDR block of a VPC, a vSwitch, and an on-premises network.
   - **Client Subnet**: Enter the client CIDR block that the client uses to connect to the SSL server.
   - **Advanced Configuration**: Use **default** advanced configurations.

Step 3: Create and download an SSL client certificate

1. In the left-side navigation pane, choose **VPN > SSL Clients**.
2. In the top navigation bar, select the region where the SSL client is deployed.
3. On the **SSL Clients** page, click **Create Client Certificate**.
4. On the **Create SSL Client Certificate** page, set the following parameters for the SSL client, and then click **Submit**.
   - **Organization**: Select the organization to which the SSL client certificate belongs.
   - **Resource Set**: Select the resource set to which the SSL client certificate belongs.
   - **Region**: Select the region where you want to create the SSL client certificate.
   - **Zone**: Select the zone where you want to create the SSL client certificate.
   - **Name**: Enter a name for the SSL client certificate.
   - **VPN Gateway**: Select the VPN gateway to be associated with the SSL client certificate.
   - **SSL Server**: Select the SSL server to be associated with the SSL client certificate.
5. On the **SSL Clients** page, find the SSL client certificate and click **Download** in the **Actions** column.

   The SSL client certificate is downloaded to your on-premises device.

Step 4: Configure the client

Perform the following steps to configure the Linux client:

1. Run the following command to install the OpenVPN client:

   ```
   yum install -y openvpn
   ```

2. Extract the downloaded SSL client certificate and copy it to the */etc/openvpn/conf/* directory.

3. Run the following command to launch OpenVPN:

```
openvpn --config /etc/openvpn/conf/config.ovpn --daemon
```

Step 5: Test the connectivity

Run the **ping** command to test the connectivity between the client and an Elastic Compute Service (ECS) instance in the VPC.

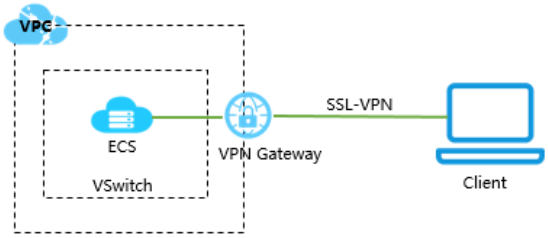
> **Note** Make sure that the security group rules of the ECS instance allow remote access from Linux clients.

19.4.2. Connect a Windows client to a VPC

This topic describes how to connect a Windows client to a virtual private cloud (VPC) through SSL-VPN connections.

Context

The following scenario is used as an example.



Prerequisites

Before you start, make sure that the following requirements are met:

- A VPC is created.
- The CIDR block of the VPC must be different from that of the on-premises device.
- Your client can access the Internet.

Step 1: Create a VPN gateway

Perform the following operations to create a VPN gateway:

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN Gateway** page, set the following parameters for the VPN gateway, and then click **Submit**.
   - **Organization**: Select the organization to which the VPN gateway belongs.
   - **Resource Set**: Select the resource set to which the VPN gateway belongs.
   - **Region**: Select the region where you want to deploy the VPN gateway.

     > **Note** Make sure that the VPC and the VPN gateway for the VPC are deployed in the same region.

   - **Instance Name**: Enter a name for the VPN gateway.

     The name must be 2 to 128 characters in length and can contain letters, digits, periods (.), colons (:), underscores (_), and hyphens (-). It must start with a letter and cannot start with `http://` or `https://`.
   - **VPC**: Select the VPC network to be associated with the VPN gateway.

- **vSwitch**: Select the vSwitch to which you want to attach the VPN gateway.
- **Bandwidth**: Specify the maximum bandwidth of the VPN gateway. The bandwidth is used for data transfer over the Internet.
- **IPsec-VPN**: Specify whether to enable IPsec-VPN for the VPN gateway. In this example, **Disable** is selected.
- **SSL-VPN**: Specify whether to enable SSL-VPN for the VPN gateway. In this example, **Enable** is selected.

  SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without configuring a gateway for the client.
- **SSL Connections**: Specify the maximum number of concurrent SSL connections that the VPN gateway supports.

5. Return to the **VPN Gateways** page to view the VPN gateway.

   The newly created VPN gateway is in the **Preparing** state. The VPN gateway changes to the **Normal** state after about 2 minutes. The **Normal** state indicates that the VPN gateway is initialized and ready for use.

   > **Note** It takes about 1 to 5 minutes to create a VPN gateway.

Step 2: Create an SSL server

Perform the following steps to create an SSL server:

1. In the left-side navigation pane, choose **VPN > SSL Servers**.
2. In the top navigation bar, select the region where you want to create the SSL server.
3. On the **SSL Servers** page, click **Create SSL Server**.
4. On the **Create SSL Server** page, set the following parameters for the SSL server, and then click **Submit**.
   - **Organization**: Select the organization to which the SSL server belongs.
   - **Resource Set**: Select the resource set to which the SSL server belongs.
   - **Region**: Select the region where you want to deploy the SSL server.
   - **Zone**: Select the zone where you want to deploy the SSL server.
   - **Name**: Enter a name for the SSL server.
   - **VPN Gateway**: Select a VPN gateway from the drop-down list.
   - **Local Network**: Enter the CIDR block of the network to which you want to connect. Click ⊕ to add more CIDR blocks. You can add the CIDR block of a VPC, a vSwitch, and an on-premises network.
   - **Client Subnet**: Enter the client CIDR block that the client uses to connect to the SSL server.
   - **Advanced Configuration**: Use **default** advanced configurations.

Step 3: Create and download an SSL client certificate

1. In the left-side navigation pane, choose **VPN > SSL Clients**.
2. In the top navigation bar, select the region where the SSL client is deployed.
3. On the **SSL Clients** page, click **Create Client Certificate**.
4. On the **Create SSL Client Certificate** page, set the following parameters for the SSL client, and then click **Submit**.
   - **Organization**: Select the organization to which the SSL client certificate belongs.
   - **Resource Set**: Select the resource set to which the SSL client certificate belongs.
   - **Region**: Select the region where you want to create the SSL client certificate.
   - **Zone**: Select the zone where you want to create the SSL client certificate.
   - **Name**: Enter a name for the SSL client certificate.

- **VPN Gateway**: Select the VPN gateway to be associated with the SSL client certificate.
- **SSL Server**: Select the SSL server to be associated with the SSL client certificate.

5. On the **SSL Clients** page, find the SSL client certificate and click **Download** in the **Actions** column.

   The SSL client certificate is downloaded to your on-premises device.

Step 4: Configure the client

Perform the following steps to configure the Windows client:

> **Notice** You must run the client as an administrator.

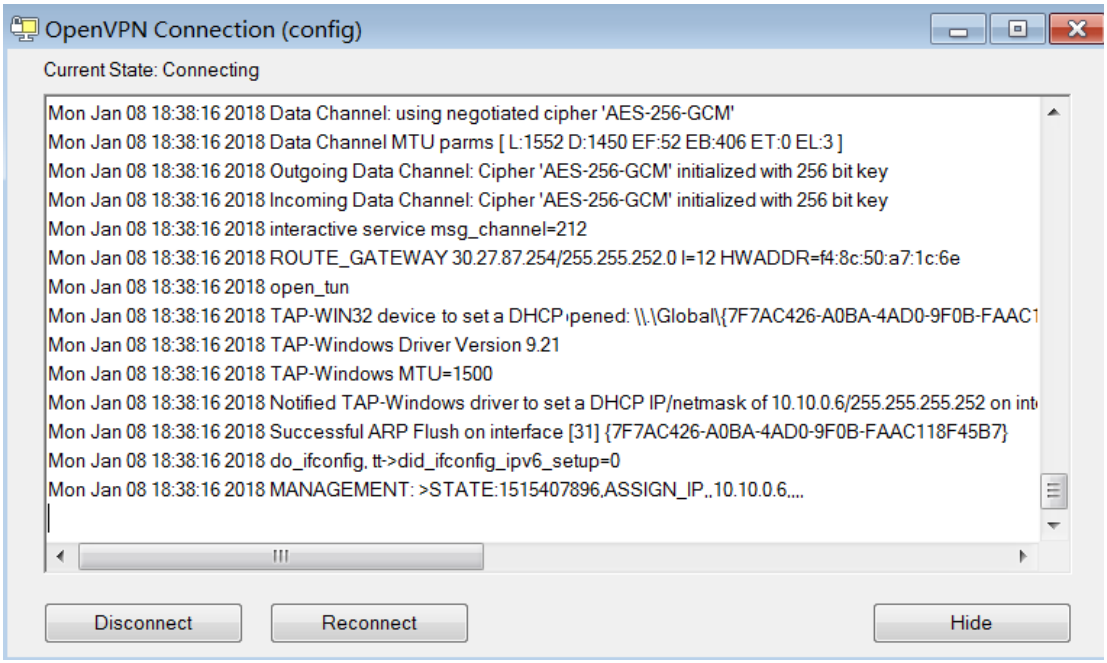
1. Download and install the OpenVPN client.

   Download OpenVPN.

2. Extract the downloaded SSL client certificate and copy it to the *OpenVPN\config* directory.

   In this example, the certificate is copied to the *C:\Program Files\OpenVPN\config* directory. You must copy the certificate to the directory where the OpenVPN client is installed.

3. Start the OpenVPN client and click **Connect** to initiate a connection.



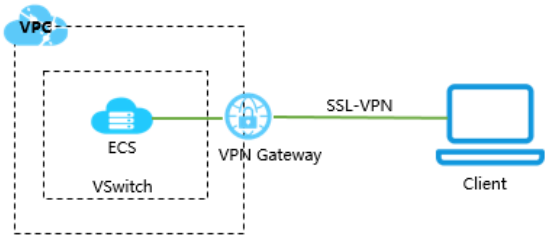
Step 5: Test the connectivity

Run the **ping** command to test the connectivity between the client and an Elastic Compute Service (ECS) instance in the VPC.

> **Note** Make sure that the security group rules of the ECS instance allow remote access from Windows clients.

19.4.3. Connect a macOS client to a VPC

This topic describes how to connect a macOS client to a virtual private cloud (VPC) through SSL-VPN connections.



Prerequisites

Before you start, make sure that the following requirements are met:

- A VPC is created.
- The CIDR block of the VPC must be different from that of the on-premises device.
- Your client can access the Internet.

Step 1: Create a VPN gateway

Perform the following operations to create a VPN gateway:

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN Gateway** page, set the following parameters for the VPN gateway, and then click **Submit**.
   - **Organization**: Select the organization to which the VPN gateway belongs.
   - **Resource Set**: Select the resource set to which the VPN gateway belongs.
   - **Region**: Select the region where you want to deploy the VPN gateway.

     > **Note** Make sure that the VPC and the VPN gateway for the VPC are deployed in the same region.

   - **Instance Name**: Enter a name for the VPN gateway.

     The name must be 2 to 128 characters in length and can contain letters, digits, periods (.), colons (:), underscores (_), and hyphens (-). It must start with a letter and cannot start with `http://` or `https://`.
   - **VPC**: Select the VPC network to be associated with the VPN gateway.
   - **vSwitch**: Select the vSwitch to which you want to attach the VPN gateway.
   - **Bandwidth**: Specify the maximum bandwidth of the VPN gateway. The bandwidth is used for data transfer over the Internet.
   - **IPsec-VPN**: Specify whether to enable IPsec-VPN for the VPN gateway. In this example, **Disable** is selected.
   - **SSL-VPN**: Specify whether to enable SSL-VPN for the VPN gateway. In this example, **Enable** is selected.

     SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without configuring a gateway for the client.
   - **SSL Connections**: Specify the maximum number of concurrent SSL connections that the VPN gateway supports.
5. Return to the **VPN Gateways** page to view the VPN gateway.

   The newly created VPN gateway is in the **Preparing** state. The VPN gateway changes to the **Normal** state after about 2 minutes. The **Normal** state indicates that the VPN gateway is initialized and ready for use.

   > **Note** It takes about 1 to 5 minutes to create a VPN gateway.

Step 2: Create an SSL server

Perform the following steps to create an SSL server:

1. In the left-side navigation pane, choose **VPN > SSL Servers**.
2. In the top navigation bar, select the region where you want to create the SSL server.
3. On the **SSL Servers** page, click **Create SSL Server**.
4. On the **Create SSL Server** page, set the following parameters for the SSL server, and then click **Submit**.
   - **Organization**: Select the organization to which the SSL server belongs.
   - **Resource Set**: Select the resource set to which the SSL server belongs.
   - **Region**: Select the region where you want to deploy the SSL server.
   - **Zone**: Select the zone where you want to deploy the SSL server.
   - **Name**: Enter a name for the SSL server.
   - **VPN Gateway**: Select a VPN gateway from the drop-down list.
   - **Local Network**: Enter the CIDR block of the network to which you want to connect. Click ⊕ to add more CIDR blocks. You can add the CIDR block of a VPC, a vSwitch, and an on-premises network.
   - **Client Subnet**: Enter the client CIDR block that the client uses to connect to the SSL server.
   - **Advanced Configuration**: Use **default** advanced configurations.

Step 3: Create and download an SSL client certificate

1. In the left-side navigation pane, choose **VPN > SSL Clients**.
2. In the top navigation bar, select the region where the SSL client is deployed.
3. On the **SSL Clients** page, click **Create Client Certificate**.
4. On the **Create SSL Client Certificate** page, set the following parameters for the SSL client, and then click **Submit**.
   - **Organization**: Select the organization to which the SSL client certificate belongs.
   - **Resource Set**: Select the resource set to which the SSL client certificate belongs.
   - **Region**: Select the region where you want to create the SSL client certificate.
   - **Zone**: Select the zone where you want to create the SSL client certificate.
   - **Name**: Enter a name for the SSL client certificate.
   - **VPN Gateway**: Select the VPN gateway to be associated with the SSL client certificate.
   - **SSL Server**: Select the SSL server to be associated with the SSL client certificate.
5. On the **SSL Clients** page, find the SSL client certificate and click **Download** in the **Actions** column.

   The SSL client certificate is downloaded to your on-premises device.

Step 4: Configure the client

Perform the following steps to configure the macOS client:

1. Run the following command to install the OpenVPN client:

   ```
   brew install openvpn
   ```

   > **Note** Make sure that homebrew is installed before you install OpenVPN.

2. Extract the certificate that you downloaded in Step 3 and copy it to the directory where the OpenVPN client is installed. Then, initiate an SSL-VPN connection.
   i. Back up the default configuration file.

ii. Run the following command to delete the default configuration file:

```
rm /usr/local/etc/openvpn/*
```

iii. Run the following command to copy the file to the configuration directory:

```
cp cert_location /usr/local/etc/openvpn/
```

In the preceding command, replace `cert_location` with the directory where the certificate is downloaded in Step 3. For example: */Users/example/Downloads/certs6.zip*.

iv. Run the following command to decompress the SSL client certificate package:

```
cd /usr/local/etc/openvpn/
unzip /usr/local/etc/openvpn/certs6.zip
```

v. Run the following command to initiate a connection:

```
sudo /usr/local/opt/openvpn/sbin/openvpn --config /usr/local/etc/openvpn/config.ovpn
```

Step 5: Test the connectivity

Run the **ping** command to test the connectivity between the client and an Elastic Compute Service (ECS) instance in the VPC.

> **Note** Make sure that the security group rules of the ECS instance allow remote access from macOS clients.

19.5. Manage a VPN Gateway

19.5.1. Create a VPN gateway

This topic describes how to create a VPN gateway. You must create a VPN gateway before you can use the IPsec-VPN and SSL-VPN features. After you create a VPN gateway, a public IP address is assigned to the VPN gateway.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways** .
3. On the **VPN Gateways** page, click **Create VPN Gateway**.
4. On the **Create VPN Gateway** page, set the following parameters for the VPN gateway, and then click **Submit**.

Parameter	Description
Organization	Select the organization to which the VPN gateway belongs.
Resource Set	Select the resource set to which the VPN gateway belongs.
Region	Select the region where you want to create the VPN gateway. You can create IPsec-VPN connections on VPN gateways to connect a data center to a VPC or connect two VPCs. Make sure that the VPC and the VPN gateway associated with the VPC are deployed in the same region.

Parameter	Description
Instance Name	Enter a name for the VPN gateway. The name must be 2 to 128 characters in length, and can contain letters, digits, periods (.), underscores (_), and hyphens (-). It must start with a letter, and cannot start with `http://` or `https://`.
VPC	Select the VPC network to be associated with the VPN gateway.
vSwitch	Select the vSwitch to which you want to attach the VPN gateway.
Bandwidth	Select a maximum bandwidth value for the VPN gateway. The bandwidth is used for data transfer over the Internet.
IPsec-VPN	Specify whether to enable IPsec-VPN for the VPN gateway. The default value is **Enable IPsec**. After IPsec-VPN is enabled, you can create a secure IPsec tunnel to connect a data center to a VPC, or connect two VPCs.
SSL-VPN	Specify whether to enable SSL-VPN for the VPN gateway. The default value is **Disable**. SSL-VPN connections are point-to-site connections. SSL-VPN allows you to connect a client to Alibaba Cloud without the need to configure a customer gateway.
SSL Connections	Select the maximum number of concurrent SSL connections that the VPN gateway supports. **Note** You can set this parameter only after SSL-VPN is enabled.

19.5.2. Modify a VPN gateway

This topic describes how to modify the name and description of a VPN gateway.

Prerequisites

A VPN gateway is created. For more information, see Create a VPN gateway.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the target VPN gateway, and click the icon in the **Instance ID/Name** column. In the dialog box that appears, enter a new name and click **OK**.

   The name must be 2 to 100 characters in length, and can contain letters, digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.
5. Click the icon in the **Description** column. In the dialog box that appears, enter a new description and click **OK**.

   The description must be 2 to 256 characters in length, and cannot start with http:// or https://.

19.5.3. Configure routes of a VPN Gateway

19.5.3.1. Route overview

After you create an IPsec-VPN connection by using a VPN gateway, you must add a route to the VPN gateway.

Route-based IPsec-VPN allows you to route network traffic in multiple ways, and facilitates the configuration and maintenance of VPN policies.

You can add the following two types of route to a VPN gateway:

- Policy-based routes.
- Destination-based routes.

Policy-based routes

Policy-based routes forward traffic based on source and destination IP addresses.

For more information, see Add a policy-based route entry.

> **Note** Policy-based routes take precedence over destination-based routes.

Destination-based routes

Destination-based routes forward traffic to specified destination IP addresses.

For more information, see Add a destination-based route entry.

19.5.3.2. Work with a policy-based route

A policy-based route forwards traffic based on source and destination IP addresses. This topic describes how to create, advertise, modify, and delete a policy-based route.

Prerequisites

An IPsec-VPN connection is created. For more information, see Create an IPsec-VPN connection.

Add a policy-based route

After you create an IPsec-VPN connection, you can create a policy-based route for the IPsec-VPN connection.

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways** .
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the VPN gateway you want to manage and click the gateway ID in the **Instance ID/Name** column.
5. Click the **Policy-based Routing** tab, and then click **Add Route Entry**.
6. In the **Add Route Entry** panel, set the following parameters and click **OK**.

Parameter	Description
Destination CIDR block	The private CIDR block that you want to access.
Source CIDR Block	The private CIDR block of the VPC.
Next Hop Type	Select IPsec Connection.
Next Hop	Select the IPsec-VPN connection for which you want to create the policy-based route.

Parameter	Description
Publish to VPC	Specify whether to advertise the route to the VPC route table. Valid values: ○ **Yes**: automatically advertises the route to the route table of the VPC. We recommend that you select this value. ○ **No**: does not advertise the route to the VPC route table. **Note** If you select **No**, you must manually advertise the route to the VPC route table.
Weight	Select a weight. Valid values: ○ **100**: specifies a high priority for the policy-based route. ○ **0**: specifies a low priority for the policy-based route. **Note** If two policy-based routes are configured with the same destination CIDR block, you cannot set the weights of the routes to 100.

Advertise a policy-based route

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways** .
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the VPN gateway you want to manage and click the gateway ID in the **Instance ID/Name** column.
5. On the **Policy-based Routing** tab, find the policy-based route that you want to advertise and click **Publish** in the **Actions** column.
6. In the **Publish Route Entry** message, click **OK**.

   If you want to withdraw the policy-based route, click **Unpublish**.

Modify a policy-based route

You can change the weight of a policy-based route.

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways** .
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the VPN gateway you want to manage and click the gateway ID in the **Instance ID/Name** column.
5. On the **Policy-based Routing** tab, find the policy-based route that you want to modify and click **Edit** in the **Actions** column.
6. In the panel that appears, specify a new weight for the route and click **OK**.

Delete a policy-based route

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways** .
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the VPN gateway you want to manage and click the gateway ID in the **Instance ID/Name** column.

5. On the **Policy-based Routing** tab, find the policy-based route that you want to delete and click **Delete** in the **Actions** column.
6. In the **Delete Route Entry** message, click **OK**.

19.5.3.3. Manage destination-based routes

Destination-based routing is a technique that routes network traffic to specified destination IP addresses. This topic describes how to create, advertise, modify, and delete a destination-based route.

Prerequisites

An IPsec-VPN connection is created. For more information, see Create an IPsec-VPN connection.

Create a destination-based route

After you create an IPsec-VPN connection, you can create a destination-based route for the IPsec-VPN connection.

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways** .
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the VPN gateway you want to manage and click the gateway ID in the **Instance ID/Name** column.
5. On the **Destination-based routing** tab, click **Add Route Entry**.
6. In the **Add Route Entry** dialog box, set the following parameters and click **OK**.

Parameter	Description
Destination CIDR block	Enter the CIDR block that you want to access.
Next Hop Type	Select IPsec Connection.
Next Hop	Select the IPsec-VPN connection for which you want to create a destination-based route.
Publish to VPC	Specify whether to advertise the destination-based route to the virtual private cloud (VPC) route table. ○ **Yes**: automatically advertises the route to the route table of the VPC. We recommend that you select this value. ○ **No**: does not advertise the destination-based route to the VPC route table. **Note** If you select **No**, you must manually advertise the destination-based route to the VPC route table.
Weight	Select a weight. Valid values: ○ **100**: specifies a high priority for the destination-based route. ○ **0**: specifies a low priority for the destination-based route. **Note** If two destination-based routes are configured with the same destination CIDR block, you cannot set the weights of the routes to 100.

Advertise the destination-based route

1. Log on to the VPN Gateway console.

2. In the left-side navigation pane, choose **VPN > VPN Gateways** .
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the VPN gateway you want to manage and click the gateway ID in the **Instance ID/Name** column.
5. On the **Destination-based Routing** tab, find the destination-based route that you want to manage and click **Publish** in the **Actions** column.
6. In the **Publish Route Entry** message, click **OK**.

   If you want to withdraw the destination-based route, click **Unpublish**.

Modify the destination-based route

You can change the weight of the destination-based route.

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways** .
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the VPN gateway you want to manage and click the gateway ID in the **Instance ID/Name** column.
5. On the **Destination-based Routing** tab, find the destination-based route that you want to manage and click **Edit** in the **Actions** column.
6. In the panel that appears, specify the weight of the destination-based route and click **OK**.

Delete the destination-based route

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways** .
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the VPN gateway you want to manage and click the gateway ID in the **Instance ID/Name** column.
5. On the **Destination-based Routing** tab, find the destination-based route that you want to manage and click **Delete** in the **Actions** column.
6. In the **Delete Route Entry** message, click **OK**.

19.5.4. Delete a VPN gateway

This topic describes how to delete a VPN gateway. After you delete a VPN gateway, you can no longer use the VPN gateway to establish IPsec-VPN or SSL-VPN connections.

Context

Before you delete a VPN gateway, make sure that the following conditions are met:

- The IPsec-VPN connections on the VPN gateway are deleted. For more information, see Delete an IPsec-VPN connection.
- The SSL server associated with the VPN gateway is deleted. For more information, see Delete an SSL server.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways**.
3. Select the region where the VPN gateway is deployed.
4. On the **VPN Gateways** page, find the VPN gateway that you want to delete, and then click **Delete** in the **Actions** column.

5. In the **Delete VPN Gateway** message, click **OK**.

19.5.5. View the monitoring information about a VPN gateway

This topic describes how to view the monitoring information about a VPN gateway.

Prerequisites

Before you start, make sure that the following requirements are met:

- Log Service is activated.
- CloudMonitor is activated.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > VPN Gateways** .
3. On the **VPN Gateway** page, find the VPN gateway you want to manage and click the gateway ID.
4. On the details page of the VPN gateway, click the **Monitor** tab.
5. On the **Monitor** tab, view the monitoring information.

   By default, the system displays the monitoring information within the last hour. You can also view the monitoring information within the last 3, 6, or 12 hours. In addition, you can view the monitoring information in a specified time period. VPN Gateway provides the following monitoring information:

Metric	Description
Vpn rxPkgs	The rate at which packets are received by the VPN gateway. Unit: packet/s. This is the default unit. You can also select kilopacket/s or megapacket/s from the drop-down list next to the monitored item.
Vpn txPkgs	The rate at which packets are sent by the VPN gateway. Unit: packet/s. This is the default unit. You can also select kilopacket/s or megapacket/s from the drop-down list next to the monitored item.
Vpn net rate	The rate of inbound traffic. Unit: bit/s. This is the default unit. You can also select Kbit/s, Mbit/s, or Gbit/s from the drop-down list next to the monitored item.
Vpn net rate	The rate of outbound traffic. Unit: bit/s. This is the default unit. You can also select Kbit/s, Mbit/s, or Gbit/s from the drop-down list next to the monitored item.
ssl connect count(count)	The number of clients that are connected to Alibaba Cloud by using the SSL-VPN connection.

19.6. Manage a customer gateway

19.6.1. Create a customer gateway

This topic describes how to create a customer gateway. You can use a customer gateway to establish an IPsec-VPN connection between a virtual private cloud (VPC) and a data center or between two VPCs. After you create a customer gateway, you can update the information about a gateway device in the data center to Alibaba Cloud. Then, you can connect the customer gateway to a VPN gateway. A customer gateway can connect to multiple VPN gateways.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > Customer Gateways**.
3. Select the region where you want to deploy the customer gateway.

   > **Note** Make sure that the customer gateway and the VPN gateway to be connected belong to the same region.

4. On the **Customer Gateways** page, click **Create Customer Gateway**.
5. On the **Create Customer Gateway** page, set the following parameters and click **Submit**.

Parameter	Description
Organization	Select the organization to which the customer gateway belongs.
Resource Set	Select the resource set to which the customer gateway belongs.
Region	Select the region where you want to deploy the customer gateway. **Note** Make sure that the customer gateway and the VPN gateway to be connected belong to the same region.
Zone	Select the zone where you want to deploy the customer gateway.
Name	Enter a name for the customer gateway. The name must be 2 to 128 characters in length and can contain digits, hyphens (-), and underscores (_). The name must start with a letter and cannot start with `http://` or `https://`.
IP Address	Enter the static public IP address of the gateway device in the data center.
Description	Enter a description for the customer gateway. The description must be 2 to 256 characters in length and can contain digits, hyphens (-), underscores (_), periods (.), commas (,), and colons (:). The description must start with a letter and cannot start with `http://` or `https://`.

19.6.2. Modify a customer gateway

This topic describes how to modify the name and description of a customer gateway.

Prerequisites

A customer gateway is created. For more information, see Create a customer gateway.

Procedure

1. Log on to the VPN Gateway console.

2. In the left-side navigation pane, choose **VPN > Customer Gateways**.
3. Select the region where the customer gateway is deployed.
4. On the **Customer Gateways** page, find the target customer gateway, click the icon in the **Instance ID** column. In the dialog box that appears, enter a name and click **OK**.

   The name must be 2 to 128 characters in length, and can contain digits, underscores (_), and hyphens (-). It must start with a letter or Chinese character.
5. Click the icon in the **Description** column. In the dialog box that appears, enter a new description and click **OK**.

   The description must be 2 to 256 characters in length, and cannot start with http:// or https://.

19.6.3. Delete a customer gateway

This topic describes how to delete a customer gateway.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > Customer Gateways**.
3. Select the region where the customer gateway is deployed.
4. On the **Customer Gateways** page, find the customer gateway that you want to delete, and then click **Delete** in the **Actions** column.
5. In the **Delete Customer Gateway** message, click **OK**.

19.7. Configure IPsec-VPN connections

19.7.1. Configuration overview

This topic describes how to connect a VPC to an on-premises data center through IPsec-VPN.

Prerequisites

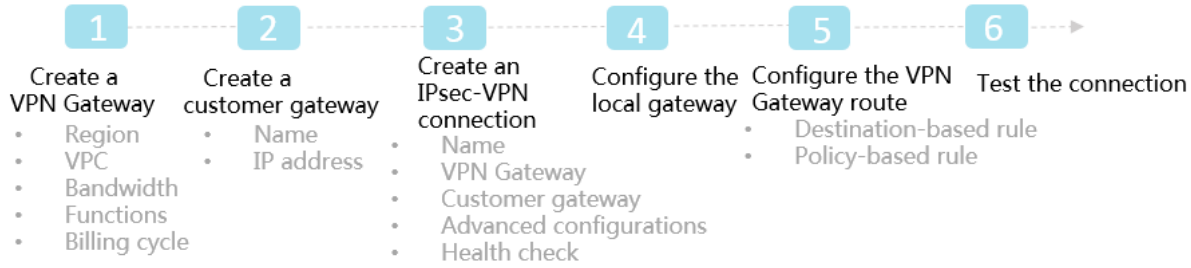
Before creating a site-to-site VPN connection, make sure the following conditions are met:

- The protocols IKEv1 and IKEv2 are supported by the gateway device of the on-premises data center.

  IPsec-VPN supports IKEv1 and IKEv2 protocols. Devices that support these two protocols can connect to Alibaba Cloud VPN Gateway, including devices of Huawei, H3C, Hillstone, SANGFOR, Cisco ASA, Juniper, SonicWall, Nokia, IBM, and Ixia.
- A static public IP address is configured for the local gateway.
- The IP address ranges of the VPC and on-premises data center to be connected do not conflict with each other.

Procedure

The following figure shows the procedure of connecting a VPC to an on-premises data center through IPsec-VPN.



1. Create a VPN Gateway

   Enable the IPsec-VPN function. Up to 10 IPsec-VPN connections can be established in a VPN Gateway.

2. Create a customer gateway

   By creating a customer gateway, you can register the local gateway to Alibaba Cloud and connect the customer gateway to the VPN Gateway. A customer gateway can be connected to multiple VPN Gateways.

3. Create an IPsec connection

   An IPsec connection is a VPN channel established between a VPN Gateway and a customer gateway. The encrypted communication between the VPN Gateway and the on-premises data center can be achieved only after the IPsec connection is established.

4. Configure the local gateway

   You need to load the VPN Gateway configurations to the local gateway device.

5. Configure the VPN Gateway route

   You need to configure a route in the VPN Gateway and publish it to the VPC route table.

6. Test the connection

   Log on to an ECS instance (without a public IP address) in the connected VPC. **ping** the private IP address of a server in the on-premises data center to check whether the connection is established.

19.7.2. Manage an IPsec-VPN connection

19.7.2.1. Create an IPsec-VPN connection

This topic describes how to create an IPsec-VPN connection. After you create a VPN gateway and a customer gateway, you can create an IPsec-VPN connection between the two gateways for encrypted data transmission.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. In the top navigation bar, select the region where you want to create the IPsec-VPN connection.
4. On the **IPsec Connections** page, click **Create IPsec Connection**.
5. On the **Create IPsec Connection** page, configure the IPsec-VPN connection based on the following information and click **Submit**.

Parameter	Description
Organization	Select the organization to which the IPsec-VPN connection belongs.
Resource Set	Select the resource set to which the IPsec-VPN connection belongs.

Parameter	Description
Region:	Select the region where the IPsec-VPN connection is created.
Zone	Select the zone where the IPsec-VPN connection is created.
Name	Enter a for the IPsec-VPN connection. The name must be 2 to 128 characters in length, and can contain digits, hyphens (-), and underscores (_). It must start with a letter and cannot start with `http://` or `https://` .
VPN Gateway	Select the VPN gateway to be connected through the IPsec-VPN connection.
Customer Gateway	Select the customer gateway to be connected through the IPsec-VPN connection.
Local Network	Enter the CIDR block of the VPC to be connected to the data center. The CIDR block is used in Phase 2 negotiations. You can add multiple CIDR blocks of the VPC only if IKEv2 is used.
Remote Network	Enter the CIDR block of the data center to be connected to the VPC. This CIDR block is used in Phase 2 negotiations. You can add multiple CIDR blocks of the data center only if IKEv2 is used.
Effective Immediately	Specify whether to start connection negotiations immediately. ◦ **Yes**: immediately starts negotiations after you complete the configuration. ◦ **No**: starts negotiations when traffic is detected.
Advanced Configurations	Select the type of advanced configurations. ◦ **Default**: Use default settings. ◦ **Configure**: Use custom settings.
Advanced configuration: IKE configuration	
Pre-Shared Key	Enter the pre-shared key used for authentication between the VPN gateway and the customer gateway. You can specify a key, or use the default key that is randomly generated by the system.
Version	Select an IKE version. ◦ **ikev1** ◦ **ikev2** IKEv1 and IKEv2 are supported. Compared with IKEv1, IKEv2 simplifies the Security Association (SA) negotiation process and provides better support for scenarios where multiple CIDR blocks are used. We recommend that you select IKEv2.
Negotiation Mode	Select the negotiation mode of IKEv1. ◦ **main**: This mode offers higher security during negotiations. ◦ **aggressive**: This mode is faster and has a higher success rate. Connections negotiated in both modes ensure the same security level of data transmission.

Parameter	Description
Encryption Algorithm	Select the encryption algorithm to be used in Phase 1 negotiations. Supported algorithms are aes, aes192, aes256, des, and 3des.
Authentication Algorithm	Select the authentication algorithm to be used in Phase 1 negotiations. Supported algorithms are sha1 and md5.
DH Group	Select the Diffie-Hellman key exchange algorithm to be used in Phase 1 negotiations.
SA Life Cycle (seconds)	Specify the lifecycle of the SA after Phase 1 negotiations succeed. Default value: **86400**. Unit: seconds.
LocalId	Specify the ID of the VPN gateway. The ID is used in Phase 1 negotiations. The default value is the public IP address of the VPN gateway. If you set LocalId to a FQDN, we recommend that you set Negotiation Mode to Aggressive.
RemoteId	Specify the ID of the customer gateway. The ID is used in Phase 1 negotiations. The default value is the public IP address of the customer gateway. If you set RemoteId to a FQDN, we recommend that you select set Negotiation Mode to Aggressive.
Advanced configuration: IPSec configuration	
Encryption Algorithm	Select the encryption algorithm to be used in Phase 2 negotiations. Supported algorithms are aes, aes192, aes256, des, and 3des.
Authentication Algorithm	Select the authentication algorithm to be used in Phase 2 negotiations. Supported algorithms are sha1 and md5.
DH Group	Select the Diffie-Hellman key exchange algorithm to be used in Phase 2 negotiations. ◦ If you select a value other than **disabled**, the PFS feature is enabled by default, which necessitates key update for every renegotiation. Therefore, you must also enable PFS for the client. ◦ For clients that do not support PFS, select **disabled**.
SA Life Cycle (seconds)	Specify the lifecycle of the SA after Phase 2 negotiations succeed. Default value: **86400**. Unit: seconds.

19.7.2.2. Modify an IPsec-VPN connection

This topic describes how to modify the name, advanced settings, and health check for an IPsec-VPN connection.

Prerequisites

An IPsec-VPN connection is created. For more information, see Create an IPsec-VPN connection.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. In the top navigation bar, select the region where the IPsec-VPN connection is created.
4. On the **IPsec Connections** page, find the target IPsec-VPN connection and then click **Edit** in the **Actions** column.
5. In the **Modify IPsec Connections** dialog box, modify the name, advanced settings, and health check, and click **Submit**.

19.7.2.3. Download the configuration file of an IPsec-VPN connection

This topic describes how to download the configurations of an IPsec-VPN connection, and load the configurations to the customer gateway device after an IPsec-VPN connection is configured.

Prerequisites

An IPsec-VPN connection is created. For more information, see Create an IPsec-VPN connection.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. In the top navigation bar, select the region where the IPsec-VPN connection is created.
4. On the **IPsec Connections** page, find the target IPsec-VPN connection, and then choose **More > Download Configuration** in the **Actions** column.

   > **Note** RemoteSubnet and LocalSubnet in the downloaded configurations are opposite to RemoteSubnet and LocalSubnet that you specify when you create an IPsec-VPN connection. For a VPN gateway, RemotSubnet refers to the CIDR block of the on-premises data center and LocalSubnet refers to the CIDR block of the VPC network. For a customer gateway, LocalSubnet refers to the CIDR block of the on-premises data center and RemoteSubnet refers to the CIDR block of the VPC network.

19.7.2.4. Configure a security group

This topic describes how to configure a security group to control the inbound and outbound traffic of ECS instances in the security group after an IPsec-VPN connection is created.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. In the top navigation bar, select the region where the IPsec-VPN connection is created.
4. On the **IPsec Connections** page, find the IPsec-VPN connection you want to manage, and then choose **More > Configure Routing Group** in the **Actions** column.
5. In the **Configure Routing Group** panel, set the following parameters, and then click **Submit**.

Parameter	Description
Security Group	Select the security group to which you want to add the security group rule.
Rule Direction	Select the direction in which the rule applies. ○ **Outbound**: from the ECS instances in the current security group to other ECS instances on Alibaba Cloud or resources on the Internet. ○ **Inbound**: from other ECS instances on Alibaba Cloud or resources on the Internet to the ECS instances in the current security group.

Parameter	Description
Policy	Select an authorization policy. ○ **Allow**: allows access requests on the specified ports. ○ **Deny**: discards requests on the specified ports without returning messages. If you specify different authorization policies for two security group rules but the other settings are the same, the **Deny** rule prevails over the **Allow** rule.
Protocol Type	Select a protocol type.
Port Range	Select a port range for the security group rule. Specify the port range in the format of 1/200 or 80/80. ○ 1/200 specifies a port range from 1 to 200. ○ 80/80 specifies port 80. Valid values: -1 and 1 to 65535. A value of -1/-1 specifies all ports.
Priority	Set a priority for the rule. Valid values: 1 to 100. The default value is 1, which specifies the highest priority.
Authorization Type	Select the authorization type of the security group rule. You can select only **Address**.
Network Type	Select a network interface controller (NIC) type. ○ **Internal**: controls inbound and outbound traffic within Alibaba Cloud. ○ **External**: controls inbound and outbound traffic over the Internet.
Authorization Object	Select the CIDR blocks to be authorized by the security group rule. You can specify up to 10 CIDR blocks at a time.
Enable Automatically Configure Routers	Specify whether to automatically configure routers. The feature is enabled by default.
Description	Enter a description for the security group rule. The description must be 2 to 256 characters in length, and cannot start with **http://** or **https://**. You can leave this parameter empty.

19.7.2.5. View IPsec-VPN connection logs

This topic describes how to view IPsec-VPN connection logs that are generated within the last 30 days to troubleshoot connection errors. You can query log data generated within 10 minutes.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. In the top navigation bar, select the region where the IPsec-VPN connection is created.
4. On the **IPsec Connections** page, find the target IPsec-VPN connection, and then choose **More > View Logs**

in the **Actions** column.

5. In the **IPsec Connection Logs** dialog box, set the time range and query the logs.

19.7.2.6. Delete an IPsec-VPN connection

This topic describes how to delete an IPsec-VPN connection.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. In the top navigation bar, select the region where you want to delete the IPsec-VPN connection.
4. On the **IPsec Connections** page, find the IPsec-VPN connection that you want to delete, and click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

19.7.3. View the monitoring information about an IPsec-VPN connection

This topic describes how to view the monitoring information about an IPsec-VPN connection.

Prerequisites

Before you start, make sure that the following requirements are met:

- Log Service is activated.
- CloudMonitor is activated.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > IPsec Connections**.
3. On the **IPsec Connections** page, find the IPsec-VPN connection that you want to manage and click its ID.
4. On the **Monitor** tab of the IPsec-VPN connection, view the monitoring information about the connection.

   By default, the system displays monitoring information within the last hour. You can also view monitoring information within the last 3, 6, or 12 hours. In addition, you can view monitoring information within a specified time period. VPN Gateway provides the following monitoring information:

Metric	Description
Ipsec receive pkg Counter	The rate at which packets are received by the IPsec-VPN connection. Unit: packet/s. This is the default unit. You can also select kilopacket/s or megapacket/s from the drop-down list next to the monitored item.
Ipsec transform pkg Counter	The rate at which packets are sent by the IPsec-VPN connection. Unit: packet/s. This is the default unit. You can also select kilopacket/s or megapacket/s from the drop-down list next to the monitored item.

Metric	Description
Ipsec receive rate	The rate of inbound traffic. Unit: bit/s. This is the default unit. You can also select Kbit/s, Mbit/s, or Gbit/s from the drop-down list next to the monitored item.
Ipsec transform rate	The rate of outbound traffic. Unit: bit/s. This is the default unit. You can also select Kbit/s, Mbit/s, or Gbit/s from the drop-down list next to the monitored item.

19.7.4. MTU considerations

The maximum transmission unit (MTU) is the size of the largest packet that can be transmitted over a network layer protocol, such as TCP. Packets are measured in bytes. The MTU takes both the sizes of headers and data into account.

Segments transmitted over an IPsec tunnel are encrypted and then encapsulated into packets for routing purpose. The size of a segment must fit the MTU of the packet that carries the segment. Therefore, the MTU of the segment must be smaller than the MTU of the packet.

Gateway MTU

You must set the MTU of the local VPN gateway to a value no greater than 1,360 bytes. We recommend that you set the MTU to 1,360 bytes.

The TCP protocol negotiates the maximum segment length (MSS) of each packet segment between the sender and the receiver. We recommend that you set the TCP MSS of the on-premises VPN gateway to 1,359 bytes to facilitate the encapsulation and transfer of TCP packets.

19.8. Configure SSL-VPN

19.8.1. SSL-VPN configuration overview

This topic describes how to remotely access a VPC through SSL-VPN.

Prerequisites

The following conditions must be met before you deploy a VPN Gateway:

- The client and the VPC are not using the same private CIDR block.
- The client is able to access the Internet.

Procedure

The following figure describes the process for configuring remote access to a VPC through SSL-VPN.

1. Create a VPN gateway

   Create a VPN gateway and enable the SSL-VPN function.

2. Create an SSL server

   Specify the range of IP addresses to be accessed and the range of IP addresses to be allocated to the client for making connections.

3. Create a client certificate

Create a client certificate according to the SSL server configuration, and then download the client certificate and the configuration file.

4. Configure the client

   Download and install the VPN client, and then import the client certificate and the configuration file.

5. Configure the security group

   Make sure that the rules in the security group of the ECS instance allow remote access from clients.

19.8.2. Manage an SSL server

19.8.2.1. Create an SSL server

This topic describes how to create an SSL server. Before you can create an SSL-VPN connection, you must create an SSL server.

Prerequisites

A VPN gateway is created and SSL-VPN is enabled for the VPN gateway. For more information, see Create a VPN gateway.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > SSL Servers**.
3. In the top navigation bar, select the region where you want to create the SSL server.
4. On the **SSL Servers** page, click **Create SSL Server**.
5. On the **Create SSL Server** page, set the following parameters and click **Submit**.

Parameter	Description
Organization	Select the organization to which the SSL server belongs.
Resource Set	Select the resource set to which the SSL server belongs.
Region	Select the region where you want to deploy the SSL server.
Zone	Select the zone where you want to deploy the SSL server.
Name	Enter a name for the SSL server. The name must be 2 to 128 characters in length, and can contain digits, hyphens (-), and underscores (_). It must start with a letter and cannot start with `http://` or `https://`.
VPN Gateway	Select the VPN gateway that you want to associate with the SSL server. Make sure that SSL-VPN is enabled for the VPN gateway.

Parameter	Description
Local Network	Enter the CIDR block that the client needs to access through the SSL-VPN connection. It can be the CIDR block of a VPC, a vSwitch, a data center connected to a VPC through an Express Connect circuit, or a cloud service such as ApsaraDB RDS or Object Storage Service (OSS). Click + to add more CIDR blocks. Note The subnet mask of the specified CIDR block must be 16 to 29 bits in length.
Client CIDR Block	Enter the CIDR block from which an IP address is allocated to the virtual NIC of the client. Do not enter the private CIDR block of the client. When the client accesses the destination network through an SSL-VPN connection, the VPN gateway allocates an IP address from the client CIDR block to the client.
Advanced Configurations	Select the type of advanced configurations. ○ **Default**: Use the default advanced configurations. ○ **Custom**: Use custom configurations. You can set the following parameters: ■ **Protocol**: Select the protocol used by the SSL-VPN connection. Valid values: UDP and TCP. ■ **Port**: Specify the port used by the SSL-VPN connection. Invalid values: 22, 2222, 22222, 9000, 9001, 9002, 7505, 80, 443, 53, 68, 123, 4510, 4560, 500, and 4500. ■ **Encryption Algorithm**: Select the encryption algorithm used by the SSL connection. Valid values: AES-128-CBC, AES-192-CBC, AES-256-CBC, and none. ■ **Enable Compression**: Specify whether to compress the data that is transmitted over the SSL-VPN connection.

19.8.2.2. Modify an SSL server

This topic describes how to modify the name, server CIDR block, client CIDR block, and advanced settings of an SSL server.

Prerequisites

An SSL server is created. For more information, see Create an SSL server.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > SSL Servers**.
3. In the top navigation bar, select the region where you want to create the SSL server.
4. In the top navigation bar, select the region where the SSL server is created.
5. On the **SSL Servers** page, find the SSL server, and then click **Edit** in the **Actions** column.
6. On the **Edit SSL Server** page, modify the name, server CIDR block, client CIDR block, and advanced settings of the SSL server, and then click **OK**.

19.8.2.3. Configure a security group

This topic describes how to configure a security group to control the inbound and outbound traffic of ECS instances in the security group after an IPsec-VPN connection is created.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > SSL Servers**.
3. Select the region where the SSL server is deployed.
4. On the **SSL Servers** page, find the SSL server you want to manage, and then click **Configure Routing Group** in the **Actions** column.
5. In the **Configure Routing Group** panel, set the following parameters, and then click **Submit**.

Parameter	Description
Security Group	Select the security group to which you want to add the security group rule.
Rule Direction	Select the direction in which the rule applies. ○ **Outbound**: from the ECS instances in the current security group to other ECS instances on Alibaba Cloud or resources on the Internet. ○ **Inbound**: from other ECS instances on Alibaba Cloud or resources on the Internet to the ECS instances in the security group.
Policy	Select an authorization policy. ○ **Allow**: allows access requests on the specified ports. ○ **Deny**: discards requests received on the specified ports without returning messages. If you specify different authorization policies for two security group rules but the other settings are the same, the **Deny** rule prevails over the **Allow** rule.
Protocol Type	Select a protocol type.
Port Range	Specify a port range for the security group rule. Specify the port range in the format of 1/200 or 80/80. ○ 1/200 specifies a port range from 1 to 200. ○ 80/80 specifies port 80. Valid values: -1 and 1 to 65535. A value of -1/-1 specifies all ports.
Priority	Set a priority for the rule. Valid values: 1 to 100. The default value is 1, which specifies the highest priority.
Authorization Type	Select the authorization type of the security group rule. You can select only **Address**.
Network Type	Select the network interface controller (NIC) type. ○ **Internal**: controls inbound and outbound traffic within Alibaba Cloud. ○ **External**: controls inbound and outbound traffic over the Internet.
Authorization Object	Select the CIDR blocks to be authorized by the security group rule. You can specify up to 10 CIDR blocks at a time.

Parameter	Description
Description	The description of the security group rule. The description must be 2 to 256 characters in length, and cannot start with `http://` or `https://`. You can leave this parameter empty.

19.8.2.4. Delete an SSL server

This topic describes how to delete an SSL server.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > SSL Servers**.
3. In the top navigation bar, select the region where you want to delete the SSL server.
4. On the **SSL Servers** page, find the SSL server that you want to delete, and click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

19.8.3. Manage an SSL client certificate

19.8.3.1. Create an SSL client certificate

After you create an SSL server, you must create an SSL client certificate based on the configuration of the SSL server.

Prerequisites

An SSL server is created. For more information, see Create an SSL server.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > SSL Clients**.
3. Select the region where the SSL client is deployed.
4. On the **SSL Clients** page, click **Create Client Certificate**.
5. On the **Create SSL Client Certificate** page, configure the client certificate based on the following information, and then click **Submit**.

Parameter	Description
Organization	Select the organization to which the SSL client belongs.
Resource Set	Select the resource set to which the SSL client belongs.
Region:	Select the region where the SSL client is deployed.
Zone	Select the zone where the SSL client is deployed.

Parameter	Description
Name	Enter a name for the SSL client certificate. The name must be 2 to 128 characters in length, and can contain digits, hyphens (-), and underscores (_). It must start with a letter and cannot start with `http://` or `https://`.
VPN Gateway	Select the VPN gateway that you want to associate with the SSL client certificate.
SSL Server	Select the SSL server that you want to associate with the SSL client certificate.

19.8.3.2. Download an SSL client certificate

This topic describes how to download an SSL client certificate. Before you use an SSL client to initiate an SSL-VPN connection, you must import the SSL client certificate to the SSL client.

Prerequisites

An SSL client certificate is created. For information, see Create an SSL client certificate.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > SSL Clients**.
3. Select the region where the SSL client is deployed.
4. On the **SSL Clients** page, find the target SSL client certificate, and then click **Download** in the **Actions** column.

19.8.3.3. Delete an SSL client certificate

This topic describes how to delete an SSL client certificate.

Procedure

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > SSL Clients**.
3. Select the region where the SSL client is deployed.
4. On the **SSL Clients** page, find the SSL client certificate that you want to delete, and click **Delete** in the **Actions** column.
5. In the message that appears, click **OK**.

19.8.4. Query SSL-VPN connection logs

This topic describes how to query the logs of an SSL server and an SSL client. To troubleshoot the issues in an SSL-VPN connection, you can query the logs of the SSL server and the SSL client to which the connection is established.

Context

You can query logs that are created within the most recent month. The time range that you can specify for a query cannot exceed 10 minutes.

Query the logs of an SSL server.

1. Log on to the VPN Gateway console.

2. In the left-side navigation pane, choose **VPN > SSL Servers**.
3. In the top navigation bar, select the region where you want to create the SSL server.
4. On the **SSL Servers** page, find the SSL server that you want to manage and click **View Logs** in the **Actions** column.
5. On the **SSL VPN Connection Logs** page, specify a time range. The system queries logs that are created during the specified time period.

Query the logs of an SSL client

1. Log on to the VPN Gateway console.
2. In the left-side navigation pane, choose **VPN > SSL Clients**.
3. Select the region where the SSL client is deployed.
4. On the **SSL Clients** page, find the SSL client certificate that you want to manage and click **View Logs** in the **Actions** column.
5. On the **SSL-VPN Client Logs** page, specify a time range. The system queries logs that are created during the specified time period.

20.Elastic IP Address

20.1. What is Elastic IP Address?

This topic provides an overview of Elastic IP Address. An elastic IP address (EIP) is a public IP address that you can purchase and use as an independent resource. You can associate an EIP with an Elastic Compute Service (ECS) instance, an internal-facing Server Load Balancer (SLB) instance, or a secondary elastic network interface (ENI) deployed in a virtual private cloud (VPC). You can also associate an EIP with a NAT gateway, or a high-availability virtual IP address (HAVIP).

An EIP is a NAT IP address provisioned in the Internet-facing gateway of Alibaba Cloud and is mapped to the associated cloud resource by using NAT. After an EIP is associated with a cloud resource, the cloud resource can use the EIP to communicate with the Internet.

Differences between an EIP and the static public IP address of an ECS instance

The following table describes the differences between an EIP and the static public IP address of an ECS instance.

Item	EIP	Static public IP address
Supported network	VPC	VPC
Used as an independent resource	Supported	Not supported
Associated with and disassociated from an ECS instance at any time	Supported	Not supported
Displayed in the ENI information of the operating system of the associated ECS instance	Not displayed.	Not displayed

Benefits

EIPs have the following benefits:

- Purchase and use as independent resources

  You can purchase and use an EIP as an independent resource. EIPs are not bundled with other computing or storage resources.

- Associate with resources at any time

  You can associate an EIP with a cloud resource as needed. You can also disassociate and release the EIP at any time.

- Modify bandwidth limits on demand

  You can modify the bandwidth limit of an EIP at any time to meet your business requirements. The modification immediately takes effect.

20.2. Log on to the EIP console

This topic describes how to log on to the Apsara Uni-manager Management Console to manage your elastic IP addresses (EIPs). The Google Chrome browser is used as an example.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.

- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top menu bar, choose **Products > Networking > Elastic IP Address**.

20.3. Quick start

20.3.1. Tutorial overview

This topic provides an overview of the tutorial that guides you in creating an EIP and associating an EIP with an ECS instance to allow the ECS instance to access the Internet.

This tutorial walks you through the following tasks:

1. Apply for new EIPs

   An EIP is a public IP address that you can purchase and hold as an independent resource. To get started, you must create an EIP.

2. Associate an EIP with an ECS instance

   You can associate an EIP with an ECS instance deployed in a VPC to enable the ECS instance to connect to the Internet.

3. Disassociate an EIP from a cloud resource

   You can disassociate an ECS instance from an EIP when the ECS instance no longer requires access to the Internet.

4. Release an EIP

   You can release an EIP if it is no longer needed.

20.3.2. Apply for EIPs

This topic describes how to apply for elastic IP addresses (EIPs). An EIP is a public IP address that you can purchase and hold as an independent resource.

Procedure

1. Log on to the EIP console.
2. On the **Elastic IP Addresses** page, click **Create EIP**.
3. On the **Create Elastic IP Address** page, set the following parameters and click **Submit**.

Parameter	Description
Organization	Select the organization to which the EIP belongs.
Resource Set	Select the resource set to which the EIP belongs.
Region	Select the region where you want to create the EIP. Make sure that the EIP and the cloud resources to be associated with the EIP are deployed in the same region.
Quantity	Enter the number of EIPs that you want to create.
EIP Name	Enter the name of the EIP that you want to create.
Connection Type	Select a line type for the EIP.
Network Type	Select a network type for the EIP. Valid values: ○ **Internet**: The EIP is used for communication over the Internet. ○ **Hybrid Cloud**: The EIP is used for communication within a hybrid cloud. If you want to allow a data center to access the Internet by using SNAT and DNAT, you must select this type.
IP Address	Enter the EIP that you want to request. Make sure that you enter an idle IPv4 address. Otherwise, you cannot request the specified EIP. **Note** If you do not specify an EIP, the system automatically assigns one.
Maximum Bandwidth	Specify the maximum bandwidth value for the EIP. Unit: Mbit/s.

20.3.3. Associate an EIP with an ECS instance

This topic describes how to associate an elastic IP address (EIP) with an Elastic Compute Service (ECS) instance that is deployed in a virtual private cloud (VPC). ECS instances can communicate with the Internet after they are associated with EIPs.

Prerequisites

An ECS instance is created. For more information, see the **Create an instance** topic in the **Quick start** chapter of *Elastic Compute Service User Guide*.

Procedure

1. Log on to the EIP console.
2. In the top navigation bar, select the region where the EIP is deployed.
3. On the **Elastic IP Addresses** page, find the EIP that you want to manage and click **Bind Resource** in the **Actions** column.
4. In the **Bind Elastic IP Address to Resources** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select **ECS Instance**.

Parameter	Description
Binding mode	Select the mode in which you want to associate the EIP. You can select only Normal. In NAT Mode: ○ The EIP is associated with the ECS instance in NAT mode. Both the private IP address and public IP address of the ECS instance are available. ○ The EIP is not displayed in the operating system. To query the public IP address of the ECS instance, call the DescribeInstances operation. ○ The EIP does not support NAT application layer gateway (ALG) protocols such as H.323, Session Initiation Protocol (SIP), Domain Name System (DNS), Real-Time Streaming Protocol (RTSP), and Trivial File Transfer Protocol (TFTP).
Select an instance to bind	Select the ECS instance to be associated with the EIP. Make sure that the following requirements are met: ○ The ECS instance is deployed in a VPC. ○ The ECS instance is in the Running or Stopped state. ○ Each ECS instance can be associated with only one EIP. ○ The ECS instance and the EIP reside in the same region. ○ The ECS instance is not assigned a static public IP address. In addition, the ECS instance is not associated with another EIP.

20.3.4. Disassociate an EIP from a cloud resource

This topic describes how to disassociate an elastic IP address (EIP) from a cloud resource. After an EIP is disassociated from a cloud resource, the cloud resource can no longer communicate with the Internet by using the EIP.

Procedure

1. Log on to the EIP console.
2. In the top navigation bar, select the region where the EIP is deployed.
3. On the **Elastic IP Addresses** page, find the EIP that you want to manage and click **Unbind** in the **Actions** column.
4. In the message that appears, click **OK**.

20.3.5. Release an EIP

This topic describes how to release an elastic IP address (EIP) that you no longer need.

Prerequisites

The EIP is not associated with a cloud resource. For more information, see Disassociate an EIP from a cloud resource.

Procedure

1. Log on to the EIP console.
2. In the top navigation bar, select the region where the EIP is deployed.
3. On the **Elastic IP Addresses** page, find the EIP that you want to manage and choose > **Release** in the **Actions** column.
4. In the **Release EIP** dialog box, click **OK**.

20.4. Manage EIPs

20.4.1. Apply for EIPs

This topic describes how to apply for elastic IP addresses (EIPs). An EIP is a public IP address that you can purchase and hold as an independent resource.

Procedure

1. Log on to the EIP console.
2. On the **Elastic IP Addresses** page, click **Create EIP**.
3. On the **Create Elastic IP Address** page, set the following parameters and click **Submit**.

Parameter	Description
Organization	Select the organization to which the EIP belongs.
Resource Set	Select the resource set to which the EIP belongs.
Region	Select the region where you want to create the EIP. Make sure that the EIP and the cloud resources to be associated with the EIP are deployed in the same region.
Quantity	Enter the number of EIPs that you want to create.
EIP Name	Enter the name of the EIP that you want to create.
Connection Type	Select a line type for the EIP.
Network Type	Select a network type for the EIP. Valid values: ○ **Internet**: The EIP is used for communication over the Internet. ○ **Hybrid Cloud**: The EIP is used for communication within a hybrid cloud. If you want to allow a data center to access the Internet by using SNAT and DNAT, you must select this type.
IP Address	Enter the EIP that you want to request. Make sure that you enter an idle IPv4 address. Otherwise, you cannot request the specified EIP. **Note** If you do not specify an EIP, the system automatically assigns one.
Maximum Bandwidth	Specify the maximum bandwidth value for the EIP. Unit: Mbit/s.

20.4.2. Bind an EIP to a cloud instance

20.4.2.1. Associate an EIP with an ECS instance

This topic describes how to associate an elastic IP address (EIP) with an Elastic Compute Service (ECS) instance that is deployed in a virtual private cloud (VPC). ECS instances can communicate with the Internet after they are associated with EIPs.

Prerequisites

An ECS instance is created. For more information, see the **Create an instance** topic in the **Quick start** chapter of *Elastic Compute Service User Guide*.

Procedure

1. Log on to the EIP console.
2. In the top navigation bar, select the region where the EIP is deployed.
3. On the **Elastic IP Addresses** page, find the EIP that you want to manage and click **Bind Resource** in the **Actions** column.
4. In the **Bind Elastic IP Address to Resources** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select **ECS Instance**.
Binding mode	Select the mode in which you want to associate the EIP. You can select only Normal. In NAT Mode: ○ The EIP is associated with the ECS instance in NAT mode. Both the private IP address and public IP address of the ECS instance are available. ○ The EIP is not displayed in the operating system. To query the public IP address of the ECS instance, call the DescribeInstances operation. ○ The EIP does not support NAT application layer gateway (ALG) protocols such as H.323, Session Initiation Protocol (SIP), Domain Name System (DNS), Real-Time Streaming Protocol (RTSP), and Trivial File Transfer Protocol (TFTP).
Select an instance to bind	Select the ECS instance to be associated with the EIP. Make sure that the following requirements are met: ○ The ECS instance is deployed in a VPC. ○ The ECS instance is in the Running or Stopped state. ○ Each ECS instance can be associated with only one EIP. ○ The ECS instance and the EIP reside in the same region. ○ The ECS instance is not assigned a static public IP address. In addition, the ECS instance is not associated with another EIP.

20.4.2.2. Associate an EIP with an SLB instance

This topic describes how to associate an elastic IP address (EIP) with a Server Load Balancer (SLB) instance. After you associate an EIP with an SLB instance, the SLB instance can forward requests from the Internet.

Prerequisites

An SLB instance is created. For more information, see the **Create an SLB instance** topic in the **Quick start** chapter of *Server Load Balancer User Guide*.

Procedure

1. Log on to the EIP console.
2. In the top navigation bar, select the region where the EIP is deployed.
3. On the **Elastic IP Addresses** page, find the EIP that you want to manage and click **Bind Resource** in the **Actions** column.

4. In the **Bind Elastic IP Address to Resources** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select **SLB Instance**.
Select an instance to bind	Select the SLB instance to be associated with the EIP. Make sure that the following requirements are met: ○ The SLB instance is deployed in a virtual private cloud (VPC). ○ The SLB instance and the EIP reside in the same region. ○ Each SLB instance can be associated with only one EIP. **Note** If you associate the EIP with an internal-facing SLB instance and the SLB instance has traffic of private network workloads, transient connections may occur. We recommend that you perform the association during off-peak hours or switch the workloads to another SLB instance.

20.4.2.3. Associate an EIP with a NAT gateway

This topic describes how to associate an elastic IP address (EIP) with a NAT gateway. After you associate an EIP with a NAT gateway, you can create DNAT and SNAT entries for the EIP.

Prerequisites

A NAT gateway is created. For more information, see the **Create a NAT gateway** topic in the **Quick start** chapter of *NAT Gateway User Guide*.

Procedure

1. Log on to the EIP console.
2. In the top navigation bar, select the region where the EIP is deployed.
3. On the **Elastic IP Addresses** page, find the EIP that you want to manage and click **Bind Resource** in the **Actions** column.
4. In the **Bind Elastic IP Address to Resources** dialog box, set the following parameters and click **OK**.

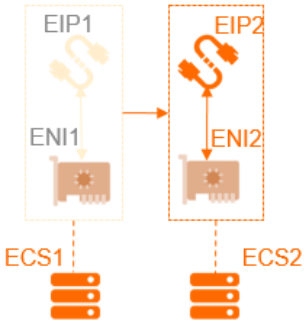
Parameter	Description
Instance Type	Select **NAT Gateway**.
Select an instance to bind	Select the NAT gateway to be associated with the EIP. Make sure that the following requirements are met: ○ The NAT gateway and the EIP reside in the same region. ○ Each NAT gateway can be associated with at most 20 EIPs, among which at most 10 pay-by-data-transfer EIPs can be associated.

20.4.2.4. Bind an EIP to a secondary ENI

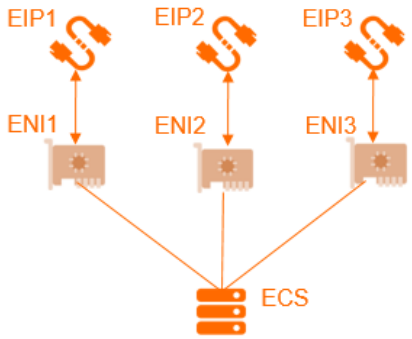
20.4.2.4.1. Overview

You can associate elastic IP addresses (EIPs) with elastic network interfaces (ENIs). Then, you can associate the ENIs with an Elastic Compute Service (ECS) instance. This way, the ECS instance can use multiple EIPs. You can use EIPs to improve the service availability, flexibility, and scalability.

Each ENI is assigned a private IP address. After you associate an EIP with an ENI, both the private IP address and the EIP are available for the ENI. You can change the private IP address and public IP address of an ECS instance by replacing the secondary ENI that is associated with the ECS instance. When you replace the secondary ENI of an ECS instance, the reliability and availability of your service are not affected.



You can associate multiple ENIs with an ECS instance. Make sure that an EIP is associated with each ENI. This way, the ECS instance can use multiple EIPs. The ECS instance can use the EIPs to provide Internet-facing services. You can configure security group rules for the ECS instance to control access from the Internet.



Association modes

You can associate an EIP with an ENI in NAT mode.

The following table describes the features in NAT mode.

Item	NAT mode
Whether the EIP is displayed in the ENI information of the operating system	No
Types of ENIs that can be associated with EIPs	Primary and secondary ENIs
Number of EIPs that can be associated with a primary ENI	1
Number of EIPs that can be associated with a secondary ENI	Depends on the number of private IP addresses of the secondary ENI **Note** Each EIP is mapped to a private IP address of a secondary ENI. If a secondary ENI is assigned 10 private IP addresses, at most 10 EIPs can be associated with the secondary ENI.
Whether the private network features of a secondary ENI are available after an EIP is associated with the secondary ENI	Yes

Item	NAT mode
Supported protocols	EIPs deployed as NAT application layer gateways (ALGs) do not support protocols such as H.323, Session Initiation Protocol (SIP), Domain Name System (DNS), and Real-Time Streaming Protocol (RTSP).

20.4.2.4.2. Associate an EIP with a secondary ENI in NAT mode

This topic describes how to associate an elastic IP address (EIP) with a secondary elastic network interface (ENI) in NAT mode. After you associate an EIP with a secondary ENI, both the private IP address and public IP address that are assigned to the secondary ENI are available. In this case, the EIP is not displayed in the secondary ENI information.

Prerequisites

Before you associate an EIP with a secondary ENI in NAT mode, make sure that the following requirements are met:

- A secondary ENI that is deployed in a virtual private cloud (VPC) is created. The secondary ENI and the EIP reside in the same region. For more information, see the **Create an ENI** topic in the **Elastic network interfaces** chapter of *Elastic Compute Service User Guide*.
- The secondary ENI is not associated with an Elastic Compute Service (ECS) instance. If the secondary ENI is associated with an ECS instance, disassociate the secondary ENI from the ECS instance first. Then, associate the EIP with the secondary ENI in NAT mode and associate the secondary ENI with the ECS instance. For more information, see the **Unbind a secondary ENI from an instance** topic in the **Elastic network interfaces** chapter of *Elastic Compute Service User Guide*.

Procedure

1. Log on to the EIP console.
2. In the top navigation bar, select the region where the EIP is deployed.
3. On the **Elastic IP Addresses** page, find the EIP that you want to manage and click **Bind Resource** in the **Actions** column.
4. In the **Bind Elastic IP Address to Resources** dialog box, set the following parameters and click **OK**.

Parameter	Description
Instance Type	Select **Secondary ENI**.
Binding mode	Select **Normal**. In NAT Mode: ○ The number of EIPs that can be associated with a secondary ENI is based on the number of private IP addresses that are assigned to the secondary ENI. ○ When an EIP is associated with a secondary ENI in NAT mode, both the private IP address and public IP address that are assigned to the secondary ENI are available. ○ The EIP is not displayed in the operating system. To query the EIP, call the DescribeEipAddresses operation. ○ The EIP does not support NAT application layer gateway (ALG) protocols such as H.323, Session Initiation Protocol (SIP), Domain Name System (DNS), Real-Time Streaming Protocol (RTSP), and Trivial File Transfer Protocol (TFTP).

Parameter	Description
Select an instance to bind	Select the secondary ENI to be associated with the EIP. Make sure that the following requirements are met: ○ The secondary ENI is deployed in a VPC. ○ The secondary ENI and the EIP reside in the same region.

20.4.3. Resize the maximum bandwidth

This topic describes how to resize the maximum bandwidth for elastic IP addresses (EIPs). After you change the maximum bandwidth value for an EIP, the new value immediately takes effect.

Procedure

1. Log on to the EIP console.
2. In the top navigation bar, select the region where the EIP is deployed.
3. On the **Elastic IP Addresses** page, find the EIP that you want to manage and choose > **Modify Configuration** in the **Actions** column.
4. On the **Change Specifications** page, specify a new bandwidth value and click **Submit**.

20.4.4. Disassociate an EIP from a cloud resource

This topic describes how to disassociate an elastic IP address (EIP) from a cloud resource. After an EIP is disassociated from a cloud resource, the cloud resource can no longer communicate with the Internet by using the EIP.

Procedure

1. Log on to the EIP console.
2. In the top navigation bar, select the region where the EIP is deployed.
3. On the **Elastic IP Addresses** page, find the EIP that you want to manage and click **Unbind** in the **Actions** column.
4. In the message that appears, click **OK**.

20.4.5. Release an EIP

This topic describes how to release an elastic IP address (EIP) that you no longer need.

Prerequisites

The EIP is not associated with a cloud resource. For more information, see Disassociate an EIP from a cloud resource.

Procedure

1. Log on to the EIP console.
2. In the top navigation bar, select the region where the EIP is deployed.
3. On the **Elastic IP Addresses** page, find the EIP that you want to manage and choose > **Release** in the **Actions** column.
4. In the **Release EIP** dialog box, click **OK**.

21.Apsara Stack Security

21.1. What is Apsara Stack Security

Apsara Stack Security is a solution that protects Apsara Stack assets with a full suite of security features, such as network, server, application, data, and security management.

Background information

Traditional security solutions for IT services detect attacks on network perimeters. These solutions use hardware products such as firewalls and intrusion prevention systems (IPSs) to protect networks against attacks.

With the development of cloud computing, an increasing number of enterprises and organizations use cloud computing services instead of traditional IT services. Cloud computing features low costs, on-demand flexible configuration, and high resource utilization. Cloud computing environments do not have definite network perimeters. As a result, traditional security solutions cannot effectively safeguard cloud assets.

With the powerful data analysis capabilities and professional security operations team of Alibaba Cloud, Apsara Stack Security provides integrated security protection services for networks, applications, and servers.

Complete security solution

Apsara Stack Security consists of Apsara Stack Security Standard Edition and optional security services to provide a comprehensive security solution.

Security domain	Service name	Description
Security management	Threat Detection Service (TDS)	Monitors traffic and overall security status to audit and centrally manage assets.
Server security	Server Guard	Protects Elastic Compute Service (ECS) instances against intrusions and malicious code.
	Server Security	Protects physical servers against intrusions.
Application security	Web Application Firewall (WAF)	Protects web applications against attacks and ensures that mobile and PC users can securely access web applications over the Internet.
Network security	Anti-DDoS	Ensures the availability of network links and improves business continuity.
	Cloud Firewall	Allows you to centrally manage access control policies for traffic transferred within your business system (east-west) and between the Internet and your business system (north-south).
Data security	Sensitive Data Discovery and Protection (SDDP)	Prevents data leaks and helps your business system meet compliance requirements.
Security O&M service	On-premises security service	Helps you establish and optimize the cloud security system to protect your business system against attacks by using security features of Apsara Stack Security and other Apsara Stack services.

21.2. Usage notes

Before you log on to Apsara Stack Security Center, you must verify that your computer meets the configuration requirements.

For more information about the configuration requirements, see Configuration requirements.

Configuration requirements

Item	Requirement
Browser	• Internet Explorer: V11 or later • Google Chrome (recommended): V42.0.0 or later • Mozilla Firefox: V30 or later • Safari: V9.0.2 or later • GmSSL browser that runs the Chrome kernel: V69.0.0 or later
Operating system	• Windows XP • Windows 7 or later • macOS

21.3. Quick start

21.3.1. User roles and permissions

This topic describes the user roles involved in Apsara Stack Security.

All roles in Apsara Stack Security Center are provided by default. You cannot add custom roles. Before you log on to Apsara Stack Security Center, make sure that your account is assigned the required role. For more information, see Default roles in Apsara Stack Security.

Default roles in Apsara Stack Security

Role	Permission
System administrator of Apsara Stack Security Center	Manages and configures system settings for Apsara Stack Security Center. The system administrator has permissions to manage Apsara Stack accounts, synchronize data, configure alerts, and configure global settings.
Security administrator of Apsara Stack Security Center	Monitors the security status across Apsara Stack and configures security policies for each functional module of Apsara Stack Security. The security administrator has permissions on all features under Threat Detection, Network Security, Application Security, Server Security, Physical Server Security, and Asset Management. **Note** The permissions on Web Application Firewall (WAF) and Cloud Firewall must be separately assigned.
Department security administrator	Monitors the security status of cloud resources in a specific department and configures security policies for each functional module of Apsara Stack Security for this department. The department security administrator has permissions on all features under Threat Detection, Network Security, Application Security, Server Security, Physical Server Security, and Asset Management. In addition, the department security administrator can specify alert notification methods and alert contacts in the department. **Note** The permissions on WAF and Cloud Firewall must be separately assigned.
Auditor of Apsara Stack Security Center	Conducts security audits across Apsara Stack. The auditor can view audit events and raw logs, configure audit policies, and access all features under Security Audit.

If you do not have an account that assumes the required role, contact the administrator to create an account and assign the role to the account. For more information, see the **Create a user** topic in *Apsara Uni-manager Management Console User Guide*.

21.3.2. Log on to Apsara Stack Security Center

This topic describes how to log on to Apsara Stack Security Center.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, choose **Security > Apsara Stack Security**.
5. On the **Apsara Stack Security Center** page, select **Region**.
6. Click **YD** to go to Apsara Stack Security Center.

21.4. Threat Detection Service

21.4.1. Overview

This topic introduces the basic concepts related to Threat Detection Service (TDS).

TDS provides comprehensive protection for enterprises. It can monitor vulnerabilities, intrusions, web attacks, DDoS attacks, threat intelligence, and public opinions. TDS uses modeling and analysis to obtain key information based on traffic characteristics, host behavior, and host operation logs. In addition, TDS identifies intrusions that cannot be detected by traffic inspection or file scan. You can use the input of cloud analysis models and intelligence data to discover sources and behavior of attacks and assess threats.

TDS provides the following features:

- Overview: provides a security situation overview and information about security screens.
- Security Alerts: displays security alerts that occur in your business system.
- Attack Analysis: displays application attacks and brute-force attacks that occur in your system.
- Cloud Service Check: checks whether risks exist in the configurations of Apsara Stack services.
- Application Whitelist: allows you to create and apply application whitelist policies to your servers that require

special protection. After you create the policies, Apsara Stack Security identifies trusted, suspicious, and malicious programs based on intelligent learning. This prevents unauthorized programs from running.

- Assets: manages servers and cloud services on Apsara Stack.
- Security Reports: allows you to configure security report tasks on Apsara Stack.

21.4.2. Security overview

21.4.2.1. View security overview information

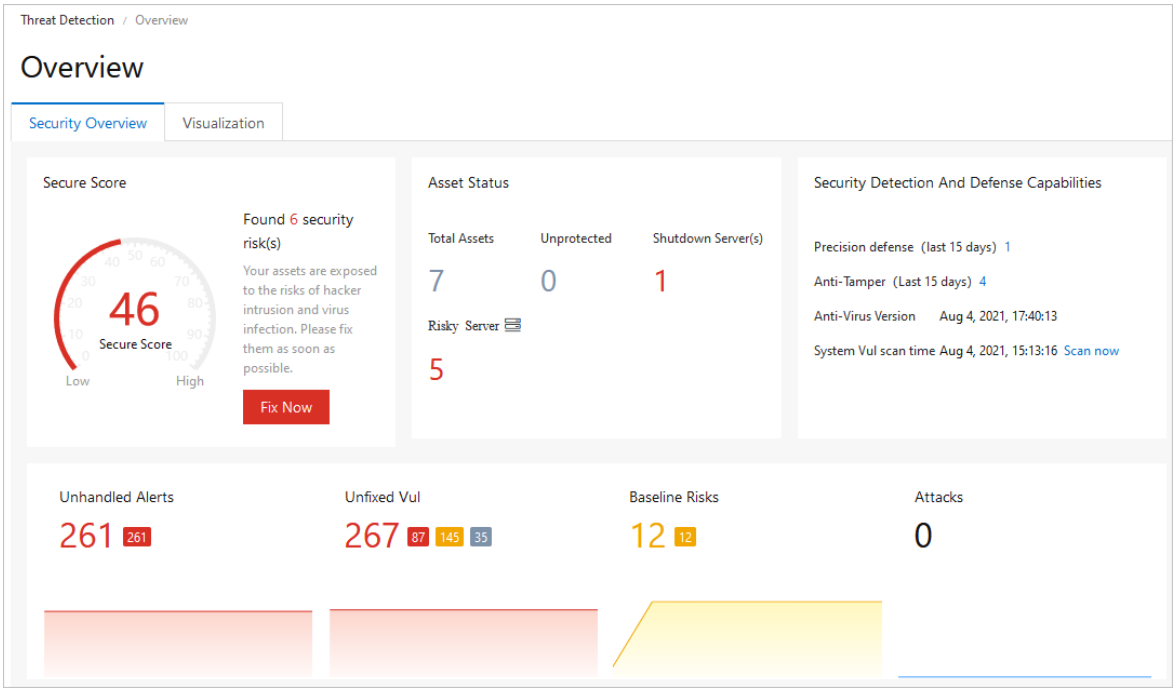
This topic describes how to view security statistics, attack trends, and network traffic information on the Apsara Stack platform.

Context

The **Security Overview** tab provides an overview of detected security events, the latest threats, and inherent vulnerabilities of the system. A security administrator can view information on the **Security Overview** tab to better understand the security posture of the system.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Overview**. On the page that appears, click the **Security Overview** tab.
3. View the security posture of the Apsara Stack platform.



Sections on the Security Overview tab

Section	Description
Secure Score	The security score of assets and the number of detected security risks.
Asset Status	The total number of assets and the numbers of servers that are not protected, servers that are stopped, and servers that are at risk.

Section	Description
Security Detection And Defense Capabilities	The numbers of precise defense events and anti-tampering events over the last 15 days, the time when the antivirus database was last updated, and the time when vulnerability scanning was last performed. This allows you to obtain the defense situation and security status of your assets in real time.
Threat statistics	The numbers of alerts that are not handled, vulnerabilities that are not fixed, baseline risks, and attacks.
Config Assessment Risks	Risks in the baseline configurations of cloud services.
Issue Resolved	Statistics on alerts, vulnerabilities, and baseline risks that have been processed over the last 15 days. The statistics are displayed in a bar and trend chart.

21.4.3. Security alerts

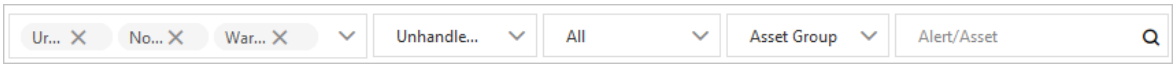
21.4.3.1. View security alerts

This topic describes how to view security alerts on the Security Alerts page.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Security Alerts**.
3. (Optional)Set filter conditions for security alerts.

   Note If you want to view all alerts, do not set the conditions.

Filter condition	Description
Severity	The severity level. You can select one or more levels. Valid values: ○ Urgent ○ Warning ○ Notice
Alert status	The status of alerts. Valid values: ○ Unhandled Alerts ○ Handled
Alert type	The type of alerts. Select **All** or a specific type.
Affected asset group	The affected asset group. Select **Asset Group** or a specific group.
Search for alerts by name or asset	Enter an alert name or a keyword of affected assets to search for alerts.

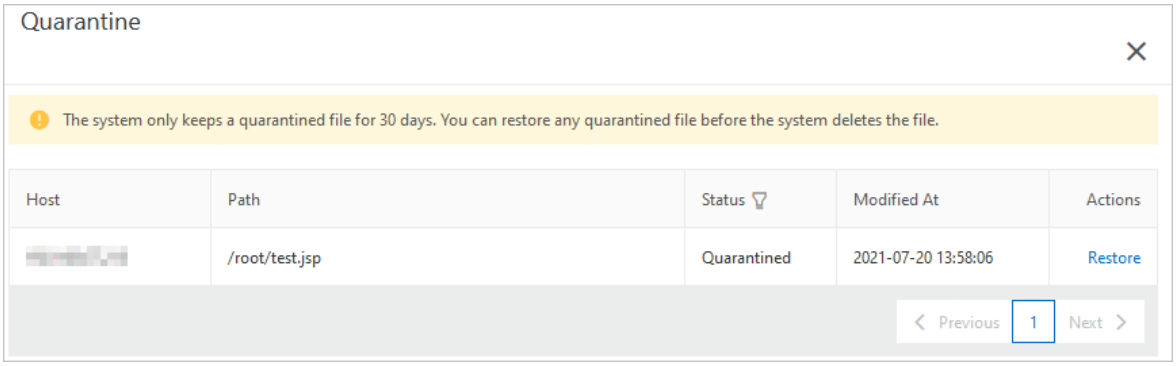
4. View security alerts and their details in the list.

21.4.3.2. Manage quarantined files

This topic describes how to manage threat files that are quarantined by the system. The system deletes a quarantined file 30 days after the file is quarantined. You can restore the file before it is deleted.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Security Alerts**.
3. In the upper-right corner of the **Alerts** page, click **Quarantine**.
4. In the **Quarantine** panel, view the information about a quarantined file, such as the IP address of the host, path, status, and operation time.



5. (Optional)If a file is incorrectly quarantined, click **Restore** in the **Actions** column to restore the file.

> **Notice** Before you restore a quarantined file, make sure that the file is normal and does not bring risks.

The restored file is removed from the Quarantine panel and is displayed in the security alert list again.

21.4.3.3. Configure security alerts

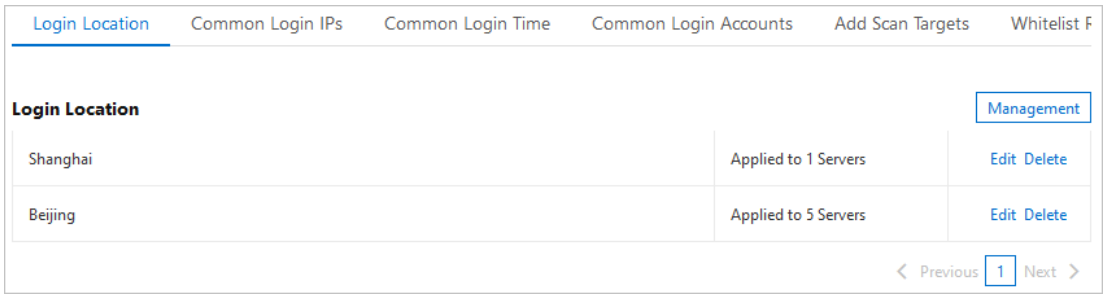
This topic describes how to configure logon settings and web directories that are scanned.

Procedure

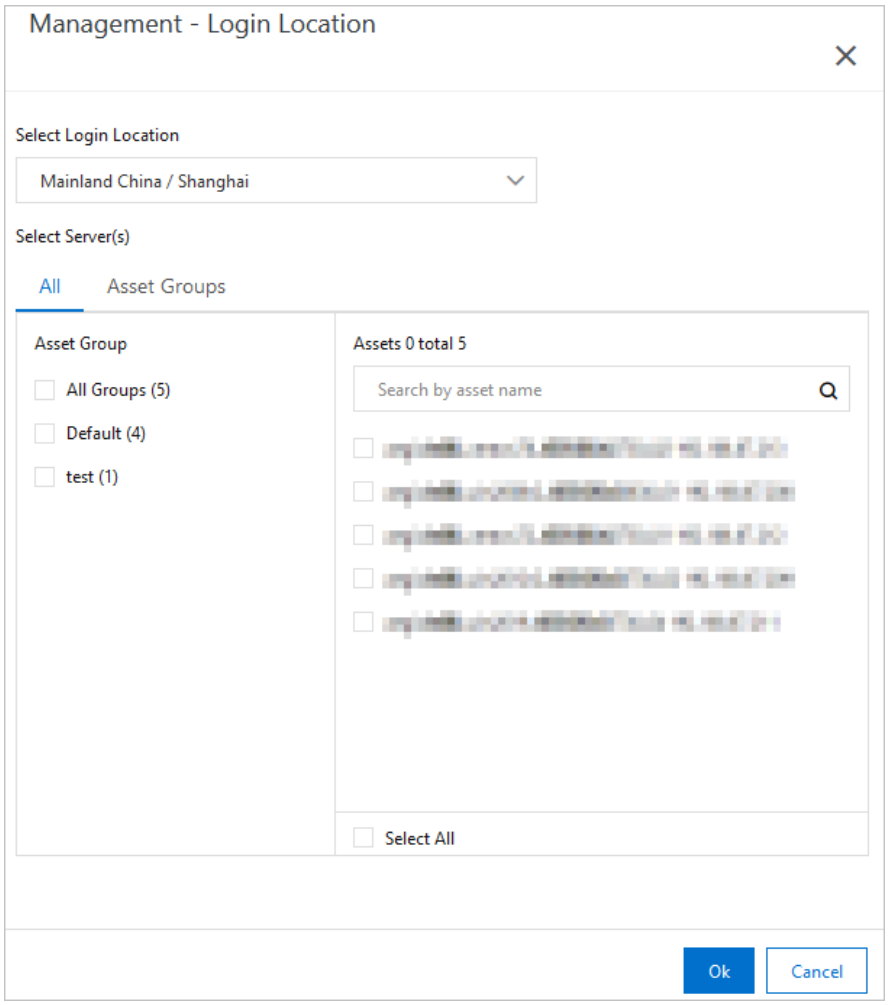
1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Security Alerts**.
3. In the upper-right corner of the page that appears, click **Settings**.

   You can perform the following operations:

   - **Add an approved logon location**
     a. In the **Login Location** section, click **Management** on the right.



b. Select the logon location that you want to add, and select the servers that allow logons from the added location.



c. Click **Ok**.

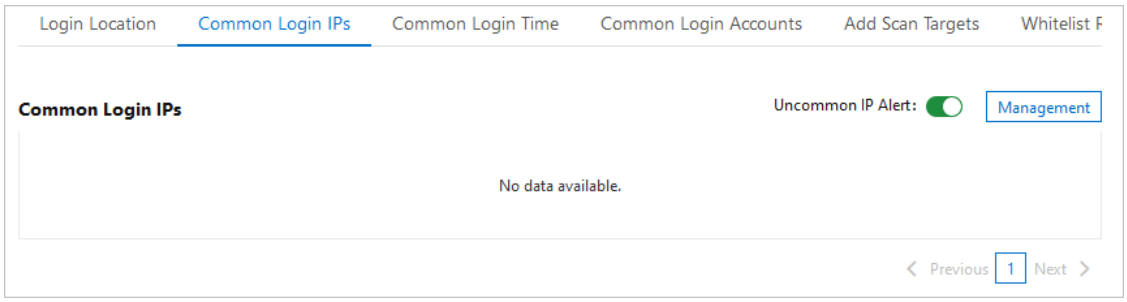
Threat Detection Service (TDS) allows you to edit and delete added logon locations.

- Find the required logon location and click **Edit** on the right to change the servers that are allowed to be logged on to from this location.
- Find the required logon location and click **Delete** on the right to delete the logon location.

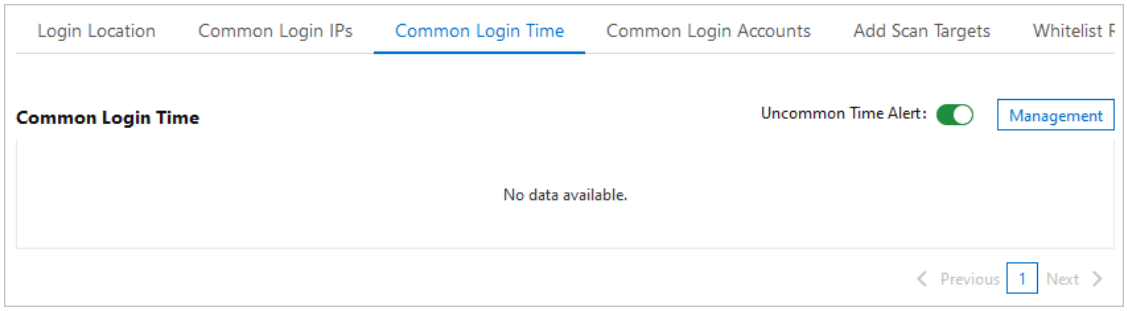
- **Configure advanced logon settings**

> **Note** You can specify the IP addresses, accounts, and time periods that are allowed to log on to your assets. After you configure these settings, alerts are triggered if your assets receive logon requests that do not meet the requirements. The procedure to configure advanced logon settings is similar to that to configure **common logon locations**. You can follow the preceding procedure to **add**, **edit**, and **delete** advanced logon settings.

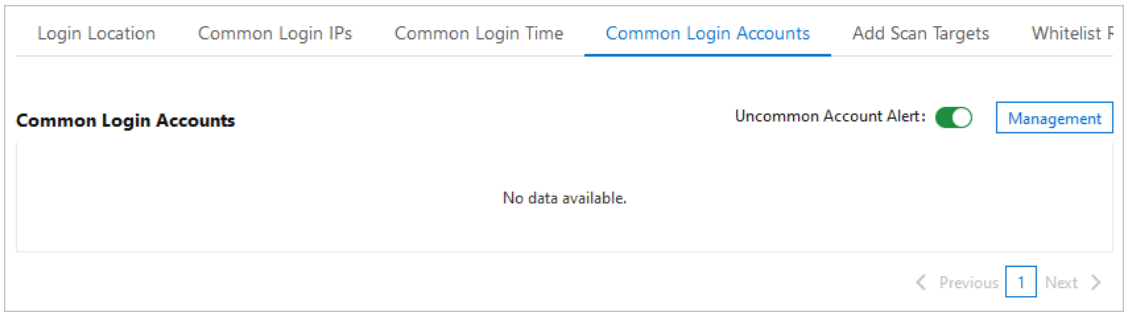
- On the right of **Common Login IPs**, turn on or off Uncommon IP Alert. After the switch is turned on, alerts are triggered if your assets receive logon requests from unapproved IP addresses.



- On the right of **Common Login Time**, turn on or off Uncommon Time Alert. After the switch is turned on, alerts are triggered if your assets receive logon requests at an unapproved time.



- On the right of **Common Login Accounts**, turn on or off Uncommon Account Alert. After the switch is turned on, alerts are triggered if your assets receive logon requests from unapproved accounts.



- Add Scan Targets

  Apsara Stack Security automatically scans web directories of data assets in your servers and runs dynamic and static scan tasks. You can also manually add other web directories of your servers.

  a. On the right of **Add Scan Targets**, click **Add**.

b. Enter a valid web directory and select the servers on which the directory is scanned. The web directory is added to the scan list.

> **Note** Root directories are not allowed. This ensures performance and efficiency.

c. Click **Ok**.

21.4.4. Attack analysis

This topic describes the statistics provided by the attack analysis feature. The statistics include the total number of attacks, distribution of attack types, top five attack sources, top five attacked assets, and an attack list.

Background information

The attack analysis feature provides basic attack detection and prevention capabilities in Apsara Stack Security Center. We recommend that you optimize firewalls and enhance business security to develop a more fine-grained and in-depth defense system.

On the **Attack Awareness** page, you can specify a time range to view these attack details. You can view the attack analysis statistics of the current day, last 7 days, or last 15 days. You can also set Time Range to **Custom** to view the statistics of a time range within the last 30 days.

- **Attacks**: the total number of attacks detected in your assets within a specific time range.
- **Attack Type Distribution**: the attack types and the number of attacks for each type.
- **Top 5 Attack Sources**: the top five IP addresses from which the most attacks are launched.
- **Top 5 Attack Assets**: the top five assets that are attacked the most frequently.
- **Attack list**: the details about each attack. The details include the attack time, source IP address, attacked asset, attack type, and total number of attacks.

> **Note** The attack list displays a maximum of 10,000 attacks. You can specify **Time Range** to view details about the attacks that occur over the specified time range.

Parameters in the attack list

Parameter	Description
Attacked At	The time at which an attack occurs.
Attack Source	The source IP address of an attack.
Attacked Asset	The name, public IP address, and private IP address of an attacked asset.
Attacks	The total number of attacks.
Attack Type	The type of an attack. The types of attacks that can be detected include SSH brute-force attacks and remote code execution attacks.

- Search for an attack.

  To view the details about a specific attack, specify search conditions in the search box above the attack list. Search conditions include the attack type, attacked asset, and source IP address.

- View the details of an attacked asset.

  To view the details about an attacked asset, move the pointer over the name of the attacked asset.

- Export the attack list.

To export and save the attack list to your computer, click the icon in the upper-left corner above the attack list. The attack list is exported to an Excel file.

21.4.5. Cloud service check

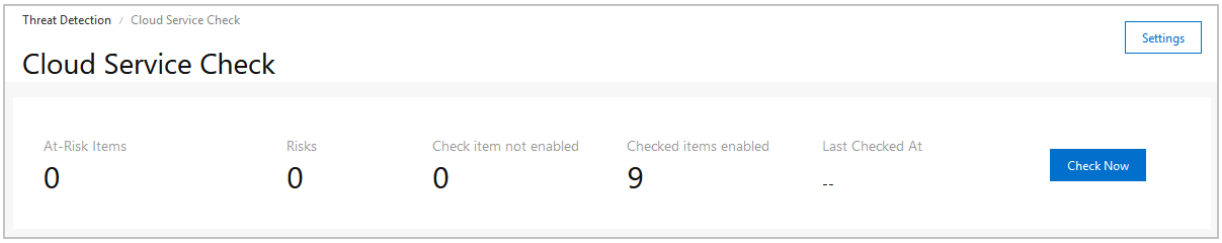
21.4.5.1. Overview

Threat Detection Service (TDS) provides the cloud service check feature. This feature allows you to check for the configuration risks of your Apsara Stack services. This topic describes the features and check items that are supported by the cloud service check feature.

Background information

The cloud service check feature allows you to perform network access control and data security checks. The checks help you detect configuration risks of your Apsara Stack services and provide repair solutions.

You can view the number of **Checked items enabled** on the **Cloud Service Check** page.



Cloud service check list

The following table describes the check items.

Type	Supported item	Description
	PolarDB - Backup configurations	Checks whether the automatic backup feature is enabled for PolarDB. Regular backups help you improve database security. You can restore data if an error occurs in your database. PolarDB supports automatic backup. We recommend that you enable automatic backup to create a backup on a daily basis.
	Container Registry - Repository permission configurations	Checks whether a Container Registry repository is set to private. Container Registry supports public and private repositories. Public repositories allow users to anonymously download images over the Internet. If images in a repository contain sensitive information, we recommend that you set the repository to private. If images in a repository do not contain sensitive information, ignore related alerts.
	OSS - Server-side encryption	Checks whether the data encryption feature is enabled for Object Storage Service (OSS) buckets. OSS supports server-side encryption to secure data that is persistently stored in OSS. We recommend that you enable server-side encryption to protect sensitive data.
	OSS - Sensitive information leakage scans	Checks whether access permissions on sensitive files in OSS buckets are required.

Type	Supported item	Description
Data security	ApsaraDB RDS - Cross-region backup configurations	Checks whether the cross-region backup feature is enabled for ApsaraDB RDS instances. ApsaraDB RDS for MySQL provides the cross-region backup feature that automatically synchronizes local backup files to OSS buckets in another region. This implements geo-disaster recovery. We recommend that you enable the cross-region backup feature.
	KVStore for Redis - Backup configurations	Checks whether the data backup feature is enabled for KVStore for Redis instances.
	ApsaraDB for MongoDB - SSL encryption	Checks whether SSL encryption is enabled for ApsaraDB for MongoDB databases. We recommend that you enable the SSL encryption feature to improve the security of data links in ApsaraDB for MongoDB databases.
	ApsaraDB for MongoDB - Backup configurations	Checks whether the automatic backup feature is enabled for ApsaraDB for MongoDB databases. Regular backups help you improve database security. You can restore data if an error occurs in your database. ApsaraDB for MongoDB provides automatic backup policies. We recommend that you enable automatic backup to create a backup on a daily basis.
	ECS - Disk encryption	Checks whether encryption is enabled for disks on Elastic Compute Service (ECS) instances.
	ECS - Automatic snapshot policies	Checks whether the automatic snapshot feature is enabled for the disks on ECS instances. The automatic snapshot feature improves the security of ECS instances and supports disaster recovery.
	OSS - Bucket permissions	Checks whether the OSS bucket ACL is set to *private*.
	OSS - Logging	Checks whether the logging feature is enabled for OSS.
	OSS - Cross-region replication	Checks whether the cross-region replication feature is enabled for OSS.
	ApsaraDB RDS - Database security policies	Checks whether the SQL audit, SSL encrypted transmission, and transparent database encryption features are enabled for ApsaraDB RDS databases.
	ApsaraDB RDS - Backup configurations	Checks whether the data backup feature is enabled for ApsaraDB RDS instances.
	SSL Certificates Service - Expiration check	Checks whether your SSL certificate expires. If your SSL certificate expires, you are not allowed to use SSL Certificates Service.
	ECS - Security group policies	Checks the security group policies of ECS. We recommend that you grant permissions to users based on the principle of least privilege. We also recommend that you specify 0.0.0.0/0 only for the ports that must be open to all services, such as port 80, 443, 22, or 3389.
	OSS - Bucket hotlink protection	Checks whether the hotlink protection feature is enabled for OSS buckets. The OSS hotlink protection feature checks the Referer header to deny access from unauthorized users. We recommend that you enable this feature.

Type	Supported item	Description
Network access control	VPC - DNAT rules	Checks whether a port is open to the Internet. When you create a DNAT rule for a NAT gateway that is deployed in a virtual private cloud (VPC), we recommend that you do not open internal management ports to the Internet. Do not open all ports or an important port, for example, ports 22, 3389, 1433, or 3306, to the Internet.
	Apsara Stack Security - Back-to-origin configuration for Anti-DDoS	Checks whether Anti-DDoS is configured to allow the requests from only Web Application Firewall (WAF) back-to-origin IP addresses. After you set up Anti-DDoS or WAF, you must hide the IP addresses of the backend servers to prevent attacks on the cloud assets.
	Apsara Stack Security - WAF back-to-origin configurations	Checks whether WAF allows requests from only WAF back-to-origin IP addresses. After you set up Anti-DDoS or WAF, you must hide the IP addresses of the backend servers to prevent attacks on the cloud assets.
	SLB - IP address whitelist configurations	Checks the access control configurations of Server Load Balancer (SLB) instances. Checks whether access control is enabled for HTTP and HTTPS services and checks whether 0.0.0.0/0 is added to the IP address whitelist.
	SLB - Open ports	Checks whether SLB opens ports to the Internet for forwarding unnecessary public services.
	ApsaraDB RDS - IP address whitelist configurations	Checks whether a whitelist is configured for ApsaraDB RDS and whether the whitelist contains 0.0.0.0/0. If the whitelist contains 0.0.0.0/0, requests from all IP addresses are allowed. We recommend that you configure the whitelist to allow requests only from specific IP addresses.
	KVStore for Redis - IP address whitelist configurations	Checks whether a whitelist is configured for KVStore for Redis and whether the whitelist contains 0.0.0.0/0. If the whitelist contains 0.0.0.0/0, requests from all IP addresses are allowed. We recommend that you configure the whitelist to allow requests only from specific IP addresses.
	AnalyticDB for PostgreSQL - IP address whitelist configurations	Checks whether a whitelist is configured for AnalyticDB for PostgreSQL and whether the whitelist contains 0.0.0.0/0. If the whitelist contains 0.0.0.0/0, requests from all IP addresses are allowed. We recommend that you configure the whitelist to allow requests only from specific IP addresses.
	PolarDB - IP address whitelist configurations	Checks whether a whitelist is configured for PolarDB and whether the whitelist contains `0.0.0.0/0`. If the whitelist contains 0.0.0.0/0, requests from all IP addresses are allowed. We recommend that you configure the whitelist to allow requests only from specific IP addresses.
	ApsaraDB for MongoDB - IP address whitelist configurations	Checks whether a whitelist is configured for ApsaraDB for MongoDB and whether the whitelist contains `0.0.0.0/0`. If the whitelist contains 0.0.0.0/0, requests from all IP addresses are allowed. We recommend that you configure the whitelist to allow requests only from specific IP addresses.

21.4.5.2. Run cloud service checks

Threat Detection Service (TDS) provides the cloud service check feature. This feature allows you to check for security risks in the configurations of your cloud services. This topic describes how to manually run cloud service checks on your cloud services. This topic also describes how to specify a detection interval for periodic automatic checks.

Context

Apsara Stack Security supports manual checks and periodic automatic checks to scan for security risks in the configurations of cloud services.

- Manual checks: On the **Cloud Service Check** page, you can click **Check Now** to check for security risks in the configurations of your cloud services.
- Periodic automatic checks: By default, Apsara Stack Security automatically runs checks during the time range `00:00 - 06:00` every other day. You can also customize a time range for periodic automatic checks. This way, you can detect and handle the security risks in the configurations of your cloud services at the earliest opportunity.

Manual checks

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Cloud Service Check**.
3. On the **Cloud Service Check** page, click **Check Now** to check whether the configurations of all your cloud services contain risks and the number of affected assets.

   > **Note** Do not perform other operations until the check is complete.

   After the check is complete, the detected risks are listed based on risk severities in descending order.

Automatic checks

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Cloud Service Check**.
3. In the upper-right corner of the **Cloud Platform Configuration Assessment** page, click **Settings**.
4. In the **Settings** dialog box, configure the **Detection Cycle** and **Detection Time** parameters.

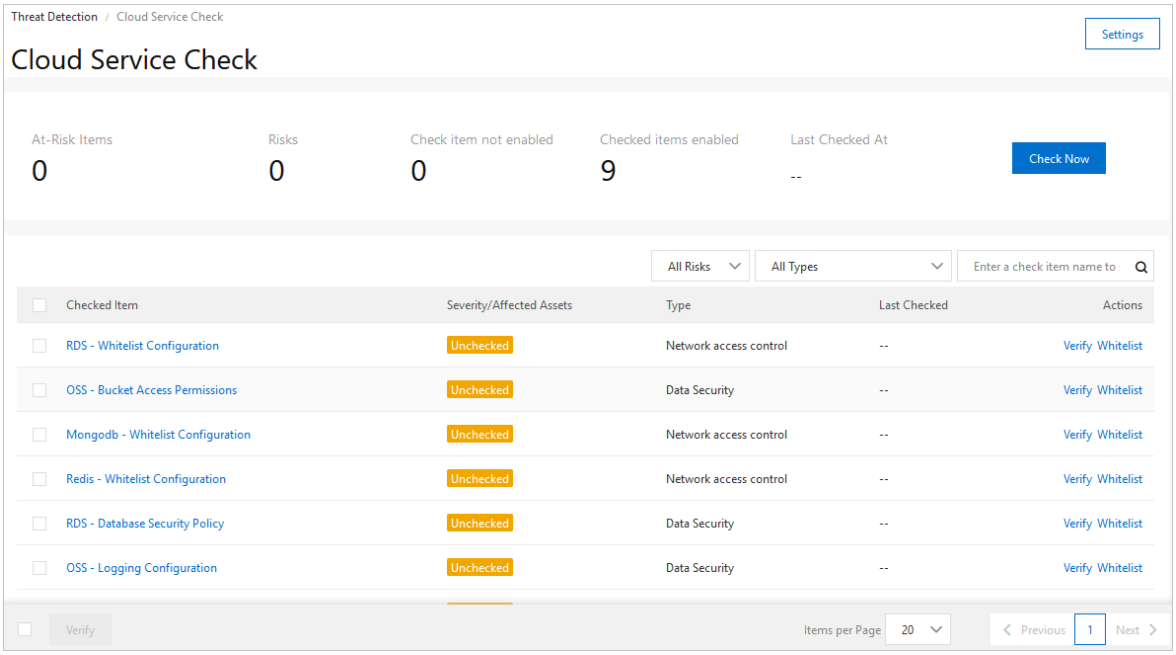
   
   - **Detection Cycle**: Monday to Sunday. You can select multiple values.
   - **Detection Time**: Valid values are `24:00 - 06:00`, `06:00 - 12:00`, `12:00 - 18:00`, and `18:00 - 24:00`. You can select only one time range.
5. Click **Ok**.
   During the selected time range, Apsara Stack Security automatically runs checks on all check items.

21.4.5.3. View the check results of configuration assessment for your cloud services and handle the detected risks

This topic describes how to view the check results of configuration assessment for your cloud services and handle the detected configuration risks in Apsara Stack Security. You can view the check items, details of check items, potential impacts caused by the detected configuration risks, and suggestions on how to handle the detected configuration risks. You can handle the detected configuration risks on the Cloud Service Check page in a centralized manner.

View check results

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Cloud Service Check**.
3. On the **Cloud Service Check** page, view the details of check results.



- **View the statistics of the last check**

  You can view the total number of at-risk items and the numbers of risks at different levels in the **At-Risk Items** section, and the number of assets on which risks are detected in the **Risks** section. You can also view the number of disabled check items in the Check item not enabled section, the number of enabled check items in the Checked items enabled section, and the time when the check was last performed in the Last Checked At section.

- **View check items**

  You can view the information about the check items in the check item list. The information includes the risk severities of check items, the number of affected assets, the types of affected assets, the types of check items, and the time when the check was last performed.

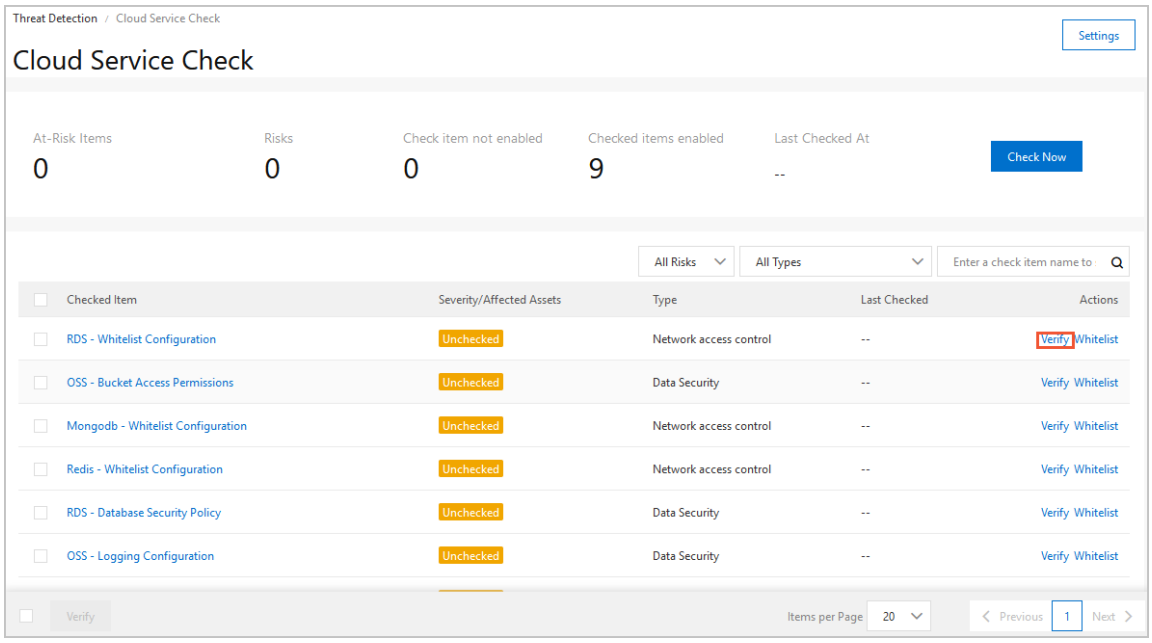
- **View the details of check results**

  You can click the name of a check item in the **Checked Item** column to go to the panel that displays the details of the check item. In the panel, you can view the description of the check item, potential impacts caused by the detected risks, and suggestions on how to handle the risks.

Handle the detected configuration risks of your cloud services

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Cloud Service Check**.
3. On the **Cloud Service Check** page, handle the configuration risks detected on your cloud services.
   - **Verify the configurations after modification**

If you have modified the configurations for which risks are detected, find the check item in the check item list and click **Verify** in the Actions column to check whether the new configurations are at risk.



- **Add check items to a whitelist**

  If you trust a check item for which risks are detected, find the check item in the check item list and click **Whitelist** in the Actions column to add the check item to a whitelist. Then, the state of the check item is displayed as **Ignored** in the Severity/Affected Assets column. **Ignored** check items are not counted in the total number of at-risk items in the **At-Risk Items** section.

  In the check item list, you can click **Remove** to remove the ignored check items from the whitelist.

  > Note After you add a check item to the whitelist, the risk that is detected for the check item is ignored only for this time. If the risk is detected again, Apsara Stack Security still displays the check result of this check item.

21.4.6. Application whitelist

The application whitelist feature prevents unauthorized programs from running on your servers and provides a trusted running environment for your servers.

Context

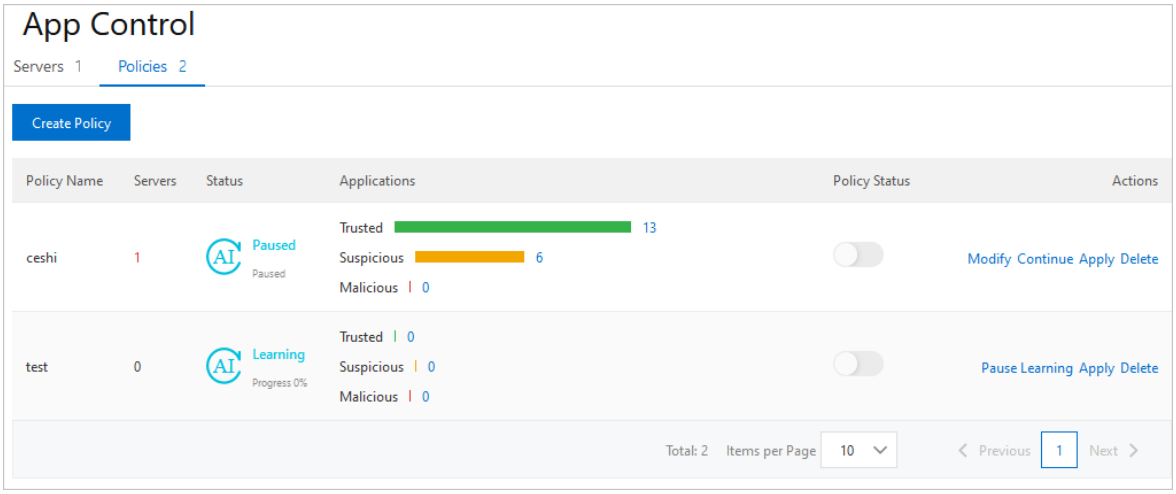
The application whitelist feature allows you to apply application whitelist policies to your servers that require special protection. Apsara Stack Security identifies trusted, suspicious, and malicious programs based on the policies. Then, you can add the identified programs to an application whitelist based on your business requirements. This prevents unauthorized programs from running. This feature protects your servers from untrusted and malicious programs and improves resource usage.

After you create an application whitelist policy, you can apply it to a server that requires special protection. Then, Apsara Stack Security scans for suspicious or malicious programs on the server and generates alerts for the programs that are not in the application whitelist.

Note If a program that is not in the application whitelist starts, an alert is generated. The program may be a normal program that is newly started or a malicious program that is inserted into your compromised server. If the program is a normal program, a frequently used program, or a third-party program installed by you, we recommend that you add the program to the application whitelist. After you add the program to the application whitelist, Apsara Stack Security no longer generates alerts for this program the next time the program starts. If the program is malicious, we recommend that you immediately delete this program and check whether the configuration files such as cron tasks are tampered with.

Step 1: Create an application whitelist policy

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Application Whitelists**.
3. On the **Application Whitelist** page, click the **Policies** tab.
4. On the App Control page, click the **Policies** tab. Then, click **Create Policy**.
5. In the Create Policy step of the **Create Whitelist Policy** panel, configure the following parameters:
   - **Policy Name**: the name of the application whitelist policy.
   - **Intelligent Learning Duration**: the duration for Apsara Stack Security to perform intelligent learning. Valid values: 1 Day, 3 Days, 7 Days, and 15 Days. The intelligent learning feature uses machine learning to automatically collect and categorize large amounts of alert data. Apsara Stack Security can identify suspicious or malicious processes based on the collected data.
   - **Servers for Intelligent Learning**: the servers to which you want to apply the application whitelist policy.
6. Click **Next** to create the application whitelist policy.
   After the application whitelist policy is created, the policy details are displayed in the policy list on the Policies tab.



The following table describes the parameters in the list of application whitelist policies.

Parameter	Description
Policy Name	The name of the application whitelist policy.
Servers	The number of servers to which the application whitelist policy is applied.

Parameter	Description
Status	The status of the policy. Valid values: ○ **Applied**: Intelligent learning is complete. The policy has been applied to servers. ○ **Pending Confirmation**: Intelligent learning is complete. The policy must be confirmed and enabled. After intelligent learning is complete, you must turn on the switch in the **Policy Status** column to enable this policy. The policy takes effect only after it is enabled. Apsara Stack Security automatically identifies the programs on your servers as trusted, suspicious, or malicious programs. ○ **Paused**: Intelligent learning is manually paused. You can click **Continue** in the Actions column to resume intelligent learning. ○ **Learning**: Intelligent learning is in progress. After an application a whitelist policy is created, Apsara Stack Security automatically performs intelligent learning based on the policy. The status of a new application whitelist policy is **Learning**.
Applications	The number of programs of each type on all servers to which the policy is applied. The program types include trusted, suspicious, and malicious.
Actions	The operations that you can perform on a policy. You can perform the following operations: ○ **Apply**: Add or remove servers to which the policy is applied in the **Apply Whitelist Policy** panel. ○ **Modify**: Modify the policy in the **Modify Whitelist Policy** panel. You can change the values of **Policy Name** and **Intelligent Learning Duration**, and add or remove the servers on which intelligent learning is automatically performed. ○ **Pause Learning**: Pause intelligent learning. ○ **Continue**: Resume intelligent learning. After you click **Continue**, the status of the policy changes to **Learning**. You can view the learning progress of the policy in the **Status** column. ○ **Delete**: Delete the policy. After the policy is deleted, the servers to which the policy is applied are no longer protected by the policy.

Step 2: Apply the created application whitelist policy to servers

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Application Whitelists**.
3. On the **Servers** tab of the App Control page, click **Add Server**.
4. In the **Add Server** panel, configure the following parameters:
   - **Whitelist Policy**: Select the created application whitelist policy from the drop-down list.
   - **Event Handling**: The default value is **Alert**, which indicates that Apsara Stack Security generates an alert when a suspicious program is detected.

     If a program that is not in the application whitelist starts, Apsara Stack Security automatically generates an alert. You can click the number in the **Suspicious Events** column to go to the **Alerts** tab of the server details page and view the alert details.
   - **Servers**: Select the server to which you want to apply the application whitelist policy. You can select multiple servers.

To search for a server, enter the server name in the **Servers** search box and click the search icon. **Fuzzy match is supported.**

5. Click **OK**. The application whitelist policy is applied to the selected servers.
   After the application whitelist is created, you can view the protected servers and the name of the application whitelist policy in the server list on the **Servers** tab.

   The **Servers** tab displays the following information of a protected server:

   - **Server Name/IP**: the name and IP address of the server to which the application whitelist policy is applied.
   - **Whitelist Policy**: the name of the application whitelist policy that is applied to the server.
   - **Suspicious Events**: the number of programs that are not in the application whitelist and have started. If a suspicious program starts on the server, Apsara Stack Security detects the program and generates an alert.
   - **Event Handling**: The default value is **Alert**, which indicates that Apsara Stack Security generates an alert when a suspicious program is detected.

     If a program that is not in the application whitelist starts, Apsara Stack Security automatically generates an alert. You can click the number in the **Suspicious Events** column to go to the **Alerts** tab of the server details page and view the alert details.
   - **Actions**: After you click **Delete** in the **Actions** column, the application whitelist policy no longer applies to the server.

     After you click Delete in the Actions column, the application whitelist policy becomes invalid for the server. In this case, if a program that is added to the application whitelist starts on this server, Apsara Stack Security generates an alert.

Add a program to or remove a program from an application whitelist

After you configure an application whitelist policy for your server, you can view the detailed information in the server list on the **Servers** tab. The information includes the details of the protected server and the name of the application whitelist policy that is applied to the server. You can click a policy name in the **Whitelist Policy** column to view the programs running on the server. You can also view the number of trusted, suspicious, and malicious programs and their detailed information.

The following information about each program on the server is displayed:

- **Type**: the type of the program. Programs are classified into trusted, suspicious, and malicious programs.
- **Process Name**: the name of the program.
- **Hash**: the hash function of the program. A hash function is used to identify whether a program is unique. This helps protect servers against malicious programs.
- **Path**: the file path of the program on the server.
- **Degree of Trustability**: the degree of trustability for the program. The value of this parameter is determined by Apsara Stack Security. Valid values: 0%, 60%, and 100%. The value 0% indicates malicious programs, 60% indicates suspicious programs, and 100% indicates trusted programs.

  > **Note** We recommend that you handle the program whose Degree of Trustability is 0% at the earliest opportunity.

- **Actions**: the operations that can be performed on the program. You can determine whether to add the program to the whitelist based on the services deployed on your server. You can perform the following operations:
  - **Add to Whitelist**: If you trust the program, add it to the whitelist.
  - **Remove from Whitelist**: After you remove the program from the whitelist, Apsara Stack Security identifies the program as untrusted. If this program starts, Apsara Stack Security generates an alert.

21.4.7. Assets

21.4.7.1. View the security status of a server

The Assets page displays security information about each protected server. The information includes the virtual private could (VPC) where each server resides, server status, and risk status. This topic describes how to search for specific servers and view the security status of these servers. This topic also describes how to specify search conditions and select the items that you want to display on the Assets page.

Procedure

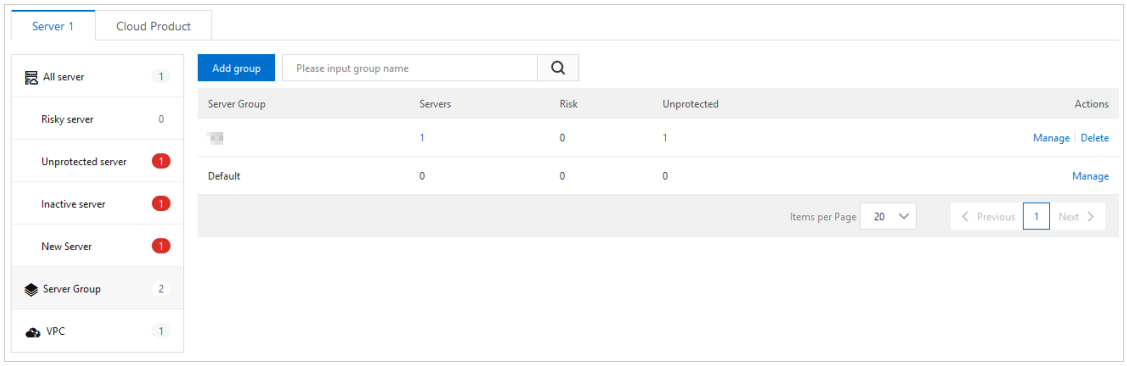
1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server(s)** tab of the Assets page, view the security status of each server.

   You can perform the following operations:

   - **Filter servers by status**
     - In **All server**, you can view the numbers of all servers, risky servers, unprotected servers, new servers, and servers that are shut down.

       
       To view the security information about a server, you can click the name of the server or click **Fix** in the **Actions** column. For more information, see View the details of a single asset.
     - You can click **Risky server**, **Unprotected server**, **Shutdown Server(s)**, or **New Server(s)** to view security information about specific servers.
   - **Filter servers by group**

- You can click **Server Group** to view the numbers of all servers, servers that are at risk, and unprotected servers in each server group. You can also view the total number of server groups.

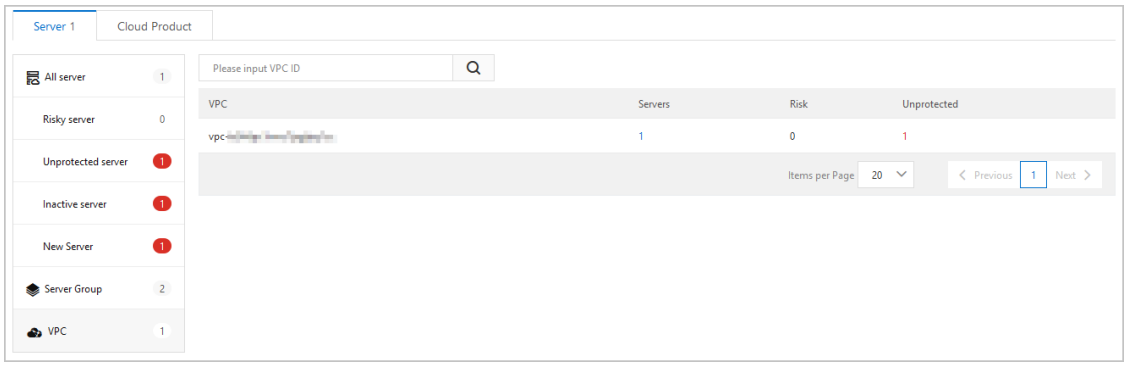


To manage server groups, you can click **Manage** or **Delete** in the Actions column. For more information, see Manage asset groups.

- You can select a server group and click the number in the **Servers**, **Risk**, or **Unprotected** column to view the security information about specific servers in this group.

Filter servers by VPC ID

- You can click **VPC** to view the numbers of all servers, servers that are at risk, and unprotected servers in each VPC. You can also view the total number of VPCs.



- You can find a VPC and click the number in the **Servers**, **Risk**, or **Unprotected** column to view the security information about specific servers in this VPC.

Filter servers by tag

In the navigation tree, you can click a tag to view the security information about servers to which the tag is added.

Filter servers by condition

If you click **All Servers**, **Server Group**, **VPC**, or a tag in the navigation tree, you can specify filter conditions above the right-side list to search for specific servers.

- Use one filter condition to search for specific servers:

  You can select a filter condition and select or enter keywords to search for specific servers. The filter conditions include **Internet IP**, **Private IP**, **Instance name**, **System**, **Baseline problems**, **Vul problems**, **Alert problems**, **Risk Status**, **Online or Offline**, **Tag**, **Group name**, **OS**, and **Is there a snapshot risk**.

  > **Note**
  >
  > You can specify multiple filter conditions at a time and specify a Boolean operator for the conditions. The following list describes the Boolean operators:
  >
  > - Boolean operators:
  >   - **AND**: specifies the **AND** logical relation for the conditions.
  >   - **OR**: specifies the **OR** logical relation for the conditions.
  > - If you want to search for servers that meet at least one of the filter conditions, you must set the Boolean operator to **OR**.
  > - If a filter condition requires you to enter a keyword, you must enter the keyword and click the **Search** icon. Results are displayed only after you click the Search icon.

- Use multiple filter conditions to search for specific servers:

  If you select multiple filter conditions, they are all applied to search for specific servers.

  You can also click **Server Group**, **VPC**, or a tag, and use the search box above the asset list to search for specific servers.

- **Save frequently used filter conditions**

  You can save the filter conditions that are applied as frequently used search conditions. To save the conditions, click **Save** above the right-side list, and enter a name in the **Save condition** dialog box. Then, you can select the saved conditions from the **Frequent search conditions** drop-down list on the right of the Search icon.

- **Customize displayed items**

  On the **Assets** page, you can click the  icon in the upper-right corner. Then, you can select the items that you want to display on the Assets page.

21.4.7.2. View the security status of cloud services

The Assets page displays the security information about each protected cloud service. The information includes the at-risk services and the types of services such as SLB and NAT Gateway. This topic describes how to configure search conditions to view the security status of cloud services.

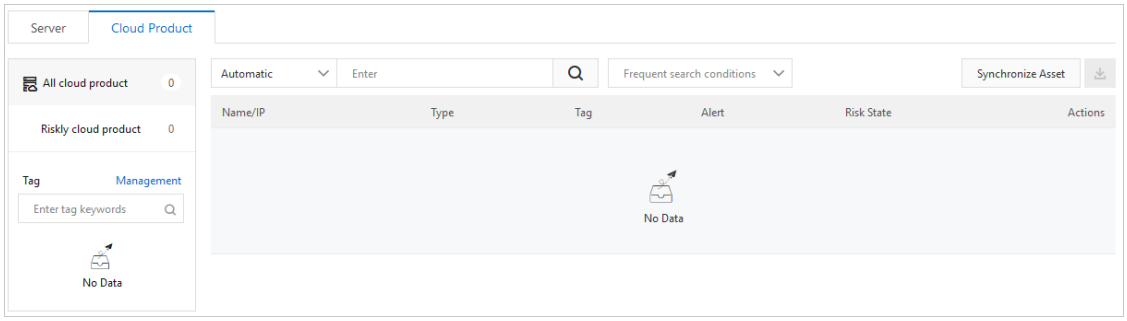
Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Cloud Product** tab of the Assets page, view the security status of cloud services.

   You can perform the following operations based on your business requirements:

   - **Search by asset status**

- In the left-side pane of the **Cloud Product** tab, you can view the numbers of **All cloud product** and **Risky cloud product**. You can also view the security status of all cloud services.



- Click **Risky cloud product** to view the cloud services that are at risk.

You can click the name of the required cloud service or click **View** in the Actions column that corresponds to a service to view detailed information. For more information, see View the details of a single asset.

- **Search by asset type**

  Cloud services are classified into two asset types:

  - **SLB**
  - **NAT Gateway**

  In the left-side pane of the Cloud Product tab, you can view the number of cloud services of each type. You can click **SLB** or **NAT** to view the security status of the required cloud service.

- **Search by tag**

  In the **Tag** section in the left-side pane of the Cloud Product tab, you can view the number of cloud services to which each tag is added. You can click a tag to view the security status of cloud services to which the tag is added.

- **Filter by search condition**

  You can click **All cloud product**, **SLB**, or **NAT** in the left-side pane of the **Cloud Product** tab and configure search conditions in the search box to search for specific assets.

  For example, you can click **All cloud product** and configure search conditions to search for specific assets.

  - Use multiple subconditions to search for specific assets:

    Select a condition from the drop-down list of the search box on the **Cloud Product** tab, and select a subcondition or enter a keyword into the search box to search for specific assets. Supported search conditions are **Internet IP**, **Instance name**, **Alert problems**, **Risk Status**, **Tag**, and **Group name**.

    > **Note**
    >
    > You can configure multiple search conditions at a time and specify a Boolean operator for search conditions. The following list describes the Boolean operators:
    >
    > - Boolean operators:
    >   - **AND**: specifies the **AND** logical relation for the search conditions.
    >   - **OR**: specifies the **OR** logical relation for the search conditions.
    > - If you need to use one search condition and multiple keywords to search for specific servers, set the Boolean operator to **OR**.
    > - If the search condition requires you to enter a keyword, enter a keyword and click the **Search** icon. Results appear after you click the Search icon.

- Use multiple filter conditions to search for specific servers:

  Apply multiple search conditions.

  - You can click **SLB**, **NAT**, or a tag specified in the **Tag** section and configure conditions in the search box on the **Cloud Product** tab to search for specific assets.
  - You can also click **All cloud product**, **SLB**, or **NAT** and select a tag specified in the **Tag** section to search for specific assets.

- **Set frequently used search conditions**

  You can save the filter conditions that are applied as frequently used search conditions. Click **Save** below the search box and enter a name in the **Save condition** dialog box. Then, you can select the saved search condition from the Frequent search conditions drop-down list on the right of the search box.

21.4.7.3. View the details of a single asset

The Assets page provides details about all assets. These details include basic information, alert management status, baseline check analysis, and asset fingerprints. This topic describes how to view the details of a server or a cloud service.

Context

The basic information about assets is displayed on the **Assets** page. Different types of assets, such as servers and cloud services, are managed in different ways.

The following table lists the features that are supported by servers and cloud services on the **Assets** page. The following list describes the marks that are used to indicate whether a feature is supported by servers or cloud services:

- Cross (×): not supported.
- Tick (√): supported.

Feature	Description	Server	Cloud service
Basic Information	Risk state: displays the number of risks detected on an asset. The following types of risks can be detected: • **Vulnerability** • **Alert** • **Baseline risk**	√	√ (Only alerts can be processed.)
	Detail: displays the configuration and protection status of an asset. You can specify a group and a tag for the asset.	√	√ (Asset grouping is not supported.)
	Asset investigation: displays asset fingerprints, including ports, software, processes, and accounts.	√	X
	Vulnerability check: displays the types of vulnerabilities that can be detected. You can specify the types of vulnerabilities that you want to detect for an asset.	√	X
	Login security setting: displays the configured logon locations, IP addresses, time periods, and accounts. You can manage relevant alerts for an asset.	√	X
Vulnerabilities	Displays the results of vulnerability detection on an asset.	√	X

Feature	Description	Server	Cloud service
Alerts	Displays the alerts that are generated for an asset.	√	√
Baseline Risks	Displays the results of the baseline check on an asset.	√	X
Asset Fingerprints	Displays the details of asset fingerprints for an asset.	√	X

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Assets** page, click the **Server(s)** or **Cloud Product** tab.
4. On the **Server(s)** or **Cloud Product** tab, find the required asset and click its name.
5. View the details of the asset.

   On the asset details page, click the **Basic Information**, **Vulnerabilities**, **Alerts**, **Baseline Risks**, or **Asset Fingerprints** tab to view relevant details.

   The following list describes the details of the asset:

   - **Basic Information**: This tab consists of sections in which you can view asset details and manage an asset.
     - **Risk State**: This section displays the numbers of vulnerabilities, alerts, and baseline risks on the asset. You can click the number under Vulnerabilities, Alerts, or Baseline Risks to view the details.
     - **Detail**: This section displays information about the asset configuration and security protection settings, and allows you to manage asset tags and groups.
       - **Change asset groups**

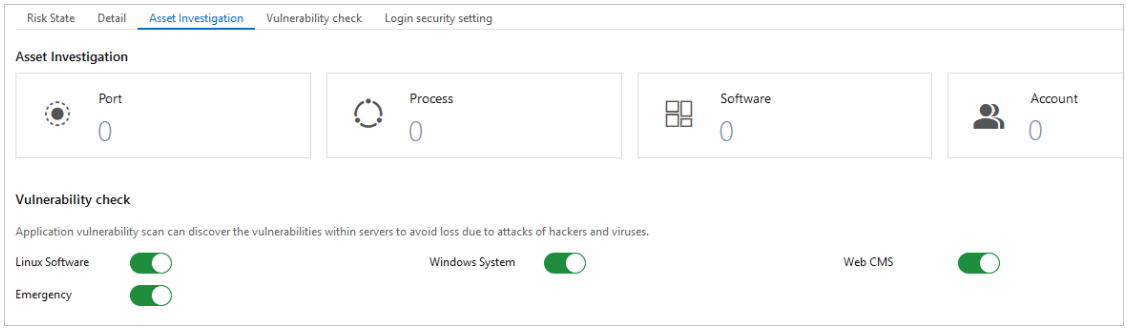
         Click **Group**. In the **Group** dialog box, select a new group and click **OK**.

         
       - **Modify tags**

         Click the icon. In the **Add tag** dialog box, select a tag and click **OK**.

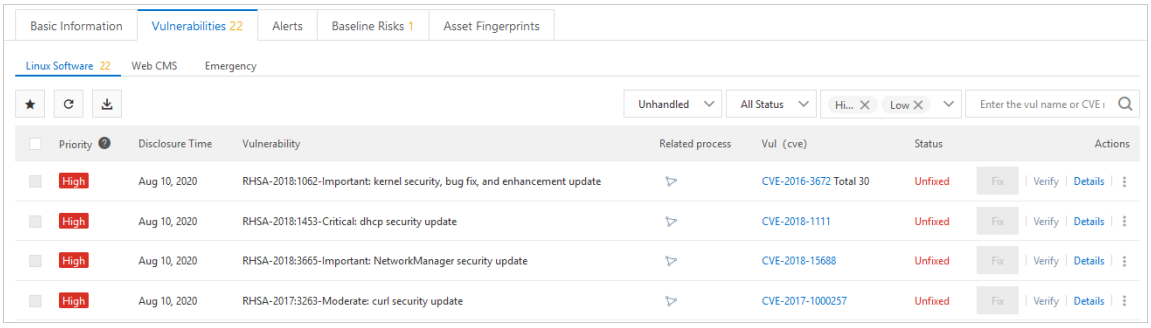
         
         You can click the icon in the right of a tag to delete the tag.

- **Asset Investigation**: This section displays the fingerprints of an asset. You can click the number under an item to go to the **Asset Fingerprints** tab to view the details.

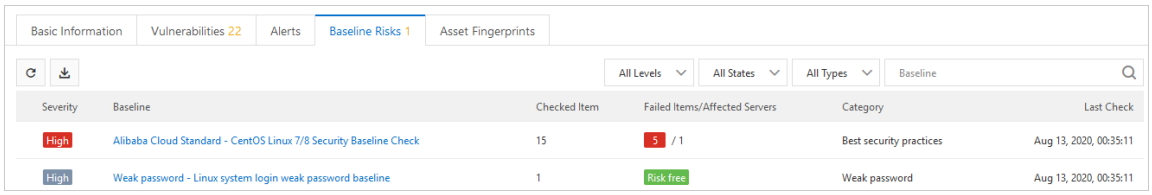


- **Vulnerability check**: This section displays vulnerability check items that are enabled or disabled for an asset. You can enable or disable different types of vulnerability checks for the asset. The vulnerabilities include Linux software vulnerabilities, Windows system vulnerabilities, Web CMS vulnerabilities, and urgent vulnerabilities.
- **Login security setting**: This section allows you to specify approved logon locations, configure advanced logon settings, and turn on or turn off alerting for unapproved IP addresses, time, and accounts. The advanced logon settings include approved IP addresses, time periods, and accounts. You can also specify approved IP addresses, time periods, and accounts for a specific asset.

  - **Vulnerabilities**: This tab displays vulnerabilities detected on an asset.



- **Alerts**: This tab displays alerts generated for an asset.
- **Baseline Risks**: This tab displays baseline risks of an asset.



- **Asset Fingerprints**: This tab displays the fingerprints, including ports, processes, software, and accounts of an asset.

  You can manually collect the latest fingerprints of an asset.

  a. You can click the **Port**, **Software**, **Process**, **Account**, or **Scheduled Tasks** tab. In the upper-right corner, click **Collect data now**.

  b. In the **Collect data** message, click **OK**.

  After the data collection task is submitted, it takes one to five minutes to collect the fingerprints of the required asset. After the data collection task is complete, you can view the latest fingerprints of the asset.

21.4.7.4. Enable and disable server protection

This topic describes how to enable and disable server protection.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server(s)** tab of the page that appears, enable or disable server protection for specified servers.
   - **Enable server protection**

     Select one or more servers where the agent is in the **Close** state, and choose **More operations > Turn on protection**.

     After server protection is enabled, the status in the Agent column changes to **Enable**.
   - **Disable server protection**

     If you confirm that a server does not require protection from Apsara Stack Security, you can disable protection for the server. Select one or more servers where the agent is in the **Enable** state, and choose **More operations > Suspend Protection**.

     > **Note** After server protection is disabled, Apsara Stack Security stops protecting your servers. For example, Apsara Stack Security no longer detects vulnerabilities or generates alerts for detected risks. We recommend that you proceed with caution.

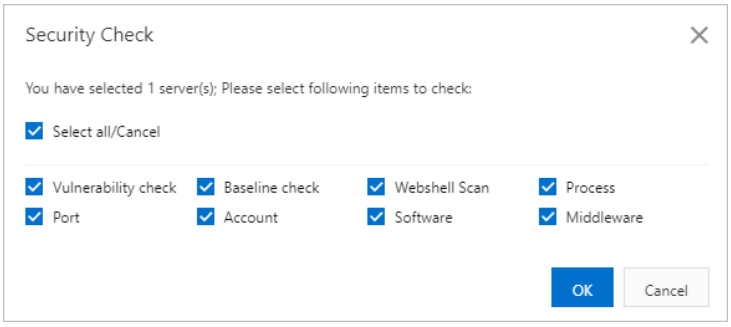
     After server protection is disabled, the status of the agent on your servers changes to **Close**.

21.4.7.5. Perform a quick security check

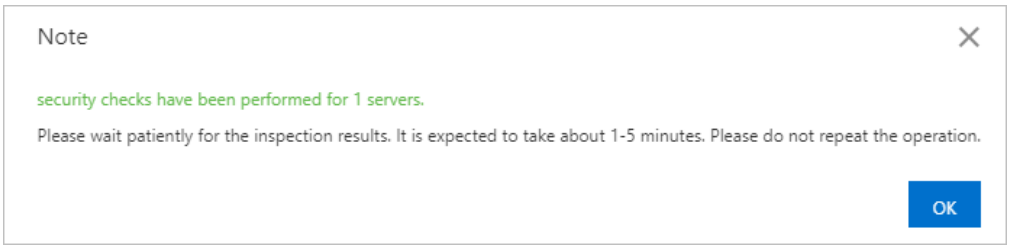
The Server tab of the Assets page allows you to run security checks. You can dispatch security check tasks to scan for vulnerabilities, baseline risks, or webshells, and collect asset fingerprints on a specific server. The asset fingerprints are ports, software, processes, and accounts. This topic describes how to perform a security check on servers.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server** tab, select one or more servers on which you want to perform a security check.
4. In the lower part of the page, click **Security check**.
5. In the **Security Check** dialog box, select check items.



6. Click **OK** to start the check.
7. In the message that appears, click **OK**.



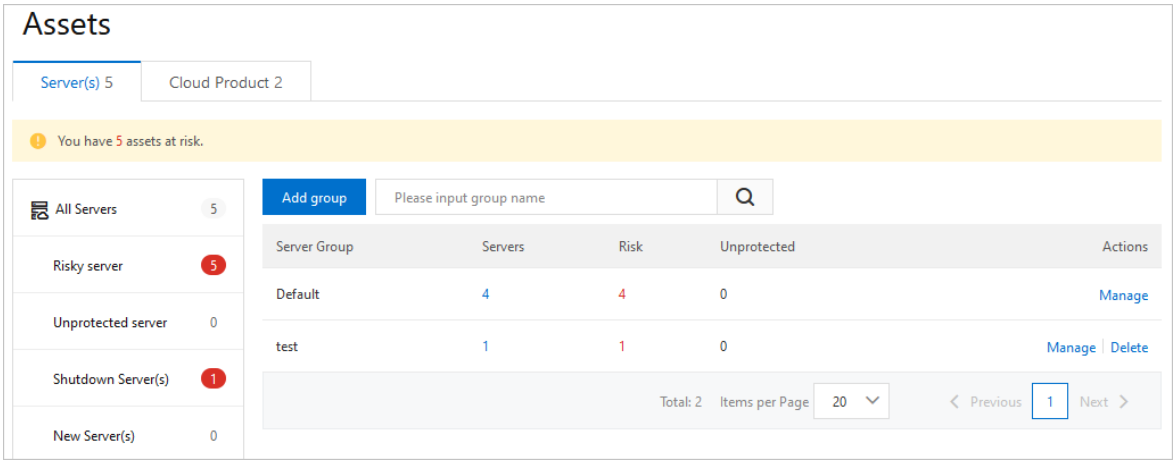
After the security check is complete, the check results are automatically displayed on the details pages of the selected servers.

21.4.7.6. Manage server groups

This topic describes how to create, modify, delete, and replace server groups.

Create a server group

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server(s)** tab of the page that appears, click **Server Group** in the navigation tree.



Note By default, the assets that are not grouped are in the **Default** group.

4. Click **Add group**.
5. In the **Add group** dialog box, configure parameters for the new group.

   To configure the parameters, perform the following steps:

   i. Enter a name for the new group in the **Group name** field.

   ii. Add servers to the new group.

   You can add servers in the Default group to the new group. You can also move servers from another group to the new group. To add or move servers, select **Default** or other groups in the **Asset Group** section, and select or clear the required check boxes in the asset list in the right area of the section.

6. Click **OK**.
   In the server group list, you can view the new group.

Modify or delete a server group

The following procedure describes how to modify or delete a server group. When you modify a server group, you can rename the group or adjust the servers in the group.

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the **Server(s)** tab of the page that appears, click **Server Group** in the navigation tree.
4. Find the server group that you want to modify or delete. In the Actions column, click **Manage** or **Delete**.

   You can perform the following operations based on your business requirements:

   - **Modify the group**
     a. In the Actions column, click **Manage**. The Group dialog box appears.
     b. In the **Group** dialog box, select the group in the **Asset Group** section.
     c. In the right area of the section, clear the check boxes that correspond to the required servers in the asset list.
     d. Click **OK**. The server group is modified.
   - **Delete the group**

     In the Actions column, click **Delete**. In the message that appears, click **OK**.

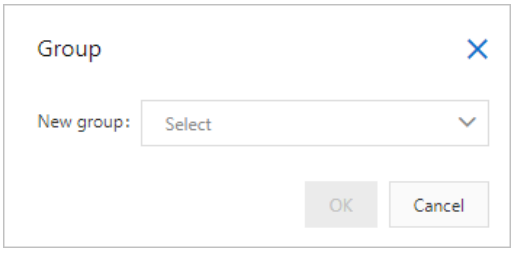
     > **Note** After you delete a group, servers in this group are moved to the **Default** group.

Replace a server group

You can add servers to a server group to manage multiple servers at a time. We recommend that you add the same types of servers to a server group. For example, if you configure a baseline check template, you can specify a server group and apply the template to all servers in the group. You can also filter and view servers based on server groups.

To add servers to a specific server group, perform the following steps:

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the Server(s) tab of the page that appears, select one or more servers and click **Group** in the lower part of the page.
4. In the **Group** dialog box, select a new server group.



5. Click **OK**.

21.4.7.7. Manage asset tags

This topic describes how to add asset importance tags to your assets and how to create, modify, and delete custom tags.

Context

Apsara Stack Security provides the asset importance tags described in the following table to classify assets. You

can select appropriate importance tags for your assets.

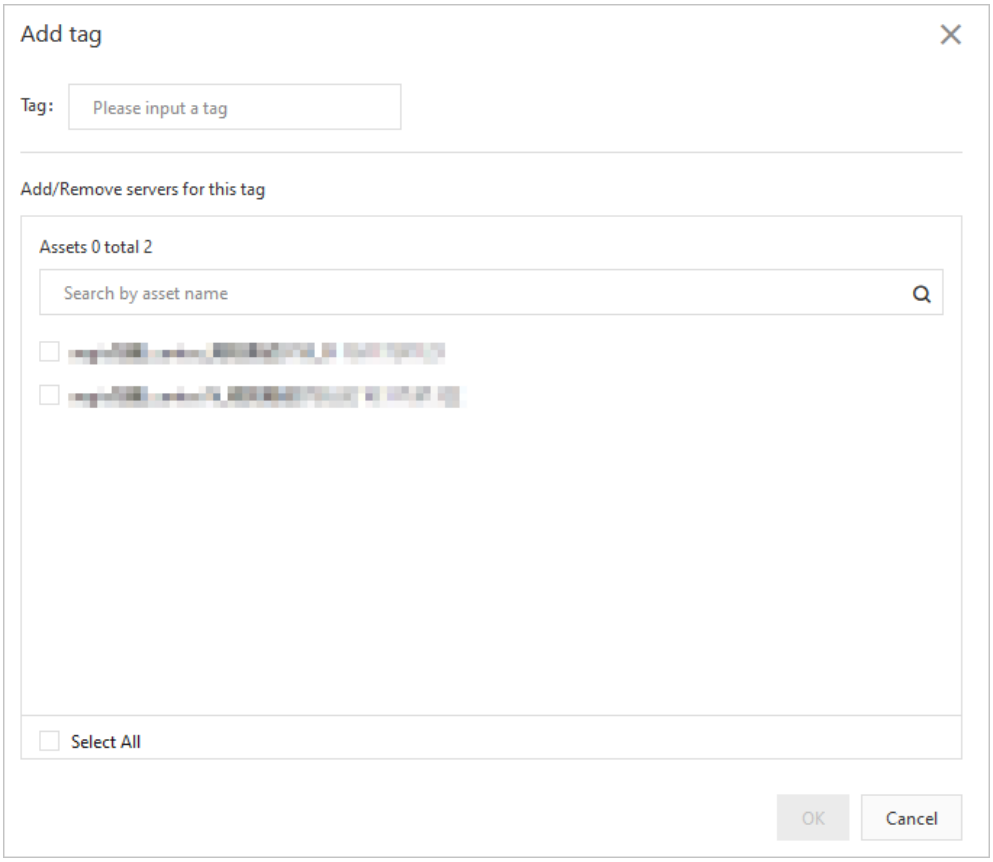
An asset importance tag is transformed to an **asset importance score**. An **asset importance score** is used to calculate a vulnerability priority score. You can determine whether to preferentially fix a vulnerability based on the vulnerability priority score. We recommend that you add importance asset tags to core assets. Apsara Stack Security prompts you to fix vulnerabilities based on the importance of each asset. The following table describes the relationships between asset importance tags and asset importance scores.

Asset importance tag	Asset importance score	Recommendation
Important Assets	1.5	Assets that are related to crucial business or store core business data. Virus intrusion into the assets adversely affects the system and causes major loss.
General Assets	1	Assets that are related to non-crucial business and are highly replaceable. Virus intrusion into the assets causes less impact on the system.
Test Assets	0.5	Assets for functional or performance tests, or assets that can cause less impact on the system.

Note If you do not add asset importance tags, the **General Assets** tag is automatically added to each asset. This tag indicates that the asset importance score is 1.

Create a custom tag

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the page that appears, click the **Server(s)** or **Cloud Product** tab.
4. In the navigation tree of the **Server(s)** or **Cloud Product** tab, click **Management** on the right of **Tag**.
5. In the **Add tag** dialog box, enter the tag name in the **Tag** field.



6. In the **Asset Group** section, select a server group. Then, select the required servers to add the new tag to the selected servers in the right area of the section.
7. Click **OK**.

   In the asset list of the Server(s) or Cloud Product tab, you can click the icon in the **Tag** column to add the new tag to an asset.

   > **Note** You can add multiple tags to one asset. All tags of an asset are displayed in the **Tag** column.

Modify or delete a custom tag

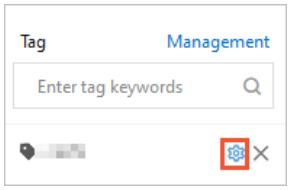
The following procedure describes how to modify or delete a custom tag. When you modify a tag, you can rename the tag or adjust the servers to which the tag is added.

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Assets**.
3. On the page that appears, click the **Server(s)** or **Cloud Product** tab.
4. On the **Server(s)** or **Cloud Product** tab, modify or delete a tag.

   Perform the following operations to modify or delete a tag:

   - **Modify a tag**

a. Find the tag that you want to modify and move the pointer over the icon on the right of the tag.

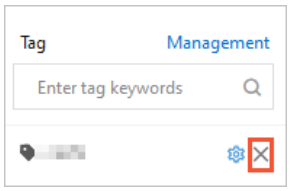


b. In the **Tag** dialog box, enter a new name in the **Tag** field, add the tag to more servers, or remove the tag from specific servers.

c. Click **OK**.

- **Delete a tag**

  Find the tag that you want to delete and click the icon in the Tag column. In the message that appears, click **OK**.



21.4.8. Vulnerability scan

21.4.8.1. Quick start

This topic describes how to get started with the vulnerability scan feature.

The following procedure shows how to use the vulnerability scan feature:

1. Configure the following detection items and the required cycles based on your environment requirements:
   - Overall Monitoring: Configure detection features and the monitoring cycle of each detection feature. For more information, see Configure overall monitoring.
   - Basic Monitoring: Configure Weak Password Vulnerability Monitoring, Operation Security Vulnerability Monitoring, CMS Application Vulnerability Monitoring, and Baseline Monitoring. For more information, see Configure basic monitoring.
   - Web Monitoring: Configure the monitoring cycle and the types of web vulnerabilities that you want to monitor. For more information, see Configure web monitoring.
   - Whitelist: Add the assets that do not require detection to the whitelist. For more information, see Configure a whitelist.
2. Import assets that require vulnerability scans.
   - Import internal assets: Configure a scan engine to import your internal assets in virtual private clouds (VPCs). For more information, see Configure a scan engine for internal assets.
   - Import Internet assets: Import your Internet assets. For more information, see Import assets.

   > **Note** The number of imported assets cannot exceed the specified upper limit.

3. View and confirm the results of vulnerability scans.
   - View the overall information to obtain the results of vulnerability scans. For more information, see View the information on the Overview page.
   - View and confirm vulnerability risks. For more information, see Manage security vulnerabilities.
   - View and confirm host compliance risks. For more information, see Manage host compliance risks.

- View and confirm external risks, such as code leak risks. For more information, see Manage external risks.

4. Generate vulnerability scan reports.

   Generate reports to audit the vulnerabilities and baseline risks on assets on a regular basis. For more information, see Manage external risks.

21.4.8.2. View the information on the Overview page

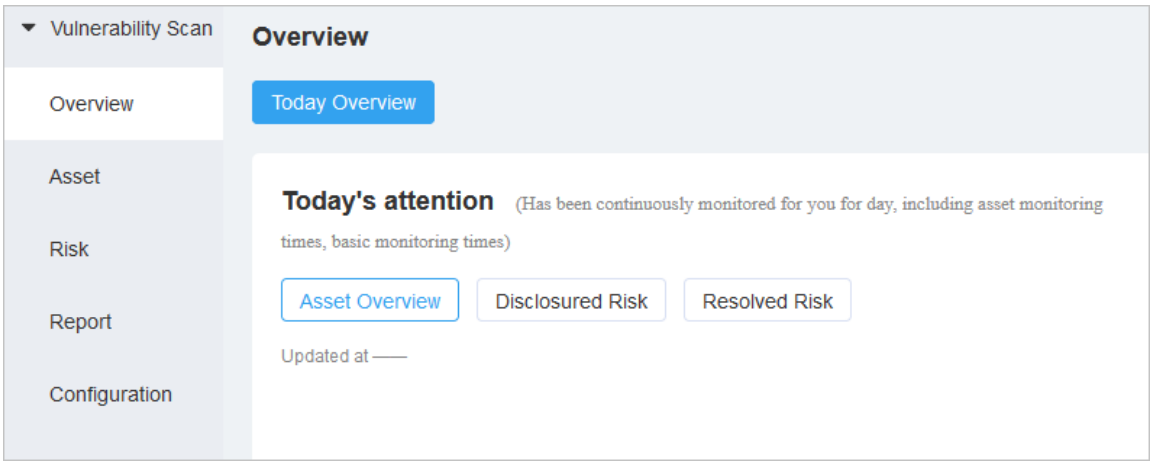
This topic describes the overall results of vulnerability scans. Security administrators can understand the vulnerability situation based on the overall results.

Context

The vulnerability scan feature can identify the following vulnerabilities: web security vulnerabilities, content management system (CMS) application vulnerabilities, weak password vulnerabilities, O&M security vulnerabilities, and baseline security vulnerabilities.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Overview**.
3. View the overall results of vulnerability scans.



Section	Description

Section	Description
Today's attention	View Asset Overview, Disclosured Risk, and Resolved Risk of the current day. ○ **Asset Overview**: displays the numbers of hosts, websites, and domain names for the current day and provides a security score for the current assets. The radar chart on the right shows the distribution of web security vulnerabilities, CMS application vulnerabilities, weak password vulnerabilities, O&M security vulnerabilities, and baseline security vulnerabilities. ○ **Disclosured Risk**: displays the numbers of high-risk vulnerabilities, medium-risk vulnerabilities, and low-risk vulnerabilities, and the total number of these vulnerabilities for the current day. These vulnerabilities are not fixed. The **Disclosured Risk Distribution** section on the right displays the distribution of unfixed vulnerabilities. ○ **Resolved Risk**: displays the numbers of high-risk vulnerabilities, medium-risk vulnerabilities, and low-risk vulnerabilities, and the total number of these vulnerabilities for the current day. These vulnerabilities are fixed. The **Resolved Risk Distribution** section on the right displays the distribution of fixed vulnerabilities.
Asset Risk Top 5	View the top five assets that are at risk on the **Security Vulnerabilities** and **Host Compliance** tabs. These assets are displayed by asset or group.
Risk Monitoring Trend	View the trend charts of vulnerabilities on the **Security Vulnerabilities** and **Host Compliance** tabs. Fixed and unfixed vulnerabilities are identified by lines in different colors. You can move the pointer over a line to view the numbers of unfixed vulnerabilities and fixed vulnerabilities for the specific day.
Asset Monitoring Trend	View the trends in the numbers of protected hosts and websites. Hosts and websites are identified by lines in different colors. You can move the pointer over a line to view the number of protected hosts and websites for the specific day.
Risk Asset Ranking List	View the rankings of assets that are at risk on the **Latest Risk** and **High Risk** tabs.
Port Service Statistics	View the statistics on the **Port** and **Host Service** tabs.

21.4.8.3. Asset management

21.4.8.3.1. View the results of asset analysis

This topic describes how to view the analysis results of websites and hosts.

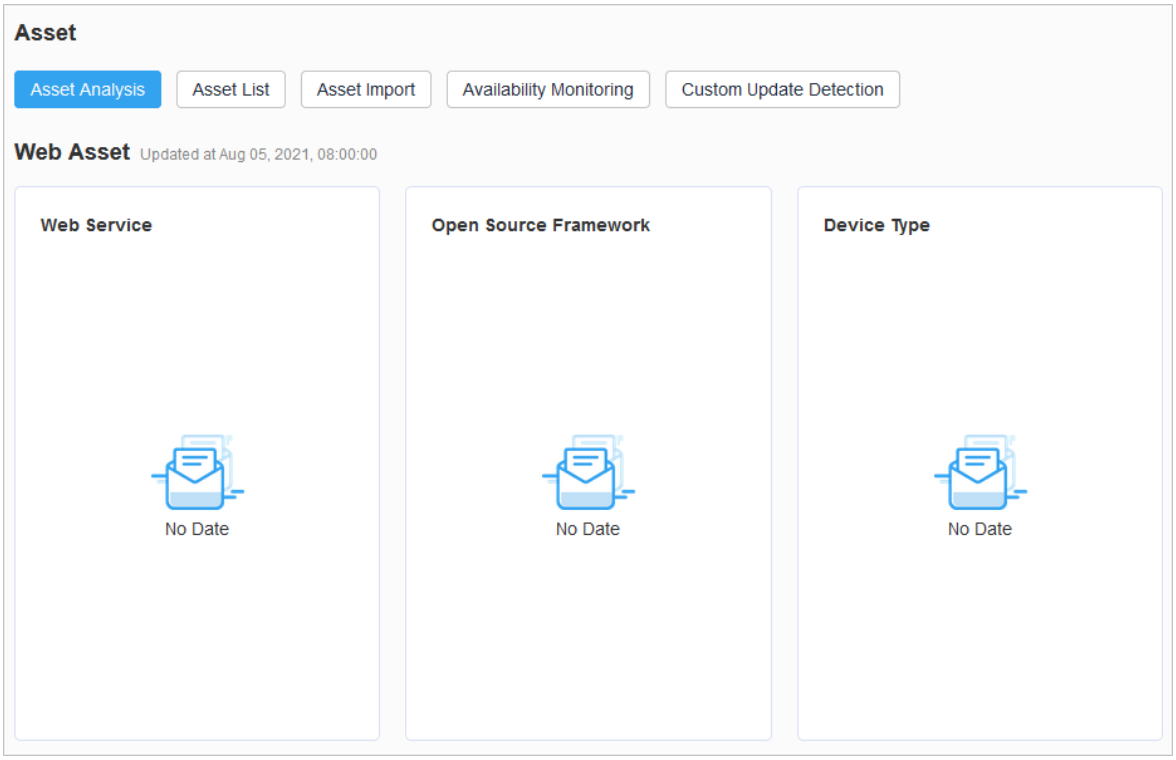
Context

The asset analysis feature allows you to view the analysis results of websites and hosts. For the websites, you can view Web Service, Open Source Framework, and Device Type. For the hosts, you can view Host Port, Host Service, and Operation System.

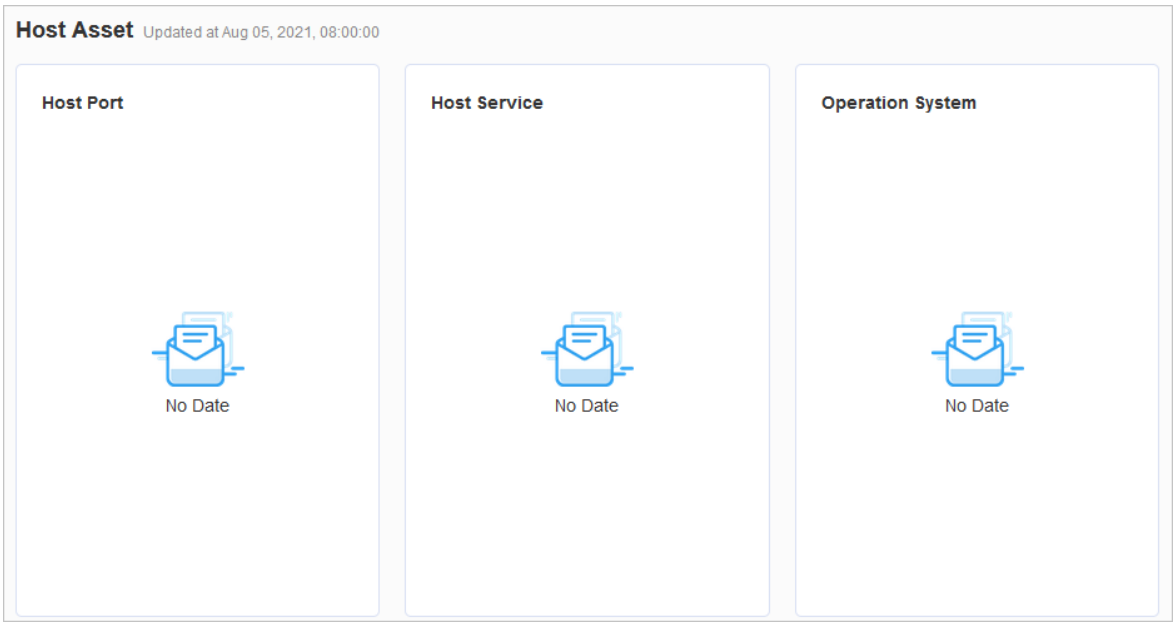
Procedure

1. Log on to Apsara Stack Security Center.

2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan**.
3. In the **Vulnerability Scan** pane, click **Asset**.
4. On the **Asset** page, click the **Asset Analysis** tab to view websites.



5. View hosts.



21.4.8.3.2. Import assets

This topic describes how to import Internet assets.

Context

The vulnerability scan feature works only on imported assets. If you want to scan the vulnerabilities of your assets,

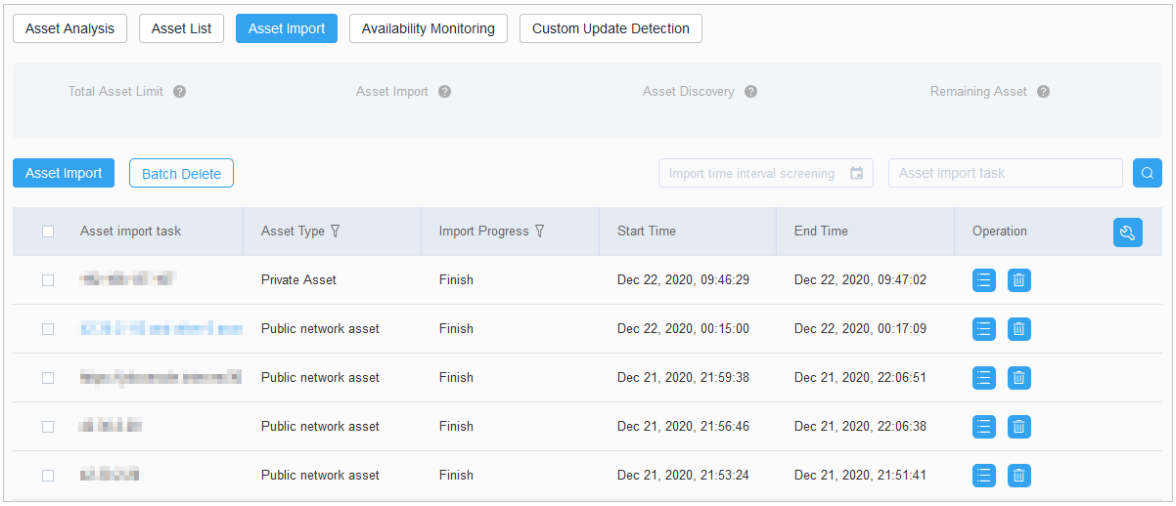
you must import your assets.

The assets that the feature supports include Internet assets and internal assets. The internal assets refer to the assets in a virtual private cloud (VPC).

- To import internal assets, you must add a scan engine. For more information, see Configure a scan engine for internal assets.
- To import Internet assets, perform the operations provided in this topic.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan**.
3. In the **Vulnerability Scan** pane, click **Asset**.
4. On the **Asset** page, click the **Asset Import** tab to view imported assets.



5. Click **Asset Import**. On the **Public network asset Import** page, create an asset import task.
   i. In the **Import Asset** section, select **Manual Import** and enter the required assets in the field. Then, read and select the disclaimer.
      - You can enter domain names, URLs, IP addresses, and CIDR blocks.
      - You can enter the information about multiple assets at a time. Press Enter after you enter the information about one asset.
      - You cannot enter the information about the assets in VPCs.
      - The number of imported assets must be less than the number of remaining assets supported by the platform.

        Note For example, if the number of remaining assets supported by the platform is 100 and 90 assets are entered, all the assets can be scanned. If 110 assets are entered, only 100 assets can be scanned, and the 10 assets that remain cannot be scanned.

   ii. In the **Asset Info** section, group the imported assets and configure an owner and a tag for the assets.
      - **Asset Group**: Select a group from the drop-down list. You can click the icon to create, edit, or delete a group.
      - **Person in charge**: Select an owner from the drop-down list. You can click the icon to create, edit, or delete an owner.
      - **Asset Tag**: Click **Add Tag** to add a tag to the imported assets.

iii. In the **Import Set** section, select the operations that you want to perform after the assets are imported.

Operation		Description
Asset Discovery	*Auto Import subdomains*	Automatically queries the subdomain assets of the imported domain names.
	Auto import associated IP	Automatically adds IP address assets that are mapped to the domain names.
	Auto synchronize tags and groups	Applies the group and tag of the imported assets to the assets that are discovered by the system.
Web Asset	*Open WEB Monitoring*	Enables the web monitoring feature on the imported website assets. If you want to select the web monitoring rules to use, click the icon. In the dialog box that appears, select the required web monitoring rules. For more information about how to configure web monitoring rules, see Configure web monitoring.

iv. In the **Whitelist** section, add the assets that do not need to be scanned.

You can enter IP addresses and URLs. If you add more than one asset, you must press Enter after you enter the information about an asset.

v. Click **Save**.

6. Manage the created asset import task.

After the asset import task is created, you can view the task in the task list. You can also perform the following operations on the new asset import task.

Icon	Description
	View the details, results, and process of the asset import task.
	Delete the asset import task.

21.4.8.3.3. Manage assets

This topic describes how to view and manage assets.

Context

You can view the information about assets in the asset list. If the purpose or owner of an asset changes, security administrators can move the asset to another group or change the owner.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan**.
3. In the Vulnerability Scan pane, click **Asset**.
4. On the **Asset** page, click the **Asset List** tab to view assets.
5. Click the **Web Asset** tab and manage websites.

i. Specify filter conditions to search for specific websites.

The filter feature allows you to search for the required websites in a more efficient manner.

Filter condition	Description
Asset Type	The asset type, such as Internet assets or a specific VPC.
Asset Source	The source from which the asset is imported. Valid values: **Manual** and **System Find**.
Asset Group	The group to which the asset belongs.
Web Status	The status of the website.
Person in charge	The owner of the website.
Asset Change	The change status of the asset. Valid values: **All**, **New**, **Update**, **No Update**, and **Offline**.
Web Monitoring	The monitoring status of the website.
Risk Level	The risk level of the asset.
Web Service	The service type and version of the website.
WAF Recognition	Specifies whether the asset is identified by WAF.
Open Source Framework	The open source framework type of the asset.
Device Type	The type of the device.
Time range	The time range during which assets are imported.
Key information	The crucial information of the asset. The crucial information includes the website, domain name, IP address, title, and tag.

ii. Click **Export** to export the asset list to an Excel file.

iii. Select one or more websites that you want to manage. The following table describes the operations that you can perform on websites.

Action	Description
Batch Web Monitoring	Allows you to enable or disable web monitoring for multiple websites. ■ **Batch Open Monitoring**: To enable web monitoring for multiple websites, select Batch Open Monitoring from the drop-down list of Batch Web Monitoring. ■ **Batch Stop Monitoring**: To disable web monitoring for multiple websites, select Batch Stop Monitoring from the drop-down list of Batch Web Monitoring
Change Group	Allows you to change the asset group of multiple assets at a time.
Change Person in charge	Allows you to change the owner of multiple assets at a time.
Batch Delete	Allows you to delete multiple assets at a time. After the assets are deleted, the assets are not scanned by the vulnerability scan feature.

6. Click the **Host Asset** tab and manage the hosts.

i. Specify filter conditions to search for specific hosts.

The filter feature allows you to search for the required hosts in a more efficient manner.

Filter condition	Description
Asset Type	The asset type, such as Internet assets or a specific VPC.
Asset Source	The source from which the asset is imported. Valid values: **Manual** and **System Find**.
Asset Group	The group to which the asset belongs.
Person in charge	The owner of the asset.
Asset Change	The change status of the asset. Valid values: **All**, **New**, **Update**, **No Update**, and **Offline**.
Risk Level	The risk level of the asset. Valid values: **All**, **High**, **Middle**, **Low**, and **Security**.
SurviveStatus	The status of the asset. Valid values: **Alive** and **Close**.
Operation System	The operating system of the host.
Host Port	The port of the host.
CDN Recognition	Specifies whether Content Delivery Network (CDN) is configured for the asset.
Host Service	The service of the host.
Time range	The time range during which assets are imported.
Key information	The crucial information of the asset. The crucial information includes the IP address, host, tag, and domain name.

ii. Click **Export** to export the asset list to an Excel file.

iii. Select one or more hosts that you want to manage. The following table describes the operations that you can perform on hosts.

Action	Description
Change Group	Allows you to change the asset group of multiple assets at a time.
Change Person in charge	Allows you to change the owner of multiple assets at a time.
Batch Delete	Allows you to delete multiple assets at a time. After the assets are deleted, the assets are not scanned by the vulnerability scan feature.

21.4.8.3.4. Manage asset availability

This topic describes how to manage the availability of assets.

Context

If hosts or websites are used for a long period of time, they may become unavailable due to errors. Availability monitoring allows a security administrator to discover unavailable assets. Then, the security administrator can troubleshoot the issues that cause the assets to become unavailable.

Availability monitoring supports the following methods:

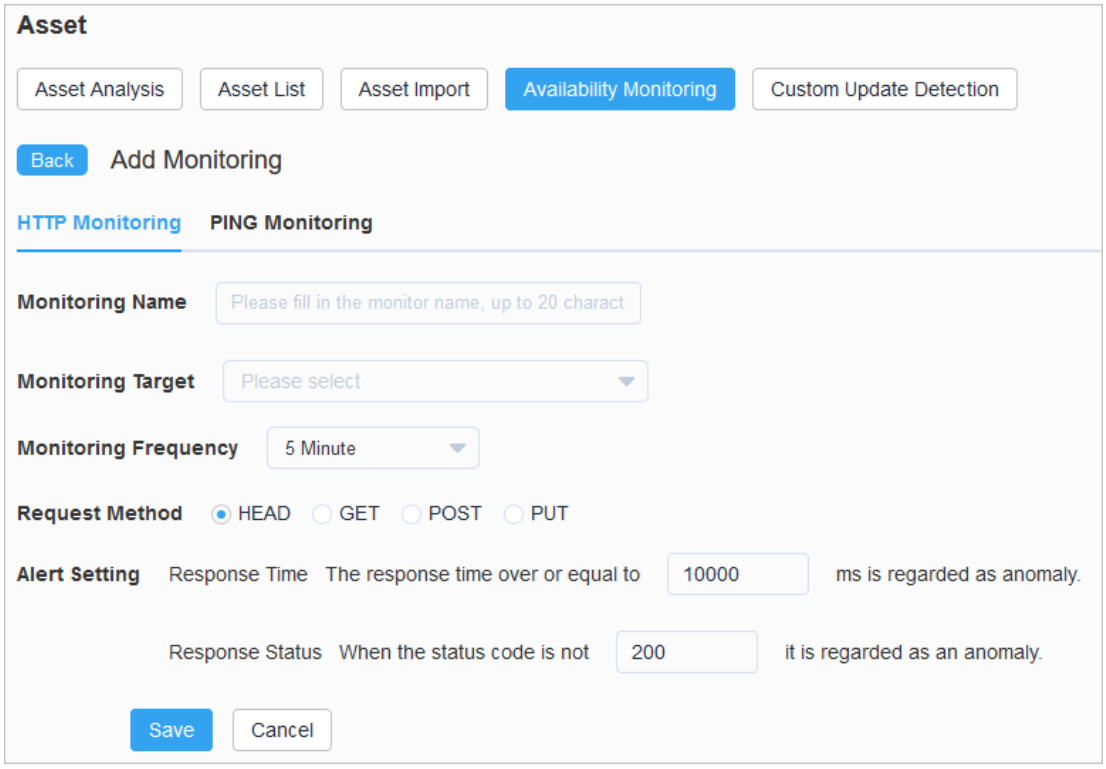
- HTTP monitoring: This method is used to monitor websites.
- PING monitoring: This method is used to monitor hosts.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan**.
3. In the **Vulnerability Scan** pane, click **Asset**.
4. On the **Asset** page, click the **Availability Monitoring** tab to view availability monitoring tasks.
5. Create an availability monitoring task.

   Availability monitoring supports HTTP monitoring and PING monitoring.

   - To create an HTTP monitoring task, perform the following steps:
     a. Click **Add Monitoring**.
     b. Click the **HTTP Monitoring** tab.

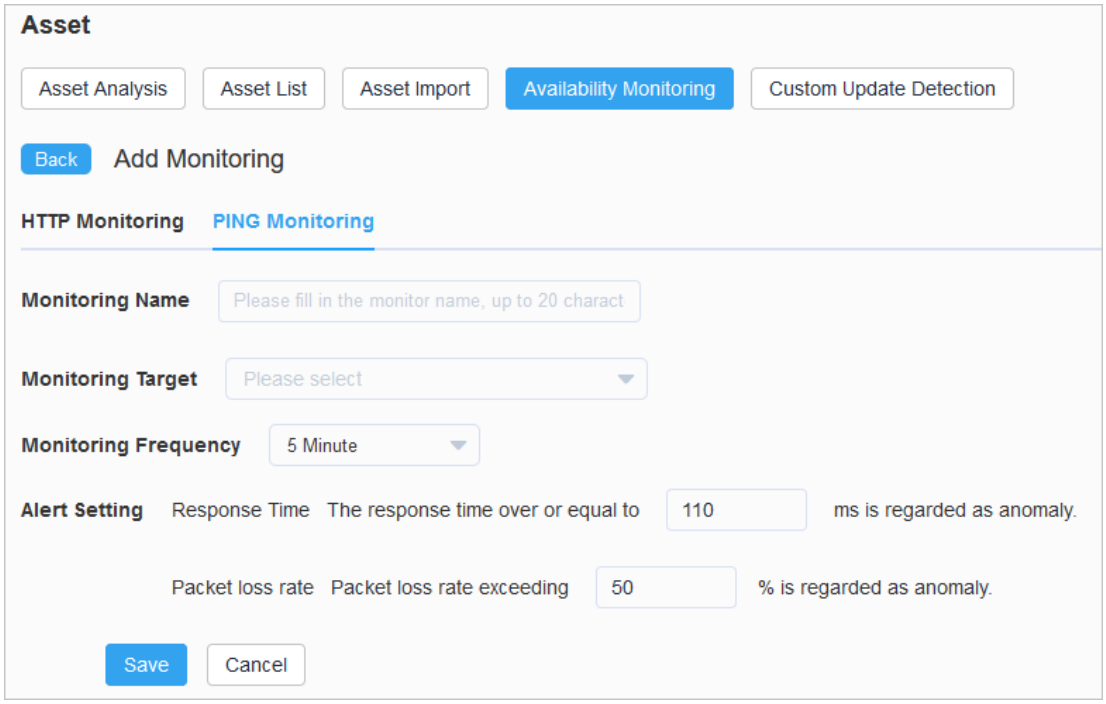


c. Configure the following parameters.

Parameter	Description
Monitoring Name	The name of the availability monitoring task.
Monitoring Target	The website that you want to monitor.
Monitoring Frequency	The interval at which you want to monitor the website. Valid values: **1 Minute**, **5 Minute**, **15 Minute**, and **30 Minute**.
Request Method	The request method that is used to send HTTP request packets. Valid values: **HEAD**, **GET**, **POST**, and **PUT**.
Alert Setting	The policy based on which Apsara Stack Security reports alerts. If one of the following conditions is met, the website is unavailable: ■ Response Time: If the actual response time is greater than the specified value, an exception occurs. ■ Response Status: If an unexpected status code is returned, an exception occurs.

d. Click **Save**.

- To create a PING monitoring task, perform the following steps:
  a. Click **Add Monitoring**.
  b. Click the **PING Monitoring** tab.



c. Configure the following parameters.

Parameter	Description
Monitoring Name	The name of the availability monitoring task.
Monitoring Target	The host that you want to monitor.
Monitoring Frequency	The interval at which you want to monitor the host. Valid values: **1 Minute**, **5 Minute**, **15 Minute**, and **30 Minute**.
Alert Setting	The policy based on which Apsara Stack Security reports alerts. If one of the following conditions is met, the host is unavailable: ■ Response Time: If the actual response time is greater than the specified value, an exception occurs. ■ Response Status: If an unexpected status code is returned, an exception occurs.

d. Click **Save**.

6. Manage more than one availability monitoring task at a time.

   You can manage more than one availability monitoring task in the monitoring task list at a time.

   - Start more than one availability monitoring task at a time

     Select more than one availability monitoring task and choose **Batch Monitoring Manage > Batch Open Monitoring**.

   - Stop more than one availability monitoring task at a time

     Select more than one availability monitoring task and choose **Batch Monitoring Manage > Batch Stop Monitoring**.

   - Delete more than one availability monitoring task at a time

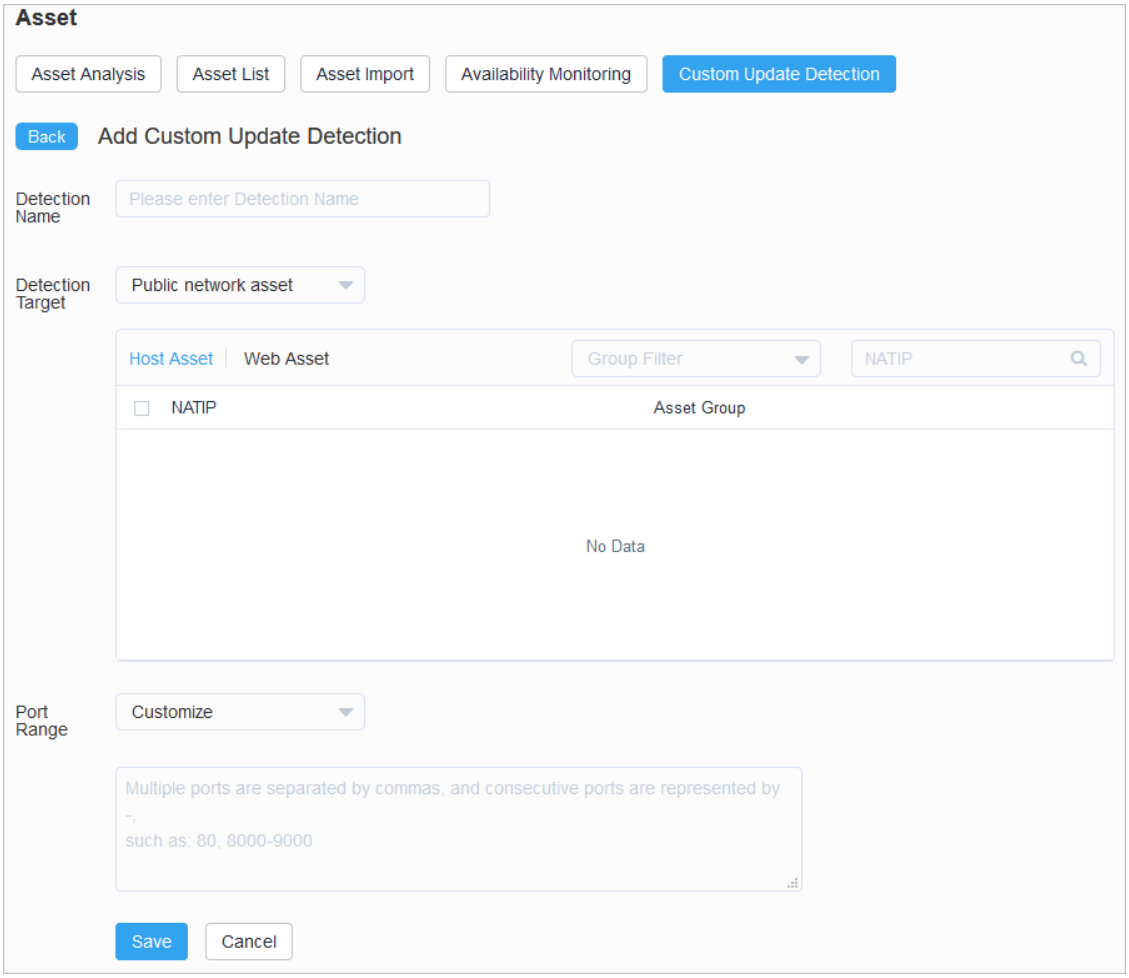
     Select more than one availability monitoring task and choose **Batch Monitoring Manage > Batch Delete Monitoring**.

21.4.8.3.5. Manage custom update detection tasks

This topic describes how to manage custom update detection tasks.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan**.
3. In the **Vulnerability Scan** pane, click **Asset**.
4. On the **Asset** page, click **Custom Update Detection** to view custom update detection tasks.
5. Create a custom update detection task.
   i. Click **Add Detection**.
   ii. On the **Add Custom Update Detection** page, configure the parameters.



Parameter	Description
Detection Name	The name of the custom update detection task.
Detection Target	The asset that you want to detect. The value is fixed as **Public network asset**. a. Click **Host Asset** or **Website Asset** based on your business requirements. b. Select the assets that you want to detect from the asset list. **Note** You can search for assets by **Asset Group** or **IP**.
Port Range	The range of ports that you want to detect. Valid values: **Customize**, **Full Port**, **Top100**, and **Top1000**. **Note** The **Port Range** parameter appears only after you set the **Detection Target** parameter to Host Asset. ■ **Customize**: You can specify custom ports to detect. ■ **Full Port**: All ports are detected. ■ **Top 100**: Top 100 ports are detected. ■ **Top 1000**: Top 1000 ports are detected.

iii. Click **Save**.

21.4.8.4. Risk management

21.4.8.4.1. Manage vulnerabilities

This topic describes how to view and handle the vulnerabilities that are detected by the vulnerability scan feature.

Context

On the **Security Vulnerability** tab, security administrators can view the vulnerabilities that are detected by the vulnerability scan feature.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan**.
3. In the **Vulnerability Scan** pane, click **Risk**.
4. On the **Risk** page, click the **Security Vulnerability** tab to view vulnerabilities.

   - Click the **Disclosured** or **Resolved** tab to view unfixed vulnerabilities or fixed vulnerabilities.
   - View risk statistics. The statistics include **Unfixed Risks**, **Recovered Risks**, **Unconfirmed Risks**, **Confirmed Risks**, and **Ignored Risks**.
5. Specify search conditions to view specific vulnerabilities. The conditions include **Asset Type** and **Risk Level**.
6. Handle vulnerabilities.

   Security administrators can analyze and confirm whether the vulnerabilities affect the security of assets based on the vulnerability information.

   - Confirm risks

     If a vulnerability affects the security of assets, confirm the risk after the security vulnerability is fixed.

     a. Find the vulnerability and click the icon in the **Operation** column.

     b. In the drop-down list, select **Confirm Risk**.

     c. In the dialog box that appears, click **OK**.
   - Ignore risks

     If a vulnerability is a false positive or does not affect the security of assets, ignore the risk.

a. Find the vulnerability and click the icon in the **Operation** column.

b. In the drop-down list, select **Ignore Risk**.

c. In the dialog box that appears, click **OK**.

7. Click **Export** to export the list of vulnerabilities to your computer.

21.4.8.4.2. Manage host compliance risks

This topic describes how to view and confirm host compliance risks.

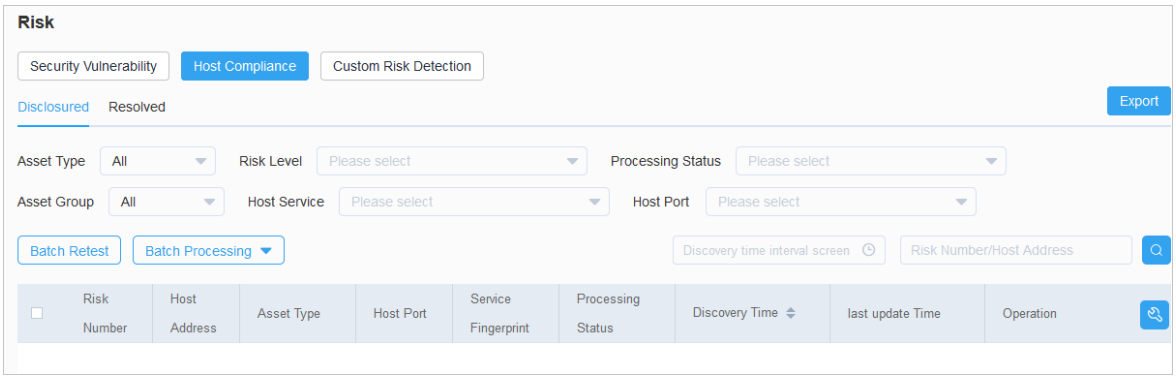
Context

On the **Host Compliance** tab, security administrators can view the host compliance issues that are detected by the vulnerability scan feature.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan**.
3. In the **Vulnerability Scan** pane, click **Risk**.
4. On the **Risk** page, click the **Host Compliance** tab to view host compliance risks.

   You can click the **Disclosured** or **Resolved** tab to view **unfixed vulnerabilities** or **fixed vulnerabilities**.



5. Specify conditions to search for host compliance risks based on the conditions. The conditions include **Asset Type** and **Risk Level**.
6. Handle host compliance risks.

   Security administrators can analyze and confirm whether host compliance risks affect the security of assets based on the risk information.

   - Confirm risks

     If a host compliance risk affects the security of assets, harden the security of hosts and confirm the risk.

     a. Find the required risk and click the icon in the **Actions** column.

     b. In the drop-down list, select **Confirm Risk**.

     c. In the message that appears, click **OK**.

   - Ignore risks

     If a host compliance risk proves to be a false positive or does not affect the security of assets, ignore the risk.

     a. Find the required risk and click the icon in the **Actions** column.

b. In the drop-down list, select **Ignore Risk**.

c. In the message that appears, click **OK**.

7. Click **Export** to export the list of host compliance risks to your computer.

21.4.8.4.3. Manage external risks

This topic describes how to view and identify external risks, such as code leaks.

Prerequisites

A GitHub account is available, and the tokens of the account are obtained.

Context

On the **External Risk** page, security administrators can use the vulnerability scan feature to check whether the GitHub library has risks of code leaks.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Risk > External Risk**.
3. Click the **Code Disclosure** tab.
4. Add the assets that you want to monitor.
   i. In the **Asset Monitoring List** section, click **Token setting**.
   ii. In the **Enter GitHub Token** dialog box, enter the tokens.

   You can enter multiple tokens. Press Enter each time you enter a token.
   iii. Click **Add Asset** and select the external assets that you want to monitor.
5. View the assets that have risks of code leaks.

   You can view the unfixed and fixed risks on the **Resolved** and **Disclosured** tabs.
6. Handle the risks of code leaks.

   Security administrators can analyze and check whether the security of the assets is affected based on the risk information.
   - Confirm risks

     If the risks of code leaks affect the security of your assets, harden the hosts and confirm the risks.
   - Ignore risks

     If the risks of code leaks prove to be false positives or do not affect the security of your assets, ignore the risks.

21.4.8.4.4. Create a custom risk detection task

This topic describes how to create a custom risk detection task.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan**.
3. In the **Vulnerability Scan** pane, click **Risk**. On the Risk page, click the **Custom Risk Detection** tab.
4. On the Custom Risk Detection tab, click **Add Detection**.
5. On the **Add Custom Risk Detection** page, configure the parameters.

Parameter	Description
Detection Name	The name of the custom risk detection task.
Detection Target	The asset on which you want to perform risk detection. The value is fixed as **Public network asset**.
Emergency Detection	The switch that is used to enable or disable the emergency detection feature. If you enable this feature, you can select emergency detection items from the detection item list.
Basic Risk Detection	The switch that is used to enable or disable the basic risk detection feature. For more information about how to configure this feature, see Configure basic monitoring.
WEB Risk Detection	The switch that is used to enable or disable the web risk detection feature. For more information about how to configure this feature, seeConfigure web monitoring.

6. Click **Save**.

21.4.8.5. Report management

21.4.8.5.1. Create a report

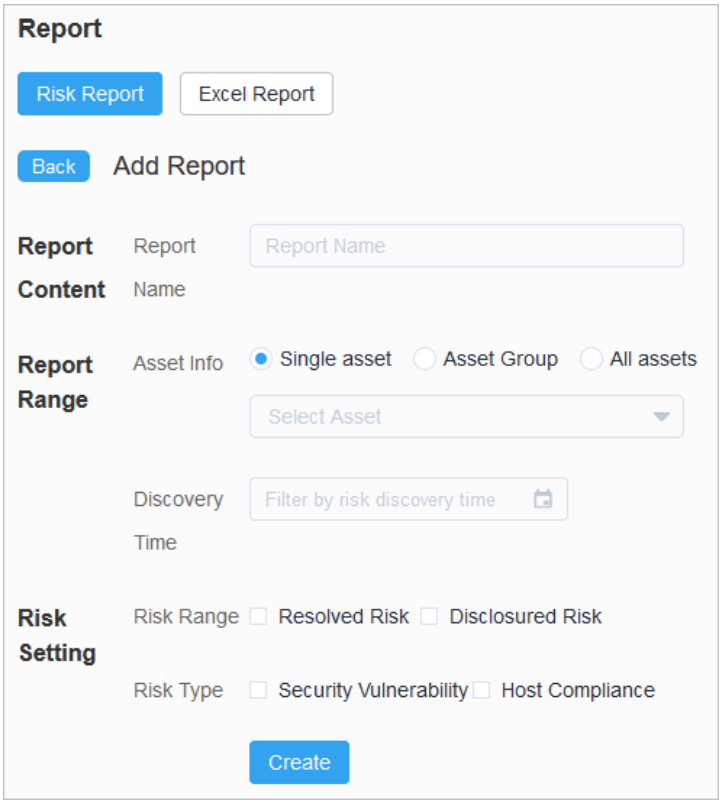
This topic describes how to create a report.

Context

A security administrator can create a report to view the security statuses of specific assets during a period of time and implement security measures as required.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Report**.
3. On the Report page, click the **Risk Report** tab and then the **Add Report** tab.
4. Configure the following parameters.



Parameter		Description
Report Content	**Report Name**	The name of the report that you want to create.
Report Range	**Asset Info**	The scope of assets that you want to include in the report. Valid values: **Single asset**, **Asset Group**, and **All assets**. ○ **Single asset**: Select an asset. ○ **Asset Group**: Select an asset group and a tag. **Note** After you select an asset group and a tag, the assets in the group that have the selected tag are included in the report. ○ **All assets**: Select assets by tag.
	Discovery Time	The time range in which you want to perform risk detection.
Risk Setting	**Risk Range**	The scope of risks that you want to include in the report. Valid values: **Resolved Risk** and **Disclosured Risk**.
	Risk Type	The types of risks that you want to include in the report. Valid values: **Security Vulnerability** and **Host Compliance**.

5. Click **Create**.

Result

After the report is created, it appears in the report list on the **Report** page.

21.4.8.5.2. Delete multiple reports at a time

This topic describes how to delete multiple reports at a time.

Context

You can delete multiple reports that are no longer required at a time to save storage space.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Report**.
3. Click **Risk Report**.
4. In the report list, select the reports that you want to delete.
5. Click **Batch Delete**.

21.4.8.6. Configuration management

21.4.8.6.1. Configure overall monitoring

This topic describes how to configure overall monitoring for the vulnerability scan feature. Overall monitoring includes Asset Monitoring Configuration, Base Risk Monitoring Configuration, External Risk Monitoring Configuration, and Scan Configuration.

Context

Overall monitoring allows you to configure detection features and the monitoring cycle for each detection feature.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Configuration > Monitoring Configuration > Overall Monitoring**.
3. In the **Monitoring Status** section, view the status of overall monitoring.
4. Configure detection features.

   Detection features include **Asset Monitoring Configuration**, **Base Risk Monitoring Configuration**, **External Risk Monitoring Configuration**, and **Scan Configuration**.

   In this step, the **Asset Monitoring Configuration** detection feature is used as an example.

   i. Turn on Asset Monitoring Configuration to enable the asset monitoring feature.

   - After the switch is turned on, the switch is in the **On** state. When in the On state, the switch is blue. After the switch is turned off, the switch is in the **Off** state. When in the Off state, the switch is gray.
   - You must turn on **Asset Monitoring Configuration** and **Base Risk Monitoring Configuration** to enable the two features. External Risk Monitoring Configuration and Scan Configuration are automatically enabled.

   ii. Configure the following parameters.

   Asset Monitoring Configuration

Parameter	Description

Parameter	Description
Monitoring Item	The item that you want to monitor. Valid value: **Subdomain Discovery**. If you want to import assets, you can set the Import Set parameter to **Auto Import subdomains**. Then, subdomains are automatically imported. If you select **Subdomain Discovery**, Apsara Stack Security regularly discovers subdomains for assets whose Import Set parameter is set to **Auto Import subdomains**.
Monitoring Cycle	The cycle based on which you want to perform detection. Valid values: **customization**, **per week**, and **per month**. ■ **customization**: Specify the interval at which you want to perform detection. Unit: days. ■ **per week**: Specify the days of each week on which you want to perform detection. ■ **per month**: Specify the days of each month on which you want to perform detection.
Detection Time	The time when you want to perform detection. The time varies based on the value of the **Monitoring Cycle** parameter. ■ If you set the **Monitoring Cycle** parameter to **customization**, select a time range of the day in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **per week**, select the days of each week and the time range in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **per month**, select the days of each month and the time range in which you want to perform detection. **Note** For example, if you set the **Monitoring Cycle** parameter to **per week** and select **Monday** to **Sunday** and 00:00:00 to 24:00:00 for the **Detection Time** parameter, Apsara Stack Security performs detection 24 hours a day, 7 days a week.
Port Range	The ports on which you want to perform detection. Valid values: **customization**, **Full port**, **TOP100**, and **TOP1000**. ■ **customization**: Specify the ports to scan. ■ **Full port**: Scan all ports. ■ **TOP100**: Scan top 100 ports. You can click **Add** to add more ports. ■ **TOP1000**: Scan top 1,000 ports. You can click **Add** to add more ports.
Host Alive Detection Settings	The option that is used to check whether a host is running. By default, the ping feature is used to check whether a host is running. If the host has the ping feature disabled, the status of the host is detected based on top 20 ports and custom ports. To specify custom ports, click **Settings**. In the Host Alive Detection Settings dialog box, specify the ports in the **Custom Port** field.

Base Risk Monitoring Configuration

Parameter	Description
Monitoring Item	The item that you want to monitor. Valid values: **Weak Password**, **Common Vulnerabilities**, **Baseline Monitoring**, and **Host Compliance**. ■ **Weak Password**: Attackers can guess passwords or launch brute-force attacks to crack passwords. Then, the attackers can obtain relevant permissions. If you select this item, weak password vulnerabilities can be identified. ■ **Common Vulnerabilities**: Web security vulnerabilities and CMS application vulnerabilities are included. If you select this item, common vulnerabilities can be identified. Then, you can install patches at the earliest opportunity. ■ **Baseline Monitoring**: Risks in host configuration and account configuration are detected. ■ **Host Compliance**: Host compliance risks are detected.
Monitoring Cycle	The cycle based on which you want to perform detection. Valid values: **customization**, **per week**, and **per month**. ■ **customization**: Specify the interval at which you want to perform detection. Unit: days. ■ **per week**: Specify the days of each week on which you want to perform detection. ■ **per month**: Specify the days of each month on which you want to perform detection.
Detection Time	The time when you want to perform detection. The time varies based on the value of the **Monitoring Cycle** parameter. ■ If you set the **Monitoring Cycle** parameter to **customization**, select a time range of the day in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **per week**, select the days of each week and the time range in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **per month**, select the days of each month and the time range in which you want to perform detection. **Note** For example, if you set the **Monitoring Cycle** parameter to **per week** and select **Monday** to **Sunday** and 00:00:00 to 24:00:00 for the **Detection Time** parameter, Apsara Stack Security performs detection 24 hours a day, 7 days a week.

External Risk Monitoring Configuration

Parameter	Description
Monitoring Item	The item that you want to monitor. Valid value: **Code Disclosure**. If you select Code Disclosure, Apsara Stack Security detects leaked source code of your assets.

Parameter	Description
Monitoring Cycle	The cycle based on which you want to perform detection. Valid values: **customization**, **per week**, and **per month**. ■ **customization**: Specify the interval at which you want to perform detection. Unit: days. ■ **per week**: Specify the days of each week on which you want to perform detection. ■ **per month**: Specify the days of each month on which you want to perform detection.
Detection Time	The time when you want to perform detection. The time varies based on the value of the **Monitoring Cycle** parameter. ■ If you set the **Monitoring Cycle** parameter to **customization**, select a time range of the day in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **per week**, select the days of each week and the time range in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **per month**, select the days of each month and the time range in which you want to perform detection. **Note** For example, if you set the **Monitoring Cycle** parameter to **per week** and select **Monday** to **Sunday** and 00:00:00 to 24:00:00 for the **Detection Time** parameter, Apsara Stack Security performs detection 24 hours a day, 7 days a week.

Scan Configuration

Parameter	Description
Risk Re-detection	The time at which you want to perform detection again. If risks are detected in specific assets, Apsara Stack Security scans the assets again each day at the time you specify.
Asset Scanning Rate	The scan rate. Valid values: **Slow Mode**, **General Mode**, **Fast Mode**, and **Turbo Mode**.
Risk Scanning Rate	The scan rate. Valid values: **Slow Mode**, **General Mode**, **Fast Mode**, and **Turbo Mode**.
UserAgent Setting	The User-Agent property.

iii. Click **Save**.

21.4.8.6.2. Configure basic monitoring

This topic describes how to configure basic monitoring.

Context

Basic monitoring includes Weak Password Vulnerability Monitoring, Operation Security Vulnerability Monitoring, CMS Application Vulnerability Monitoring, and Baseline Monitoring.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan**.
3. In the **Vulnerability Scan** pane, click **Configuration**.
4. On the **Configuration** page, click the **Monitoring Configuration** tab.
5. On the **Basic Monitoring** tab of the Monitoring Configuration tab, click **Weak Password Vulnerability Monitoring** to configure rules to monitor weak passwords.
   - By default, all monitoring items on weak passwords use the default weak password library.
   - To disable a monitoring item, perform the following step:

     Find the required metric and click the icon in the **Operation** column.
   - To enable a monitoring item, perform the following step:

     Find the required monitoring item and click the icon in the **Operation** column.
   - To specify custom weak passwords for a monitoring item, perform the following steps. In this example, **MySQL Weak Password Vulnerability** is used.
     a. In the **Default Weak Password** column, turn off the switch. The switch status changes to .
     b. In the **Operation** column, click the icon.
     c. In the **Customize MySQL Weak Password** dialog box, specify custom weak passwords.
     d. Click **Yes**.
   - To apply the same custom weak passwords to multiple monitoring items, perform the following steps:
     a. In the **Default Weak Password** column, turn off the switches for the monitoring items that you want to apply the same custom weak passwords. The switch status changes to .

        Note If you want to apply a custom weak password to a monitoring item, you must turn off the switch in the Default Weak Password column of the monitoring item.
     b. Click **Tailored Overall Weak Password**.
     c. In the **Tailored Overall Weak Password** dialog box, specify custom weak passwords.
     d. Click **Yes**.
6. Click **Operation Security Vulnerability Monitoring** and configure O&M security vulnerability monitoring.

No.	Description
1	The switch that is used to enable or disable the **Operation Security Vulnerability Monitoring** feature. We recommend that you enable this feature to enhance system security.
2	The switch that is used to enable or disable a monitoring item. You can disable monitoring items based on your business requirements.

7. Click **CMS Application Vulnerability Monitoring** and configure monitoring on content management system (CMS) application vulnerabilities.

No.	Description

No.	Description
1	The switch that is used to enable or disable the **CMS Application Vulnerability Monitoring** feature. We recommend that you enable this feature to enhance system security.
2	The switch that is used to enable or disable a monitoring item. You can disable monitoring items based on your business requirements.

8. Click **Baseline Monitoring** and configure baseline monitoring.

   To add a baseline monitoring item, perform the following steps:

   i. Click **Add**.

   ii. In the **Add Baseline** dialog box, configure the baseline monitoring item.

   In this example, a baseline monitoring item is added to block Telnet-based access.

Parameter	Description
Baseline Name	The name of the baseline monitoring item. Example: Block Telnet-based access.
Baseline Rule	The detection rule that is used by the baseline monitoring item. This rule checks whether hosts use disabled ports or run disabled services. Valid values: ■ **Port Disabled**: ports that you want to disable. Example: 23. ■ **Service Disabled**: services that you want to disable. Example: Telnet.
Baseline Range	The scope of assets to which the baseline monitoring item can be applied. Valid values: **Private IP** and **NatIP**. You must specify this parameter and select specific assets.

   iii. Click **OK**.

21.4.8.6.3. Configure web monitoring

This topic describes how to configure web monitoring.

Context

Web monitoring allows you to configure monitoring items for monitoring web vulnerabilities. You can also configure conditions to block website crawlers.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan**.
3. In the **Vulnerability Scan** pane, click **Configuration**.
4. On the Configuration page, click the **Monitoring Configuration** tab and then the **Web Monitoring** tab to view existing rules.

   > **Note** **Default rules** are created by the system. You can only view details of the default rules, but cannot modify or delete them.

5. Create a web monitoring rule.

i. Click **Add Rule**.

ii. On the **Add Web Monitoring Rule** page, configure the following parameters.

Parameter	Description
Rule Name	The name of the web monitoring rule.
Monitoring Cycle	The monitoring cycle. Valid values: **Customization**, **Per Week**, and **Per Month**. ■ **Customization**: Specify the interval at which you want to perform detection. ■ **Per Week**: Specify the days of each week on which you want to perform detection. ■ **Per Month**: Specify the days of each month on which you want to perform detection.
Detection Time	The time when you want to perform detection. The time varies based on the value of the **Monitoring Cycle** parameter. ■ If you set the **Monitoring Cycle** parameter to **Customization**, select a time range of the day in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **Per Week**, select the days of each week and the time range in which you want to perform detection. ■ If you set the **Monitoring Cycle** parameter to **Per Month**, select the days of each month and the time range in which you want to perform detection. **Note** For example, if you set the **Monitoring Cycle** parameter to **Per Week** and select **Monday** to **Sunday** and 00:00:00 to 24:00:00 for the **Detection Time** parameter, Apsara Stack Security performs detection 24 hours a day, 7 days a week.
Monitoring Options	The type of web vulnerabilities that you want to monitor. Supported operations: **Select All**, **Inverse**, and **Clear**.
UserAgent	The User-Agent field of the HTTP request packet. The User-Agent field identifies the application type, operating system, software developer, and version number of the proxy software that initiates requests.
Cookies	The cookie parameters.
Key Page	The web directories or pages that you want to monitor.
Excluded Page	The web directories or pages that you do not want to monitor.
Crawler Depth	The capturing depth of crawlers. Valid values: **10**, **15**, and **30**.
URL Numbers	The number of URLs that are used for crawling. Valid values: **500**, **1000**, and **2000**.
scanning Frequency	The scan frequency of web monitoring. Valid values: **Request 10 Times Per Second** and **Request 15 Times Per Second**.

iii. Click **Yes**.

6. Manage the web monitoring rule.

Icon	Description
	Modify the rule.
	Delete the rule.
Batch Delete	If you want to delete multiple rules, select the rules you want to delete and click **Batch Delete**.

21.4.8.6.4. Configure a whitelist

This topic describes how to configure a whitelist.

Context

Apsara Stack Security does not scan the assets that are added to a whitelist. Before you add assets to a whitelist, make sure that the assets are secure.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan**.
3. In the **Vulnerability Scan** pane, click **Configuration**.
4. On the Configuration page, click the **Monitoring Configuration** tab and then the **Whitelist** tab to view the assets that are added to a whitelist.

   > **Note** By default, the whitelist feature is enabled. If you do not want to use the whitelist feature, turn off the switch in the upper-right corner.

5. Add assets to a whitelist.
   i. Click **Add**.
   ii. In the **Add Whitelist** dialog box, configure the parameters.
   - If you select **Asset Group** for the **Whitelist** parameter, select a group from the second drop-down list. The assets in this group are added to the whitelist.
   - If you select **Customization** for the **Whitelist** parameter, enter the IP addresses or URLs that you want to add to the whitelist in the field that appears.

   iii. Click **Yes**.
6. Manage the assets that are added to a whitelist.
   - Delete an asset from a whitelist

     Find the required asset and click the  icon in the **Operation** column.
   - Remove multiple assets from a whitelist at a time

     Select the required assets and click **Batch Delete**.

21.4.8.6.5. Configure a scan engine for internal assets

This topic describes how to configure a scan engine for internal assets, such as the assets of a virtual private cloud (VPC).

Context

You must add a scan engine for a VPC before you can scan for vulnerabilities on the assets of the VPC.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Vulnerability Scan > Configuration**. On the page that appears, click the **Scan Engine Manage** tab. Then, click the **Private-sector assets** tab.
3. Click the name of the VPC whose assets you want to scan.
4. Click **Add Scan Engine**.
5. In the **Add Scan Engine** dialog box, select a vSwitch for the VPC from the **vSwitch** drop-down list.
6. Click **OK**.

21.4.9. Create a security report

Security reports help monitor the security status of your assets. You can specify the content, types of statistics, and email addresses of recipients to create a security report. This topic describes how to create a security report.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Threat Detection > Security Reports**.
3. On the **Reports** page, click **Create Report**.

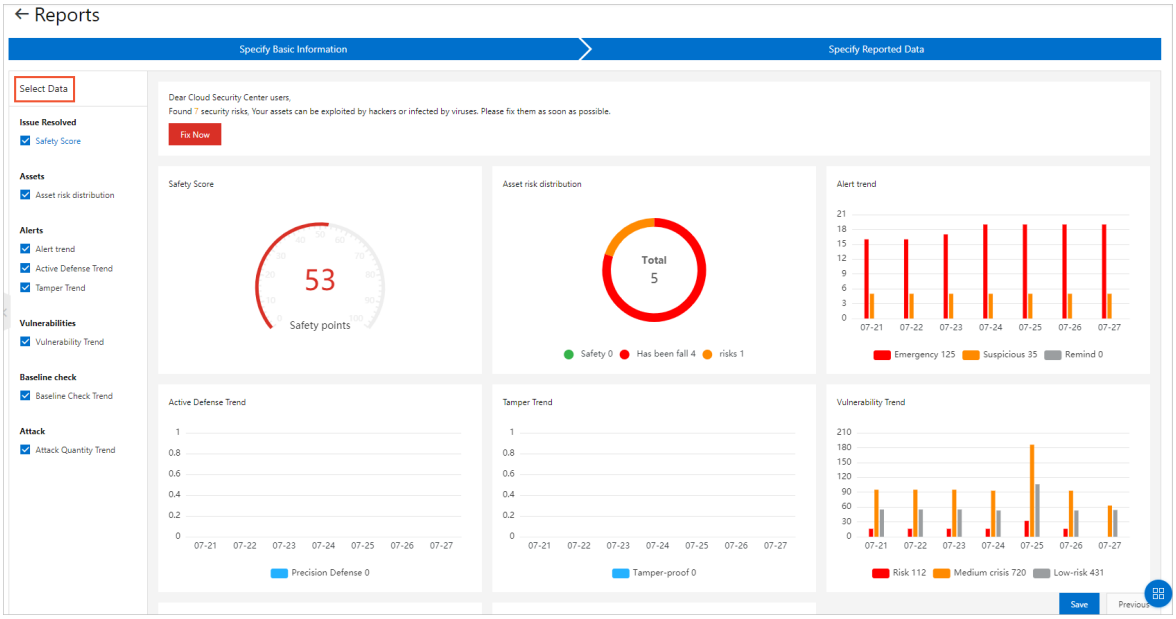
   > **Notice** In addition to the default security report created by Apsara Stack Security, you can create a maximum of nine security reports.

4. In the **Specify Basic Information** step, configure the parameters.

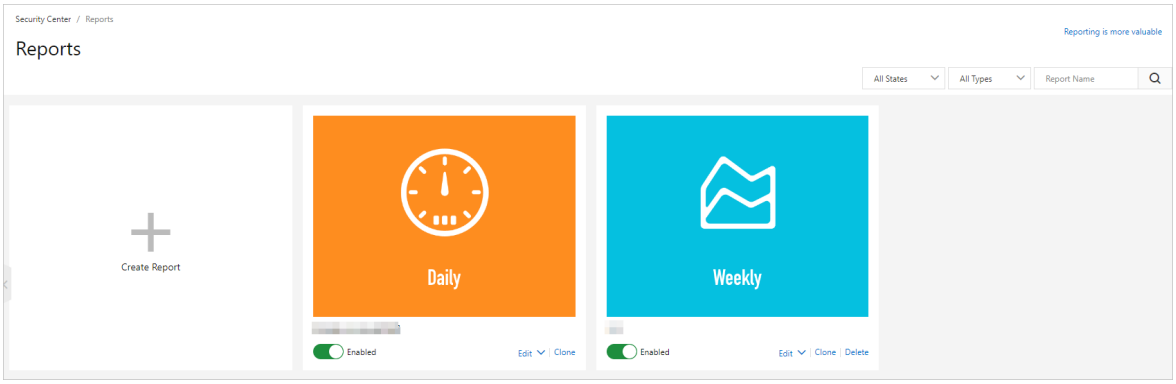
   Configure the following parameters:

   - **Report Name**: Enter a name for the security report.
   - **Report Type**: Select a report type from the drop-down list. Valid values: *Daily*, *Weekly*, *Monthly*, and *Custom*.

     If you select *Custom*, you must also set the **Data Collection Period** parameter to specify the cycle on which data is collected.
   - **Language**: Select a natural language for the report. Valid values: **简体中文** and **English**.
5. Click **Next**.
6. In the **Specify Reported Data** step, select the types of data that you want to view in the security report. You can select assets, alerts, vulnerabilities, baselines, attacks, and other data related to security operations.



7. Click **Save**. The security report is created.
   You can view the newly created security report on the **Reports** page.

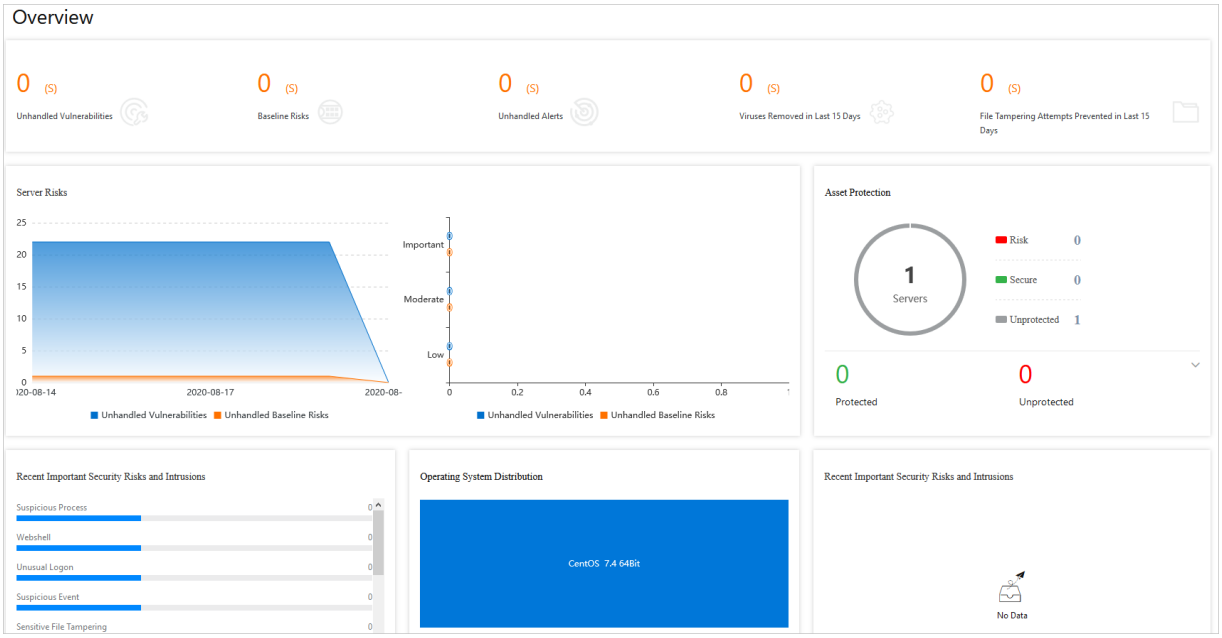


21.5. Server security

21.5.1. Server security overview

This topic describes how to view the details about the security of servers on the server security overview page of Apsara Stack Security Center. This helps security administrators understand the security status of the servers. The servers refer to servers on the cloud.

To view the details about the security of servers, log on to Apsara Stack Security Center and choose **Server Security > Overview**. On the page that appears, you can view detailed information on the following sections: overall statistics, Server Risks, Asset Protection, Operating System Distribution, and Recent Important Security Risks and Intrusions.



- **Overall statistics**: This section displays the numbers of security vulnerabilities and security events on servers. For security vulnerabilities, you can view **Unhandled Vulnerabilities** and **Baseline Risks**. For security events, you can view **Unhandled Alerts**, **Viruses Removed in Last 15 Days**, and **File Tampering Attempts Prevented in Last 15 Days**.
- **Server Risks**: This section displays the number of unhandled vulnerabilities, the number of baseline risks, and the distribution of risk levels.
- **Asset Protection**: This section displays the number of protected servers and the number of offline servers.
- **Recent Important Security Risks and Intrusions**: This section displays the recent important risks and events on your servers. You can click a risk or an event to view the details.
- **Operating System Distribution**: This section displays your servers by operating system.

21.5.2. Server fingerprints

21.5.2.1. Manage listening ports

This topic describes how to view the information about the listening port of a server. The information helps you identify suspicious listening behavior.

Context

This topic is suitable for the following scenarios:

- Check for servers that listen on a specific port.
- Check for ports that a specific server listens.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**.
3. On the **Asset Fingerprints** page, click the **Port** tab to view **listening ports**, **network protocols**, and server information.

You can search for a port by using the port number, server process name, server name, or server IP address.

In the server information list, you can view the **process**, **IP address**, and **latest scan time** of a server.

21.5.2.2. Manage software versions

This topic describes how to regularly view and collect the software version information about a server. This helps you check your software assets.

Context

This topic covers the following scenarios:

- Check for software assets that are installed without authorization.
- Check for outdated versions of software assets.
- Locate affected assets if vulnerabilities are detected.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Software** tab.
3. View all the **software assets** that are in use and the **numbers of servers** that use the software assets.

   You can search for specific software by using its name, version, installation directory, server name, or IP address.
4. Click software to view the details, such as the software versions and the servers that use the software.

   You can click the icon in the upper-right corner to download a software version table to your computer for subsequent asset check.

21.5.2.3. Manage processes

This topic describes how to regularly collect the process information on a server and record changes. This way, you can view process information and historical process changes.

Context

This task is suitable for the following scenarios:

- Check for servers on which a specific process runs.
- Check for processes that run on a specific server.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Process** tab.
3. View all running processes and the numbers of servers on which these processes run.

   You can search for a process by using the **process name**, **running user**, **startup parameter**, or **server name or IP address**.
4. Click the name of a process to view the details of the process, such as the servers, paths, and startup parameters.

21.5.2.4. Manage account information

This topic describes how to regularly collect the account information on a server and record changes to the accounts. This way, you can check your accounts and view historical changes to your accounts.

Context

You can use the information collected in this topic for the following scenarios:

- Check for servers on which a specific account is created.
- Check for accounts that are created on a server.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Account** tab.
3. View all the logged-on accounts and the numbers of servers on which the accounts are created.

   You can search for an account by using the account name, root permissions, server name, or IP address.
4. Click an account name to view the details, such as the server information, root permissions, and user group.

21.5.2.5. Manage scheduled tasks

This topic describes how to view scheduled tasks on servers.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. On the page that appears, click the **Scheduled Tasks** tab.
3. View the paths of all tasks and the numbers of servers that run these tasks.

   You can search for a task by using the path, server name, or IP address.
4. Click a task path to view the details, such as the servers, executed commands, and task cycles.

21.5.2.6. Set the fingerprint collection frequency

You can set the frequency at which the data of running processes, system accounts, listening ports, and software versions is collected.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Servers > Server Fingerprints**. In the upper-right corner of the page that appears, click **Settings**.
3. Select the collection frequency from each drop-down list.
4. Click **OK**.

21.5.3. Threat protection

21.5.3.1. Vulnerability management

21.5.3.1.1. Manage Linux vulnerabilities

This topic describes how to manage Linux vulnerabilities.

Context

Apsara Stack Security automatically scans the software that is installed on your servers to detect the vulnerabilities provided in the Common Vulnerabilities and Exposures (CVE) list. Apsara Stack Security also sends you alerts about the detected vulnerabilities. In addition, Apsara Stack Security provides commands that you can use to fix vulnerabilities and allows you to verify vulnerability fixes.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**. On the page that appears, click the **Linux Software** tab.
3. View the detected Linux vulnerabilities.

   > **Note** You can search for specific vulnerabilities by using the search and filter features.

4. Click a vulnerability. In the panel that appears, you can view details about the vulnerability and the servers that are affected by the vulnerability.

   > **Note** You can find affected servers by using the search and filter features.

   - **Detail**: This tab displays the basic information about the vulnerability, including the name, Common Vulnerability Scoring System (CVSS) score, and description.
   - **Pending vulnerability**: This tab displays the servers that are affected by the vulnerability.
5. Handle the vulnerability based on its impact.

   Actions on vulnerabilities

Action	Impact
Fix	Select this action to fix the vulnerability.
Ignore	Select this action to ignore the vulnerability. The system no longer reports alerts for ignored vulnerabilities.
Verify	Click **Verify** to verify the vulnerability fix. If you do not manually verify a fix, the system automatically verifies the fix within 48 hours after the vulnerability is fixed.

   You can manage a vulnerability for one or multiple affected servers at a time.

   - To manage a vulnerability for one affected server, find the server and select an action from the **Actions** column of the server.
   - To manage a vulnerability for multiple affected servers, select the servers and select an action in the lower-left corner.

21.5.3.1.2. Manage Windows vulnerabilities

This topic describes how to manage Window vulnerabilities.

Context

Apsara Stack Security automatically checks whether the latest Microsoft updates are installed on your servers, and notifies you of the detected vulnerabilities. Apsara Stack Security also automatically detects and fixes major vulnerabilities on your servers.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**. On the page that appears, click the **Windows System** tab.
3. View the detected Windows vulnerabilities.

   > **Note** You can search for specific vulnerabilities by using the search and filter features.

4. Click a vulnerability. In the panel that appears, you can view details about the vulnerability and the servers that are affected by the vulnerability.

   > **Note** You can find affected servers by using the search and filter features.

   - **Detail**: This tab displays the basic information about the vulnerability.
   - **Pending vulnerability**: This tab displays the servers that are affected by the vulnerability.
5. Handle the vulnerability based on its impact. Actions on vulnerabilities describes the actions.

   Actions on vulnerabilities

Action	Impact
Fix	Select this action to fix the vulnerability. The system caches an official Windows patch in the cloud. Your server can automatically download the patch for updates.
Ignore	Select this action to ignore the vulnerability. The system no longer reports alerts for ignored vulnerabilities.
Verify	Click **Verify** to verify the vulnerability fix.

   You can manage a vulnerability for one or multiple affected servers at a time.

   - To manage a vulnerability for one affected server, select an action from the **Actions** column of the server.
   - To manage a vulnerability for multiple affected servers, select the servers and select an action in the lower-left corner.

21.5.3.1.3. Manage Web CMS vulnerabilities

This topic describes how to manage Web CMS vulnerabilities.

Context

The Web CMS vulnerability detection feature obtains information about the latest vulnerabilities and provides patches in the cloud. This helps you detect and fix vulnerabilities.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**. On the page that appears, click the **Web CMS** tab.
3. View vulnerabilities.

   > **Note** You can search for specific vulnerabilities by using the search and filter features.

4. Click a vulnerability. In the panel that appears, you can view details about the vulnerability and servers that are affected by the vulnerability.

> **Note** You can find affected servers by using the search and filter features.

5. Handle the vulnerability based on its impact. Actions on vulnerabilities describes the actions.

   Actions on vulnerabilities

Action	Description
Fix	If you select this action, the system replaces the web files affected by the vulnerability on your server to fix the Web CMS vulnerability. **Note** Before you fix the vulnerability, we recommend that you back up the web files affected by the vulnerability. For more information about the paths of the web files, click Details in the Actions column.
Verify	After a vulnerability is fixed, you can click **Verify** to verify the fix. If you do not manually verify the fix of a vulnerability, the system automatically verifies the fix within 48 hours after the vulnerability is fixed.

   You can manage a vulnerability for one or more affected servers at a time.

   - To manage a vulnerability for one affected server, find the server and select an action in the **Actions** column of the asset.
   - To manage a vulnerability for multiple affected servers, select the servers and select an action in the lower-left corner.

21.5.3.1.4. Manage urgent vulnerabilities

This topic describes how to manage urgent vulnerabilities.

Context

Apsara Stack Security automatically detects vulnerabilities on servers, such as the unauthorized Redis access vulnerability and Struts S2-052 vulnerability, and generates vulnerability alerts. After you fix a vulnerability, you can also check whether the fix is successful.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**. On the page that appears, click the **Emergency** tab.
3. View all vulnerabilities.

   You can search for a specific vulnerability by using the search and filter features.
4. Click a vulnerability. In the panel that appears, view the details in the following sections: **Details**, **Suggestions**, and **Affected Assets**.

   You can find affected servers by using the search and filter features.
5. Handle the vulnerability based on the impact of the vulnerability. Actions on vulnerabilities describes the actions that you can use to handle the vulnerability.

   Follow the instructions to manually fix the vulnerabilities on the **Emergency** tab.

   Actions on vulnerabilities

Action	Description
Ignore	Select this action to ignore the vulnerability. The system no longer reports alerts for ignored vulnerabilities.
Verify	Click **Verify** to verify the vulnerability fix. If you do not manually verify a fix, the system automatically verifies the fix within 48 hours after the vulnerability is fixed.

You can manage a vulnerability for one or more affected servers at a time.

- To manage a vulnerability for one affected server, find the server and select an action from the **Actions** column of the server.
- To manage a vulnerability for multiple affected servers, select the servers and select an action in the lower-left corner.

21.5.3.1.5. Configure vulnerability management policies

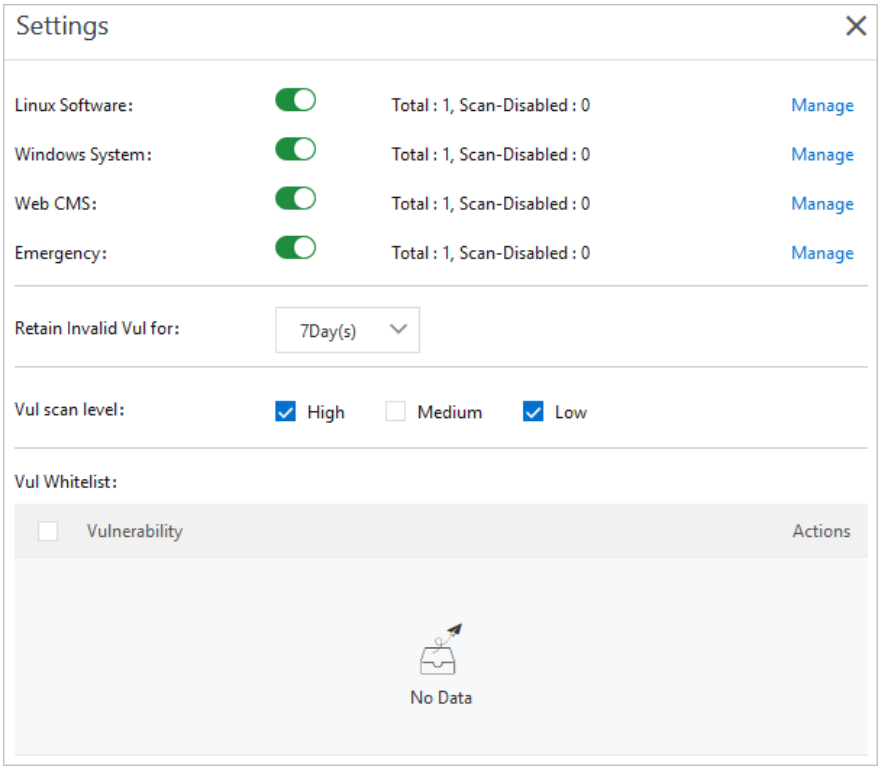
You can enable or disable automatic detection for different types of vulnerabilities and enable vulnerability detection for specific servers. You can also set a time duration for which invalid vulnerabilities are retained and configure a vulnerability whitelist.

Context

A vulnerability whitelist allows you to exclude vulnerabilities from the detection list. You can add multiple vulnerabilities in the vulnerability list to the whitelist. The system does not detect vulnerabilities that are added to the whitelist. You can manage the vulnerability whitelist on the vulnerability settings page.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Vulnerabilities**.
3. In the upper-right corner, click **Settings** to configure vulnerability management policies.



- Select a vulnerability type and enable or disable detection for vulnerabilities of this type.
- Click **Manage** next to a vulnerability type and specify the servers on which vulnerabilities of this type are detected.
- Select a time duration during which invalid vulnerabilities are retained. For example, you can select 7 days, 30 days, or 90 days.

  > **Note** If you do not take an action on a detected vulnerability, the system determines that the alert is invalid. The system deletes the vulnerability after the specified duration.

- Select the vulnerability severities for scanning.
  - **High**: Vulnerabilities of this severity must be fixed as soon as possible.
  - **Medium**: Vulnerabilities of this severity can be fixed later.
  - **Low**: Vulnerabilities of this severity are less urgent and can be fixed later.
- Select vulnerabilities in the whitelist and click **Remove** to enable the system to detect these vulnerabilities and generate alerts for these vulnerabilities.

21.5.3.2. Baseline check

21.5.3.2.1. Baseline check overview

The baseline check feature automatically checks the security configurations on servers and provides detailed check results and suggestions for baseline reinforcement.

Description

After you enable the baseline check feature, Apsara Stack Security automatically checks for risks related to the operating systems, accounts, databases, passwords, and security compliance configurations of your servers, and provides reinforcement suggestions. For more information, see Baselines.

By default, a full baseline check is automatically performed from 00:00 to 06:00 every day. You can create and manage scan policies for baseline checks. When you create or modify a policy, you can specify the baselines, interval, and time period, and select the servers to which you want to apply this policy. For more information, see Add a custom baseline check policy.

Precautions

By default, the following baselines are disabled. To check these baselines, make sure that these baselines do not affect your business and select them when you customize a scan policy.

- Baselines related to weak passwords for specific applications such as MySQL, PostgreSQL, and SQL Server

  > **Note** If these baselines are enabled, the system attempts to log on to servers with weak passwords. The logon attempts consume server resources and generate a large number of logon failure records.

- Baselines related to China classified protection of cybersecurity
- Baselines related to the Center for Internet Security (CIS) standard

Baselines

Category	Baseline
High risk exploit	• High risk exploit - CouchDB unauthorized access high exploit risk • High risk exploit - Docker unauthorized access high vulnerability risk • High risk exploit - Elasticsearch unauthorized access high exploit vulnerability risk • High risk exploit - Memcached unauthorized access high exploit vulnerability risk • High risk exploit - Apache Tomcat AJP File Read/Inclusion Vulnerability • High risk exploit - ZooKeeper unauthorized access high exploit vulnerability risk

Category	Baseline
	Security baseline check against the Alibaba Cloud standard: • Alibaba Cloud Standard-Aliyun Linux 2 Security Baseline Check • Alibaba Cloud Standard - CentOS Linux 6 Security Baseline Check • Alibaba Cloud Standard - CentOS Linux 7 Security Baseline Check • Alibaba Cloud Standard - Debian Linux 8 Security Baseline • Alibaba Cloud Standard - Redhat Linux 6 Security Baseline Check • Alibaba Cloud Standard - Redhat Linux 7 Security Baseline Check • Alibaba Cloud Standard - Ubuntu Security Baseline Check • Alibaba Cloud Standard - Windows Server 2008 R2 Security Baseline Check • Alibaba Cloud Standard - Windows 2012 R2 Security Baseline • Alibaba Cloud Standard - Windows 2016/2019 R2 Security Baseline
	Security baseline check against the CIS standard: • Alibaba Cloud Aliyun Linux 2 CIS Benchmark • CIS CentOS Linux 6 LTS Benchmark • CIS CentOS Linux 7 LTS Benchmark • CIS Debian Linux 8 Benchmark • CIS Ubuntu Linux 14 LTS Benchmark • CIS Ubuntu Linux 16/18 LTS Benchmark • CIS Microsoft Windows Server 2008 R2 Benchmark • CIS Microsoft Windows Server 2012 R2 Benchmark • CIS Microsoft Windows Server 2016/2019 R2 Benchmark

Category	Baseline
CIS and China's Protection of Cybersecurity	Baseline check on compliance of China classified protection of cybersecurity level III: • Aliyun Linux 2 Baseline for China classified protection of cybersecurity-Level III • CentOS Linux 6 Baseline for China classified protection of cybersecurity-Level III • CentOS Linux 7 Baseline for China classified protection of cybersecurity-Level III • Debian Linux 8 Baseline for China classified protection of cybersecurity-Level III • Redhat Linux 6 Baseline for China classified protection of cybersecurity-Level III • Redhat Linux 7 Baseline for China classified protection of cybersecurity-Level III • SUSE Linux 10 Baseline for China classified protection of cybersecurity-Level III • SUSE Linux 11 Baseline for China classified protection of cybersecurity-Level III • SUSE Linux 12 Baseline for China classified protection of cybersecurity-Level III • Ubuntu 14 Baseline for China classified protection of cybersecurity-Level III • Waiting for Level 3-Ubuntu 16/18 compliance regulations inspection • China's Level 3 Protection of Cybersecurity - Windows Server 2008 R2 Compliance Baseline Check • Windows 2012 R2 Baseline for China classified protection of cybersecurity-Level III • Windows 2016/2019 R2 Baseline for China classified protection of cybersecurity-Level III

Category	Baseline
Best security practices	• Alibaba Cloud Standard-Aliyun Linux 2 Security Baseline Check • Alibaba Cloud Standard - Apache Security Baseline Check • Alibaba Cloud Standard - CentOS Linux 6 Security Baseline Check • Alibaba Cloud Standard - CentOS Linux 7/8 Security Baseline Check • Alibaba Cloud Standard - Debian Linux 8 Security Baseline • Alibaba Cloud Standard - IIS 8 Security Baseline Check • Alibaba Cloud Standard - Memcached Security Baseline Check • Alibaba Cloud Standard - MongoDB 3.x Security Baseline Check • Alibaba Cloud Standard - Mysql Security Baseline Check • Alibaba Cloud Standard - Nginx Security Baseline Check • Alibaba Cloud Standard - Redhat Linux 6 Security Baseline Check • Alibaba Cloud Standard - Redhat Linux 7 Security Baseline Check • Alibaba Cloud Standard - Redis Security Baseline Check • Alibaba Cloud Standard - Ubuntu Security Baseline Check • Alibaba Cloud Standard - Windows Server 2008 R2 Security Baseline Check • Alibaba Cloud Standard - Windows 2012 R2 Security Baseline • Alibaba Cloud Standard - Windows 2016/2019 R2 Security Baseline • Alibaba Cloud Standard-Apache Tomcat Security Baseline

Category	Baseline
Weak password	• Weak Password-MongoDB Weak Password baseline(support version 2. X) • Weak password - Ftp login weak password baseline • Weak password - Linux system login weak password baseline • Weak password - MongoDB login weak password baseline • Weak password - SQL Server DB login weak password baseline • Weak password - Mysql DB login weak password baseline • Weak password - Mysql DB login weak password baseline(Windows version) • Weak password - PostgreSQL DB login weak password baseline • Weak password - Redis DB login weak password baseline • Weak password - rsync login weak password baseline • Weak password - svn login weak password baseline

21.5.3.2.2. Configure baseline check policies

This topic describes how to create, modify, and delete baseline check policies and how to specify baseline check levels.

Context

By default, the baseline check feature uses the **default policy** to check the baseline risks of assets. You can also customize baseline check policies based on your business requirements. For example, you can customize a baseline check policy to check the compliance with China classified protection of cybersecurity-Level II.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Baseline Check**.
3. In the upper-right corner of the page that appears, click **Manage Policies**. In the **Manage Policies** panel, create, modify, or delete a baseline check policy. You can also modify the default policy.
   - In the upper-right corner of the panel, click **Create Policy** to customize a baseline check policy. Then, click **Ok**.

Parameter	Description
Policy Name	Enter a policy name.
Schedule	Set the time interval for scheduled scan tasks to 1 Day(s), 3 Day(s), 7 Day(s), or 30 Day(s). Then, select one of the following time ranges for scheduled scan tasks: 00:00 to 06:00, 06:00 to 12:00, 12:00 to 18:00, and 18:00 to 24:00.
Check Items	Select the baseline items that need to be checked from the following categories: High risk exploit, Container security, CIS and China's Protection of Cybersecurity, Best security practices, and Weak password.

Parameter	Description
Servers	Select the server groups to which you want to apply the baseline check policy. **Note** By default, newly purchased servers are classified into the **Default** group under **Asset Groups**. To apply this policy to new servers, select **Default**.

- Click **Edit** or **Delete** next to the new policy to modify or delete it.

  Note You cannot restore a policy after you delete it.

- Find the **Default** policy and click **Edit** in the **Actions** column to modify the server groups to which the default policy is applied.

  Note You cannot delete the default policy or modify the baseline items of the default policy. You can only modify the server groups to which the default policy is applied.

- In the lower part of the **Manage Policies** panel, specify the baseline check levels. Valid values: High, Medium, and Low.

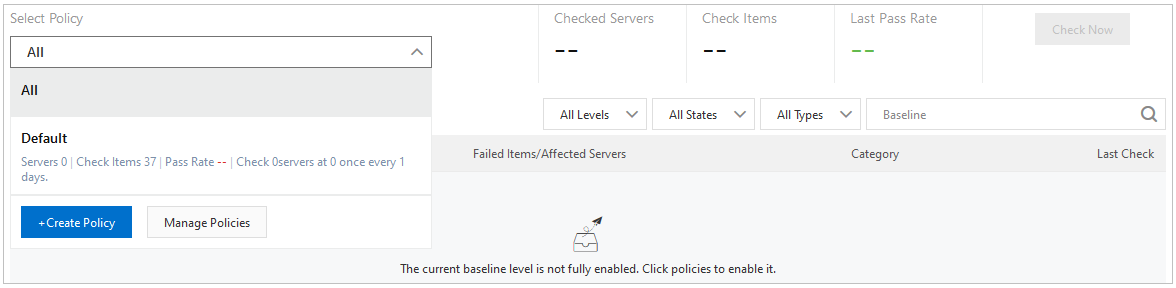
4. Click **Ok**.

21.5.3.2.3. View baseline check results and manage failed check items

Apsara Stack Security Center provides detailed baseline check results and suggestions on how to manage failed check items. This topic describes how to view baseline check results and manage failed check items in Apsara Stack Security Center. The check results include affected assets, checked items, and suggestions.

View the summary of baseline check results

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Baseline Check**.
3. In the upper part of the **Baseline Check** page, view the summary of baseline check results. You can filter data by policy.



You can select a policy from the **Select Policy** drop-down list to view the following information:

- **Checked Servers**: The number of servers on which the baseline check runs. These servers are specified in the selected baseline check policy.
- **Check Items**: The number of **check items** specified in the selected baseline check policy.
- **Last Pass Rate**: The pass rate of the last baseline check.

If the number below **Last Pass Rate** is green, the pass rate of the checked servers is high. If the number is red, a large number of failed check items have been detected on the checked servers. We recommend that you view the check result details and manage the failed check items.

View all baselines

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Baseline Check**.
3. Select **All** from the **Select Policy** drop-down list.
   The **Baseline Check** page displays details about all baselines, including **Baseline**, **Checked Item**, **Failed Items/Affected Servers**, **Category**, and **Last Check**.

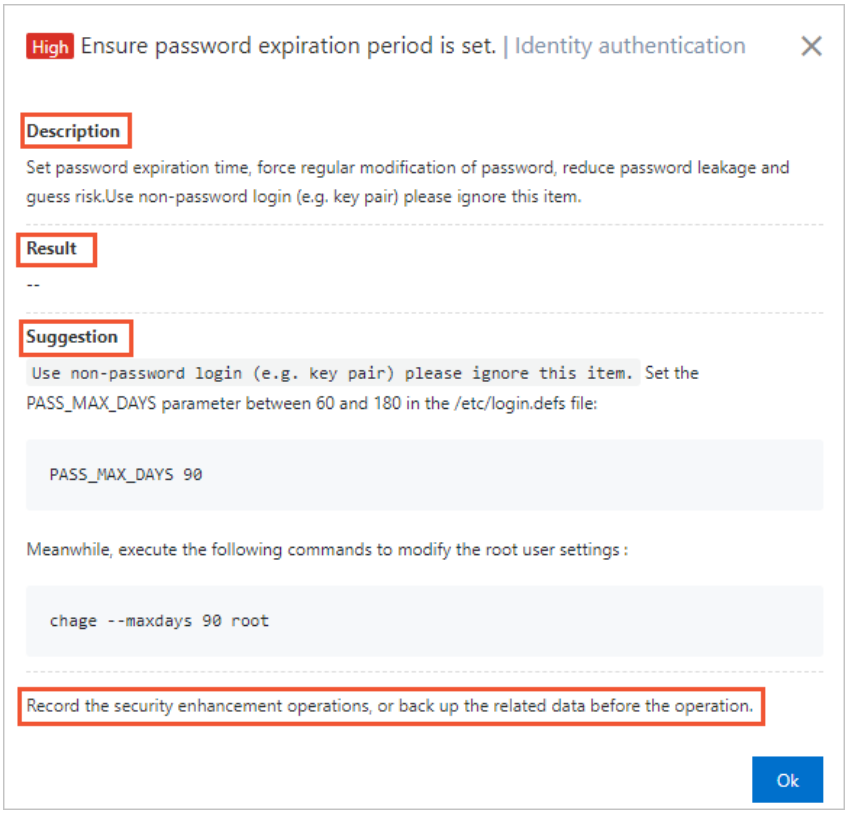
> **Note** You can also select a baseline check policy from the **Select Policy** drop-down list to view the baselines specified in this policy.

View details about a baseline

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Threat Prevention > Baseline Check**.
3. In the **Baseline** column, click a baseline to view its details.
   Baseline details include the affected assets and numbers of **Passed Items** and **At-Risk Items**.
4. In the details panel, manage the failed check items.
   - Find the asset that you want to manage and click **View** in the **Actions** column to open the **At-Risk Items** panel.
   - You can click **Verify** in the **Actions** column to check whether the baseline risks of an asset have been managed. If the verification is passed, the number of **At-Risk Items** is reduced, and the status of the check items change to **Passed**.

View details about a failed check item

1. Find the baseline that you want to manage and click it. In the panel that appears, find the asset that you want to manage and click **View** in the **Actions** column to view failed check items.
   You can view the check items of the asset and the statuses of the check items. The status can be **Passed** or **Failed**.
2. You can click **Details** in the **Actions** column to view the description, result, and suggestion for this check item.



> **Note** We recommend that you follow the suggestions to manage check items whose status is **Failed** at the earliest opportunity, especially high-risk check items.

Manage failed check items

In the At-Risk Items panel, manage failed check items.

- **Add check items to the whitelist**

  If you want to disable alerts for a check item, click **Whitelist** to add the check item to the whitelist. Check items in the whitelist do not trigger alerts.

  > **Note** You can also select multiple check items and click **Whitelist** in the lower-left corner to add the check items to the whitelist at a time.

- **Remove check items from the whitelist**

  If you want to enable alerts for a check item in the whitelist, you can click **Remove** to remove the check item from the whitelist. You can remove one or more check items from the whitelist at a time. After a check item is removed from the whitelist, the check item triggers alerts again.

- **Verify the fix of a failed check item**

  After you fix a baseline risk, you can click **Verify** to check whether the risk has been fixed. After you click Verify, the status of the check item changes to **Verifying**.

  If you do not manually perform the verification, Apsara Stack Security automatically verifies the fix based on the detection interval specified in the policy.

  If the verification is passed, the **Status** of the check item changes to **Passed**.

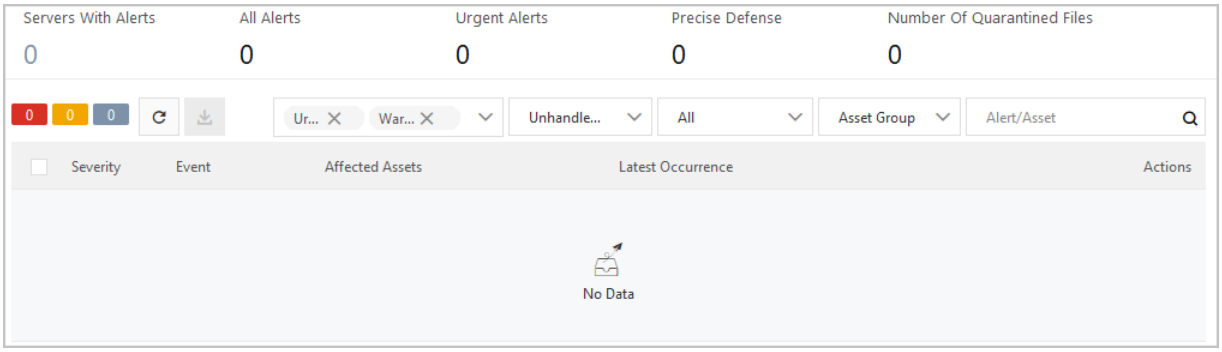
21.5.4. Intrusion prevention

21.5.4.1. Intrusion events

21.5.4.1.1. Intrusion event types

If the Server Security feature detects sensitive file tampering, webshells, unusual logons, suspicious processes, and malicious processes, it generates alerts. Based on these alerts, you can monitor the security status of your assets and handle potential threats at the earliest opportunity.

Apsara Stack Security provides statistics based on alerts. This helps you understand the overall protection situation. To view statistics on alerts, you must choose **Server Security > Intrusion Prevention > Intrusions**.



Alert types

The following table describes the alert items.

Alert type	Description
Threat intelligence	Identify potential threats in assets based on the threat intelligence of Apsara Stack Security. Threat intelligence can correlate threat information to help you analyze and process the information. If threats are detected, alerts are reported. This helps improve the detection efficiency and response speed. Intelligence types include the following items: • Malicious domain names • Malicious IP addresses • IP addresses of dark web services • IP addresses of command and control (C&C) servers • IP addresses of mining pools • Malicious URLs • Malicious download sources
Unusual Logon	Detect unusual logons to your servers. You can specify approved logon IP addresses, time periods, and accounts. Logons from disapproved IP addresses, accounts, or time periods trigger alerts. You can manually add approved logon locations or configure the system to automatically update approved logon locations. You can also specify assets on which alerts are triggered when disapproved logon locations are detected. Apsara Stack Security can detect the following events: • Logons to Elastic Compute Service (ECS) instances from disapproved IP addresses • Logons to ECS instances from disapproved locations • Execution of unusual commands after SSH-based logons to ECS instances • Brute-force attacks on SSH passwords of ECS instances

Alert type	Description
Webshell	Use engines developed by Alibaba Cloud to scan common webshell files. Apsara Stack Security supports scheduled scan tasks, provides real-time protection, and quarantines webshell files. • Apsara Stack Security scans the entire web directory early in the morning on a daily basis. A change made to files in the web directory triggers dynamic detection. • You can specify the assets on which Apsara Stack Security scans for webshells. • You can quarantine, restore, or ignore detected trojan files.
Precision defense	The **antivirus** feature provides precise protection against common ransomware, DDoS trojans, mining programs, trojans, malicious processes, webshells, and computer worms.
Suspicious Account	Detect logons to your assets from disapproved accounts.
Cloud threat detection	Detect threats in other cloud services.
Persistence	Detect suspicious scheduled tasks on servers and generates alerts when advanced persistent threats (APTs) on the servers are detected.
Unusual Network Connection	Detect disconnections or suspicious network connections.
Suspicious Process	Detect whether suspicious processes exist.
Malicious Process	Detect your servers in real time. An agent is used to collect process information, and the information is uploaded to the cloud for detection. You can manage detected viruses in Apsara Stack Security Center. Apsara Stack Security can detect the following malicious activities and processes: • Accesses from malicious IP addresses • Mining programs • Self-mutating trojans • Malicious programs • Trojans
Sensitive File Tampering	Check whether sensitive files on your server are maliciously modified. The sensitive files include preloaded configuration files in Linux shared libraries.
Other	Detect other types of attacks, such as DDoS attacks.
Web Application Threat Detection	Detect server intrusions that use web applications.
Application intrusion event	Detect server intrusions that use system application components.

21.5.4.1.2. View and handle detected intrusion events

This topic describes how to view and handle detected intrusion events on the Intrusions page.

Background information

After intrusion events are detected, the intrusion events are displayed on the Intrusions page. You can choose **Server Security > Intrusion Prevention > Intrusions** to go to the Intrusions page.

If the intrusion events are not handled, they are displayed in the **Unhandled Alerts** list on the **Intrusions** page. After the intrusion events are handled, the status changes from **Unhandled Alerts** to **Handled**.

> **Note** Apsara Stack Security retains the records of **Unhandled Alerts** and **Handled** on the **Intrusions** page. By default, the records of **Unhandled Alerts** are displayed.

View intrusion events

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions**.
3. On the page that appears, search for or view intrusion events. You can also view the details about the events.

Handle intrusion events

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions**.
3. On the **Intrusions** page, find the intrusion event that you want to handle and click **Process** in the **Actions** column. In the dialog box that appears, set Process Method and click **Process Now**.

   > **Note** If the intrusion event contains multiple correlated exceptions, on the page that appears after you click **Process**, you can handle the exceptions.

   - **Ignore**: If you ignore the intrusion event, the status of the intrusion event changes to **Handled**. Server Guard no longer generates alerts for the event.
   - **Add To Whitelist**: If the intrusion event is a false positive, you can add the intrusion event to the whitelist. Then, the status of the intrusion event changes to **Handled**. Server Guard no longer generates alerts for the event. In the **Handled** list, you can click **Cancel whitelist** to remove a specific intrusion event from the whitelist.

     > **Note** A false positive indicates that Server Guard has generated a false alert on a normal process. A common false positive is a **suspicious process that sends TCP packets**. The false positive notifies you that suspicious scans on other devices are detected on your servers.

   - **Batch unhandled**: This method allows you to handle multiple intrusion events at a time. Before you handle multiple intrusion events at a time, we recommend that you view the details of the intrusion events.
4. (Optional)If you confirm that one or more intrusion events are false positives or need to be ignored, go to the **Intrusions** page. Then, select the intrusion events and click **Ignore Once** or **Whitelist**.

Export intrusion events

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions**.
3. In the upper-left corner above the intrusion event list on the **Intrusions** page, click the  icon to export the list.

   After the list is exported, the **Done** message appears in the upper-right corner.
4. In the **Done** notification of the **Alerts** page, click **Download**.
   The alert list is downloaded to your computer.

21.5.4.1.3. View exceptions related to an alert

Server Guard supports automatic analysis of exceptions related to an alert. You can click an alert in the alert list to view and manage all exceptions that are related to the alert. You can also view the results of automatic attack tracing to analyze and handle the exceptions.

Context

- Security Center automatically associates alerts with exceptions in real time to detect potential threats.
- Exceptions related to an alert are listed in chronological order. This allows you to analyze and handle the exceptions to improve the emergency response mechanism of your system.
- An automatically correlated alert is identified by the icon.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions**.
3. On the Intrusions page, click the **name of the alert** that you want to manage. The alert details panel appears.
4. In the alert details panel, view the details and related exceptions of the alert. Then, handle the exceptions.
   - View alert details

     You can view the assets that are affected by the alert, the first and latest time when the alert was triggered, and the details about the related exceptions.
   - View affected assets

     You can move the pointer over the name of an **affected asset** to view the details about the asset. The details include information about all the alerts, vulnerabilities, baseline risks, and asset fingerprints on the asset.
   - View and manage **related exceptions**

     In the **Related Exceptions** section, you can view the details about all the exceptions that are related to the alert. You can also view suggestions on how to handle the exceptions.
     - Click **Note** to the right of an exception to add a note for the exception.
     - Click the icon to the right of a note to delete the note.

21.5.4.1.4. Use the file quarantine feature

Sever Guard can quarantine malicious files. Quarantined files are listed in the quarantine box on the Intrusions page. The system automatically deletes a quarantined file 30 days after the file is quarantined. You can restore a quarantined file with a few clicks before the file is deleted. This topic describes how to view and restore quarantined files.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions**.
3. In the upper-right corner of the **Intrusions** page, click **Quarantine**.

   In the **Quarantine** panel, you can perform the following operations:
   - View information about quarantined files. The information includes server IP addresses, paths that store the files, file status, and modification time.
   - Click **Restore** in the **Actions** column to remove a file from the quarantine box. The restored file appears in the alert list again.

21.5.4.1.5. Configure security alerts

This topic describes how to configure security alerts, which allows you to specify approved logon locations and custom web directories to scan.

Context

Server Guard supports advanced logon settings. You can configure more fine-grained logon detection rules. For example, you can specify approved logon IP addresses, logon time, and logon accounts to block unauthorized requests sent to your assets.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Intrusions**.
3. In the upper-right corner, click **Settings**.

   Configure parameters on different tabs.

   - **Add an approved logon location**
     a. In the **Login Location** section, click **Management** on the right.
     b. Select the logon location that you want to add and select the servers that allow logons from the added location.
     c. Click **OK**.

     Server Guard allows you to **edit** or **delete** approved logon locations.

     - Find a specific logon location and click **Edit** on the right to change the servers that allow logons from this location.
     - Find a specific logon location and click **Delete** on the right to delete the logon location.

   - **Configure advanced logon settings**

     > **Note** When you configure advanced logon settings, you can specify the IP addresses, accounts, and time ranges that are allowed for logons to your assets. After the advanced logon settings are configured, Server Guard sends you alerts if your assets receive unauthorized logon requests. The procedure of configuring advanced logon settings is similar to that of configuring **Login Location**. You can **add**, **edit**, or **delete** advanced logon settings in a similar way.

     - Turn on or turn off Uncommon IP Alert to the right of **Common Login IPs**. If you turn on Uncommon IP Alert and your assets receive logon requests from unauthorized IP addresses, alerts are triggered.
     - Turn on or turn off Uncommon Time Alert to the right of **Common Login Time**. If you turn on Uncommon Time Alert and your assets receive logon requests in unauthorized time ranges, alerts are triggered.
     - Turn on or turn off Uncommon Account Alert to the right of **Common Login Accounts**. If you turn on Uncommon Account Alert and your assets receive logon requests from unauthorized accounts, alerts are triggered.

   - **Add web directories to scan**

     Server Guard automatically scans web directories of data assets in your servers and runs dynamic and static scan tasks. You can also manually add other web directories.

     a. In the **Add Scan Targets** section, click **Management** on the right.
     b. Specify a valid web directory and select the servers on which the specified web directory is scanned.

        > **Note** To ensure the scan performance and efficiency, we recommend that you do not specify a root directory.

     c. Click **OK**.

21.5.4.1.6. Cloud threat detection

The cloud threat detection feature provided by Server Guard is integrated with widely-used antivirus engines. The feature detects viruses based on large amounts of threat intelligence data provided by Alibaba Cloud and the exception detection model designed by Alibaba Cloud. This model is designed based on machine learning and deep learning. This way, the cloud threat detection feature can provide full-scale and dynamic antivirus protection to safeguard your servers.

The cloud threat detection feature scans hundreds of millions of files on a daily basis and protects millions of servers on the cloud.

Detection capabilities

The cloud threat detection feature uses the Server Guard agent to collect process information and scans the retrieved data for viruses in the cloud. If a malicious process is detected, you can stop the process and quarantine the source files.

The cloud threat detection feature provides the following capabilities:

- **Deep learning engine developed by Alibaba Cloud**: The deep learning engine is built on deep learning technology and a large number of attack samples. The engine detects malicious files on the cloud and automatically identifies potential threats to supplement traditional antivirus engines.
- **Cloud sandbox developed by Alibaba Cloud**: The cloud sandbox feature allows you to simulate cloud environments and monitor attacks launched by malicious samples. The cloud sandbox feature automatically detects threats and offers dynamic analysis and detection capabilities based on big data analytics and machine learning modeling techniques.
- **Integration with major antivirus engines**: The cloud threat detection feature is integrated with major antivirus engines and updates its virus library in real time.
- **Threat intelligence detection**: The cloud threat detection feature works with the exception detection module to detect malicious processes and operations based on threat intelligence data provided by Alibaba Cloud Security.

Detectable virus types

The cloud threat detection feature is developed based on the security technologies and expertise of Alibaba Cloud. The feature provides end-to-end security services, including threat intelligence collection, data masking, threat identification, threat analysis, and malicious file quarantine and restoration. You can quarantine and restore files that contain viruses in the Security Center console.

The cloud threat detection feature can detect the following types of viruses.

Virus	Description
Mining program	A mining program consumes server resources and mines cryptocurrency without authorization.
Computer worm	A computer worm uses computer networks to replicate itself and spread to a large number of computers within a short period of time.
Ransomware	Ransomware, such as WannaCry, uses encryption algorithms to encrypt files and prevent users from accessing the files.
Trojan	A trojan is a program that allows an attacker to access information about servers and users, gain control of the servers, and consume system resources.
DDoS trojan	A DDoS trojan hijacks servers and uses zombie servers to launch DDoS attacks, which interrupts your service.
Backdoor	A backdoor is a malicious program injected by an attacker. Then, the attacker can use the backdoor to control the server or launch attacks.

Virus	Description
Computer virus	A computer virus inserts malicious code into normal programs and replicates the code to infect the whole system.
Malicious program	A malicious program may pose threats to system and data security.

Benefits

- **Self-developed and controllable**: The cloud threat detection feature is based on deep learning, machine learning, and big data analytics with a large number of attack and defense practices. The feature uses multiple detection engines to dynamically protect your assets against viruses.
- **Lightweight**: The cloud threat detection feature consumes only 1% of CPU resources and 50 MB of memory.
- **Dynamic**: The cloud threat detection feature dynamically retrieves startup logs of processes to monitor the startup of viruses.
- **Easy to manage**: You can manage all servers and view their status at any time in the Security Center console.

Threat detection limits

Apsara Stack Security Center allows you to detect and process security alerts, scan for and fix vulnerabilities, analyze attacks, and check security settings. Apsara Stack Security Center can analyze alerts and automatically trace attacks. This allows you to protect your assets. Apsara Stack Security supports a wide range of protection features. We recommend that you install the latest system patches on your assets. We also recommend that you use security services, such as Cloud Firewall and Web Application Firewall (WAF), to better protect your assets against attacks.

> **Note** Attacks and viruses are evolving, and security breaches may occur in various business environments. We recommend that you use the alerting, vulnerability detection, baseline check, and configuration assessment features provided by Apsara Stack Security to better protect your assets against attacks.

21.5.4.2. Website tamper-proofing

21.5.4.2.1. Overview

Tamper protection monitors website directories in real time, restores modified files or directories, and protects websites from trojans, hidden links, and uploads of violent and illicit content.

Background information

To make illegal profits or conduct business attacks, attackers exploit vulnerabilities in websites to insert illegal hidden links and tamper with the websites. Defaced web pages affect normal user access and may lead to serious economic losses, damaged brand reputation, or political risks.

Tamper protection allows you to add Linux and Windows processes to the whitelist and update protected files in real time.

How tamper protection works

The Security Center agent automatically collects the list of processes that attempt to modify files in the protected directories of the protected servers. It identifies unusual processes and file changes in real time and blocks unusual processes.

The alert list is displayed on the Tamper Protection page. You can view unusual file changes, the corresponding processes, and the number of attempts made by each process in the alert list. If a file is modified by a trusted process, you can add the process to the whitelist. After the process is added to the whitelist, tamper protection no longer blocks the process. In scenarios where the content of websites, such as news and education websites, is frequently modified, the whitelist saves you the effort of frequently enabling and disabling tamper protection.

Versions of operating systems and kernels supported by tamper protection

OS	Supported operating system version	Supported kernel version
Windows	Windows Server 2008 and later	All versions
CentOS	6.5, 6.6, 6.7, 6.8, 6.9, 6.10, 7.0, 7.1, 7.2, 7.3, 7.4, 7.5, and 7.6	• 2.6.32-x • 3.10.0-x
Ubuntu	14, 16, and 18	• 3.13.0-32-generic • 3.13.0-86-generic • 4.4.0-62-generic • 4.4.0-63-generic • 4.4.0-93-generic • 4.4.0-151-generic • 4.4.0-117-generic • 4.15.0-23-generic • 4.15.0-42-generic • 4.15.0-45-generic • 4.15.0-52-generic

Note

- The preceding table lists kernel versions supported by tamper protection. Servers that use an unsupported kernel version cannot use tamper protection. Make sure that your server uses a supported kernel version. If a kernel version is not supported, you must upgrade it to a supported version. Otherwise, you cannot add processes to the whitelist.
- Before you upgrade the server kernel, back up your asset data.

21.5.4.2.2. Configure tamper protection

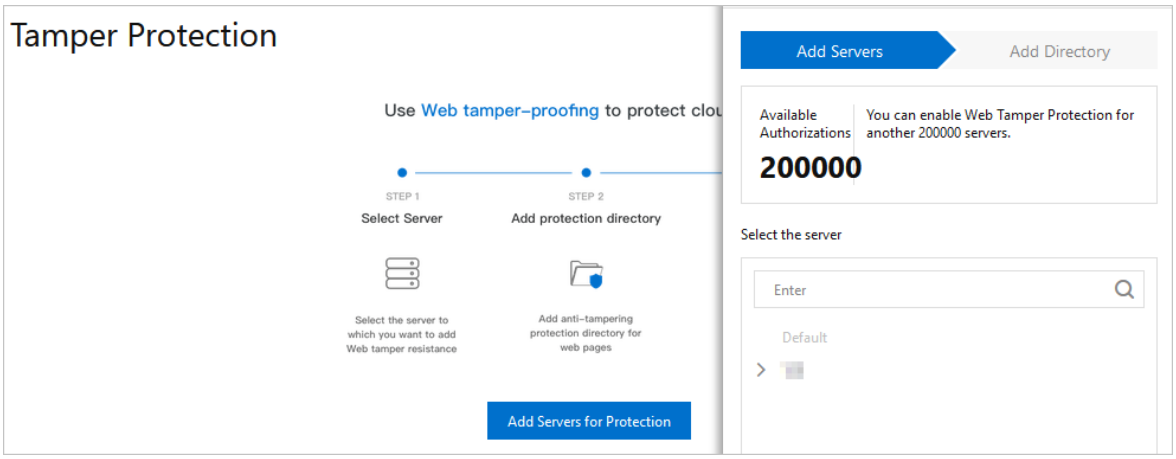
The Server Security feature allows you to configure tamper protection for web pages.

Limits

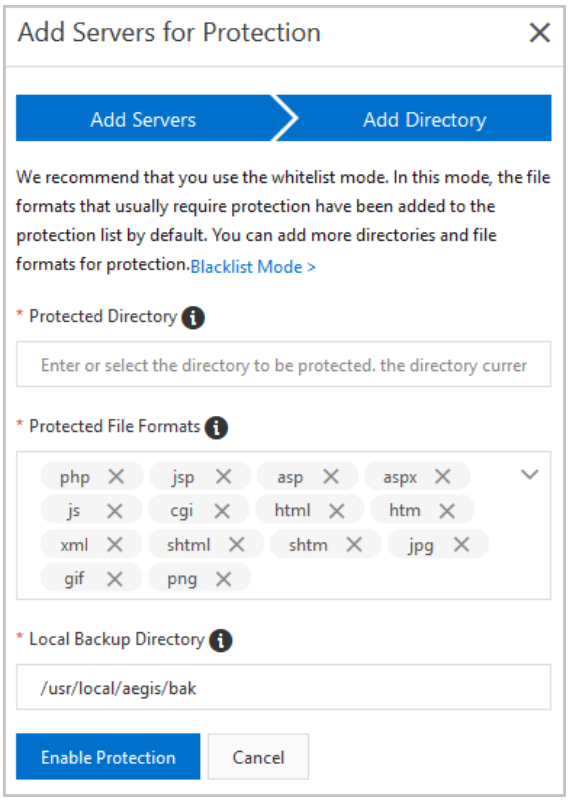
- For each server, you can add a maximum of 10 directories for protection.
- If you want to add directories that are on a Windows server, the directories must meet the following requirements: The size of each directory does not exceed 20 GB. Each directory contains no more than 2,000 folders. The number of directory levels does not exceed 20. The size of each file does not exceed 3 MB.
- If you want to add directories that are on a Linux server, the directories must meet the following requirements: The size of each directory does not exceed 20 GB. Each directory contains no more than 3,000 folders. The number of directory levels does not exceed 20. The size of each file does not exceed 3 MB.
- Before you add a directory for protection, make sure that the directory meets the preceding requirements.
- We recommend that you exclude file formats that do not require protection, such as *LOG*, *PNG*, *JPG*, *MP4*, *AVI*, and *MP3*. Multiple file formats can be separated by semicolons (;).

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > File Tamper Protection**.
3. On the **Tamper Protection** page, click **Add Servers for Protection**.
4. In the **Add Servers for Protection** panel, select a server that you want to protect.



5. Click **Next** to go to the **Add Directory** step.
6. In the **Add Directory** step, configure the parameters.



Select a protection mode. The settings of other parameters vary based on the protection mode. You can select **Whitelist Mode** or **Blacklist Mode**. In whitelist mode, tamper protection is enabled for the specified directories and file formats. In blacklist mode, tamper protection is enabled for the subdirectories, file formats, and files that are not specified. By default, Whitelist Mode is selected.

- The following table describes the parameters that you must configure if you select Whitelist Mode.

Parameter	Description
Protected Directory	Enter the path of the directory that you want to protect. **Note** Servers that run Linux or Windows operating systems use different path formats. Enter a valid directory path based on the type of your operating system.
Protected File Formats	Select file formats that you want to protect from the drop-down list, such as *js*, *html*, *xml*, and *jpg*.
Local Backup Directory	The default path in which backup files of the protected directories are stored. By default, Apsara Stack Security assigns */usr/local/aegis/bak* to Linux servers and *C:\Program Files (x86)\Alibaba\Aegis\bak* to Windows servers. You can change the default path based on your business requirements.

- The following table describes the parameters that you must configure if you select Blacklist Mode.

Parameter	Description
Protected Directory	Enter the path of the directory that you want to protect.
Excluded Sub-Directories	Enter the subdirectories that you do not want to protect. Click **Add Sub-Directory** to add more subdirectories. Apsara Stack Security does not provide tamper protection for files in the excluded subdirectories.
Excluded File Formats	Select file formats that you do not want to protect from the drop-down list. Valid values: **log**, **txt**, and **ldb**. Apsara Stack Security does not provide tamper protection for the files in the excluded formats.
Excluded Files	Enter the path of the files for which you do not want to protect. Click **Add File** to add more files. Apsara Stack Security does not provide tamper protection for the excluded files.
Local Backup Directory	The default path in which backup files of the protected directories are stored. By default, Apsara Stack Security assigns */usr/local/aegis/bak* to Linux servers and *C:\Program Files (x86)\Alibaba\Aegis\bak* to Windows servers. You can change the default path based on your business requirements.

7. Click **Enable Protection**.
   After you enable this feature for a server, the server is displayed on the Management tab of the **Tamper Protection** page.

   Note By default, tamper protection is in the **Off** state for the server. To enable tamper protection for the server, you must **turn on** the switch in the Protection column on the **Tamper Protection** page.

8. On the **Tamper Protection** page, find the server that you add. Then, click the **Management** tab and turn on the switch in the **Protection** column to enable protection for the server.

> **Note** By default, tamper protection is in the **Off** state for the server. To enable tamper protection for the server, you must turn on the switch in the Protection column on the **Tamper Protection** page.

After tamper protection is enabled, the status of the server changes to **Running**.

> **Note** If the status of the server is **Exception**, move the pointer over **Exception** in the Status column to view the cause and click **Retry** to enable tamper protection again.

What to do next

After you enable tamper protection for a server, you can go to the **Alerts** page and select Webpage Tampering from the alert type drop-down list to view the alerts generated upon tampering events.

> **Note**
>
> Tamper protection does not take effect immediately after you configure the protected directory, and you can still write files to the directory. In this case, you must go to the **Management** page, disable **Protection** for the server where the directory is located, and then enable **Protection** again.

Handling suggestions for abnormal protection states

State	Description	Suggestion
Initializing	Tamper protection is being initialized.	If this is your first time enabling tamper protection for a server, the protection status becomes **Initializing**. Tamper protection will be enabled in a few seconds.
Running	Tamper protection is enabled and running as expected.	None.
Exception	An error occurred when tamper protection was enabled.	Move the pointer over **Exception** in the Status column to view the exception cause and click Retry.
Not Initialized	Web tamper protection is disabled.	**Turn on** the switch in the Protection column to enable tamper protection.

21.5.4.2.3. View protection status

This topic describes how to view the status of tamper protection for your assets.

Context

The tamper protection feature monitors changes to the files in website directories in real time and blocks suspicious file changes. To view the status of and details about the tamper protection feature, you must log on to Apsara Stack Security Center and choose **Server Security > Intrusion Prevention > File Tamper Protection**. The following information is displayed:

- Tamper protection overview

  You can view the numbers of files that are changed on the current day and in the last 15 days, the number of protected servers, and the number of protected directories.

- Distribution of protected file types

Protected file types include TXT, PNG, MSI, and ZIP. You can also add more types of files for tamper protection based on your business requirements.

> **Note** All types of files for tamper protection can be added.

- Top five files

  This section shows the names and paths of the top five files that are ranked based on the number of changes to files in descending order in the last 15 days.

- Tamper protection alerts

  This section lists the alerts generated for blocked suspicious changes to files for your assets. You can view details about the alerts, including the severity, alert name, affected assets, paths of files with suspicious changes, and protection status.

  > **Note**
  > - If an alert is reported more than 100 times, we recommend that you handle the alert at your earliest opportunity.
  > - Only alerts at the **Medium** level are displayed in the console.
  > - Only alerts in the **Defended** state are displayed. These alerts are triggered when the tamper protection feature blocks suspicious processes that attempt to modify files without authorization.

21.5.4.3. Configure the anti-virus feature

Server Guard provides the anti-virus feature. This feature allows you to customize settings for virus and webshell detection.

Detect and remove viruses

The anti-virus feature can automatically quarantine common Internet viruses, such as common trojans, ransomware, mining programs, and DDoS trojans. Apsara Stack Security experts check and verify all the automatically quarantined viruses to ensure a minimum false positive rate.

If the virus blocking feature is disabled, Server Guard generates alerts when viruses are detected. You must manually manage detected viruses in Apsara Stack Security Center. We recommend that you enable the virus blocking feature to improve the security of your servers.

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Virus Defence**.
3. On the **Anti-virus** tab, click **Scan**.
4. In the dialog box that appears, select the servers that you want to scan.
5. Click **Scan**.
6. On the **Anti-virus** page, click the **Real-time protection** tab and enable the virus blocking feature.

   After the virus blocking feature is enabled, Server Guard automatically quarantines common viruses that are detected. Quarantined viruses are listed on the Alerts page. To filter quarantined viruses, you can select the **Precision defense** type.

Detect and remove webshells

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Intrusion Prevention > Virus Defence**.
3. Specify servers for webshell detection.
   i. In the **Webshell Detection** section, click **Manage**.

ii. Select the servers for which you want to enable webshell detection.

iii. Click **OK** to complete the configuration.

21.5.5. Log retrieval

21.5.5.1. Log retrieval overview

The log retrieval function provided by Server Security allows you to manage logs scattered in various systems of Apsara Stack in a centralized manner, so that you can easily identify the causes of issues that occur on your servers.

The log retrieval function supports storage of logs for 180 days and query of logs generated within 30 days.

Benefits

The log retrieval function provides the following benefits:

- **End-to-end log retrieval platform**: Allows you to retrieve logs of various Apsara Stack services in a centralized manner and trace issues easily.
- **Cloud-based SaaS service**: Allows you to query logs on all servers in Apsara Stack without additional installment and deployment.
- Supports TB-level data retrieval. It also allows you to add a maximum of 50 inference rules (Boolean expressions) in a search condition and obtain full-text search results within several seconds.
- Supports a wide range of log sources.
- Supports log shipping, which allows you to import security logs to Log Service for further analysis.

Scenarios

You can use log retrieval to meet the following requirements:

- **Security event analysis**: When a security event is detected on a server, you can retrieve the logs to identify the cause and assess the damage and affected assets.
- **Operation audit**: You can audit the operation logs on a server to identify high-risk operations and serious issues in a meticulous way.

Supported log types

Log types

Log type	Description
Logon history	Log entries about successful system logons
Brute-force attack	Log entries about system logon failures that are generated during brute-force attacks
Process snapshot	Log entries about processes on a server at a specific time
Listening port snapshot	Log entries about listening ports on a server at a specific time
Account snapshot	Log entries about account logon information on a server at a specific time
Process initiation	Log entries about process initiation on a server
Network connection	Log entries about active connections from a server to external networks

21.5.5.2. Query logs

This topic describes how to search for and view server logs.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Log Retrieval**.
3. Specify search conditions.

Search condition	Description
Log source	The log source that you want to query. For more information, see Log sources.
Field	The field that is recorded for the log source. For more information, see Log sources.
Keyword	The keyword of the field.
Logical operator	The equality operator.
+	The inference rules in a search condition for a log source.
Add conditions	The search conditions for different log sources.

4. Click **Search** and view the search result.
   - **Reset**: Click **Reset** to clear the search condition configurations.
   - **Save Search**: Click **Save Search** to save the search condition configurations which you can use to search for logs in the future.
   - **Saved Searches**: Click **Saved Searches** to select and use a search condition that you saved.

21.5.5.3. Supported log sources and fields

This topic describes the log sources and fields that are supported by the log retrieval feature.

The log retrieval feature allows you to query the following types of log sources. You can click a log source link to view the fields that can be retrieved.

Log source	Description
Logon history	Log entries about successful system logons
Logs of brute-force attacks	Log entries about failed system logons during brute-force attacks
Process snapshot logs	Log entries about processes on a server at a specific point in time
Logs of listening port snapshots	Log entries about listening ports on a server at a specific point in time
Account snapshot logs	Log entries about account-based logons on a server at a specific point in time
Process startup logs	Log entries about process startups on a server
Network connection logs	Log entries about active connections from a server to the Internet.

Logon history

The following table describes the fields that you can use to query the logon history.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
warn_ip	string	The source IP address used for the logon.
warn_port	string	The logon port.
warn_user	string	The username used for the logon.
warn_type	string	The logon type.
warn_count	string	The number of logon attempts.

Logs of brute-force attacks

The following table describes the fields that you can use to query logs of brute-force attacks.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
warn_ip	string	The source IP address of the attack.
warn_port	string	The target port of the attack.
warn_user	string	The target username of the attack.
warn_type	string	The attack type.
warn_count	string	The number of brute-force attack attempts.

Process startup logs

The following table describes the fields that you can use to query process startup logs.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
pid	string	The ID of the process.
groupname	string	The user group.
ppid	string	The ID of the parent process.
uid	string	The ID of the user.
username	string	The username.
filename	string	The file name.

Field	Data type	Description
pfilename	string	The name of the parent process file.
cmdline	string	The command line.
filepath	string	The path of the process file.
pfilepath	string	The path of the parent process file.

Logs of listening port snapshots

The following table describes the fields that you can use to query logs about listening port snapshots.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
src_port	string	The listening port.
src_ip	string	The listening IP address.
proc_path	string	The path of the process file.
pid	string	The ID of the process.
proc_name	string	The name of the process.
proto	string	The protocol.

Account snapshot logs

The following table describes the fields you can use to query account snapshot logs.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
perm	string	Indicates whether the user has root permissions.
home_dir	string	The home directory.
warn_time	string	The time when a password expiration notification is sent.
groups	string	The group to which the user belongs.
login_ip	string	The IP address of the last logon.
last_chg	string	The time when the password was last changed.
shell	string	The Linux shell command.

Field	Data type	Description
domain	string	The Windows domain.
tty	string	The logon terminal.
account_expire	string	The time when the account expires.
passwd_expire	string	The time when the password expires.
last_logon	string	The last logon time.
user	string	The username.
status	string	The account status. Valid values: • 0: disabled • 1: normal

Process snapshot logs

The following table describes the fields that you can use to query process snapshot logs.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
path	string	The path of the process file.
start_time	string	The time when the process was started.
uid	string	The ID of the user.
cmdline	string	The command line.
pname	string	The name of the parent process.
name	string	The name of the process.
pid	string	The ID of the process.
user	string	The username.
md5	string	The MD5 hash value of the process file. If the size of the process file exceeds 1 MB, the system does not calculate the MD5 hash value of the process file.

Network connection logs

The following table describes the fields that you can use to query network connection logs.

Field	Data type	Description
uuid	string	The ID of the client.

Field	Data type	Description
IP	string	The IP address of the server.
src_ip	string	The source IP address.
src_port	string	The source port.
proc_path	string	The path of the process file.
dst_port	string	The destination port.
proc_name	string	The name of the process.
dst_ip	string	The destination IP address.
status	string	The status.

21.5.5.4. Logical operators

The log retrieval feature supports multiple search conditions. You can add multiple logical operators to one search condition for one log source, or combine multiple search conditions for several log sources by using different logical operators. This topic describes the logical operators that are supported in log retrieval. Examples are provided to help you understand these operators.

The following table describes the logical operators that are supported in log retrieval.

Logical operators

Logical operator	Description
and	Binary operator. This operator is in the format of `query 1 and query 2`, which indicates the intersection of the query results of `query 1` and `query 2`. **Note** If no logical operators are used for multiple keywords, the default operator is AND.
or	Binary operator. This operator is in the format of `query 1 or query 2`, which indicates the union of the query results of `query 1` and `query 2`.
not	Binary operator. This operator is in the format of `query 1 not query 2`, which indicates the results that match `query 1` but do not match `query 2`. This format is equivalent to `query 1 - query 2`. **Note** If you use only `not query 1`, the log data that does not contain the query results of `query 1` is returned.

21.5.6. Settings

21.5.6.1. Install the Server Guard agent

This topic describes how to install the Server Guard agent.

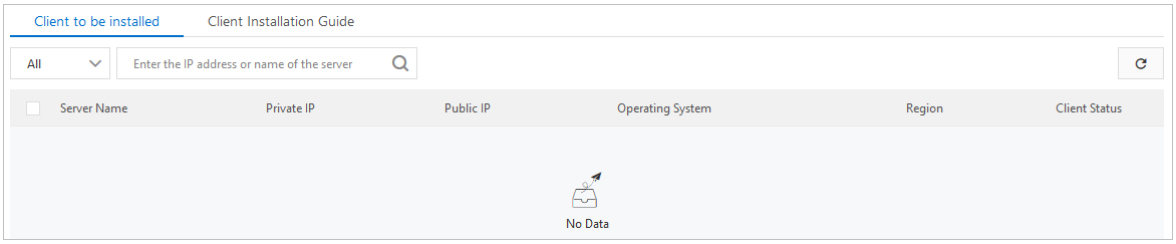
Context

To use the protection services provided by Server Guard, you must install the Server Guard agent on the operating system of your server.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Server Security > Server Settings > Client Installation**.
3. (Optional)On the Client Installation page, click the **Client to be installed** tab to view the number of servers on which the Server Guard agent is not installed. On this tab, you can also view the information about the servers.

   You can specify the operating system type, IP address, or server name to search for a server.



4. Click the **Client Installation Guide** tab.
5. Obtain and install the Server Guard agent based on the operating system type of your server.
   - **Windows**
     a. In the left-side pane of the page, click **Click to download** to download the installation package to your computer.
     b. Upload the installation package to your server. For example, you can use an FTP client to upload the installation package to your server.
     c. Run the installation package on your server as an administrator.

     > **Note** If you install the agent on a server that is not in Alibaba Cloud, you are prompted to enter the installation verification key. You can find the installation verification key on the Client Installation Guide tab.

   - **Linux**
     a. In the right-side pane of the page, select Alibaba Cloud Server or Non-Alibaba Server.
     b. Select the installation command for your 32-bit or 64-bit operating system and click **Copy** to copy the command.
     c. Log on to your Linux server as an administrator.
     d. Run the installation command on your Linux server to download and install the Server Guard agent.

21.5.6.2. Manage protection modes

This topic describes how to manage protection modes for each server to improve the efficiency and security of the server.

Procedure

1. Log on to Apsara Stack Security Center.

2. In the left-side navigation pane, choose **Server Security > Server Settings > Protection Mode**.
3. On the Protection Mode page, click **Manage**.

   Configure protection modes for servers.

   - **Business First Mode**: The peak CPU utilization is less than 10%, and the peak memory usage is less than 50 MB.
   - **Protection First Mode**: The peak CPU utilization is less than 20%, and the peak memory usage is less than 80 MB.
4. Click **OK**.

21.6. Physical server security

21.6.1. Create and grant permissions to a security administrator account

The physical server security feature is used to ensure the security of physical servers on the platform side. This feature requires you to use a dedicated security administrator account for the platform. This topic describes how to create and grant permissions to a security administrator account.

Procedure

1. Log on to the Apsara Uni-manager Management Console as a system administrator.

   For more information, see the **"Log on to the Apsara Uni-manager Management Console"** topic of *Apsara Uni-manager Management Console User Guide*.
2. Create a dedicated organization that is used to manage the security of physical servers, and obtain the primary key of the organization.

   > **Notice** Make sure that the organization is used only to manage the security of physical servers. Do not add Elastic Compute Service (ECS) instances to the organization.

   i. Create the dedicated organization.

   For more information, see **Enterprise Center > Organization Management > Create Organization** in *Apsara Uni-manager Management Console User Guide*.

   ii. Obtain the **primary key** of the newly created organization.

   For more information, see **Enterprise CenterOrganization ManagementObtain the AccessKey pair of an organization** in *Apsara Uni-manager Management Console User Guide*.
3. Create a dedicated account to manage the security of physical servers.

   For more information, see **Enterprise Center > User Management > System User Management > Create User** in *Apsara Uni-manager Management Console User Guide*.

   > **Note** When you create the account, take note of the following points for the **organization** and **role**:
   >
   > - In the **Organization** section, select the organization that is created in the previous step.
   > - In the **Role** section, select **Platform Security Configuration Administrator** and **Security System Configuration Administrator**.
4. Log on to Apsara Stack Security Center by using the newly created account.

   For more information, see Log on to Apsara Stack Security Center.
5. Add the **primary key** of the newly created organization to the protection configuration of physical servers.

i. In the left-side navigation pane, choose **Security Management Center (SOC) > System Configuration > Global Settings**.
ii. On the **Global Settings** page, click the **Physical Server Protection** tab.
iii. Click **Add Account**.
iv. In the **Add Account** dialog box, specify the **Username** and **Primary Key** parameters.
   - **Username**: Enter the account that you created in Step 3.
   - **Primary Key**: Enter the primary key that you obtained in Step 2.
v. Click **OK**.

Result

After you complete the configuration, the **Physical Server Security** feature appears in the left-side navigation pane of Apsara Stack Security. Then, you can use the account created in this topic to maintain the security of physical servers.

21.6.2. View the information on the Overview page

Security administrators can view the security status of all physical servers on the Overview page of Apsara Stack Security.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Overview**.
3. On the **Overview** page, view the security status of your physical servers.
   - Security event statistics: displays the numbers of security events on the physical servers. Security events include unusual logons, webshells, and server exceptions.
   - **Events**: displays the trends of security events on the physical servers. A security event is an intrusion event that is detected on a physical server.
   - **Protection Status**: displays the number of physical servers that are protected and the number of offline physical servers.
   - **Recent Important Events**: displays the recent important security events that are detected on the physical servers. You can click a security event to view its details.

21.6.3. Physical servers

21.6.3.1. Manage physical server groups

This topic describes how to manage physical server groups. To facilitate the security management of physical servers, you can add the physical servers to groups and view their security events by group.

Context

By default, physical servers do not belong to a server group. You must add your physical servers to a server group. If you delete a group, all the physical servers in the group are retained but no longer belong to a server group.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

> **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Servers**.
3. In the left-side group pane, manage sever groups.
   - Create a group.

     Click the Add Subgroup icon next to **All Servers** or a specific group, enter a group name, and click **OK**.

     > **Note** The system supports a maximum of three levels of groups.

   - Modify a group.

     Click the Modify Group Name icon next to the target group, enter a new name, and click **OK**.

   - Delete a group.

     Click the Delete icon next to the target group. In the message that appears, click **OK**.

     > **Note** After you delete a group, all servers in the group are automatically moved to the **default** group.

   - Sort groups.

     Click **Manage Groups** to sort groups in descending order by priority.
4. Change the server group of specific physical servers.
   i. Select servers from the list on the right.
   ii. Click **Change Group**.
   iii. In the Change Group dialog box that appears, select a group from the drop-down list.
   iv. Click **OK**.

21.6.3.2. Manage physical servers

This topic describes how to manage servers. On the Servers page, you can view the status of servers protected by Server Guard.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Servers**.
3. (Optional)Search for a server.

   To view the agent status of a server, enter the server IP address in the search bar, and click **Search**. Detailed server information, such as security information, is displayed.
4. View the agent status and detailed security information of the server.

   Click

   in the upper-right corner of the page to select the information columns you want to display. The following table lists the information categories.

Category	Information
Basic information	○ Server IP/Name ○ Tag ○ OS ○ Region
Agent status	Agent Status
Threat prevention	○ Vulnerability ○ Baseline Risk
Intrusion detection	○ Unusual Logons ○ Webshells ○ Suspicious Servers
Server fingerprints	○ Processes ○ Ports ○ Root Accounts/Total Accounts

5. Manage servers.

Action	Description
Change Group	Select servers and click **Change Group** to add the selected servers to a new group.
Modify Tag	Select servers and click **Modify Tag** to modify tags for the servers.
Security Inspection	Select servers and click **Security Inspection** to select the items to be checked.
Delete External Servers	Select **external** servers, and choose **More > Delete External Servers**.
Disable Protection	Select the servers whose agent status is **Online**, and choose **More > Disable Protection**. This temporarily disables protection for these servers to reduce server resource consumption.
Enable Protection	Select the servers whose agent status is **Disable Protection**, and choose **More > Enable Protection**. This enables protection for these servers.

21.6.4. Intrusion detection

21.6.4.1. Configure policies to identify unusual logons

This topic describes how to configure logon security. You can set approved locations, IP addresses, time periods, and accounts for logons.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

> **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Intrusion Detection**.
3. Click the **Unusual Logons** tab.
4. Click **Logon Security** in the upper-right corner of the page.
5. Set approved logon locations.

   To add an approved logon location, follow these steps:

   i. Click **Add**.
   ii. Select a logon location from the drop-down list.
   iii. Specify the servers on which the selected logon location takes effect.
   - Click **All Servers** to select specific servers.
   - Click **Server Groups** to select servers by group.

   iv. Click **OK**.

   > **Note** Click **Modify** or **Delete** to modify or delete an approved logon location.

6. Set approved logon IP addresses.

   Turn on the **Disapproved IP Alert** switch. The switch is turned on if it turns green.

   To add an approved logon IP address, follow these steps:

   i. Click **Add**.
   ii. In the **Specify an Approved Logon IP** section, enter an IP address.
   iii. Specify the servers on which the specified IP address takes effect.
   - Click **All Servers** to select specific servers.
   - Click **Server Groups** to select servers by group.

   iv. Click **OK**.

   Click **Modify** or **Delete** to modify or delete an approved logon IP address.
7. Set approved logon time periods.

   Turn on the **Disapproved Time Alert** switch. The switch is turned on if it turns green.

   To add an approved logon time period, follow these steps:

   i. Click **Add**.
   ii. In the **Specify an Approved Logon Duration** section, specify a time period.
   iii. Specify the servers on which the specified logon time period takes effect.
   - Click **All Servers** to select specific servers.
   - Click **Server Groups** to select servers by group.

   iv. Click **OK**.

   Click **Modify** or **Delete** to modify or delete an approved logon time period.
8. Set approved accounts.

   Turn on the **Disapproved Account Alert** switch. The switch is turned on if it turns green.

   To add an approved account, follow these steps:

   i. Click **Add**.
   ii. In the **Specify an Approved Account** section, enter an account.

iii. Select the servers on which the specified account takes effect.
- Click **All Servers** to select specific servers.
- Click **Server Groups** to select servers by group.

iv. Click **OK**.

Click **Modify** or **Delete** to modify or delete an approved account.

What's next

After you configure policies to identify unusual logons, you can view and handle unusual logons on the **Unusual Logons** tab. For more information, see Handle unusual logons.

21.6.4.2. Handle unusual logons

This topic describes how to handle unusual logons. The unusual logons include logons from disapproved locations or IP addresses, logons by using brute-force attacks or disapproved accounts, and logons at a disapproved time.

Context

For more information about the policies that are configured to identify unusual logons, see Configure policies to identify unusual logons.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Intrusion Detection**.
3. Click the **Unusual Logons** tab.
4. (Optional)Specify the filter conditions to locate unusual logons. The filter conditions include **Asset**, **Alert Type**, and **Status**.

   > **Note** If you skip this step, all unusual logons appear in the event list.

5. In the event list, view and handle unusual logons.

   Check whether an unusual logon is a false positive.
   - If the unusual logon is a false positive, click **Ignore**.
   - If the unusual logon is not a false positive, harden the security of the physical server and click **Ignore**. To harden the security of the physical server, you can specify a more complex password, fix vulnerabilities, or check configuration items.

21.6.5. Server fingerprints

21.6.5.1. Configure data refresh frequencies

You can configure the frequencies at which the data of running processes, system accounts, listening ports, and software versions is collected and refreshed.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

> **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Server Fingerprints**.
3. In the upper-right corner of the Server Fingerprints page, click **Configure**.
4. In the **Configure** dialog box, configure the data refresh frequencies for the listening ports, running processes, system accounts, and software versions.
5. Click **OK**.

21.6.5.2. View listening ports

Apsara Stack Security regularly collects information about listening ports on a server.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Server Fingerprints**.
3. Click the **Listening Port** tab.
4. (Optional)Specify **Port Number** and **Process Name**. Then, click **Search** to search for the specified port or process.

   > **Note** If you skip this step, all listening ports appear in the port list.

5. In the port list, view **Port Number**, **Network Protocol**, and **Servers**.
6. Click a port number to view the information about the assets and processes that are associated with the port.

21.6.5.3. View running processes

Apsara Stack Security regularly collects the process information of a server.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Server Fingerprints**.
3. Click the **Running Process** tab.
4. (Optional)Specify **Process Name** and **User** and click **Search** to search for the specified process or user.

   > **Note** If you skip this step, all processes appear in the process list.

5. In the process list, view **Process Name** and **Servers**.
6. Click the name of a running process to view the information about the assets, paths, and running users that are associated with the process.

21.6.5.4. View account information

Apsara Stack Security regularly collects the account information of a server.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Server Fingerprints**.
3. Click the **Account Information** tab.
4. (Optional)Specify **Username** and click **Search** to search for the specific account.

   > **Note** If you skip this step, all accounts appear in the account list.

5. In the account list, view **Account** and **Servers**.
6. Click the name of an account to view the information about the assets and user groups that are associated with the account. You can also check whether the account has root permissions

21.6.5.5. View software versions

This topic describes how to view the information about the software versions of physical servers. The information facilitates the management of software assets.

Context

This topic covers the following scenarios:

- Check for software assets that are installed without authorization.
- Check for outdated versions of software assets.
- Find affected assets if vulnerabilities are detected.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Server Fingerprints**.
3. Click the **All Versions** tab.
4. (Optional)Specify **Software Name**, **Version Name**, and **Software Installation Path**. Then, click **Search** to search for specific software.

   > **Note** If you skip this step, all software appears in the software list.

5. In the software list, view the information in the **Software Name** and **Hosts** columns.
6. Click the name of the software to view the host, version, and installation directory of the software.

21.6.6. Log retrieval

21.6.6.1. Supported log sources and fields

This topic describes the log sources and fields that are supported by the log retrieval feature.

The log retrieval feature allows you to query the following types of log sources. You can click a log source link to view the fields that can be retrieved.

Log source	Description
Logon history	Log entries about successful system logons
Logs of brute-force attacks	Log entries about failed system logons during brute-force attacks
Process snapshot logs	Log entries about processes on a server at a specific point in time
Logs of listening port snapshots	Log entries about listening ports on a server at a specific point in time
Account snapshot logs	Log entries about account-based logons on a server at a specific point in time
Process startup logs	Log entries about process startups on a server
Network connection logs	Log entries about active connections from a server to the Internet.

Logon history

The following table describes the fields that you can use to query the logon history.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
warn_ip	string	The source IP address used for the logon.
warn_port	string	The logon port.
warn_user	string	The username used for the logon.
warn_type	string	The logon type.
warn_count	string	The number of logon attempts.

Logs of brute-force attacks

The following table describes the fields that you can use to query logs of brute-force attacks.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
warn_ip	string	The source IP address of the attack.
warn_port	string	The target port of the attack.

Field	Data type	Description
warn_user	string	The target username of the attack.
warn_type	string	The attack type.
warn_count	string	The number of brute-force attack attempts.

Process startup logs

The following table describes the fields that you can use to query process startup logs.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
pid	string	The ID of the process.
groupname	string	The user group.
ppid	string	The ID of the parent process.
uid	string	The ID of the user.
username	string	The username.
filename	string	The file name.
pfilename	string	The name of the parent process file.
cmdline	string	The command line.
filepath	string	The path of the process file.
pfilepath	string	The path of the parent process file.

Logs of listening port snapshots

The following table describes the fields that you can use to query logs about listening port snapshots.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
src_port	string	The listening port.
src_ip	string	The listening IP address.
proc_path	string	The path of the process file.
pid	string	The ID of the process.
proc_name	string	The name of the process.

Field	Data type	Description
proto	string	The protocol.

Account snapshot logs

The following table describes the fields you can use to query account snapshot logs.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
perm	string	Indicates whether the user has root permissions.
home_dir	string	The home directory.
warn_time	string	The time when a password expiration notification is sent.
groups	string	The group to which the user belongs.
login_ip	string	The IP address of the last logon.
last_chg	string	The time when the password was last changed.
shell	string	The Linux shell command.
domain	string	The Windows domain.
tty	string	The logon terminal.
account_expire	string	The time when the account expires.
passwd_expire	string	The time when the password expires.
last_logon	string	The last logon time.
user	string	The username.
status	string	The account status. Valid values: • 0: disabled • 1: normal

Process snapshot logs

The following table describes the fields that you can use to query process snapshot logs.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
path	string	The path of the process file.

Field	Data type	Description
start_time	string	The time when the process was started.
uid	string	The ID of the user.
cmdline	string	The command line.
pname	string	The name of the parent process.
name	string	The name of the process.
pid	string	The ID of the process.
user	string	The username.
md5	string	The MD5 hash value of the process file. If the size of the process file exceeds 1 MB, the system does not calculate the MD5 hash value of the process file.

Network connection logs

The following table describes the fields that you can use to query network connection logs.

Field	Data type	Description
uuid	string	The ID of the client.
IP	string	The IP address of the server.
src_ip	string	The source IP address.
src_port	string	The source port.
proc_path	string	The path of the process file.
dst_port	string	The destination port.
proc_name	string	The name of the process.
dst_ip	string	The destination IP address.
status	string	The status.

21.6.6.2. Logical operators

The log retrieval feature supports multiple search conditions. You can add multiple logical operators to one search condition for one log source, or combine multiple search conditions for several log sources by using different logical operators. This topic describes the logical operators that are supported in log retrieval. Examples are provided to help you understand these operators.

The following table describes the logical operators that are supported in log retrieval.

Logical operators

Logical operator	Description
and	Binary operator. This operator is in the format of `query 1 and query 2`, which indicates the intersection of the query results of `query 1` and `query 2`. **Note** If no logical operators are used for multiple keywords, the default operator is AND.
or	Binary operator. This operator is in the format of `query 1 or query 2`, which indicates the union of the query results of `query 1` and `query 2`.
not	Binary operator. This operator is in the format of `query 1 not query 2`, which indicates the results that match `query 1` but do not match `query 2`. This format is equivalent to `query 1 - query 2`. **Note** If you use only `not query 1`, the log data that does not contain the query results of `query 1` is returned.

21.6.6.3. Query logs

This topic describes how to search for and view physical server logs.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   Note For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Log Retrieval**.
3. Specify search conditions.

   Note For more information about log sources, log fields, and logical operators, see Supported log sources and fields and Inference rules and logical operators.

4. Click **Search** and view the search result.

- **Reset**: Click **Reset** to clear the search condition configurations.
- **Save Search**: Click **Save Search** to save the search condition configurations which you can use to search for logs in the future.
- **Saved Searches**: Click **Saved Searches** to select and use a search condition that you saved.

21.6.7. Configure security settings for physical servers

This topic describes how to configure security settings for physical servers. You can enable or disable periodic trojan scans. You can also specify the working mode of the Server Guard agent.

Procedure

1. Log on to Apsara Stack Security Center by using an Apsara Stack tenant account.

   > **Note** For more information about the Apsara Stack tenant account, see Create and grant permissions to a security administrator account.

2. In the left-side navigation pane, choose **Physical Server Security > Settings**.
3. Enable periodic trojan scans for physical servers.
   i. In the Trojan Scan section, click **Manage**.
   ii. In the All Servers section, select the physical servers on which you want to perform periodic trojan scans. Then, click the rightwards arrow.
   iii. Click **OK**.
4. On the Protection Mode page, click **Manage**.

   Configure protection modes for servers.

   - **Business First Mode**: The peak CPU utilization is less than 10%, and the peak memory usage is less than 50 MB.
   - **Protection First Mode**: The peak CPU utilization is less than 20%, and the peak memory usage is less than 80 MB.

21.7. Application security

21.7.1. Quick start

This topic helps you get started with the features of Web Application Firewall (WAF).

WAF uses intelligent semantic analysis algorithms to identify web attacks. WAF also uses a learning model to enhance its analysis capabilities and meet your daily security protection requirements without relying on traditional rule libraries.

The following content describes the procedure for using WAF:

1. Customize WAF protection rules.

   WAF provides default protection policies. You can also customize policies that suit your business requirements.

   - For more information about how to configure protection policies, see Configure protection policies.
   - For more information about how to configure custom rules, see Create a custom rule.
   - For more information about how to configure HTTP flood protection rules, see Configure an HTTP flood protection rule.
2. Add websites that you want to protect.

WAF can protect Internet websites and virtual private cloud (VPC) websites.

- For more information about how to add an Internet website to WAF for protection, see Add an Internet website for protection.
- For more information about how to add a VPC website to WAF for protection, see Add a VPC website for protection.

3. Configure Domain Name System (DNS) resolution.

   For more information about how to change the DNS-resolved source IP address for a website to a virtual IP address assigned by WAF, see Modify DNS resolution settings.

4. View WAF protection results.
   - For more information about how to view the protection overview, see View protection overview.
   - For more information about how to view the service access information, see View Web service access information.
   - For more information about how to view the detection logs for web attacks, see View attack detection logs.
   - For more information about how to view the detection logs for HTTP flood attacks, see View HTTP flood protection logs.

21.7.2. Detection overview

21.7.2.1. View protection overview

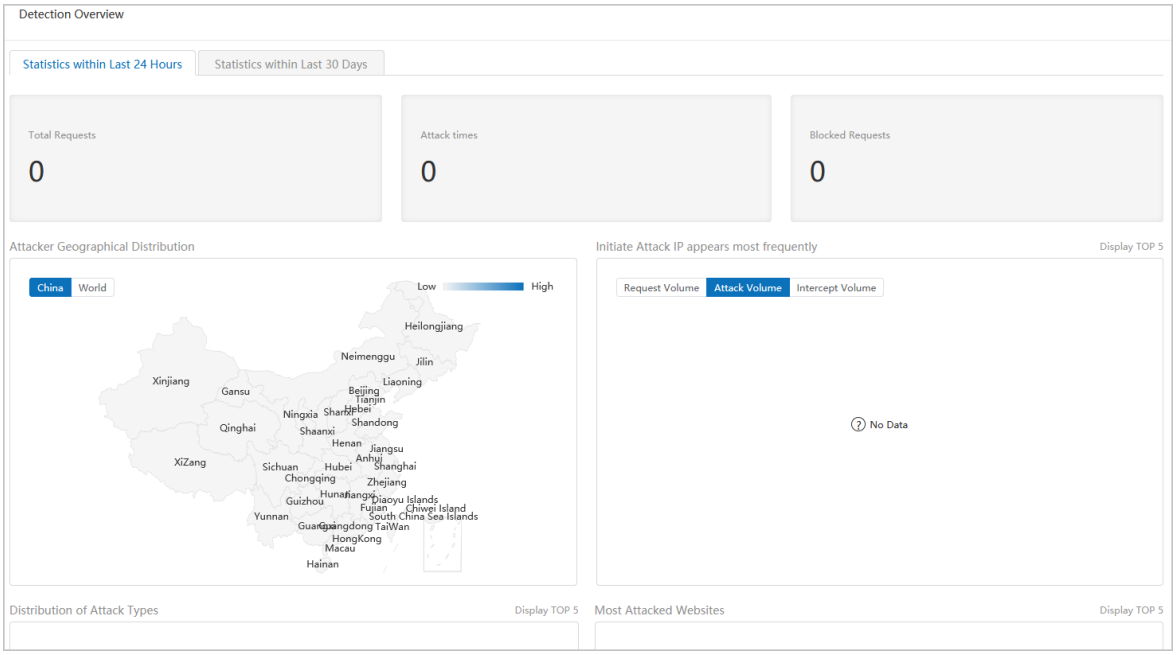
This topic describes how to view the Web Application Firewall (WAF) protection overview.

Context

The Detection Overview page displays information such as the statistics of previous attacks, the geographical distribution of attackers, the total number of requests, and the number of blocked requests. You can also view details about the attacks. This way, you can customize rules to protect your web services.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. Choose **Statistic > Detection Overview**.
4. On the **Detection Overview** page, view data on the **Statistics within Last 24 Hours** and **Statistics within Last 30 Days** tabs.



- Total Requests

  Displays the total number of requests.

- Attack times

  Displays the total number of attacks.

- Blocked Requests

  Displays the number of blocked requests.

- Attacker Geographical Distribution

  Displays the distribution of attackers on a map. You can select a map of China or a map of the world.

- Initiate Attack IP appears most frequently (Display TOP 5)

  Displays the top five IP addresses from which the most attacks are launched in a bar chart. The x-axis indicates the numbers of requests. The y-axis indicates the IP addresses.

- Distribution of Attack Types (Display TOP 5)

  Displays the distribution of the top five attack types and the number of attacks of each type in a bar chart.

- Most Attacked Websites (Display TOP 5)

  Displays the top five attacked websites and the number of attacks on each website in a bar chart.

21.7.2.2. View access information

This topic describes how to view access information about web services.

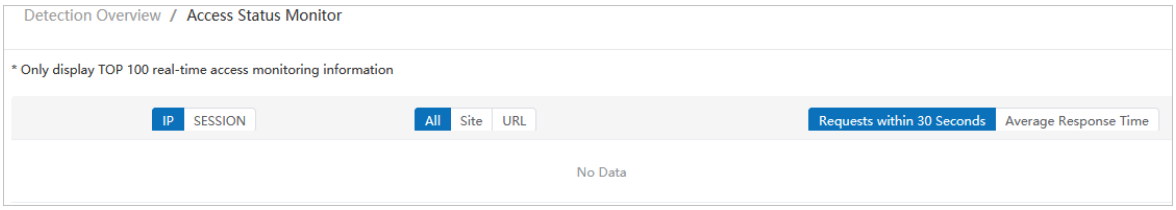
Context

Web Application Firewall (WAF) monitors the access of web services. This way, security administrators can analyze the service access information to detect vulnerabilities and improve security of the services.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree of the **WAF** page, choose **Statistic > Access Status Monitor**.

4. Filter access records to view details.



21.7.3. Protection logs

21.7.3.1. View attack detection logs

This topic describes how to view attack detection logs.

Context

These logs allow you to analyze attacks on your web services. You can update the protection policies and custom rules, and fix the web service vulnerabilities based on the analysis results.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. Choose **Detection Logs > Attack Detection Logs**.
4. Click **Filter**, specify filter conditions, and then click **OK**.

   > **Note** If you specify multiple conditions, they are evaluated by using a logical AND. The system returns the required logs only when all the conditions are met.

5. View the attack detection logs.

21.7.3.2. View HTTP flood protection logs

This topic describes how to view HTTP flood protection logs.

Context

These logs allow you to analyze HTTP flood attacks on your web services. In addition, you can update the HTTP flood protection rules and HTTP flood whitelist, and fix the web service vulnerabilities based on the analysis results.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. Choose **Detection Logs > HTTP Flood Detection Logs**.
4. Click **Filter**, specify filter conditions, and then click **OK**.

   > **Note** If you specify multiple conditions, they are evaluated by using a logical AND. The system returns the required logs only when all the conditions are met.

5. View the HTTP flood detection logs.

   The blocked HTTP flood attacks, related rules, and attack time are displayed.

21.7.3.3. View system operation logs

This topic describes how to view system operation logs.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree, choose **Detection Logs > System operation log**.
4. View the system operation logs.

   The usernames, content, IP addresses, and creation time are displayed.

21.7.3.4. View access logs

This topic describes how to view access logs.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. Choose **Detection Logs > Access Log**.
4. Click **Filter**, specify filter conditions, and then click **OK**.

   > **Note** If you specify multiple conditions, they are evaluated by using a logical AND. The system returns the required logs only when all the conditions are met.

5. View the access logs.

   The requested addresses, destination IP addresses, source IP addresses, methods, response status codes, and time are displayed.

21.7.4. Protection configuration

21.7.4.1. Configure protection policies

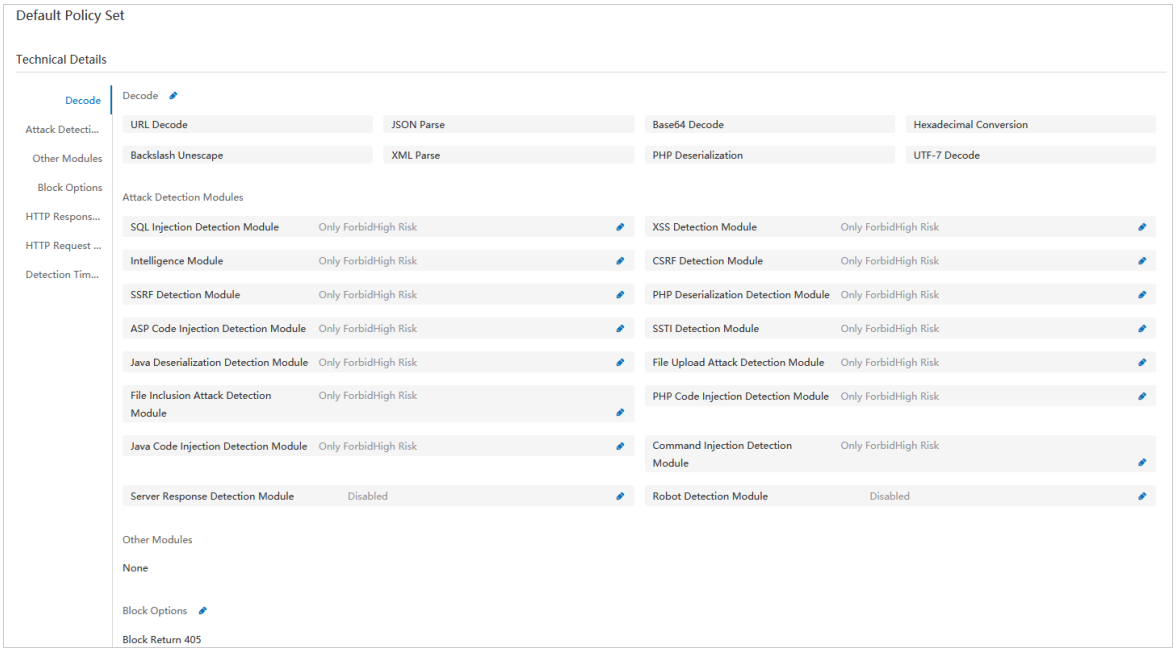
This topic describes how to configure Web Application Firewall (WAF) protection policies.

Context

WAF provides a default protection policy. You can also customize protection policies to suit your business requirements.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree of the **WAF** page, choose **Protection Configuration > Website Protection Policies**.
4. Click **Add a protection policy**. In the panel that appears, specify **Policy name** and click **Confirm**.
5. In the **Operation** column of the new protection policy, click the icon to view or edit the policy.



Parameter	Description
Decode	Select algorithms that you want to use to decode the requests.
Attack Detection Modules	Specify the types of attacks that you want to detect and the risk levels of attacks that you want to block.
Block Options	Specify the HTTP status code and image that you want WAF to return when it blocks an attack.
HTTP Response Processing	Specify **Enable HTTP response processing** and **Response Detection Max Body Size**.
HTTP Request Body Detection	Specify **Response Detection Max Body Size**.
Detection Timeout	Specify **Enable Detection Timeout** and **Timeout Threshold**.

For example, perform the following steps to configure modules in the **Attack Detection Modules** section:

i. Move the pointer over a specific module in the **Attack Detection Modules** section. In this example, move the pointer over **SQL Injection Detection Module** and click the **modify** icon.

ii. In the **SQL Injection Detection Module** panel, configure the following parameters.

Parameter	Description
Enabled	Specify whether to enable the detection module.
Blocking Threshold	Valid values: **NotForbid**, **Only ForbidHigh Risk**, **ForbidMedium or High Risk**, and **Forbid All**.
Record Threshold	Valid values: **Notrecord**, **Onlyrecord High Risk**, **recordMedium or High Risk**, and **record All**.
Detect Non-Injected SQL	Specify whether to enable detection for NoSQL injection vulnerabilities.

iii. Click **OK**.

6. Manage protection policies.

   To delete a protection policy, select the protection policy. Then, in the upper-right corner, choose **More > Delete Selected Protection Policies**. In the message that appears, click **OK**.

   > **Note** You cannot delete the default protection policy.

21.7.4.2. Create a custom rule

This topic describes how to create a custom rule for Web Application Firewall (WAF).

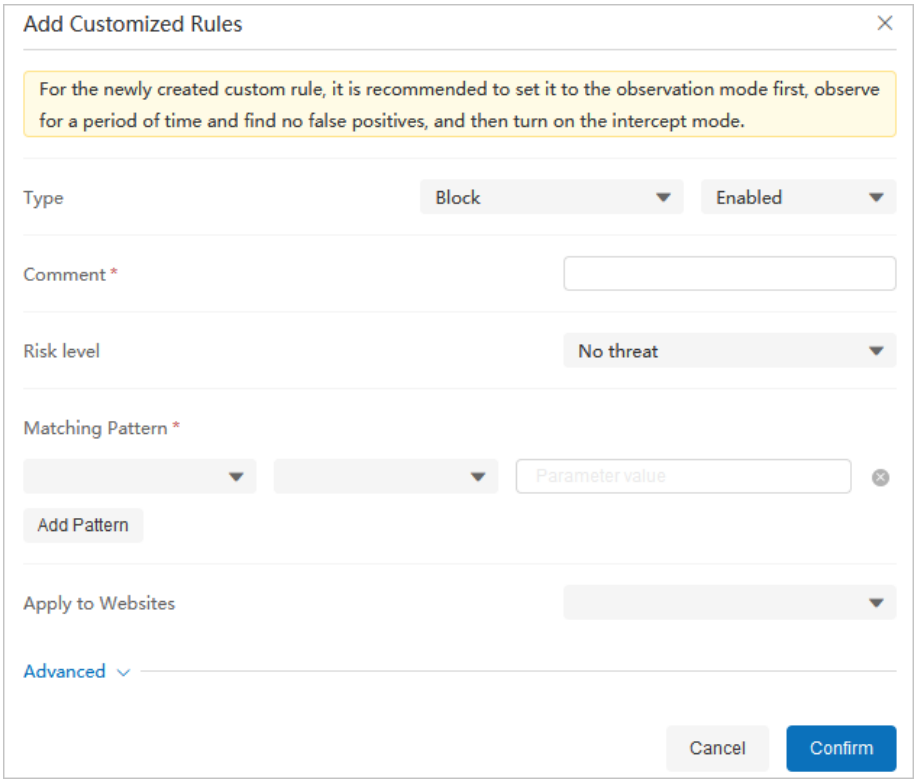
Context

You can create custom rules to meet different requirements for intrusion detection. You can create, edit, or delete custom rules as an administrator. You can use custom rules to filter out requests that meet specific conditions.

Multiple custom rules are evaluated by using a logical **OR**. If two custom rules use the same conditions but trigger different actions such as blocking traffic or allowing traffic, WAF runs the first rule.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree of the **WAF** page, choose **Protection Configuration > Customized Rules**.
4. In the upper-right corner, click **Add Rule**. In the **Add Customized Rules** panel, configure the parameters.



Parameters used to create a custom rule

Parameter	Description

Parameter	Description
Type	The operating mode of the rule. Valid values: **Block**, **Allow**, **Monitor**, and **Detection module control**. ○ **Block**: If an HTTP request meets the conditions of the rule, the HTTP request is blocked. ○ **Allow**: If an HTTP request meets the conditions of the rule, the HTTP request is allowed. ○ **Monitor**: If an HTTP request meets the conditions of the rule, the HTTP request is recorded and allowed. ○ **Detection module control**
Comment	The remarks about the rule. We recommend that you enter the purpose of the rule.
Risk level	The risk level. Valid values: **No threat**, **Low Risk**, **Medium Risk**, and **High Risk**.
Matching Pattern	The conditions that trigger the rule. Click **Add Pattern** to specify more than one condition. Multiple conditions are evaluated by using a logical **AND**. The custom rule takes effect only when all conditions are met.
Apply to Websites	The websites that you want the rule to protect.
Log Recording Option	Specifies whether to record a log when the rule is triggered. The default value is Enable Log Recording. After Log Recording Option is set to Enable Log Recording, all interception events are recorded in the intrusion detection logs.
Attack Type	The type of attack that you want the rule to block.
Expiration Time	The time at which the rule expires.

5. Click **Confirm**.
6. Manage custom rules.
   - Edit a rule.

     To edit a rule, click the icon in the **Actions** column.
   - Enable a rule.

     To enable a rule that is disabled, select the rule and choose **More** > **Enable Selected Rules**.
   - Disable a rule.

     To disable a rule that is enabled, select the rule and choose **More** > **Disable Selected Rules**.
   - Export a rule.

     To export a rule, select the rule and choose **More** > **Export Selected Rules**.
   - Delete a rule.

     To delete a rule that you no longer need, select the rule and choose **More** > **Delete Selected Rules**.

21.7.4.3. Configure an HTTP flood protection rule

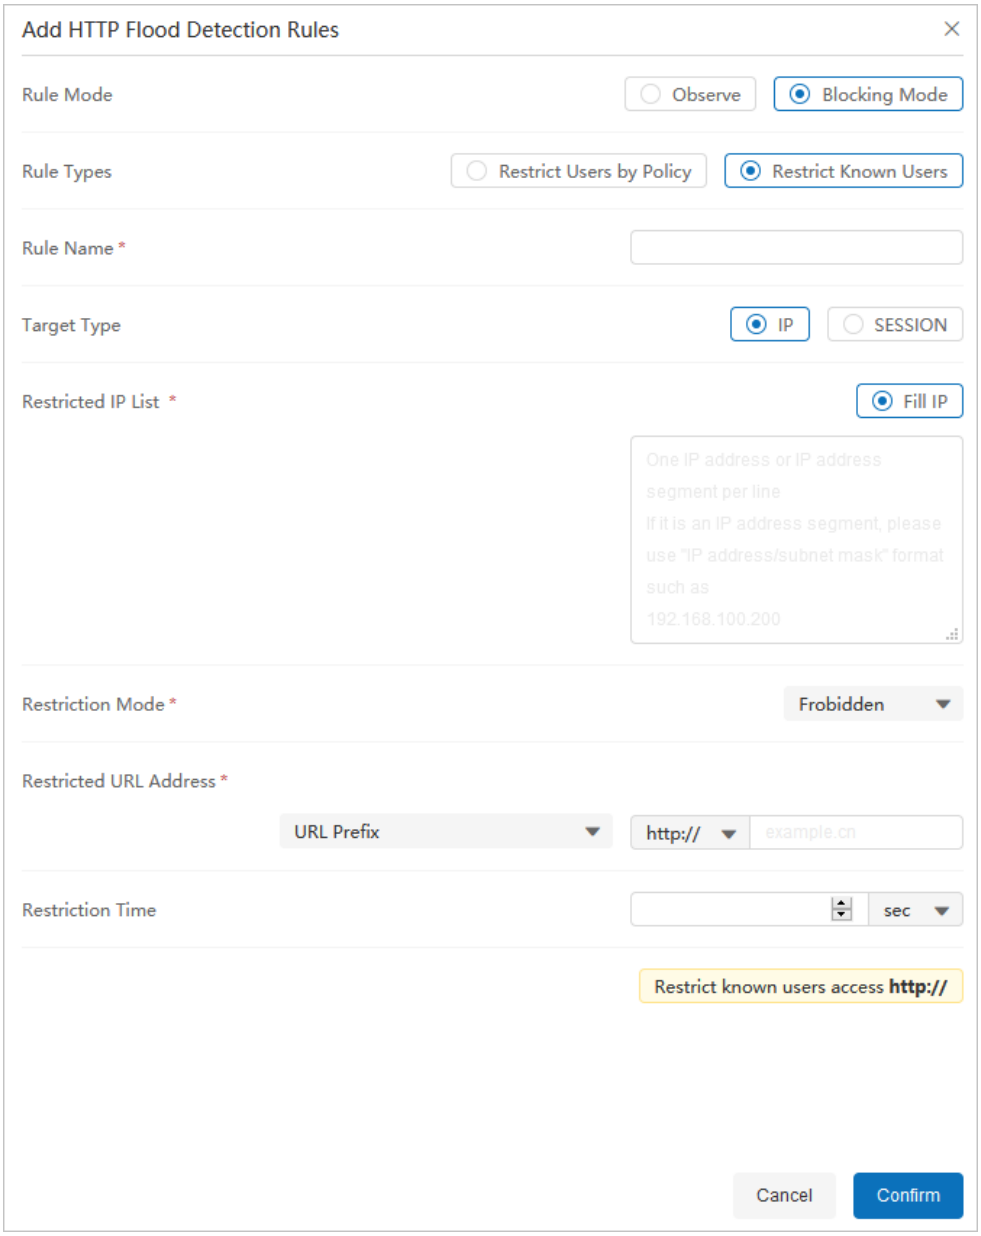
This topic describes how to configure an HTTP flood protection rule.

Context

An HTTP flood attack is a type of DDoS attack that targets the application layer. Attackers use proxy servers or zombies to overwhelm targeted web servers by sending a large number of HTTP requests.

Create an HTTP flood protection rule

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree of the **WAF** page, choose **Protection Configuration > HTTP Flood Detection**.
4. Click **Add Rule**. The **Add HTTP Flood Detection Rules** panel appears.
5. Configure parameters and click **Confirm**.



Parameter	Description

Parameter	Description
Rule Mode	The action on requests after the HTTP flood protection rule is triggered. Valid values: **Blocking Mode** and **Observe**. ○ Blocking Mode: limits the requests that trigger the HTTP flood protection rule. ○ Observe: records the requests that trigger the HTTP flood protection rule, but does not limit the requests.
Rule Types	The type of the HTTP flood protection rule. Valid values: **Restrict Users by Policy** and **Restrict Known Users**. The difference between the two types is determined by whether requests of users are initiated from a specific IP address or in a specific session. ○ **Restrict Users by Policy**: limits requests that meet all the configuration items of the HTTP flood protection rule. Configuration items include **Restriction Trigger Threshold**, **Restricted URL Address**, **Restriction Mode**, **Restriction Time**, and **Statistical Range of Visits** in the Advanced section. ○ **Restrict Known Users**: limits requests that are initiated from specific IP addresses or in specific sessions based on the HTTP flood protection rule. To achieve this purpose, you must configure the IP address or session list and the limit mode. After you configure the list, the HTTP flood protection rule limits requests based on the list.
Rule Name	The name of the HTTP flood protection rule.
Target Type	The type of source for requests that are limited. Valid values: **IP** and **SESSION**. **Note** If you set **Target Type** to **SESSION**, you can apply the HTTP protection rule only to a website whose **User Identification** is set to **WAF User System**. For more information, see Add an Internet website for protection.
Restriction Trigger Threshold	If you set **Rule Types** to **Restrict Users by Policy**, you must configure the triggering conditions for the HTTP flood protection rule.
Restricted URL Address	If you set **Rule Types** to **Restrict Users by Policy**, you must specify the URL addresses that are protected based on the HTTP flood protection rule. ○ **URL Prefix** ○ **URL** ○ **Record all IP addresses**
Restricted IP List or **Restricted SESSION List**	If you set **Rule Types** to **Restrict Known Users**, you must enter the IP addresses or sessions from which you want to limit requests based on the setting of **Target Type**. You can enter only one IP address or session in each line.

Parameter	Description
Restricted URL Address	If you set **Rule Types** to **Restrict Known Users**, you must specify the URL addresses that are protected based on the HTTP flood protection rule. ○ **URL Prefix** ○ **URL** ○ **Restrict user access to all addresses**
Restriction Mode	The mode in which the HTTP flood protection rule limits requests. Valid values: ○ **Forbidden**: The rule blocks specific sources from accessing the specified URL address. ○ **Frequency control**: The rule limits the frequency at which specific sources access the specified URL address.
Restriction Time	The time at which the action specified in the HTTP flood protection rule takes effect.
Statistical Range of Visits	If you set **Rule Type** to **Restrict Users by Policy**, you can specify the range of data records to limit requests in the Advanced section. ○ Statistics Full Access Data: If you select this option, the frequency of requests is limited when the requests are forwarded to WAF and meet the HTTP flood protection rule, regardless of which data records the requests access. This decreases system performance. ○ Statistics TOP Access Data: If you select this option, the frequency of requests is limited when the requests meet the preceding conditions and access the top 100 data records. This option helps minimize the decrease in system performance. You can select this option when the number of accessed data records is larger than 100. Note that the top 100 data records are measured based on real-time monitoring.

Manage HTTP flood protection rules

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the rule list, manage existing HTTP flood protection rules. Modification is allowed.
   - Search for a rule.

     Click **Filter**. In the **Filter Item** panel, specify filter conditions.
   - Enable a rule.

     Select a rule that is in the Disabled state and choose **More > Enable Selected Rules**.
   - Disable a rule.

     Select a rule that is in the Enabled state and choose **More > Disable Selected Rules**.
   - Delete a rule.

     Select a rule and choose **More > Delete Selected Rules**.

21.7.4.4. Configure the HTTP flood whitelist

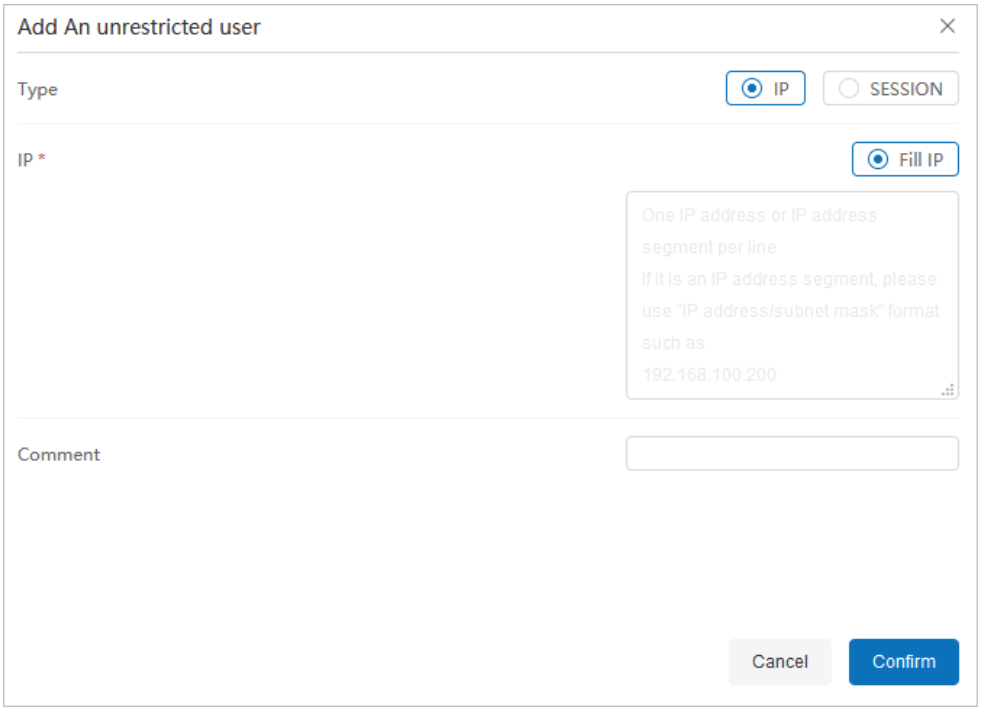
This topic describes how to configure the HTTP flood whitelist.

Context

If a request source is trusted, you can add this request source to the HTTP flood whitelist to allow all requests from this source.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree of the **WAF** page, choose **Protection Configuration > HTTP Flood Detection**.
4. On the **HTTP Flood Detection Whitelist** tab, click **Add Whitelist Item**, add a trusted request source, and then click **Confirm**.



Parameter	Description
Type	Select the type of the request source. Valid values: **IP** and **SESSION**.
IP or **SESSION**	Specify the IP addresses or sessions based on the setting of **Type**. You can enter only one IP address or session in each line.
Comment	Enter remarks for the request source.

5. Manage request sources in the whitelist.
   - Search for a request source in the whitelist.

     Click **Filter**. In the panel that appears, specify a filter condition or click **Add Filter Item** to specify more filter conditions.
   - Remove a request source from the whitelist.

     Select the request source and choose **More > Delete Selected Items**.

21.7.4.5. Manage SSL certificates

This topic describes how to upload or delete SSL certificates.

Context

After you upload an SSL certificate on the **SSL Certificate Management** page, you can select this certificate when you add an HTTPS website for protection on the **Protection Site Management** page.

> **Note** When you add an HTTPS website for protection on the **Protection Site Management** page, you must select the SSL certificate that corresponds to the domain name of the HTTPS website.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. Choose **Protection Configuration > SSL Certificate Management**.
4. Upload a new certificate.
   i. Click **Upload SSL Certificate**.
   ii. In the **Name** field, enter a **name for the new certificate**.
   We recommend that you enter the domain name for easier management.
   > **Note** If your Certificate Authority (CA) certificate and private key are in the same file, select **Include private key in certificate file**.
   iii. In the **File** section, upload the CA certificate file and private key file.
   iv. Specify **Certificate Password**.
   v. Click **Confirm**.
5. (Optional)Delete the uploaded SSL certificate.
   If an uploaded SSL certificate expires, you can delete it.
   i. In the SSL certificate list, select the certificate that you want to delete.
   ii. Choose **More > Delete selected SSL certificate**.
   iii. In the message that appears, click **OK**.

21.7.4.6. Add Internet websites for protection

This topic describes how to add Internet websites to Web Application Firewall (WAF).

Context

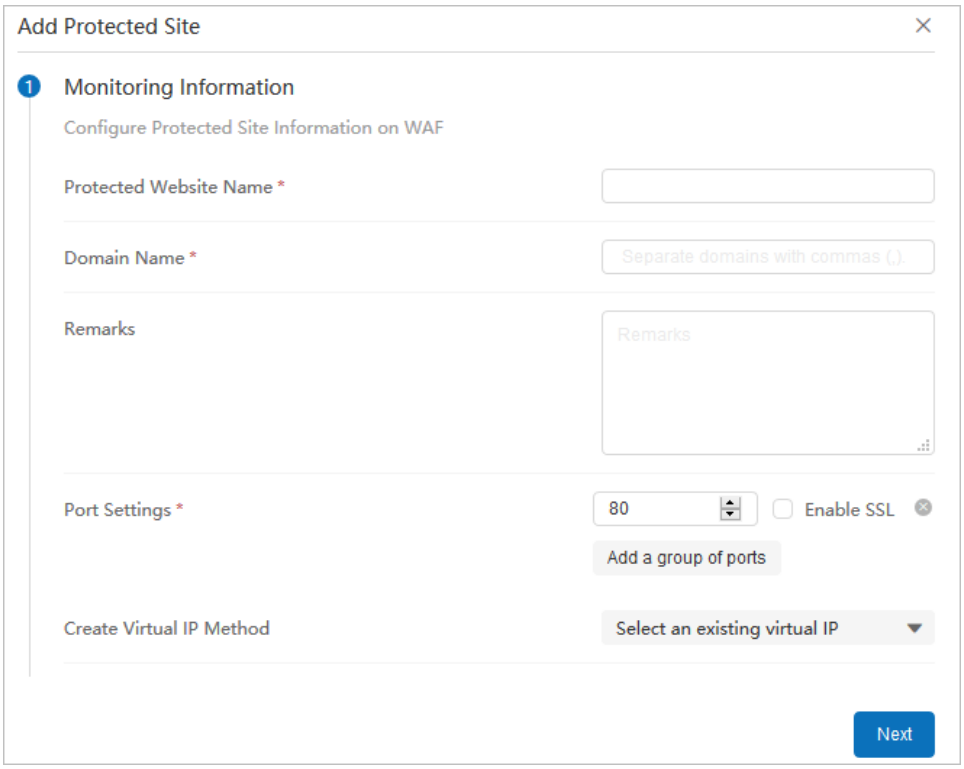
WAF can protect the following types of websites:

- Internet websites.
- Virtual Private Cloud (VPC) websites. For more information about how to add VPC websites to WAF, see Add a VPC website for protection.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. Choose **Protection Configuration > Protection Site Management**. On the page that appears, click the **Internet Websites** tab.
4. In the upper-right corner, click **Add a site**. The Add Protected Site panel appears.
5. In the Monitoring Information step, configure parameters and click **Next**.

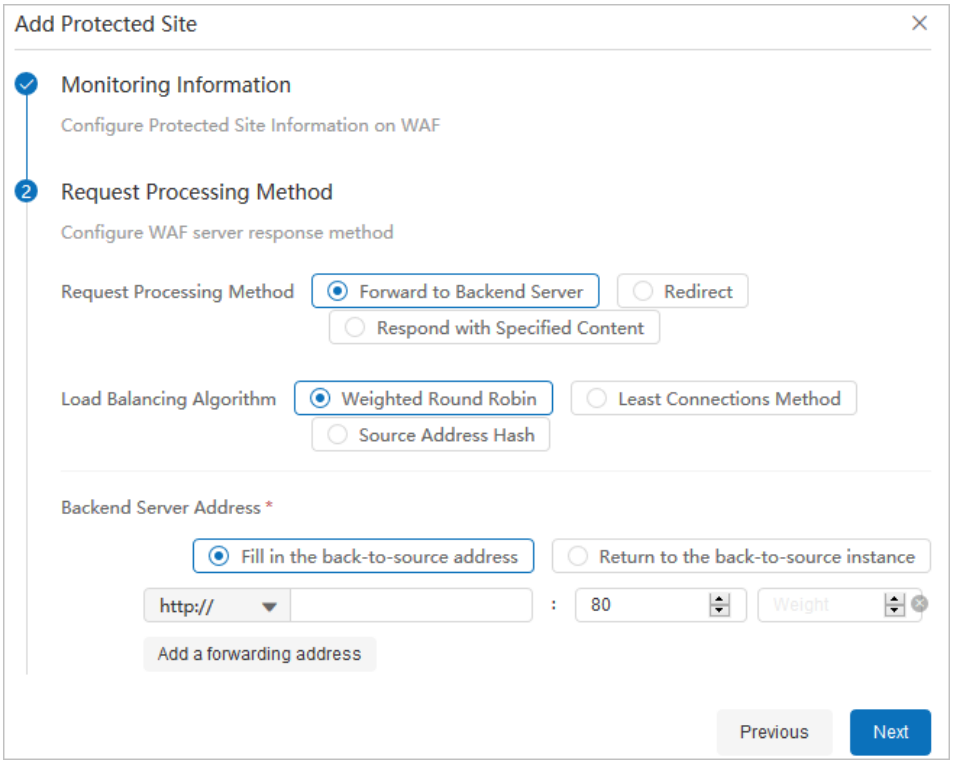
Specify the Internet website that you want WAF to protect. WAF can protect both HTTP and HTTPS websites.



Parameter	Description
Protected Website Name	The name of the website that you want WAF to protect.
Domain Name	The domain name of the website. ◦ You can use an asterisk (*) as a wildcard. ◦ If you specify multiple domain names, separate them with commas (,).
Port Settings	The port that WAF listens on. ◦ If the website supports HTTPS requests, select **Enable SSL** and upload an HTTPS certificate. ◦ If the website can be accessed over multiple ports, click **Add a group of ports** to add the required ports.

Parameter	Description
Cert Setting	The HTTPS certificate of the website. Valid values: *Upload a New Certificate* and *Choose an Existing Certificate*. ○ *Upload a New Certificate*: If the HTTPS certificate of the website has not been uploaded to WAF, select this option. By default, the HTTPS certificate and private key are separately uploaded. If you select **Include private key in certificate file**, upload only one file that contains both the HTTPS certificate and private key. ○ *Choose an Existing Certificate*: If the HTTPS certificate of the website has been uploaded to WAF, select this option. Then, select the required HTTPS certificate from the drop-down list. **Note** This parameter is required only if you select **Enable SSL** next to the **listening port** field.
Name	The name of the HTTPS certificate. **Note** This parameter is required only if you select **Enable SSL** next to the **listening port** field.
File	The HTTPS certificate and private key. By default, the HTTPS certificate and private key are separately uploaded. If you select **Include private key in certificate file** next to **Name**, upload only one file that contains both the HTTPS certificate and private key. **Note** This parameter is required only if you select **Enable SSL** next to the **listening port** field.
Virtual IP	The IP address type and virtual IP address. **Note** You can select an IPv6 address as the virtual IP address for WAF. By default, WAF provides 10 virtual IP addresses. You can add more virtual IP addresses based on your business requirements. **Note** A virtual IP address is available only for the department to which the creator of the virtual IP address belongs.

6. In the Request Processing Method step, configure parameters and click **Next**.



Response mode	Parameter	Description
Forward to Backend Server	**Load Balancing Algorithm**	The algorithm for load balancing. Valid values: **Weighted Round Robin**, **Source Address Hash**, and **Least Connections Method**.
	Backend Server Address	The address of the origin server to which WAF forwards inbound traffic. Valid values: **Fill in the back-to-source address** and **Return to the back-to-source instance**. ○ **Fill in the back-to-source address**: Enter the address of the origin server. If you enter multiple addresses, load balancing is performed based on the specified **load balancing algorithm**. ○ **Return to the back-to-source instance**: Enter the address of a specific ECS or SLB instance. If you enter multiple addresses, load balancing is performed based on the specified **load balancing algorithm**.
	X-Forwarded-For	The pass-through mode of the actual source IP address. The X-Forwarded-For (XFF) header is used to identify the actual source IP address of an HTTP client. The header is used for traffic forwarding services, such as HTTP proxy and load balancing.

Response mode	Parameter	Description
Redirect	**Response Status Code**	The HTTP status code that WAF returns when it redirects inbound traffic to a specified address. Valid values: **301**, **302**, and **307**. ○ **301**: The requested page is permanently moved to another URL. ○ **302**: The requested page is temporarily moved to another URL. The requester must continue to use the original URL for future requests. ○ **307**: The requested page is temporarily moved to another URL. The requester must continue to use the original URL for future requests.
	Redirect address	The destination URL for redirection.
Respond with Specified Content	**Response Status Code**	The HTTP status code that WAF returns when it returns specified content. Valid values: **200**, **404**, and **503**.
	Response	The content to return. For example, you can upload an image for the **Response** parameter. If a user visits the website, WAF returns the uploaded image.

7. In the Protection Policy step, configure parameters and click Next. Then, go to the **Finish** step.

> **Note** You can configure a protection policy only if you set **Request Processing Method** to **Forward to Backend Server**.

Parameter	Description
Protection Policy	Select a WAF protection policy. For more information, see Configure protection policies.
User Identification	Specify whether to enable the user identification feature. **Note** If you enabled HTTP flood protection for the protected website and set **Target Type** to **SESSION** when you configured the HTTP flood protection rule, you must set **User Identification** to **WAF User System**.

21.7.4.7. Add VPC websites for protection

This topic describes how to add Virtual Private Cloud (VPC) websites to Web Application Firewall (WAF) for protection.

Context

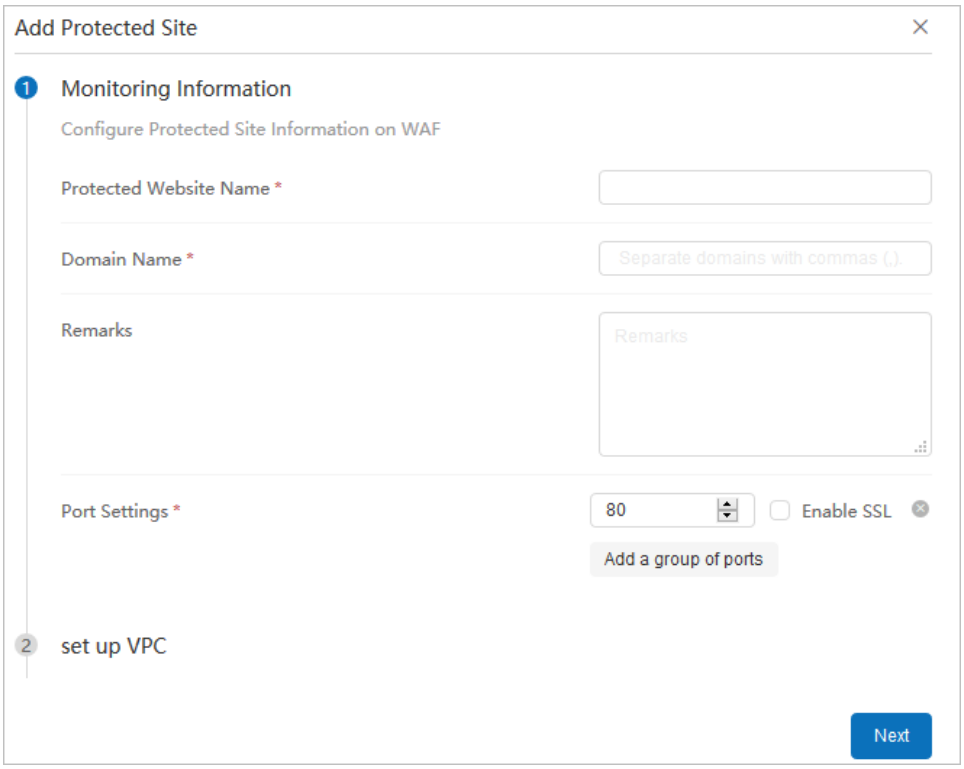
WAF can protect the following types of websites:

- Internet websites. For more information about how to add an Internet website for protection, see Add an Internet website for protection.
- VPC websites.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF > Protection Configuration > Protection Site Management**. On the page that appears, click the **VPC Websites** tab.
3. In the upper-right corner, click **Add a site**. The **Add Protected Site** panel appears.
4. In the Monitoring Information step, configure parameters and click **Next**.

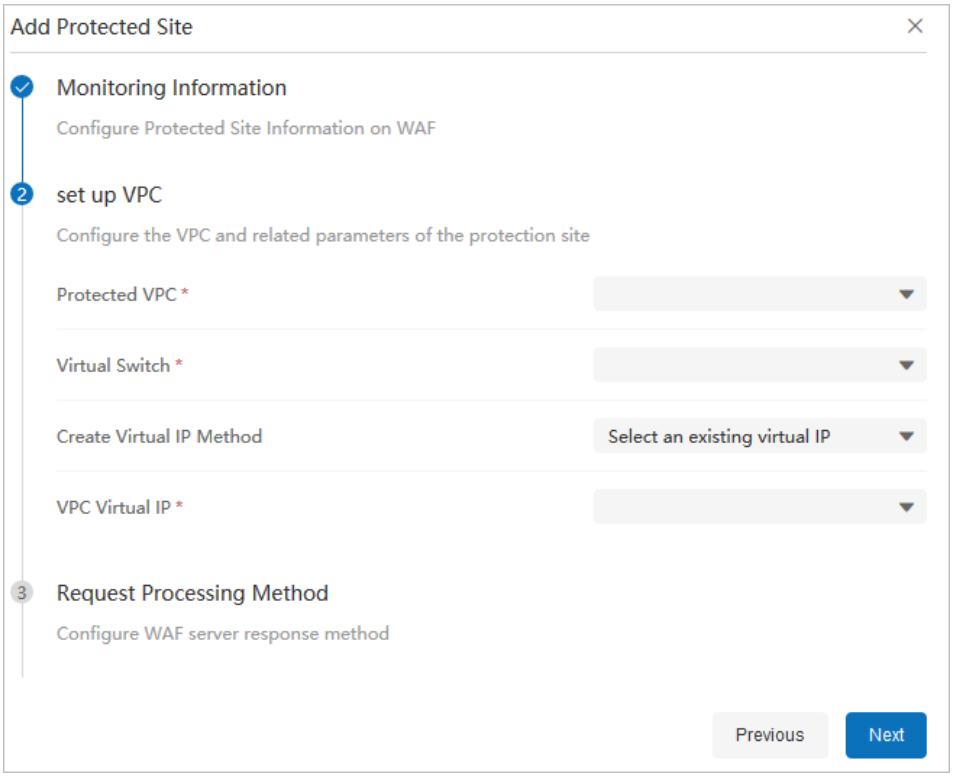
   Specify the VPC website that you want WAF to protect. WAF can protect both HTTP and HTTPS websites.



Parameter	Description
Protected Website Name	The name of the website that you want WAF to protect.
Domain Name	The domain name of the website. ○ You can use an asterisk (*) as a wildcard. ○ If you specify multiple domain names, separate them with commas (,).
Port Settings	The port that WAF listens on. ○ If the website supports HTTPS requests, select **Enable SSL** and upload an HTTPS certificate. ○ If the website can be accessed over multiple ports, click **Add a group of ports** to add the specific ports.

Parameter	Description
Cert Settings	The HTTPS certificate of the website. Valid values: **Upload a New Certificate** and **Choose an Existing Certificate**. **Note** Specify this parameter only if you select **Enable SSL** next to **Port Settings**. ○ **Upload a New Certificate**: If the HTTPS certificate used by the website has not been uploaded to WAF, select this option. By default, the HTTPS certificate and private key are separately uploaded. If you select **Include private key in certificate file**, upload only a file that contains both the HTTPS certificate and private key. ○ **Choose an Existing Certificate**: If the HTTPS certificate used by the website is uploaded to WAF, select this option. Then, select the specific HTTPS certificate from the drop-down list.
Name	The name of the HTTPS certificate. **Note** Specify this parameter only if you select **Enable SSL** next to **Port Settings** and set Cert Setting to Upload a New Certificate.
File	The HTTPS certificate and private key to upload. By default, the HTTPS certificate and private key are separately uploaded. If you select **Include private key in certificate file** next to **Name**, upload only a file that contains both the HTTPS certificate and private key. **Note** Specify this parameter only if you select **Enable SSL** next to **Port Settings** and set Cert Setting to Upload a New Certificate.

5. In the set up VPC step, configure parameters and click **Next**.



Parameter	Description
Protected VPC	The VPC to which the website belongs.
Virtual Switch	The vSwitch associated with the specified VPC.
Create Virtual IP Method	The method to create a virtual IP address. Valid values: **Select an existing virtual IP** and **Create virtual IP**.
VPC Virtual IP	◦ If you set **Create Virtual IP Method** to **Select an existing virtual IP**, select an existing virtual IP address from the **VPC Virtual IP** drop-down list. ◦ If you set **Create Virtual IP Method** to **Create virtual IP**, click **Click to Create Vip** next to **VPC Virtual IP** to generate a virtual IP address.

6. In the Request Processing Method step, configure parameters and click **Next**.

Response mode	Parameter	Description
	Load Balancing Algorithm	The algorithm for load balancing. Valid values: **Weighted Round Robin**, **Source Address Hash**, and **Least Connections Method**.

Response mode	Parameter	Description
Forward to Backend Server	**Backend Server Address**	The IP address of the origin server to which WAF forwards inbound traffic. Valid values: **Fill in the back-to-source address** and **Return to the back-to-source instance**. ○ **Fill in the back-to-source address**: Enter the address of the origin server. If you enter multiple addresses, load balancing is performed based on the specified **load balancing algorithm**. ○ **Return to the back-to-source instance**: Enter the address of a specific Elastic Compute Service (ECS) or Server Load Balancer (SLB) instance. If you enter multiple addresses, load balancing is performed based on the specified **load balancing algorithm**.
	X-Forwarded-For	The passthrough mode of the actual source IP address. The X-Forwarded-For (XFF) header is used to identify the actual source IP address of an HTTP client. The header is used for request forwarding services, such as HTTP proxy and load balancing.
Redirect	**Response Status Code**	The HTTP status code that WAF returns when it forwards inbound traffic to a specified address. Valid values: **301**, **302**, and **307**. ○ **301**: The requested page is permanently moved to another URL. ○ **302**: The requested page is temporarily moved to another URL. The requester must continue to use the original URL for future requests. ○ **307**: The requested page is temporarily moved to another URL. The requester must continue to use the original URL for future requests.
	Redirect address	The required URL for redirection.
Respond with Specified Content	**Response Status Code**	The HTTP status code that WAF returns when it returns specified content. Valid values: **200**, **404**, and **503**.
	Response	The content to return. For example, you can upload an image for the **Response** parameter. If a user visits the website, WAF returns the uploaded image.

7. In the Protection Policy step, configure parameters and click Next. Then, go to the **Finish** step.

Parameter	Description
Protection Policy	Select a WAF protection policy. For more information, see Configure protection policies.
User Identification	Specify whether to enable the user identification feature.

21.7.4.8. Verify the configurations of a website on your on-premises server

This topic describes how to verify the configurations of a website on your on-premises server.

Context

Before you use Web Application Firewall (WAF) to scrub traffic destined for a website, we recommend that you verify the configurations of the website on your on-premises server. After you add the virtual IP address and the domain of a website to the hosts file on your on-premises server, the request to access the domain from a local browser passes through WAF first.

Procedure

1. Log on to Apsara Stack Security Center.
2. Add the virtual IP address and domain name to the *hosts* file on your on-premises server.

   If your computer runs Windows 7, the hosts file is stored in the following path: *C:\Windows\System32\drivers\etc\hosts*.

   i. Open the hosts file by using a text editor, such as Notepad.

   ii. Add the following content to the end of the file: `<The virtual IP address that is assigned by WAF><Protected domain name>` .

   
   > **Note** The IP address preceding the domain name is the virtual IP address that is assigned by WAF.

3. Ping the protected domain name from your on-premises server.

   The returned IP address must be the virtual IP address that is assigned by WAF in the hosts file. If the returned IP address is still the IP address of the origin server, refresh the local Domain Name System (DNS) cache.

4. Enter the domain name in the address bar of your browser and press Enter.

   If the access configurations on WAF are correct, you can visit the website.

5. Verify the protection capability of WAF.

   Simulate a web attack request and check whether WAF blocks the request.

   For example, add `/?alert(xss)` after the URL. If you try to visit `www.example.com/?alert(xss)` , WAF is expected to block the request.

21.7.4.9. Modify DNS resolution settings

This topic describes how to modify the Domain Name System (DNS) resolution settings to connect your website to Web Application Firewall (WAF).

Context

Before you can modify the DNS resolution settings, you must verify the settings on your computer and make sure that the settings are correct. Then, the traffic destined for your website can be redirected to WAF after you modify the settings.

The domain name of a protected website may not be resolved by a DNS provider. For example, a website may use a Server Load Balancer (SLB) instance to connect to the Internet. In this case, you can perform the following operation to protect the website by using WAF: Specify the virtual IP address that WAF assigns to your website as the back-to-origin IP address of the SLB instance.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree of the **WAF** page, choose **Protection Configuration > Protection Site Management**.
4. Find the website whose DNS resolution settings you want to modify and click the icon in the **Operation** column.
5. On the **Basic Information** tab, record the virtual IP address assigned to the website.
6. Log on to the console of the DNS provider and find the DNS resolution settings for the domain name of the website. Then, change the IP address in the A record to the virtual IP address assigned to the website.

> **Note** We recommend that you set the TTL to 600 seconds in DNS resolution settings. The larger the TTL is, the longer it takes to synchronize and update DNS records.

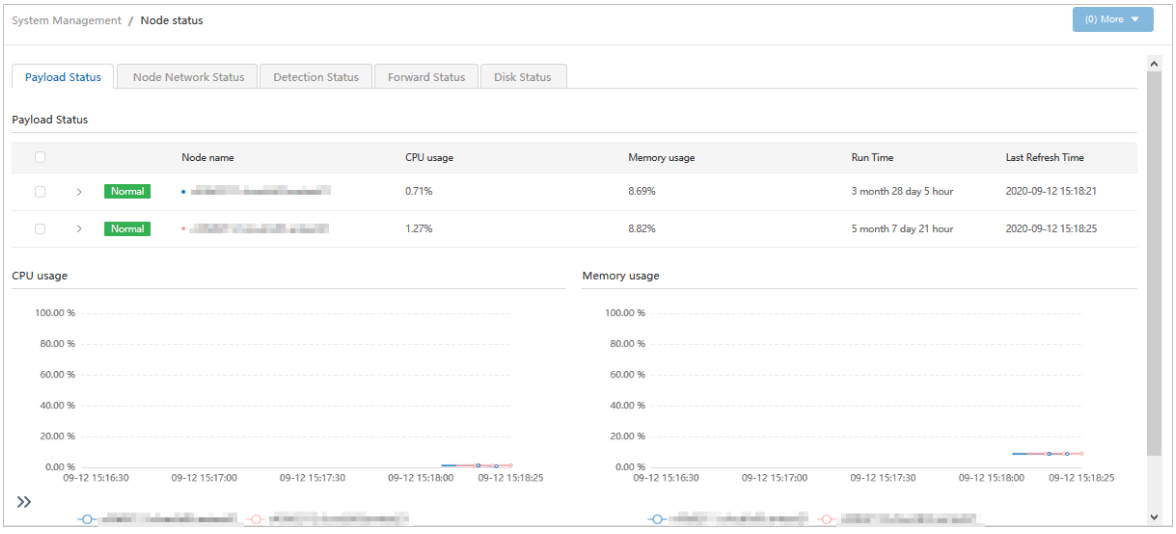
21.7.5. System management

21.7.5.1. View the load status of nodes

This topic describes how to view the load status of Web Application Firewall (WAF) nodes. The status information includes CPU utilization and memory usage. You can identify faults based on the status and check whether scale-out or scale-up is required.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree of the **WAF** page, choose **System Info > Node status**.
4. On the **Payload Status** tab, view the load status of WAF nodes.



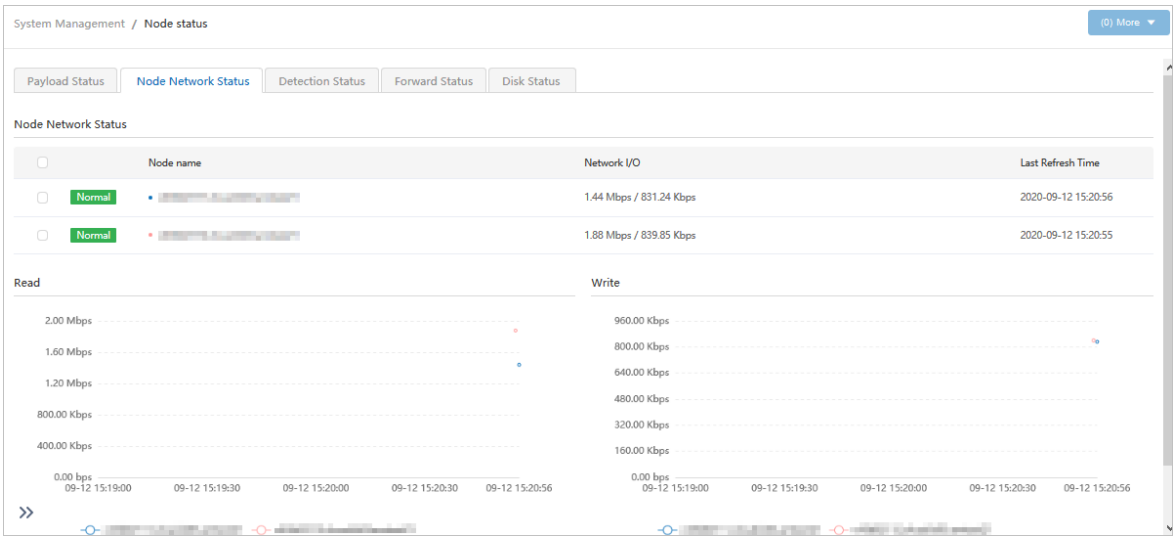
In the Payload Status section, you can view the CPU utilization and memory usage of WAF nodes. In the CPU usage and Memory usage sections, you can view the changes in CPU utilization and memory usage over a specific period of time.

21.7.5.2. View the network status of nodes

This topic describes how to view the network status of Web Application Firewall (WAF) nodes. The status information includes network I/O, traffic detection status, and traffic forwarding status.

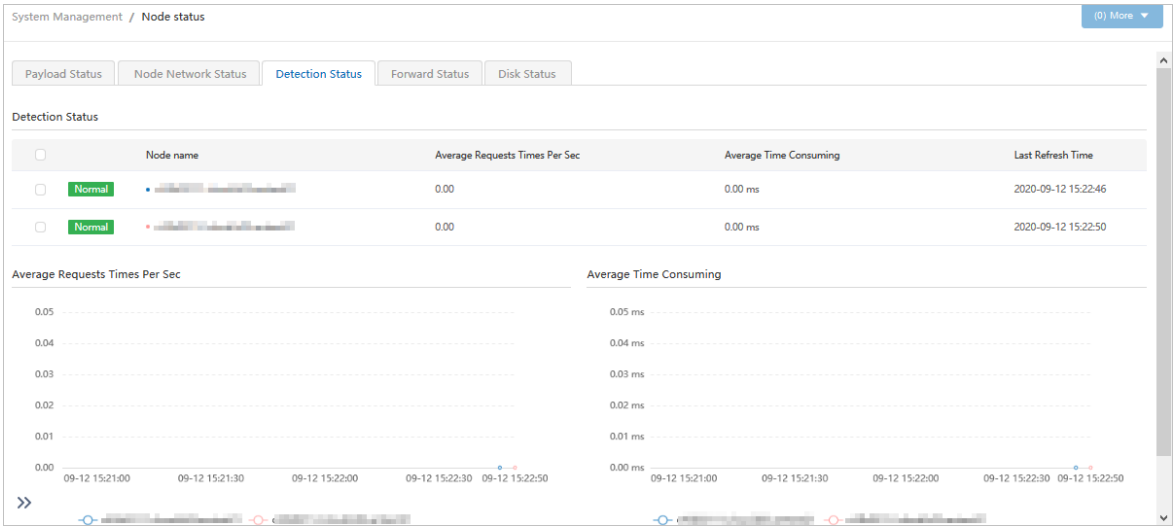
Node network status

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. Choose **System Info > Node status**.
4. Click the **Node Network Status** tab.
5. View the network I/O of WAF nodes.



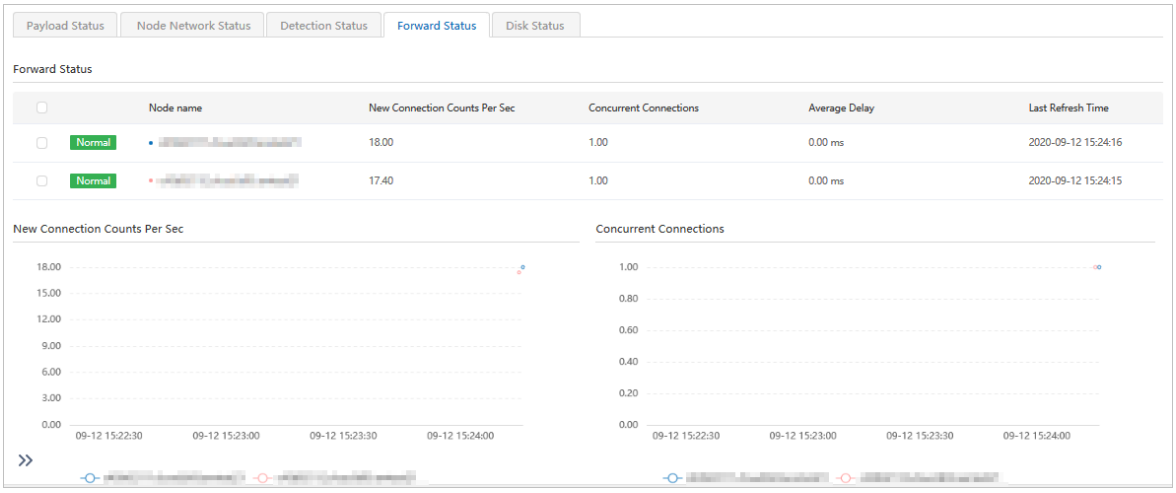
Traffic detection status

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF > System Info > Node status**.
3. Click the **Detection Status** tab.
4. View the traffic detection status of WAF nodes.



Traffic forwarding status

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF > System Info > Node status**.
3. Click the **Forward Status** tab.
4. View the traffic forwarding status of WAF nodes.

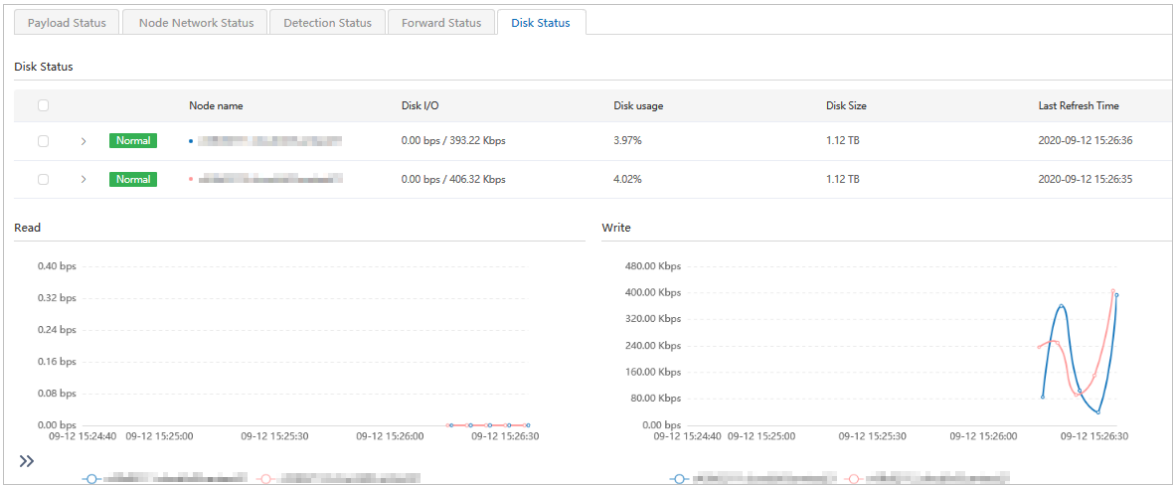


21.7.5.3. View the disk status of nodes

This topic describes how to view the disk status of Web Application Firewall (WAF) nodes. You can identify faults based on the status and check whether scale-out or scale-up is required.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree of the **WAF** page, choose **System Info > Node status**.
4. Click the **Disk Status** tab to view the disk status of WAF nodes.



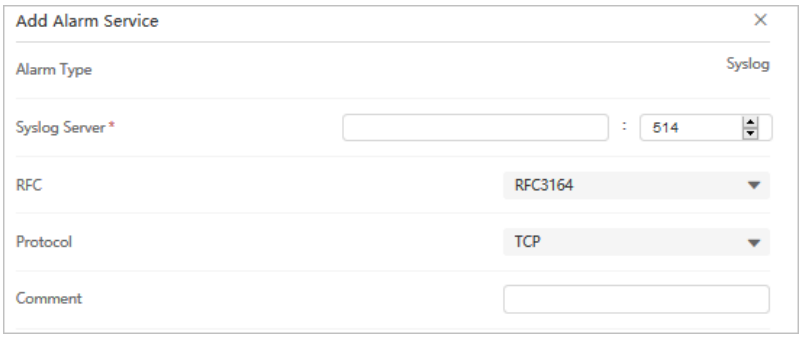
In the Disk Status section, you can view the disk I/O and disk usage of WAF nodes. In the **Read** and **Write** sections, you can view the changes in disk reads and writes over a specific period of time.

21.7.5.4. Configure alerts

This topic describes how to add a syslog server to Web Application Firewall (WAF). After the syslog server is added, WAF alert logs can be pushed to the syslog server over the syslog protocol.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**.
3. In the left-side navigation tree of the **WAF** page, choose **System Settings > Syslog Configuration**.
4. On the **Alarm Service Configuration** tab, click **Add alarm service**.
5. In the **Add Alarm Service** panel, configure parameters.



Parameter	Description
Syslog Server	The IP address and port number of the syslog server.
RFC	The Request for Comments (RFC) document that defines the syslog protocol. Valid values: **RFC3164** and **RFC5424**.
Protocol	The transmission protocol. Valid values: **TCP** and **UDP**.
Comment	The description of the syslog server. This information facilitates subsequent identification and management.
General	The type of alert. Valid values: System Management and System Monitor and Alarm.

Parameter	Description
Security	The module whose alert logs are sent to the syslog server.

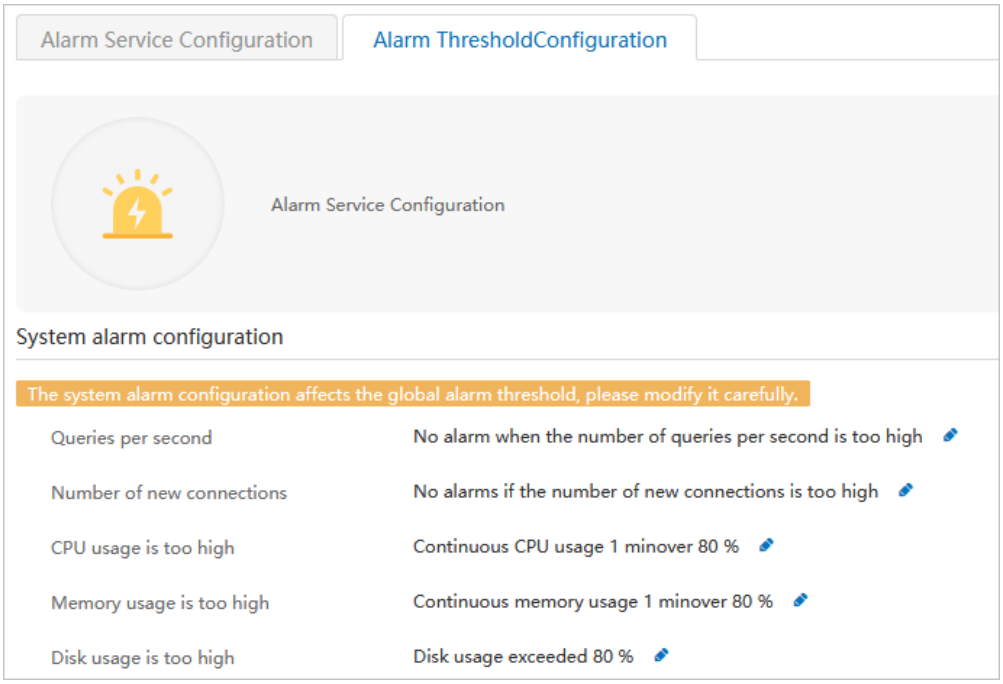
6. Click **Confirm**. The newly added syslog server appears in the list of the Alarm Service Configuration tab.
7. Find the newly added syslog server and click the icon in the **Operation** column to test whether alerts are sent.
   - If a message appears, indicating that the alert test is successful, the syslog server is added.
   - If an error message appears, WAF cannot connect to the syslog server.

21.7.5.5. Configure alert thresholds

This topic describes how to configure alert thresholds.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Application Security > WAF**. On the page that appears, choose **System Settings > Syslog Configuration**.
3. Click the **Alarm ThresholdConfiguration** tab and click the icon next to the threshold that you want to modify.
4. In the panel that appears, specify the threshold.



Threshold	Description
Queries per second	If queries per second exceed this threshold, alerts are sent. If this threshold is set to 0, no alerts are sent.
Number of new connections	If a large number of new connections exist, no alerts are sent.

Threshold	Description
CPU usage is too high	If CPU utilization exceeds this threshold in a specific period of time, alerts are sent.
Memory usage is too high	If memory usage exceeds this threshold in specific a period of time, alerts are sent.
Disk usage is too high	If disk usage exceeds this threshold, alerts are sent.

5. Click **OK**.

21.8. Security Operations Center (SOC)

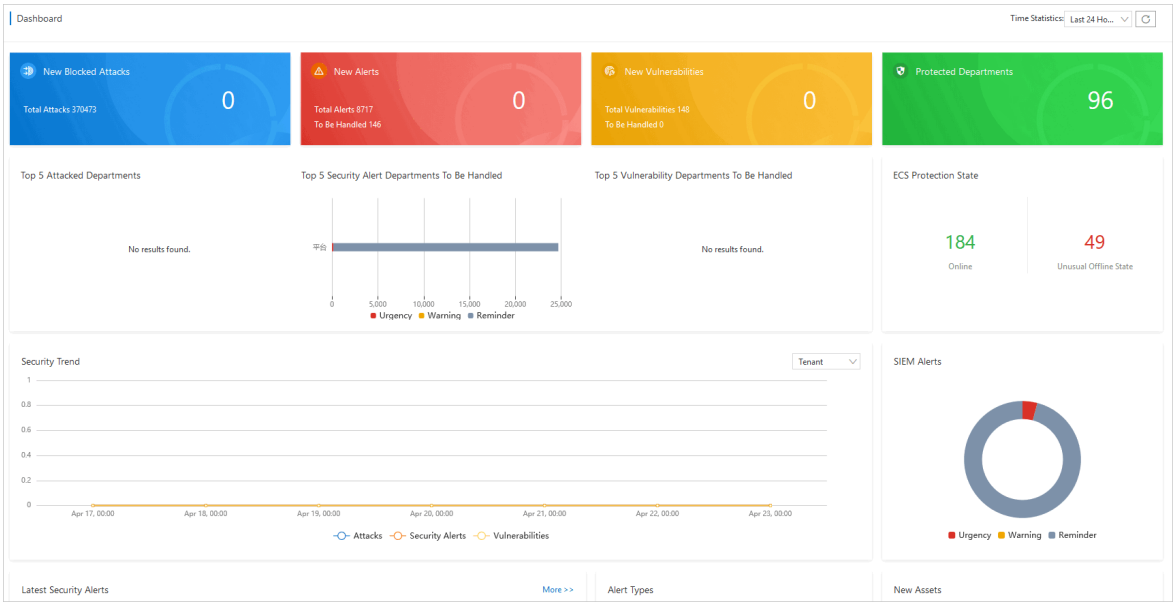
21.8.1. View the dashboard

This topic describes how to view the overall security information about the Apsara Stack network environment.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Overview**.
3. In the upper-right corner of the **Dashboard** page, select a time range from the **Time Statistics** drop-down list.

   Valid values: *Last 24 Hours*, *Last 7 Days*, and *Last 30 Days*.
4. View the overall security information.



The Dashboard page displays the following information:

- **New Blocked Attacks**, **New Alerts**, **New Vulnerabilities**, and **Protected Departments**
- **Top 5 Attacked Departments**, **Top 5 Security Alert Departments To Be Handled**, and **Top 5 Vulnerability Departments To Be Handled**
- **Security Trend**, which supports a switchover between Tenant and Platform
- **Latest Security Alerts** and **Alert Types**
- **Latest Attacks** and **Attack Types**
- **ECS Protection State**, **New Assets**, and **Protected Assets**

21.8.2. Security Monitoring

21.8.2.1. View security monitoring data of tenants

This topic describes how to view the security monitoring data of tenants on the Attack Protections, Security Alerts, and Vulnerabilities tabs.

Attack Protections

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Tenant Security Monitoring**.
3. On the **Attack Protections** tab, view all attack events.

   You can specify search conditions to search for attack events based on the following table.

   
Search condition	Description
Department	The department to which the assets affected by the attack belong.
Data source	The data source.
Status	The attack status.
Attack type	The attack type.
Start time and end time	The time range to query the attack event.
Attack name or asset keyword	The attack name or the keywords of affected assets.

4. View details in the attack event list.
5. Click the icons in the upper-left corner to refresh or export the list.

   The following list describes how to perform the operations:

   - Click the icon to refresh the attack event list.
   - Click the icon to export the attack event list.

6. Find an attack event. In the Actions column, block requests from a specific IP address, create a tag for the event, or view logs and details of the event.

   The following list describes how to perform the operations:

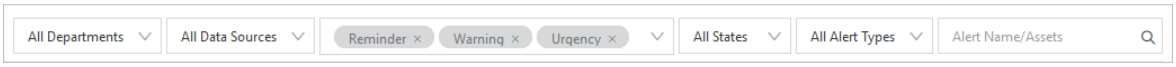
   - Block requests from a specific IP address: Click **Block IP Addresses**. In the **Block IP Addresses** dialog box, configure parameters to block requests from a specific IP address. For more information, see Block IP Addresses.

     In the upper-right corner, click **View Blocked IPs** to view details about the blocked IP addresses.
   - Create a tag: Click **Tag**. In the **Customize Tag** dialog box, create a tag for the attack event and click **OK**.
   - View logs: Click **View Log**. On the **Cloud Tenant Logs** tab of the **Log Audit** page, view the logs of tenants.
   - View details: Click **Details** to view the details of the attack event.

Security Alerts

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Tenant Security Monitoring**. On the page that appears, click the **Security Alerts** tab.
3. (Optional)Specify search conditions.

   > **Note** If you want to view all security alerts, skip this step.

Search condition	Description
Department	The department to which the assets affected by the alert belong.
Data source	The data source.
Level	The alert level. You can select one or more alert levels. Valid values: ○ Urgency ○ Warning ○ Reminder
Status	The alert status.
Type	The alert type. You can select **All Alert Types** or a specific alert type.
Start time and end time	The time range to query the alert.
Alert name or asset keyword	The alert name or the keywords of affected assets.

4. View details in the security alert list.
5. Click the icons in the upper-left corner to refresh or export the list.

   The following list describes how to perform the operations:

   - Click the  icon to refresh the security alert list.
   - Click the  icon to export the security alert list.

Vulnerabilities

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Tenant Security Monitoring**. On the page that appears, click the **Vulnerabilities** tab.
3. Click the **Vulnerabilities** or **Server Configurations** tab.
   - **Vulnerabilities**: provides vulnerability information.
   - **Server Configurations**: provides information about server baseline risks.
4. Specify search conditions.

> **Note** If you want to view all vulnerabilities or server baseline risks, skip this step.

Search condition	Description
Department	The department to which the assets affected by the vulnerability or server baseline risk belong.
Level	The level of the vulnerability or server baseline risk.
Type	The type of the vulnerability or server baseline risk.
Status	The status of the vulnerability or server baseline risk.
Start time and end time	The time range to query the vulnerability or server baseline risk.
Vulnerability or risk name, asset keyword, or CVE ID keyword	The name of the vulnerability or server baseline risk, or the keywords of affected assets or CVE IDs.

5. Click the icons in the upper-left corner to refresh or export the list of vulnerabilities or server baseline risks.

   The following list describes how to perform the operations:

   - Click the icon to refresh the list of vulnerabilities or server baseline risks.
   - Click the icon to export the list of vulnerabilities or server baseline risks.

21.8.2.2. View security monitoring data of the Apsara Stack platform

This topic describes how to view the security monitoring data of the Apsara Stack platform on the Attack Protections, Security Alerts, and Vulnerabilities tabs.

Attack Protections

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Platform Security Monitoring**.
3. On the **Attack Protections** tab, view all attack events.

   You can specify search conditions to search for attack events based on the following table.

Search condition	Description
Data source	The data source.
Status	The attack status.
Attack type	The attack type.
Start time and end time	The time range to query the attack event.

Search condition	Description
Attack name or asset keyword	The attack name or the keywords of affected assets.

4. View details in the attack event list.
5. Click the icons in the upper-left corner to refresh or export the list.

   The following list describes how to perform the operations:

   - Click the icon to refresh the attack event list.
   - Click the icon to export the attack event list.
6. Find an attack event. In the Actions column, block requests from a specific IP address, create a tag for the event, or view logs and details of the event.

   The following list describes how to perform the operations:

   - Block requests from a specific IP address: Click **Block IP Addresses**. In the **Block IP Addresses** dialog box, configure parameters to block requests from a specific IP address. For more information, see Block IP Addresses.

     In the upper-right corner, click **View Blocked IPs** to view details about the blocked IP addresses.
   - Create a tag: Click **Tag**. In the **Customize Tag** dialog box, create a tag for the attack event and click **OK**.
   - View logs: Click **View Logs**. On the **Cloud Platform Logs** tab of the **Log Audit** page, view the logs of the platform.
   - View details: Click **Details** to view the details of the attack event.

Security Alerts

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Platform Security Monitoring**. On the page that appears, click the **Security Alerts** tab.
3. (Optional)Specify search conditions.

   > **Note** If you want to view all security alerts, skip this step.

Search condition	Description
Data source	The data source.
Level	The alert level. You can select one or more alert levels. Valid values: - Urgency - Warning - Reminder
Status	The alert status.
Type	The alert type. You can select **All Alert Types** or a specific alert type.
Start time and end time	The time range to query the alert.
Alert name or asset keyword	The alert name or the keywords of affected assets.

4. View details in the security alert list.
5. Click the icons in the upper-left corner to refresh or export the list.

The following list describes how to perform the operations:

- Click the icon to refresh the security alert list.
- Click the icon to export the security alert list.

Vulnerabilities

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Platform Security Monitoring**. On the page that appears, click the **Vulnerabilities** tab and the **Platform Baseline** tab.
3. Specify search conditions.

> **Note** If you want to view all baseline risks of the platform, skip this step.

Search condition	Description
Level	The level of the baseline risk.
Type	The type of the baseline risk.
Status	The status of the baseline risk.
Start time and end time	The time range to query the baseline risk.
Risk name or asset keyword	The risk name or the keywords of affected assets.

4. Click the icons in the upper-left corner to refresh or export the list of platform baseline risks.

The following list describes how to perform the operations:

- Click the icon to refresh the list of platform baseline risks.
- Click the icon to export the list of platform baseline risks.

21.8.2.3. View the global traffic

This topic describes how to view the global traffic, including the average traffic, peak traffic, overall traffic trends, traffic of tenants, and traffic of platforms.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Security Monitoring > Global Traffic Analysis**.
3. On the **Global Traffic Analysis** page, view the global traffic.

You can view the following information on this page:

- View the average traffic and peak traffic
  a. In the upper-right corner of the **Global Traffic Analysis** page, select a time range and traffic direction.

     Valid values of time ranges: **Last 6 Hours**, **Last 24 Hours**, and **Last 7 Days**.

     Valid values of traffic directions: **Inbound** and **Outbound**.

  b. In the upper-left corner of the Global Traffic Analysis page, view the average and peak traffic of the specified traffic direction within the specified time range.
- View traffic trends
  a. In the upper-right corner of the **Global Traffic Analysis** page, select a traffic type.
  b. View the overall traffic trends of each traffic type within the specified time range.
- View the traffic of tenants on the **Tenant Traffic** tab
- View the traffic of platforms on the **Platform Traffic** tab

21.8.3. Asset Management

21.8.3.1. View tenant assets

This topic describes how to view the assets of users. The assets include Elastic Compute Service (ECS) instances, ApsaraDB RDS instances, Object Storage Service (OSS) buckets, Server Load Balancer (SLB) instances, and elastic IP addresses (EIPs).

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Asset Management > Tenant Assets**.
3. Select the required service. Example: **Elastic Compute Service (ECS)**.
4. Specify search conditions to view a specific asset.

   > **Note** If you want to view all assets, skip this step.

Search condition	Description
Department	The department to which the asset belongs.
VPC	The virtual private cloud (VPC) to which the asset belongs.
Status	The running status of the asset.
New	Specifies whether the asset to query is newly added.
Server name or IP address	The keywords of the asset name.

5. View asset information in the asset list.

21.8.3.2. View platform assets

This topic describes how to view the assets of the platform.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Asset Management > Platform Assets**.
3. Specify search conditions to view a specific asset.

   > **Note** If you want to view all assets, skip this step.

4. View asset information in the asset list.

21.8.4. Log Analysis

21.8.4.1. View the Log Overview page

This topic describes how to view the logs that are displayed in the widgets on the Log Overview page.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Overview**.
3. On the **Log Overview** page, view the widgets of the logs.

   You can perform the following operations to **modify** or **delete** the widgets on the **Log Overview** page:

   - To modify a widget, click **Modify** in the upper-right corner of the widget.
     a. In the **Modify** dialog box, reconfigure the **Chart Type**, **Category**, and **Value** parameters. When you configure the **Category** and **Value** parameters, take note of the following points:
        - **Category**: If you set **Chart Type** to **Bar Chart**, **Line Chart**, **Pie Chart**, or **Sheet**, you must specify this parameter.
        - **Value**: If you set **Chart Type** to **Pie Chart** or **Individual Value Plot**, you must specify this parameter.

     b. Click **Refresh** to preview the widget in the right side of the Modify dialog box.
     c. Above the widget, enter a new name to rename the widget.
     d. Click **OK**. The widget is updated on the **Log Overview** page.
   - To delete a widget, click **Delete** in the upper-right corner of the widget.

   The widgets on the **Log Overview** page are created on the **Log Audit** page. To create a widget, click **Please go to the log audit page to add a chart** in the **Add custom visualization chart** section in the lower part of the **Log Overview** page. On the **Log Audit** page, create a custom widget. For more information, see View global logs.

21.8.4.2. View global logs

This topic describes how to view global logs. Global logs are classified into logs of tenants, logs of the platform, and logs of data centers based the department to which the logs belong.

View a log widget

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Audit**.
3. Click the tab on which you want to view the logs of a department. For example, if you want to view the logs of tenants, click the **Cloud Tenant Logs** tab.
4. Specify search conditions and click the icon. Then, you can view the logs that meet the search conditions in

the sections of log distribution chart and log list.

Search condition	Description
Department	If you want to view the logs of a tenant, you can specify this search condition. Select the department to which the tenant belongs.
Log source	Select the type of the system from which you want to collect the logs, the name of the system from which you want to collect the logs, and the log type from the drop-down list.
Duration	Select the time range within which you want to collect the logs. Valid values: **Last 15 Minutes**, **Last 30 Minutes**, **Last 24 Hours**, **Last 7 Days**, **Last 30 Days**, and **Custom**.
Start time and end time	Specify the start and end time within which you want to collect the logs.
Log content	Enter the log content in the search box. If you want to save the search conditions as frequently used search conditions, click **Save Search Condition**. If you want to use these frequently used search conditions, click **Historical Records**. Then, you can view the logs that meet the search conditions.

If you want to search for logs by using JSON domain-specific language (DSL) statements, click **Advanced Search**. In the **Advanced Search** dialog box, enter JSON DSL statements and click **Submit**.

Create a log widget

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Audit**.
3. Click the tab on which you want to view the logs of a department. For example, if you want to view the logs of tenants, click the **Cloud Tenant Logs** tab.
4. In the lower part of the Log Audit page, click the **Visualization** tab.
5. On the **Visualization** tab, configure parameters in the **Chart** section.

Parameter	Description
Chart Type	The type of widget that you want to display on the **Overview** page. Valid values: **Bar Chart**, **Line Chart**, **Pie Chart**, **Individual Value Plot**, and **Sheet**.
Category	This parameter is required only if you select **Bar Chart**, **Line Chart**, **Pie Chart**, or **Sheet** for **Chart Type**. The type of item that you want to display in the horizontal axis or the column header of the widget.
Value Category	The type of item that you want to display in the vertical axis or the row header of the widget.
Value Type	The type of value that you want to display in the widget. Valid values: **count**, **max**, **min**, **avg**, **sum**, **unique_count**, and **median**. If you want to display multiple value types in the widget, click **Add Value Field**. Then, you can configure the **Value Category** and **Value Type** parameters.

6. In the upper-left corner of the preview section on the Visualization tab, enter a name for the widget.

7. Click **Update**.

   After the widget is created, you can view the widget on the **Log Overview** page.

   To configure the content to be displayed in the log list, you can perform the following steps: In the lower part of the Log Audit page, click the **Log** tab. Then, click the icon. To export the log list, click the icon.

21.8.4.3. Log configurations

21.8.4.3.1. Manage log sources

This topic describes how to view and manage the log sources that are connected to Security Operations Center (SOC).

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Configurations**.
3. Click the **Log Sources** tab. On the **Log Sources** tab, view the overview log information and log list.

   This tab provides the following information:

   - In the upper section of the **Log Sources** tab, you can view the total volume of log data and the total number of connected log sources.
   - In the upper-right corner above the log source list, you can specify conditions to search for specific log sources.

Search condition	Description
Access system type	The type of the source system in the log source that is connected to SOC. Valid values: **Host**, **Storage**, **Application**, **Networking**, **Data**, **Security**, and **Other**.
Log Type	The type of log that is collected by SOC. Valid values: **Operations Log**, **Operational Log**, **Alert Log**, and **Others**.
Access mode	The mode that is used to collect logs. Valid values: **Custom** and **Built-in**.
Status	The status of the log source that is connected to SOC. Valid values: **On** and **Off**. In the log source list, find a log source and click the icon in the **Status** column to set the log source to on or off. In the Tips message, click **OK**.

4. Find a log source and click **Modify** in the Actions column.
5. In the **Edit** dialog box, configure the Storage Days and View Permissions parameters. Then, click **OK**.

21.8.4.3.2. Create a log collection task

This topic describes how to create a log collection task.

Prerequisites

If you use Logtail to collect logs, make sure that the following conditions are met:

- The Logtail agent is installed.
- A server group for which you want to configure Logtail is created.

For more information, see Manage log collectors.

1. Log on to Apsara Stack Security Center.

2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Configurations**.
3. On the **Log Configurations** page, click the **Log Access Task** tab.
4. On the **Log Access Task** tab, click **Add**.
5. In the **Configure Log Source** step of the **Create Task** wizard, configure parameters and click **Next**.

Parameter	Description
Task Name	The name of the log collection task.
Access System Name	The name of the source system from which you want to collect the logs. Example: Windows operating system.
Access System Type	The type of the source system from which you want to collect the logs. Valid values: **Host**, **Storage**, **Application**, **Networking**, **Data**, **Security**, and **Other**.
Log Source Name	The subtype of the log type.
Log Type	The type of log that you want to collect. Valid values: **Operations Log**, **Operational Log**, **Alert Log**, and **Others**.
Source	The department to which the logs belong. Valid values: **Cloud Tenant**, **Cloud Platform**, and **On-Premises Data Center**.

6. In the left-side navigation tree of the **Configure Access Method** step, select a data source type, configure parameters, and then click **Next**.

   Valid values of Data Source Type: Syslog, SLS, and Logtail.

   - If you select Syslog, you must configure the following parameters.

Parameter	Description
IP Address	The IP address or CIDR block used to report syslog logs.
Protocol	The network protocol used when the logs are collected. Valid values: **UDP** and **TCP**.
Access System Type	The type of source system from which you want to collect the logs. Valid values: **Host**, **Application**, **Networking**, and **Other**.
Keyword	The keyword of log data.

   - If you select SLS, you must configure the following parameters.

Parameter	Description
Log Project	The name of the project in Log Service.
Log Store	The name of the Logstore in Log Service.
Endpoint	The endpoint used to connect to the project in a specific region.
accessKey	The AccessKey ID of your account used to access Log Service.
secretKey	The AccessKey secret of your account used to access Log Service.

   - If you select Logtail, you must configure the following parameters.

Parameter	Description
Name	The name of the log collector.
Log type	The type of log that you want to collect. Valid values: **JSON**, **Apsara**, **Separator**, and **Regular Expression**.
Log Pattern	The format of log file names. Example: *access*.log*.
Log Path	The path used to store the logs that you want to collect. Absolute paths and relative paths are supported. You can use wildcards in relative paths.
Log Sample	A sample log entry from the logs that you want to collect.
Regular Expression to Match First Log Entry	After you enter the **sample log entry**, click **Generate Automatically**. A regular expression is generated to match the first line of the log entry.
Regular Expression	Click **Regular Expression**. In the **Generate Regular Expression** dialog box, select the fields that you want to extract and click **Generate Regular Expression**. After the regular expression is generated, click **OK**.
Date Format	The date format that is automatically generated based on the extracted time fields.
Apply to Server Group	The server group for which you want to configure Logtail.

7. In the **Parse and Normalize Data** step, configure parameters and click **Next**.

Parameter	Description
Data acquisition method	The method used to obtain the sample log entry. Valid values: **Automatically Obtain** and **Manual Input**.
Data Sample	If you select **Manual Input** as the data acquisition method, you must enter the sample log entry.
Resolver	The parser, which can be selected based on the sample log entry. Valid values: **JSON** and **jsonArray**.
Extract Values	The content that can be extracted from the logs. Click **Add Field**. In the **Add Field** dialog box, configure the **Original Extract Key**, **Original Extract Value**, **Enrich Data**, and **TargetType** parameters. Then, click **OK**. Valid values of **Enrich Data**: **Retain Original Field**, **Tag Field**, **Delete Field**, **Rename Field**, **Automatically Fill System Time**, **Assign Value to Constant**, and **Assign Value to Variable**.

8. In the **Generate Task** step, configure the **Log Source Name**, **Storage Duration**, and **View Permissions** parameters.
9. Click **Save**.

   After the log collection task is created, the task appears in the list of log collection tasks. You can publish, modify, or delete the task in the Actions column of the task.

   - **Publish**: After the log collection task is created, logs are not automatically collected. You must click **Publish**. After the task is published, the  icon appears in the **Access Status** column of the task.

     You can click the switch in the **Access Status** column to change the status of the log collection task.
   - **Edit**: You can click **Edit** to change the configurations in the **Parse and Normalize Data** and **Generate**

Task steps. You cannot change the data source type or log collector.

- **Delete**: If you no longer need the log collection task, you can click **Delete** in the Actions column of the task.

21.8.4.3.3. Manage log collectors

Before you can use Logtail to collect logs, you must install the Logtail agent, add log collectors, and create server groups. This topic describes how to install the Logtail agent, add log collectors, and create server groups.

Install the Logtail agent

If the Logtail agent has been installed, the system automatically uninstalls the existing version of the Logtail agent, deletes the */usr/local/ilogtail* directory, and then reinstalls the Logtail agent. After the new version of the Logtail agent is installed, it automatically runs, and a startup application is added to the registry.

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Configurations**.
3. On the **Log Configurations** page, click the **Collectors** tab.
4. Install the Logtail agent.

   On the **Collectors** tab, install the Logtail agent based on the operating system of the server and the installation method that is supported by the Logtail agent.

   - If the server runs a Linux operating system and the Logtail agent supports manual installation, perform the following steps:
     a. In the **Linux Operating Systems** section, click **Download Installation Package** and determine whether to download a 32-bit or 64-bit installation file to your computer.
     b. Log on to the server as an administrator. Then, run the installation command to install the Logtail agent.
   - If the server runs a Windows operating system and the Logtail agent supports manual installation, perform the following steps:
     a. In the **Windows Operating Systems** section, click **Download Installation Package** to download the installation file to your computer.
     b. Upload the installation file to the server. For example, you can use an FTP client to upload the installation file to the server.
     c. Run the installation file on the server as an administrator.

   After the Logtail agent is installed, it automatically runs, and a startup application is added to the registry.

Add a log collector

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Configurations**.
3. In the **Collectors** section, click **Add Collector**.
4. In the **Add Collector** dialog box, configure the following parameters and click **OK**.

Parameter	Description
Collector IP Address	The IP address of the source whose logs you want to collect.
Server Name	The name of the server where the Logtail agent is installed.
Operating System	The operating system of the server where the Logtail agent is installed.

After the log collector is added, you can view the information of the log collector in the **Collectors** section.

The information includes **Collector IP Address** and **Server Name**.

Create a server group

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Configurations**.
3. In the **Server Groups** section, click **Create Server Group**.
4. In the **Create Server Group** dialog box, configure the following parameters and click **OK**.

Parameter	Description
Server Group Name	The name of the server group.
IP Addresses	The IP addresses of the servers that you want to add to the server group. To add a server to the server group, perform the following steps: i. In the **Ungrouped Servers** section, select the server that you want to add to the group. ii. Click the > icon to add the server to the **Servers to Be Grouped** section.

After the server group is created, you can view basic information of the server group in the **Server Groups** section. If you want to view detailed information of a server group or delete a server group, perform the following steps:

- Find the server group. Then, click **Details** in the Actions column to view the detailed information of the server group.
- Find the server group. Then, click **Delete** in the Actions column to delete the server group.

21.8.4.3.4. Manage storage policies

This topic describes how to view and configure storage policies for logs.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Log Configurations**.
3. On the **Log Configurations** page, click the **Policies** tab.
4. On the **Policies** tab, view the storage policy for logs.
5. Click **Modify**.
6. On the **Policies** tab, configure parameters such as the storage periods for logs and monitoring data. Then, click **Modify**.

Section	Parameter	Description
Log Storage (Advanced)	Maximum Log Size	The upper limit of the storage space that can be used to store logs.
	Maximum Storage Period	The maximum number of days during which logs can be stored.
Security Monitoring Data Storage (Advanced)	ApsaraDB RDS Storage Period	The maximum number of days during which monitoring data can be stored.

21.8.4.4. Security Audit

21.8.4.4.1. Overview

A security audit refers to the systemic and independent inspection and verification of activities and behavior in the computer network environment. Delegated by property owners and authorized by management authorities, professional auditors give their assessments according to relevant laws and regulations. When the administrator needs to backtrack system operations, the administrator can perform a security audit.

Security audits are long-term security management activities throughout the lifecycle of cloud services. The security audit feature of Apsara Stack Security can collect system security data, analyze weaknesses in system operations, report audit events, and classify audit events into important, moderate, and low risk levels. The security administrator views and analyzes audit events to continuously improve the system and ensure the security and reliability of cloud services.

21.8.4.4.2. View security audit overview

This topic describes how to view the summarized information about security audit.

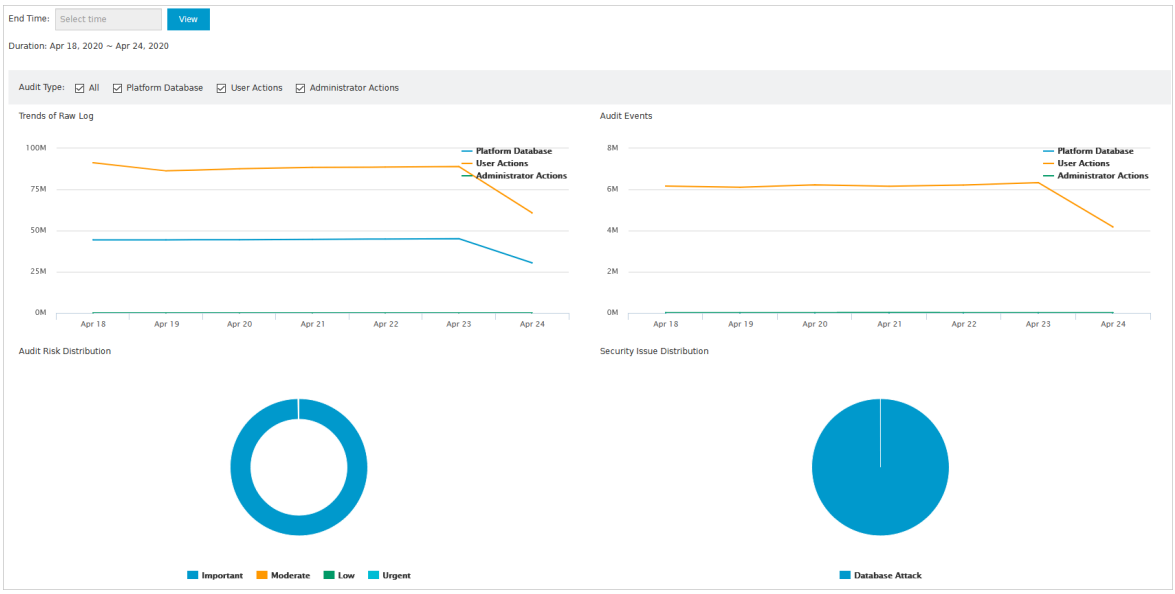
Context

The **Overview** tab provides reports on the raw log trend, audit event trend, audit risk distribution, and security event distribution. The reports are displayed in run charts or pie charts to help security administrators analyze the trend of risks in your cloud services.

On the **Overview** tab, security administrators can check the number of log entries and the storage usage in a specific time range.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Overview** tab.
3. On the **Overview** tab, view the audit summary for the last seven days.



- Trends of Raw Log

This chart displays the trend of logs generated by physical servers, network devices, ApsaraDB RDS instances, Elastic Compute Service (ECS) instances, and API calls in the last seven days. Security administrators can analyze the trend to check whether the number of log entries is at a normal level.

- Audit Events

  This chart displays the trend of audit events that are generated by physical servers, network devices, ApsaraDB RDS instances, ECS instances, and API calls in the last seven days. Security administrators can analyze the trend to check whether the number of audit events is at a normal level.

- Audit Risk Distribution

  This chart displays the percentage distribution of audit events at different risk levels in the last seven days. Risk levels are important, moderate, and low. Security administrators can analyze the trend to check whether the audit events are at acceptable risk levels.

- Security Issue Distribution

  This chart displays the percentage distribution of different event types in the last seven days. Security administrators can analyze this chart to check for the most frequent audit events and identify high-risk events to improve security protection.

- Log Size

  This chart displays the volume of online logs and offline logs. If these logs consume many storage resources, we recommend that you back up required audit logs and delete unnecessary logs.

- Audit Log Size

  This chart displays the size of logs for each audit type.

4. View the audit summary in a specific time range.
   i. Specify **End Time** as the end of the time range to query.
   ii. In **Audit Type**, select the audit types to query.
   iii. Click **View** to view the audit summary in the last seven days before the specified end time.

21.8.4.4.3. Query audit events

This topic describes how to query audit events.

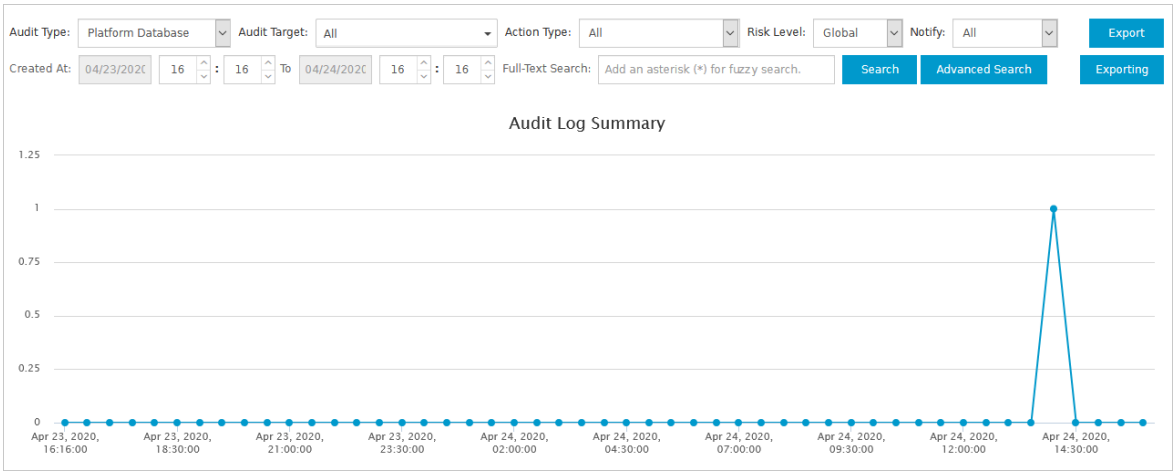
Context

On the **Audit Query** tab, you can view the details of audit events, including the log creation time, audit type, audit object, action type, risk level, and log content.

The system matches the logs that are collected by a security audit module with audit rules. If the log content matches the regular expression in an audit rule, an audit event is reported. For more information about audit rules, see Add an audit policy.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Audit Query** tab.
3. On the **Audit Query** tab, configure query conditions to view audit events within the specified time range.



- Basic query
  a. Configure **Audit Type**, **Audit Target**, **Action Type**, **Risk Level**, and **Notify**.
  b. Specify a time range to query.
  c. In the **Full-Text Search** search box, enter a keyword.
  d. Click **Search**.
- Advanced query

  In addition to the basic query conditions, you can configure advanced query conditions.
  a. Configure basic query conditions.
  b. Click **Advanced Search**.
  c. Below **Filter Condition**, configure **User**, **Target**, **Action**, **Result**, and **Cause**.
  d. Click **Save**.

4. Click **Export** to export the audit events.

   Download the exported file for analysis. For more information, see Manage export tasks.

21.8.4.4.4. View raw logs

This topic describes how to view raw audit logs.

Context

On the **Raw Log** tab, you can view the raw logs generated by a running audit object. Raw logs contain information that is required for debugging. Security administrators can use these raw logs to troubleshoot system failures.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Raw Log** tab.
3. On the **Raw Log** tab, configure query conditions to view the log summary chart and raw logs within a specific time range.
   i. Specify **Audit Type** and **Audit Target**.
   ii. Enter a keyword.
   iii. Specify a time range to query.
   iv. Click **Search**.
4. Click **Export** to export the data.

Download the exported file for analysis. For more information, see Manage export tasks.

21.8.4.4.5. Manage log sources

This topic describes how to view and manage log sources.

Context

You can view the number of log entries by log type or log source. You can also specify whether to display logs.

- The Log Types sub-tab provides the number of all log entries for a specific audit object of a specific device instance.
- The Log Sources sub-tab provides the number of log entries for all audit objects of a specific device instance.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Log Sources** tab.
3. Click the **Log Types** tab and view the number of log entries for each audit object.

   You can view the number of log entries that are recorded on the current day and the number of log entries that are recorded during the last 30 days for each audit object.

   If you do not want to display the log entries for an audit object, perform the following steps:

   i. Find the audit object and click **Hide** in the **Actions** column.

   ii. In the Note message, click **Confirm**.

   > **Note** The process that is used to display the log entries for an audit object is similar to the process that is used to hide the log entries.

4. Click the **Log Sources** sub-tab and view the number of log entries for each device instance.

   You can view the number of log entries that are recorded on the current day and the number of log entries that are recorded during the last 30 days for each device instance.

   If you do not want to display the log entries for an audit object from a specific device instance, perform the following steps:

   i. Find the device instance and click **Hide** in the **Actions** column.

   ii. In the Note message, click **Confirm**.

   > **Note** The process that is used to display the log entries for an audit object is similar to the process that is used to hide the log entries.

21.8.4.4.6. Policy settings

21.8.4.4.6.1. Manage audit rules

This topic describes how to create, modify, or delete an audit rule.

Context

If a log entry matches an audit rule, an audit event is reported. You can specify regular expressions in an audit rule to match log entries. A regular expression defines a matching pattern for character strings and can be used to check whether a string contains a specific substring. The following table provides examples about the pattern.

Regular expression	Description
^\d{5,12}$	Matches the consecutive numbers from the fifth number to the twelfth number.
load_file\(	Matches the "load_file(" string.

The security audit module defines the default audit rule based on the string that is generated in the log. This applies when an audit event is reported. The security administrator can also customize audit rules based on the string that is generated in the log. This applies when the system encounters an attack.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Policies** tab.
3. On the **Policies** tab, click the **Audit Rules** sub-tab.
4. Create an audit rule.
   i. Click **New** in the upper-right corner.
   ii. In the **Add Policy** dialog box, configure parameters.

   iii. Click **Add**.

The system sends an alert email to the specified alert recipient after you create an audit rule. This applies if one string in an audit log of the specified audit type, audit object, or risk level matches the regular expression of the audit rule.

5. Manage audit rules.

   You can create, query, disable, enable, and delete audit rules.

   - Query audit rules

     Specify **Audit Type** and **Audit Target**. Enter a keyword in the search box and click **Search**.

   - Disable an audit rule

     Find the audit rule that you want to disable and click **Disable** in the **Actions** column.

   - Enable an audit rule

     Find the audit rule that has been disabled and click **Enable** in the **Actions** column.

   - Delete an audit rule

     Find the audit rule that you want to delete and click **Delete** in the **Actions** column.

     > **Note** You can delete only custom rules.

21.8.4.4.6.2. Configure alert recipients

This topic describes how to configure the recipients of alerts on audit events.

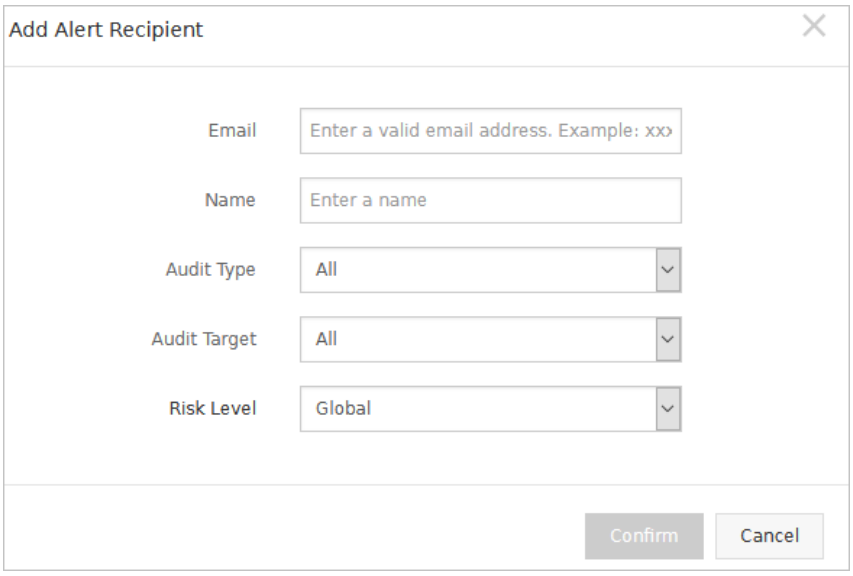
Context

You can add an alert recipient by entering an email address that can be used to receive alerts on audit events.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Policies** tab.
3. On the **Policies** tab, click the **Alert Settings** sub-tab.
4. Create an alert recipient.
   i. Click **New**.

ii. In the **Add Alert Recipient** dialog box, configure parameters.



iii. Click **Confirm**.

5. Manage alert recipients.
   - Search for alert recipients

     Specify **Audit Type**, **Audit Target**, and **Risk Level**, enter the keyword of the email address, and then click **Search**.
   - Delete alert recipients

     Find the email address that you want to delete and click **Delete** in the Actions column.

21.8.4.4.6.3. Manage archives of events and logs

This topic describes how to query and download the archives of audit events and raw logs.

Context

You can download the archives of events and logs to analyze audit events. This ensures the security of the Apsara Stack environment.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Policies** tab.
3. On the **Policies** tab, click the **Archiving** sub-tab.
4. Query the archives of events and logs.
   i. Specify **Audit Type** and **Archiving Type**.
   ii. Specify a time range to query.
   iii. Click **Search**.
5. Find the file where the archive information is stored and click **Download** in the **Actions** column to save the archive file to your on-premises machine.

21.8.4.4.6.4. Manage export tasks

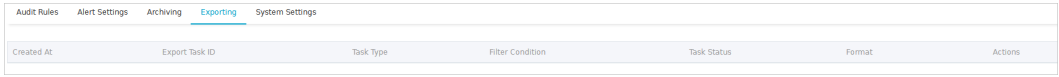
This topic describes how to download or delete exported audit events and logs.

Context

You can export audit events or logs on the **Audit Query** or **Raw Log** tab of the Security Audit page. After you export audit events or logs, you can manage the export tasks on the Exporting sub-tab.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Policies** tab.
3. On the **Policies** tab, click the **Exporting** sub-tab.
4. View the created export tasks.



5. Click **Download** to download audit events or logs to your on-premises server.
6. Click **Delete** to delete the export task.

21.8.4.4.6.5. Modify system settings

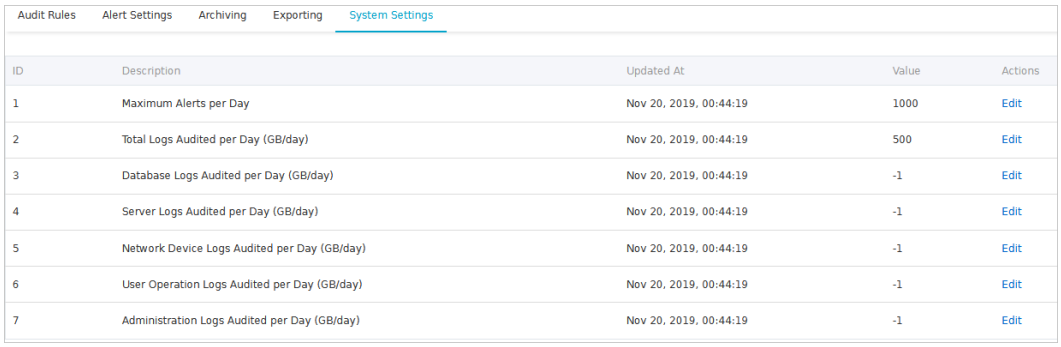
This topic describes how to configure system parameters for security audit.

Context

You can configure system parameters to specify the maximum number of system alerts per day and the maximum number of audits per day for raw logs.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Log Analysis > Security Audit**. On the page that appears, click the **Policies** tab.
3. On the **Policies** tab, click the **System Settings** sub-tab.
4. Find the configuration item that you want to modify and click **Edit** in the **Actions** column.



5. Enter a required value in the Value column and click **Confirm** in the Actions column.

21.8.5. Rules

21.8.5.1. Create an IPS rule for traffic monitoring

This topic describes how to create an intrusion prevention system (IPS) rule for traffic monitoring in Cloud Firewall. Cloud Firewall has built-in IPS rules. This topic describes how to customize IPS rules based on your business requirements and network environment.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Rules**.
3. On the Rules page, click the **Cloud Firewall IPS Rules** tab.
4. Click **Create Rule**.
5. In the **Create Rule** panel, configure parameters.

Parameter	Description
Rule Name	The name of the IPS rule. We recommend that you enter an informative name for easy management.
Rules Engine	The rules engine that you want to use. Valid values: **Basic Policies** and **Virtual Patches**.
Attack Type	The type of attack to be detected by the rule.
Severity	The level of the severity. Valid values: **Low**, **Medium**, and **High**.
CVE	The Common Vulnerabilities and Exposures (CVE) ID of the vulnerability to be listed in the rule. **Note** CVE provides a list of the public security vulnerabilities. CVE IDs are allocated by a CVE Numbering Authority (CNA).
Application	The name of the attacked application.
Rule Mode	The mode of the rule. Valid values: **Packet** and **Traffic**.
Direction	The direction of traffic to be monitored by the rule. Valid values: **Inbound and Outbound**, **Inbound**, and **Outbound**.
Rule Content	The content of the rule, which must be specified by using the Snort syntax. **Note** To prevent negative impact on your business, make sure that you enter valid content for the rule.
Rule Description	The description of the rule. We recommend that you enter information such as the purpose or impact of the rule.
Description	The remarks for the rule. We recommend that you enter information such as the purpose or impact of the rule.

6. Click **OK**.

21.8.5.2. Manage IPS rules of Cloud Firewall

This topic describes how to view, enable, and disable the intrusion prevention system (IPS) rules of Cloud Firewall.

Context

On the **Cloud Firewall IPS Rules** tab of the Rules page in Apsara Stack Security Center, you can view the built-in and custom IPS rules, and enable or disable the rules based on your business requirements.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Rules**.
3. On the Rules page, click the **Cloud Firewall IPS Rules** tab.
4. Manage IPS rules of Cloud Firewall.

   In the list of IPS rules, you can view rule details, enable rules, and disable rules.

   - View rule details

     Find the rule whose details you want to view and click **Details** in the **Actions** column to view the rule details.

   - Enable a rule

     Find the rule that you want to enable and turn on the switch in the **Enable or not** column to change the status of the rule from **Disable** to **Enable**.

   - Disable a rule

     If a rule is not suitable for your business, you can disable the rule.

     Find the rule that you want to disable and turn off the switch in the **Enable or not** column to change the status of the rule from **Enable** to **Disable**.

21.8.5.3. Create IDS rules for traffic monitoring

This topic describes how to create intrusion detection system (IDS) rules for traffic monitoring.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Rules**.
3. On the Rules page, click the **Traffic Monitoring IDS Rules** tab.
4. Click **Create Rule**.
5. In the **Create Rule** panel, configure parameters.

Parameter	Description
Rule Name	The name of the IPS rule. We recommend that you enter an informative name for easy management.
Rules Engine	The rules engine that you want to use. Valid values: **Basic Policies** and **Virtual Patches**.
Attack Type	The type of attack to be detected by the rule.
Severity	The level of the severity. Valid values: **Low**, **Medium**, and **High**.
CVE	The Common Vulnerabilities and Exposures (CVE) ID of the vulnerability to be listed in the rule. **Note** CVE provides a list of the public security vulnerabilities. CVE IDs are allocated by a CVE Numbering Authority (CNA).

Parameter	Description
Application	The name of the attacked application.
Rule Mode	The mode of the rule. Valid values: **Packet** and **Traffic**.
Direction	The direction of traffic to be monitored by the rule. Valid values: **Inbound and Outbound**, **Inbound**, and **Outbound**.
Rule Content	The content of the rule, which must be specified by using the Snort syntax. **Note** To prevent negative impact on your business, make sure that you enter valid content for the rule.
Rule Description	The description of the rule. We recommend that you enter information such as the purpose or impact of the rule.
Description	The remarks for the rule. We recommend that you enter information such as the purpose or impact of the rule.

6. Click **OK**.

21.8.5.4. Manage IDS rules for traffic monitoring

This topic describes how to view, enable, and disable intrusion detection system (IDS) rules for traffic monitoring.

Context

On the **Traffic Monitoring IDS Rules** tab, you can view the built-in and custom IDS rules. It can also be used to enable or disable the rules based on your business requirements.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Rules**.
3. On the Rules page, click the **Traffic Monitoring IDS Rules** tab.
4. Manage IDS rules for traffic monitoring.

   In the IDS rule list, you can view rule details, enable rules, and disable rules.

   - View rule details

     Find the rule whose details you want to view and click **Details** in the **Actions** column to view the rule details.

   - Enable a rule

     Find the rule that you want to enable and turn on the switch in the **Enable or not** column to change the status of the rule from **Disable** to **Enable**.

   - Disable a rule

     If a rule is not suitable for your business, you can disable the rule.

     Find the rule that you want to disable and turn off the switch in the **Enable or not** column to change the status of the rule from **Enable** to **Disable**.

21.8.5.5. Specify custom thresholds for DDoS traffic scrubbing policies and traffic redirection

This topic describes how to specify custom thresholds for DDoS traffic scrubbing policies and traffic redirection. Default thresholds are provided. If you want to specify custom thresholds, perform the following steps:

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Rules**.
3. Specify a custom threshold for a DDoS traffic scrubbing policy.
   i. Click the **AliGuard Rules** tab to open the **Scrubbing Policy** tab.
   ii. Find the policy for which you want to specify a custom threshold and click **Modify Threshold** in the **Actions** column.
   iii. In the **Modify Threshold** dialog box, enter a threshold value.
   iv. Click **OK**.
4. Specify a custom threshold for traffic redirection.
   i. Click the **AliGuard Rules** tab and the **Reroute Threshold** tab.
   ii. Find a specific rule and click **Modify Threshold** in the **Actions** column.
   iii. In the **Modify Threshold** dialog box, enter threshold values.
   iv. Click **OK**.

21.8.5.6. View Server Guard rules

This topic describes how to view the operations of Server Guard rules. You can view the list of vulnerabilities, baselines, and host exceptions.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Rules**. On the page that appears, click the **Server Guard Rules** tab.
3. In the overview section, you can view the total number of **vulnerability libraries**, number of **baselines**, and number of **host exceptions** as well as the available **engines**.
4. View the vulnerability list.
   i. Click the **Vulnerabilities** tab.
   ii. In the overview section, you can view the total number of **Linux vulnerabilities**, total number of **Windows vulnerabilities**, total number of **Web-CMS vulnerabilities**, and total number of **urgent vulnerabilities**.
   iii. Specify search conditions to view the vulnerabilities that meet the search conditions.

   > **Note** If you want to view all vulnerabilities, skip this step.

   In the vulnerability list, you can view the **vulnerability name**, **CVE ID**, **vulnerability type**, **system**, **update time**, and **status**.
5. View the baseline list.
   i. Click the **Baselines** tab.
   ii. In the overview section, you can view the numbers of baseline types and check items.

iii. Specify search conditions to view the baselines that meet the search conditions

> **Note** If you want to view all baselines, skip this step.

In the baseline list, you can view the **baseline type**, **check item category**, **check item name**, **risk level**, **update time**, and **status**.

6. View the host exception list.
   i. Click the **Server Exceptions** tab.
   ii. In the overview section, you can view the number of **rule alert subcategories**, number of webshells, and number of malicious viruses.
   iii. Specify search conditions to view the host exceptions that meet the search conditions.

> **Note** If you want to view all exceptions, skip this step.

In the host exception list, you can view the **subcategory name**, **rule category**, **risk level**, **update time**, **source**, and **status**.

21.8.6. Threat intelligence

21.8.6.1. Enable the service configuration feature

The threat intelligence module integrates threat monitoring and big data analysis. This can be used to obtain the latest information about developments in the threat intelligence field. After you enable the service configuration feature, the system starts to monitor and collect threat intelligence. This topic describes how to enable the service configuration feature.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Threat Intelligence > Service Configuration** .
3. On the **Service Configuration** page, view the data types and descriptions on the Situation Awareness and Web application firewall tabs.
4. Click the tab where you want to enable threat monitoring and turn on **Activation status**.

   After you turn on **Activation status**, the system starts to monitor and collect threat intelligence for the data types listed on the tab.

What's next

After you enable the service configuration feature, choose **Security Operations Center (SOC) > Threat Intelligence**. On the **Overview** page, you can view the overall situation and statistics of threats during the last 30 days. For more information, see View the Overview page.

21.8.6.2. View the Overview page

The Overview page displays the overall situation and statistics of threats to your assets over the last 30 days.

Prerequisites

The **service configuration** feature is enabled. For more information, see Enable the service configuration feature.

Procedure

1. Log on to Apsara Stack Security Center.

2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Threat Intelligence > Overview**.
3. On the **Overview** page, view the statistics and threats that are detected on Apsara Stack services by the threat intelligence module.

   On the **Overview** page, you can perform the following operations:

   - View **Total malicious metric intelligence**

     In the **Total malicious metric intelligence** section of the **Overview** page, view the information about the detected threats on Apsara Stack services. The information includes the number of malicious IP addresses, malicious domain names, and malicious URLs.
   - View **Threat trends in the last 30 days**
   - Search for an IP address to check whether the IP address is malicious.

     Enter the IP address that you want to check in the search box in the upper-right corner of the IP Report page and click the icon. To view the details of the IP address, choose **Security Operations Center (SOC) > Threat Intelligence > IP Address Search**. On the page that appears, click the **IP Report** tab. For more information, see Search for an IP address.
   - View **Top 10 active IP malicious addresses**

     In the **Top 10 active IP malicious addresses** section of the **Overview** page, view the information about the top 10 malicious IP addresses. The information includes **IP address**, **First malicious observation**, **Last malicious observation**, and **Malicious label**.

21.8.6.3. Search for and view the information about a suspicious or malicious IP address

The threat intelligence module allows you to search for threat intelligence. This module helps you handle suspicious or malicious IP addresses at the earliest opportunity.

Prerequisites

The **service configuration** feature is enabled. For more information, see Enable the service configuration feature.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Threat Intelligence > IP Address Search**.
3. In the search box on the **Search** page, enter the suspicious or malicious IP address that you want to query and click the icon.
4. On the **IP Report** page, view **Threat Level**, **Basic Information**, **Threat Overview**, **IP Details**, and **Attack Risk Level Analysis** of the IP address.

   You can view the following information on the IP Report page:

   - **Threat Level**: View the threat level of the suspicious or malicious IP address.

     The threat intelligence module classifies IP addresses into three threat levels. The levels are normal, suspicious, and high-risk. If the IP address is identified as high-risk, we recommend that you handle the IP address at the earliest opportunity.
   - **Basic Information**: View the basic information about the suspicious or malicious IP address.

     The basic information includes the server in a data center, Abstract Syntax Notation One (ASN.1), country and city to which the IP address belongs, and the number of domain names for the IP address.

- View the statistics of the suspicious or malicious IP address.

  You can view **Threat Overview**, **IP Details**, and **Threat Details** of the IP address.

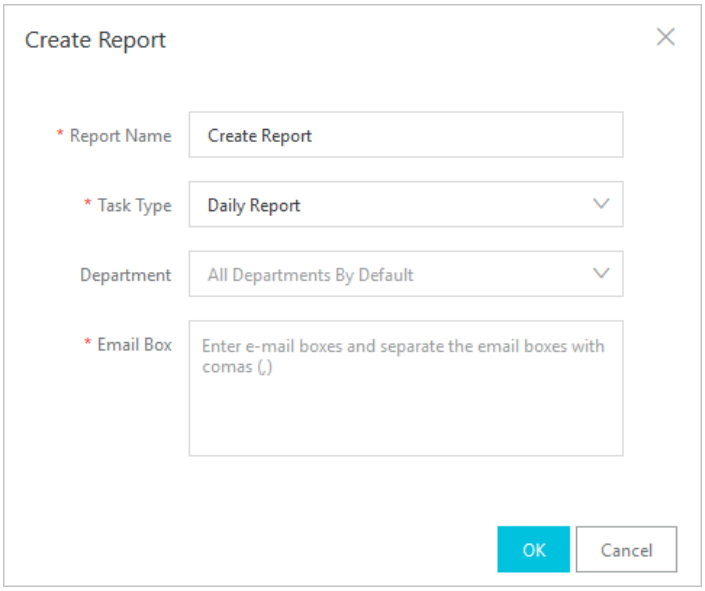
  - The **Threat Overview** tab displays **Top 5 Attack Preference**, **Attack Number**, and **Attack Level Analysis** of the IP address.
  - The **IP Details** tab displays **WHOIS** and **IP reverse check information** of the IP address.
  - The **Threat Details** tab displays the **threat tag** list of the IP address. The list contains specific information. The information includes the intelligence source, time when the IP address is detected for the first time, time when the IP address is active for the last time, and threat tag.

21.8.7. Create a report task

This topic describes how to create a report task. After you create a report task, the system sends reports on a regular basis.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > Report Management**.
3. On the Report Management page, click **Create Report**.
4. In the **Create Report** dialog box, configure parameters.



Parameter	Description
Report Name	The name of the report task. We recommend that you enter information such as the report purpose for easier identification and management.
Task Type	The type of the task. Valid values: **Daily Report**, **Weekly Report**, and **Monthly Report**.
Department	The department related to the report.
Email Box	The email address of the report recipient. If you enter more than one email address, separate the email addresses with commas (,).

5. Click **Confirm**.

Result

In the report task list, you can view, edit, and delete the newly created report tasks.

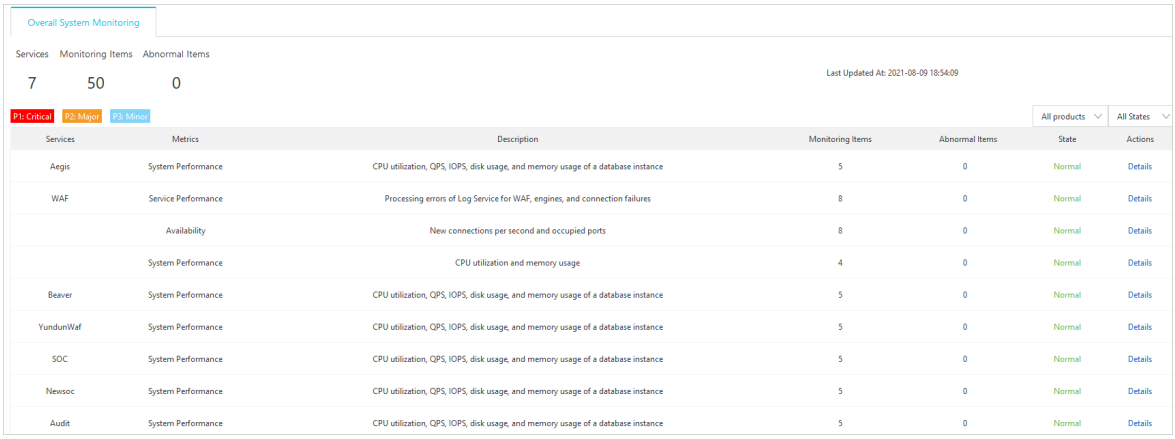
21.8.8. System Configurations

21.8.8.1. View and manage metrics

Apsara Stack Security Center allows you to monitor security services. This helps find performance bottlenecks at the earliest opportunity. Then, you can scale out, scale up, or downgrade services to prevent system failures. This topic describes how to view the information about security services in Apsara Stack Security Center and how to manage metrics.

View information about overall system monitoring

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Security Monitoring**.
3. On the **Overall System Monitoring** tab, view the overall information about security services in Apsara Stack Security Center and the list of monitored security services.



In the upper-left corner of the **Overall System Monitoring** tab, you can view the overall information about security services.

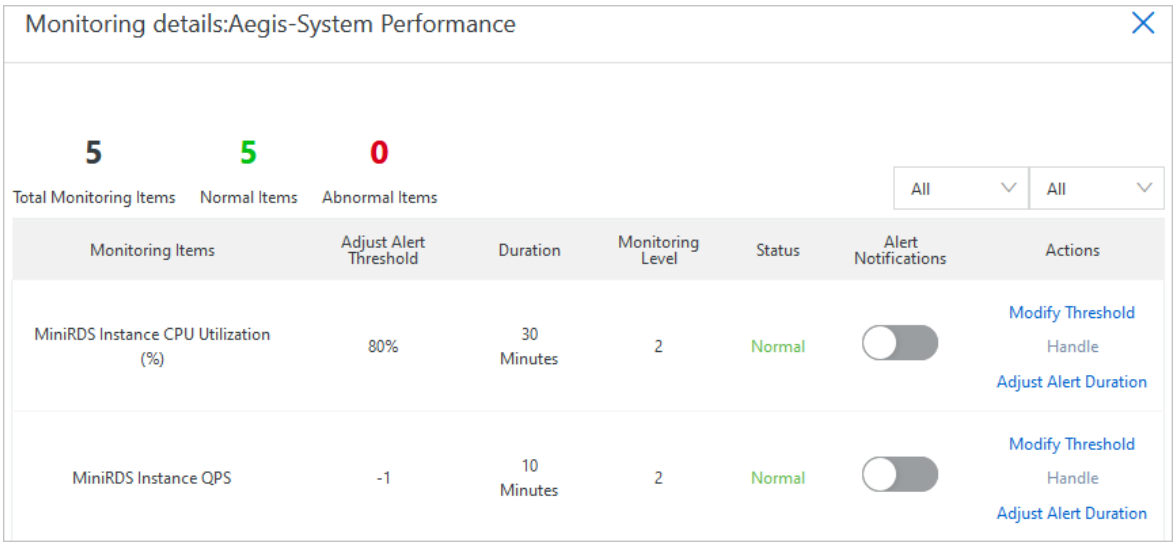
- **Services**: the total number of security services monitored in Apsara Stack Security Center.
- **Monitoring Items**: the total number of metrics.
- **Abnormal Items**: the number of metrics whose status is abnormal.

In the list of monitored security services, you can view the following information.

Parameter	Description
Services	The security service monitored in Apsara Stack Security Center.
Metrics	The monitoring indicator for the monitored security service.
Description	The description of the monitoring indicator.
Monitoring Items	The total number of metrics that belong to the monitoring indicator.

Parameter	Description
Abnormal Items	The number of metrics whose status is abnormal, and the number of metrics at each urgency level. The urgency levels are indicated by different colors. The red color indicates a critical exception, the orange color indicates an important exception, and the blue color indicates a moderate exception. 
State	The status of the monitoring indicator.

4. Click **Details** in the **Actions** column of a monitoring indicator. In the **Monitoring details** panel, view the details of metrics that belong to the monitoring indicator.



In the upper-left corner of the **Monitoring details** panel, you can view the overall information about the metrics.

- **Total Monitoring Items**: the total number of metrics that belong to the monitoring indicator.
- **Normal Items**: the number of metrics in the normal state.
- **Abnormal Items**: the number of metrics in the abnormal state.

In the metric list, you can view the following information.

Parameter	Description
Monitoring Items	The name of the metric.
Adjust Alert Threshold	The threshold for the metric. If the value of the metric reaches the threshold and lasts for the specified period of time, the status of the metric becomes abnormal.
Duration	The period of time. If the value of the metric reaches the threshold and lasts for the specified period of time, the status of the metric becomes abnormal.
Monitoring Level	The urgency level displayed when the status of the metric becomes abnormal.
Status	The status of the metric.

Parameter	Description
Alert Notifications	The switch of the alert notification feature. You can turn on or off the switch in the **Alert Notifications** column based on your business requirements. If the  icon appears in the Alert Notifications column, a notification is sent when the status of the metric becomes abnormal.

Manage metrics

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Security Monitoring**.
3. On the **Overall System Monitoring** tab, find a monitoring indicator and click **Details** in the **Actions** column.
4. In the **Monitoring details** panel, find a metric and click **Modify Threshold**, **Handle**, or **Adjust Alert Duration** in the **Actions** column to manage the metric.

   You can perform the following operations on the metric:

   - **Modify Threshold**: In the **Modify Threshold** dialog box, modify the threshold and click **OK**.

     
     After the threshold is modified, an alert is generated when the value of the metric reaches the new threshold.

   - **Handle**: You can configure the status of the metric based on your business requirements.
     - If you do not want to handle the alert generated from the metric, select **Ignore** from the drop-down list. The status of the metric becomes **Ignored**.
     - After you handle the alert generated from the metric, select **Handled** from the drop-down list. The status of the metric becomes **handled**.
   - **Adjust Alert Duration**: In the **Adjust Alert Duration** dialog box, modify the period of time and click **OK**.

     
     When the value of the metric reaches the threshold and lasts for the specified period of time, the status of the metric becomes abnormal.

21.8.8.2. Alert settings

21.8.8.2.1. Configure alert contacts

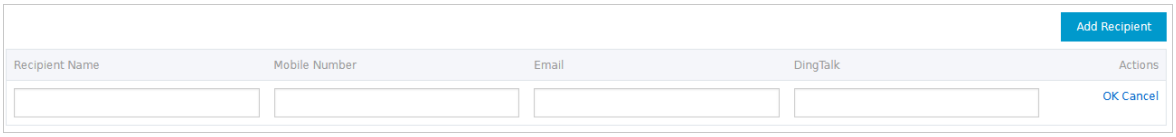
This topic describes how to configure and manage alert contacts.

Context

Apsara Stack Security sends alert notifications to alert contacts by text message, email, or DingTalk. When the detected information matches an alert rule, Apsara Stack Security sends an alert notification to the alert contacts.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Alert Settings**. On the page that appears, click the **Alert Recipient** tab.
3. Click **Add Recipient**.
4. Enter the contact information and click **OK**.



5. Manage alert contacts.

   In the contact list, find a contact and click **Edit** in the Actions column to edit the contact information.

21.8.8.2.2. Configure alert notifications

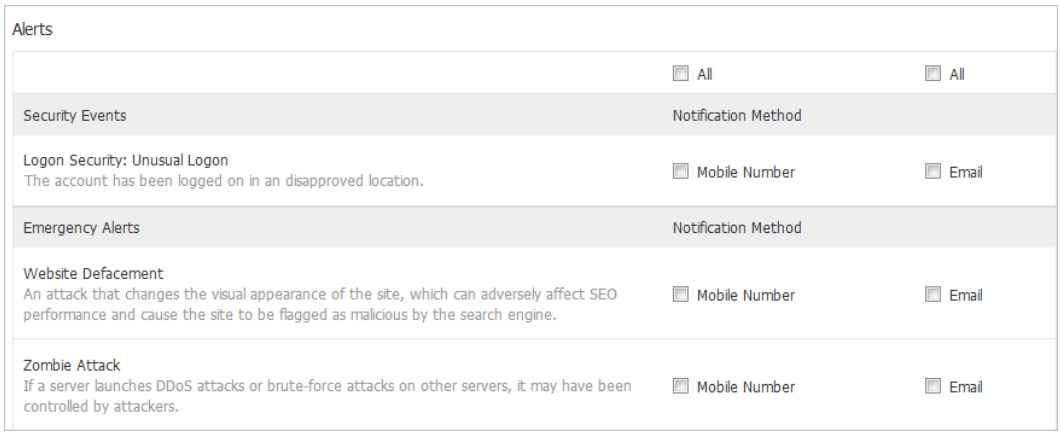
This topic describes how to configure the alert notification method for security events on tenants or platforms.

Context

In the **Alerts** section, security administrators can configure the alert notification method for security events. When a security event occurs, the system notifies the alert contacts by email, text message, or DingTalk. For more information about how to configure alert contacts, see Set alert recipients.

Alerts on tenants

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Alert Settings**. On the page that appears, click the **Tenant Alerts** tab.
3. In the **Alerts** section, select notification methods for each security event.



4. Click **Confirm**.

Alerts on the platform

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Alert Settings**. On the page that appears, click the **Platform Alerts** tab.
3. In the **Alerts** section, select notification methods for each security event.
4. Click **Confirm**.

21.8.8.3. Updates

21.8.8.3.1. Overview of the system updates feature

The system updates feature allows you to manually or automatically update the Apsara Stack Security and rule libraries for up-to-date protection.

The supported package import method depends on the Apsara Stack network environment.

- If Apsara Stack is connected to the Internet, you can choose **Automatically Download Update Packages**.
- If Apsara Stack is not connected to the Internet, you can choose **Manually Import Update Packages**.

The following table lists the update statuses of a rule library.

Update statuses of a rule library

Status	Description
To Be Updated	Indicates that a new version of the rule library is available for update.
Updating	Indicates that the rule library is being downloaded from Alibaba Cloud for update.
Updated	Indicates that the rule library has been updated.
Update Failed	Indicates that the rule library failed to be updated.

21.8.8.3.2. Enable automatic update check and update rule libraries

This topic describes how to enable automatic download of update packages and update rule libraries.

Context

If the Apsara Stack environment can connect to the Internet, you can enable automatic download of update packages to update the rule libraries.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Updates**.
3. Turn on **Auto Update Configuration** to enable automatic download of update packages.

   After this switch is turned on, the system automatically downloads update packages on a regular basis.
4. Update a rule library.

   You can update one or more rule libraries at a time.

- Update multiple rule libraries at a time

  Click **Batch Update** in the upper-right corner to update all rule libraries.

- Update a single rule library

  a. Click the tab of the rule type that you want to update. For example, click **Server Security**.

  b. In the **Actions** column, click **Update**.

21.8.8.3.3. Manually import an update package and update your service

This topic describes how to manually import an update package and update your service.

Prerequisites

The security administrator has obtained the offline update package.

Context

If the Apsara Stack environment cannot connect to the Internet, you can update a rule library after you import an offline update package.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Updates**.
3. Manually import an update package.

   i. Click **Import Update Package** next to **Manual Update** in the upper-left corner.

   ii. In the **Import Update Package** dialog box, click **Browse** to select an offline update package that is downloaded to your on-premises server.

   iii. Click **Confirm**.
4. Update a rule library.

   You can update one or more rule libraries at a time.

   - Update multiple rule libraries at a time

     Click **Batch Update** in the upper-right corner to update all rule libraries.

   - Update a single rule library

     a. Click the tab of the rule type that you want to update. For example, click **Server Security**.

     b. Click **Update** in the **Actions** column.

21.8.8.3.4. Roll back a rule library

This topic describes how to roll a rule library back to a previous version.

Context

If an error occurs with an updated rule library, you can roll the library back to a previous version to avoid service interruption.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations >**

Updates.

3. Click the tab of the rule library that you want to roll back. Example: **Server Security**
4. In the Actions column for the rule library, choose **More > Roll Back**.
5. In the **Version Rollback** dialog box, click **Confirm**.

21.8.8.3.5. View the update history of a rule library

This topic describes how to view the update history of a rule library.

Context

You can view the update history of a rule library. If an error occurs with the latest version, you can locate the issue and roll back the rule library to an earlier version.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Updates**.
3. Click the tab of the specific rule library. Example: **Server Security**.
4. In the **Actions** column of a rule library, click **History**.

   On the **Previous Updates** page, you can view the update history of the rule library. Click **Details** to view the details of an update package.

21.8.8.4. Global configuration

21.8.8.4.1. Set CIDR blocks for traffic monitoring

21.8.8.4.1.1. Add a CIDR block for traffic monitoring

This topic describes how to add a Classless Inter-Domain Routing (CIDR) block for traffic monitoring. Network Traffic Monitoring System of Apsara Stack Security monitors the traffic of a specific CIDR block.

Context

CIDR blocks are configured for Network Traffic Monitoring System. Security administrators can change the CIDR blocks for monitoring based on business requirements. The settings of CIDR blocks apply only to a data center that is deployed in the region to which the specific CIDR block belongs.

> **Note**
>
> Changes to CIDR block settings immediately take effect without the intervention of security administrators.
>
> If you add the same CIDR block on the traffic collection CIDR block setting page and region setting page, make sure that you select the same region on both pages.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Traffic Collection IP Range** tab.
3. Click **Add**.
4. In the **Add CIDR Block for Monitoring** dialog box, configure parameters.

- **CIDR Block**: Enter a CIDR block for traffic monitoring.

  > **Note** Take note that the CIDR block that you entered must be valid and unique.

- **Region**: Select the region of the data center.

5. Click **Confirm**.

21.8.8.4.1.2. Manage CIDR blocks for traffic monitoring

This topic describes how to modify or delete Classless Inter-Domain Routing (CIDR) blocks for traffic monitoring.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Traffic Collection IP Range** tab.
3. Select a region, enter the CIDR block that you want to query, and then click **Search**.

   View the information about the CIDR block for traffic monitoring and the region in the search result.
4. In the **Actions** column, manage a CIDR block for traffic monitoring.
   - Modify the CIDR block for traffic monitoring

     Click **Modify** to modify the region of the CIDR block for traffic monitoring.
   - Delete the CIDR block for traffic monitoring

     Click **Delete** to delete the CIDR block for traffic monitoring.

21.8.8.4.2. Region settings

21.8.8.4.2.1. Add a CIDR block for a region

This topic describes how to add Classless Inter-Domain Routing (CIDR) blocks for regions that are detected and reported by using Server Guard.

Context

Region settings are used for region detection of the Server Guard agent. Server Guard servers automatically detect and match the regions of servers based on the IP address information that is reported by the Server Guard agent.

> **Note** You can change the region of a CIDR block. After the region is modified, you must also modify the region for all assets in the CIDR block on the Asset Overview page.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Region** tab.
3. Click **Add**.
4. In the **Add CIDR Block** dialog box, configure parameters.

   - **CIDR Block**: Enter a CIDR block for the region.

     > **Note** Enter a valid CIDR block. You cannot enter a CIDR block that has been configured for the region.

   - **Region**: Select a region.
5. Click **Confirm**.

21.8.8.4.2.2. Manage CIDR blocks for a region

This topic describes how to modify or delete Classless Inter-Domain Routing (CIDR) blocks for a region.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Region** tab.
3. Select a region, enter the CIDR block that you want to modify or delete, and then click **Search**.

   You can view the information about the CIDR block for the region in the search result.
4. In the **Actions** column, click Modify or Delete to manage the CIDR block for the region.
   - Modify the CIDR block for the region

     Click **Modify** to modify the CIDR block for the region.
   - Delete the CIDR block for the region

     Click **Delete** to delete the CIDR block for the region.

21.8.8.4.3. Configure whitelists

This topic describes how to configure the whitelist for the feature that blocks brute-force attacks in Server Guard and the following whitelists in Threat Detection Service (TDS). The whitelists contain IP addresses allowed by server brute-force attack blocking, IP addresses allowed by application attack blocking, and IP addresses allowed by web attack blocking.

Context

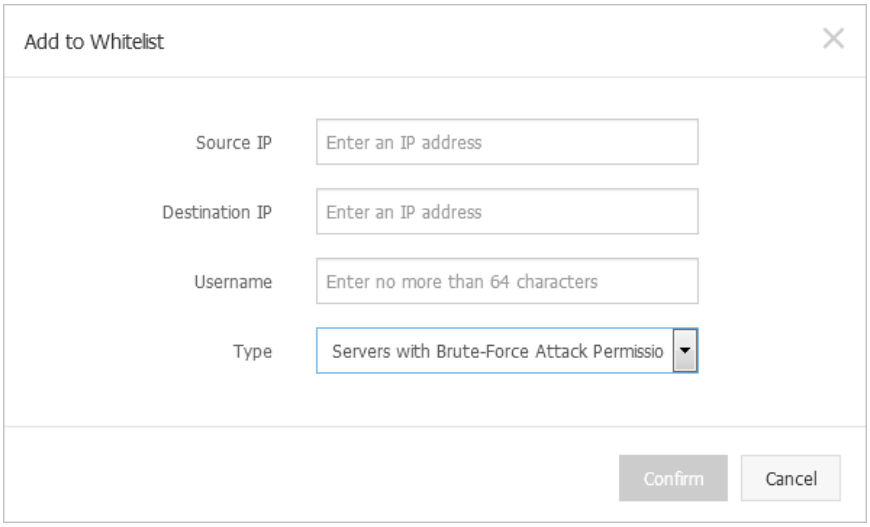
If a normal request is regarded as an attack by the attack blocking feature of TDS or the unusual logon detection

feature of Server Guard, you can add the source IP address of the request to a whitelist to avoid further false positives.

> **Note** Make sure that the IP addresses in the whitelist are trusted.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Whitelist** tab.
3. Click **Add**.
4. In the **Add to Whitelist** dialog box, configure the parameters.



Parameter	Description
Source IP	Enter a source IP address or Classless Inter-Domain Routing (CIDR) block.
Username	Enter the name of the user who creates the whitelist.
Type	◦ **Brute-Force Attack Blocking Whitelist**: Server Guard does not generate alerts for brute-force attacks or unusual logons from the IP addresses that are contained in this whitelist. ◦ **BWAF Whitelist**: The attack blocking feature does not generate alerts for the web attacks from the IP addresses that are contained in this whitelist. ◦ **Servers with Brute-Force Attack Permissions**: The attack blocking feature does not generate alerts for the brute-force attacks from the IP addresses that are contained in this whitelist. ◦ **IPs with Application Attack Permissions**: The traffic from the IP addresses in this whitelist is not detected as suspicious application attack traffic.

5. Click **OK**.
   If you want to delete an existing whitelist, click **Delete** in the Actions column. In the **Delete Whitelist** message, click **Confirm**.

21.8.8.4.4. Configure attack blocking policies

This topic describes how to enable web attack blocking and brute-force attack blocking.

Context

The attack blocking features protect your servers against web attacks and brute-force attacks.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings > Region**.
3. Turn on or off the switches in the Actions column to enable or disable **Web Attack Blocking** or **Brute-Force Attack Blocking**.

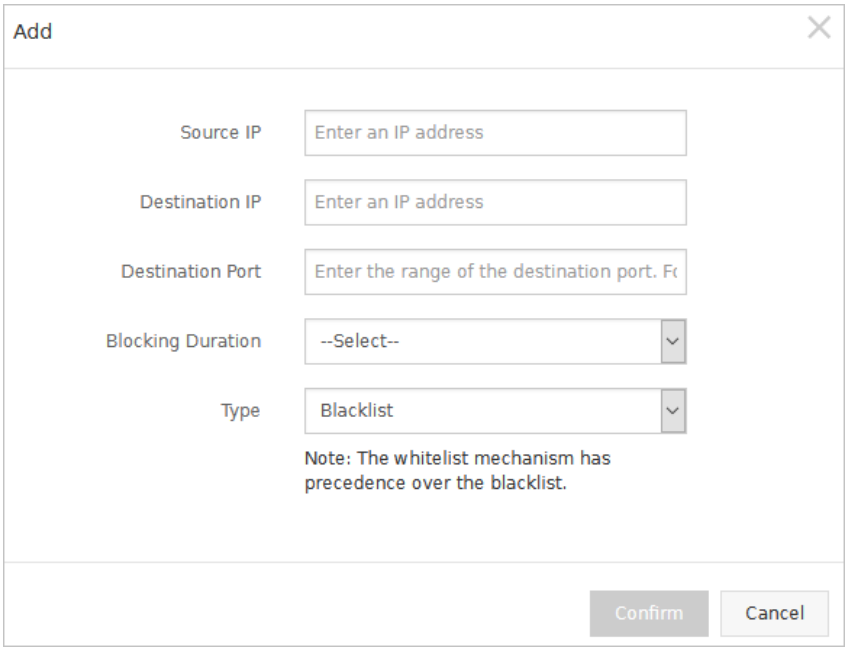
> **Note**
>
> In the Actions column, a red switch indicates a disabled feature and a green switch indicates an enabled feature.
>
> After you disable the blocking feature for an attack type, Apsara Stack Security Center generates only alerts for this type of attacks.

21.8.8.4.5. Block IP addresses

This topic describes how to manually block requests for a specific IP address with a few clicks.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**.
3. On the **Global Settings** page, click the **Block IP Addresses** tab.
4. In the upper-right corner of the tab, click **Add**.
5. In the **Add** dialog box, configure parameters.



Parameter	Description
IP protocol	Specify the protocol type. Valid values: **IPv4** and **IPv6**.
Source IP	Enter the source IP address that you want to block.
Destination IP	Enter the destination IP address that you want to block.
Destination Port	Enter the destination port that is used with the specified destination IP address.
Blocking Duration	Select a time range during which you want to block requests. Valid values: **1 Day**, **7 Days**, and **30 Days**.
Type	Select the blocking mode. Valid values: **Whitelist** and **Blacklist**.
Remarks	Enter the reason for blocking.

6. Click **Confirm**.

21.8.8.4.6. Configure custom IP addresses and locations

21.8.8.4.6.1. Add custom IP addresses and locations

This topic describes how to add custom IP addresses and locations. You can customize internal IP addresses based on your network plan. After you configure the internal IP addresses, IP addresses from the public address library do not match the addresses outside China.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Custom IP Location** tab.
3. Click **Add**.

   If you want to add multiple IP addresses and locations at a time, click **Batch Upload (.txt)**. This can be used to import multiple IP addresses and locations as a template.

4. In the **Add** dialog box, configure parameters.
5. Click **OK**.

21.8.8.4.6.2. Manage custom IP addresses and locations

This topic describes how to modify and delete custom IP addresses and locations.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Global Settings**. On the page that appears, click the **Custom IP Location** tab.
3. In the **Actions** column, manage custom IP addresses and locations.
   - To modify a custom IP address and a location:

     Click **Modify**. In the **Modify** dialog box, modify the custom geographic location.
   - To delete a custom IP address and a location:

     Click **Delete**. In the **Delete** message, click **OK**.

21.8.8.5. System Monitoring

21.8.8.5.1. Configure CIDR blocks for traffic redirection in Cloud Firewall

Before you can use Cloud Firewall, you must configure CIDR blocks for traffic redirection.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > System Monitoring**.
3. On the **ICFW** tab in the **Service Monitoring** section of the **System Monitoring** page, click **Add** to the right of **Traffic Forwarding Configuration - Service CIDR Block**.
4. In the **Add** dialog box, configure the **Device Cluster ID**, **CIDR Block for Traffic Diversion**, **Type**, and **Service Description** parameters.
5. Click **OK**.
   After you configure the CIDR blocks, you can view related information in **Traffic Forwarding Configuration - Service CIDR Block**, **Service Check Status**, and **Interface Status**.

21.8.8.6. Inspect services

This topic describes how to inspect services such as Cloud Firewall and Network Traffic Monitoring System in Apsara Stack Security Center. You can monitor the status and features of the services.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > System Monitoring**.
3. In the **System Inspection** section of the **Network Security** tab, inspect the services in the inspection list.

   To inspect a single service or multiple services at a time, perform the following operations:

- Inspect multiple services at a time: In the **System Inspection** section, click **One-click Inspection** to inspect all services in the inspection list.
- Inspect a single service: In the **System Inspection** section, click **Inspect Now** in the **Actions** column of the service that you want to inspect.

After the services are inspected, the status of the services changes to **Complete** in the **Inspection Status** column.

4. View the inspection results.

   You can view the following information about a service:

   - In the inspection list, view the service name, last inspection time, number of inspection items, number of inspection items whose status is normal, number of inspection items whose status is abnormal, and inspection status.
   - Click **Details** in the **Actions** column of a service. In the **Inspection Result Details** panel, view the number of inspection items whose status is normal, number of inspection items whose status is abnormal, and details of each item.
   - Click **Download** in the **Actions** column of a service. Download the inspection results to your computer as prompted for backup and reference.

21.8.8.7. Remote operations

21.8.8.7.1. Enable remote operations

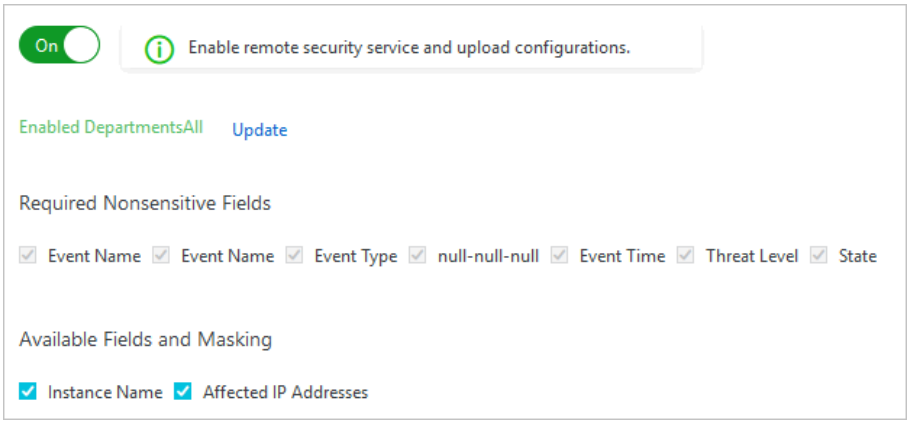
This topic describes how to enable remote operations.

Context

The **remote operations** feature provides remote security operations and rules operations.

Procedure

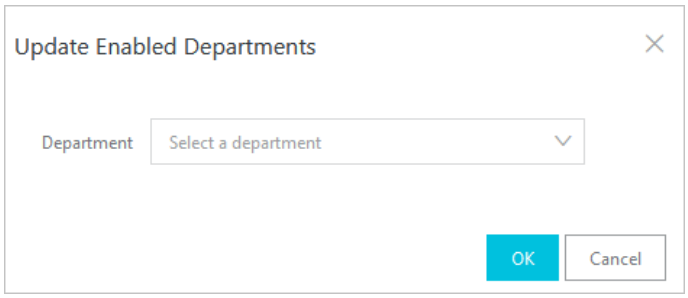
1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Remote O&M**.
3. On the **Remote O&M** page, turn on the switch to enable remote operations.



> **Note** If the switch turns green, the feature is enabled.

4. Select the departments for which you want to enable remote operations.
   i. Click **Update** to the right of **Enabled Departments**.

ii. In the **Update Enabled Departments** dialog box, click the **Department** drop-down list to select the departments for which you want to enable remote operations.



iii. Click **OK**.

> **Note** After you perform these operations, the security logs of departments specified by **Enabled Departments** are encrypted and uploaded to Apsara Stack Security Center.

5. Select fields to encrypt and upload for remote operations.
   - If you select **Required Nonsensitive Fields**, the system encrypts and uploads the data.
   - If you select **Available Fields and Masking**, the system masks the data before it encrypts and uploads the data.

21.8.8.8. Account management

21.8.8.8.1. View and modify an Apsara Stack tenant account

This topic describes how to view and modify the information about your Apsara Stack tenant account that is bound to the system.

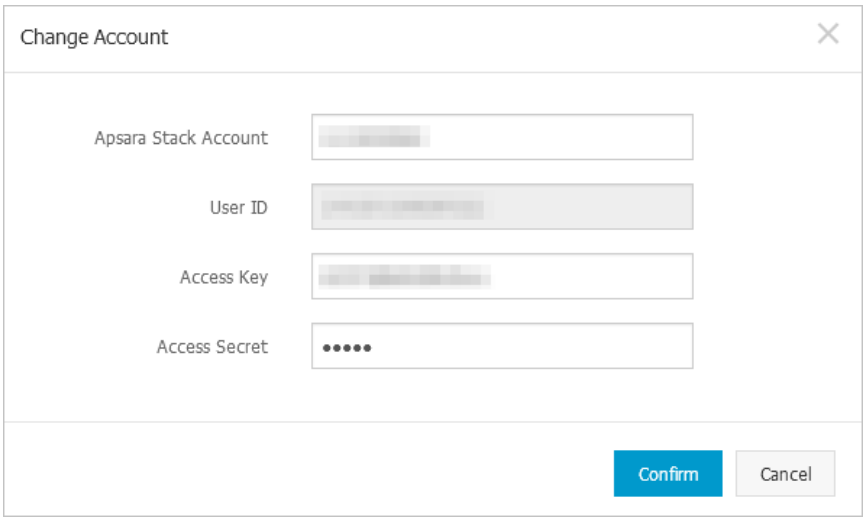
Context

> **Note** All assets in Apsara Stack Security are bound to your Apsara Stack tenant account. You can modify the account information. Proceed with caution.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Accounts**. On the page that appears, click the **Apsara Stack Account** tab.
3. Modify the information about your Apsara Stack tenant account.
   i. In the Actions column, click **Modify**.

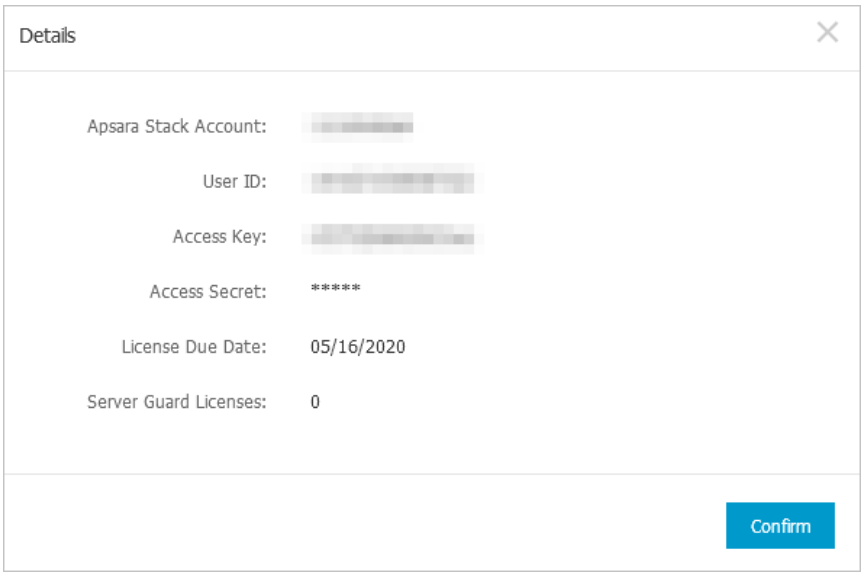
ii. In the **Change Account** dialog box, modify the account information.



iii. Click **Confirm**.

4. View the details of your Apsara Stack tenant account.

   Click **Details** to view the details of your Apsara Stack tenant account.



21.8.8.8.2. Add an Alibaba Cloud account

This topic describes how to add an Alibaba Cloud account in Apsara Stack Security Center. After you add the account, you can use features in a hybrid cloud.

Context

After you add an Alibaba Cloud account in Apsara Stack Security Center, you can manage the Anti-DDoS Pro, Anti-DDoS Premium, and Web Application Firewall (WAF) instances that belong to the Alibaba Cloud account in Apsara Stack Security Center. This way, you can use features in a hybrid cloud.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Security Operations Center (SOC) > System Configurations > Accounts**. On the page that appears, click the **Public Cloud Account** tab.

3. On the **Feature Integration** tab, click **Add**.
4. In the **Add Account** dialog box, enter the information about your Alibaba Cloud account and select Alibaba Cloud services to use.

   - Enter the **AccessKey ID** and **AccessKey secret** of your Alibaba Cloud account.
   - Select Alibaba Cloud services to use. Valid values: **Anti-DDoS Pro**, **Web Application Firewall**, and both.
5. Click **Confirm**.

Result

After the account is added, it is displayed on the **Public Cloud Account** tab. To modify or delete the account, you can click **Modify** or **Delete** in the Actions column.

21.9. Optional security products

21.9.1. Anti-DDoS settings

21.9.1.1. Overview

In Distributed Denial of Service (DDoS) attacks, attackers exploit the client-server model to combine multiple computers into a platform that can launch attacks on one or more targets. This greatly increases the threat of attacks.

Common DDoS attack types include:

- **Network-layer attacks**: A typical example is UDP reflection attacks, such as NTP flood. These attacks use heavy traffic to congest the network of the victim, disabling proper responses to user requests.
- **Transport-layer attacks**: Typical examples include SYN flood and connection flood. These attacks consume a large number of connection resources of a server to cause denial of service.
- **Session-layer attacks**: A typical example is SSL flood. These attacks consume the SSL session resources of a server to cause denial of service.
- **Application-layer attacks**: Typical attack types include DNS flood, HTTP flood, and game zombie attacks. These attacks consume a large amount of application processing resources of a server to cause denial of service.

Apsara Stack Security can redirect, scrub, and re-inject attack traffic to protect your server against DDoS attacks and ensure normal business operations.

> **Note** Apsara Stack Security cannot scrub the traffic between internal networks.

21.9.1.2. View and configure DDoS mitigation policies

This topic describes how to view and configure DDoS mitigation policies. Anti-DDoS provides default DDoS mitigation policies and DDoS traffic scrubbing policies.

Context

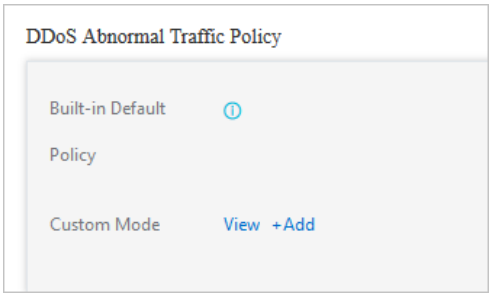
After an alert threshold of DDoS traffic for an IP address is set, an alert is triggered when traffic to the IP address reaches the threshold. The alert threshold for an IP address must be set based on the traffic volume. An abnormally large traffic volume may indicate DDoS attacks. We recommend that you set an alert threshold to a value slightly higher than the peak traffic volume.

Apsara Stack Security supports a global alert threshold, alert threshold for a specific CIDR block, and alert threshold for an IP address.

- Global alert threshold: You cannot set a global alert threshold. It is automatically set when Apsara Stack Security is initialized.
- Alert threshold for a specific CIDR block: You can set an alert threshold for a specific CIDR block based on its traffic volume. CIDR block-specific alert thresholds allow you to control the traffic to each CIDR block.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Policy Configuration > DDoS Defense Policy**.
3. View and customize DDoS mitigation policies.



Operation	Description
View the default policy	Move the pointer over the icon next to Built-in Default Policy in the preceding figure to view the default DDoS mitigation policy.
Customize a policy	Click View to view CIDR block-specific policies. Click +Add to customize a DDoS mitigation policy for a CIDR block.

To customize a policy for a CIDR block, perform the following steps:

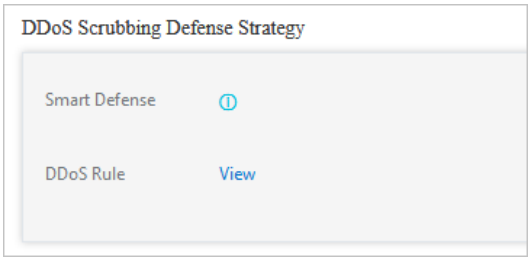
i. Click **+Add** next to **Custom Mode**.

ii. In the **Set Thresholds for Alerts** dialog box, configure the parameters.

Parameter	Description
CIDR Block	The CIDR block for which the alert thresholds are used.
Bandwidth Threshold	The alert threshold for bandwidth usage in a data center. When the sum of inbound and outbound traffic reaches this threshold, DDoS detection is triggered. Set this parameter to a value slightly higher than the peak traffic volume. We recommend that you set the value to 100 or higher. Unit: Mbit/s.
Packets Threshold	The alert threshold for the packet rate in a data center. When the sum of inbound and outbound packet rates reaches this threshold, DDoS detection is triggered. Set this parameter to a value slightly higher than the peak packet rate. We recommend that you set the value to 20000 or higher. Unit: packets per second (PPS).

iii. Click **OK**.

4. In the **DDoS Scrubbing Defense Strategy** section, click **View** to view DDoS traffic scrubbing policies.



21.9.1.3. View DDoS events

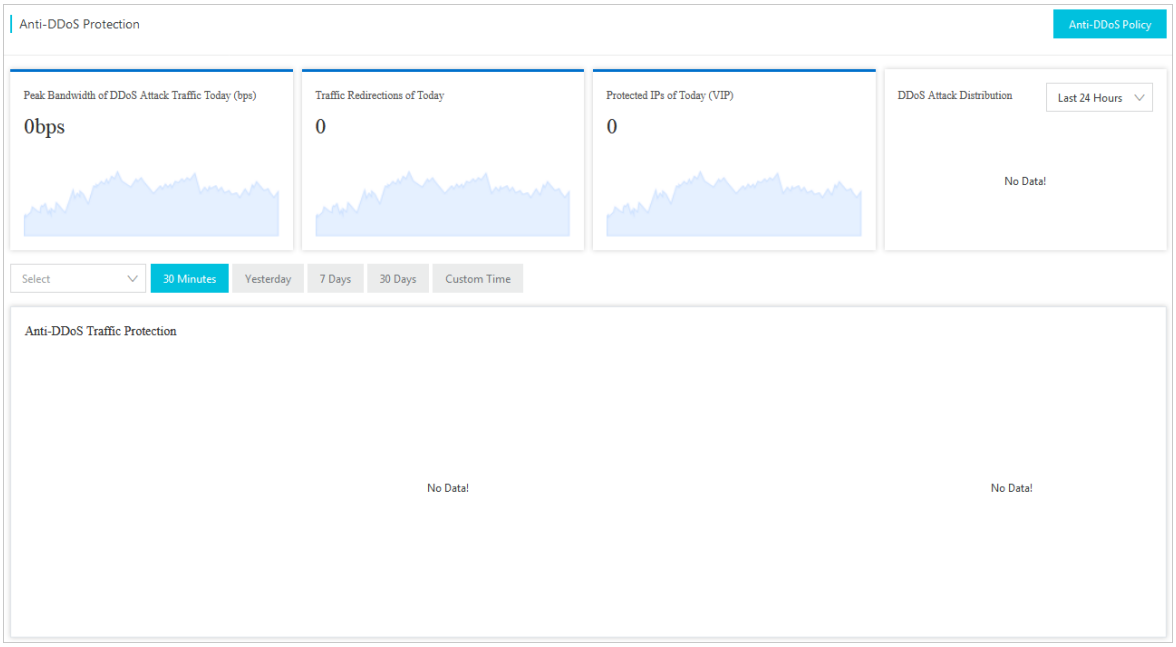
This topic describes how to view DDoS events.

Context

During or after traffic scrubbing, Apsara Stack Security reports security events to Apsara Stack Security Center.

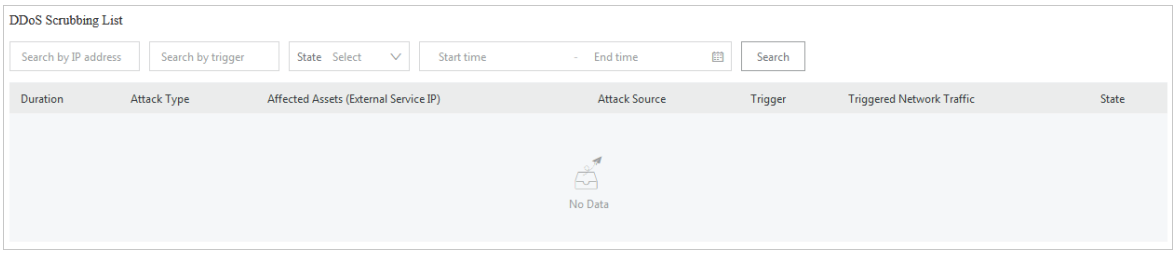
Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Network Protection**.
3. View anti-DDoS statistics.



4. (Optional)In the **DDoS Scrubbing List** section, specify search conditions and click **Search**.

> **Note** If you need to view all traffic scrubbing events, skip this step.



Search condition	Description
IP address	The IP address that was under a DDoS attack.
Trigger	The metric that exceeds the configured alert threshold in the DDoS attack traffic.
State	○ Scrubbing: indicates that traffic scrubbing is in progress. ○ Scrubbing Complete: indicates that traffic scrubbing is complete.
Start time and End time	The start time and end time of DDoS traffic scrubbing.

5. In the DDoS Scrubbing List section, view details about DDoS traffic scrubbing events.

21.9.2. Cloud Firewall

21.9.2.1. Policy configuration

21.9.2.1.1. Synchronize assets for the Internet firewall

If new IP addresses are not in the IP address list of the Internet firewall, you can manually synchronize the IP address assets for the Internet firewall. This topic describes how to manually synchronize assets for the Internet firewall.

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Policy Configuration > Firewall Switch Policy**.
3. Click the **Internet Firewall** tab. In the upper-right corner of the page, click **Update Assets**.
4. In the **Update Assets** message, click **OK**.
   After the assets are synchronized, the system updates the IP address list.

21.9.2.1.2. Create a VPC firewall

A virtual private cloud (VPC) firewall is a distributed firewall that can detect and control traffic between VPCs. Cloud Firewall can be used to analyze and control traffic between two VPCs only after a VPC firewall is created and enabled. This topic describes how to create a VPC firewall.

Context

A VPC firewall can be created only between two VPCs that are connected. VPCs can be connected by using Express Connect or Cloud Enterprise Network (CEN).

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Policy Configuration > Firewall Switch Policy**.
3. On the **Firewall Switches** page, click the **VPC-VPC** tab. Find the required instance and click **Create** in the Actions column.

Parameter	Description
Instance Name	Enter a name for the VPC firewall. We recommend that you enter a unique and informative name that indicates specific business to help identify the VPC firewall. The name can contain letters, digits, underscores (_), and hyphens (-). However, the name cannot contain only digits.
Route Table	When you create a VPC, the system automatically creates a default route table. You can add system routes to the route table to manage VPC traffic. VPC allows you to create multiple route tables. When you create a VPC firewall in the Cloud Firewall console, Cloud Firewall automatically reads your VPC route tables. Express Connect supports multiple route tables. If you create a VPC firewall for Express Connect, you can view multiple VPC route tables and can select specific route tables for protection.
Destination CIDR Block	After you select a route table from the Route Table drop-down list, the default destination Classless Inter-Domain Routing (CIDR) block of the route table appears in the Destination CIDR Block field. If you want to protect traffic destined for other CIDR blocks, you can manually modify the destination CIDR block. You can enter multiple CIDR blocks and separate them with commas (,).
Peer Route Table	Confirm the region and name of the peer VPC, and select the route table for protection.

Parameter	Description
Peer Destination CIDR Blocks	Confirm the destination CIDR block of the peer VPC.
Firewall Mode	◦ Test: In this mode, the VPC firewall tests the health status of CIDR blocks or IP addresses to ensure normal links. ◦ Active: In this mode, the VPC firewall redirects and protects traffic. ◦ Bypass: In this mode, the VPC firewall does not redirect traffic. If a self-test or a health test fails, the VPC firewall automatically changes to the Bypass mode. When you create a VPC firewall, you can set Firewall Mode only to Test. After the firewall is created, you can change its mode to Active or Bypass. You cannot directly change the mode from Bypass to Active. You must change the mode from **Bypass** to **Test** first, and then to **Active**. In the **Health Test** section, enter 32-bit test IP addresses that belong to the local and peer VPCs.
IPS Mode	Select the working mode of the intrusion prevention system (IPS). Valid values: ◦ Monitoring Mode: If Cloud Firewall detects malicious traffic, it monitors the traffic and sends alerts. ◦ Traffic Control Mode: Cloud Firewall intercepts malicious traffic and blocks intrusion attempts.
IPS Capabilities	Select the intrusion prevention policies that you want to enable. Valid values: ◦ Basic Policies: This feature provides basic intrusion prevention capabilities, such as protection against brute-force attacks and attacks that exploit command execution vulnerabilities. This feature also allows you to manage and control the connections from infected hosts to a command and control (C&C) server. ◦ Virtual Patches: This feature defends against the most common and high-risk application vulnerabilities in real time.
Enable VPC Firewall	If you turn on Enable VPC Firewall, the VPC firewall is automatically enabled after it is created. If you do not require the VPC firewall to be automatically enabled, turn the switch off.

4. Click **Submit**.

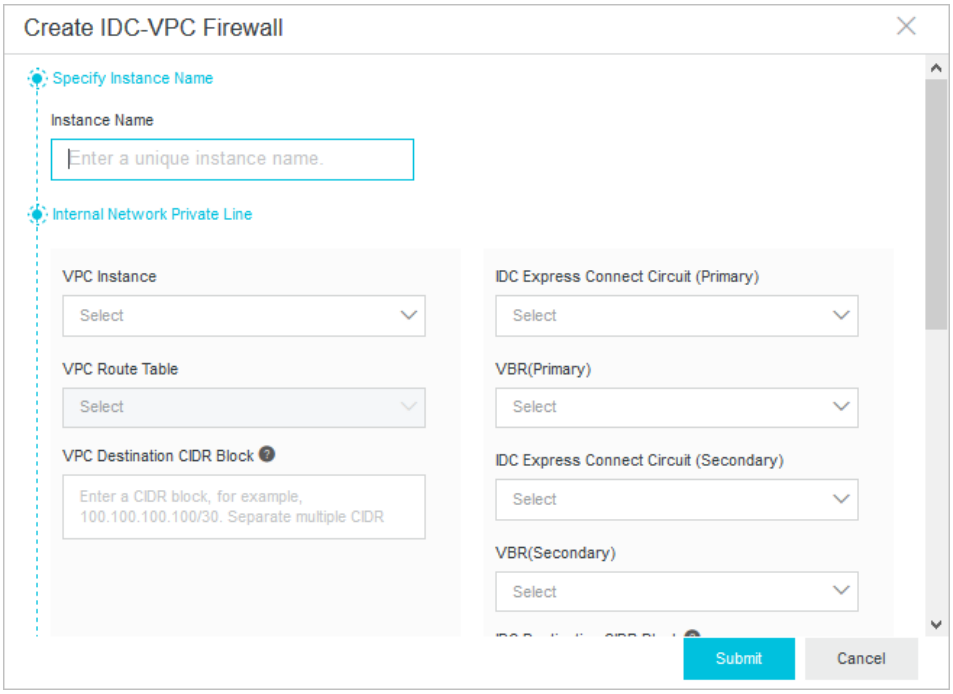
   If Firewall Status of the VPC firewall changes to **Enabled**, the VPC firewall takes effect.

21.9.2.1.3. Create an IDC-VPC firewall

An IDC-VPC firewall can detect the traffic between a data center and a virtual private cloud (VPC). Cloud Firewall allows you to control traffic through IDC-VPC firewalls. This topic describes how to create an IDC-VPC firewall.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Policy Configuration > Firewall Switch Policy**.
3. On the **Firewall Switches** page, click the **IDC-VPC** tab. In the upper-right corner of the tab, click **Create**.



Parameter	Description
Instance Name	The name of the IDC-VPC firewall. We recommend that you enter a unique and informative name that indicates specific business to help identify the IDC-VPC firewall. The name can contain letters, digits, underscores (_), and hyphens (-). However, the name cannot contain only digits.
VPC Instance	The ID of the VPC. The ID is the unique identifier of the VPC. Cloud Firewall automatically synchronizes the VPCs that are connected to the data center.
VPC Route Table	When you create a VPC, the system automatically creates a default route table. You can add system routes to the route table to manage VPC traffic. VPC allows you to create multiple route tables. When you create a VPC firewall in the Cloud Firewall console, Cloud Firewall automatically reads your VPC route tables. Express Connect supports multiple route tables. If you create a VPC firewall for Express Connect, you can view multiple VPC route tables and can select specific route tables for protection.
VPC Destination CIDR Block	After you select a route table from the VPC Route Table drop-down list, the default destination CIDR block of the route table is automatically displayed for the VPC Destination CIDR Block field. If you need to protect traffic to other CIDR blocks, you can manually modify destination CIDR blocks. You can add multiple CIDR blocks. Separate the CIDR blocks with commas (,).
IDC Express Connect Circuit (Primary)	The ID of the Express Connect circuit that you create when you connect your data center to Apsara Stack. When the customer edge (CE) in your data center connects to the primary and secondary vSwitches, you must specify a primary Express Connect circuit. The IDC-VPC firewall automatically synchronizes the primary Express Connect circuit that you specify. You must specify this parameter when you create the IDC-VPC firewall.

Parameter	Description
VBR(Primary)	The virtual border router (VBR) that is bound to the primary Express Connect circuit in your data center. The VBR facilitates communication between the VPC and your data center. The IDC-VPC firewall automatically synchronizes the VBR that you specify. You must specify this parameter when you create the IDC-VPC firewall.
IDC Express Connect Circuit (Secondary)	The ID of the Express Connect circuit that you create when you connect your data center to Apsara Stack. You must specify a secondary Express Connect circuit when the CE in your data center connects to the primary and secondary vSwitches. The value of this parameter cannot be the same as that of the IDC Express Connect Circuit (Primary) parameter. The IDC-VPC firewall automatically synchronizes the secondary Express Connect circuit that you specify. You must specify this parameter when you create the IDC-VPC firewall.
VBR(Secondary)	The VBR that is bound to the secondary Express Connect circuit in your data center. The VBR facilitates communication between the VPC and your data center. The IDC-VPC firewall automatically synchronizes the VBR that you specify. You must specify this parameter when you create the IDC-VPC firewall.
IDC Destination CIDR Block	The destination CIDR block of the peer VPC.
Configure Firewall Mode	◦ Test: This mode is used to test the health status of the CIDR block or the IP address to ensure that the link is normal. ◦ Active: This mode is used to redirect and protect traffic. ◦ Bypass: The firewall does not redirect traffic in this mode. If the self-check or the health test fails, the firewall is automatically changed to the Bypass mode. When you create an IDC-VPC firewall, you can set Configure Firewall Mode only to Test. After the firewall is created, you can change its mode to Active or Bypass. You cannot directly change the mode from Bypass to Active. You must change the mode from **Bypass** to **Test** and then to **Active**. In the **Health Test** section, enter a 32-bit test IP address that is created in the local VPC.
IPS Mode	The working mode of the intrusion prevention system (IPS). Valid values: ◦ Monitoring Mode: In this mode, Cloud Firewall monitors malicious traffic and generates alerts on the traffic. ◦ Traffic Control Mode: In this mode, Cloud Firewall intercepts malicious traffic and blocks intrusion attempts.
IPS Capabilities	The intrusion prevention policies that you want to enable. Valid values: ◦ Basic Policies: This feature provides basic intrusion prevention capabilities, such as protection against brute-force attacks and attacks that exploit command execution vulnerabilities. It also allows you to manage and control the connections from compromised hosts to a command and control (C&C) server. ◦ Virtual Patches: This feature protects against common high-risk application vulnerabilities in real time.
Enable VPC Firewall	After you turn on Enable VPC Firewall, an IDC-VPC firewall is automatically enabled after it is created. If you do not require the IDC-VPC firewall to be automatically enabled, turn off the switch.

4. Click **Submit**.

   If the status of the IDC-VPC firewall changes to **Enabled**, the IDC-VPC firewall is in effect.

21.9.2.2. Access control

21.9.2.2.1. Manage address books

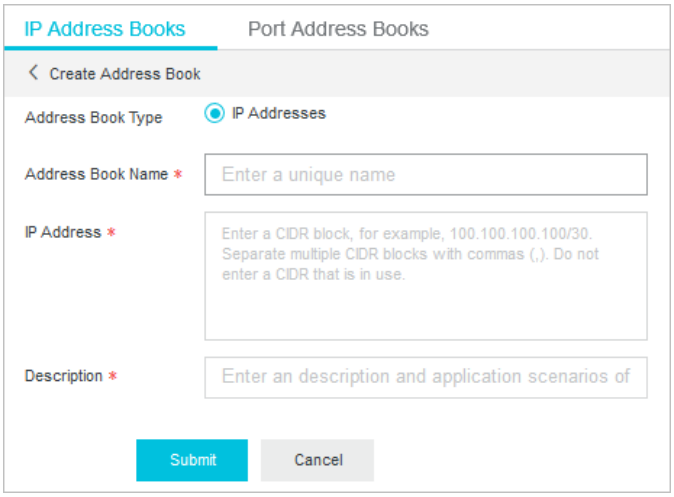
This topic describes how to create and manage IP address books and port address books. You can use address books to store one or more CIDR blocks or ports.

Context

You can store frequently used IP addresses and ports in address books to facilitate configurations of the Internet firewall.

Create an IP address book

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. On the page that appears, click the **Internet Firewall** tab.
4. In the upper-right corner, click **Manage Address Books**. In the dialog box that appears, click the **IP Address Books** tab.
5. Click **+Create Address Book** to configure the parameters.

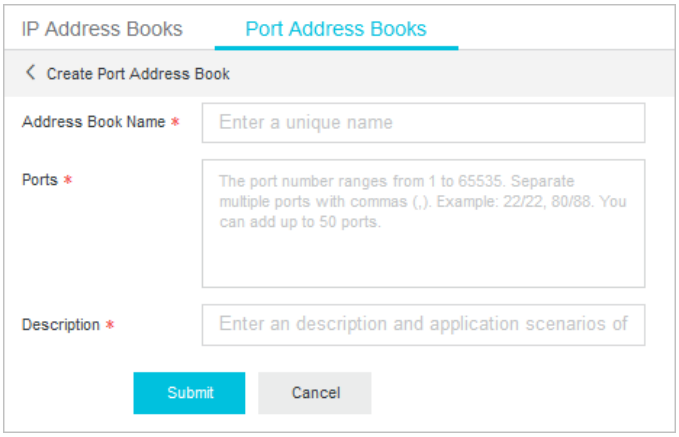


Parameter	Description
Address Book Type	The type of the address book. Set the value to **IP Addresses**.
Address Book Name	The name of the address book. The name must be unique. The name can contain letters, digits, and underscores (_). However, the name cannot contain only digits.
IP Address	The CIDR block that you want to add. Separate multiple CIDR blocks with commas (,).
Description	The content and use scenarios of the address book. The description must be 2 to 512 characters in length.

6. Click **Submit**.
After the address book is created, you can view the address book on the **IP Address Books** tab. You can click **Modify** or **Delete** in the Actions column of an address book to manage the address book.

Create a port address book

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. On the page that appears, click the **Internet Firewall** tab.
4. In the upper-right corner, click **Manage Address Books**. In the dialog box that appears, click the **Port Address Books** tab.
5. Click **+Create Address Book** to configure the parameters.



Parameter	Description
Address Book Name	The name of the address book. The name must be unique. The name can contain letters, digits, and underscores (_). However, the name cannot contain only digits.
Ports	The port number or port range that you want to add. Separate multiple port numbers or ranges with commas (,).
Description	The content and use scenarios of the address book. The description must be 2 to 512 characters in length.

6. Click **Submit**.
   After the address book is created, you can view the address book on the **Port Address Books** tab. You can click **Modify** or **Delete** in the Actions column of an address book to manage the address book.

21.9.2.2.2. Configure access control policies on the Internet firewall

The access control feature allows you to configure access control policies on the Internet firewall. You can configure inbound and outbound policies on the Internet Firewall tab to forbid unauthorized access between the Internet and your servers.

Context

The Internet firewall supports **Outbound Policies** and **Inbound Policies**.

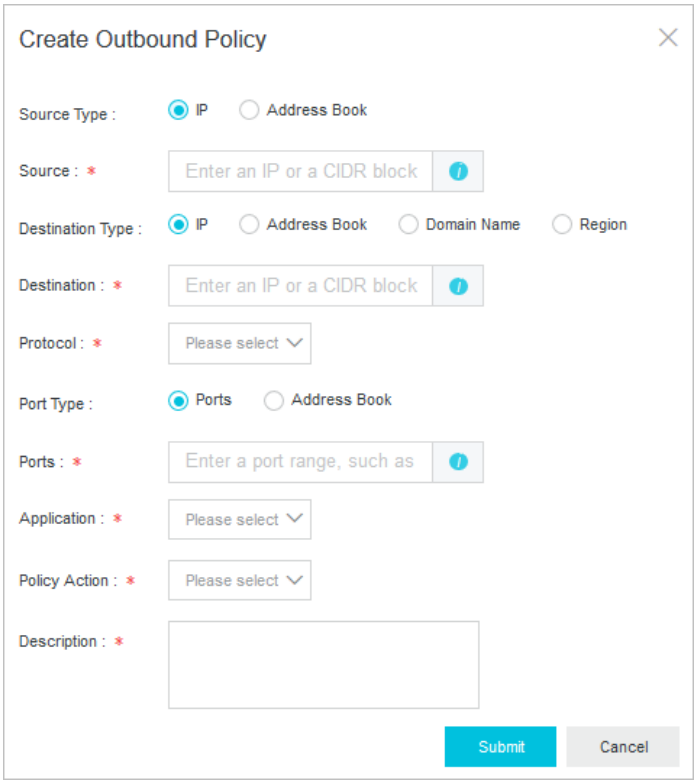
In this topic, IP address books, port address books, and domain address books are used. For more information about how to create these address books, see Manage address books.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. Click the **Internet Firewall** tab.
4. Click the **Outbound Policies** tab. You can also click the **Inbound Policies** tab if required.

   - **Outbound Policies** tab: You can configure policies for traffic from your internal network to the Internet.
   - **Inbound Policies** tab: You can configure policies for traffic from the Internet to your internal network.
5. Click **Create**.

   In the **Create Outbound Policy** dialog box, configure the parameters.



Parameter	Description
Source Type	The type of the traffic source. Valid values: **IP** and **Address Book**. ○ **IP**: If you select this option, enter only one CIDR block in the Source field. ○ **Address Book**: If you select this option, select a pre-configured IP address book for the Source field. An IP address book contains multiple CIDR blocks. This allows you to control traffic from multiple IP addresses.
Source	The source address that is allowed to access the Internet. ○ If you set **Source Type** to **IP**, enter a CIDR block. Example: 1.XX.XX.1/32. ○ If you set **Source Type** to **Address Book**, click **Select Address Book**. In the **Select Address Book as Source** dialog box, select an IP address book.

Parameter	Description
Destination Type	The type of the traffic destination. Valid values: **IP**, **Address Book**, **Domain Name**, and **Region**.
Destination	The destination address that can be accessed. You must set **Destination** to an address on the Internet. ○ If you set **Destination Type** to **IP**, enter a CIDR block. Example: 1.XX.XX.1/32. ○ If you set **Destination Type** to **Address Book**, click **Select Address Book**. In the **Select Address Book as Destination** dialog box, select an IP address book. ○ If you set **Destination Type** to **Domain Name**, enter a domain name. Example: www.example.com. ○ If you set **Destination Type** to **Region**, select one or more destination regions from the drop-down list.
Protocol	The protocol of outbound traffic. Valid values: **TCP**, **UDP**, **ICMP**, and **ANY**. If you do not know which protocol is used, select ANY.
Port Type	The type of the port that is used for the selected protocol. Valid values: **Ports** and **Address Book**. ○ **Ports**: If you select this option, enter a port range in the Ports field. ○ **Address Book**: If you select this option, select a pre-configured port address book for the Ports field. A port address book contains multiple ports. This allows you to control traffic on multiple ports.
Ports	The ports on which you want to control traffic. Enter a port range or select a port address book based on the value of the Port Type parameter. ○ If you set **Port Type** to **Ports**, enter a port range. ○ If you set **Port Type** to **Address Book**, click **Select Address Book**. In the **Select Ports** dialog box, select a port address book.
Application	The application for the traffic.
Policy Action	The action on the traffic. ○ **Allow**: If outbound traffic meets the preceding conditions that you specify for the policy, the traffic is allowed. ○ **Monitor**: If outbound traffic meets the preceding conditions that you specify for the policy, the traffic is recorded and allowed. ○ **Deny**: If outbound traffic meets the preceding conditions that you specify for the policy, the traffic is blocked.
Description	The description of the policy. Enter an informative description to help identify the policy. The description can contain digits, letters, and underscores (_).

6. Click **Submit**.

Result

After the policy is created, it is displayed in the policy list. In the **Actions** column that corresponds to the policy, you can click **Modify**, **Delete**, **Insert**, or **Move** to manage the policy.

21.9.2.2.3. Create a policy group

This topic describes how to create a policy group for an internal firewall. You can configure access control policies to forbid unauthorized access between Elastic Compute Service (ECS) instances.

Context

An internal firewall is implemented by leveraging the security group module of ECS. The access control policies that you configure on the **Internal Firewall** tab are automatically synchronized to the security group module of ECS.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. Click the **Internal Firewall** tab.
4. In the upper-right corner, click **Create Policy Group**.
5. In the **Create Policy Group** dialog box, configure parameters based on your business requirements.

Parameter	Description	Configuration method
Name	The name of the policy group. The name must be 2 to 128 characters in length.	Enter an informative name to help identify the policy group.
VPC	The virtual private cloud (VPC) to which the policy group is applied.	Select a VPC from the **VPC** drop-down list. **Note** You can select only one VPC.
Instance ID	The ID of the ECS instance in the selected VPC.	Select an ECS instance ID from the **Instance ID** drop-down list. **Note** You can select multiple instance IDs.
Description	The description of the policy group. The description must be 2 to 256 characters in length.	Enter an informative description to help identify the policy group.
Template	The template of the policy group.	Select a template from the **Template** drop-down list. Valid values: ○ **default-accept-login**: allows all inbound traffic on ports 22 and 3389. ○ **default-drop-all**: blocks all traffic in the policy group. ○ **default-accept-all**: allows all traffic in the policy group.

6. Click **Submit**.

21.9.2.2.4. Configure access control policies on an internal firewall

This topic describes how to view the policy groups of an internal firewall, configure access control policies in the policy groups, and synchronize the policies to the security group module of Elastic Compute Service (ECS).

Context

On the **Internal Firewall** tab, you can view custom policy groups and security groups that are synchronized from ECS.

For more information about how to create a custom policy group, see Create a policy group.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. Click the **Internal Firewall** tab.
4. (Optional)Specify filter conditions and click **Search** to search for the required policy group.

   > **Note** If you want to view all policy groups, skip this step.

   The required policy group appears in the policy group list.
5. Find the required policy group and configure an access control policy in this group.
   i. In the **Actions** column, click **Configure Policy**.
   ii. On the **Policies** page, click **Create Policy**.

   > **Note** If you want to modify or delete an access control policy, you can perform the following steps: Click the **Inbound** or **Outbound** tab, find the policy, and then click **Modify** or **Delete** in the Actions column.

   iii. In the **Create Policy** dialog box, configure the parameters.

Parameter	Description
Network Type	The type of the network to which the policy is applied. Default value: **Internal**, which indicates that the policy is applied to an internal network.
Direction	The direction of traffic that is controlled by the policy. Valid values: ■ **Inbound**: Traffic is from other ECS instances to the specified ECS instance. ■ **Outbound**: Traffic is from the specified ECS instance to other ECS instances.
Policy Type	The action on traffic that is controlled by the policy. Valid values: ■ **Allow**: Traffic is allowed in the internal network. ■ **Deny**: Traffic is blocked in the internal network.
Protocol Type	The protocol of traffic that is controlled by the policy. Select a protocol from the **Protocol Type** drop-down list. Valid values: ■ **TCP** ■ **UDP** ■ **ICMP** ■ **ANY**: If you do not know which protocol is used, select **ANY**.
Port Range	The port range of traffic that is controlled by the policy. The traffic is destined for ports in this range. Enter a port range. Example: 22/22.

Parameter	Description
Priority	The priority of the policy. **Note** The priority number must be an integer from 1 to 100. Different policies can have the same priority. If an Allow policy and a Deny policy have the same priority, the **Deny** policy takes effect. If two **Allow** policies have the same priority, both policies take effect.
Source Type	The type of the traffic source. Valid values: ■ **CIDR Block**: The traffic source is a CIDR block. ■ **Policy Group**: The traffic source is an ECS instance in the policy group. **Note** If you create a policy in the security group module of ECS, you **cannot** set **Source Type** to **Policy Group**.
Source	The source of traffic that is controlled by the policy. Enter a CIDR block or select a policy group based on how you set the **Source Type** parameter. ■ If you set Source Type to **CIDR Block**, enter only one CIDR block. ■ If you set Source Type to **Policy Group**, select a policy group from the **Source** drop-down list. In this case, the traffic source is an ECS instance in the policy group. **Note** You can select only one policy group from the **Source** drop-down list.
Destination	The destination of traffic that is controlled by the policy. Valid values: ■ **All ECS Instances**: The policy is applied to traffic destined for your ECS instances. ■ **CIDR Block**: The policy is applied to traffic destined for the specified CIDR block.
Description	The description of the policy. Enter an informative description to help identify the policy. The description must be 2 to 256 characters in length.

iv. Click **Submit**.

6. Find the required policy group and click **Publish** in the **Actions** column to apply the policy and synchronize it to the security group module of ECS.

21.9.2.2.5. Configure access control policies on a VPC firewall

A virtual private cloud (VPC) firewall detects and controls the traffic between two VPCs. This topic describes how to configure access control policies on a VPC firewall.

Prerequisites

VPC firewalls are not automatically created. Before you configure access control policies for VPCs, you must create and enable a VPC firewall. For more information, see Create a VPC firewall.

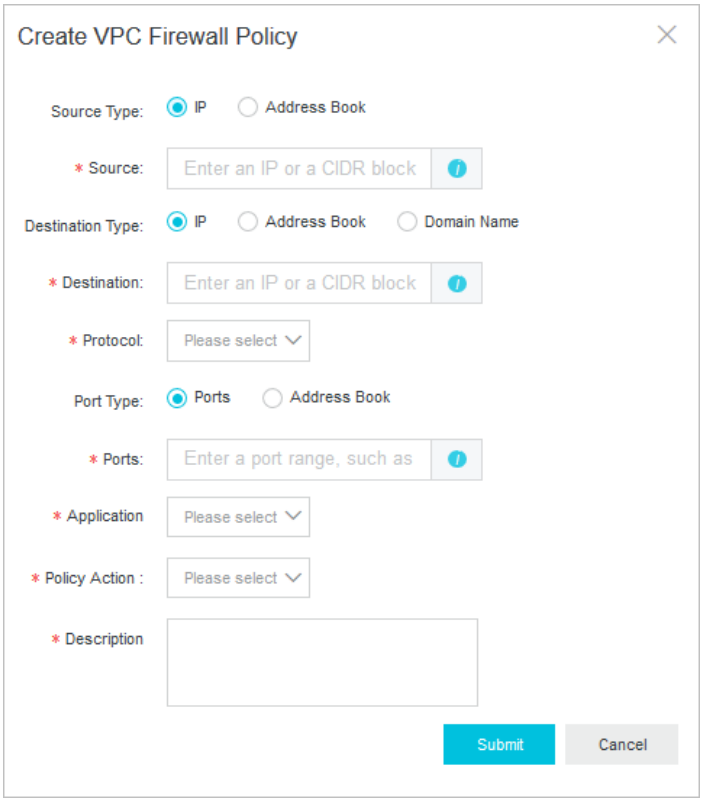
Context

Access control policies of a VPC firewall take effect only after you enable the VPC firewall.

By default, a VPC firewall allows all traffic. If you want to control traffic between VPCs, you can configure access control policies to block traffic from untrusted sources. You can also allow traffic from trusted sources and block traffic from all other sources.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. Click the **VPC Firewall** tab.
4. Click **Create**.
5. In the **Create VPC Firewall Policy** dialog box, configure an access control policy.



Parameter	Description
Source Type	The type of the traffic source. Valid values: IP and Address Book. ○ **IP**: If you select this option, you must enter a CIDR block in the Source field. ○ **Address Book**: If you select this option, you must select a pre-configured address book for the Source field. You can add multiple CIDR blocks to an address book to simplify policy configuration.
Source	The source of the traffic. **Note** You can enter only one CIDR block. Example: 1.*.*.1/32. If you set Source Type to Address Book, select a pre-configured address book.

Parameter	Description
Destination Type	The type of the traffic destination. Valid values: ○ **IP**: If you select this option, you must enter an IP address in the Destination field. ○ **Address Book**: If you select this option, you must select an address book for the Destination field. ○ **Domain Name**: If you select this option, you must enter a domain name in the Destination field. Wildcard domain names are supported. Example: **.aliyun.com*. **Note** By default, if an HTTP header does not contain the Host field or an HTTPS request does not contain the Server Name Indication (SNI), Cloud Firewall allows the traffic.
Destination	The destination of the traffic. You can enter only one CIDR block. If you set Destination Type to Domain Name, enter a domain name. Wildcard domain names are supported. Example: **.aliyun.com*.
Protocol	The protocol of the traffic. Valid values: ○ **ANY**: all protocols ○ **TCP** ○ **UDP** ○ **ICMP**
Ports	The port range of the traffic. The value 0/0 indicates all ports. **Note** If you set Protocol to ICMP, the port configuration does not take effect. If you set Protocol to ANY, the port configuration does not take effect in controlling ICMP traffic.
Application	The application for the traffic. Valid values: ANY, HTTP, HTTPS, Memcache, MongoDB, MQTT, MySQL, RDP, Redis, SMTP, SMTPS, SSH, and VNC If you set Protocol to TCP, multiple applications are supported. If you set Protocol to another value, only ANY is supported. **Note** Cloud Firewall identifies applications based on packet characteristics, instead of port numbers. If Cloud Firewall fails to identify the application for a packet, it allows the packet.
Policy Action	The action on the traffic. Valid values: ○ **Allow**: If traffic meets the preceding conditions that you specify for the policy, the traffic is allowed. ○ **Deny**: If traffic meets the preceding conditions that you specify for the policy, the traffic is blocked. ○ **Monitor**: If traffic meets the preceding conditions that you specify for the policy, the traffic is recorded and allowed. After you observe the traffic for a period of time, you can change the policy action to Allow or Deny.

Parameter	Description
Description	The description of the policy. Enter an informative description to help identify the policy.

6. Click **Submit**.

21.9.2.2.6. Configure access control policies on an IDC-VPC firewall

Cloud Firewall detects and controls access traffic between Internet data centers (IDCs) and virtual private clouds (VPCs). This topic describes how to create and manage access control policies on an IDC-VPC firewall.

Prerequisites

IDC-VPC firewalls are not automatically created. Before you configure access control policies between an IDC and a VPC, you must create and enable an IDC-VPC firewall.

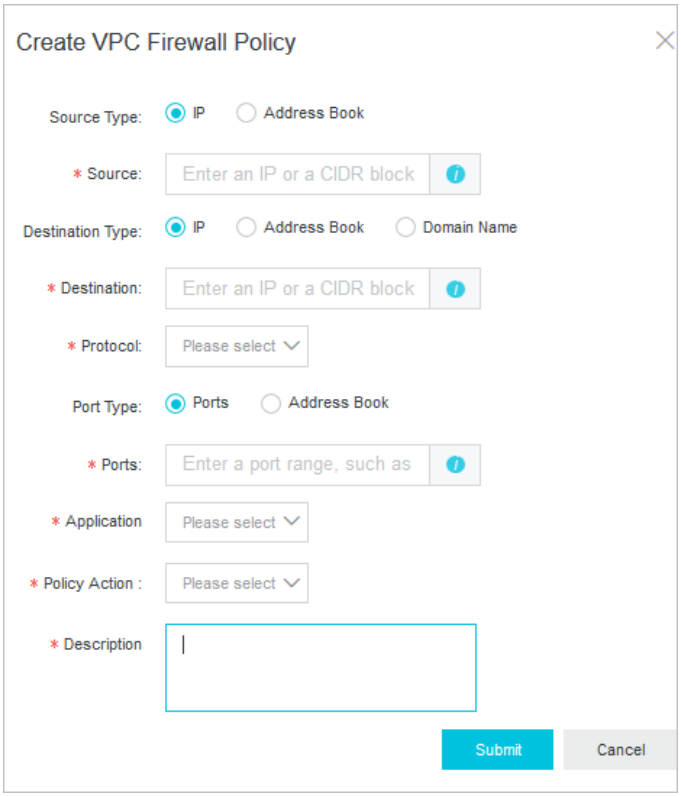
Access control policies of an IDC-VPC firewall take effect only after you enable the IDC-VPC firewall.

Context

By default, an IDC-VPC firewall allows all traffic. If you want to control traffic between an IDC and a VPC, you can configure access control policies to block traffic from untrusted sources. You can also allow traffic from trusted sources and block traffic from all other sources.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Access Control**.
3. On the page that appears, click the **IDC-VPC Firewall** tab.
4. Click **Create**.
5. In the **Create IDC-VPC Firewall Policy** dialog box, configure an access control policy.



Parameter	Description
Source Type	The type of the traffic source. Valid values: ○ **IP**: If you select this option, you must enter an IP address or a Classless Inter-Domain Routing (CIDR) block in the Source field. ○ **Address Book**: If you select this option, you must select a pre-configured address book for the Source field. You can add multiple CIDR blocks to an address book to simplify policy configuration.
Source	The source of the traffic. **Note** You can enter only one CIDR block. Example: 1.*.*.1/32. If you set Source Type to Address Book, select a pre-configured address book.
Destination Type	The type of the traffic destination. Valid values: ○ **IP**: If you select this option, you must enter an IP address or a CIDR block in the Destination field. ○ **Address Book**: If you select this option, you must select an address book for the Destination field. ○ **Domain Name**: If you select this option, you must enter a domain name in the Destination field. Wildcard domain names are supported. Example: **.aliyun.com*. **Note** By default, if an HTTP header does not contain the Host field or an HTTPS request does not contain the Server Name Indication (SNI), Cloud Firewall allows the traffic.

Parameter	Description
Destination	The destination of the traffic. You can enter only one CIDR block. If you set Destination Type to Domain Name, enter a domain name. Wildcard domain names are supported. Example: **.aliyun.com*.
Protocol	The protocol of the traffic. Valid values: ○ **ANY**: all protocols ○ **TCP** ○ **UDP** ○ **ICMP**
Ports	The port range of the traffic. The value 0/0 indicates all ports. **Note** If you set Protocol to ICMP, the port configuration does not take effect. If you set Protocol to ANY, the port configuration does not take effect in controlling ICMP traffic.
Application	The application for the traffic. Valid values: ANY, HTTP, HTTPS, Memcache, MongoDB, MQTT, MySQL, RDP, Redis, SMTP, SMTPS, SSH, SSL, and VNC If you set Protocol to TCP, multiple applications are supported. If you set Protocol to another value, only ANY is supported. **Note** Cloud Firewall identifies applications based on packet characteristics, instead of port numbers. If Cloud Firewall fails to identify the application for a packet, it allows the packet.
Policy Action	The action on the traffic. Valid values: ○ **Allow**: If traffic meets the preceding conditions that you specify for the policy, the traffic is allowed. ○ **Deny**: If traffic meets the preceding conditions that you specify for the policy, the traffic is blocked. ○ **Monitor**: If traffic meets the preceding conditions that you specify for the policy, the traffic is recorded and allowed. After you observe the traffic for a period of time, you can change the policy action to Allow or Deny.
Description	The description of the policy. Enter an informative description to help identify the policy.

6. Click **Submit**.

21.9.2.3. Intrusion prevention

21.9.2.3.1. Configure intrusion prevention policies

Cloud Firewall uses a built-in threat detection engine to defend against intrusions and common cyberattacks. It provides virtual patches to protect against vulnerabilities and intelligently block intrusion attempts.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Policy Configuration > Intrusion Prevention Policies**.
3. Select a running mode for the threat engine.

Valid values: **Monitoring Mode** and **Traffic Control Mode**.

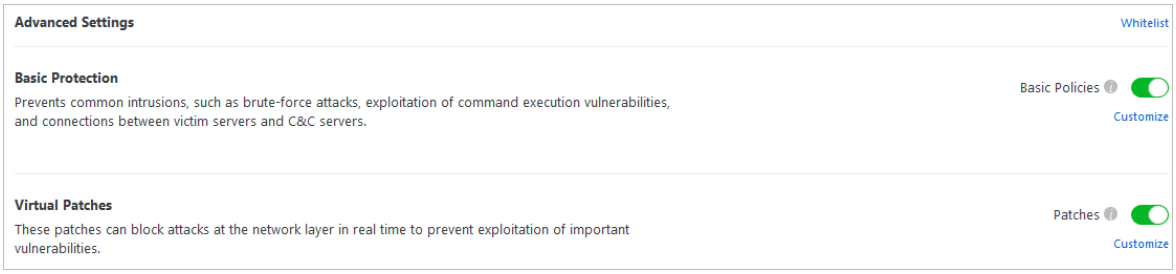
- **Monitoring Mode**: In this mode, the system generates alerts on malicious traffic instead of blocking the traffic.
- **Traffic Control Mode**: In this mode, the system automatically blocks malicious traffic and generates alerts.

To configure **Traffic Control Mode**, perform the following steps:

i. Select **Traffic Control Mode**.

ii. In the message that appears, click **OK**.

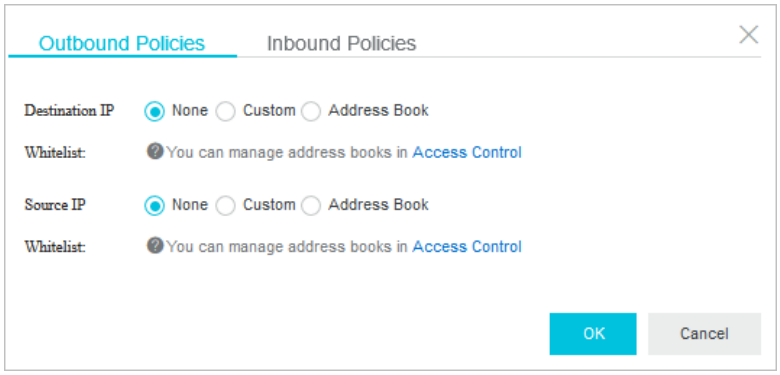
4. Configure the advanced features.



- Cloud Firewall allows traffic from IP addresses in the whitelists that you configured.

  In the **Advanced Settings** section, click **Whitelist** to add trusted IP addresses to a whitelist.

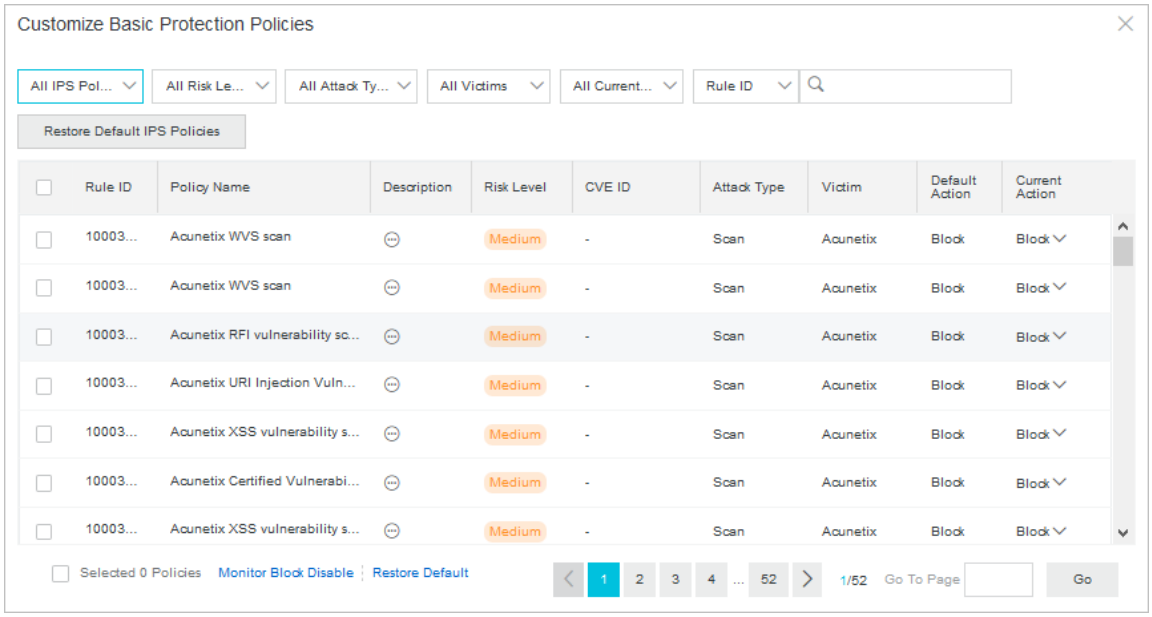
  You can add trusted source IP addresses, destination IP addresses, or address books of both inbound and outbound traffic to the whitelist.



- The basic protection feature defends against common intrusions, such as brute-force attacks and attacks that exploit command execution vulnerabilities. The basic protection feature also manages connections from compromised hosts to a command and control (C&C) server. After you enable the basic protection feature, it provides basic protection for your assets.

  a. Turn on **Basic Policies** to enable the basic protection feature.

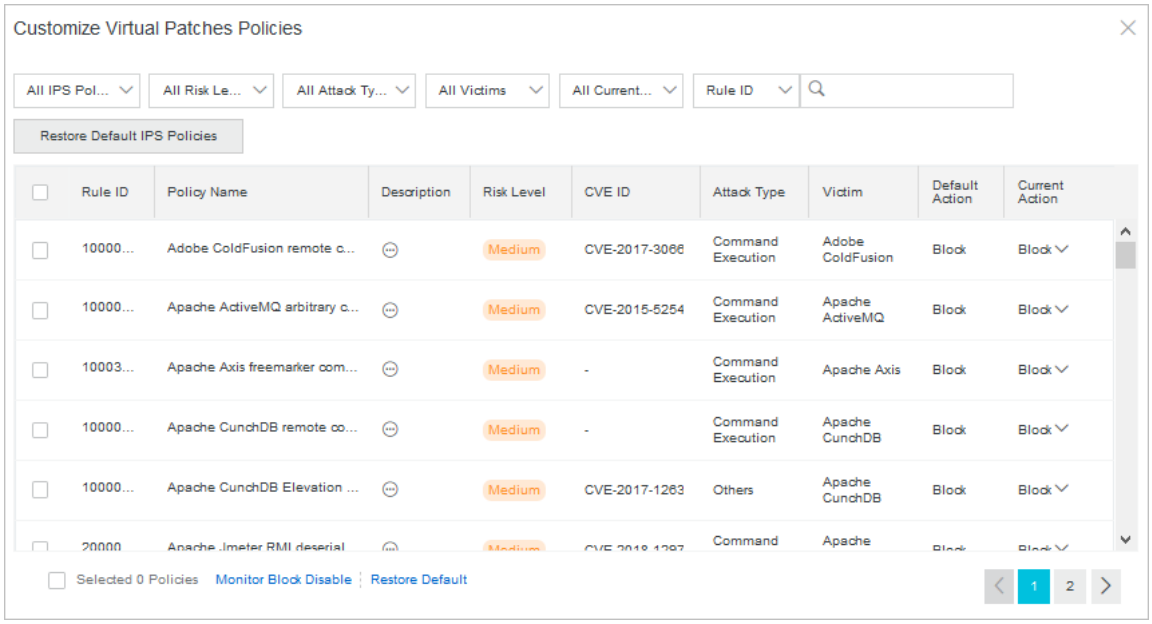
b. In the Basic Protection section, click **Customize**. In the **Customize Basic Protection Policies** dialog box, customize one or more basic protection policies.



- Virtual patches are installation-free. You can use them to protect against common high-risk application vulnerabilities.

  a. Turn on **Patches** to enable the virtual patching feature.

  b. In the **Virtual Patches** section, click **Customize**. In the **Customize Virtual Patches Policies** dialog box, customize one or more basic virtual patching policies.



21.9.2.3.2. View the traffic blocked by IPS

This topic describes how to view the details about Internet and VPC attacks that are blocked by the intrusion prevention system (IPS) feature of Cloud Firewall.

Procedure

1. Log on to Apsara Stack Security Center.

2. In the left-side navigation pane, choose **Network Security > Intrusion Prevention**.
3. Click the **Internet Traffic Blocking** and **VPC Traffic Blocking** tabs to view the details of the IPS-blocked traffic.
   - **Internet Traffic Blocking**

     On the **Internet Traffic Blocking** tab, you can view the blocking events of inbound and outbound traffic from the last one hour, one day, or seven days.

     The Internet Traffic Blocking tab contains the following sections:

     - **Defended Attacks**: displays the number and trend of attacks whose inbound or outbound traffic is blocked by IPS.
     - **Attack Types**: displays the distribution of attacks whose inbound or outbound traffic is blocked by IPS.
     - **Frequently Attacked Apps**: displays the applications whose inbound or outbound traffic is blocked by IPS.
     - **Frequently Attacked Destinations**: displays the traffic distribution of attack targets whose inbound or outbound traffic is blocked by IPS.
     - **Frequently Attacked Sources**: displays the traffic distribution of attack sources whose inbound or outbound traffic is blocked by IPS.
     - **Detailed Data**: displays the details of each traffic blocking event. The details include the risk level, number of times the event occurred, source IP address, and destination IP address.

       In the **Detailed Data** section, you can perform the following operations:

       - Specify a risk level, module, traffic direction, or time range to search for events.
       - Find a traffic blocking event and click **View Details** in the **Action** column to view the details. The details include the event description.

   - **VPC Traffic Blocking**

     The **VPC Traffic Blocking** tab displays the suspicious traffic blocked by IPS between VPCs. You can view the details of a traffic blocking event over a specific time range. The details include the event name, risk level, and attack type.

     On the **VPC Traffic Blocking** tab, you can perform the following operations:

     - Specify a risk level, defense mode, attack type, or time range to search for events. After you specify the filter conditions, you must click **Search**.
     - Find a traffic blocking event and click **View Details** in the **Action** column to view the details. The details include the event description and defense mode.

21.9.2.4. View security groups

This topic describes how to view the details about and relationships between security groups and Elastic Compute Service (ECS) instances in a virtual private cloud (VPC).

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Security Groups**.
3. On the **Visual Security Groups** page, view information about security groups and ECS instances in VPCs.

   Select a VPC and view the numbers of security groups, vSwitches, and ECS instances in the VPC.
4. Click the VPC of the security groups that you want to view. Then, you can view details about the security groups and ECS instances in the VPC.

   You can specify a time range to view the details. The time range can be one hour, one day, seven days, or one month.
   - View details about all security groups and ECS instances in the VPC.

- On the right side of the **Visual Security Group** page, you can view the total numbers of security groups and ECS instances in the VPC, the number of first visits, and the list of security groups in the **Security Group** view.

  > **Note** **First Visits** indicates the total number of first visits between the ECS instances that have dependency relationships in a security group.

  By default, the **Visual Security Groups** page displays the icons of all security groups. In Security Group List, you can find a security group and click the icon in the **Actions** column to hide the icon of the security group on the Visual Security Groups page.

- In the upper-right corner of the **Visual Security Groups** page, click **Data Details**. On the **Service Nodes** tab, you can view all the security groups in the VPC in the **Security Group** view.

- View details about a single security group and the ECS instances in the security group.
  - On the **Visual Security Group** page, click the icon in the **Actions** column in Security Group List. On the **Service Nodes** tab, you can view details about the ECS instances in the security group in the **ECS** view.
  - On the **Visual Security Groups** page, click the icon of a security group. On the right side of the page, you can view the total number of ECS instances in the security group, the number of dependency security groups, the number of dependent security groups, the number of first visits, and the lists of the two types of security groups in the **Security Group** view. Dependency security groups indicate the security groups on which the current security group depends, and dependent security groups indicate the security groups that depend on the current security group. The popover of the security group displays **data details**, including the following items:
    - ECS instance details: You can click the icon to view details about the ECS instances in the security group.
    - Dependency security groups: You can click the icon to view details about the dependency security groups.
    - Dependent security groups: You can click the icon to view details about the dependent security groups.
    - First visits: You can click the icon to view details about the security groups or ECS instances that have dependency relationships.
- View details about a single ECS instance.
  - On the **Visual Security Groups** page, double-click the icon of the security group that contains the ECS instance. Then, all ECS instances in the security group appear. On the right side of the page, you can view the total number of ECS instances in the security group, the numbers of dependency and dependent security groups, the number of first visits, and the ECS instance list in the **ECS** view.

    By default, the Visual Security Groups page displays the icons of all ECS instances in a security group. In ECS Instance List, you can find an ECS instance and click the icon in the **Actions** column to hide the icon of the ECS instance on the Visual Security Groups page.

- On the **Visual Security Groups** page, click the icon of an ECS instance. On the right side of the page, you can view the total numbers of dependency and dependent ECS instances, the number of first visits, and the lists of the two types of security groups in the **ECS** view. The popover of the ECS instance displays **data details**, including the following items:
  - Dependency ECS instances: You can click the icon to view details about the dependency ECS instances.
  - Dependent ECS instances: You can click the icon to view details about the dependent ECS instances.
  - First visits: You can click the icon to view details about the ECS instances that have dependency relationships.

21.9.2.5. Log audit

21.9.2.5.1. View event logs

All traffic that passes through Cloud Firewall is recorded on the Log Audit page. The logs are classified into traffic logs and event logs. You can use the logs to audit your network traffic in real time and take specific actions. This topic describes how to view event logs.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the left-side navigation pane, choose **Network Security > Log Audit > Event Log**.
3. On the **Event Logs** tab, click **Internet Firewall**, **VPC-VPC Firewall**, or **IDC-VPC Firewall**.
4. Specify the search conditions and click **Search**.

   > **Note** If you want to view all event logs, skip this step.

Search condition	Description
Source IP	The source IP address of the event.
Destination IP	The destination IP address of the event.
Type	The type of the event.
Action	The action for the event. Valid values: *All*, *Monitor*, and *Discard*.
Time	The time range to query. You can specify a time range within the last seven days.

5. View the required information in the event list. The information includes the detection time, threat type, traffic direction (inbound or outbound), source IP address, destination IP address, application type, severity, and policy action.

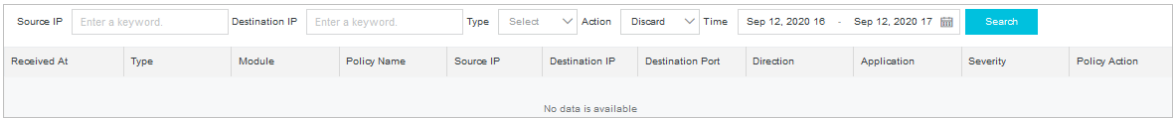
21.9.2.5.2. View traffic logs

All traffic that passes through Cloud Firewall is recorded on the Log Audit page. The logs are classified into traffic logs and event logs. You can use the logs to audit your network traffic in real time and take specific actions. This topic describes how to view traffic logs.

Procedure

1. Log on to Apsara Stack Security Center.

2. In the left-side navigation pane, choose **Network Security > Log Audit > Traffic Log**.
3. On the **Event Logs** tab, click **Internet Firewall**, **VPC-VPC Firewall**, or **IDC-VPC Firewall**.
4. Specify the search condition and click **Search**.



> **Note** If you want to view all traffic logs, skip this step.

Search condition	Description
Source IP	The source IP address of the traffic.
Destination IP	The destination IP address of the traffic.
Application	The application type of the traffic.
Time	The time range to query. You can specify a time range within the last seven days.

To enable the advanced search, perform the following steps:

- **Show Advanced Search**

  Click **Show Advanced Search** to configure more search conditions.

- **List Configuration**

  Click **List Configuration** to select items for the traffic list.

5. View the required information of access traffic. The information includes the start time and end time, traffic direction (inbound or outbound), source IP address, destination IP address, application type, supported protocol, action, bytes, and packets.

21.9.3. Data Encryption Service

21.9.3.1. Data Encryption Service overview

Data Encryption Service is an encryption solution in the cloud. The underlying layer of the service uses hardware cryptographic devices that are tested and certified by the Office of the State Commercial Cryptography Administration (OSCCA). The service uses virtualization technologies to help you meet compliance and regulatory requirements in data security. This helps ensure the confidentiality of business data in the cloud.

Data Encryption Service allows you to manage keys in a secure and reliable manner and ensures reliable data encryption and decryption by using various encryption algorithms.

The following figure shows the communication mode used by Data Encryption Service. Elastic Compute Service (ECS) instances and hardware security modules (HSMs) must be in the same virtual private cloud (VPC).

Features

Data Encryption Service provides the following features:

- Key management: allows you to store and use keys in a secure manner, generate sub-keys by using multiple components, and import and export keys by using secure packets.
- Data encryption: supports all cryptographic algorithms that are approved for use in mainland China and some globally used algorithms.
- Message authentication code (MAC) calculation: supports multiple MAC algorithms that are defined in the China Financial Integrated Circuit (IC) Card Specifications. PBOC for short.
- Transaction authentication: verifies the authorization request cryptogram (ARQC) and generates the

authorization response cryptogram (ARPC) based on PBOC 2.0 and 3.0.

21.9.3.2. Management of Data Encryption Service instances

21.9.3.2.1. Create a Data Encryption Service instance

This topic describes how to create a Data Encryption Service instance.

Context

Before you can use Data Encryption Service, you must create an instance.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the top navigation bar, choose **Security > Data Encryption Service**. On the page that appears, click Data Encryption Service.
3. On the **Data Encryption Service** page, click **Create Instance**.
4. On the page that appears, specify **Region**, **Network Type**, **Manufacturer**, and **Device Model**.
5. Click **Create Instance**.

21.9.3.2.2. Configure a Data Encryption Service instance

This topic describes how to configure a Data Encryption Service instance.

Context

You can use a Data Encryption Service instance only in a virtual private cloud (VPC). After you create a Data Encryption Service instance, you must configure a VPC and a private IP address for the instance.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the top navigation bar, choose **Security > Data Encryption Service**. On the page that appears, click Data Encryption Service.
3. On the Data Encryption Service page, find the instance that you create and click **Configure** in the **Operation** column.
4. In the **Configure IP** dialog box, configure the following parameters.

Parameter	Description
VPC network ID	Select a VPC. The instance and your Elastic Compute Service (ECS) instances must reside in the same VPC.
VPC subnet	Select a VPC subnet.
Allocate private IP address	Specify a private IP address. The private IP address must be within the CIDR block that is specified by **VPC subnet**.

5. Click **OK**.

21.9.3.2.3. Release a Data Encryption Service instance

This topic describes how to release a Data Encryption Service instance.

Context

The number of Data Encryption Service instances that you can create in Data Encryption Service is limited. If you no longer need an instance, you can release the instance.

Procedure

1. Log on to Apsara Stack Security Center.
2. In the top navigation bar, choose **Security > Data Encryption Service**. On the page that appears, click Data Encryption Service.
3. On the **Data Encryption Service** page, find the instance that you want to release and click **Release** in the **Operation** column.
4. In the message that appears, click **OK**.

21.10. Restrictions

Before logging on to Apsara Stack Security Center, make sure that your local PC meets the requirements.

Configuration requirements

Item	Requirements
Browser	• Internet Explorer: 11 or later • Google Chrome (recommended): 42.0.0 or later • Mozilla Firefox: 30 or later • Safari: 9.0.2 or later
Operating system	• Windows XP, Windows 7, or later • Mac

21.11. Log on to Cloud Security Operations Center

This topic describes how to log on to Cloud Security Operations Center.

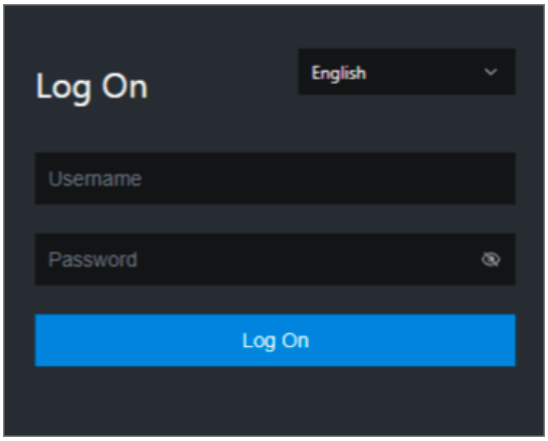
Prerequisites

- The endpoint of the Apsara Uni-manager Operations Console and the username and password used to log on to the console are obtained from the deployment personnel or an administrator.

  The endpoint of the Apsara Uni-manager Operations Console is in the following format: *region-id*.ops.console.*intranet-domain-id*.
- A browser is available. We recommend that you use Google Chrome.

Procedure

1. Open your browser.
2. In the address bar, enter the endpoint of the Apsara Uni-manager Operations Console. Press the Enter key.



> **Note** You can select a language from the drop-down list in the upper-right corner of the page.

3. Enter your username and password.

> **Note** Obtain the username and password used to log on to the Apsara Uni-manager Operations Console from the deployment personnel or an administrator.

When you log on to the Apsara Uni-manager Operations Console for the first time, you must change the password of your username.

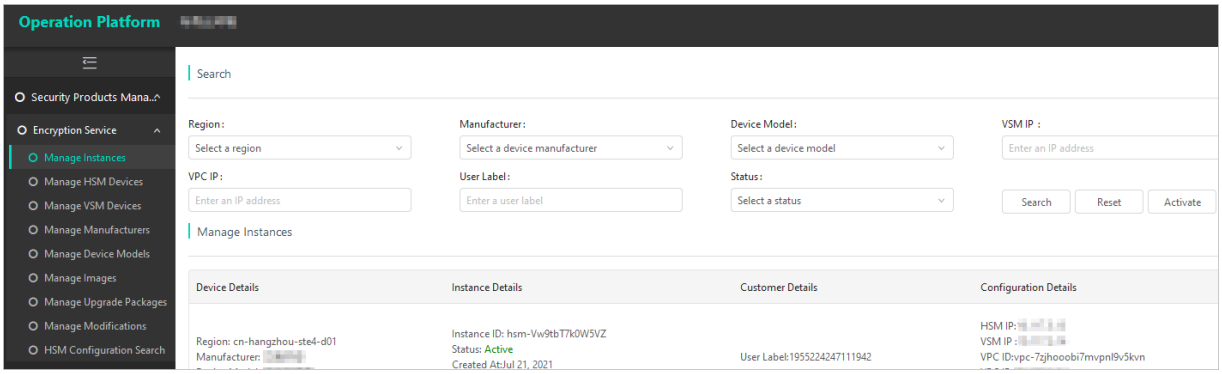
For security reasons, your password must meet the following requirements:

- The password contains uppercase and lowercase letters.
- The password contains digits.
- The password contains special characters such as exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).
- The password must be 10 to 20 characters in length.

4. Click **Log On**.
5. In the top navigation bar of the Apsara Uni-manager Operations Console, click **O&M**. In the left-side navigation pane, choose **Product Management > Products**. On the page that appears, click **Cloud Security Operation Center** in the **Security Services** section.

Result

On the **Operations Platform** page, you can view the following information.



21.12. Services

21.12.1. Data Encryption Service

21.12.1.1. Manage Data Encryption Service instances

21.12.1.1.1. Create an instance

This topic describes how to create a Data Encryption Service instance.

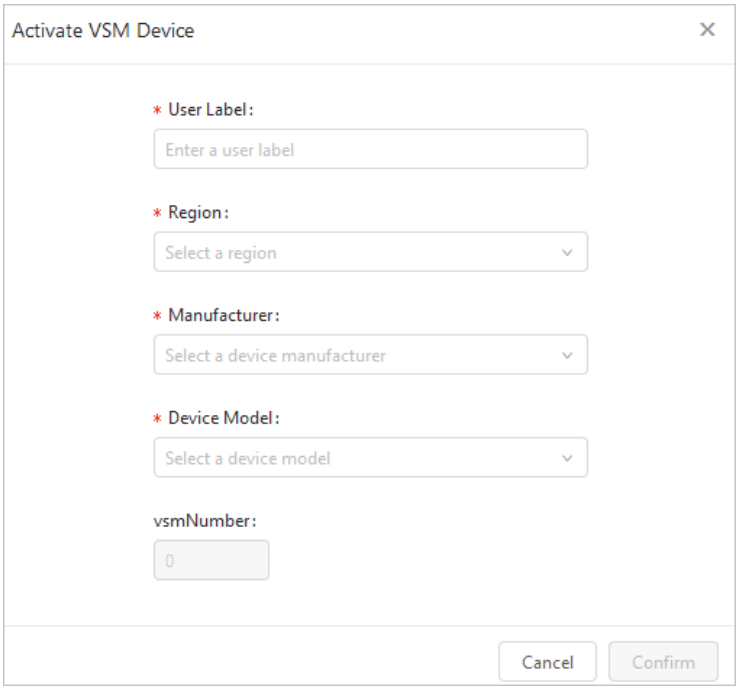
Context

After you create an instance, you can view the instance in the **Manage Instances** section. The instance is in the *Not Configured* **state**.

Note Before you use Data Encryption Service, you must configure a virtual private cloud (VPC) for the instance. For more information, see Configure VPC.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage Instances**.
3. On the page that appears, click **Activate** in the **Search** section.
4. In the **Activate VSM Device** dialog box, configure the following parameters.



Note You can view the user ID in **Apsara Stack Security Center**. To view the user ID, log on to Apsara Stack Security Center, choose **System Configuration > Accounts**. On the page that appears, view the user ID in the **User ID** column.

5. Click **Yes**.

21.12.1.1.2. Configure a VPC

This topic describes how to configure a virtual private cloud (VPC) for a Data Encryption Service instance.

Prerequisites

A VPC is created.

Context

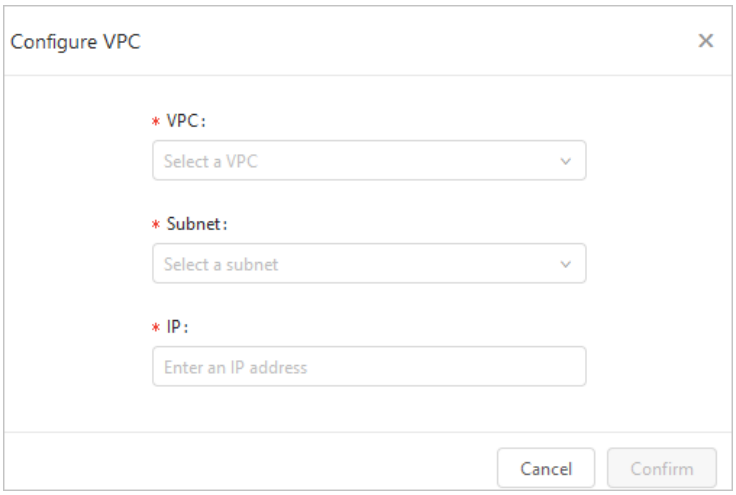
Before you can use a Data Encryption Service instance, you must configure a VPC for the instance.

> **Note** After you create an instance, you must configure a VPC for the instance.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage Instances**.
3. On the page that appears, find the instance for which you want to configure a VPC in the **Manage Instances** section and click **Configure VPC** in the Actions column.

   In the **Search** section, you can specify the search conditions to find an instance.
4. In the Configure VPC dialog box, configure the following parameters for a VPC.



Parameter	Description
vpc	The VPC that you want to bind with the instance.
Subnet	The subnet of the VPC that you want to bind with the instance.
IP	The IP address of the instance. The IP address must be within the subnet of the VPC.

5. Click **Confirm**.

21.12.1.1.3. Manage an instance

This topic describes how to unbind a virtual private cloud (VPC) from a Data Encryption Service instance. This topic also describes how to release and delete the instance.

Context

You can perform the following operations on an existing instance.

Operation	Description
Unbind a VPC from the instance.	If the VPC or the subnet of the VPC to which the instance belongs is changed, you can unbind the VPC by performing the steps described in this topic. After you unbind the VPC, the **state** of the instance is changed to *Not Configured*. If you want to use the instance again, you must configure a VPC for the instance.
Release the instance.	If you no longer need the instance, you can release the instance. You can activate and reuse the instance that you released.
Delete the instance.	If the instance is in the *Released* **state**, you can delete the instance.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage Instances**.
3. On the page that appears, find the instance that you want to manage in the **Manage Instances** section and perform the following operations based on your business requirements.
   - Click **Unbind VPC** to unbind the VPC from the instance.
   - Click **Release** to release the instance.
   - Click **Delete** to delete the instance that you released.
4. In the dialog box that appears, click **OK**.

21.12.1.2. Manage HSMs

21.12.1.2.1. Add an HSM

This topic describes how to add a hardware security module (HSM).

Prerequisites

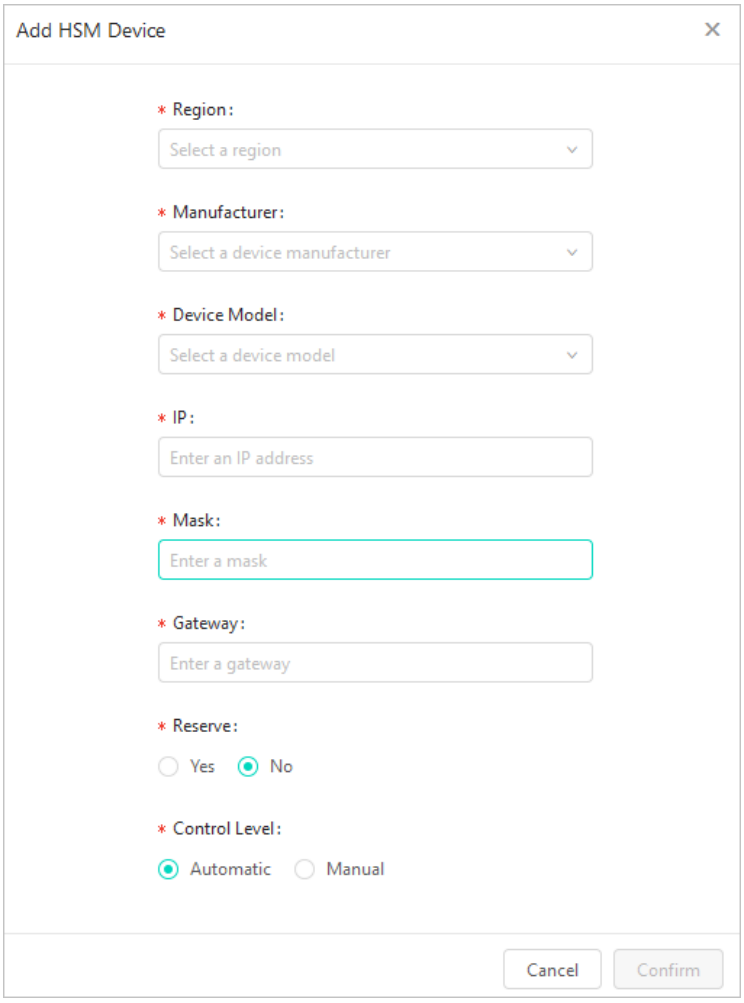
- The HSM can communicate with Cloud Security Operations Center.
- The HSM and all the virtual security modules (VSMs) on the HSM are in the running state.

Context

An HSM is a physical cryptographic device provided by a manufacturer. An HSM can host multiple VSMs.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage HSM Devices**.
3. On the page that appears, click **Add** in the **Search** section.
4. In the Add HSM Device dialog box, configure the following parameters.



Parameter	Description
Region	Select the region of the HSM.
Manufacturer	Select the manufacturer of the HSM.
Device Model	Select the model of the HSM.
IP	Specify the IP address of the HSM.
Mask	Specify the mask of the HSM.
Gateway	Specify the IP address of the gateway.
Reserve	Determine whether to reserve the HSM. All the VSMs on the reserved HSM are allocated and used only when you want to migrate or update an HSM.
Control Level	The control level of the HSM. Valid values: ◦ Automatic ◦ Manual

5. Click **Confirm**.

   The task of adding the HSM requires some time to complete. You can go to the **Manage Modifications** page to view the task.

21.12.1.2.2. Configure the network information for an HSM

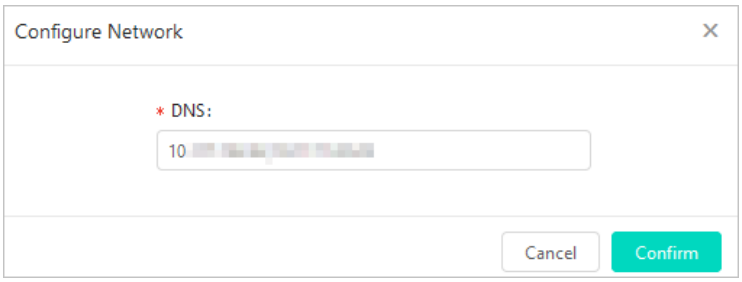
This topic describes how to configure the Domain Name System (DNS) information for a hardware security module (HSM).

Context

The network information for an HSM is configured. For more information about how to configure the network information, see Add an HSM. If you want to modify the network information of the HSM, find the HSM and click **Configure Network** in the Actions column. Then, modify the DNS information.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage HSM Devices**.
3. In the **Manage HSM Devices** section, find the HSM whose network information you want to modify and click **Configure Network**.
4. In the Configure Network dialog box, configure the DNS parameter.



5. Click **Confirm**.

21.12.1.2.3. Migrate an HSM

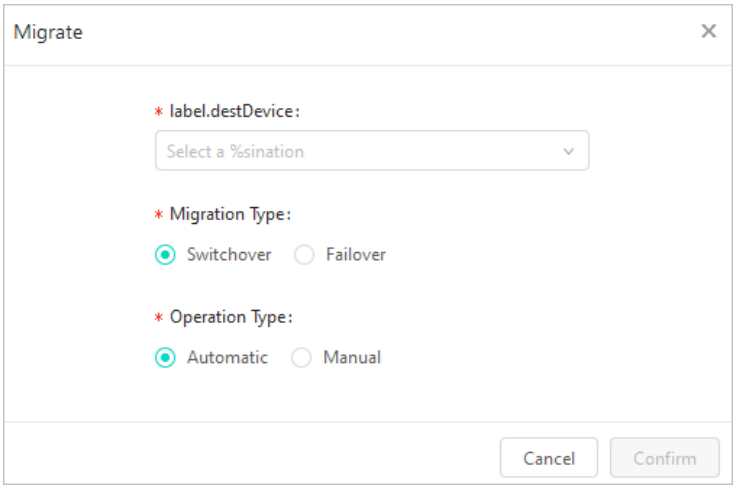
This topic describes how to migrate a source hardware security module (HSM) to a destination HSM.

Context

If a source HSM requires to be maintained or fails, you can migrate the source HSM to a destination HSM to ensure service continuity. After the source HSM recovers, the service is switched back to the source HSM.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage HSM Devices**.
3. On the page that appears, find the source HSM in the **Manage HSM Devices** section and click **Migrate**.
4. In the Migrate dialog box, configure the following parameters.



Parameter	Description
Destination HSM	Specify the destination HSM.
Migration Type	Select a scenario in which you want to migrate the source HSM to the destination HSM. Valid values: ○ Switchover: Select Switchover for daily maintenance. For example, you can select Switchover when you want to update the source HSM. After the update is complete, you can migrate the service back to the source HSM. ○ Failover: Select Failover if the source HSM fails.
Operation Type	Select a migration type. Valid values: ○ Automatic The source HSM is automatically migrated without manual operations. In most cases, we recommend that you select Automatic. ○ Manual The source HSM must be manually migrated. If you select Manual, you are redirected to the **Job Details** page. On this page, you must manually migrate the source HSM.

5. Click **Confirm**.
6. Determine whether to view the migration process.
   - If you do not want to view the migration process, click **Cancel** to stay in the **Manage HSM Devices** section.
   - If you want to view the migration process, click **Confirm** and click OK in the message that appears to go to the **Job Details** page. On this page, you can view the migration process.

21.12.1.2.4. Update an HSM

This topic describes how to update a hardware security module (HSM).

Context

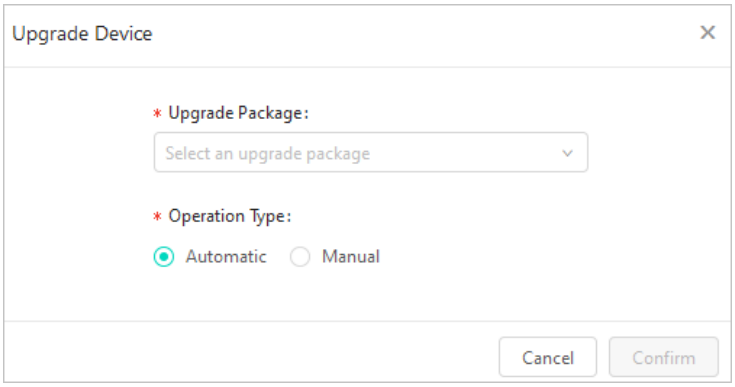
Before you update an HSM, you must migrate the HSM to another HSM that is of the same model and is running.

You must update or roll back an HSM and the VSMs in the following order:

- If you want to update an HSM and the VSMs at the same time, you must first update the HSM and then the VSMs.
- If you want to roll back an HSM and the VSMs at the same time, you must first roll back the VSMs and then the HSM.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage HSM Devices**.
3. On the page that appears, find the HSM that you want to update in the **Manage HSM Devices** section and click **Upgrade**.
4. In the **Upgrade Device** dialog box, configure the Upgrade Package and Operation Type parameters.



5. Click **Confirm**.

21.12.1.2.5. Manage an HSM

This topic describes how to manage a hardware security module (HSM), such as view details about the HSM, reload the HSM, and configure Network Time Protocol (NTP) for the HSM.

Context

You can perform the following operations on an existing HSM.

Operation	Description
Refresh the URL that is used to export snapshots. A snapshot contains the keys and configuration data on the HSM.	If the snapshots fail to be exported, the specified export URL may be invalid. Click Refresh Export Image URL to refresh the URL. Then, export the snapshots again.
View the details about the HSM.	View the details about the HSM.
Reserve the HSM.	A reserved HSM is allocated and used only when you want to migrate or update an HSM. If you want to update an HSM or migrate an HSM, the HSM is migrated to the reserved HSM first.
Refresh the information about Log Service.	Refresh the information about Log Service.
Reload the information about the HSM.	If the information in the dialog box that appears after you click **Device Details** is different from the information in the database that is connected to Data Encryption Service, click **Reload** to synchronize the information.
Enable or disable monitoring on the HSM.	Enable or disable monitoring on the HSM.

Operation	Description
Configure NTP for the HSM.	Configure NTP to synchronize the clock between the HSM and the NTP server.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage HSM Devices**.
3. On the page that appears, find the HSM that you want to manage in the **Manage HSM Devices** section and perform the following operations based on your business requirements:
   - Click **Refresh Image Export URL** to refresh the URL that is used to export snapshots.
   - Click **Device Details** to view the details about the HSM.
   - Click **Reserve** to reserve the HSM.
   - Click **Refresh SLS** to refresh the information about Log Service.
   - Click **Reload** to reload the information about the HSM.
   - Click **Modify** to enable or disable monitoring on the HSM.
   - Click **Configure NTP** to configure the NTP server and synchronization frequency.
4. In the message or dialog box that appears, click **OK** or Confirm.

21.12.1.3. Manage VSMs

21.12.1.3.1. Configure the network information for a VSM

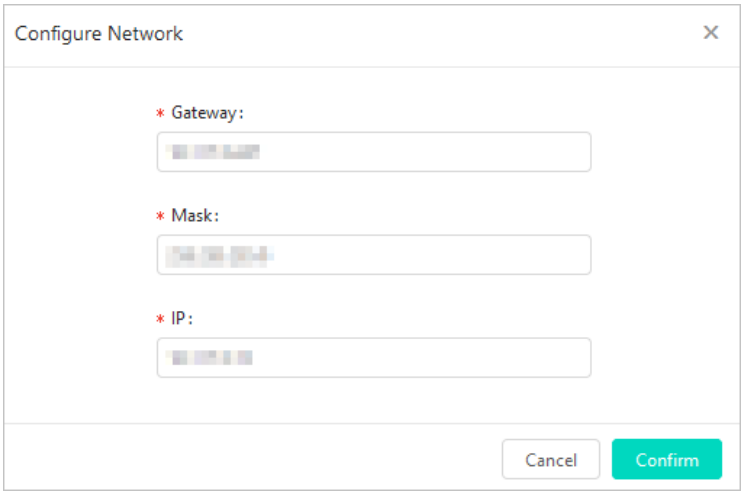
This topic describes how to configure the gateway, mask, and IP address of a virtual security module (VSM).

Context

If you want to modify the network information of the VSM, find the VSM and click **Configure Network** in the Actions column. Then, change the gateway, the mask, or the IP address of the VSM.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage VSM Devices**.
3. In the **Manage VSM Devices** section, find the VSM whose network information you want to modify and click **Configure Network**.
4. In the Configure Network dialog box, configure the Gateway, Mask, and IP parameters.



5. Click **Confirm**.

21.12.1.3.2. Update a VSM

This topic describes how to update a virtual security module (VSM).

Context

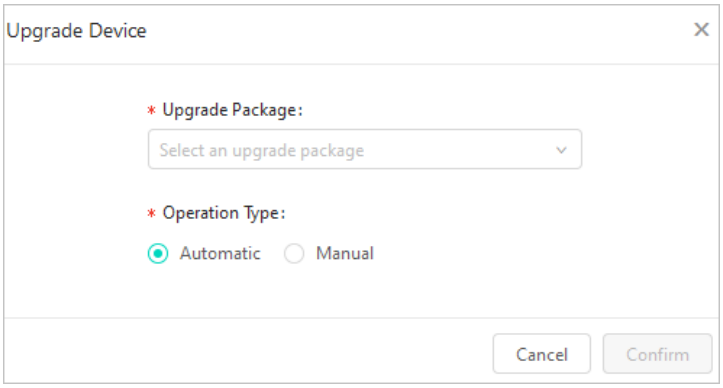
Before you update a VSM, you can migrate the VSM to another VSM that is of the same type and is running.

You must update and roll back an HSM and the VSMs in the following order:

- If you want to update an HSM and the VSMs at the same time, you must first update the HSM and then the VSMs.
- If you want to roll back an HSM and the VSMs at the same time, you must first roll back the VSMs and then the HSM.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage VSM Devices**.
3. On the page that appears, find the VSM that you want to update in the **Manage VSM Devices** section and click **Upgrade**.
4. In the **Upgrade Device** dialog box, configure the Upgrade Package and Operation Type parameters.



5. Click **Confirm**.

21.12.1.3.3. Export snapshots

This topic describes how to export the snapshots of a virtual security module (VSM). A snapshot contains keys and configuration data on the VSM.

Context

The exported snapshots can be used to restore the VSM.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage VSM Devices**.
3. On the page that appears, find the VSM whose snapshots you want to export in the **Manage VSM Devices** section and click **Export Snapshot**.
4. In the message that appears, click **OK**.

   After the snapshots are exported, you can view the information about the snapshots. To view the information, click Manage Images in the left-side navigation pane. On the page that appears, view the information in the **Manage Images** section.

21.12.1.3.4. Manage a VSM

This topic describes how to manage a virtual security module (VSM), such as view details about the VSM, reserve the VSM, and restart the VSM.

Context

You can perform the following operations on the VSM.

Operation	Description
View the details about the VSM.	View the details about the VSM.
Reserve the VSM.	A reserved VSM is allocated and used only when you want to migrate or update a VSM. If you want to update or migrate a VSM, the VSM is migrated to the reserved VSM first.
Reset the VSM.	If the VSM is released but data on the VSM is not deleted, reset the VSM.
Stop the VSM.	Stop the running VSM.
Restart the VSM.	Restart the VSM.
Enable or disable monitoring on the VSM.	Enable or disable monitoring on the VSM.
Delete the VSM.	Delete the VSM that you no longer need.
Change the state of the VSM to Running.	After the VSM that was in the *System Unavailable* state becomes available, click Activate to change the state of the VSM to *Running*. Then, the system can allocate the VSM.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage VSM Devices**.
3. On the page that appears, find the VSM that you want to manage in the **Manage VSM Devices** section and perform the following operations based on your business requirements:
   - Click **Device Details** to view the details about the VSM.

- Click **Reserve** to reserve the VSM.
- Click **Reset** to reset the VSM.
- Click **Stop** to stop the running VSM.
- Click **Restart** to restart the VSM.
- Click **Modify** to enable or disable monitoring on the VSM.
- Click **Delete** to delete the VSM.
- Click **Activate** to change the state of the VSM from *System Unavailable* to *Running*.

4. In the message or dialog box that appears, click **OK** or Confirm.

21.12.1.4. Manage manufacturers

21.12.1.4.1. Add a manufacturer

This topic describes how to add a manufacturer.

Context

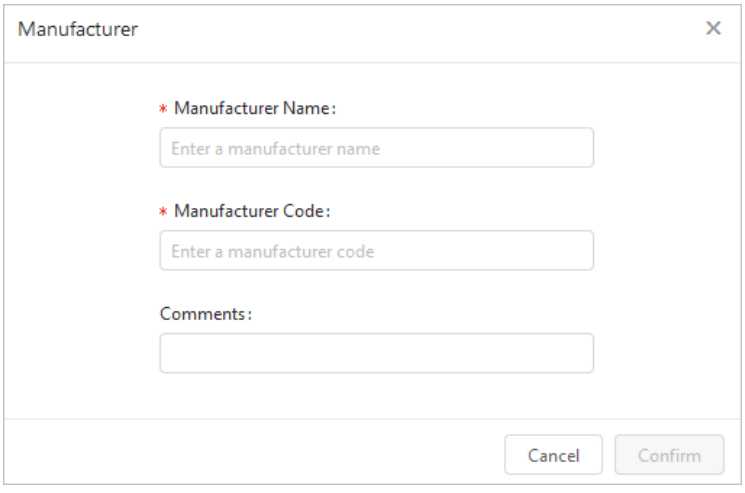
Accurate manufacturer information is required for Data Encryption Service instances and hardware security modules (HSMs). Before you use an HSM that you purchased, you must configure the manufacturer information.

The following manufacturer is supported.

Manufacturer	Code
TASS	jnta

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage Manufacturers**.
3. In the upper-right corner of the page that appears, click **Add**.
4. In the Manufacturer dialog box, configure the parameters.



5. Click **Confirm**.

21.12.1.4.2. Manage a manufacturer

This topic describes how to modify the information about a manufacturer and delete a manufacturer.

Context

Accurate manufacturer information is required for Data Encryption Service instances and hardware security modules (HSMs). Before you use an HSM that you purchased, you must configure the manufacturer information.

The following manufacturer is supported.

Manufacturer	Code
TASS	jnta

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage Manufacturers**.
3. On the page that appears, delete a manufacturer or modify the information about a manufacturer.
   - Click **Delete** to delete a manufacturer.
   - Click **Modify** to modify the information about a manufacturer.
4. Click OK or **Confirm**.

21.12.1.5. Manage HSM models

21.12.1.5.1. Add an HSM model

This topic describes how to add a hardware security module (HSM) model.

Context

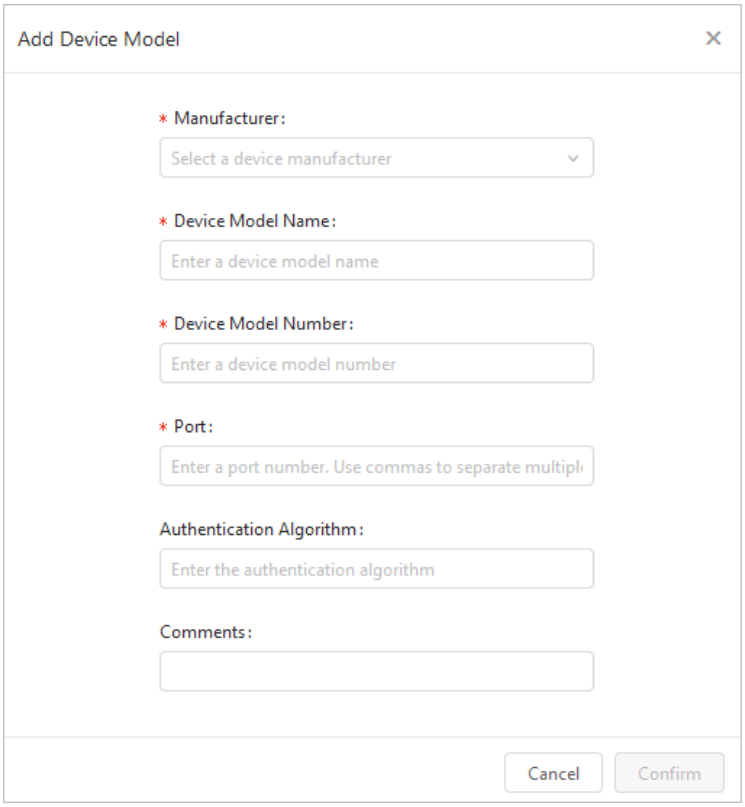
Accurate information about the HSM model is required for Data Encryption Service instances and HSMs. Before you use an HSM that you purchased, you must configure the HSM model information.

The following HSM models are supported.

Manufacturer	HSM model	HSM model number
TASS	Financial HSM	jnta.EVSM
TASS	Server HSM	jnta.GVSM
TASS	Signature verification HSM	jnta.SVSM

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage Device Models**.
3. In the upper-right corner of the page that appears, click **Add**.
4. In the Add Device Model dialog box, configure the parameters.



5. Click **Confirm**.

21.12.1.5.2. Manage an HSM model

This topic describes how to modify the information about a hardware security module (HSM) model or delete an HSM model.

Context

Accurate information about the HSM model is required for Data Encryption Service instances and HSMs. Before you use an HSM that you purchased, you must configure the HSM model information.

The following HSM models are supported.

Manufacturer	HSM model	HSM model number
TASS	Financial HSM	jnta.EVSM
TASS	Server HSM	jnta.GVSM
TASS	Signature verification HSM	jnta.SVSM

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage Device Models**.
3. On the page that appears, find the HSM model that you want to manage and perform the following operations based on your business requirements:
   - Click **Delete** to delete the HSM model.
   - Click **Modify** to modify the information about the HSM model.
4. Click **Confirm**.

21.12.1.6. View the information about snapshots

This topic describes how to view the snapshots of a virtual security module (VSM). A snapshot contains keys and configuration data on the VSM.

Context

You can use the snapshots that are displayed in the **Manage Images** section to restore VSMs. For more information about how to export snapshots, see Export snapshots.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage Images**.
3. View the information about the snapshots.

21.12.1.7. Manage update files

21.12.1.7.1. Upload an update file

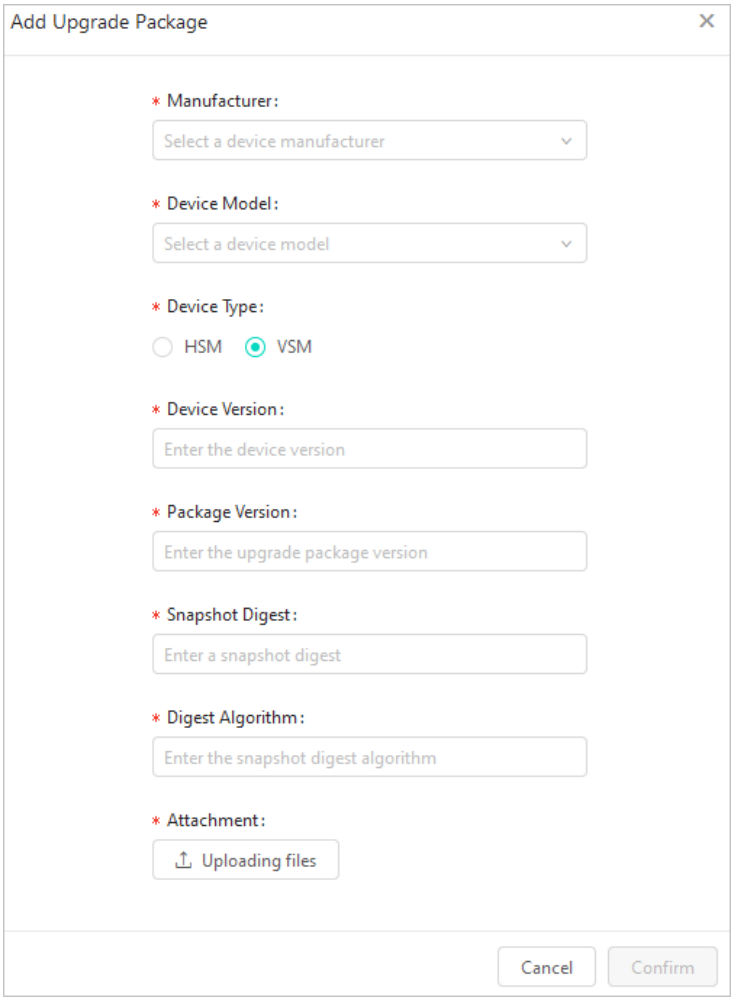
This topic describes how to upload an update file for a hardware security module (HSM) or a virtual security module (VSM).

Context

You can upload an update file based on your business requirements. If an update file fails to be uploaded, you must import the required HTTPS certificate on your browser. To import the required HTTPS certificate, you can open a new browser window, import the certificate, enter the upload URL in the address bar, and then re-upload the file.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage Upgrade Packages**.
3. On the page that appears, click **Add** in the **Search** section.
4. In the Add Upgrade Package dialog box, configure the parameters.



5. Click **Uploading files**. Then, select and upload a update file from your computer.
6. Click **Confirm**.

21.12.1.7.2. Delete an update file

This topic describes how to delete an update file of a hardware security module (HSM) or a virtual security module (VSM).

Context

You can delete update files that you no longer need to free up storage space.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage Upgrade Packages**.
3. On the page that appears, find the update file that you want to delete in the Manage Upgrade Packages section and click **Delete** in the Operation column.

21.12.1.8. Manage tasks

21.12.1.8.1. View task details

This topic describes how to view task details.

Context

If you perform an operation in Data Encryption Service, a task is generated and displayed on the Modification Details page. The task details show how the task is executed. If the task fails, you can view the task details to identify the issues.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage Modifications**.
3. On the page that appears, find the task whose details you want to view and click **Job Details** in the Operation column.
4. View the details about the task.

21.12.1.8.2. Terminate a task

This topic describes how to terminate a running task.

Context

You can terminate running tasks that are performed by mistake or no longer needed.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > Manage Modifications**.
3. On the page that appears, find the running task that you want to terminate and click **Stop**.

21.12.1.9. Query the configurations of an HSM

This topic describes how to query the configurations of a hardware security module (HSM).

Context

You can query the configurations of an HSM. The configurations include the manufacturer, status, and network information about an HSM, and the virtual security modules (VSMs) on the HSM.

Procedure

1. Log on to Cloud Security Operations Center.
2. Choose **Security Products Management > Encryption Service > HSM Configuration Search**.
3. On the page that appears, configure **Manufacturer** and **HSM IP** in the **Search** section and click **Search**
4. View the configurations of the HSM and VSMs.

22.Key Management Service (KMS)

22.1. Manage keys in the KMS console

22.1.1. Log on to the KMS console

This topic describes how to log on to the Key Management Service (KMS) console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the operations administrator before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use Google Chrome.

Procedure

1. In the address bar, enter the URL used to log on to the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that are used to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username as prompted. For security purposes, your password must meet the minimum complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters.
   > - Digits.
   > - Special characters including exclamation points (!), at signs (@), number signs (#), dollar signs ($), and percent signs (%).

3. Click **Login**.
4. In the top navigation bar, choose **Products > Security > Key Management Service**.

22.1.2. Create a CMK

This topic describes how to create a CMK for subsequent encryption and decryption operations.

Procedure

1. Log on to the KMS console.
2. On the Keys page, click **Create Key**.
3. On the **Create Key** page, select an organization from the **Organization** drop-down list. Then, the **Resource Set** and **Region** parameters are automatically set.
4. In the **Basic Settings** section, set the **Key Type**, **Key Purpose**, and **Protection Level** parameters.

   You can select one of the following key types:

   - Symmetric keys:
     - Aliyun_AES_256
     - Aliyun_SM4
   - Asymmetric keys:

- RSA_2048
- EC_P256
- EC_P256K
- EC_SM2

> **Note** Aliyun_SM4 and EC_SM2 types are supported only in mainland China regions where managed HSMs are available.

5. In the **Basic Settings** section, set the **Alias** and **Description** parameters.
6. In the **Advanced Settings** section, set the **Rotation Period** parameter.
   - **Disable**: The key is not automatically rotated.
   - **Enable**: The key is automatically rotated. You can select or customize an interval for rotation.

     > **Note**
     > - You can set this parameter only if the Key Type parameter is set to Aliyun_AES_256 or Aliyun_SM4.
     > - If the Key Material Source parameter is set to External, automatic rotation is not supported.
7. In the **Advanced Settings** section, set the **Key Material Source** parameter.
   - **Key Management Service**: Use KMS to generate key material.
   - **External**: Import key material from an external source.

     > **Note** You can set this parameter only if the Key Type parameter is set to Aliyun_AES_256 or Aliyun_SM4.
8. Click **Submit**.

22.1.3. View the details of a CMK

After you create a CMK, you can view the details of the CMK, such as the key ID, status, purpose, and creation time.

Procedure

1. Log on to the KMS console. For more information, see Log on to the KMS console.
2. On the Keys page, find the CMK that you want to view and click its alias or choose **More**>**Key Details** in the Actions column.
3. In the **Key Details** section, view the details of the CMK, such as the key ID, status, purpose, and creation time.

22.1.4. Enable a CMK

This topic describes how to enable a CMK that is in the disabled state.

Procedure

1. Log on to the KMS console. For more information, see Log on to the KMS console.
2. Find a CMK in the **Disabled** state and click **Enable** in the **Actions** column.
3. In the **Enable Key** message, click **OK**.

   After the CMK is enabled, the status of the CMK is changed from **Disabled** to **Enabled**.

22.1.5. Disable a CMK

This topic describes how to disable a CMK.

Context

If a CMK is disabled, the CMK cannot be used for encryption and decryption. The ciphertext encrypted by using this CMK cannot be decrypted until you re-enable the CMK.

Procedure

1. Log on to the KMS console. For more information, see Log on to the KMS console.
2. Find a CMK in the **Enabled** state and click **Disable** in the **Actions** column.
3. In the **Disable Key** message, click **OK**.

   After the CMK is disabled, the status of the CMK is changed from **Enabled** to **Disabled**.

22.1.6. Schedule the deletion of a CMK

You can schedule the deletion of a CMK by specifying a waiting period. After the period ends, the CMK is automatically deleted.

Context

You can specify a waiting period of 7 to 30 days.

> **Warning**
>
> - During the waiting period, the CMK is in the Pending Deletion state. It cannot be used to encrypt data, decrypt data, or generate data keys.
> - Deleting a CMK may have a severe impact on data availability. Therefore, in most cases, we recommend that you disable a CMK instead of deleting it.
> - After a CMK is deleted, it cannot be recovered. The data encrypted by using this CMK and the ciphertext data keys generated by using this CMK cannot be decrypted. Therefore, KMS only allows you to schedule the deletion of a CMK. You cannot immediately delete a CMK.
> - KMS deletes the CMK within 24 hours after the specified waiting period ends.
>
>   For example, if you submit a deletion application at 14:00, September 10, 2017 and specify a waiting period of seven days, KMS deletes the CMK within 24 hours after 14:00, September 17, 2017.

Procedure

1. Log on to the KMS console.
2. Find the CMK for which you want to schedule the deletion and choose **More** > **Schedule Key Deletion** in the **Actions** column.
3. In the **Schedule Key Deletion** dialog box, specify **Delete In (7-30 days)**.
4. Click **OK**.

   The status of the CMK becomes **Pending Deletion**.

   Before the specified period ends, you can cancel the scheduled deletion by performing the following operations: Choose **More** > **Cancel Key Deletion** and click **OK** in the **Cancel Key Deletion** message.

22.1.7. Configure the rotation policy of a CMK

This topic describes how to configure the rotation policy of a CMK.

Procedure

1. Log on to the KMS console.

2. On the Keys page, find a symmetric CMK whose **Key Spec** is Aliyun_AES_256 or Aliyun_SM4 and choose **More** > **Key Details** in the **Actions** column.
3. In the **Key Version** section, click **Set Rotation Policy**.
4. In the **Set Rotation Policy** dialog box, set the **Rotation Period** parameter.
   - Disable: The automatic rotation is disabled for the CMK.
   - 30 Days, 90 Days, 180 Days, and 365 Days: Select an interval for automatic CMK rotation.
   - Customize: Customize the interval for automatic CMK rotation.
5. Click **OK**.

Related information

- Automatic key rotation
- Manual CMK rotation

22.1.8. Generate a data key

Data keys can be used to encrypt and decrypt on-premises data. This topic describes how to generate a data key.

Procedure

1. Log on to the KMS console. For more information, see Log on to the KMS console.
2. Find a symmetric CMK for which the Key Purpose parameter is set to **Encrypt/Decrypt** and click its alias or choose **More** > **Key Details** in the Actions column.

   > **Note** The type of symmetric CMKs is Aliyun_AES_256 or Aliyun_SM4.

3. In the **DataKey management** section, click **DataKey management**.
4. On the **Generate data key** tab, set the parameters as required and click **Submit**.
   i. In the **Generate dataKey parameters** section, set the **Key Spec** and **Encryption Context** parameters.
   ii. In the **Generate dataKey parameters** section, set the **Export using public key encryption** parameter. Valid values:
   - **Yes**: Encrypt a data key by using a specific public key and export the data key. In the **Specify the export publicKey** section, set the **Publickey Type**, **Public Key**, and **Key Algorithm** parameters.
   - **No**: Export a data key without encrypting the data key by using a specific public key. This way, you can directly generate a data key.

   > **Note** After the data key is generated, you can view the ciphertext of the data key in the **Data key export results** dialog box.

5. Optional. Click the **Data key transfer protection** tab, set the parameters as required, and then click **Submit**.

Transfer protection scenario	Step
Use public key to protect	i. In the **Parameters to export dataKey** section, set the **Data Key Ciphertext** and **Encryption Context** parameters. ii. In the **Specify the export publicKey** section, set the **Publickey Type**, **Public Key**, and **Key Algorithm** parameters.

Transfer protection scenario	Step
Data key transfer protection in the same region	i. In the **Parameters to export dataKey** section, set the **Data Key Ciphertext** and **Source EncryptionContext** parameters. ii. In the **Target key parameters** section, set the **Target KeyId** and **Target EncryptionContext** parameters.
Data key transfer protection across regions	i. In the **Parameters to export dataKey** section, set the **Data Key Ciphertext** and **Source EncryptionContext** parameters. ii. In the **Target key parameters** section, set the **Target RegionId**, **Target Asymmetric KeyID**, **Target Asymmetric KeyVersionID**, **Target KeyId**, and **Target EncryptionContext** parameters.

> **Note** After transfer protection is configured for the data key, you can view the ciphertext of the data key in the **Data key transfer protection result** dialog box.

22.1.9. Generate a CSR

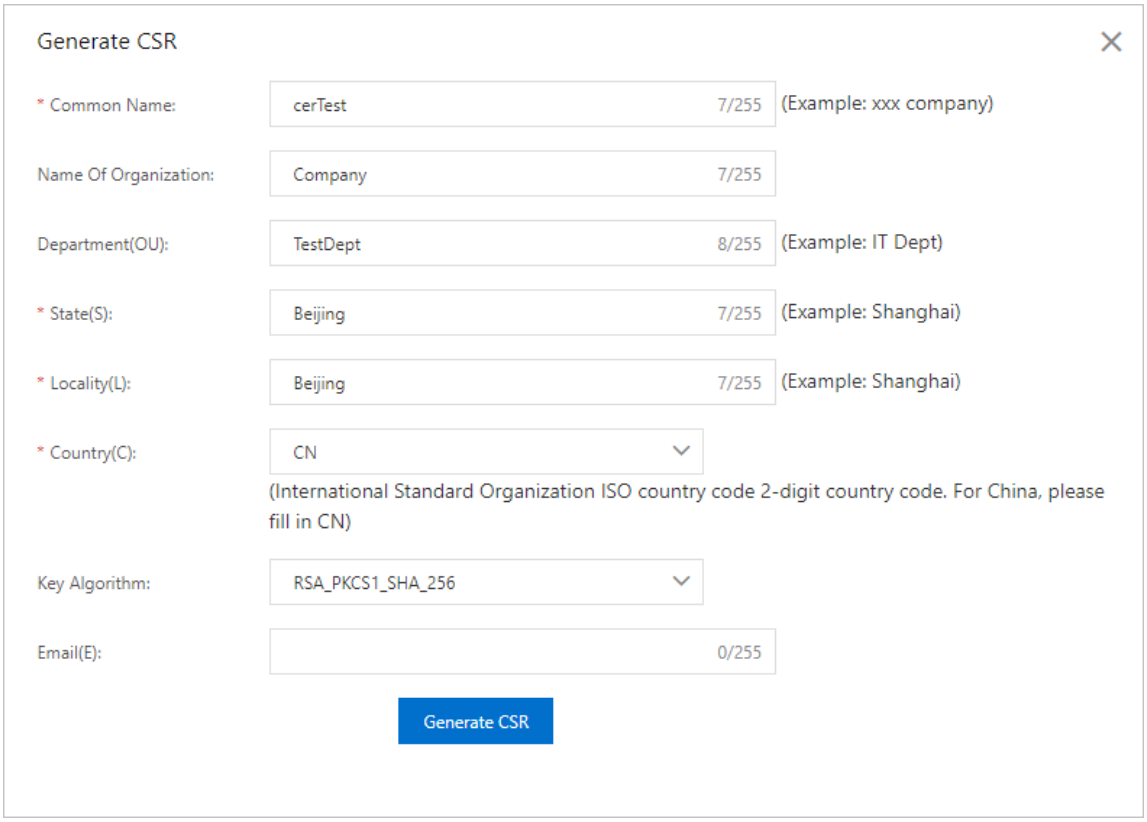
To generate a certificate, you must submit a certificate signing request (CSR) to a certificate authority (CA). This topic describes how to generate a CSR.

Procedure

1. Log on to the KMS console. For more information, see Log on to the KMS console.
2. Find an asymmetric CMK for which the Key Purpose parameter is set to **Sign/Verify** and click its alias or choose **More** > **Key Details** in the Actions column.

   > **Note** The type of asymmetric CMKs is RSA_2048, EC_P256, EC_P256K, or EC_SM2.

3. In the **Key Version** section, click **Generate CSR** in the **Actions** column.
4. In the **Generate CSR** dialog box, set the parameters as required.



5. Click **Generate CSR**.
6. Click **Download CSR file** to save the CSR file to your on-premises computers.

22.2. Use RAM for access control

Key Management Service (KMS) uses Resource Access Management (RAM) to control access to resources. This topic describes the resource types, actions, and policy conditions in KMS.

Apsara Stack tenant accounts have full operation permissions on their own resources. RAM users and roles are granted only operation permissions on specified resources.

Resource types in KMS

The following table describes all resource types and corresponding Alibaba Cloud Resource Names (ARNs) in KMS. They can be used in the Resource parameter of a RAM policy.

Resource type	ARN
Abstract key container	acs:kms:${region}:${account}:key
Abstract alias container	acs:kms:${region}:${account}:alias
Key	acs:kms:${region}:${account}:key/${key-id}
Alias	acs:kms:${region}:${account}:alias/${alias-name}

Actions in KMS

KMS defines actions used in RAM policies for each API operation that requires access control. Actions must be in the `kms:${api-name}` format.

> **Note** The DescribeRegions operation requires no access control. It can be called by Apsara Stack tenant accounts, RAM users, or RAM roles after they pass authentication.

The following table describes the RAM actions and resource types that correspond to each KMS API operation.

- Key service operations

Operation	Action	Resource type
ListKeys	kms:ListKeys	Abstract key container
CreateKey	kms:CreateKey	Abstract key container
DescribeKey	kms:DescribeKey	Key
UpdateKeyDescription	kms:UpdateKeyDescription	Key
EnableKey	kms:EnableKey	Key
DisableKey	kms:DisableKey	Key
ScheduleKeyDeletion	kms:ScheduleKeyDeletion	Key
CancelKeyDeletion	kms:CancelKeyDeletion	Key
GetParametersForImport	kms:GetParametersForImport	Key
ImportKeyMaterial	kms:ImportKeyMaterial	Key
DeleteKeyMaterial	kms:DeleteKeyMaterial	Key
ListAliases	kms:ListAliases	Abstract alias container
CreateAlias	kms:CreateAlias	Alias and key
UpdateAlias	kms:UpdateAlias	Alias and key
DeleteAlias	kms:DeleteAlias	Alias and key
ListAliasesByKeyId	kms:ListAliasesByKeyId	Key
CreateKeyVersion	kms:CreateKeyVersion	Key
DescribeKeyVersion	kms:DescribeKeyVersion	Key
ListKeyVersions	kms:ListKeyVersions	Key
UpdateRotationPolicy	kms:UpdateRotationPolicy	Key
Encrypt	kms:Encrypt	Key
Decrypt	kms:Decrypt	Key
ReEncrypt	○ kms:ReEncryptFrom ○ kms:ReEncryptTo ○ kms:ReEncrypt*	Key
GenerateDataKey	kms:GenerateDataKey	Key

Operation	Action	Resource type
GenerateDataKeyWithoutPlaintext	kms:GenerateDataKeyWithoutPlaintext	Key
ExportDataKey	kms:ExportDataKey	Key
GenerateAndExportDataKey	kms:GenerateAndExportDataKey	Key
AsymmetricSign	kms:AsymmetricSign	Key
AsymmetricVerify	kms:AsymmetricVerify	Key
AsymmetricEncrypt	kms:AsymmetricEncrypt	Key
AsymmetricDecrypt	kms:AsymmetricDecrypt	Key
GetPublicKey	kms:GetPublicKey	Key

- Tag management operations

Operation	Action	Resource type
ListResourceTags	kms:ListResourceTags	Key
UntagResource	kms:UntagResource	Key
TagResource	kms:TagResource	Key

Policy conditions in KMS

You can add conditions to RAM policies to control access to KMS. RAM authentication will be successful only when the specified conditions are met. For example, you can use `acs:CurrentTime` to control the time period when a RAM policy is valid.

In addition to global conditions, you can use tags as filters to restrict the use of cryptographic operations such as Encrypt, Decrypt, and GenerateDataKey. Filters must be in the `kms:tag/${tag-key}` format.

RAM policy examples

- A RAM policy that allows users to access all KMS resources

```
{
 "Version": "1",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "kms:*"
   ],
   "Resource": [
    "*"
   ]
  }
 ]
}
```

- A RAM policy that allows users only to query keys, aliases, and key usage permissions

```
{
 "Version": "1",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "kms:List*", "kms:Describe*",
    "kms:Encrypt", "kms:Decrypt", "kms:GenerateDataKey"
   ],
   "Resource": [
    "*"
   ]
  }
 ]
}
```

- A RAM policy that allows users to use keys that contain the following tag to perform cryptographic operations:
  - Tag key: `Project`
  - Tag value: `Apollo`

```
{
  "Version": "1",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "kms:Encrypt", "kms:Decrypt", "kms:GenerateDataKey"
      ],
      "Resource": [
        "*"
      ],
      "Condition": {
        "StringEqualsIgnoreCase": {
          "kms:tag/Project": [
            "Apollo"
          ]
        }
      }
    }
  ]
}
```

22.3. Use aliases

Aliases are optional to CMKs. Aliases must be unique in a region for each Apsara Stack tenant account. An Alibaba Stack tenant account can use the same alias in different regions. An alias can be bound to only one CMK in a region, but a CMK can have multiple aliases.

Overview

Although each alias is bound to a CMK, aliases are resources independent from the CMKs to which they are bound. Take note of the following points about aliases:

- You can call the UpdateAlias operation to bind an alias to a different CMK. This operation does not affect the original CMK.
- If you delete an alias, the CMK to which the alias is bound is not deleted.
- RAM users must be authorized before they can perform operations on an alias. For more information, see Use RAM for access control.

- Aliases cannot be modified. To change the alias of a CMK, you must delete the original alias and create another one for the CMK.

You can replace the CMK ID in the request parameters of the following API operations with an alias that is bound to the CMK:

- DescribeKey
- Encrypt
- GenerateDataKey
- GenerateDataKeyWithoutPlaintext

> **Note** For more information about the API operations, see the *API reference* topic of *Developer Guide*.

To specify an alias instead of a CMK ID in the request parameters of the preceding operations, a RAM user must have the relevant permissions on the CMK. The RAM user does not need to have permissions on the alias.

When you use an alias, you must make sure that the alias is complete. Example:

```
// A complete alias must have the alias/ prefix.
alias/example
```

Create an alias

An alias must contain the `alias/` prefix. An alias, excluding the prefix, can contain letters, digits, underscores (_), hyphens (-), and forward slashes (/). An alias, excluding the prefix, must be 1 to 255 characters in length.

To allow a RAM user to create an alias, you must create a custom policy to grant the RAM user the permissions on the alias and the CMK to which the alias is bound. The following sample policy allows User 123456 to create an alias named `alias/example` for CMK 08ec3bb9-034f-485b-b1cd-3459baa8****:

```
{
 "Version": "1",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "kms:CreateAlias"
   ],
   "Resource": [
    "acs:kms:cn-hangzhou:123456:key/08ec3bb9-034f-485b-b1cd-3459baa8****",
    "acs:kms:cn-hangzhou:123456:alias/example"
   ]
  }
 ]
}
```

> **Note** A new alias created for a CMK does not affect the existing aliases of the CMK.

You can use one of the following methods to create an alias:

- Create an alias in the KMS console.
  i. Log on to the KMS console.
  ii. In the left-side navigation pane, click **Keys**.
  iii. Find the CMK for which you want to create an alias and click its alias. In the Aliases section, click **Create Alias**.
  iv. In the **Create Alias** dialog box, set the Alias Name parameter.

v. Click **OK**.

- Create an alias by calling the CreateAlias operation.
- Create an alias by running the `aliyun kms CreateAlias` command in Apsara Stack CLI.

```
aliyun kms CreateAlias --KeyId 08ec3bb9-034f-485b-b1cd-3459baa8**** --AliasName alias/example
```

Bind an alias to a different CMK

You can bind an existing alias to a different CMK.

To allow a RAM user to bind an existing alias to a different CMK, you must create a custom policy to grant the RAM user the permissions on the original CMK, new CMK, and alias. The following sample policy allows User 123456 to bind the `alias/example` alias to CMK 127d2f84-ee5f-4f4d-9d41-dbc1aca2****. The original CMK to which this alias is bound is 08ec3bb9-034f-485b-b1cd-3459baa8****.

```
{
 "Version": "1",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "kms:UpdateAlias"
   ],
   "Resource": [
    "acs:kms:cn-hangzhou:123456:key/08ec3bb9-034f-485b-b1cd-3459baa8****",
    "acs:kms:cn-hangzhou:123456:key/127d2f84-ee5f-4f4d-9d41-dbc1aca2****",
    "acs:kms:cn-hangzhou:123456:alias/example"
   ]
  }
 ]
}
```

You can use one of the following methods to bind an alias to a different CMK:

- Bind an alias to a different CMK by calling the UpdateAlias operation.
- Bind an alias to a different CMK by running the `aliyun kms UpdateAlias` command in Apsara Stack CLI.

```
aliyun kms UpdateAlias --AliasName alias/example --KeyId 127d2f84-ee5f-4f4d-9d41-dbc1aca2****
```

Delete an alias

You can delete aliases that are not required. If you delete an alias, the CMK to which the alias is bound is not affected.

To allow a RAM user to delete an alias, you must create a custom policy to grant the RAM user the permissions on the alias and the CMK to which the alias is bound. The following sample policy allows User 123456 to delete the `alias/example` alias that is bound to CMK 127d2f84-ee5f-4f4d-9d41-dbc1aca2****:

```
{
 "Version": "1",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "kms:DeleteAlias"
   ],
   "Resource": [
    "acs:kms:cn-hangzhou:123456:key/127d2f84-ee5f-4f4d-9d41-dbc1aca2****",
    "acs:kms:cn-hangzhou:123456:alias/example"
   ]
  }
 ]
}
```

You can use one of the following methods to delete an alias:

- Delete an alias in the KMS console.
  i. Log on to the KMS console.
  ii. In the left-side navigation pane, click **Keys**.
  iii. Find the CMK for which you want to delete an alias and click its alias.
  iv. In the **Aliases** section, click **Delete Alias** next to the alias to be deleted.
  v. In the **Delete Alias** message, click **OK**.
- Delete an alias by calling the DeleteAlias operation.
- Delete an alias by running the `aliyun kms DeleteAlias` command in Apsara Stack CLI.

```
aliyun kms DeleteAlias --AliasName alias/example
```

Query aliases

You can query all aliases that belong to your Apsara Stack tenant account in the current region.

To allow a RAM user to query aliases, you must create a custom policy to grant the RAM user the permissions on aliases. The following sample policy allows User 123456 to query aliases:

```
{
 "Version": "1",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "kms:ListAliases"
   ],
   "Resource": [
    "acs:kms:cn-hangzhou:123456:alias"
   ]
  }
 ]
}
```

You can use one of the following methods to query aliases:

- Query aliases by calling the ListAliases operation.
- Query aliases by running the `aliyun kms ListAliases` command in Apsara Stack CLI.

```
aliyun kms ListAliases
```

Query aliases bound to a specified CMK

If you query the aliases bound to a specified CMK, only the related aliases are returned.

To allow a RAM user to query the aliases bound to a specified CMK, you must create a custom policy to grant the RAM user the permissions on the CMK. The following sample policy allows User 123456 to query the aliases bound to CMK 127d2f84-ee5f-4f4d-9d41-dbc1aca2****:

```
{
 "Version": "1",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "kms:ListAliasesByKeyId"
   ],
   "Resource": [
    "acs:kms:cn-hangzhou:123456:key/127d2f84-ee5f-4f4d-9d41-dbc1aca2****"
   ]
  }
 ]
}
```

You can use one of the following methods to query aliases bound to a specified CMK:

- Query aliases bound to a specified CMK by calling the ListAliasesByKeyId operation.
- Query aliases bound to a specified CMK by running the `aliyun kms ListAliasesByKeyId` command in Apsara Stack CLI.

```
aliyun kms ListAliasesByKeyId --KeyId 127d2f84-ee5f-4f4d-9d41-dbc1aca2****
```

22.4. Use CMKs

The key service is a core component of Key Management Service (KMS). The key service provides fully managed keys and key protection features. The key service supports simple data encryption and digital signature management based on cloud-native API operations.

Key-based cryptographic algorithms

The following table describes the encryption algorithms supported by KMS.

Algorithm class	Algorithm subclass	Encryption and decryption	Signature generation and verification
Symmetric key algorithm	AES	Supported	Not supported
Symmetric key algorithm	SM4 Note	Supported	Not supported
Asymmetric key algorithm	RSA	Supported	Supported
Asymmetric key algorithm	ECC	Not supported	Supported
Asymmetric key algorithm	SM2 Note	Supported	Supported

Symmetric keys are used to encrypt or decrypt data. If you do not specify the KeySpec parameter during key creation, KMS creates a symmetric key. You can call the Encrypt or Decrypt operation to encrypt or decrypt data without the need to obtain the plaintext of a symmetric key. For more information, see Overview of symmetric encryption.

Asymmetric keys can be used to encrypt data, decrypt data, generate a signature, or verify a signature. An asymmetric CMK in KMS consists of a public key and a private key, which are cryptographically related to each other. The public key can be made available for anyone to use, but the private key must be kept secure. To keep private keys secure, KMS does not provide an API operation for you to export the private key of an asymmetric key pair. You can use a private key to decrypt data or generate a signature by calling the related operations. Anyone with a public key can use it to encrypt data or verify the signature generated by the corresponding private key. For more information, see Overview of asymmetric keys.

> Note
> - Only hardware security modules (HSMs) support SM2 and SM4 keys.
> - Only KMS of the Advanced edition supports Rivest-Shamir-Adleman (RSA) and elliptic-curve cryptography (ECC) keys.

Key protection level

KMS provides the managed HSM feature. You can set the protection level of your CMK to HSM to manage the CMK in an HSM. The managed HSM feature allows you to use HSMs as dedicated hardware to safeguard keys. For a CMK whose protection level is HSM, the plaintext of its key material is stored only inside an HSM. KMS calls an HSM-related API operation to perform cryptographic operations. During the operations, no one can have access to the plaintext of the key material. The plaintext of the key material cannot be exported from the HSM.

Key managers

In most cases, you are the manager of your CMKs in KMS, and their Creator attributes are set to the ID of your Apsara Stack tenant account.

Apsara Stack services can be integrated with KMS to implement server-side encryption (SSE). In this scenario, KMS allows a service to automatically manage an encryption key that can be used only by the service to encrypt your data. This makes it easier for you to use the entry-level data encryption features and reduces your workload in the management of key lifecycles and permissions. These service-managed keys are called service keys. To facilitate identification, KMS sets the Creator attribute of the service key managed by an Apsara Stack service to the code of this service and assigns an alias in the format of `acs/<Code of the Apsara Stack service>` to the service key. For example, the Creator attribute of the service key managed by Object Storage Service (OSS) is set to OSS and the acs/oss alias is bound to the service key.

22.5. Use symmetric keys

22.5.1. Overview

This topic describes symmetric encryption, which is the most commonly used data encryption method. KMS provides easy-to-use API operations that allow you to encrypt and decrypt data on the cloud.

> Note For more information about the API operations, see the *API reference* topic of *Developer Guide*.

If you do not specify the KeySpec parameter during key creation, KMS creates a symmetric key. KMS supports popular symmetric key algorithms and provides high-level data security by using strong cryptography.

Types of symmetric keys

The following table describes the types of symmetric keys that KMS supports.

Algorithm	Key length	Key type	Data encryption mode	Protection level
AES	256 bits	Aliyun_AES_256	GCM	• Software • HSM
SM4[Note]	128 bits	Aliyun_SM4	GCM	HSM

Encryption and decryption features

To encrypt data, you need only to specify the ID or alias of an CMK . KMS uses the specified CMK for encryption and returns the ciphertext. When you call the Decrypt operation to decrypt data, you need only to specify the ciphertext that you want to decrypt. You do not need to specify the CMK. The Decrypt operation is available for you to decrypt the ciphertext that is generated by calling the Encrypt, GenerateDataKey, or GenerateDataKeyWithoutPlaintext operation.

AAD

Symmetric keys of KMS use Galois/Counter Mode (GCM) for block ciphers. You can use additional authenticated data (AAD) to provide supplemental protection for the integrity of encrypted data. KMS allows you to customize authentication data by encapsulating the entered ADD. For more information, see EncryptionContext.

Envelope encryption

KMS allows you to generate a two-level key hierarchy to accelerate envelope encryption by calling the GenerateDataKey and GenerateDataKeyWithoutPlaintext operations.

For more information about envelope encryption, see the *Envelope encryption* in the *Features* topic of *Technical White Paper*.

Rotation of symmetric keys

Each symmetric CMK that is generated in KMS supports multiple key versions. KMS automatically rotates CMKs by generating new key versions. You can customize the key rotation policy.

If a CMK has multiple versions, the latest version of the CMK is used in the Encrypt, GenerateDataKey, and GenerateDataKeyWithoutPlaintext operations to encrypt data. To decrypt the data, you do not need to specify the ID or the CMK or key version. KMS automatically identifies the CMK and its key version with which the data is encrypted. Then, KMS uses the key material of the identified key version to decrypt the ciphertext.

KMS rotates a CMK by generating a new version of the CMK. After a rotation is complete, KMS automatically uses the new key version to encrypt data. However, the earlier key version is still available for decrypting the ciphertext generated before the rotation. For more information, see Automatic key rotation.

BYOK feature

KMS allows you to encrypt your data in the cloud by using the Bring Your Own Key (BYOK) feature. This feature helps you meet stringent security and compliance requirements. We recommend that you use a managed hardware security module (HSM) to protect your keys by importing key material into CMKs with HSM-grade security. The keys imported into the managed HSM can only be destroyed, and their plaintext cannot be exported.

22.5.2. EncryptionContext

EncryptionContext is a JSON string that may be used in KMS API operations, such as Encrypt, GenerateDataKey, and Decrypt.

Roles of EncryptionContext

EncryptionContext is a JSON string, and it must be in the string:string format. EncryptionContext is used to ensure data integrity.

If this parameter is specified during encryption, you must specify an equivalent EncryptionContext value for decryption. You can call the Encrypt or GenerateDataKey operation for encryption and call the Decrypt operation for decryption. EncryptionContext is related to decryption, but EncryptionContext is not included in ciphertext that is specified by the CipherBlob parameter.

Valid values of EncryptionContext

A valid value of EncryptionContext is a JSON string of up to 8,192 characters in the string:string format. When you specify EncryptionContext for an API operation, take note of the escape characters.

Sample valid EncryptionContext:

```
{"ValidKey":"ValidValue"}
{"Key1":"Value1","Key2":"Value2"}
```

Sample invalid EncryptionContext:

```
[{"Key":"Value"}] // JSON array
{"Key":12345} //String-int
{"Key":["value1","value2"]} // String:Array
```

Equivalent EncryptionContext

EncryptionContext is a map or hash table in the string:string format. When EncryptionContext is used as a parameter, two values of the EncryptionContext parameter are considered to be equivalent if their key-value pairs are consistent. If EncryptionContext is specified during encryption, you can specify an equivalent EncryptionContext value to decrypt the ciphertext. The sequences of the key-value pairs of two EncryptionContext values can be different.

Sample equivalent EncryptionContext values:

```
{"Key1":"Value1","Key2":"Value2"} is equivalent to {"Key2":"Value2","Key1":"Value1"}.
```

22.5.3. Import and delete key material

This topic describes how to import and delete external key material for a CMK.

Context

CMKs are basic resources of KMS. A CMK is composed of a key ID, basic metadata such as key status, and key material that is used to encrypt and decrypt data. By default, KMS generates key material when you call the CreateKey operation to create a CMK. You can select an external key as the material source. In this case, KMS does not create key material. You must import external key material to the CMK. You can call the DescribeKey operation to check the key material source of an existing CMK.

> **Note** For more information about the API operations, see the *API reference* topic of *Developer Guide*.

Keys can be divided into normal keys and external keys based on the source of key material.

- If the value of Origin in KeyMetadata is *Aliyun_KMS*, the key material is generated by KMS. In this case, the CMK is considered a **common key**.
- If the value of Origin is *EXTERNAL*, the key material is imported from an external source. In this case, the CMK is considered an **external key**.

Before you import external key material, take note of the following points:

- Make sure that the source of randomness from which the key material is generated meets security requirements.
- Make sure that the key material is reliable.

- KMS ensures the high availability of imported key material. However, KMS cannot ensure that the imported key material has the same reliability as the key material generated by KMS.
- You can call the DeleteKeyMaterial operation to delete the key material that you have imported. You can also set a validity period to enable KMS to automatically delete the key material after the validity period ends. The CMK is not deleted. To delete key material generated by KMS, you can only call the ScheduleKeyDeletion operation to specify a waiting period of 7 to 30 days for deleting the CMK. The key material is deleted with the relevant CMK after the waiting period ends.
- After you delete the imported key material, you can re-import the same key material to make the relevant CMK available again. Therefore, we recommend that you save a copy of the key material.

- Key material is unique for each CMK. When you import key material into a CMK, the CMK is associated with that key material. Even after the key material expires or is deleted, you cannot import different key material into that CMK. If you need to rotate a CMK that uses external key material, you must create a CMK and then import new key material.
- CMKs are independent. You cannot use a CMK to decrypt data that is encrypted by using another CMK, even if the two CMKs use the same key material.
- The key material to be imported must be a 256-bit symmetric key.

Import key material

1. Create an external key.

   You can use one of the following methods to create an external key:

   - Method 1: Log on to the KMS console and click Create Key. On the Create Key page, set the Key Material Source parameter to External in the Advanced Settings section. For more information, see Create a CMK.
   - Method 2: Call the CreateKey operation. Set the Origin parameter to *EXTERNAL*.

     ```
     ./aliyun --skip-secure-verify  --region ${please-repleace-your-region}  --endpoint ${please-repleace-your-endpoint} --access-key-id ${please-repleace-your-access-key-id} --access-key-secret ${please-repleace-your-access-key-secret} kms CreateKey  --Origin EXTERNAL --Description "External key"
     ```

2. Obtain the parameters that are used to import key material.

   The parameters include a public key and an import token. The public key is used to encrypt the key material. You can use one of the following methods to obtain the parameters:

   - Method 1: Obtain the parameters in the KMS console.
   - Method 2: Obtain the parameters by calling the GetParametersForImport operation.

     ```
     ./aliyun --skip-secure-verify  --region ${please-repleace-your-region}  --endpoint ${please-repleace-your-endpoint} --access-key-id ${please-repleace-your-access-key-id} --access-key-secret ${please-repleace-your-access-key-secret} kms GetParametersForImport --KeyId 1339cb7d-54d3-47e0-b595-c7d3dba8**** --WrappingAlgorithm RSAES_OAEP_SHA_1 --WrappingKeySpec RSA_2048
     ```

3. Import key material.

   > **Note**
   >
   > - You can import key material into an external key that does not have key material. You can also reset the expiration time of key material or re-import key material that has expired or been deleted.
   > - Each import token is bound to a public key that is used to encrypt key material. A CMK is specified when an import token is generated. The import token can only be used to import key material into the specified CMK.
   > - The lifecycle of an import token is 24 hours. It can be used repeatedly within this period. After it expires, you must obtain a new import token and a new public key.

i. Use the public key to encrypt the key material.

The public key is a 2,048-bit Rivest-Shamir-Adleman (RSA) public key. The encryption algorithm must be the same as that specified when you obtain the parameters that are used to import the key material. The public key returned when you call the GetParametersForImport operation is Base64-encoded. You must first decode the public key. KMS supports the following encryption algorithms: RSAES_OAEP_SHA_1, RSAES_OAEP_SHA_256, and RSAES_PKCS1_V1_5.

ii. Encode the encrypted key material in the Base64 format.

iii. Call the ImportKeyMaterial operation to import the encoded key material and the import token to KMS.

```
./aliyun --skip-secure-verify  --region ${please-repleace-your-region}  --endpoint ${please-repleace-your-endpoint} --access-key-id ${please-repleace-your-access-key-id} --access-key-secret ${please-repleace-your-access-key-secret} kms ImportKeyMaterial --KeyId 1339cb7d-54d3-47e0-b595-c7d3dba8**** --EncryptedKeyMaterial xxx --ImportToken xxxx
```

Delete key material

After you import key material into an external key, you can use the external key in the same way as a normal key. The only difference lies in that the key material of an external key may expire and can be independently deleted. After the key material of an external key expires or is deleted, the external key can no longer be used, and the ciphertext encrypted by using this external key cannot be decrypted. To use the external key and decrypt the related ciphertext again, you must re-import the same key material.

If an external key is in the PendingDeletion state when its key material expires or is deleted, the key status does not change after the key material expires or is deleted. Otherwise, the key status becomes PendingImport after the key material expires or is deleted.

You can use one of the following methods to delete key material:

- Method 1: Delete the key material in the KMS console.
- Method 2: Delete the key material by calling the DeleteKeyMaterial operation.

```
./aliyun --skip-secure-verify  --region ${please-repleace-your-region}  --endpoint ${please-repleace-your-endpoint} --access-key-id ${please-repleace-your-access-key-id} --access-key-secret ${please-repleace-your-access-key-secret} kms DeleteKeyMaterial --KeyId 1339cb7d-54d3-47e0-b595-c7d3dba8****
```

Use OpenSSL to encrypt and upload key material

1. Create an external key.
2. Create key material.

   The key material must be a 256-bit symmetric key. In this example, OpenSSL is used to generate a 32-byte random number.

   ```
   openssl rand -out KeyMaterial.bin 32
   ```

3. Obtain parameters that are used to import the key material.
4. Encrypt the key material.

   i. Decode the public key that is used to encrypt the key material in the Base64 format.

   ii. Use an encryption algorithm such as RSAES_OAEP_SHA_1 to encrypt the key material.

   iii. Encode the encrypted key material in the Base64 format and save it to a text file.

   ```
   openssl rand -out KeyMaterial.bin 32
   openssl enc -d -base64 -A -in PublicKey_base64.txt -out PublicKey.bin
   openssl rsautl -encrypt -in KeyMaterial.bin -oaep -inkey PublicKey.bin  -keyform DER  -pubin -out EncryptedKeyMaterial.bin
   openssl enc -e -base64 -A -in EncryptedKeyMaterial.bin -out EncryptedKeyMaterial_base64.txt
   ```

   iv. Upload the encrypted key material and import token.

Use SDK for Java to encrypt and upload key material

```
// Use the latest KMS SDK for Java.
//KmsClient.java
import com.aliyuncs.DefaultAcsClient;
import com.aliyuncs.exceptions.ClientException;
import com.aliyuncs.http.FormatType;
import com.aliyuncs.kms.model.v20160120.*;
import com.aliyuncs.profile.DefaultProfile;
// Encapsulate KMS API operations
public class KmsClient {
  DefaultAcsClient client;
  public KmsClient(String regionId, String ak, String secret) {
    DefaultProfile profile = DefaultProfile.getProfile(regionId, ak, secret);
    this.client = new DefaultAcsClient(profile);
  }
  // Specify a custom endpoint. In most cases, a VPC endpoint is specified. You can also specify a custom endpoint when you cannot obtain the IP address in the Apsara Stack environment based on the regionId parameter.
  public KmsClient(String regionId, String ak, String secret, String endpoint) {
    DefaultProfile.addEndpoint(regionId, "kms", endpoint);
    DefaultProfile profile = DefaultProfile.getProfile(regionId, ak, secret);
    this.client = new DefaultAcsClient(profile);
  }
  public CreateKeyResponse createKey() throws Exception {
    CreateKeyRequest request = new CreateKeyRequest();
    request.setOrigin("EXTERNAL"); // Create an external key.
    return this.client.getAcsResponse(request);
  }
  public GetParametersForImportResponse getParametersForImport(String keyId, String wrappingKeySpec, String wrappingAlgorithm) throws ClientException {
    GetParametersForImportRequest request = new GetParametersForImportRequest();
    request.setAcceptFormat(FormatType.JSON);
    request.setKeyId(keyId);
    request.setWrappingKeySpec(wrappingKeySpec);
    request.setWrappingAlgorithm(wrappingAlgorithm);
    return this.client.getAcsResponse(request);
  }
  public ImportKeyMaterialResponse importKeyMaterial(String keyId, String importToken, String encryptedKeyMaterial, Long expireTimestamp) throws ClientException {
    ImportKeyMaterialRequest request = new ImportKeyMaterialRequest();
    request.setAcceptFormat(FormatType.JSON);
    request.setKeyId(keyId);
    request.setImportToken(importToken);
    request.setEncryptedKeyMaterial(encryptedKeyMaterial);
    request.setKeyMaterialExpireUnix(expireTimestamp);
    return this.client.getAcsResponse(request);
  }
  //... Omitted. The remaining operations are encapsulated in the same way as the preceding operations.
}
//example.java
import com.aliyuncs.kms.model.v20160120.*;

```

```
public class CreateAndImportExample {
  public static void main(String[] args) {
    String regionId = "cn-hangzhou";
    String accessKeyId = "*** Provide your AccessKeyId ***";
    String accessKeySecret = "*** Provide your AccessKeySecret ***";
    KmsClient kmsclient = new KmsClient(regionId, accessKeyId, accessKeySecret);
    //String endpoint = "*** VPC Endpoint ***";
    //KmsClient kmsclient = new KmsClient(regionId, accessKeyId, accessKeySecret, endpoint);
    //Create External Key
    try {
      CreateKeyResponse keyResponse = kmsclient.createKey();
      String keyId = keyResponse.getKeyMetadata().getKeyId();
      // Generate a 32-byte random number.
      byte[] keyMaterial = new byte[32];
      new Random().nextBytes(keyMaterial);
      // Obtain the parameters that are used to import key material.
      GetParametersForImportResponse paramResponse = kmsclient.getParametersForImport(keyId, "RSA_2048", "RSA
ES_OAEP_SHA_256");
      String importToken = paramResponse.getImportToken();
      String encryptPublicKey = paramResponse.getPublicKey();
      // Decode the public key in the Base64 format.
      byte[] publicKeyDer = DatatypeConverter.parseBase64Binary(encryptPublicKey);
      // Use RSA to parse the public key.
      KeyFactory keyFact = KeyFactory.getInstance("RSA");
      X509EncodedKeySpec spec = new X509EncodedKeySpec(publicKeyDer);
      PublicKey publicKey = keyFact.generatePublic(spec);
      // Encrypt the key material.
      Cipher oaepFromAlgo = Cipher.getInstance("RSA/ECB/OAEPWithSHA-1AndMGF1Padding");
      String hashFunc = "SHA-256";
      OAEPParameterSpec oaepParams = new OAEPParameterSpec(hashFunc, "MGF1", new MGF1ParameterSpec(hashF
unc), PSpecified.DEFAULT);
      oaepFromAlgo.init(Cipher.ENCRYPT_MODE, publicKey, oaepParams);
      byte[] cipherDer = oaepFromAlgo.doFinal(keyMaterial);
      // Encode the encrypted key material in the Base64 format.
      String encryptedKeyMaterial = DatatypeConverter.printBase64Binary(cipherDer);
      // Import the key material.
      Long expireTimestamp = 1546272000L; // The UNIX timestamp, which is precise to the second. The value 0 indicates
that the key material does not expire.
      kmsclient.importKeyMaterial(keyId, importToken, encryptedKeyMaterial, expireTimestamp);
    } catch (Exception e) {
      //... Omitted.
    }
  }
}
```

22.6. Use asymmetric keys

22.6.1. Overview

Unlike symmetric keys, asymmetric keys are used to verify digital signatures or encrypt sensitive information between systems with different trust levels.

You can create asymmetric CMKs in KMS. An asymmetric key pair consists of a public key and a private key, which are cryptographically related to each other. The public key is available for all to use, but the private key must be kept secure and used only by trusted users. KMS supports popular asymmetric key algorithms and provides sufficient security strength to ensure the security of encrypted data and digital signatures.

Types of asymmetric keys

The following table describes the types of asymmetric keys that KMS supports.

Algorithm	Key type	Description	Purpose
RSA	RSA_2048	RSA asymmetric cryptosystem	• Encrypt or decrypt data. • Generate a digital signature.
ECC	• EC_P256: National Institute of Standards and Technology (NIST)-recommended elliptic curve P-256 • EC_P256K: Standards for Efficient Cryptography Group (SECG) elliptic curve secp256k1	Elliptic-curve cryptography (ECC)	Generate a digital signature.
SM2	EC_SM2	ECC defined by GB/T 32918	• Encrypt or decrypt data. • Generate a digital signature.

Data encryption

Asymmetric keys are used to encrypt and transmit sensitive information. The following steps describe a typical scenario:

1. An information receiver distributes a public key to a transmitter.
2. The transmitter uses the public key to encrypt sensitive information.
3. The transmitter sends the ciphertext generated from the sensitive information to the information receiver.
4. The information receiver uses the private key to decrypt the ciphertext.

The private key can be used only by the information receiver. This ensures that the plaintext of sensitive information cannot be intercepted and decrypted by unauthorized parties during transmission. This encryption method is widely used to exchange keys. For example, session keys are exchanged in Transport Layer Security (TLS) handshakes, and encryption keys are exported and imported between different hardware security modules (HSMs).

For more information, see Encrypt and decrypt data by using an asymmetric CMK.

Digital signature

Asymmetric keys are also used to generate digital signatures. Private keys can be used to sign messages or information. Private keys are strictly protected and can be used only by trusted users to generate signatures. After a signature is generated, you can use the corresponding public key to verify the signature to achieve the following purposes:

- Verify data integrity. If the data does not match its signature, the data may be tampered with.
- Verify message authenticity. If a message does not match its signature, the message transmitter does not hold the private key.
- Provide non-repudiation for signatures. If the data matches its signature, the signer cannot deny this signature.

The following operations describe a typical signature verification scenario:

1. A signer sends a public key to a receiver.
2. The signer uses the private key that matches the public key to sign data.
3. The signer sends the data and signature to the message receiver.

4. After the data and signature are received, the receiver uses the public key to verify the signature.

Digital signatures are widely used to defend against data tampering and authenticate identities.

For more information, see Generate and verify a digital signature by using an asymmetric CMK.

Key versions

KMS does not support automatic rotation of asymmetric CMKs due to the limits of public and private keys. You can call the CreateKeyVersion operation to create another key version in a specific CMK and generate a new pair of public and private keys. If you use a new key version to generate a digital signature or encrypt data, you must also distribute the new version of the public key.

In addition, unlike symmetric CMKs, asymmetric CMKs do not have a primary key version. Therefore, you must specify the corresponding CMK ID or CMK alias and a key version if you need to call the operations related to asymmetric CMKs in KMS.

Public key operations

In most cases, you can call the GetPublicKey operation to obtain a public key and distribute the public key to users for encryption or verification. Then, the users can use cryptographic libraries such as OpenSSL and Java Cryptography Extension (JCE) to perform calculation in their business systems.

You can also call the AsymmetricEncrypt or AsymmetricVerify operation to perform public key operations. KMS records the logs of the calls and allows you to use RAM to limit the use of public keys. Compared with calculation in business systems, KMS offers flexible features that better suit your needs.

Private key operations

You can only call the AsymmetricDecrypt or AsymmetricSign operation to decrypt data or generate a digital signature with a private key.

22.6.2. Encrypt and decrypt data by using an asymmetric CMK

This topic describes how to use an asymmetric customer master key (CMK) to encrypt and decrypt data in Alibaba Cloud CLI.

Asymmetric encryption and decryption generally include the following steps:

1. An information receiver distributes a public key to a transmitter.
2. The transmitter uses the public key to encrypt sensitive information.
3. The transmitter sends the ciphertext generated from the sensitive information to the information receiver.
4. The receiver uses the private key to decrypt the ciphertext.

Before you start

Call the CreateKey operation to create an asvmmetric CMK in KMS. Set the KeySpec parameter to a desired key type and the KeyUsage parameter to `ENCRYPT/DECRYPT`.

The following code demonstrates how to create an RSA encryption key:

```
$ aliyun kms CreateKey --KeySpec=RSA_2048 --KeyUsage=ENCRYPT/DECRYPT --ProtectionLevel=HSM
```

Obtain the public key

1. Call the GetPublicKey operation to obtain the public key of the asymmetric key pair.

```
$ aliyun kms GetPublicKey --KeyId=**** --KeyVersionId=****
```

Sample success responses:

```
{
    "RequestId": "82c383eb-c377-4mf6-bxx8-81hkc1g5g7ab",
    "KeyId": "*****",
    "KeyVersionId": "*****",
    "PublicKey": "PublicKey-DataBlob"
}
```

2. Save the public key to the rsa_publickey.pub file. PublicKey-DataBlob is a placeholder. You must replace it with the obtained public key.

```
$ echo PublicKey-DataBlob > rsa_publickey.pub
```

Use the public key to encrypt data

1. Create a sample plaintext file plaintext-file.txt that contains "this is plaintext".

```
echo "this is plaintext" > plaintext-file.txt
```

2. Use OpenSSL to encrypt the file and write the obtained binary ciphertext into the plaintext-file.enc file.

```
openssl pkeyutl -encrypt -in plaintext-file.txt \
 -inkey rsa_publickey.pub -pubin \
 -pkeyopt rsa_padding_mode:oaep \
 -pkeyopt rsa_oaep_md:sha256 \
 -pkeyopt rsa_mgf1_md:sha256 \
 -out plaintext-file.enc
```

Call the KMS API to decrypt data

You must call the KMS API and use the private key to decrypt data.

1. Before you transmit the encrypted data over the network, encode it in Base64.

```
$ openssl base64 -in plaintext-file.enc
```

The following Base64-encoded ciphertext is returned:

```
5kdCB06HHeAwgfH9ARY4/9Nv5vlpQ94GXZcmaC9FE59Aw8v8RYdozT6ggSbyZbi+
8STKVq9402MEfmUDmwJLuu0qgAZsCe5wU4JWHh1y84Qn6HT068j0qOy5X2HIlrjs
fCdetgtMtVorSgb3bbERk2RV67nHWrDkecNbUaz+6ik4AlZxv2uWrV62eQ9yUBYm
Jb956LbqnfWdCFxUSHH/qB5QCnLpijzvPmfNlZr653H4nF08gpZjnmlF4FjTu3i2
mGLzK4J3Rh/l7PQHiVMdc4hSnXosg68QmMVdZBGLK9/cD9SYngPDiirU7z0q7Git
dIeloyCAUDFyuQC6a+SqzA==
```

2. Pass the Base64-encoded ciphertext to KMS to decrypt data.

```
aliyun kms AsymmetricDecrypt \
 --KeyId **** \
 --KeyVersionId **** \
 --Algorithm RSAES_OAEP_SHA_256 \
 --CiphertextBlob 5kdCB06HHeAwgfH9ARY4/9Nv5vlpQ94GXZcmaC9FE59Aw8v8RYdozT6ggSbyZbi+8STKVq9402MEfmUD
mwJLuu0qgAZsCe5wU4JWHh1y84Qn6HT068j0qOy5X2HIlrjsfCdetgtMtVorSgb3bbERk2RV67nHWrDkecNbUaz+6ik4AlZxv2
uWrV62eQ9yUBYmJb956LbqnfWdCFxUSHH/qB5QCnLpijzvPmfNlZr653H4nF08gpZjnmlF4FjTu3i2mGLzK4J3Rh/l7PQHiVMd
c4hSnXosg68QmMVdZBGLK9/cD9SYngPDiirU7z0q7GitdIeloyCAUDFyuQC6a+SqzA==
```

The following results are returned:

```
{
    "KeyId": "****",
    "KeyVersionId": "****",
    "Plaintext": "dGhpcyBpcyBwbGFpbnRleHQgDQo=",
    "RequestId": "6be7a8e4-35b9-4549-ad05-c5b1b535a22c"
}
```

3. Decode the returned Base64-encoded plaintext in Base64.

```
echo dGhpcyBpcyBwbGFpbnRleHQgDQo= | openssl base64 -d
```

The following decrypted plaintext is returned:

```
this is plaintext
```

22.6.3. Generate and verify a digital signature by using an asymmetric CMK

This topic uses Alibaba Cloud CLI as an example to describe how to use an asymmetric customer master key (CMK) to generate and verify a digital signature. You can also perform this operation by using the KMS SDK.

Asymmetric encryption generally includes the following steps:

1. A signer sends a public key to a message receiver.
2. The signer uses the private key to sign data.
3. The signer sends the data and signature to the message receiver.
4. After receiving the data and signature, the message receiver uses the public key to verify the signature.

Before you start

Call the CreateKey operation to create an asvmmetric CMK in KMS. Set the KeySpec parameter to a desired key type and the KeyUsage parameter to `SIGN/VERIFY`.

- Create an RSA signature key:

  ```
  aliyun kms CreateKey --KeySpec=RSA_2048 --KeyUsage=SIGN/VERIFY --ProtectionLevel=HSM
  ```

- Create a NIST P-256 signature key:

  ```
  aliyun kms CreateKey --KeySpec=EC_P256 --KeyUsage=SIGN/VERIFY --ProtectionLevel=HSM
  ```

- Create a secp256k1 signature key:

  ```
  aliyun kms CreateKey --KeySpec=EC_P256K --KeyUsage=SIGN/VERIFY --ProtectionLevel=HSM
  ```

Preprocess signature: compute a message digest

Both RSA and ECC signature operations involve first computing the digest of an unsigned message and then signing the digest.

> **Note** The algorithm used to obtain a message digest must match the algorithm used to call KMS to compute a signature. For example, the ECDSA_SHA_256 signature algorithm must be used in conjunction with the SHA-256 digest algorithm. It does not support the SHA-384 digest algorithm.

The following example uses the SHA-256 digest algorithm.

1. Save the message "this is message" that needs to be signed into the file message-file.txt:

```
echo "this is message" > message-file.txt
```

2. Compute the SHA-256 digest of the message and save the binary digest to the file message-sha256.bin:

```
openssl dgst -sha256 -binary -out message-sha256.bin  message-file.txt
```

Call KMS to compute the signature

You must call the KMS API to compute the signature of a message with the private key.

1. Before you transmit the message digest over the network, encode it in Base64.

```
openssl base64 -in message-sha256.bin
```

The following Base64 encoded digest is returned:

```
hRP2cuRFSlfEoUXCGuPyi7kZr18VCTZeVOTw0jbUB6w=
```

2. Pass the Base64 encoded digest to KMS to generate a signature.

> **Note** The parameters passed and the results generated vary depending on key types and signature algorithms. Each signature result generated in the example is stored in a different file.

- **RSASSA-PSS**

  For RSA keys, you can use the RSASSA-PSS signature algorithm and the SHA-256 digest algorithm to create a signature. Run the following command:

  ```
  aliyun kms AsymmetricSign --KeyId=**** --KeyVersionId=**** \
    --Algorithm=RSA_PSS_SHA_256 --Digest=hRP2cu...
  {
      "KeyId": "****",
      "KeyVersionId": "****",
      "Value": "J7xmdnZ...",
      "RequestId": "70f78da9-c1b6-4119-9635-0ce4427cd424"
  }
  ```

  Decode the signature value in Base64 and generate a binary signature. This signature is saved in the file rsa_pss_signature.bin:

  ```
  echo J7xmdnZ... | openssl base64 -d -out rsa_pss_signature.bin
  ```

- **RSASSA_PKCS1_V1_5**

  For RSA keys, you can use the RSASSA_PKCS1_V1_5 signature algorithm and the SHA-256 digest algorithm to create a signature. Run the following command:

  ```
  aliyun kms AsymmetricSign --KeyId=**** --KeyVersionId=**** \
    --Algorithm=RSA_PKCS1_SHA_256 --Digest=hRP2cu...
  {
      "KeyId": "****",
      "KeyVersionId": "****",
      "Value": "qreBkH/u...",
      "RequestId": "4be57288-f477-4ecd-b7be-ad8688390fbc"
  }
  ```

Decode the signature value in Base64 and generate a binary signature. This signature is saved in the file rsa_pkcs1_signature.bin:

```
echo qreBkH/u... | openssl base64 -d -out rsa_pkcs1_signature.bin
```

- **NIST P-256**

  For NIST curve P-256, you can use the ECDSA signature algorithm and the SHA-256 digest signature to create a signature. Run the following command:

```
aliyun kms AsymmetricSign --KeyId=**** --KeyVersionId=**** \
  --Algorithm=ECDSA_SHA_256 --Digest=hRP2cu...
{
    "KeyId": "****",
    "KeyVersionId": "****",
    "Value": "MEYCIQD33Y98...",
    "RequestId": "472d789c-d4be-4271-96bb-367f7f0f8ec3"
}
```

  Decode the signature value in Base64 and generate a binary signature. This signature is saved in the file ec_p256_signature.bin:

```
echo MEYCIQD33Y98... | openssl base64 -d -out ec_p256_signature.bin
```

- **secp256k1**

  For SECG curve secp256k1, you can use the ECDSA signature algorithm and the SHA-256 digest algorithm to create a signature. Run the following command:

```
aliyun kms AsymmetricSign --KeyId=**** --KeyVersionId=**** \
  --Algorithm=ECDSA_SHA_256 --Digest=hRP2cu...
{
    "KeyId": "****",
    "KeyVersionId": "****",
    "Value": "MEYCIQDWuuI...",
    "RequestId": "fe41abed-91e7-4069-9f6b-0048f5bf4de5"
}
```

  Decode the signature Value in Base64 and generate a binary signature. This signature is saved in the file ec_p256k_signature.bin:

```
echo MEYCIQDWuuI... | openssl base64 -d -out ec_p256k_signature.bin
```

Obtain the public key

Obtain the public key of the created asymmetric key pair from the KMS. The preceding example assumes that:

- The public key of the RSA key pair is saved to the file rsa_publickey.pub.
- The public key of the NIST P-256 key pair is saved to the file ec_p256_publickey.pub.
- The public key of the secp256k1 key pair is saved to the file ec_p256k_publickey.pub.

Use the public key to verify the signature

Run the following command lines to verify the signature (the command varies depending on the algorithm used to generate the public key):

- **RSASSA-PSS**

```
openssl dgst \
  -verify rsa_publickey.pub \
  -sha256 \
  -sigopt rsa_padding_mode:pss \
  -sigopt rsa_pss_saltlen:-1 \
  -signature rsa_pss_signature.bin \
  message-file.txt
```

- RSASSA_PKCS1_V1_5

```
openssl dgst \
  -verify rsa_publickey.pub \
  -sha256 \
  -signature rsa_pkcs1_signature.bin \
  message-file.txt
```

- NIST P-256

```
openssl dgst \
  -verify ec_p256_publickey.pub \
  -sha256 \
  -signature ec_p256_signature.bin \
  message-file.txt
```

- secp256k1

```
openssl dgst \
  -verify ec_p256k_publickey.pub \
  -sha256 \
  -signature ec_p256k_signature.bin \
  message-file.txt
```

If the verification succeeds, the system displays the following message:

```
Verified OK
```

22.7. Use managed HSMs

22.7.1. Overview

Managed HSM is an important feature of KMS to enable easy access to certified HSMs.

An HSM is a highly secure hardware device that performs cryptographic operations and generates and stores keys. You can store the keys for your most sensitive Apsara Stack workloads and assets in HSMs that are managed on Apsara Stack.

High security assurance

- Hardware protection

  Managed HSMs use secure hardware mechanisms to help you protect keys in KMS. The plaintext key material of CMKs is processed only inside HSMs for cryptographic operations. The material is kept within the hardware security boundary of HSMs.

- Secure key generation

  Randomness is crucial to the encryption strength of keys. Managed HSMs use a random number generation algorithm to generate key material. The algorithm is secure and licensed and has high system entropy seeds. This protects keys from being recovered or predicted by attackers.

Ease of operation

HSM hardware is fully managed by Apsara Stack. This eliminates the costs otherwise incurred by the following hardware management operations:

- Hardware lifecycle management
- HSM cluster management
- High availability and scalability management
- System patching
- Most disaster recovery operations

Ease of integration

Native key management capabilities allow you to use the following features:

- Key version management
- Automatic key rotation
- Resource tag management
- Controlled authorization

These features enable rapid integration of your applications with managed HSMs, and the integration of other services such as ECS and ApsaraDB RDS with managed HSMs. This way, you can implement static cloud data encryption without R&D investment.

Key control

Managed HSMs allow you to better control encryption keys on the cloud and move the most sensitive computing tasks and assets to the cloud.

If you use both managed HSMs and Bring Your Own Key (BYOK), you can have full control over the following items:

- Generation modes of key material.
- Processing of key material: The key material that you import to a managed HSM can be destroyed but cannot be exported.
- Lifecycle of keys.
- Persistence of keys.

22.7.2. Use managed HSMs to create and use keys

This topic describes how to use managed HSMs to create and use keys.

Use a managed HSM to create a key

1. Log on to the KMS console.
2. On the Keys page, click **Create Key**.
3. On the **Create Key** page, select an organization from the **Organization** drop-down list. Then, the **Resource Set** and **Region** parameters are automatically set.
4. In the **Basic Settings** section, set the **Key Type** and **Key Purpose** parameters, and set the **Protection Level** parameter to **HSM**.
5. In the **Basic Settings** section, set the **Alias** and **Description** parameters.
6. In the **Advanced Settings** section, set the **Rotation Period** parameter.
   - **Disable**: The key is not automatically rotated.
   - **Enable**: The key is automatically rotated. You can select or customize an interval for rotation.

> **Note**
> - You can set this parameter only if the Key Type parameter is set to Aliyun_AES_256 or Aliyun_SM4.
> - If the Key Material Source parameter is set to External, automatic rotation is not supported.

7. In the **Advanced Settings** section, set the **Key Material Source** parameter.
   - **Key Management Service**: Use KMS to generate key material.
   - **External**: Import key material from an external source.

   > **Note** You can set this parameter only if the Key Type parameter is set to Aliyun_AES_256 or Aliyun_SM4.

8. Click **Submit**.

Import external keys to a managed HSM

You can import a key from user-managed key infrastructure to a managed HSM. The prerequisite is that you have set **Protection Level** to **HSM** when you create the external key. For more information, see Import key material.

After you trigger the import, KMS performs the following operations:

- Calls the GetParametersForImport operation. During this process, KMS generates a key pair in a managed HSM to import the external key based on the **HSM** protection level and returns the public key of the key pair.
- Calls the ImportKeyMaterial operation. During this process, KMS imports the encrypted external key material to the managed HSM and then obtains the plaintext of the key material by using the key unwrapping mechanism of the managed HSM. The plaintext of the key material can no longer be exported.

Manage and use keys

You can apply all management and cryptographic features supported by KMS to keys created in managed HSMs. You can perform the following operations on these keys:

- Enable or disable keys
- Manage the lifecycle of keys
- Manage key aliases
- Manage key tags
- Call key-related API operations

Integrate managed HSMs with other Apsara Stack services

Keys in managed HSMs can be used to protect native data in other Apsara Stack services, such as ECS, ApsaraDB RDS, and OSS, by using the standard API of KMS. The prerequisite is that the Apsara Stack service supports SSE by using user-managed keys. To use this feature, you need only to configure a CMK in a managed HSM for the Apsara Stack service to implement SSE.

22.8. Key rotation

22.8.1. Overview

Keys are used to protect specific data. Therefore, the security of the data depends on the security of its keys. You can regularly rotate keys between key versions to improve key security and implement security policies and best practices for data protection.

Achieve security goals

You can regularly rotate keys to achieve the following goals:

- Reduce the amount of data encrypted based on each key

  The security of a key is inversely proportional to the amount of data encrypted based on the key. This amount is usually defined by the total bytes of data or the total number of messages that are encrypted based on the same key. For example, National Institute of Standards and Technology (NIST) defines the secure lifecycle of a key in Galois/Counter Mode (GCM) as the total number of messages encrypted based on the key. Regular key rotation allows each key to remain secure and minimizes vulnerability to cryptanalytic attacks.

- Respond in advance to security events

  In the early days of system design, key rotation was introduced as a routine operations and maintenance (O&M) method. This provides the system with a method to handle security events when they occur, and complies with the fail early, fail often principle of software engineering. If key rotation is not executed in the system until an emergency event has already occurred, the probability of system failure increases exponentially.

- Provide logical isolation of data

  Data encrypted before a key rotation is isolated from data encrypted after the key rotation. The impact of key-related security events can be identified and preventive measures can be taken.

- Reduce the window of time to crack keys

  Regular rotation of encryption keys ensures that you can control and reduce the window of time during which the key and its encrypted data are vulnerable to being cracked. The interval between rotation tasks during which attackers are able to crack the key is limited. This practice greatly increases the security of your data against cryptanalytic attacks.

Meet the requirements of regulatory compliance

Regular key rotation facilitates compliance with various regulations, which include but are not limited to the following regulations:

- Payment Card Industry Data Security Standard (PCI DSS)
- Cryptography-related industrial standards issued by State Cryptography Administration, such as GM/T 0051-2016
- Cryptography-related standards issued by NIST, such as NIST Publication 800-38D

22.8.2. Automatic key rotation

This topic shows you how to configure automatic rotation of CMKs in KMS.

Key versions

A CMK may have multiple key versions. Each key version represents an independently generated key. Key versions of the same CMK do not have a cryptographic relation to each other. KMS automatically rotates CMKs by generating new key versions.

Key versions are divided into the following types:

- Primary key versions
  - The primary key version of a CMK is an active encryption key. Each CMK has only one primary key version at a point in time.
  - When you call an encryption operation such as GenerateDataKey or Encrypt, KMS uses the primary key version of a specified CMK to encrypt plaintext.
  - You can call the DescribeKey operation to query the PrimaryKeyVersion attribute.
- Non-primary key versions
  - The non-primary key version of a CMK is an inactive encryption key. Each CMK can have zero to multiple non-primary key versions.
  - Each non-primary key version was a primary key version and acted as the active encryption key in the past.

- When a new primary key version is created, KMS does not delete or disable non-primary key versions, which are needed to decrypt data.

> **Note** When you call an encryption operation, the primary key version of a specified CMK is used. When you call a decryption operation, the key version that was used for encryption is used.

You can generate a key version in one of the following ways:

- Create a CMK.

  You can call the CreateKey operation to create a CMK. If you set the Origin parameter to *Aliyun_KMS*, KMS generates an initial key version and sets it as the primary key version.

- Execute an automatic rotation policy.

  After you configure an automatic rotation policy for a CMK, KMS executes the policy on a regular basis to generate key versions.

Automatic rotation

Configure a key rotation policy.

When you call the CreateKey operation to create a CMK, you can specify an automatic rotation policy for the CMK. You can call the UpdateRotationPolicy operation to update the current automatic rotation policy. When you call the operations, you must configure the following parameters:

- EnableAutomaticRotation: specifies whether to enable automatic rotation.
- RotationInterval: the interval for automatic rotation.

You can call the DescribeKey operation to view the configured automatic rotation policy. The following parameters are returned:

- AutomaticRotation: indicates whether automatic rotation is enabled. The value *Disabled* indicates that automatic rotation is disabled. The value *Enabled* indicates that automatic rotation is enabled. The value *Suspended* indicates that KMS suspends the execution of automatic rotation although automatic rotation is enabled.
- RotationInterval: indicates the interval for automatic rotation.

Execute an automatic rotation policy.

When automatic rotation is enabled, KMS calculates the time of the next rotation by using the following formula:

```
<NextRotationTime> = <LastRotationTime> + <RotationInterval>
```

where:

- `LastRotationTime`: the time when the last key version was created. You can call the DescribeKey operation and check the `LastRotationDate` parameter to obtain the time.
- `NextRotationTime`: the time when KMS performs the next rotation task to create a key version. You can call the DescribeKey operation and check the `NextRotationDate` parameter to obtain the time.

> **Notice** When you update the RotationInterval parameter of an automatic rotation policy, the value of NextRotationTime may be a point in time in the past. This does not affect the execution of the automatic rotation policy. A new key version is generated on a regular basis. If this situation occurs, KMS immediately executes the automatic rotation policy.

Impacts of CMK status on automatic rotation

A new key version can be created only for an enabled CMK. To enable a CMK, set the KeyState parameter to *Enabled*. Take note of the following items:

- If a CMK is in the *Disabled* or *Pending Deletion* state, do not call the UpdateRotationPolicy operation to update its automatic rotation policy.

- If a CMK enters the *Disabled* or *Pending Deletion* state after you enable automatic rotation for the CMK, KMS suspends the execution of automatic rotation. In this case, if you call the DescribeKey operation, the returned value of the AutomaticRotation parameter is *Suspended*. When the CMK enters the Enabled state again, its automatic rotation policy becomes active.

Limits

The following keys do not support multiple key versions:

- Service-managed keys: the default keys managed by KMS for specific cloud services. These keys belong to the users of cloud services and are used to provide basic encryption protection for user data.
- BYOK-based keys: the keys that you imported to KMS. For more information, see Import and delete key material. The Origin attribute of these keys is *EXTERNAL*. KMS does not generate key material or initiate rotation tasks for these keys.

These two types of keys do not support version-based manual or automatic key rotation. A BYOK-based key does not have multiple versions in KMS. Users have strong control over the persistence and lifecycle of BYOK-based keys. This makes management of the keys difficult and error-prone. For example, you must have on-premises key management facilities, data must be synchronized between on-premises facilities and the cloud, and no grace period is provided for key material deletion on the cloud. The complexity of maintaining multiple versions of BYOK-based keys makes key management much more risky. In addition, both primary and non-primary key versions may become unavailable at different points in time. For example, if key versions are deleted by KMS or imported again when they expire, CMKs may not be synchronized and encrypted data may fail to be decrypted due to the use of an invalid CMK. This affects system integrity.

> **Note** For information about alternative solutions in the cases where version-based key rotation is not supported, see Manual CMK rotation.

22.8.3. Manual CMK rotation

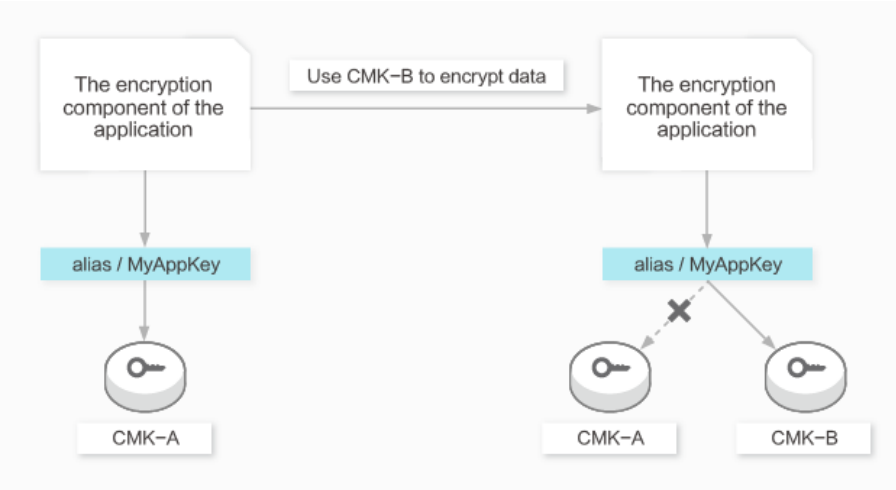
If your CMKs do not support version-based automatic rotation, you can manually rotate the CMKs based on your scenario. This is an alternative solution that can be used regardless of whether automatic CMK rotation is supported.

Scenario of custom data encryption

On-premises or cloud applications can call KMS API operations to implement custom data encryption. Examples:

- Encrypt sensitive data such as ID card numbers, credit card numbers, and home addresses before you write it to databases.
- Encrypt data on a client before you upload the data to Object Storage Service (OSS).
- Encrypt application configuration files that contain sensitive data and service configuration files such as SSL certificates and private keys.

You can use the key alias feature of KMS to rotate encryption keys within applications. The ID and alias of CMKs are not required when you call the Decrypt operation.



In this scenario, the rotation process consists of the following steps:

1. Initial configuration
   i. The administrator creates a CMK, whose ID is CMK-A.
   ii. The administrator binds the alias/MyAppKey alias to CMK-A.
   iii. When the application encryption module calls the Encrypt operation, the application encryption module sets the value of the KeyId parameter to *alias/MyAppKey*. KMS finds that the alias/MyAppKey alias is bound to CMK-A and then uses CMK-A to encrypt data.
   iv. When the application decryption module calls the Decrypt operation, the application decryption module does not set the KeyId parameter. KMS uses the CMK that is used to encrypt the data to decrypt the data.
2. Manual CMK rotation
   i. The administrator creates a CMK, whose ID is CMK-B.
   ii. The administrator calls the UpdateAlias operation to bind the alias/MyAppKey alias to CMK-B.
   iii. When the application decryption module calls the Encrypt operation, the application decryption module sets the value of the KeyId parameter to *alias/MyAppKey*. KMS finds that the alias/MyAppKey alias is bound to CMK-B and uses CMK-B to encrypt data.
   iv. When the application decryption module calls the Decrypt operation, the application decryption module does not set the KeyId parameter. KMS uses the CMK that is used to encrypt the data to decrypt the data.

Scenario of server-side encryption by cloud services

Cloud services can implement server-side encryption by calling KMS API operations. In this scenario, the following situations may occur from the perspective of key rotation:

- Automatic rotation policies configured in KMS affect the server-side encryption of cloud services.

  Cause: After encryption based on the specified CMK is configured for cloud services, these services call the GenerateDataKey operation of KMS to generate new data keys. When KMS generates a new primary key version, cloud services use the new version to encrypt the newly generated data keys. A typical example of such cloud services is OSS. In this case, if you want to enable automatic key rotation, you must not use service-managed keys or BYOK-based keys imported to KMS because these keys do not support automatic rotation.
- Automatic rotation policies configured in KMS do not affect server-side encryption of cloud services.

Cause: After encryption based on the specified CMK is configured for cloud services, the services call the GenerateDataKey operation of KMS only once to generate keys to encrypt specific resources. When KMS generates a new primary key version, cloud services do not use this version. For example, Elastic Compute Service (ECS) calls the GenerateDataKey operation of KMS once to generate a volume encryption key. This key is not updated after it is created.

If automatic rotation policies configured in KMS do not affect server-side encryption of cloud services or you want to rotate data keys when BYOK-based keys are used, you can modify configurations and copy data to achieve the same effect as key rotation. These methods depend on the features of different cloud services. For more information, see the documents of related cloud services.

23.Log Service

23.1. What is Log Service?

Log Service (SLS) is a one-stop logging service developed by Alibaba Cloud that is widely used by Alibaba Group in big data scenarios. You can use Log Service to collect, query, and consume log data.

Without the need to invest in in-house data collection and processing systems. This enables you to focus on your business, improving business efficiency and helping your business to expand.

Log Service provides the following features:

- Log collection: Log Service allows you to collect events, binary logs, and text logs in real time by using multiple methods, such as Logtail and JavaScript.
- Query and analysis: Log Service allows you to query and analyze the collected log data and view analysis results on charts and dashboards.
- Status alert: Log Service can automatically run query statements at regular intervals after you create an alert task. If the query results meet the conditions of the alert task, Log Service sends an alert to the specified recipients in real time.
- Real-time consumption: Log Service provides real-time consumption interfaces through which log consumers can consume log data.

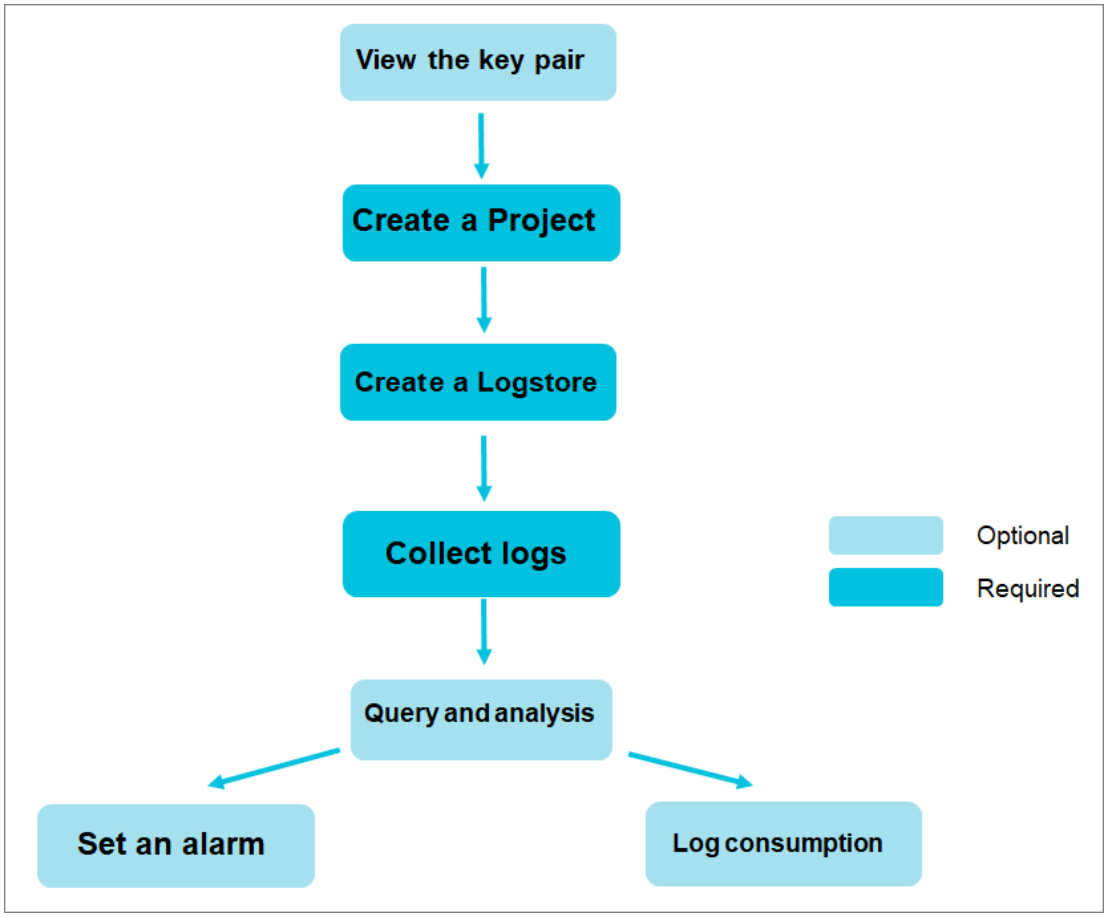
23.2. Quick start

23.2.1. Procedure

This topic provides the basic procedure to use Log Service. You can use this procedure to create projects, create Logstores, and collect log data.

The following figure shows the Procedure.

Procedure



1. Optional. Obtain an AccessKey pair.

   Before you can use Log Service through APIs or SDKs, you must have an AccessKey pair.

2. Create a project.

   Create a project in a specified region and add a description.

3. Create a Logstore.

   Create a Logstore for the project and specify the number of shards.

4. Collect text logs

   Select a method to collect log data based on your business requirements. Text log collection is used as an example.

5. Enable the index feature and configure indexes for a Logstore, and query and analyze logs.

   Log Service supports real-time log query and analysis. After you enable the indexing feature, you can query and analyze logs and configure Overview and dashboards.

6. Configure alerts.

   Log Service allows you to configure alerts based on log query results. Then, Log Service sends alerts by using multiple methods, such as a custom webhook.

7. Consume logs in real time.

   Log Service allows you to consume logs by using multiple methods, such as a Spark Streaming client, Storm spout, and Flink connector.

23.2.2. Log on to the Log Service console

This topic describes how to log on to the Log Service console.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, choose **Products > Log Service**.
5. On the page that appears, select the organization and region, and then click **SLS**. The home page of the Log Service console is displayed.

23.2.3. Obtain an AccessKey pair

An AccessKey pair consists of an AccessKey ID and an AccessKey secret. The AccessKey pair is used to implement symmetric encryption to verify the identity of the requester. The AccessKey ID is used to identify a user. The AccessKey secret is used to encrypt the signature string. This topic describes how to obtain an AccessKey pair.

Prerequisites

Only the operation administrators or level-1 organization administrators can obtain the AccessKey pair of an organization.

Context

To call Apsara Uni-manager and cloud service APIs, we recommend that you use the AccessKey pair of a personal account. If you use the AccessKey pair of a personal account, you must configure header parameters as described in the following table for access control.

Parameter	Description
x-acs-regionid	The region ID, such as cn-hangzhou-*.
x-acs-organizationid	The ID of the organization in the Apsara Uni-manager Management Console.
x-acs-resourcegroupid	The ID of the resource set in the Apsara Uni-manager Management Console.

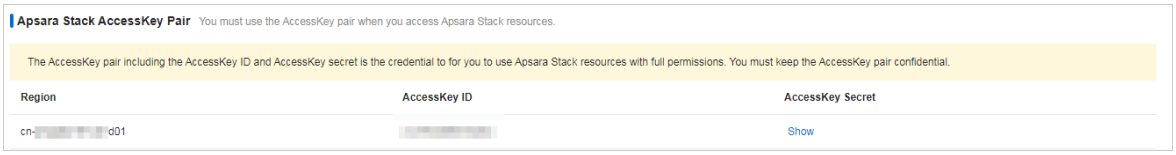
Parameter	Description
x-acs-instanceid	The ID of the instance on which you want to perform operations.

Warning The AccessKey pairs of personal accounts are under control of the Apsara Uni-manager permission system. AccessKey pairs of organization accounts have higher permissions. For security purposes, organization operations must be approved by administrators.

Obtain the AccessKey pair of a personal account

To obtain the AccessKey pair of a personal account, perform the following operations:

1. Log on to the Apsara Uni-manager Management Console.
2. In the upper-right corner of the homepage, move the pointer over the profile picture and click **Personal Information**.
3. In the **Apsara Stack AccessKey Pair** section, view your AccessKey pair.



Note The AccessKey pair consists of an AccessKey ID and an AccessKey secret. AccessKey pairs allow you to access Apsara Stack resources with full permissions for your account. You must keep your AccessKey pair confidential.

Obtain the AccessKey pair of an organization

To obtain the AccessKey pair of an organization, perform the following operations:

1. Log on to the Apsara Uni-manager Management Console as an administrator.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Organizations**.
4. In the organization navigation tree, click an organization name.
5. In the Current Organization section, click **Management Accesskey**.
6. In the Management AccessKey, view the AccessKey pair of the organization.

Note An AccessKey pair is automatically allocated to each level-1 organization. Subordinate organizations use the same AccessKey pair of their level-1 organization.

23.2.4. Manage projects

This topic describes how to create, modify, and delete projects in the Log Service console.

Context

A project in Log Service is a resource management unit. The resources in each project are isolated from resources in other projects. We recommend that you store the log data of different applications in dedicated projects. You can manage Logstores, Logtail configurations, log sources, log data, and machine groups in a project. Each project provides an endpoint for you to access the resources.

A project provides the following features:

- Allows you to store log data from different sources in different Logstores of a project. You can use Log Service to collect log data from multiple sources such as business projects, products, and environments. You can then store the log data of each source in a separate Logstore. This simplifies the downstream processes such as the consuming, exporting, and indexing of log data. In addition, you can manage access permissions at the project level.
- Provides an endpoint for you to access the resources in the project. Log Service allocates an exclusive endpoint to each project. You can use the endpoint to read, write, and manage the log data in the project.

Create a project

> **Note**
> - You can create a project only by using the Log Service console.
> - You can create up to 50 projects under each Apsara Stack tenant account.

1. Log on to the Log Service console.
2. In the **Projects** section, click **Create Project**.
3. Set the parameters based on your requirements. The following table describes the parameters.

Parameter	Description
Project Name	The name of the project. The project name must be unique across all regions. Use the following naming conventions: ○ The name can contain lowercase letters, digits, and hyphens (-). ○ The name must start and end with a lowercase letter or digit. ○ The name must be 3 to 63 characters in length. **Note** After a project is created, its name cannot be modified.
Description	The description of the project. After the project is created, the description is displayed in the **Projects** section. If you need to modify the description after the project is created, find the project in the **Projects** section, and click **Edit** in the **Actions** column. The description must be 0 to 64 characters in length and cannot contain the following characters: `<>'\"\\` .
Region	The region to which the project belongs. We recommend that you select a region that is closer to the log source. After a project is created, its region cannot be modified. This means that projects cannot be migrated across regions.

4. Click **OK**.

Modify the description of a project

To modify the description of a project, perform the following steps:

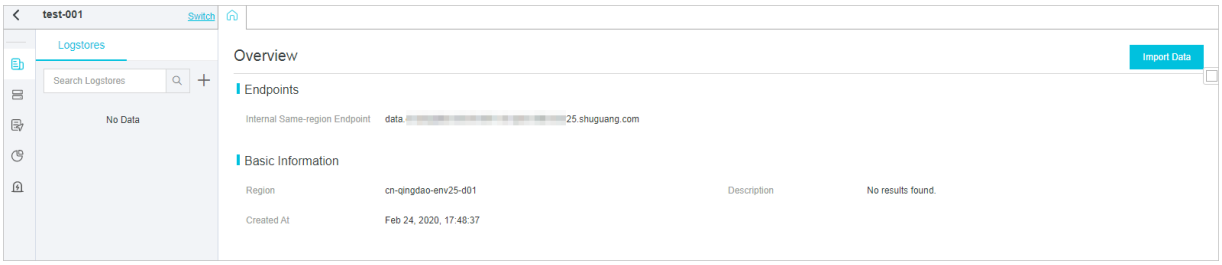
1. In the **Projects** section, find the project.
2. In the **Actions** column, click **Edit**.
3. In the **Modify Project** dialog box, modify the description of the project.

> **Note** You cannot modify the project name or region.

4. Click **OK**.

View the information of a project

To view the information of a project, click the project name in the **Projects** section. On the **Overview** page, you can view the project information such as the endpoint and region.



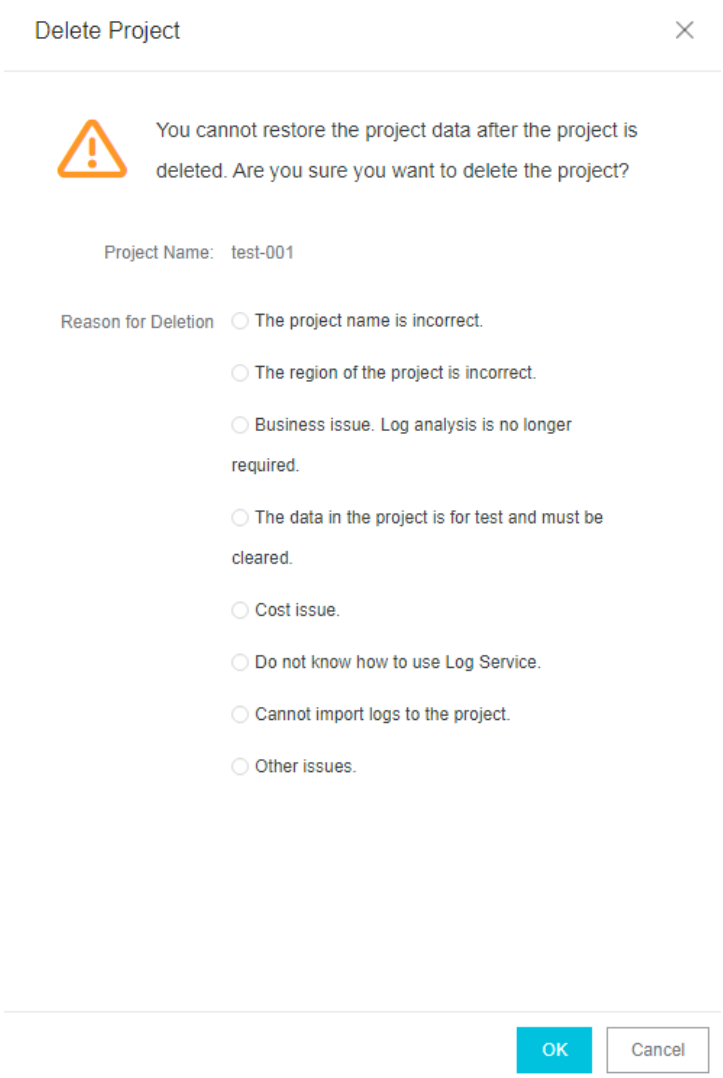
Delete a project

To delete a project, perform the following steps:

> **Warning** After you delete a project, all logs and configurations in the project are deleted and cannot be restored.

1. In the **Projects** section, find the project.
2. In the **Actions** column, click **Delete**.
3. In the dialog box that appears, select a reason for deletion.

   If you select **Other issues**, enter the reason in the text box.



4. Click **OK**.

23.2.5. Manage Logstores

This topic describes how to create, modify, and delete a Logstore in the Log Service console. A Logstore is a collection of resources inside a project. The log data in a Logstore is collected from the same source.

Context

You can create multiple Logstores in a project. We recommend that you create a Logstore for each type of application log.

Logstores provide the following features:

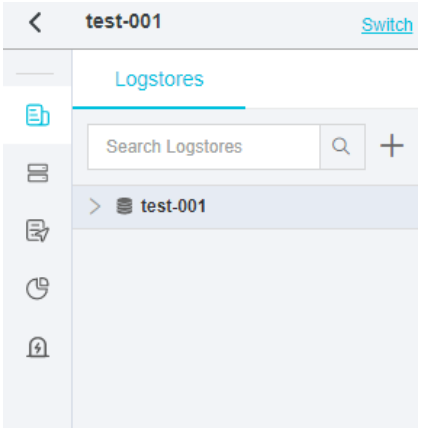
- Real-time log collection
- Log storage and real-time log consumption
- Log indexing and real-time log query

Create a Logstore

> **Note** You can create a maximum of 100 Logstores in each project.

1. Log on to the Log Service console.

2. In the **Projects** section, click the name of a project.
3. On the page that appears, click next to the search box.



4. In the **Create Logstore** pane, set the parameters and click **OK**.

Parameter	Description
Logstore Name	The name of the Logstore. The Logstore name must be unique in the project to which the Logstore belongs. ○ The name can contain lowercase letters, digits, hyphens (-), and underscores (_). ○ The name must start and end with a lowercase letter or digit. ○ The name must be 3 to 63 characters in length. **Note** After a Logstore is created, its name cannot be modified.
WebTracking	Specifies whether to enable the WebTracking feature for the Logstore. You can use WebTracking to collect the log data of HTML websites, HTML5 websites, iOS apps, or Android apps and forward the data to Log Service. This feature is not enabled by default.
Permanent Storage	Specifies whether to permanently store the log data in the Logstore. If you disable this feature, you must specify a retention period for log data.
Data Retention Period	The duration for which log data is stored in the Logstore after the log data is collected. Unit: days. Valid values: 1 to 3000. When this period expires, the log data is deleted.
Shards	The number of shards in the Logstore. You can divide a Logstore into 1 to 10 shards.
Automatic Sharding	Specifies whether to enable the automatic sharding feature. This feature is not enabled by default. If you enable this feature, Log Service automatically splits shards in the Logstore when the data transfer exceeds the capacity of the existing shards.
Maximum Shards	The maximum number of shards. This parameter is required if you enable the automatic sharding feature. Maximum value: 64.

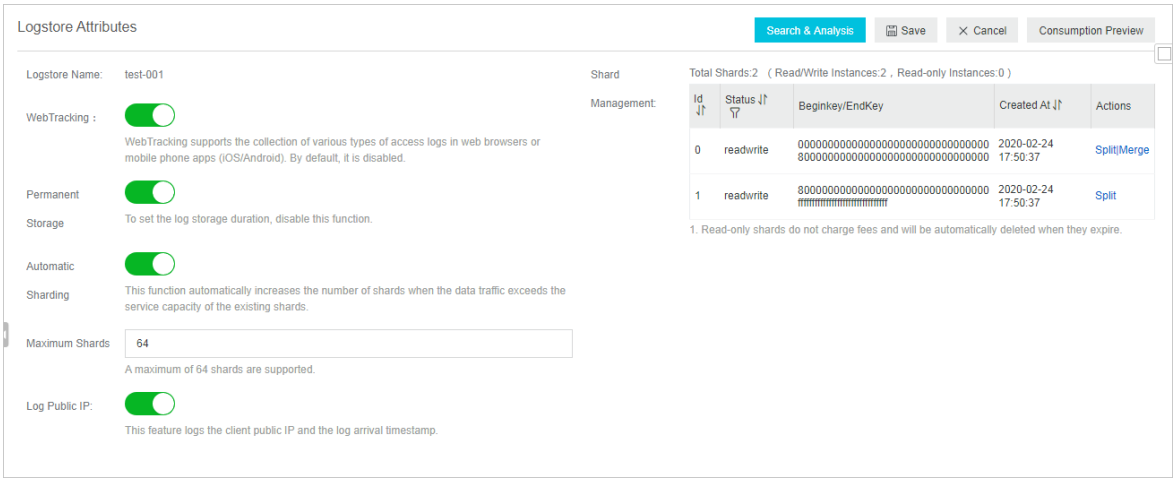
Parameter	Description
Log Public IP	Specifies whether to add the following information to the Tag field of each collected log entry: ○ `__client_ip__` : the public IP address of the log source. ○ `__receive_time__` : the time when Log Service receives the log entry. The value is a UNIX timestamp.

Modify the configurations of a Logstore

To modify the configurations of a Logstore, perform the following steps:

1. In the **Projects** section, click the name of the project to which the Logstore belongs.
2. On the page that appears, click the icon next to the Logstore, and select **Modify** from the shortcut menu.
3. In the upper-right corner of the **Logstore Attributes** page, click **Modify**.

   You can modify the **Data Retention Period**, **WebTracking**, **Automatic Sharding**, **Maximum Shards**, and **Log Public IP** parameters. You can also split or merge the existing shards.



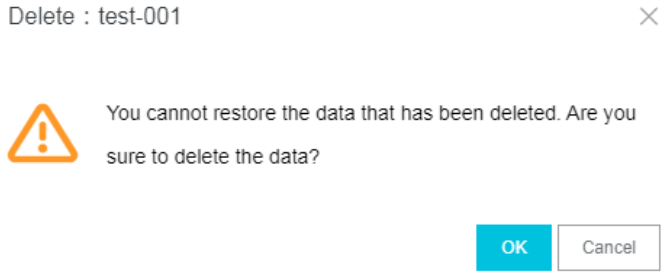
4. Click **Save**.

Delete a Logstore

To delete a Logstore, perform the following steps:

> **Note**
> - After you delete a Logstore, the log data in the Logstore is deleted and cannot be restored.
> - Before you can delete a Logstore, you must delete the Logtail configurations that are associated with the Logstore.

1. In the **Projects** section, click the name of the project to which the Logstore belongs.
2. On the page that appears, click the icon next to the Logstore, and select **Delete** from the shortcut menu.
3. In the message that appears, click **OK**.



23.2.6. Manage shards

This topic describes how to split, merge, and delete shards in the Log Service console. Logs are stored on shards in a Logstore. Each Logstore can have multiple shards. When you create a Logstore, you must specify the number of shards in the Logstore. After a Logstore is created, you can split or merge the shards.

Hash key

Log Service uses 128-bit MD5 hashes as the hash key of a Logstore. The entire MD5 hash range is [00000000000000000000000000000000,ffffffffffffffffffffffffffffffff). The hash key range of a Logstore falls within the entire MD5 hash range. When you create a Logstore, you must specify the number (N) of shards in the Logstore. The hash key range of the Logstore is evenly divided into N parts. Each part is assigned to a shard.

The hash key range of a shard is a left-closed and right-open interval that is specified by the following parameters:

- BeginKey: the start of the hash key range. The value of this parameter is included in the range.
- EndKey: the end of the hash key range. The value of this parameter is excluded from the range.

If you split a shard, the hash key range of the shard is evenly split. If you merge two shards, the hash key ranges of the shards are also merged. A hash key range determines the scope of a shard. When you push log data to a Logstore, you can specify a hash key for the log data. Log Service then writes the log data to the shard whose hash key range includes the specified hash key. This is called the hash key mode. If you do not specify a hash key for log data, the load balancing mode is used and Log Service writes the log data to a random available shard. However, when you pull log data from a Logstore, you must specify the shard where the log data is stored.

For example, a Logstore is divided into four shards and the hash key range of the Logstore is [00,FF). Example shards lists the hash key range of each shard.

Example shards

Shard	Hash key range
Shard0	[00,40)
Shard1	[40,80)
Shard2	[80,C0)
Shard3	[C0,FF)

If you set the hash key of log data to 5F, Log Service writes the log data to shard 1 because the hash key range of shard 1 includes 5F. If you set the hash key to 8C, the log data is written to shard 2 because the hash key range of shard 2 includes 8C.

Read/write capacity

Each shard provides an identical read/write capacity. Therefore, the read/write capacity of a Logstore depends on the number of shards in the Logstore. We recommend that you adjust the capacity of a Logstore based on the data traffic. For a Logstore, if the data traffic exceeds the read/write capacity, you can split shards to increase the Logstore capacity. If the data traffic is much less than the read/write capacity, you can merge shards to reduce the Logstore capacity and save costs.

For example, a Logstore consists of two read/write shards and the shards provide a maximum write capacity of 10 MB/s. If log data is written to the Logstore at a rate of 14 MB/s, we recommend that you split one of the shards into two shards. However, if log data is written at a rate of 3 MB/s, you can merge the two shards because the capacity of one shard already meets the read/write requirements.

> Note
> - If an API operation that writes data to a Logstore constantly returns 403 or 500 errors, you can check the data traffic metrics that are provided by Log Service and determine whether to split shards.
> - If the data traffic of a Logstore exceeds the read/write capacity of the Logstore, Log Service provides the best possible service but does not guarantee the service quality.

Shard status

A shard can be in one of the following states:

- Read/write
- Read-only

After a shard is created, the default status of the shard is read/write. If you split or merge shards, the status of the original shards changes to read-only and the new shards are in the read/write state. You can write data to and read data from a read/write shard. However, you can only read data from a read-only shard and cannot write data to the shard.

If you need to split a shard in a Logstore, you must specify the ID of the shard and an MD5 hash. The shard must be in the read/write state. The MD5 hash must be greater than the value of the BeginKey parameter of the shard and less than the value of the EndKey parameter of the shard. After the shard is split, the Logstore has two more shards. The status of the original shard changes from read/write to read-only. You can consume the log data in the original shard but cannot write log data to the shard. The new shards are in the read/write state and are listed below the original shard. The hash key ranges of the new shards cover that of the original shard.

If you need to merge shards in a Logstore, you must specify a read/write shard. The shard cannot be the last read/write shard in the shard list. Log Service finds the shard whose hash key range follows the hash key range of the specified shard, and merges the two shards into a new shard. The status of the original shards changes from read/write to read-only. You can consume the log data in the original shards but cannot write log data to the shards. The new shard is in the read/write state. The hash key range of the new shard covers those of the original shards.

You can perform the following operations on shards in the Log Service console:

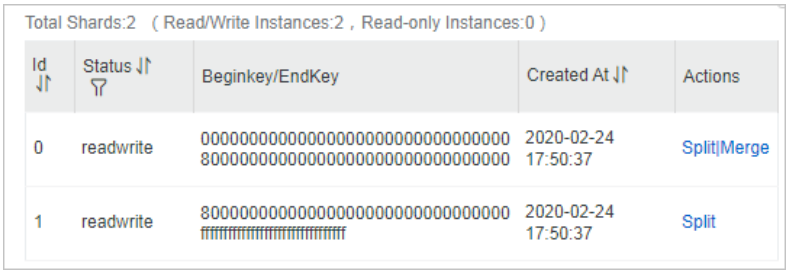
- Split a shard.
- Merge shards.

Split a shard

Each shard provides a write capacity of 5 MB/s and a read capacity of 10 MB/s. For a Logstore, if the data traffic exceeds the total read/write capacity of existing shards, we recommend that you split shards to increase the capacity.

1. Log on to the Log Service console.
2. In the **Projects** section, click the name of a project.
3. On the page that appears, click the icon next to the Logstore, and select **Modify** from the shortcut menu.
4. In the upper-right corner of the **Logstore Attributes** page, click **Modify**.

5. In the **Shard Management** section, find the shard that you want to split, and click **Split** in the **Actions** column.



6. In the drop-down list, click the number of new shards.
7. In the **Actions** column, click **OK**.
8. In the upper-right corner of the **Logstore Attributes** page, click **Save**.

Enable the automatic sharding feature

Log Service provides the automatic sharding feature.

If you enable the automatic sharding feature for a Logstore, shards are automatically split if the following conditions are met:

- The data traffic of the Logstore exceeds the total capacity of the shards in the Logstore for more than five minutes.
- The number of read/write shards does not exceed the maximum number of shards that is allowed in the Logstore after an automatic shard split.

> **Note** After a shard is split into multiple shards, the new shards will not be automatically split within 15 minutes.

When you create or modify a Logstore, you can enable the automatic sharding feature. If this feature is enabled, you must specify the maximum number of shards that is allowed in the Logstore after an automatic shard split. For more information, see Manage Logstores.

- Automatic Sharding

  Specifies whether to enable the automatic sharding feature. If you turn on this switch, the shards are automatically split when the preceding conditions are met.

- Maximum Shards

  The maximum number of shards that is allowed in the Logstore after an automatic shard split. The maximum value is 64.

Merge shards

You can merge shards in a Logstore to reduce the capacity of the Logstore.

1. In the upper-right corner of the **Logstore Attributes** page, click **Modify**.
2. In the **Shard Management** section, find the shard that you want to merge with another shard, and click **Merge** in the **Actions** column.

Total Shards:2 (Read/Write Instances:2 , Read-only Instances:0)

Id	Status	Beginkey/EndKey	Created At	Actions
0	readwrite	00000000000000000000000000000000 80000000000000000000000000000000	2020-02-24 17:50:37	Split|Merge
1	readwrite	80000000000000000000000000000000 ffffffffffffffffffffffffffffffff	2020-02-24 17:50:37	Split

3. In the upper-right corner of the **Logstore Attributes** page, click **Save**.

Delete a shard

- Automatic deletion

  When you create a Logstore, you can set a retention period for log data. When the retention period expires, the shards in the Logstore and the log data in the shards are automatically deleted.

- Manual deletion

  If you turn on the **Permanent Storage** switch when you create a Logstore, the shards in the Logstore and the log data in the shards are not automatically deleted. If you need to delete the shards and the log data in the shards, you can delete the Logstore. For more information, see Delete a Logstore.

23.3. Data collection

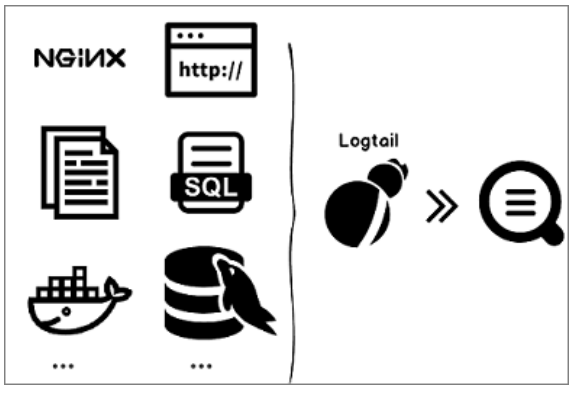
23.3.1. Collection by Logtail

23.3.1.1. Overview

23.3.1.1.1. Logtail overview

Logtail is a log collection agent provided by Log Service. You can use Logtail in Log Service console to collect logs in real time from multiple sources. These sources include Alibaba Cloud Elastic Compute Service (ECS) instances, servers deployed in on-premises data centers, and servers provided by other cloud service providers.

Logtail-based log collection



Benefits

- Provides non-intrusive log collection based on log files. You do not need to modify the application code. Log collection does not affect the operation logic of your applications.
- Supports the collection of multiple logs, such as text logs, binlogs, HTTP logs, and container stdout logs.
- Collects data from standard containers and various container clusters, such as swarm clusters and Kubernetes clusters.
- Handles various exceptions that occur in the log collection process. If a network or server exception occurs,

Logtail retries log collection and locally caches logs to ensure data security.

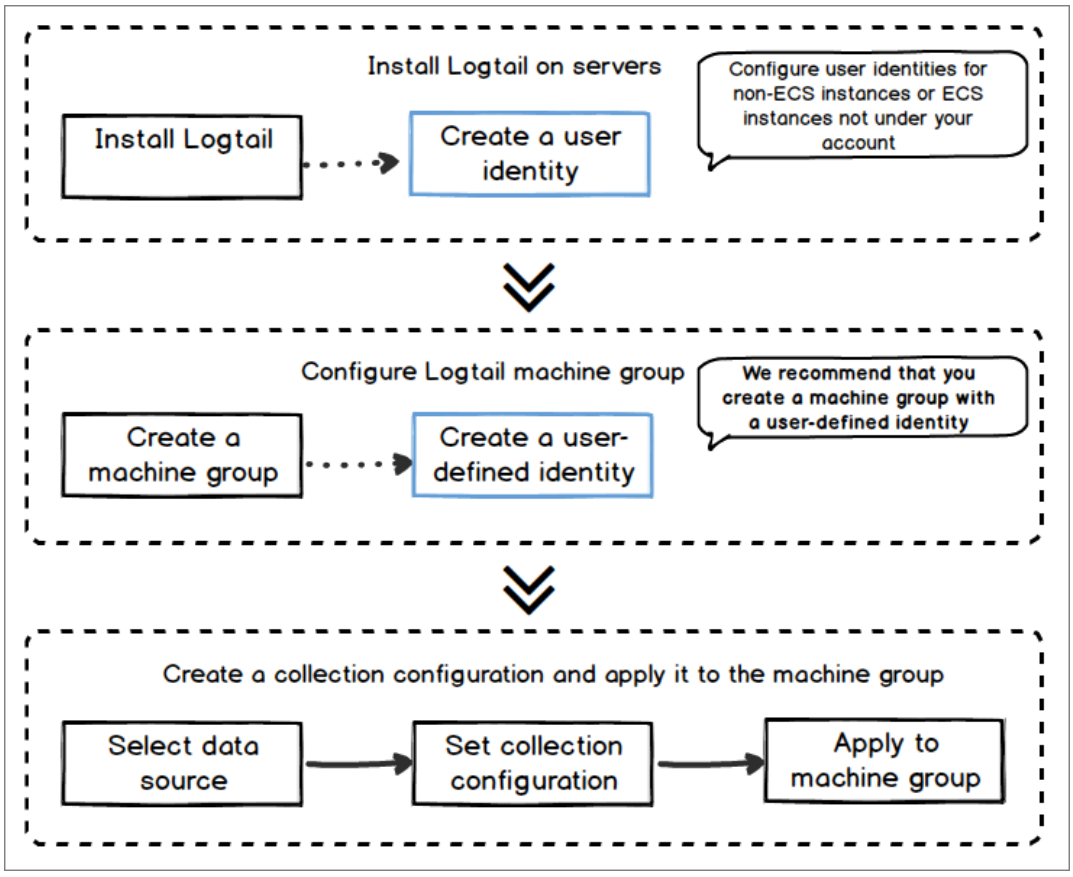
- Provides centralized management based on Log Service. After you install Logtail on the servers from which you want to collect logs, you can configure these servers and the collection method in the Log Service console. You do not need to log on to the servers.
- Provides a comprehensive self-protection mechanism. To minimize the impact of Logtail on the performance of the related servers, Logtail limits the usage of CPU, memory, and network resources.

Processing capabilities and limits

For more information, see Limits.

Configuration process

Configuration process



To collect logs from servers by using Logtail, follow these steps:

1. Install Logtail. For more information about how to install Logtail on a server from which you want to collect logs, see Install Logtail in Linux and Install Logtail in Windows.
2. Log Service use server groups to manage all servers from which you want to collect logs by using Logtail. Log Service allows you to define server groups by using IP addresses or custom identifiers. You can create a server group as prompted when you apply Logtail configurations to server groups.
3. Create a Logtail configuration and apply it to the server group. For more information about how to create a Logtail configuration, see Configure text log collection.

After the preceding process is complete, logs on the server are automatically collected and sent to the selected Logstore. However, historical logs are not collected. You can use the Log Service console, SDKs, or APIs to query these logs. Log Service allows you to view the status of log collection and check whether errors occur.

For more information, see Collect logs by using Logtail.

Containers

- For information about Alibaba Cloud Container Service for Kubernetes or user-created Kubernetes clusters, see Collect Kubernetes logs.
- For information about other user-created Docker clusters, see Collect standard Docker logs.

Terms

- Server group: A server group contains one or more servers from which logs of a specific type are collected. You can apply Logtail configurations to a server group. This enables Log Service to collect logs from all servers in the server group. You can use the Log Service console to manage a sever group. For example, you can create, delete, add, or remove a server. Each server group can contain different versions of Windows servers or Linux servers.
- Logtail: Logtail is the agent that collects logs from the servers on which Logtail runs. For more information, see Install Logtail in Linux and Install Logtail in Windows. After you install Logtail on a server, you must create a Logtail configuration and apply it to the server group to which the server belongs.
  - In Linux, Logtail is installed in the `/usr/local/ilogtail` directory. Logtail initiates two separate processes whose names start with ilogtail. One is a collection process and the other is a daemon process. The program running log is `/usr/local/ilogtail/ilogtail.LOG`.
  - In Windows, Logtail is installed in the `C:\Program Files\Alibaba\Logtail` (for 32-bit systems) or `C:\Program Files (x86)\Alibaba\Logtail` (for 64-bit systems) directory. You can choose Administrative Tools > Services to view the two Windows services generated from Logtail. One is LogtailWorker (log collection process) and the other is LogtailDaemon. The program running log is `logtail_*.log` in the installation directory.
- Logtail configuration: A Logtail configuration is a set of policies that are used by Logtail to collect logs. You can specify Logtail parameters such as the data source and collection mode. This allows you to customize log collection policies for all servers in a server group. A Logtail configuration determines how to collect a type of logs from a server, parse the logs, and send them to a specified Logstore. You can create a Logtail configuration for a Logstore in the Log Service console. This enables the Logstore to receive logs that are collected by using this Logtail configuration.

Features

Logtail provides the following features:

Feature	Description
Real-time log collection	Logtail dynamically monitors log files and reads and parses incremental logs in real time. In most cases, logs are sent to Log Service within 3 seconds after they are generated. **Note** Logtail does not collect historical data. If Logtail reads a log later than 12 hours after the log was generated, Logtail drops the log.
Automatic log rotation	Some applications rotate log files based on the file size or date. In the rotation process, the original log files are renamed and empty log files are created. For example, files such as *app.LOG.1* and *app.LOG.2* are generated for the *app.LOG* file after log rotation. You can specify the file (for example, *app.LOG*) to which collected logs are written. Logtail monitors the log rotation process to ensure that no logs are lost.
Multiple data sources	Logtail can collect text logs, syslogs, HTTP logs, and MySQL binlogs.
Automatic exception handling	If data transmission fails due to exceptions such as Log Service errors, network errors, or quota exhaustion, Logtail retries log collection based on the specific scenario. If the retry fails, Logtail writes the data to the local cache and resends the data after the exception no longer exists.

Feature	Description
Flexible collection policy configuration	You can create a Logtail configuration to specify how logs are collected from an ECS instance. You can select log directories and files by using exact match or wildcard match based on actual scenarios. You can also customize the extraction method of collected logs and the names of extracted fields. Log Service allows you to extract logs by using regular expressions. The log data models of Log Service require that each log has a precise timestamp. Logtail provides custom log time formats. This allows you to extract the required timestamps from log data of different formats.
Automatic synchronization of Logtail configurations	After you create or update a Logtail configuration in the Log Service console, Logtail receives and validates the configuration within 3 minutes. No data loss occurs during the configuration update process.
Automatic upgrade	After you install Logtail on a server, Log Service manages the automatic upgrade of Logtail without manual intervention. No data loss occurs during the Logtail upgrade process.
Status monitoring	Logtail monitors its consumption of CPU and memory in real time. This prevents Logtail from excessively consuming your resources. If the resource consumption exceeds the limit, Logtail restarts to avoid affecting other services on the server. Logtail limits network traffic to avoid excessive bandwidth consumption.
Data transmission with a signature	Logtail obtains your Alibaba Cloud AccessKey pair and uses it to sign all log data packets before they are sent. This prevents data tampering during transmission. **Note** Logtail obtains your Alibaba Cloud AccessKey pair over HTTPS to ensure the security of your AccessKey pair.

Data collection reliability

During data collection, Logtail stores the collected checkpoints to the local directory on a regular basis. If an exception (for example, an unexpected server shutdown or a process crash) occurs, Logtail restarts and then collects data from the last recorded checkpoint to prevent data loss. Logtail runs based on the resource limits specified in the configuration file. If the usage of a resource exceeds the limit for more than 5 minutes, Logtail restarts. After the restart, duplicate data may be generated.

Logtail uses multiple internal mechanisms to improve log collection reliability. However, logs may be lost in the following conditions:

- Logtail is not running but logs are rotated multiple times.
- The log rotation rate is high, for example, one rotation per second.
- The log collection rate is lower than the log generation rate for a long period of time.

23.3.1.1.2. Log collection process of Logtail

This topic describes the process that Logtail uses to collect server logs. The process consists of the following steps: monitor files, read files, process logs, filter logs, aggregate logs, and send logs.

Note After the Logtail configuration is applied to a machine group, unmodified logs on the servers in the machine group are considered as historical logs. Logtail does not collect historical logs in normal running mode. If you want to collect historical logs, see Import historical logs.

Monitor files

After you install Logtail on a server and create a Logtail configuration based on a data source, the Logtail configuration is delivered from Log Service to Logtail in real time. Then, Logtail starts to monitor files based on the Logtail configuration.

1. Logtail scans log directories and files that comply with the specified file naming rules based on the specified log path and maximum monitoring directory depth.

   Logtail registers event monitoring and periodical polling for the directory from which Logtail collect logs. In Linux, Inotify is used. In Windows, ReadDirectoryChangesW is used. This method ensures the timeliness and stability of log collection.

2. If the compliant log files in the specified directory are not modified after the configuration is applied, Logtail does not collect these files. If modification events are generated for log files, Logtail triggers the collection process and reads these files.

Read files

After Logtail detects that a log file has been updated, Logtail reads the log file.

- If Logtail reads the log file for the first time, it checks the file size.
  - If the file size is less than 1 MB, Logtail reads the file from the beginning.
  - If the file size is greater than 1 MB, Logtail reads the file from the last 1 MB of data.
- If Logtail has read the file before, Logtail reads the file from the last checkpoint.
- Logtail can read up to 512 KB of data at a time. Therefore, you must limit the log size to 512 KB.

> **Notice** If you have changed the system time on your server, you must manually restart Logtail. Otherwise, the log time is incorrect and logs are dropped.

Process logs

When Logtail reads a log, it divides the log into multiple lines, parses the log, and sets the time field of the log.

- Divide each log into multiple lines

  If you specifies **Regex to Match First Line Only** in the Logtail configuration, the log data read by Logtail at one time is divided into multiple lines based on the specified beginning of the line. If the beginning of the line is not specified, each data block is processed as a log.

- Parse each log

  Logtail parses each log based on the Logtail configuration, such as regular expressions, delimiters, and JSON.

  > **Notice** A complicated regular expression may lead to high CPU usage. Therefore, we recommend that you use an efficient regular expression.

- Handle parsing failures

  Logtail determines how to handle parsing failures based on whether the Drop Failed to Parse Logs switch is turned on in the Logtail configuration.

  - If the **Drop Failed to Parse Logs** is turned on, Logtail drops the logs that fail to be parsed and reports an error.
  - If the **feature** switch is turned off, Logtail uploads the logs that fail to be parsed. In these logs, the key is set to **raw_log** and the value is set to the log content.

- Set the time field of a log
  - If the time field of the log is not specified, the log time is the current parsing time.

- If the time field of the log is specified, the following operations are performed:
  - The log time is extracted from the parsed log fields if the difference between the log time and the current time is less than 12 hours.
  - The log is dropped and an error is reported if the difference between the log time and the current time is greater than 12 hours.

Filter logs

After Logtail process logs, it filters the logs based on the filter configuration.

- If the **Filter Configuration** is not specified, Logtail does not filter logs and proceed with the next step.
- If the **Filter Configuration** is specified, Logtail traverses and verifies all the fields of each log.
  - Logtail collects a log if the log matches the filter configuration.
  - Logtail does not collect a log if the log does not match the filter configuration.

Aggregate logs

Logtail sends the logs that match the filter configuration to Log Service. To reduce the number of network requests, Logtail caches the processed and filtered logs for a period of time. Then, Logtail aggregates and packages these logs before sending them to Log Service.

If one of the following conditions is met during caching, logs are immediately packaged and sent to Log Service.

- The log aggregation period exceeds three seconds.
- The number of aggregated logs exceeds 4,096.
- The total size of aggregated logs exceeds 512 KB.

Send logs

Logtail sends the aggregated logs to Log Service. You can set the `max_bytes_per_sec` and `send_request_concurrency` parameters in Set Logtail startup parameters to adjust the log data sending rate and the maximum concurrent requests. In this case, Logtail ensures that the sending rate and the concurrent requests do not exceed the limits.

If the log data fails to be sent, Logtail retries or stops the operation based on the error message.

Error	Description	Handling method
401	Logtail is not authorized to collect data.	Logtail drops the log packets.
404	The specified project or Logstore does not exist in the Logtail configuration.	Logtail drops the log packets.
403	The shard quota is exhausted.	Logtail waits for three seconds and retries.
500	A Log Service exception has occurred.	Logtail waits for three seconds and retries.
Network timeout	A network connection error has occurred.	Logtail waits for three seconds and retries.

23.3.1.1.3. Logtail configuration files and record files

This topic describes the basic configuration files and record files of Logtail. When Logtail is active, it uses a series of configuration files and generates record files.

The basic configuration files are as follows:

- Startup configuration file (ilogtail_config.json)
- Account ID configuration file
- User-defined identifier file (user_defined_id)

- Logtail configuration file (user_log_config.json)

The basic record files are as follows:

- AppInfo record file (app_info.json)
- Logtail operational log file (ilogtail.LOG)
- Logtail plug-in log file (logtail_plugin.LOG)
- Container path mapping file (docker_path_config.json)

Startup configuration file (ilogtail_config.json)

This file is used to query or set Logtail runtime parameters. The file is in the JSON format.

After you install Logtail, you can use the startup configuration file to perform the following operations:

- Change the values of the Logtail runtime parameters.

  You can change the CPU usage threshold, usage threshold of terminate and stay resident (TSR) programs, and other settings.

- Check whether the installation commands are correct.

  The settings of `config_server_address` and `data_server_list` in this file depend on the parameters and installation commands selected when you installed Logtail. If the region specified in config_server_address is unreachable or is different from the region where Log Service resides, the selected parameters or commands are incorrect. In this case, Logtail cannot collect logs and must be reinstalled.

> **Warning**
> - The file must be a valid JSON file. Otherwise, Logtail cannot be started.
> - If you modify the file, you must restart Logtail to validate your modifications.

The following table describes the default parameters in the startup configuration file. You can also add other parameters. For more information, see Set Logtail startup parameters.

Default parameters

Parameter	Description
config_server_address	The address that Logtail uses to receive the configuration file from Log Service. This address depends on the parameters and installation commands that you selected when you installed Logtail. Ensure that the address is reachable and is in the same region as Log Service.
data_server_list	The data server address. This address depends on the parameters and installation commands that you selected when you installed Logtail. Ensure that the address is reachable and is in the same region as Log Service.
cluster	The name of the region where a server resides.
endpoint	The endpoint of Log Service. For more information, see View the information of a project.
cpu_usage_limit	The CPU usage threshold, which is calculated by core.
mem_usage_limit	The TSR usage threshold.
max_bytes_per_sec	The traffic limit on the raw data that is sent by Logtail. If the value of this parameter is greater than 20 Mbit/s, traffic limiting does not take effect.

Parameter	Description
process_thread_count	The number of threads that Logtail uses to write data to log files.
send_request_concurrency	The number of concurrent requests for sending data packets asynchronously. Logtail sends data packets asynchronously by default. If the write transactions per second (TPS) is high, you can set a greater value for this parameter.

- File path
  - Linux: The file is stored in */usr/local/ilogtail/ilogtail_config.json*.
  - Container Service: The file is stored in a Logtail container. The file path is specified in the environment variable `ALIYUN_LOGTAIL_CONFIG` of the Logtail container. You can run the command `docker inspect ${logtail_container_name} | grep ALIYUN_LOGTAIL_CONFIG` to query the file path. For example, the file path is */etc/ilogtail/conf/cn-hangzhou/ilogtail_config.json*.
  - Windows:
    - 64-bit: The file is stored in *C:\Program Files (x86)\Alibaba\Logtail\ilogtail_config.json*.
    - 32-bit: The file is stored in *C:\Program Files\Alibaba\Logtail\ilogtail_config.json*.
- Sample file

```
$cat /usr/local/ilogtail/ilogtail_config.json
{
  "config_server_address" : "http://logtail.cn-hangzhou-intranet.log.aliyuncs.com",
  "data_server_list" :
  [
    {
      "cluster" : "ap-southeast-2",
      "endpoint" : "cn-hangzhou-intranet.log.aliyuncs.com"
    }
  ],
  "cpu_usage_limit" : 0.4,
  "mem_usage_limit" : 100,
  "max_bytes_per_sec" : 2097152,
  "process_thread_count" : 1,
  "send_request_concurrency" : 4,
  "streamlog_open" : false
}
```

Account ID configuration file

This file contains the ID of your Apsara Stack tenant account. The file indicates that the account can collect logs from the server where Logtail is installed. If you want to collect logs from ECS instances that do not belong to your account or from on-premises data centers, you must create an account ID configuration file.

> **Note**
> - The file is used only when you collect logs from ECS instances that do not belong to your account and or from on-premises data centers.
> - The file can contain only the ID of your Apsara Stack tenant account. It cannot contain the IDs of RAM users under your Apsara Stack tenant account.
> - The file name cannot contain a suffix.
> - Each Logtail can have multiple account ID configuration files. Each Logtail container can have only one account ID configuration file.

- File path

- Linux: The file is stored in `/etc/ilogtail/users/`.
- Container Service: The file is stored in a Logtail container. The file path is specified in the environment variable `ALIYUN_LOGTAIL_USER_ID` of the Logtail container. You can run the command `docker inspect ${logtail_container_name} | grep ALIYUN_LOGTAIL_USER_ID` to query the file path.
- Windows: The file is stored in `C:\LogtailData\users\`.

- Sample file

```
$ls /etc/ilogtail/users/
********** **********
```

User-defined identifier file (user_defined_id)

This file is used to configure machine groups with user-defined identifiers. For more information, see Create a machine group based on a custom ID.

> **Note**
> - This file is used only when you configure a machine group with user-defined identifiers.
> - If you configure multiple user-defined identifiers for a machine group, separate them with line breaks.

- File path
  - Linux: The file is stored in */etc/ilogtail/user_defined_id*.
  - Container Service: The file is stored in a Logtail container. The file path is specified in the environment variable `ALIYUN_LOGTAIL_USER_DEFINED_ID` of the Logtail container. You can run the command *docker inspect ${logtail_container_name} | grep ALIYUN_LOGTAIL_USER_DEFINED_ID* to query the file path.
  - Windows: The file is stored in *C:\LogtailData\user_defined_id*.

- Sample file

```
$cat /etc/ilogtail/user_defined_id
aliyun-ecs-rs1e16355
```

Logtail configuration file (user_log_config.json)

This file contains the Logtail configuration that Logtail receives from Log Service. The file is in the JSON format and is updated along with configuration updates. You can use this file to check whether the Logtail configuration is delivered to the server where Logtail is installed. If the Logtail configuration file exists and all contents in the file are up to date, the Logtail configuration is delivered.

> **Notice**
> - We recommend that you do not modify the Logtail configuration file unless you need to specify sensitive information, such as the AccessKey pair and database password.
> - You must upload this file when you submit a ticket.

- File path
  - Linux: The file is stored in */usr/local/ilogtail/user_log_config.json*.
  - Container Service: The file is stored in */usr/local/ilogtail/user_log_config.json*.
  - Windows
    - 64-bit: The file is stored in *C:\Program Files (x86)\Alibaba\Logtail\user_log_config.json*.
    - 32-bit: The file is stored in *C:\Program Files\Alibaba\Logtail\user_log_config.json*.

- Sample file

```
$cat /usr/local/ilogtail/user_log_config.json
{
  "metrics" : {
    "##1.0##k8s-log-c12ba2028*****939f0b$app-java" : {

      "version" : 1
    }
  }
}
```

AppInfo record file (app_info.json)

This file contains the startup time of Logtail. It also contains the IP address and hostname that Logtail obtains. You must check the IP address obtained by Logtail when you configure an IP address-based machine group.

In most cases, Logtail obtains server IP addresses based on the following rules:

- If the IP address of a server is associated with its hostname in the */etc/hosts* server file, Logtail obtains the IP address.
- If the IP address of a server is not associated with its hostname, Logtail obtains the IP address of the first network interface card (NIC) on the server.

> **Note**
> - The AppInfo record file contains only the basic Logtail information, which cannot be manually modified.
> - If you modify the hostname or other network settings of the server, you must restart Logtail to obtain a new IP address.

Parameters

Parameter	Description
UUID	The serial number of the server.
hostname	The hostname.
instance_id	The unique identifier of Logtail. This identifier is randomly generated.
ip	The IP address that is obtained by Logtail. If this parameter is not specified, Logtail has not obtained the IP address of a server. In this case, Logtail cannot function properly. You must set an IP address for your server and restart Logtail. **Note** If the machine group is an IP address-based machine group, ensure that the IP address specified for the machine group is the same as the value of this parameter. If the two IP address are different, modify the IP address that you specified for the machine group in the Log Service console. Check the IP addresses again after 1 minute.
logtail_version	The version of Logtail.
os	The version of the operating system.
update_time	The last startup time of Logtail.

- File path
  - Linux: The file is stored in */usr/local/ilogtail/app_info.json*.
  - Container Service: The file is stored in */usr/local/ilogtail/app_info.json*.
  - Windows
    - 64-bit: The file is stored in *C:\Program Files (x86)\Alibaba\Logtail\app_info.json*.
    - 32-bit: The file is stored in *C:\Program Files\Alibaba\Logtail\app_info.json*.
- Sample file

```
$cat /usr/local/ilogtail/app_info.json
{
  "UUID" : "",
  "hostname" : "logtail-ds-slpn8",
  "instance_id" : "E5F93BC6-B024-11E8-8831-0A58AC14039E_1**. ***. ***.***_1536053315",
  "ip" : "1**. ***. ***.***",
  "logtail_version" : "0.16.13",
  "os" : "Linux; 3.10.0-693.2.2.el7.x86_64; #1 SMP Tue Sep 12 22:26:13 UTC 2017; x86_64",
  "update_time" : "2018-09-04 09:28:36"
}
```

Logtail operational log file (ilogtail.LOG)

This file contains operational information about Logtail. Log severity levels are ranked as follows in ascending order: `INFO`, `WARN`, `ERROR`. Logs of the `INFO` level can be ignored.

- File path
  - For Linux: The file is stored in */usr/local/ilogtail/ilogtail.LOG*.
  - Container Service: The file is stored in */usr/local/ilogtail/ilogtail.LOG*.
  - Windows
    - 64-bit: The file is stored in *C:\Program Files (x86)\Alibaba\Logtail\logtail_*.log*.
    - 32-bit: The file is stored in *C:\Program Files\Alibaba\Logtail\logtail_*.log*.
- Sample file

```
$tail /usr/local/ilogtail/ilogtail.LOG
[2018-09-13 01:13:59.024679] [INFO] [3155] [build/release64/sls/ilogtail/elogtail.cpp:123] change working dir:/usr/local/ilogtail/
[2018-09-13 01:13:59.025443] [INFO] [3155] [build/release64/sls/ilogtail/AppConfig.cpp:175] load logtail config file, path:/etc/ilogtail/conf/ap-southeast-2/ilogtail_config.json
[2018-09-13 01:13:59.025460] [INFO] [3155] [build/release64/sls/ilogtail/AppConfig.cpp:176] load logtail config file, detail:{
  "config_server_address" : "http://logtail.ap-southeast-2-intranet.log.aliyuncs.com",
  "data_server_list" : [
    {
      "cluster" : "ap-southeast-2",
      "endpoint" : "ap-southeast-2-intranet.log.aliyuncs.com"
    }
]
```

Logtail plug-in log file (logtail_plugin.LOG)

This file contains operational information about plug-ins, such as stdout, binlog, and HTTP plug-ins. Log severity levels are ranked as follows in ascending order: `INFO`, `WARN`, `ERROR`. Logs of the `INFO` level can be ignored.

- File path
  - Linux: The file is stored in */usr/local/ilogtail/logtail_plugin.LOG*
  - Container Service: The file is stored in */usr/local/ilogtail/logtail_plugin.LOG*.
  - Windows: The file is not supported.
- Sample file

```
$tail /usr/local/ilogtail/logtail_plugin.LOG

```

Container path mapping file (docker_path_config.json)

This file is automatically created only when container files are collected. It records path mappings between container files and actual files. The file is in the JSON format.

> **Note** This file is only an information record file. Modifications to this file do not take effect. If you delete this file, another one is automatically created without service interruptions.

- File path

  The file is stored in */usr/local/ilogtail/docker_path_config.json*.

- Sample file

```
$cat /usr/local/ilogtail/docker_path_config.json
{
  "detail" : [
    {
      "config_name" : "##1.0##k8s-log-c12ba2028cfb444238cd9ac1286939f0b$nginx",
      "container_id" : "df19c06e854a0725ea7fca7e0378b0450f7bd3122f94fe3e754d8483fd330d10",

    }
  ],
  "version" : "0.1.0"
}
```

23.3.1.2. Installation

23.3.1.2.1. Install Logtail in Linux

This topic describes how to install Logtail on a Linux server.

Supported systems

Logtail supports the following x86-64 (64-bit) Linux operating systems:

- Aliyun Linux
- Ubuntu
- Debian
- CentOS
- openSUSE
- Red Hat

Procedure

> **Note** If you have installed Logtail, the installer will uninstall the existing version of Logtail, delete the `/usr/local/ilogtail` directory, and then reinstall Logtail. By default, Logtail runs after the installation and at startup.

1. Run the following command to download the Logtail installer:

   ```
   wget http://${service:sls-backend-server:sls_data.endpoint}/logtail.sh -O logtail.sh; chmod 755 logtail.sh
   ```

   > **Note** You must replace `${service:sls-backend-server:sls_data.endpoint}` in the command with the actual endpoint. For more information about endpoints, see View the information of a project.

2. Run the installation command.

   Start Linux PowerShell and run the following command as an administrator to install Logtail:

   ```
   ./logtail.sh install
   ```

3. Configure an account ID for a server.

View the version of Logtail

To view the version of Logtail, open the file in the `/usr/local/ilogtail/app_info.json` directory. The `logtail_version` field shows the version of Logtail.

```
$cat /usr/local/ilogtail/app_info.json
{
  "UUID" : "0DF18E97-0F2D-486F-B77F-*********",
  "hostname" : "david*******",
  "instance_id" : "F4FAFADA-F1D7-11E7-846C-00163E30349E_*********_1515129548",
  "ip" : "**********",
  "logtail_version" : "0.16.0",
  "os" : "Linux; 2.6.32-220.23.2.ali1113.el5.x86_64; #1 SMP Thu Jul 4 20:09:15 CST 2013; x86_64",
  "update_time" : "2018-01-05 13:19:08"
}
```

Upgrade Logtail

You can use the Logtail installer (logtail.sh) to upgrade Logtail. The installer selects an upgrade method based on the configurations of the existing Logtail.

> **Note** During the upgrade, Logtail is temporarily stopped. Only related files are overwritten. The configuration file, checkpoint file, and logs are retained.

Run the following commands to upgrade Logtail:

```
# Download the Logtail installer.
wget http://${service:sls-backend-server:sls_data.endpoint}/logtail.sh -O logtail.sh; chmod 755 logtail.sh
# Upgrade Logtail.
sudo ./logtail.sh upgrade
```

Response:

```
# The upgrade is successful.
Stop logtail successfully.
ilogtail is running
Upgrade logtail success
{
  "UUID" : "***",
  "hostname" : "***",
  "instance_id" : "***",
  "ip" : "***",
  "logtail_version" : "0.16.11",
  "os" : "Linux; 3.10.0-693.2.2.el7.x86_64; #1 SMP Tue Sep 12 22:26:13 UTC 2017; x86_64",
  "update_time" : "2018-08-29 15:01:36"
}
# The upgrade fails because the current version is the latest version.
[Error]:   Already up to date.
```

Start and stop Logtail

- Start Logtail

  Run the following command as an administrator:

  ```
  /etc/init.d/ilogtaild start
  ```

- Stop Logtail

  Run the following command as an administrator:

  ```
  /etc/init.d/ilogtaild stop
  ```

Uninstall Logtail

Run Linux PowerShell as an administrator to uninstall Logtail:

```
wget http://${service:sls-backend-server:sls_data.endpoint}/logtail.sh -O logtail.sh
chmod 755 logtail.sh
./logtail.sh uninstall
```

23.3.1.2.2. Install Logtail in Windows

This topic describes how to install Logtail on a Windows server.

Supported systems

Logtail supports the following Windows operating systems:

- Windows 7 (Client) 32-bit
- Windows 7 (Client) 64-bit
- Windows Server 2008 32-bit

- Windows Server 2008 64-bit
- Windows Server 2012 64-bit
- Windows Server 2016 64-bit

Procedure

1. Download the installation package.

   Run the following command to download the installation package:

   ```
   wget http://${service:sls-backend-server:sls_data.endpoint}/windows/logtail_installer.zip
   ```

   > **Note** You must replace `${service:sls-backend-server:sls_data.endpoint}` in the command with the actual endpoint. For more information about endpoints, see View the information of a project.

2. Decompress the `logtail_installer.zip` package to the current directory.
3. Run the installation command.

   Run Windows PowerShell or Command Prompt as an administrator. Enter the `logtail_installer` directory, and then run the installation command based on the network type.

   ```
   .\logtail_installer.exe install me-east-1
   ```

   > **Note** You must replace `${region}` in the command with the actual endpoint. For more information about endpoints, see View the information of a project.

4. Configure an account ID for a server.

Installation directory

After you run the installation command, Logtail is installed in the specified directory. The directory cannot be changed. In the directory, you can View the version of Logtail in the *app_info.json* file or Uninstall Logtail.

The installation directory is as follows:

- 32-bit Windows: *C:\Program Files\Alibaba\Logtail*
- 64-bit Windows: *C:\Program Files (x86)\Alibaba\Logtail*

> **Note** You can run 32-bit or 64-bit applications in a 64-bit Windows operating system. However, the operating system stores 32-bit applications in separate x86 folders to ensure compatibility.
>
> Logtail for Windows is a 32-bit application. Therefore, it is installed in the *Program Files (x86)* folder in 64-bit Windows. If Logtail for 64-bit Windows becomes available in the future, it will be installed in the *Program Files* folder.

View the version of Logtail

To view the version of Logtail, go to the default installation directory, and then use the notepad or another text editor to open the *app_info.json* file. The `logtail_version` field shows the version of Logtail.

In the following example, the version of Logtail is 1.0.0.0:

```
{
  "logtail_version" : "1.0.0.0"
}
```

Upgrade Logtail

- Automatic upgrade

Logtail later than 1.0.0.0 is automatically upgraded in Windows.

- Manual upgrade

  Logtail earlier than 1.0.0.0 must be manually upgraded. The manual upgrade procedure is the same as the installation procedure.

  > **Note** During a manual upgrade, the files in the original installation directory are deleted. We recommend that you back up the files before you perform a manual upgrade.

Start and stop Logtail

Open the **Control Panel**, choose System and Security > **Administrative Tools**, and then double-click **Services**.

Find the service based on your Logtail version.

- Logtail 0.x.x.x: LogtailWorker.
- Logtail 1.0.0.0 and later: LogtailDaemon.

Perform the following operations as required:

- Start Logtail

  Right-click the service and select **Start** from the shortcut menu.

- Stop Logtail

  Right-click the service and select **Stop** from the shortcut menu.

- Restart Logtail

  Right-click the service and select **Restart** from the shortcut menu.

Uninstall Logtail

Run Windows PowerShell or Command Prompt as an administrator. Enter the `logtail_installer` directory, and then run the following command:

```
.\logtail_installer.exe uninstall
```

After Logtail is uninstalled, the installation directory is deleted. However, some residual configuration data is still maintained in the *C:\LogtailData* directory. You can manually delete the data. The residual configuration data includes the following information:

- *checkpoint*: checkpoints of all plug-ins, for example, the Windows event log plug-in.
- *logtail_check_point*: checkpoints of Logtail.
- *users*: IDs of Apsara Stack tenant accounts.

23.3.1.2.3. Set Logtail startup parameters

This topic describes how to set Logtail startup parameters.

Context

You may need to set Logtail startup parameters in the following scenarios:

- You need to collect a large number of log files that consume much memory. You want to maintain the metadata (such as the file signature, collection location, and file name) of each file in the memory.
- The CPU usage is high due to heavy log data traffic.
- The traffic sent to Log Service is heavy due to a large amount of log data.
- You want to collect syslogs or TCP data streams.

Startup configurations

- File path

  ```
  /usr/local/ilogtail/ilogtail_config.json
  ```

- File format

  JSON

- Sample file (only partial configurations are provided)

```
{
  ...
  "cpu_usage_limit" : 0.4,
  "mem_usage_limit" : 100,
  "max_bytes_per_sec" : 2097152,
  "process_thread_count" : 1,
  "send_request_concurrency" : 4,
  "streamlog_open" : false,
  "streamlog_pool_size_in_mb" : 50,
  "streamlog_rcv_size_each_call" : 1024,
  "streamlog_formats":[],
  "streamlog_tcp_port" : 11111,
  "buffer_file_num" : 25,
  "buffer_file_size" : 20971520,
  "buffer_file_path" : "",
  ...
}
```

Startup parameters

Parameter	Description	Example
cpu_usage_limit	The CPU usage threshold for a single core. Data type: double.	For example, the value 0.4 indicates that the CPU usage of Logtail is limited to 40% processing capacity of a single core. In most cases, the processing capacity of a single core is about 24 MB/s in the simple mode and 12 MB/s in the full regex mode.
mem_usage_limit	The usage threshold of the resident memory. Data type: integer. Unit: MB.	For example, the value 100 indicates that the memory usage of Logtail is limited to 100 MB. If the threshold is exceeded, Logtail restarts. If you want to collect more than 1,000 log files, you can increase the threshold value.
max_bytes_per_sec	The traffic limit on the raw data that is sent by Logtail. Data type: integer. Unit: bytes/s.	For example, the value 2097152 indicates that the data transfer rate of Logtail is limited to 2 MB/s.
process_thread_count	The number of threads that Logtail uses to process data.	Default value: 1. Each thread provides a write speed of 24 MB/s in the simple mode and 12 MB/s in the full regex mode. We recommend that you do not modify the default value.
send_request_concurrency	Logtail sends data packets asynchronously by default. If the write transactions per second (TPS) is high, you can set this parameter to a greater value.	Twenty asynchronous concurrencies are provided by default. Each concurrency can provide 0.5 MB/s to 1 MB/s network throughput. The number of concurrencies varies with the network delay.

Parameter	Description	Example
streamlog_open	Specifies whether to receive syslogs. Data type: Boolean.	The value false indicates that syslogs are not received. The value true indicates that syslogs are received.
streamlog_pool_size_in_mb	The size of memory pool that the syslog server uses to cache syslogs. Unit: MB.	Logtail requests memory when it starts. Set the memory pool size based on the server memory size and your business requirements.
streamlog_rcv_size_each_call	The size of the buffer that Logtail uses when the linux socket rcv API is called. Unit: bytes. Valid values: 1024 to 8192.	You can set a greater value if the syslog traffic is high.
streamlog_formats	The method that is used to parse received syslogs.	N/A
streamlog_tcp_addr	The associated address that Logtail uses to receive syslogs. Default value: 0.0.0.0.	N/A
streamlog_tcp_port	The TCP port that Logtail uses to receive syslogs.	Default value: 11111.
buffer_file_num	The maximum number of cached files. If a network exception occurs or the writing quota is exceeded, Logtail writes parsed logs to local files in the installation directory. After the network recovers or a new writing quota is available, Logtail retries to send the logs to Log Service.	Default value: 25.
buffer_file_size	The maximum number of bytes that can be contained in each cache file. The maximum disk space available for cache files is the value of buffer_file_num multiplied by the value of buffer_file_size.	Default value: 20971520 bytes (20 MB).
buffer_file_path	The directory in which cached files are stored. If you modify this parameter, you must move the files (for example, *logtail_buffer_file_**) in the old cache directory to the new directory. Then, Logtail can read, send, and delete the cache files.	The default value is null, which indicates that the cached files are stored in the Logtail installation directory */usr/local/ilogtail*.
bind_interface	The name of the NIC associated with the local machine, for example, eth1. This parameter is valid only for Logtail that runs in Linux.	By default, the available NICs are automatically associated with the local machine. If you specify this parameter, Logtail will use the specified NIC to upload logs.

Parameter	Description	Example
check_point_filename	The full path in which the checkpoint file is stored. This parameter is used to customize the path to store the checkpoint file of Logtail.	Default value: */tmp/logtail_check_point*. We recommend that Docker users modify this path and mount the directory where the checkpoint file resides to the host. Otherwise, duplicate collection occurs due to checkpoint data loss when the container is released. For example, you can set check_point_filename to `/data/logtail/check_point.dat` in Docker and add `-v /data/docker1/logtail:/data/logtail` to the Docker startup command. Then, the */data/docker1/logtail* directory of the host is mounted to the */data/logtail* directory of Docker.

> **Note**
> - The preceding table lists only the common startup parameters. If the *ilogtail_config.json* file contains parameters that are not listed in the table, the default settings are used for these parameters.
> - We recommend that you do not add unnecessary parameters to the *ilogtail_config.json* file.

Modify configurations

1. Configure the *ilogtail_config.json* file as needed.

   Ensure that the modified configurations are in the valid JSON format.

2. Restart Logtail to apply the modified configurations.

```
/etc/init.d/ilogtaild stop
/etc/init.d/ilogtaild start
/etc/init.d/ilogtaild status
```

23.3.1.3. Logtail machine group

23.3.1.3.1. Overview

Log Service uses machine groups to manage the servers from which you want to collect logs by using Logtail.

A machine group is a virtual group that contains multiple servers. If you want to use a Logtail configuration file to collect logs from multiple servers, you can add the servers to a machine group. Then, you can apply the Logtail configuration file to the machine group.

To define a machine group, you can use one of the following methods:

- IP address: Add the IP addresses of all servers to a machine group. Each server can be identified by using its unique IP address.
- Custom ID: Use a custom ID to identify the machine group and use the same ID for servers in the machine group.

> **Note** Windows and Linux servers cannot be added to the same machine group.

IP address-based machine groups

You can add multiple servers to a machine group by adding their IP addresses to the machine group. Then, you can create a Logtail configuration file for all the servers at the same time.

- If you use ECS instances and have not associated them with hostnames or changed their network types, you can add their private IP addresses to the machine group.

- In other cases, you must add the server IP addresses obtained by Logtail to a machine group. The IP address of each server is recorded in the IP address field of the *app_info.json* file on the server.

  > **Note** The *app_info.json* file records the internal information of Logtail. This file includes the server IP addresses obtained by Logtail. If you modify the IP address field of the file, the IP addresses obtained by Logtail remain unchanged.

Logtail obtains a server IP address by using the following methods:

- If the IP address of a server is associated with the hostname in the */etc/hosts* file of the server, Logtail obtains this IP address.
- If the IP address of a server is not associated with the hostname, Logtail obtains the IP address of the first network interface controller (NIC) on the server.

For more information, see Create an IP address-based server group.

Custom ID-based machine groups

You can use custom IDs to dynamically define machine groups.

An application system consists of multiple modules. You can scale out each module by adding multiple servers to the module. If you want to collect logs by module, you can create a machine group for each module. Therefore, you must specify a custom ID for each server in each module. For example, a website consists of an HTTP request processing module, a caching module, a logic processing module, and a storage module. The custom IDs of these modules can be http_module, cache_module, logic_module, and store_module.

For more information, see Create a machine group based on a custom ID.

23.3.1.3.2. Create a machine group based on a server IP address

This topic describes how to create a machine group based on a server IP address. You can create a machine group based on a server IP address that is obtained by using a Logtail configuration file. You can then use the same Logtail configuration file to collect logs from the machine group.

Prerequisites

- A project is created. A Logstore is created in the project.
- One or more servers are available. The IP addresses of the servers are obtained.
- Logtail is installed on the servers. For more information, see Install Logtail in Linux or Install Logtail in Windows.
- The ID of your Apsara Stack tenant account is configured on the server. For more information, see Configure an account ID for a server.

Procedure

1. Log on to the Log Service console.
2. In the **Projects** section, click the name of a project.
3. In the left-side navigation pane, click the **Machine Groups** icon.
4. In the pane that appears, click the icon next to **Machine Group** and select **Create Machine Group** from the shortcut menu.

   You can also create a machine group in the Logtail configuration wizard.
5. Create a machine group.

i. Enter a machine group name in the **name** field.

The machine group name must be 3 to 128 characters in length and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit.

> **Notice** After the machine group is created, its name cannot be modified.

ii. Select **IP Addresses** from the **Identifier** drop-down list.

iii. Enter a topic name in the **Topic** field.

For more information about topics, see Generate a topic.

iv. Enter the IP addresses of the servers in the **IP Addresses** text box.

> **Notice**
> - Separate each IP address with a line break.
> - Do not add Windows servers and Linux servers to the same machine group.

6. Click **OK**.

Result

You can view the created machine group in the **Machine Groups** pane.

23.3.1.3.3. Create a machine group based on a custom ID

This topic describes how to create a machine group based on a custom ID.

Context

You can use a custom ID to identify a machine group in the following scenarios:

- Servers reside in multiple custom network environments such as virtual private clouds (VPCs). IP addresses of different servers may be the same. In this scenario, Log Service cannot distinguish between servers based on IP addresses.
- You want to implement automatic server discovery. To do this, you only need to set a custom ID of a new server to the custom ID of an existing machine group. Log Service automatically identifies the server and adds it to the machine group.

Procedure

1. Set a custom ID on a server.
   - **Linux Logtail**

     Set a custom ID in the `/etc/ilogtail/user_defined_id` file.

     For example, if you need to set a custom ID of a server to `userdefined`, run the following command to open the file:

     ```
     # vim /etc/ilogtail/user_defined_id
     ```

     In the file, enter `userdefined`.
   - **Windows Logtail**

Set a custom ID in the `C:\LogtailData\user_defined_id` file.

For example, if you need to set a custom ID of a server, run the following command:

```
C:\LogtailData>more user_defined_id
userdefined_windows
```

Notice

- A machine group cannot include both Linux and Windows servers. Therefore, do not set a custom ID of a Linux server and a custom ID of a Windows server to the same value.
- You can set multiple custom IDs for a single server. Separate each custom ID with a line break.
- If the */etc/ilogtail/* or *C:\LogtailData* directory or the */etc/ilogtail/user_defined_id* or *C:\LogtailData\user_defined_id* file does not exist, create the directory or the file.

2. Create a machine group.
   i. Log on to the Log Service console.
   ii. In the **Projects** section, click a project.
   iii. In the left-side navigation pane, click the **Machine Groups** icon.
   iv. Click the icon next to **Machine Groups**, and select **Create Machine Group** from the shortcut menu.
   v. Set the parameters of the machine group.
      - **name**: Enter a machine group name.

        The machine group name must be 3 to 128 characters in length and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit.

        Note After the machine group is created, its name cannot be modified.

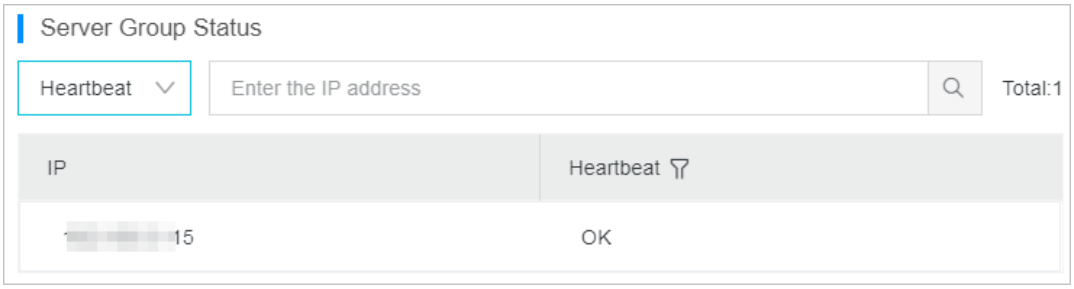
      - **Identifier**: Select **Custom ID**.
      - **Topic**: Enter a topic name for the machine group. For more information, see Generate a topic.
      - **Custom Identifier**: Enter the custom ID that you set in Step 1.

   vi. Click **OK**.

Note If you need to add a server to the machine group, set a custom ID of the server to the custom ID of the machine group. The server is then listed in the **Machine Group Status** section.

3. View the status of the machine group.

In the **Machine Groups** pane, click the name of the machine group. On the **Machine Group Settings** page, view the status of the machine group. You can view the IP address list of the servers in the machine group and their heartbeat status.



Note

- The **Machine Group Status** section lists the IP addresses of the servers whose custom ID is the same as the custom ID that you set for the machine group.

  For example, the custom ID of a machine group is userdefined and the IP addresses in the **Machine Group Status** section are 10.10.10.10, 10.10.10.11, and 10.10.10.12. This means that the custom ID userdefined is set for the three servers. If you need to add the server whose IP address is 10.10.10.13 to the machine group, set the custom ID userdefined for the server. Then, the IP address of the server is displayed in the **Machine Group Status** section. Log Service collects logs from the server based on the Logtail configuration file of the machine group.
- The heartbeat status indicates whether the connection between a server and Log Service is normal. For information about how to troubleshoot heartbeat errors, see What can I do if no heartbeat packet is received from a Logtail client?

Delete the custom IDs of a server

If you need to change the ID of a server from a custom ID to the server IP address, delete the user_defined_id file. The change takes effect within 1 minute.

- In Linux, run the following command to delete the file:

```
rm -f /etc/ilogtail/user_defined_id
```

- In Windows, run the following command to delete the file:

```
del C:\LogtailData\user_defined_id
```

Time required for a change to take effect

After you create, edit, or delete a user_defined_id file, the change takes effect within 1 minute.

If you need the change to take immediate effect, restart Logtail.

- In Linux, run the following commands to restart Logtail:

```
/etc/init.d/ilogtaild stop
/etc/init.d/ilogtaild start
```

- In Windows, perform the following steps to restart Logtail:

  Open the Control Panel. In the window that appears, choose **Control Panel > Administrative Tools > Services**. Right-click **LogtailWorker**, and select **Restart** from the shortcut menu.

Example

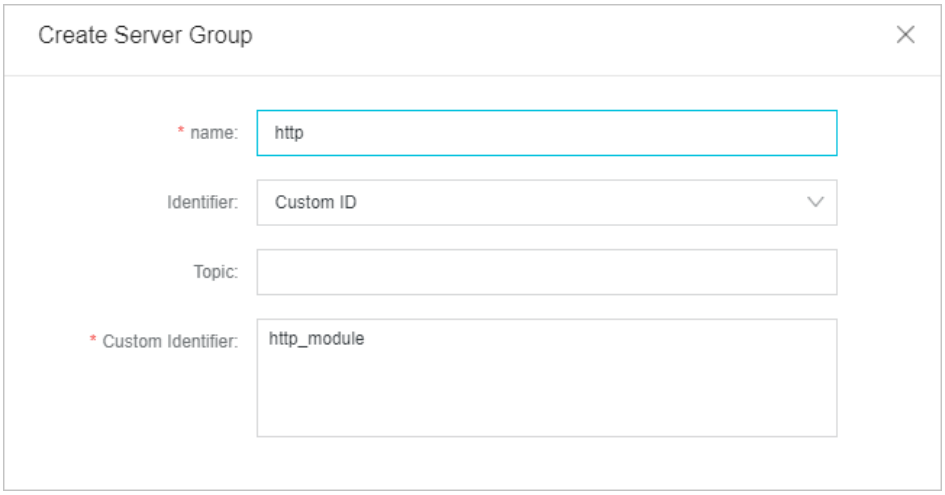
An application consists of multiple modules. Each module runs on multiple servers. For example, a website consists of an HTTP request processor, a cache, a logic processor, and a storage. You may scale out each module by adding multiple servers. You need to collect logs from both the existing and new servers.

1. Set a custom ID for each server.

   Install Logtail on the servers and set a custom ID for each server. In this example, you can use four custom IDs: http_module, cache_module, logic_module, and store_module. Each custom ID corresponds to a module.

2. Create a machine group for each module.

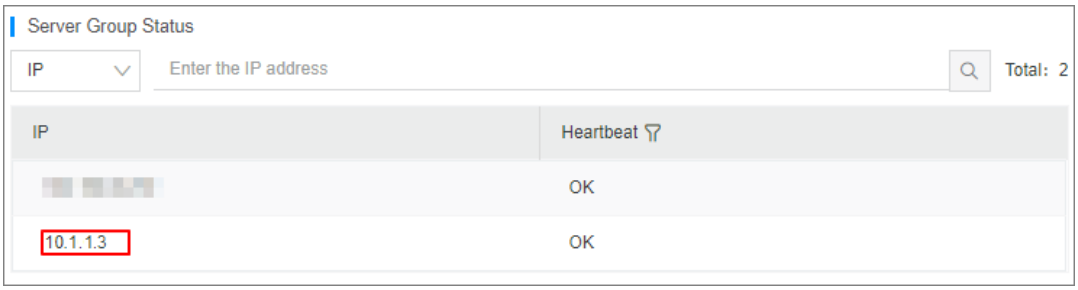
   When you create a machine group for a module, enter the custom ID of the module in the **Custom Identifier** field.



3. View the status of the machine group.

   On the **Machine Group Settings** page of the machine group, you can view the status of the machine group in the **Machine Group Status** section. You can view the list of servers in the machine group and their heartbeat status.

4. If you need to add a server whose IP address is 10.1.1.3 to the machine group whose custom ID is http_module, set the custom ID http_module for the server. Then, you can view the server in the **Machine Group Status** section.



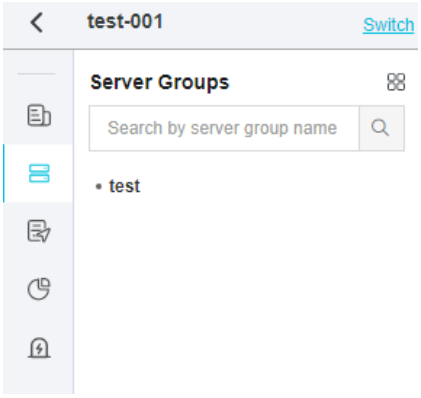
23.3.1.3.4. View server groups

This topic describes how to view the server groups of a project on the **Server Groups** page in the Log Service console.

Procedure

1. Log on to the Log Service console.
2. Find the target project in the project list and click the project name.
3. In the left-side navigation pane of the page that appears, click the **Server Groups** icon to display the list of server groups.

You can view all server groups of the project.



23.3.1.3.5. Modify a server group

This topic describes how to modify a server group in the Log Service console. After you create a server group, you can modify the parameters of the server group.

Procedure

1. Log on to the Log Service console.
2. Find the target project in the project list and click the project name.
3. In the left-side navigation pane of the page that appears, click the **Server Groups** icon to display the list of server groups.
4. Click the name of the server group to be modified. On the **Server Group Settings** page, click **Modify**.

   > **Note** The name of the server group cannot be modified.

5. Modify the parameters of the server group, and then click **Save**.

23.3.1.3.6. View the status of a server group

This topic describes how to view the status of a server group in the Log Service console. You can view the heartbeat information of Logtail to check whether Logtail is installed on the servers in a server group.

Procedure

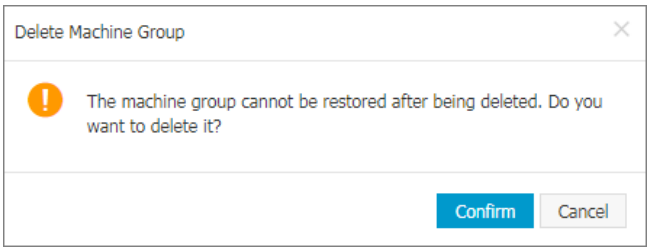
1. Log on to the Log Service console.
2. Find the target project in the project list and click the project name.
3. In the left-side navigation pane of the page that appears, click the **Server Groups** icon to display the list of server groups.
4. Click the name of the server group. On the **Server Group Settings** page, check the server group status.
   - If the heartbeat is OK, Logtail is installed on the servers in the server group and Logtail is connected to Log Service.
   - If the heartbeat status is FAIL, Logtail fails to connect to Log Service. If the FAIL state persists, perform troubleshooting based on the instructions provided in What can I do if no heartbeat packet is received from a Logtail client?

23.3.1.3.7. Delete a server group

This topic describes how to delete a server group in the Log Service console. You can delete a server group if you no longer need to collect logs from the server group.

Procedure

1. Log on to the Log Service console.
2. Find the target project in the project list and click the project name.
3. In the left-side navigation pane of the page that appears, click the **Server Groups** icon to display the list of server groups.
4. Find the server group that you want to delete, click the icon next to the server group, and then select **Delete**.
5. In the dialog box that appears, click **OK**.



23.3.1.3.8. Manage server group configurations

This topic describes how to manage server group configurations in the Log Service console. Log Service uses server groups to manage the servers from which you collect logs by using Logtail. In the Log Service console, you can create, view, modify, and delete server groups. You can also view the status of server groups, manage server group configurations, and apply server group identifiers.

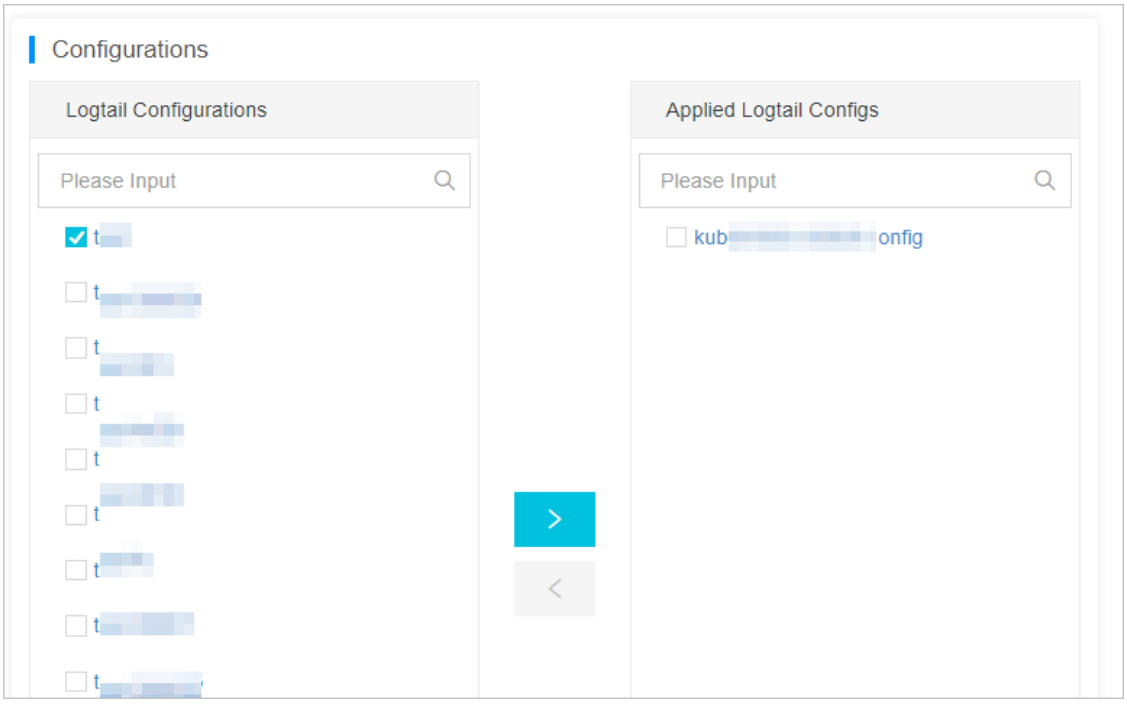
Context

Log Service allows you to manage the Logtail configurations that you create for Logtail installed on the servers in a server group. You can apply Logtail configurations to a server group. The Logtail configurations determine what logs are collected on each server, how the logs are parsed, and which Logstore the logs are written to.

Procedure

1. Log on to the Log Service console.
2. Find the target project in the project list and click the project name.
3. In the left-side navigation pane of the page that appears, click the **Server Groups** icon to display the list of server groups.
4. Click the name of the server group whose configurations you want to modify. On the **Server Group Settings** page, click **Modify**.
5. In the **Configurations** section, modify the Logtail configuration that you want to apply to the server group and click **Save**.

   After a Logtail configuration is added, it is delivered to Logtail on each server in the server group. After a Logtail configuration is removed, it is removed from Logtail.



23.3.1.3.9. Manage a Logtail configuration

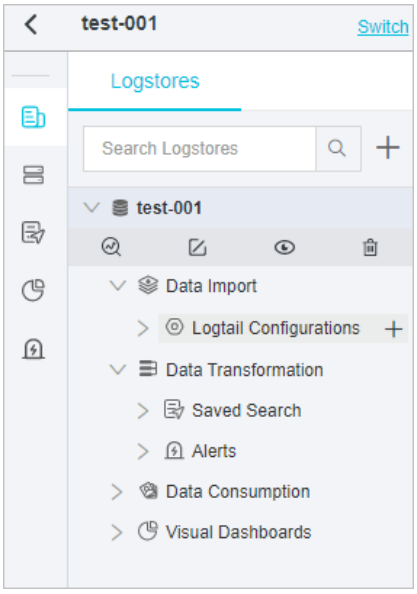
This topic describes how to manage a Logtail configuration in the Log Service console. Before you can collect logs from a server, you must install Logtail on the server. After you install Logtail, you must create a Logtail configuration in the Log Service console and apply the Logtail configuration to the server. You can create and modify Logtail configurations in Logstores.

Create a Logtail configuration

For information about how to create a Logtail configuration in the Log Service console, see Configure text log collection.

View Logtail configurations

1. Log on to the Log Service console.
2. Find the target project in the project list and click the project name.
3. In the left-side navigation pane, click the closing angle bracket (>) next to the target Logstore and choose **Data Import > Logtail Configurations**. Each item under **Logtail Configurations** indicates a Logtail configuration.



Modify a Logtail configuration

Under **Logtail Configurations**, click the name of the Logtail configuration. On the **Logtail Config** page, click **Modify**.

You can also change the log collection mode of the Logtail configuration, and then apply the Logtail configuration to the server group again. The process of modifying a Logtail configuration is the same as the process of creating a Logtail configuration.

Delete a Logtail configuration

Click the icon next to the Logtail configuration, and then select **Delete**.

After the Logtail configuration is deleted, it is disassociated from the server group. Logtail no longer collects logs specified by the Logtail configuration.

23.3.1.3.10. Configure an account ID on a server

This topic describes how to configure the ID of an Apsara Stack tenant account on a server.

Prerequisites

Logtail is installed on the server. For more information, see Install Logtail in Linux or Install Logtail in Windows.

Context

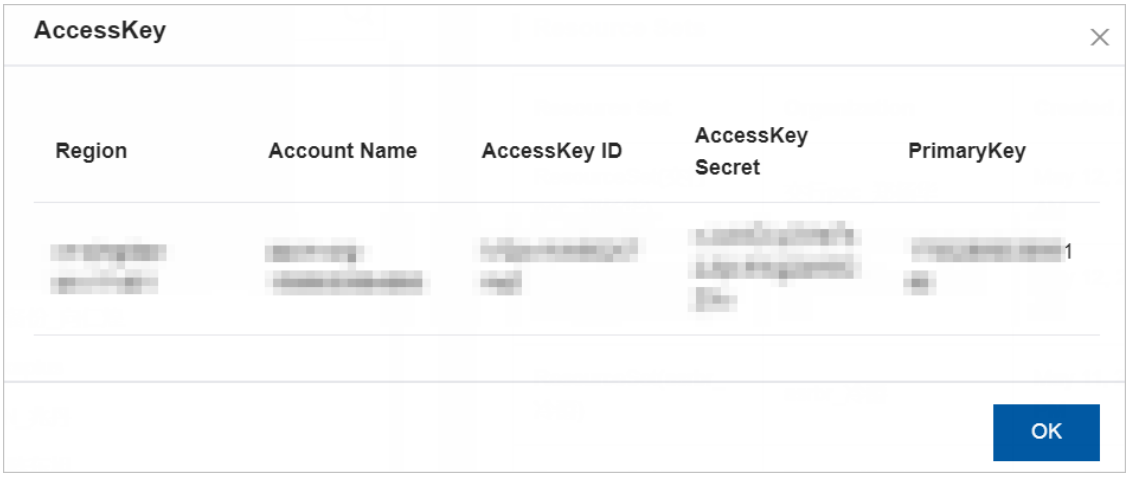
You must configure the ID if the server is an on-premises server or an ECS instance that belong to another Apsara Stack tenant account. You must also configure the ID if the server is a cloud server that is provided by a third-party vendor. Then, the Apsara Stack tenant account can use Logtail to collect logs from the server. If you do not configure the account ID on the server, Log Service cannot receive the heartbeat of the server and Logtail cannot collect logs from the server.

Procedure

1. View the ID of your Apsara Stack tenant account.
   i. Log on to the Apsara Uni-manager Management Console.
      For more information, see Log on to the Log Service console.
   ii. In the top navigation bar, click **Enterprise**.
   iii. In the left-side navigation pane, click **Organizations**.

iv. Select the destination account and click **Obtain an accesskey**

v. In the **AccessKey** dialog box, view the account ID.



2. Log on to the server and configure the account ID on the server.
   - Linux server:

     In the */etc/ilogtail/users* directory, create a file. Set the name of the file to the account ID. If the directory does not exist, create the directory first. You can configure multiple account IDs for a server. Examples:

     ```
     touch /etc/ilogtail/users/1**************
     touch /etc/ilogtail/users/1**************
     ```

     If you no longer need to collect logs from the server to a Log Service project, run the following command to delete the account ID:

     ```
     rm /etc/ilogtail/users/1**************
     ```

   - Windows server:

     In the *C:\LogtailData\users* directory, create a file. Set the name of the file to the account ID. To delete the account ID, delete the file.

     For example, you can delete the file of an account ID from the *C:\LogtailData\users\1*********** directory.

     > **Note**
     > - After you configure the ID of an Apsara Stack tenant account on a server, the account is authorized to use Logtail to collect logs from the server. If an account is no longer used to collect logs from the server, delete the account ID file from the server at the earliest opportunity.
     > - After you configure or delete an account ID, the change takes effect within 1 minute.

23.3.1.4. Text logs

23.3.1.4.1. Configure text log collection

This topic describes how to configure Logtail in the Log Service console to collect text logs from specified servers.

Prerequisites

Logtail is installed. Logtail can be installed on a Windows or Linux operating system. For more information, see Install Logtail in Linux and Install Logtail in Windows.

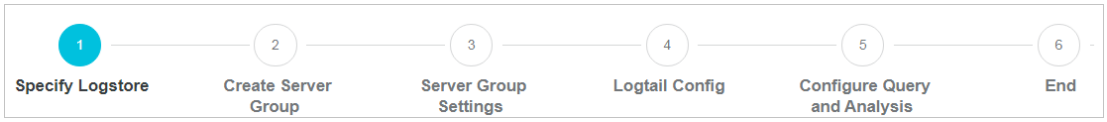
Limits

- Each log file can be collected by using only one Logtail configuration. If you want to collect a log file by using more than one Logtail configuration, we recommend that you use symbolic links. For example, to collect a log file by using two Logtail configurations in the `/home/log/nginx/log` directory, you can use the original log path for one Logtail configuration. Then, run the `ln -s /home/log/nginx/log /home/log/nginx/link_log` command to create a symbolic link for this directory and use the symbolic link as the log path for the other Logtail configuration.
- Logtail supports only Windows or Linux operating systems. For more information, see Logtail overview.

Logtail configuration procedure

You can specify Logtail configurations in the Log Service console. Logtail supports various collection modes, such as simple mode, NGINX configuration mode, Apache configuration mode, IIS configuration mode, delimiter mode, JSON mode, and full regex mode.

Configuration procedure



Collection modes

Logtail supports various collection modes, such as simple mode, NGINX configuration mode, Apache configuration mode, IIS configuration mode, delimiter mode, JSON mode, and full regex mode.

- Simple mode

  Logtail can be used to collect logs in the simple mode. For more information, see Collect logs by line.

- Full regex mode

  Logtail can be used to collect logs in the full regex mode. For more information, see Use regular expressions to collect logs.

- Delimiter mode

  Logtail can be used to collect logs in the delimiter mode. For more information, see Collect DSV formatted logs.

- JSON mode

  Logtail can be used to collect logs in the JSON mode. For more information, see Collect JSON logs.

- NGINX configuration mode

  Logtail can be used to collect logs in the NGINX configuration mode. For more information, see Collect NGINX logs.

- IIS configuration mode

  Logtail can be used to collect logs in the IIS configuration mode. For more information, see Collect IIS logs.

- Apache configuration mode

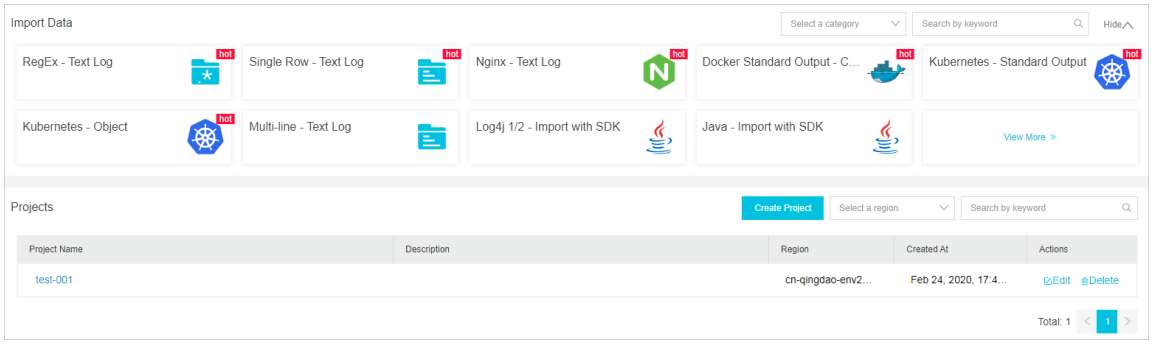
  Logtail can be used to collect logs in the Apache configuration mode. For more information, see Collect Apache logs.

Procedure

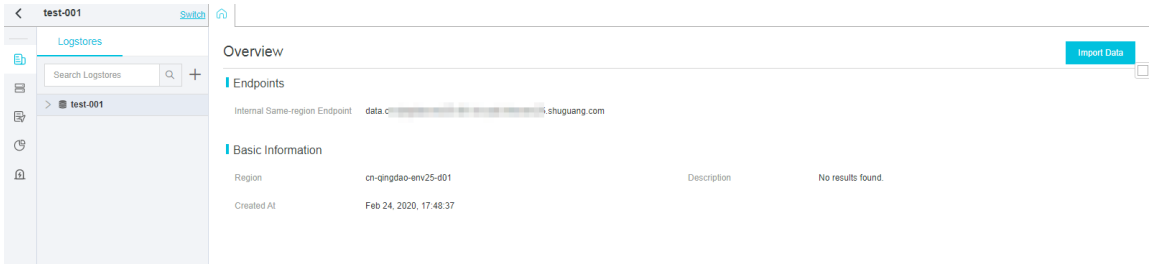
1. Log on to the Log Service console.
2. Select a data source.

   You can use one of the following three methods to select a data source:

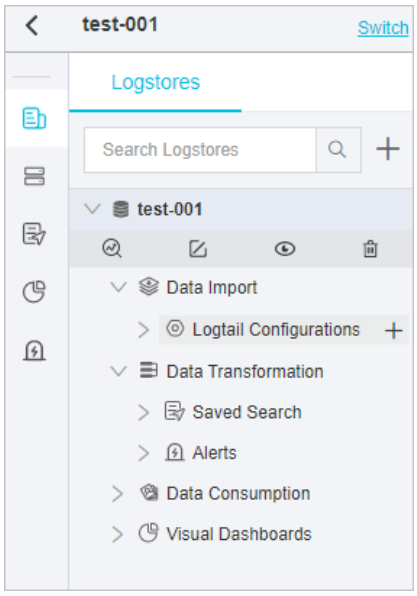
   - On the homepage of the Log Service console, select a data source in the **Import Data** section.



- In the **Projects** section, click a project name. On the **Overview** page, click **Import Data**.



- On the Logstores tab in the left-side navigation pane, find a Logstore and click the closing angle bracket (>) in front of the Logstore name. Then, click the plus sign (+) next to **Data Import**.



Select a data source based on your business requirements. Log Service supports the following log sources of text logs: **RegEx-Text Log**, **Single Row-Text Log**, **Multi-Row-Text Log**, **Delimiter Mode-Text Log**, **JSON-Text Log**, **Nginx-Text Log**, **IIS-Text Log**, and **Apache-Text Log**.

3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.

4. Create a server group.

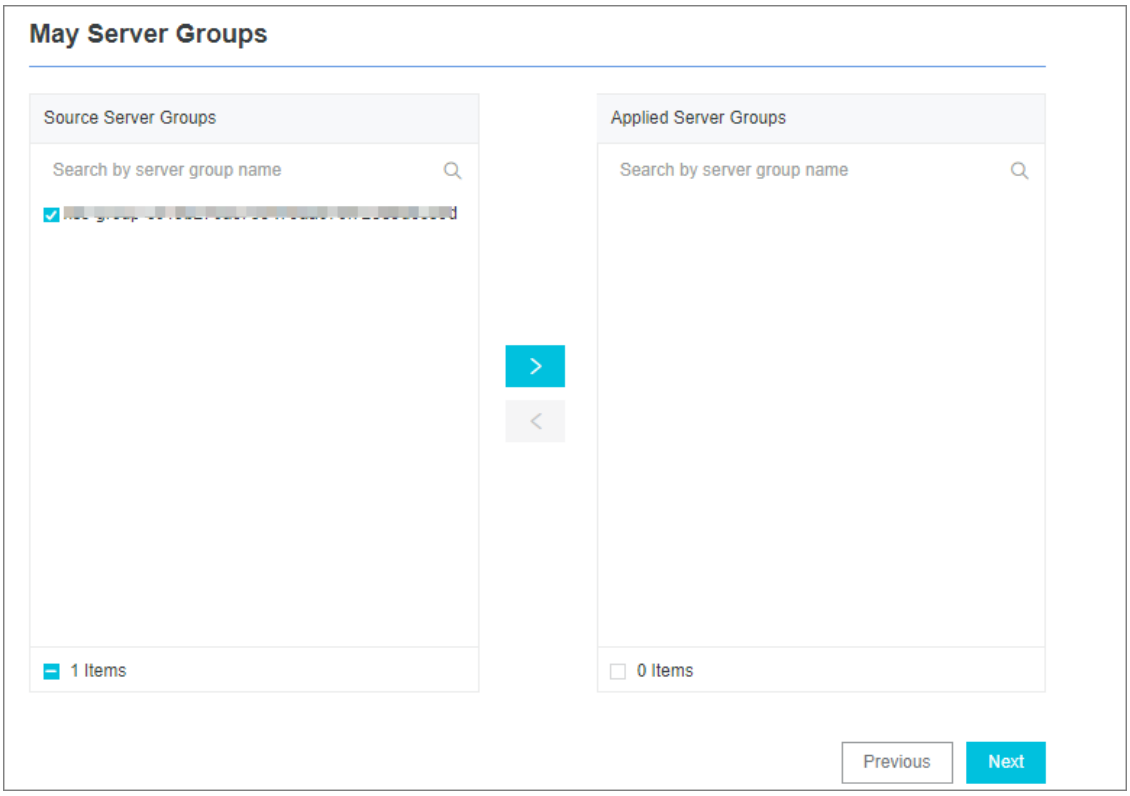
   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.

5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Specify Logtail parameters.

   Logtail parameters vary based on collection modes. For more information, see the relevant parameters for specific collection modes.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Specify **Advanced Options** based on your business requirements. We recommend that you do not modify the default settings unless otherwise required.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs.
Upload Raw Log	Specifies whether to upload raw logs. If you turn on this switch, raw logs are written to the __raw__ field and uploaded with the parsed logs.
Topic Generation Mode	◦ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic is set to an empty string and you can query logs without the need to enter a topic. ◦ **Server Group Topic Attributes**: This mode is used to differentiate log data that is generated by different frontend servers. ◦ **File Path RegEx**: If you select this mode, you must enter a value in the **Custom RegEx** field to extract part of the path as the topic. This mode is used to differentiate log data that is generated by users or instances.

Parameter	Description
Custom RegEx	Specifies a custom regular expression. If you select **File Path RegEx** for **Topic Generation Mode**, you must enter a custom regular expression.
Log File Encoding	○ utf8: indicates UTF-8 encoding. ○ gbk: indicates GBK encoding.
Timezone	Specifies the time zone where logs are collected. ○ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ○ Custom: Select a time zone.
Timeout	If a log file is not updated within a specific period of time, Logtail considers the file to be timed out. ○ Never: All log files are continuously monitored and never time out. ○ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ○ Collect logs that meet a condition: Set the condition to `Key:level Regex:WARNING|ERROR`. It indicates that only logs with the severity level of WARNING or ERROR are collected. ○ Filter logs that do not meet a condition: ■ Set the condition to `Key:level Regex:^(?!.*(INFO|DEBUG)).*`. It indicates that logs with the severity level of INFO or DEBUG are not collected. ■ Set the condition to `Key:url Regex:.*^(?!.*(healthcheck)).*`. It indicates that logs whose URL contains the keyword healthcheck are not collected. For example, logs in which the key is url and the value is `/inner/healthcheck/jiankong.html` are not collected.

8. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

After you complete the settings, you can start to collect logs.

23.3.1.4.2. Collect logs by line

This topic describes how to collect logs by line and configure indexes. You can specify the required settings in the Log Service console.

Context

To collect logs by line, you must select the simple mode. The simple mode can be divided into two types:

- Singleline mode

  In this mode, each line of log data is considered as a log. Two logs in a log file are separated by a line break.

Logtail does not extract log fields in this mode. The default regular expression is `(.*)`. Logtail records the system time of the current server as the timestamp of a log. You can modify or manage advanced Logtail settings after you have completed the configuration procedure. For more information, see Manage a Logtail configuration.

- Multi-line mode

  In the multi-line mode, a regular expression is used to match the first line of a log. The settings in the multi-line mode are similar to the settings in the full regex mode. For more information, see Use regular expressions to collect logs.

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **Single Row-Text Log**.
3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

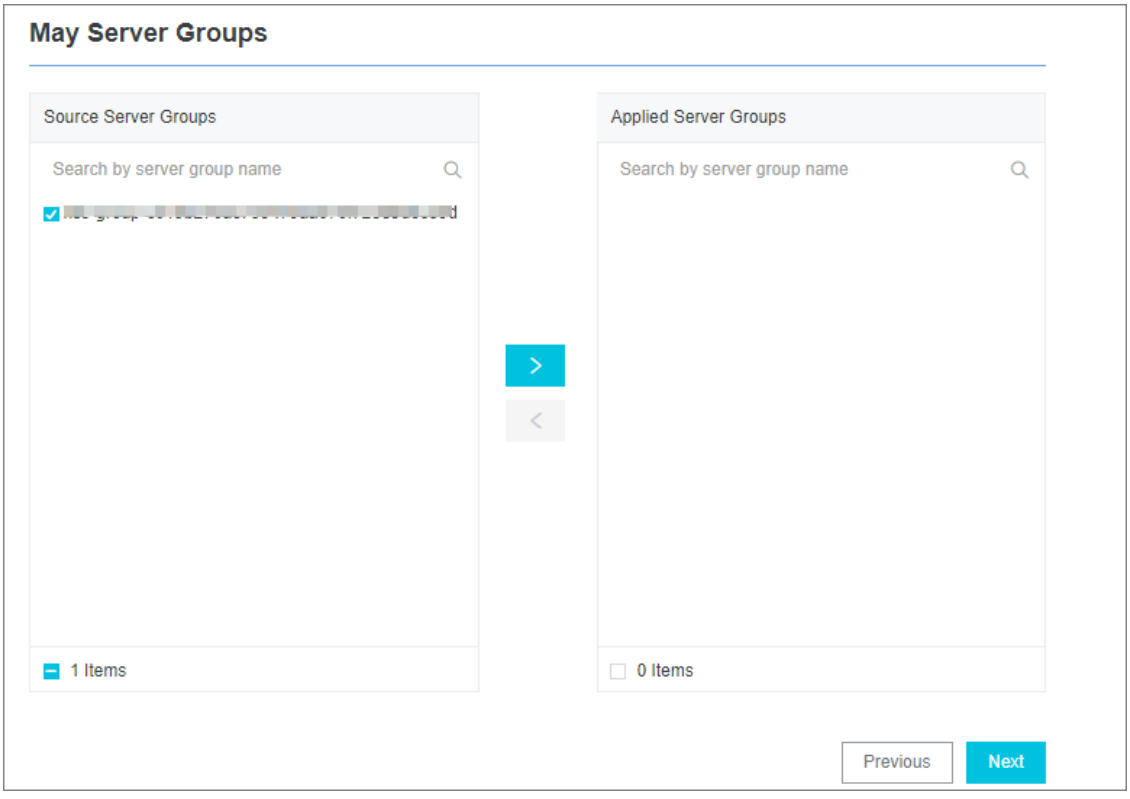
   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a server group.

   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.
5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Create a Logtail configuration.

   The following table lists the Logtail parameters.

Parameter	Description
Config Name	The configuration name must be 3 to 128 characters in length, and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.
Log Path	The directory and name of the log file. ○ The specified log file name can be a complete file name or a file name that contains wildcards. ○ Recursive directory matching is used in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ■ Example 1: `/apsara/nuwa/···/*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ■ Example 2: `/var/logs/app_*···/*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ■ Each log file can be collected by using only one Logtail configuration. ■ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If the log file to be collected is in a Docker container, you can configure the internal path and container tag. Logtail monitors the creation and destruction of the container, filters logs of the container based on the tag, and collects the filtered logs.
Mode	If you have specified **Single Row-Text Log** for the data source, the default mode is **Simple Mode**. You can change the mode.
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory that is specified in the log path is monitored.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Specify **Advanced Options** based on your business requirements. We recommend that you do not modify the default settings unless otherwise required.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs.

Parameter	Description
Upload Raw Log	Specifies whether to upload raw logs. If you turn on this switch, raw logs are written to the __raw__ field and uploaded with the parsed logs.
Topic Generation Mode	◦ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic is set to an empty string and you can query logs without the need to enter a topic. ◦ **Server Group Topic Attributes**: This mode is used to differentiate log data that is generated by different frontend servers. ◦ **File Path RegEx**: If you select this mode, you must enter a value in the **Custom RegEx** field to extract part of the path as the topic. This mode is used to differentiate log data that is generated by users or instances.
Custom RegEx	Specifies a custom regular expression. If you select **File Path RegEx** for **Topic Generation Mode**, you must enter a custom regular expression.
Log File Encoding	◦ utf8: indicates UTF-8 encoding. ◦ gbk: indicates GBK encoding.
Timezone	Specifies the time zone where logs are collected. ◦ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ◦ Custom: Select a time zone.
Timeout	If a log file is not updated within a specific period of time, Logtail considers the file to be timed out. ◦ Never: All log files are continuously monitored and never time out. ◦ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ◦ Collect logs that meet a condition: Set the condition to `Key:level Regex:WARNING|ERROR`. It indicates that only logs with the severity level of WARNING or ERROR are collected. ◦ Filter logs that do not meet a condition: ▪ Set the condition to `Key:level Regex:^(?!.*(INFO|DEBUG)).*`. It indicates that logs with the severity level of INFO or DEBUG are not collected. ▪ Set the condition to `Key:url Regex:.*^(?!.*(healthcheck)).*`. It indicates that logs whose URL contains the keyword healthcheck are not collected. For example, logs in which the key is url and the value is `/inner/healthcheck/jiankong.html` are not collected.

8. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

After you complete the settings, you can start to collect logs by line.

23.3.1.4.3. Use regular expressions to collect logs

This topic describes how to collect logs by using regular expressions and configure indexes. You can specify the required settings in the Log Service console.

Context

If you need to collect multi-line logs and extract fields from logs, we recommend that you use regular expressions. Log Service can generate a regular expression based on a sample log that you enter in the **Import Data** wizard. However, you must modify the expression to match fields in the sample log as expected. For more information, see How do I test a regular expression?.

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **RegEx-Text Log**.
3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

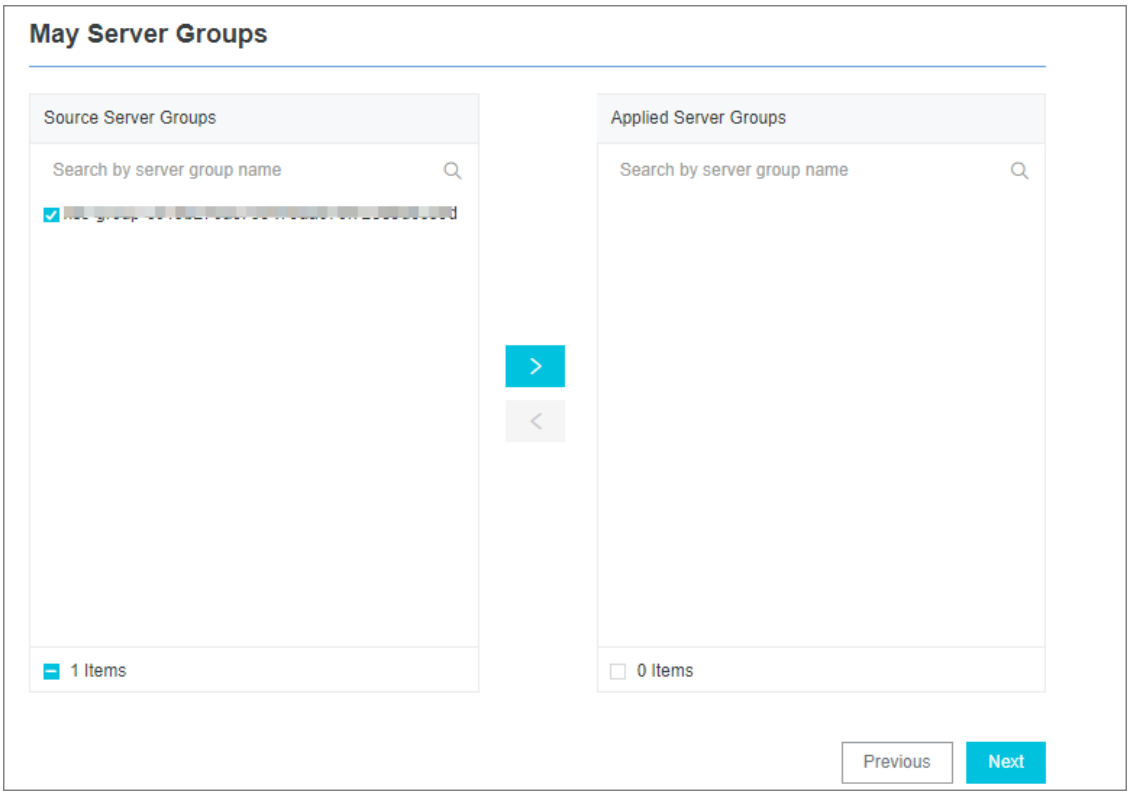
   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a server group.

   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.
5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Create a Logtail configuration.

The following table lists the Logtail parameters.

Parameter	Description
Config Name	The configuration name must be 3 to 128 characters in length, and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.
Log Path	The directory and name of the log file. ○ The specified log file name can be a complete file name or a file name that contains wildcards. ○ Recursive directory matching is used in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ■ Example 1: `/apsara/nuwa/···/*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ■ Example 2: `/var/logs/app_*···/*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ■ Each log file can be collected by using only one Logtail configuration. ■ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If the log file to be collected is in a Docker container, you can configure the internal path and container tag. Logtail monitors the creation and destruction of the container, filters logs of the container based on the tag, and collects the filtered logs.
Mode	If you have specified **RegEx-Text Log** for the data source, the default mode is **Full Regex Mode**. You can change the mode.
Singleline	The singleline mode is enabled by default. In this mode, logs are separated by line. To collect multi-line logs, such as Java program logs, you must disable the **Singleline** mode and configure **Regex to Match First Line**.
Log Sample	Enter a sample log that is retrieved from the data source. Then, Log Service generates a regular expression.
Regex to Match First Line	You can click **Auto Generate** or **Manual**. After you enter a sample log entry and click **Auto Generate**, the system generates a regular expression. If no regular expression is generated, you can switch to the manual mode and enter a regular expression for verification.

Parameter	Description
Extract Field	To analyze and process specific fields in logs, you can turn on the **Extract Field** switch. Then, the specified fields are converted to key-value pairs and sent to Log Service. You must specify a regular expression to parse the log content.
RegEx	If you turn on the Extract Field switch, you must specify this setting. ○ Automatically generate a regular expression You can select the fields to be extracted from the sample log and then click Generate Regular Expression. The system generates a regular expression. ○ Enter a regular expression You can also enter a regular expression. Click **Manually** to switch to the manual mode. After you enter a regular expression, click **Validate** to check whether the regular expression can parse the log content. For more information, see How do I test a regular expression?.
Extracted Content	If you turn on the **Extract Field** switch, you must specify this setting. After a regular expression is automatically generated or manually specified, you must specify the key name for each extracted field.
Use System Time	If you turn on the **Extract Field** switch, you must specify this setting. If you turn off the **Use System Time** switch, you must specify a field as the time field and name this field `time`. After you specify the `time` field, click **Auto Generate** in the **Time Conversion Format** field to automatically parse the time. For more information, see Configure the time format.
Drop Failed to Parse Logs	Specifies whether to upload logs to Log Service if the logs fail to be parsed. ○ If you turn on this switch, logs that fail to be parsed are not uploaded to Log Service. ○ If you turn off this switch, raw logs are uploaded to Log Service when logs fail to be parsed.
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory specified in the log path is monitored.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Specify **Advanced Options** based on your business requirements. We recommend that you do not modify the default settings unless otherwise required.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs.
Upload Raw Log	Specifies whether to upload raw logs. If you turn on this switch, raw logs are written to the __raw__ field and uploaded with the parsed logs.

Parameter	Description
Topic Generation Mode	◦ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic is set to an empty string and you can query logs without the need to enter a topic. ◦ **Server Group Topic Attributes**: This mode is used to differentiate log data that is generated by different frontend servers. ◦ **File Path RegEx**: If you select this mode, you must enter a value in the **Custom RegEx** field to extract part of the path as the topic. This mode is used to differentiate log data that is generated by users or instances.
Custom RegEx	Specifies a custom regular expression. If you select **File Path RegEx** for **Topic Generation Mode**, you must enter a custom regular expression.
Log File Encoding	◦ utf8: indicates UTF-8 encoding. ◦ gbk: indicates GBK encoding.
Timezone	Specifies the time zone where logs are collected. ◦ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ◦ Custom: Select a time zone.
Timeout	If a log file is not updated within a specific period of time, Logtail considers the file to be timed out. ◦ Never: All log files are continuously monitored and never time out. ◦ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ◦ Collect logs that meet a condition: Set the condition to `Key:level Regex:WARNING|ERROR`. It indicates that only logs with the severity level of WARNING or ERROR are collected. ◦ Filter logs that do not meet a condition: ▪ Set the condition to `Key:level Regex:^(?!.*(INFO|DEBUG)).*`. It indicates that logs with the severity level of INFO or DEBUG are not collected. ▪ Set the condition to `Key:url Regex:.*^(?!.*(healthcheck)).*`. It indicates that logs whose URL contains the keyword healthcheck are not collected. For example, logs in which the key is url and the value is `/inner/healthcheck/jiankong.html` are not collected.

8. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

After you complete the settings, you can start to use regular expressions to collect logs.

23.3.1.4.4. Collect DSV formatted logs

This topic describes how to collect delimiter-separated values (DSV) formatted logs and configure indexes. You can specify the required settings in the Log Service console.

Context

DSV formatted logs use line feeds as boundaries. Each line is a log entry. The fields of each log entry are separated with a fixed delimiter. The characters that can be used as delimiters include the tab (\t), space, vertical bar (|), comma (,), and semicolon (;). A field that contains a delimiter must be enclosed in double quotation marks (""), which are used as quotes.

Log formats

Common DSV formatted logs include comma-separated values (CSV) and tab-separated values (TSV) formatted logs.

A delimiter can contain a **single character** or **multiple characters**.

Single-character delimiter

You can specify a single-character delimiter and a quote in the console.

- **Delimiter**: The fields of each log entry are separated with a single-character delimiter, such as the tab (`\t`), vertical bar (`|`), space, comma (`,`), and semicolon (`;`). You can also specify a non-printable character as the delimiter.

  > **Note** A double quotation mark (`"`) cannot be used as a delimiter.

  If a double quotation mark (") is included in a log entry but not used as a quote, it must be escaped and processed as double quotation marks (`""`). When Log Service parse logs, it restores double quotation marks (`""`) into a double quotation mark (`"`). You can use a double quotation mark (`"`) on each boundary of a field as a quote. You can also use a double quotation mark (escaped as `""`) in the content of a field. If the use of a double quotation mark (") does not comply with the defined format, you can use the simple mode or full regex mode to parse fields.

  For example, assume that you use commas (,) as delimiters and include double quotation marks (“”) and commas (,)in a field. Enclose the field with quotes and escape the double quotation marks into `""` . For example, a processed log is `1999,Chevy,"Venture ""Extended Edition, Very Large""",,5000.00` . The log can be parsed into five fields: `1999` , `Chevy` , `Venture "Extended Edition, Very Large"` , empty field, and `5000.00` .

- **Quote**: If a log field contains delimiters, you must specify a quote to enclose the field. Otherwise, the field cannot be parsed as expected. Log Service parses the content enclosed in quotes as one field. Only delimiters can exist between fields.

  You can use one of the following characters as the quote: tab (`\t`), vertical bar (`|`), space, comma (`,`), semicolon (`;`), and non-printable characters.

  For example, a log is `1997,Ford,E350,"ac, abs, moon",3000.00` . In this example, the comma (`,`) is used as the delimiter and the double quotation mark (") is used as the quote. The log entry can be parsed into five fields: `1997` , `Ford` , `E350` , `ac, abs, moon` , and `3000.00` . Among the five fields, `ac, abs, moon` enclosed in quotes is regarded as one field.

> **Note** Log Service allows you to use a non-printable character as a delimiter or quote. Non-printable characters are characters whose decimal ASCII codes are within the range of 1 to 31 and 127. If you use a non-printable character as a delimiter or quote, you must find the hexadecimal ASCII code of this character and enter the character in the following format: `0x`*the hexadecimal ASCII code of the non-printable character* . For example, to use the non-printable character whose decimal ASCII code is 1 and hexadecimal ASCII code is 01, you must enter `0x01` .

Multi-character delimiter

Each **multi-character delimiter** can contain two or three characters, such as `||`, `&&&`, and `^_^`. If you specify a multi-character delimiter, Log Service parses logs only based on the delimiter. You do not need to use quotes to enclose log fields.

> **Note** You must ensure that log fields do not contain the delimiter. Otherwise, Log Service cannot parse these fields as expected.

For example, if the delimiter is set to `&&`, the log `1997&&Ford&&E350&&ac&abs&moon&&3000.00` is parsed into five fields: `1997`, `Ford`, `E350`, `ac&abs&moon`, and `3000.00`.

Sample logs

- **Single-character delimiter**

```
05/May/2016:13:30:28,10.10. *. *,"POST /PutData? Category=YunOsAccountOpLog&AccessKeyId=****************&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=******************************** HTTP/1.1",200,18204,aliyun-sdk-java
05/May/2016:13:31:23,10.10. *. *,"POST /PutData? Category=YunOsAccountOpLog&AccessKeyId=****************&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=******************************** HTTP/1.1",401,23472,aliyun-sdk-java
```

- **Multi-character delimiter**

```
05/May/2016:13:30:28&&10.200. **. **&&POST /PutData? Category=YunOsAccountOpLog&AccessKeyId=**************&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=pD12XYLmGxKQ%2Bmkd6x7hAgQ7b1c%3D HTTP/1.1&&200&&18204&&aliyun-sdk-java
05/May/2016:13:31:23&&10.200. **. **&&POST /PutData? Category=YunOsAccountOpLog&AccessKeyId=**************&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=********************************* HTTP/1.1&&401&&23472&&aliyun-sdk-java
```

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **Delimiter-Text Log**.
3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

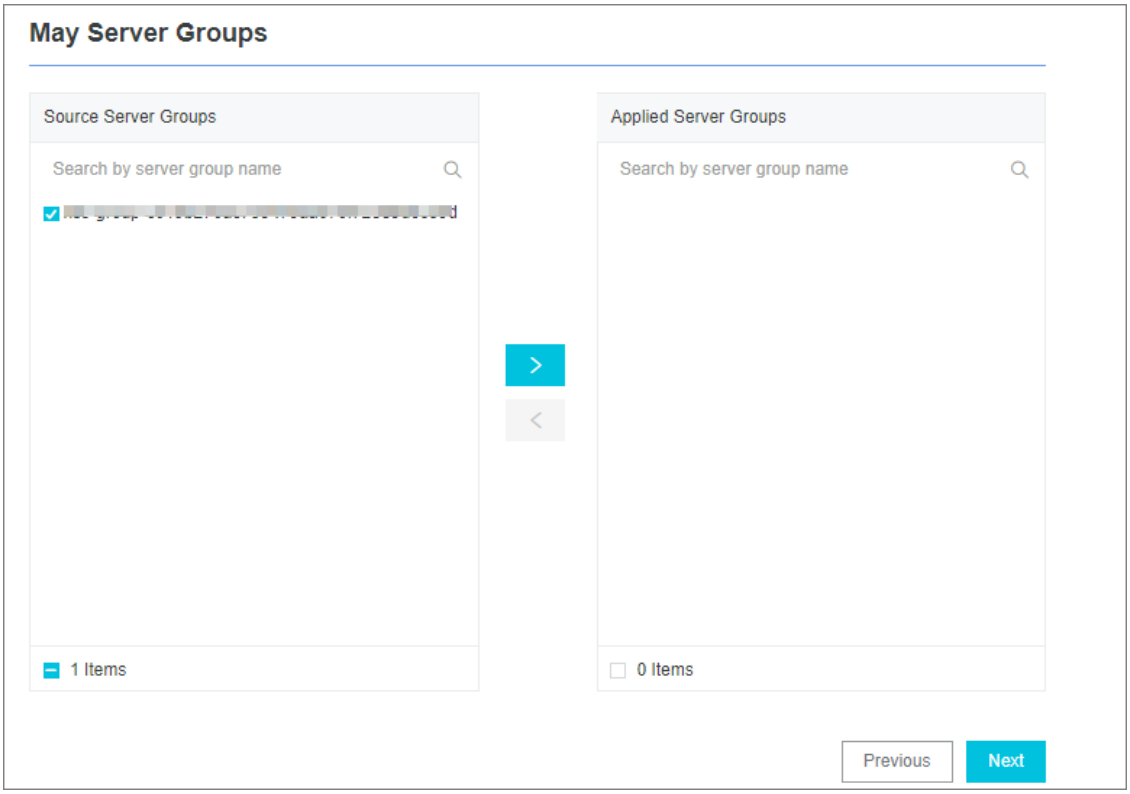
   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a server group.

   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.
5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Create a Logtail configuration file.

   The following table lists the Logtail parameters.

Parameter	Description
Config Name	The name must be 3 to 128 characters in length, and can contain only lowercase letters, digits, hyphens (-), and underscores (_). The name must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.

Parameter	Description
Log Path	The directory and name of the log file. ◦ The specified log file name can be a complete file name or a file name that contains wildcards. ◦ Recursive directory matching is used in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ■ Example 1: `/apsara/nuwa/ ··· /*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ■ Example 2: `/var/logs/app_* ··· /*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ■ Each log file can be collected by using only one Logtail configuration file. ■ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If you collect logs from Docker containers, you can configure the paths and tags of the containers. Logtail monitors the containers when they are created and destroyed, filters the logs of the containers by tag, and collects the filtered logs.
Mode	If you have specified **Delimiter-Text Log** for the data source, the default mode is **Delimiter Mode**. You can change the mode.
Log Sample	Enter a sample log entry that is retrieved from a log source in an actual scenario. Then, Log Service extracts a regular expression from the log entry.
Delimiter	Select a delimiter. Select a delimiter based on the log format. Otherwise, logs may fail to be parsed. **Note** If you use a non-printable character as a delimiter, you must find the hexadecimal ASCII code of this character and enter the character in the following format: `0x`*the hexadecimal ASCII code of the non-printable character* . For example, to use the non-printable character whose decimal ASCII code is 1 and hexadecimal ASCII code is 01, you must enter `0x01` .

Parameter	Description
Quote	Select a quote. Select a quote based on the log format. Otherwise, logs may fail to be parsed. **Note** If you use a non-printable character as a quote, you must find the hexadecimal ASCII code of this character and enter the character in the following format: `0x`*the hexadecimal ASCII code of the non-printable character*. For example, to use the non-printable character whose decimal ASCII code is 1 and hexadecimal ASCII code is 01, you must enter `0x01`.
Extracted Content	After you enter a sample log and select a delimiter, Log Service extracts log fields based on the delimiter and defines the fields as values. You must specify a key for each value.
Incomplete Entry Upload	This feature specifies whether to upload a log entry whose number of parsed fields is less than the number of the specified keys. If you turn on this switch, the log entry is uploaded. Otherwise, the log entry is dropped. For example, if you set the delimiter to the vertical bar (`|`), the log entry `11|22|33|44|55` can be parsed into the following fields: `11`, `22`, `33`, `44`, and `55`. You can set the keys to `A`, `B`, `C`, `D`, and `E`. If you turn on the **Incomplete Entry Upload** switch, the `55` field is uploaded as the value of the `D` key when Log Service collects the log entry `11|22|33|55`. If you turn off the **Incomplete Entry Upload** switch, Log Service drops the log entry because the fields and keys do not match.
Use System Time	If you turn on the Extract Field switch, you must specify this setting. If you turn off the Use System Time switch, you must specify a field as the time field and name this field `time`. After you specify the `time` field, click **Auto Generate** in the **Time Conversion Format** field to automatically parse the time. For more information, see Configure the time format.
Drop Failed to Parse Logs	Specifies whether to upload logs to Log Service if the logs fail to be parsed. ○ If you turn on this switch, logs that fail to be parsed are not uploaded to Log Service. ○ If you turn off this switch, raw logs are uploaded to Log Service when logs fail to be parsed.
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory that is specified in the log path is monitored.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Specify **Advanced Options** based on your business requirements. We recommend that you do not modify the default settings unless otherwise required.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs.

Parameter	Description
Upload Raw Log	Specifies whether to upload raw logs. If you turn on this switch, raw logs are written to the __raw__ field and uploaded with the parsed logs.
Topic Generation Mode	◦ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic is set to an empty string and you can query logs without the need to enter a topic. ◦ **Server Group Topic Attributes**: This mode is used to differentiate log data that is generated by different frontend servers. ◦ **File Path RegEx**: If you select this mode, you must enter a value in the **Custom RegEx** field to extract part of the path as the topic. This mode is used to differentiate log data that is generated by users or instances.
Custom RegEx	Specifies a custom regular expression. If you select **File Path RegEx** for **Topic Generation Mode**, you must enter a custom regular expression.
Log File Encoding	◦ utf8: indicates UTF-8 encoding. ◦ gbk: indicates GBK encoding.
Timezone	Specifies the time zone where logs are collected. ◦ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ◦ Custom: Select a time zone.
Timeout	If a log file is not updated within a specific period of time, Logtail considers the file to be timed out. ◦ Never: All log files are continuously monitored and never time out. ◦ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ◦ Collect logs that meet a condition: Set the condition to `Key:level Regex:WARNING|ERROR`. It indicates that only logs with the severity level of WARNING or ERROR are collected. ◦ Filter logs that do not meet a condition: ▪ Set the condition to `Key:level Regex:^(?!.*(INFO|DEBUG)).*`. It indicates that logs with the severity level of INFO or DEBUG are not collected. ▪ Set the condition to `Key:url Regex:.*^(?!.*(healthcheck)).*`. It indicates that logs whose URL contains the keyword healthcheck are not collected. For example, logs in which the key is url and the value is `/inner/healthcheck/jiankong.html` are not collected.

8. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

After you complete the settings, you can start to collect DSV formatted logs.

23.3.1.4.5. Collect JSON logs

This topic describes how to use Logtail to collect JSON logs and configure indexes. You can specify the required settings in the Log Service console.

Context

Logtail can parse JSON objects from logs. It extracts the keys and values from the first layer of an object as the names and values of log fields. The valid data types of field values include object, array, and primitive data types such as string or number.

JSON logs can be written in the following two types of structures:

- Object: a collection of key-value pairs.
- Array: an ordered list of values.

Lines of JSON logs are separated with `\n`. Each line is extracted as a single log.

Logtail can parse only JSON logs of the object type. If you want to parse JSON logs of other types, such as JSON arrays, you must use regular expressions to extract the fields or specify the simple mode to collect logs by line.

Sample log

A sample JSON log is as follows:

```
{"url": "POST /PutData? Category=YunOsAccountOpLog&AccessKeyId=U0Ujpek********&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=pD12XYLmGxKQ%2Bmkd6x7hAgQ7b1c%3D HTTP/1.1", "ip": "10.200.98.220", "user-agent": "aliyun-sdk-java", "request": {"status": "200", "latency": "18204"}, "time": "05/May/2016:13:30:28"}
{"url": "POST /PutData? Category=YunOsAccountOpLog&AccessKeyId=U0Ujpek********&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=pD12XYLmGxKQ%2Bmkd6x7hAgQ7b1c%3D HTTP/1.1", "ip": "10.200.98.210", "user-agent": "aliyun-sdk-java", "request": {"status": "200", "latency": "10204"}, "time": "05/May/2016:13:30:29"}
```

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **JSON-Text Log**.
3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

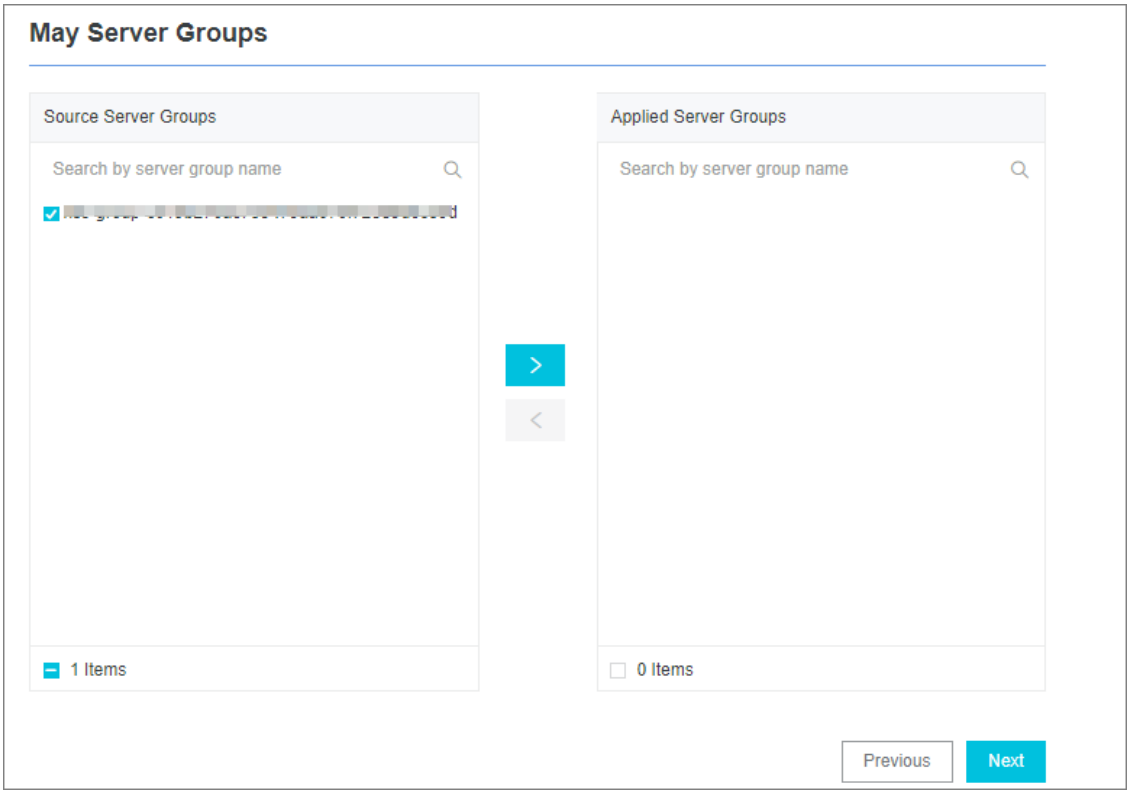
   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a server group.

   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.
5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Create a Logtail configuration.

   The following table lists the Logtail parameters.

Parameter	Description
Config Name	The configuration name must be 3 to 128 characters in length, and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.

Parameter	Description
Log Path	The directory and name of the log file. ◦ The specified log file name can be a complete file name or a file name that contains wildcards. ◦ Recursive directory matching is used in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ▪ Example 1: `/apsara/nuwa/ ··· /*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ▪ Example 2: `/var/logs/app_* ··· /*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ▪ Each log file can be collected by using only one Logtail configuration. ▪ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If the log file to be collected is in a Docker container, you can configure the internal path and container tag. Logtail monitors the creation and destruction of the container, filters logs of the container based on the tag, and collects the filtered logs.
Mode	If you have specified **JSON-Text Log** for the data source, the default mode is **JSON Mode**. You can change the mode.
Use System Time	If you turn on the Extract Field switch, you must specify this parameter. If you turn off the Use System Time switch, you must specify a field as the time field and name this field `time` . After you specify the `time` field, click **Auto Generate** in the **Time Conversion Format** field to automatically parse the time. For more information, see Configure the time format.
Drop Failed to Parse Logs	Specifies whether to upload logs to Log Service if the logs fail to be parsed. ◦ If you turn on this switch, logs that fail to be parsed are not uploaded to Log Service. ◦ If you turn off this switch, raw logs are uploaded to Log Service when logs fail to be parsed.
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory specified in the log path is monitored.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Specify **Advanced Options** based on your business requirements. We recommend that you do not modify the default settings unless otherwise required.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs.
Upload Raw Log	Specifies whether to upload raw logs. If you turn on this switch, raw logs are written to the __raw__ field and uploaded with the parsed logs.
Topic Generation Mode	◦ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic is set to an empty string and you can query logs without the need to enter a topic. ◦ **Server Group Topic Attributes**: This mode is used to differentiate log data that is generated by different frontend servers. ◦ **File Path RegEx**: If you select this mode, you must enter a value in the **Custom RegEx** field to extract part of the path as the topic. This mode is used to differentiate log data that is generated by users or instances.
Custom RegEx	Specifies a custom regular expression. If you select **File Path RegEx** for **Topic Generation Mode**, you must enter a custom regular expression.
Log File Encoding	◦ utf8: indicates UTF-8 encoding. ◦ gbk: indicates GBK encoding.
Timezone	Specifies the time zone where logs are collected. ◦ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ◦ Custom: Select a time zone.
Timeout	If a log file is not updated within a specific period of time, Logtail considers the file to be timed out. ◦ Never: All log files are continuously monitored and never time out. ◦ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ◦ Collect logs that meet a condition: Set the condition to `Key:level Regex:WARNING|ERROR`. It indicates that only logs with the severity level of WARNING or ERROR are collected. ◦ Filter logs that do not meet a condition: ▪ Set the condition to `Key:level Regex:^(?!.*(INFO|DEBUG)).*`. It indicates that logs with the severity level of INFO or DEBUG are not collected. ▪ Set the condition to `Key:url Regex:.*^(?!.*(healthcheck)).*`. It indicates that logs whose URL contains the keyword healthcheck are not collected. For example, logs in which the key is url and the value is `/inner/healthcheck/jiankong.html` are not collected.

8. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

After you complete the settings, you can start to collect JSON logs.

23.3.1.4.6. Collect NGINX logs

This topic describes how to collect NGINX logs and configure indexes. You can connect Log Service to NGINX and specify the required settings in the Log Service console.

Context

The NGINX log format and path are specified in the */etc/nginx/nginx.conf* configuration file.

NGINX log format

In the configuration file, the format of NGINX logs is defined as follows:

```
log_format main  '$remote_addr - $remote_user [$time_local] "$request" '
        '$request_time $request_length '
        '$status $body_bytes_sent "$http_referer" '
        '"$http_user_agent"';
```

The path of the log file is declared as follows. The "main" portion that follows the path indicates that logs are written in the preceding format.

```
access_log /var/logs/nginx/access.log main
```

Sample log

A sample NGINX log is as follows:

```
192.168.1.2 - - [10/Jul/2015:15:51:09 +0800] "GET /ubuntu.iso HTTP/1.0" 0.000 129 404 168 "-" "Wget/1.11.4 Red Hat modified"
```

NGINX log fields

Field	Description
remote_addr	The IP address of the client.
remote_user	The username of the client.
request	The URL and HTTP protocol of the request.
status	The status of the request.
body_bytes_sent	The number of bytes in the response that is returned to the client, excluding the size of the response header.
connection	The serial number of a connection.
connection_requests	The number of requests that are received from a connection.
msec	The time when the log is written. The time is measured in seconds, accurate to milliseconds.
pipe	Indicates whether the request is pipelined. If the request is pipelined, the field value is `p`. Otherwise, the field value is `.`.

Field	Description
http_referer	The URL of the web page linked to the resource that is being requested.
“http_user_agent”	The browser information of the client. The information must be enclosed by double quotation marks ("").
request_length	The length of the request. The length includes the request line, request header, and request body.
request_time	The time period for which the request is processed. The time period is measured in seconds, accurate to milliseconds. The time period starts when the first byte is read from the client and ends when the log is written after the last byte is sent to the client.
[$time_local]	The local time in the Common Log Format. The time must be enclosed by brackets [].

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **Nginx-Text Log**.
3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

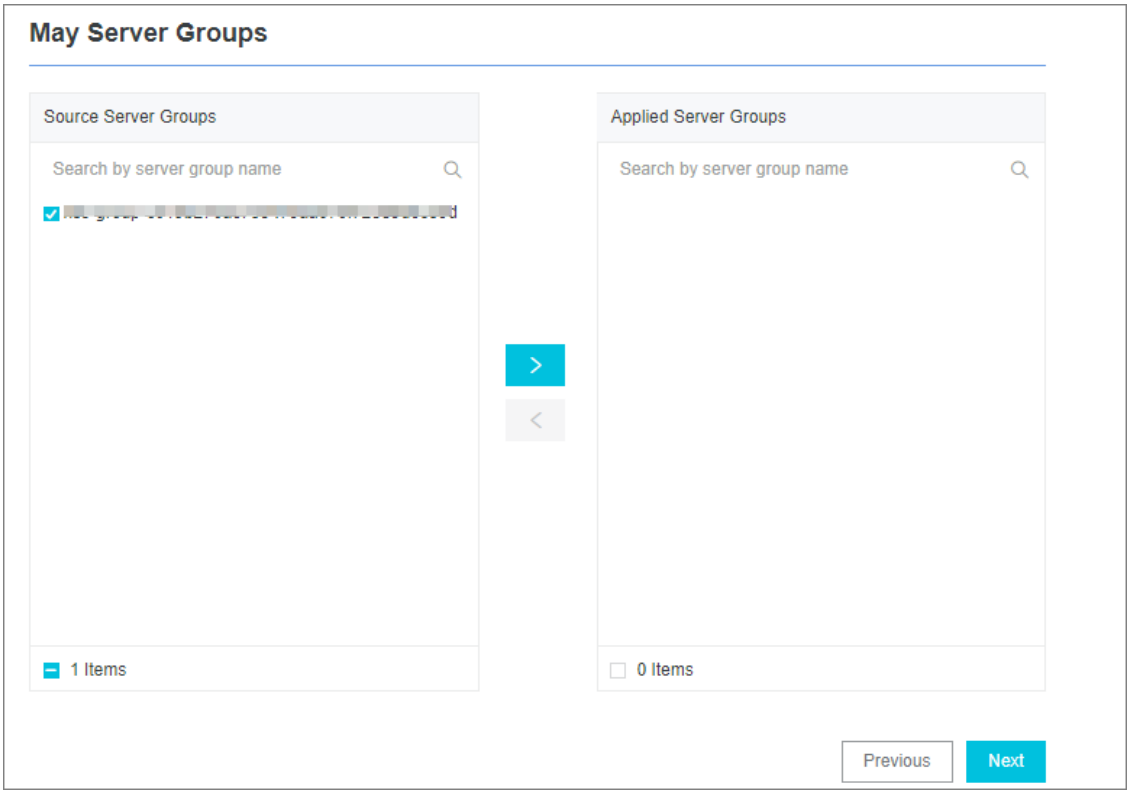
   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a server group.

   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.
5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Create a Logtail configuration.

   The following table lists the Logtail parameters.

Parameter	Description
Config Name	The configuration name must be 3 to 128 characters in length, and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.

Parameter	Description
Log Path	The directory and name of the log file. ◦ The specified log file name can be a complete file name or a file name that contains wildcards. ◦ Recursive directory matching is adopted in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ▪ Example 1: `/apsara/nuwa/ ··· /*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ▪ Example 2: `/var/logs/app_* ··· /*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ▪ Each log file can be collected by using only one Logtail configuration. ▪ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If the log file to be collected is in a Docker container, you can configure the internal path and container tag. Logtail monitors the creation and destruction of the container, filters logs of the container based on the tag, and collects the filtered logs.
Mode	If you have specified **Nginx-Text Log** for the data source, the default mode is **NGINX Configuration Mode**. You can change the mode.
NGINX Log Configuration	Enter the log configuration section that is specified in a standard NGINX configuration file. The section starts with `log_format` .
NGINX Key	Log Service reads the keys of NGINX logs.
Drop Failed to Parse Logs	Specifies whether to upload logs to Log Service if the logs fail to be parsed. ◦ If you turn on this switch, logs that fail to be parsed are not uploaded to Log Service. ◦ If you turn off this switch, raw logs are uploaded to Log Service when logs fail to be parsed.
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory specified in the log path is monitored.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Specify **Advanced Options** based on your business requirements. We recommend that you do not modify the default settings unless otherwise required.

Parameter	Description

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs.
Upload Raw Log	Specifies whether to upload raw logs. If you turn on this switch, raw logs are written to the __raw__ field and uploaded with the parsed logs.
Topic Generation Mode	◦ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic is set to an empty string and you can query logs without the need to enter a topic. ◦ **Server Group Topic Attributes**: This mode is used to differentiate log data that is generated by different frontend servers. ◦ **File Path RegEx**: If you select this mode, you must enter a value in the **Custom RegEx** field to extract part of the path as the topic. This mode is used to differentiate log data that is generated by users or instances.
Custom RegEx	Specifies a custom regular expression. If you select **File Path RegEx** for **Topic Generation Mode**, you must enter a custom regular expression.
Log File Encoding	◦ utf8: indicates UTF-8 encoding. ◦ gbk: indicates GBK encoding.
Timezone	Specifies the time zone where logs are collected. ◦ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ◦ Custom: Select a time zone.
Timeout	If a log file is not updated within a specific period of time, Logtail considers the file to be timed out. ◦ Never: All log files are continuously monitored and never time out. ◦ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ◦ Collect logs that meet a condition: Set the condition to `Key:level Regex:WARNING|ERROR`. It indicates that only logs with the severity level of WARNING or ERROR are collected. ◦ Filter logs that do not meet a condition: ▪ Set the condition to `Key:level Regex:^(?!.*(INFO|DEBUG)).*`. It indicates that logs with the severity level of INFO or DEBUG are not collected. ▪ Set the condition to `Key:url Regex:.*^(?!.*(healthcheck)).*`. It indicates that logs whose URL contains the keyword healthcheck are not collected. For example, logs in which the key is url and the value is `/inner/healthcheck/jiankong.html` are not collected.

8. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

After you complete the settings, you can start to collect NGINX logs.

23.3.1.4.7. Collect IIS logs

This topic describes how to collect Internet Information Services (IIS) logs and configure indexes. You can specify the required settings in the Log Service console.

Context

To meet log analysis requirements, we recommend that you use the W3C Extended Log File Format. To use this format, click **Select Fields** in the IIS Manager, and then select sc-bytes and cs-bytes in the Standard Fields list.

Log format

The W3C Extended Log File Format is as follows:

```
logExtFileFlags="Date, Time, ClientIP, UserName, SiteName, ComputerName, ServerIP, Method, UriStem, UriQuery, HttpStatus, Win32Status, BytesSent, BytesRecv, TimeTaken, ServerPort, UserAgent, Cookie, Referer, ProtocolVersion, Host, HttpSubStatus"
```

- Field prefixes

Prefix	Description
s-	The server action.
c-	The client action.
cs-	The client-to-server action.
sc-	The server-to-client action.

- Fields

Field	Description
date	The date on which the client sends the request.
time	The time when the client sends the request.
s-sitename	The Internet service name and instance number of the site visited by the client.
s-computername	The name of the server on which the log is generated.
s-ip	The IP address of the server on which the log is generated.
cs-method	The HTTP request method that is used by the client, for example, GET or POST.
cs-uri-stem	The URI resource requested by the client.
cs-uri-query	The query string that follows the question mark (?) in the HTTP request.
s-port	The port number of the server to which the client is connected.
cs-username	The username used by the client to access the server. Authenticated users are referenced as `domain\username`. Anonymous users are indicated by a hyphen (-).
c-ip	The IP address of the client that sends the request.

Field	Description
cs-version	The protocol version that is used by the client, for example, HTTP 1.0 or HTTP 1.1.
user-agent	The browser that is used by the client.
Cookie	The content of the sent or received cookie. A hyphen (-) is used if no cookie is sent or received.
referer	The site that the client last visited. This site provides a link to the current site.
cs-host	The header name of the host.
sc-status	The HTTP or FTP status code that is returned by the server.
sc-substatus	The HTTP substatus code that is returned by the server.
sc-win32-status	The Windows status code that is returned by the server.
sc-bytes	The number of bytes that are sent by the server.
cs-bytes	The number of bytes that are received by the server.
time-taken	The processing time of the request. Unit: milliseconds.

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **IIS-Text Log**.
3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

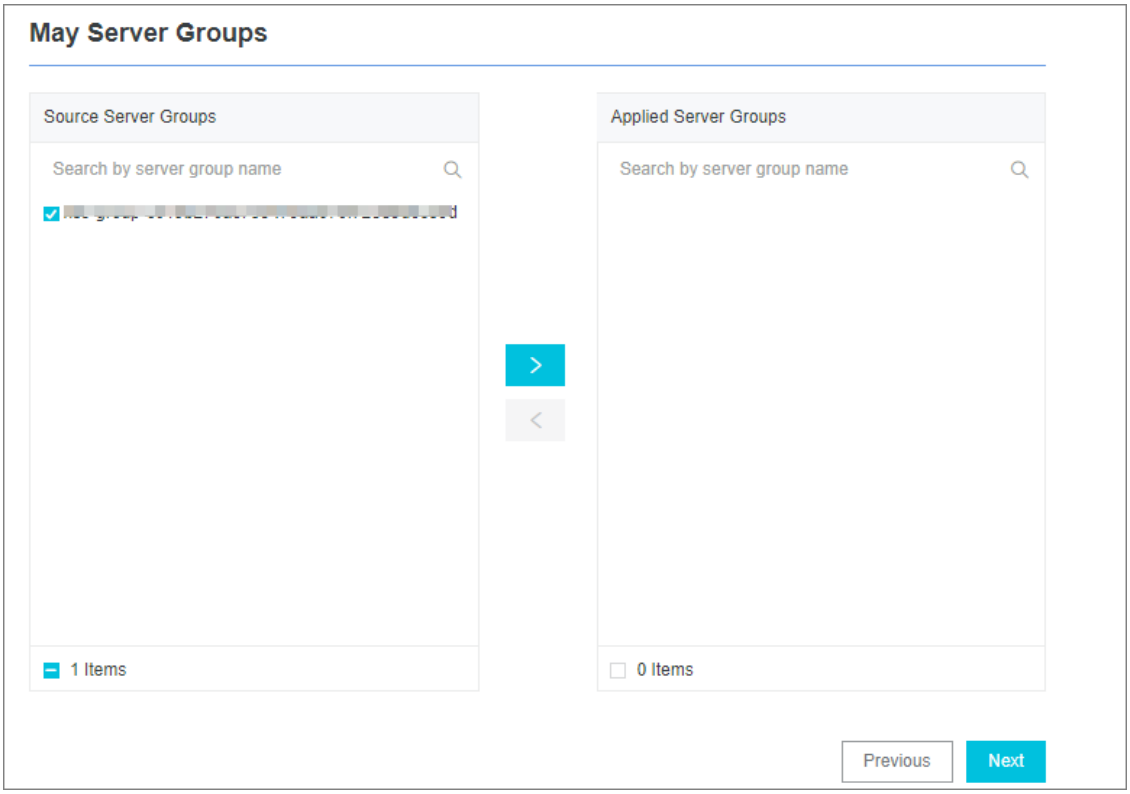
   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a server group.

   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.
5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Create a Logtail configuration.

   The following table lists the Logtail parameters.

Parameter	Description
Config Name	The configuration name must be 3 to 128 characters in length, and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.

Parameter	Description
Log Path	The directory and name of the log file. ○ The specified log file name can be a complete file name or a file name that contains wildcards. ○ Recursive directory matching is used in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ■ Example 1: `/apsara/nuwa/ ··· /*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ■ Example 2: `/var/logs/app_* ··· /*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ■ Each log file can be collected by using only one Logtail configuration. ■ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If the log file to be collected is in a Docker container, you can configure the internal path and container tag. Logtail monitors the creation and destruction of the container, filters logs of the container based on the tag, and collects the filtered logs. For more information, see Collect container text logs.
Mode	If you have specified **IIS-Text Log** for the data source, the default mode is **IIS Configuration Mode**. You can change the mode.
Log Format	Select the log format of your IIS server logs. Valid values: ○ IIS: Microsoft IIS log file format ○ NCSA: NCSA Common log file format ○ W3C: W3C Extended Log File Format
IIS Configuration	Enter the log configuration section that is specified in an IIS configuration file. ○ If you select IIS or NCSA, the fields of the IIS log format are preconfigured. ○ If you select W3C, enter the content that is specified for the logFile logExtFileFlags in the configuration file. For more information, see Specify the IIS Configuration field.
IIS Key Name	Log Service reads the keys of IIS logs.
Drop Failed to Parse Logs	Specifies whether to upload logs to Log Service if the logs fail to be parsed. ○ If you turn on this switch, logs that fail to be parsed are not uploaded to Log Service. ○ If you turn off this switch, raw logs are uploaded to Log Service when logs fail to be parsed.

Parameter	Description
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory that is specified in the log path is monitored.

7. Specify the IIS Configuration field.
   i. Open the IIS configuration file.
      - Default path of the IIS5 configuration file: *C:\WINNT\system32\inetsrv\MetaBase.bin*
      - Default path of the IIS6 configuration file: *C:\WINDOWS\system32\inetsrv\MetaBase.xml*
      - Default path of the IIS7 configuration file: *C:\Windows\System32\inetsrv\config\applicationHost.config*
   ii. Find the `logFile logExtFileFlags` field and copy the text in the quotation marks that follow the field name.
   iii. Paste the text into the quotation marks ("") in the **IIS Configuration** field.
8. (Optional)Specify **Advanced Options** and click **Next**.

   Specify **Advanced Options** based on your business requirements. We recommend that you do not modify the default settings unless otherwise required.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs.
Upload Raw Log	Specifies whether to upload raw logs. If you turn on this switch, raw logs are written to the __raw__ field and uploaded with the parsed logs.
Topic Generation Mode	◦ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic is set to an empty string and you can query logs without the need to enter a topic. ◦ **Server Group Topic Attributes**: This mode is used to differentiate log data that is generated by different frontend servers. ◦ **File Path RegEx**: If you select this mode, you must enter a value in the **Custom RegEx** field to extract part of the path as the topic. This mode is used to differentiate log data that is generated by users or instances.
Custom RegEx	Specifies a custom regular expression. If you select **File Path RegEx** for **Topic Generation Mode**, you must enter a custom regular expression.
Log File Encoding	◦ utf8: indicates UTF-8 encoding. ◦ gbk: indicates GBK encoding.
Timezone	Specifies the time zone where logs are collected. ◦ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ◦ Custom: Select a time zone.

Parameter	Description
Timeout	If a log file is not updated within a specific period of time, Logtail considers the file to be timed out. ○ Never: All log files are continuously monitored and never time out. ○ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ○ Collect logs that meet a condition: Set the condition to `Key:level Regex:WARNING|ERROR`. It indicates that only logs with the severity level of WARNING or ERROR are collected. ○ Filter logs that do not meet a condition: ■ Set the condition to `Key:level Regex:^(?!. *(INFO|DEBUG)). *`. It indicates that logs with the severity level of INFO or DEBUG are not collected. ■ Set the condition to `Key:url Regex:. *^(?!.*(healthcheck)). *`. It indicates that logs whose URL contains the keyword healthcheck are not collected. For example, logs in which the key is url and the value is `/inner/healthcheck/jiankong.html` are not collected.

9. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

After you complete the settings, you can start to collect IIS logs.

23.3.1.4.8. Collect Apache logs

This topic describes how to collect Apache logs and configure indexes. You can specify the required settings in the Log Service console.

Log formats

The Apache configuration file defines two log formats: combined log format and common log format. You can also customize a log format.

- Syntax of the combined log format:

```
LogFormat "%h %l %u %t \"%r\" %>s %b \"%{Referer}i\" \"%{User-Agent}i\"" combined
```

- Syntax of the common log format:

```
LogFormat "%h %l %u %t \"%r\" %>s %b"
```

- Syntax of a custom log format:

```
LogFormat "%h %l %u %t \"%r\" %>s %b \"%{Referer}i\" \"%{User-Agent}i\" %D %f %k %p %q %R %T %I %O" customized
```

You must specify the log format, log file directory, and log file name in the Apache configuration file. For example, the following declaration in the configuration file indicates that the combined log format is used. The log file directory is */var/log/apache2/access_log* and the log file name is access_log.

```
CustomLog "/var/log/apache2/access_log" combined
```

Apache log fields

Format string	Key name	Description
%a	client_addr	The IP address of the client in the request.
%A	local_addr	The local private IP address.
%b	response_size_bytes	The size of the response. Unit: bytes. If no bytes are sent, the value is "-".
%B	response_bytes	The size of the response. Unit: bytes. If no bytes are sent, the value is 0.
%D	request_time_msec	The time period for which the request is processed. Unit: milliseconds.
%h	remote_addr	The name of the remote host.
%H	request_protocol_supple	The request protocol.
%l	remote_ident	The identity information that is provided by a remote computer.
%m	request_method_supple	The request method.
%p	remote_port	The port number of the server.
%P	child_process	The ID of the child process.
%q	request_query	The query string. If it does not exist, the value is an empty string.
"%r"	request	The request, which includes the method name, address, and HTTP protocol.
%s	status	The HTTP status code for the response.
%>s	status	The HTTP status code for the final response.
%f	filename	The name of the requested file.
%k	keep_alive	The number of keep-alive requests.
%R	response_handler	The type of the handler that generates the response on the server.
%t	time_local	The local time when the server receives the request.
%T	request_time_sec	The time period for which the request is processed. Unit: seconds.
%u	remote_user	The username that you used to log on to the client.
%U	request_uri_supple	The requested URL, excluding query strings.
%v	server_name	The name of the server.

Format string	Key name	Description
%V	server_name_canonical	The server name based on the UseCanonicalName setting.
%I	bytes_received	The number of bytes that are received by the server. To use this field, you must enable the mod_logio module.
%O	bytes_sent	The number of bytes that are sent by the server. To use this field, you must enable the mod_logio module.
“%{User-Agent}i”	http_user_agent	The information about the client.
“%{Rererer}i”	http_referer	The URL of the web page linked to the resource that is being requested.

Sample log

```
192.168.1.2 - - [02/Feb/2016:17:44:13 +0800] "GET /favicon.ico HTTP/1.1" 404 209 "http://localhost/x1.html" "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_11_3) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/48.0.2564.97 Safari/537.36"
```

Procedure

1. Log on to the Log Service console.
2. Select a data source.

   Select **Apache-Text Log**.
3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

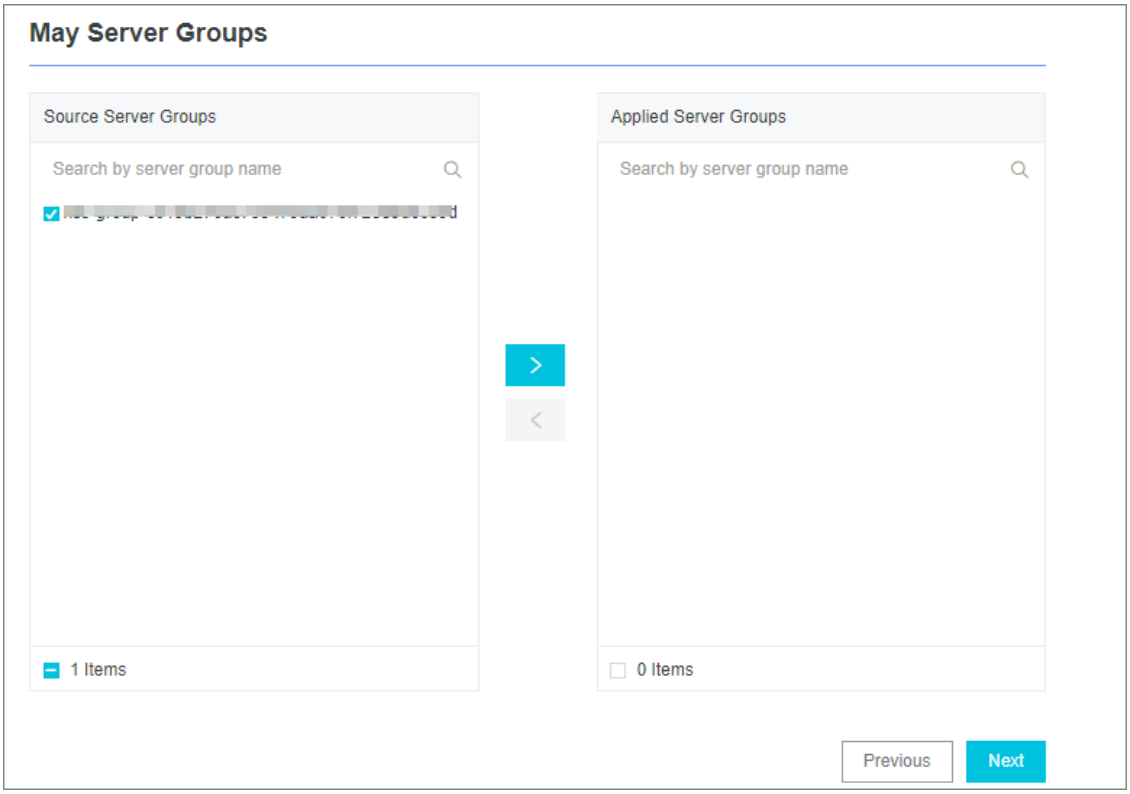
   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a server group.

   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.
5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Create a Logtail configuration.

   The following table lists the Logtail parameters.

Parameter	Description
Config Name	The configuration name must be 3 to 128 characters in length, and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit. **Note** The configuration name cannot be modified after it is created.

Parameter	Description
Log Path	The directory and name of the log file. ○ The specified log file name can be a complete file name or a file name that contains wildcards. ○ Recursive directory matching is used in the log file search. If this matching method is applied, all files that match the specified file name in the specified directory and its sub-directories are monitored. ■ Example 1: `/apsara/nuwa/ ··· /*.log` indicates the files whose extension is `.log` in the `/apsara/nuwa` directory and its sub-directories are monitored. ■ Example 2: `/var/logs/app_* ··· /*.log*` indicates the files whose file name contains `.log` in the following directories are monitored: the sub-directories of the `/var/logs` directory that match the `app_*` format and the sub-directories of these matching sub-directories. **Note** ■ Each log file can be collected by using only one Logtail configuration. ■ Only the asterisk (`*`) and question mark (`?`) can be used as wildcards in the log path.
Docker File	If the log file to be collected is in a Docker container, you can configure the internal path and container tag. Logtail monitors the creation and destruction of the container, filters logs of the container based on the tag, and collects the filtered logs. For more information, see Collect container text logs.
Mode	If you have specified **Apache-Text Log** for the data source, the default mode is **Apache Configuration Mode**. You can change the mode.
Log Format	Select a log format based on the format declared in your Apache log configuration file. To facilitate the query and analysis of log data, we recommend that you use a custom Apache log format.
APACHE Logformat Configuration	Enter the log configuration section that is specified in the Apache configuration file. The section starts with LogFormat. **Note** If the specified **Log Format** is **Common** or **Combined**, the system enters a commonly used syntax of the log format. Check whether the log format is the same as that defined in the Apache configuration file.
APACHE Key Name	Log Service reads the keys of Apache logs. Confirm the key names on the Logtail configuration page.
Drop Failed to Parse Logs	Specifies whether to upload logs to Log Service if the logs fail to be parsed. ○ If you turn on this switch, logs that fail to be parsed are not uploaded to Log Service. ○ If you turn off this switch, raw logs are uploaded to Log Service when logs fail to be parsed.

Parameter	Description
Maximum Directory Monitoring Depth	The maximum number of directory layers that can be recursively monitored when logs are collected from the data source. Valid values: 0 to 1000. The value 0 indicates that only the directory specified in the log path is monitored.

7. (Optional)Specify **Advanced Options** and click **Next**.

   Specify **Advanced Options** based on your business requirements. We recommend that you do not modify the default settings unless otherwise required.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs.
Upload Raw Log	Specifies whether to upload raw logs. If you turn on this switch, raw logs are written to the __raw__ field and uploaded with the parsed logs.
Topic Generation Mode	◦ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic is set to an empty string and you can query logs without the need to enter a topic. ◦ **Server Group Topic Attributes**: This mode is used to differentiate log data that is generated by different frontend servers. ◦ **File Path RegEx**: If you select this mode, you must enter a value in the **Custom RegEx** field to extract part of the path as the topic. This mode is used to differentiate log data that is generated by users or instances.
Custom RegEx	Specifies a custom regular expression. If you select **File Path RegEx** for **Topic Generation Mode**, you must enter a custom regular expression.
Log File Encoding	◦ utf8: indicates UTF-8 encoding. ◦ gbk: indicates GBK encoding.
Timezone	Specifies the time zone where logs are collected. ◦ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ◦ Custom: Select a time zone.
Timeout	If a log file is not updated within a specific period of time, Logtail considers the file to be timed out. ◦ Never: All log files are continuously monitored and never time out. ◦ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file.

Parameter	Description
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ◦ Collect logs that meet a condition: Set the condition to `Key:level Regex:WARNING|ERROR`. It indicates that only logs with the severity level of WARNING or ERROR are collected. ◦ Filter logs that do not meet a condition: ▪ Set the condition to `Key:level Regex:^(?!.*(INFO|DEBUG)).*`. It indicates that logs with the severity level of INFO or DEBUG are not collected. ▪ Set the condition to `Key:url Regex:.*^(?!.*(healthcheck)).*`. It indicates that logs whose URL contains the keyword healthcheck are not collected. For example, logs in which the key is url and the value is `/inner/healthcheck/jiankong.html` are not collected.

8. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

After you complete the settings, you can start to collect Apache logs.

23.3.1.4.9. Configure parsing scripts

This topic describes how to configure log contents for log collection.

Specify a method to separate log lines

A complete access log such as an NGINX access log occupies a line. Separate multiple log entries with line breaks. For example, the following shows two access logs:

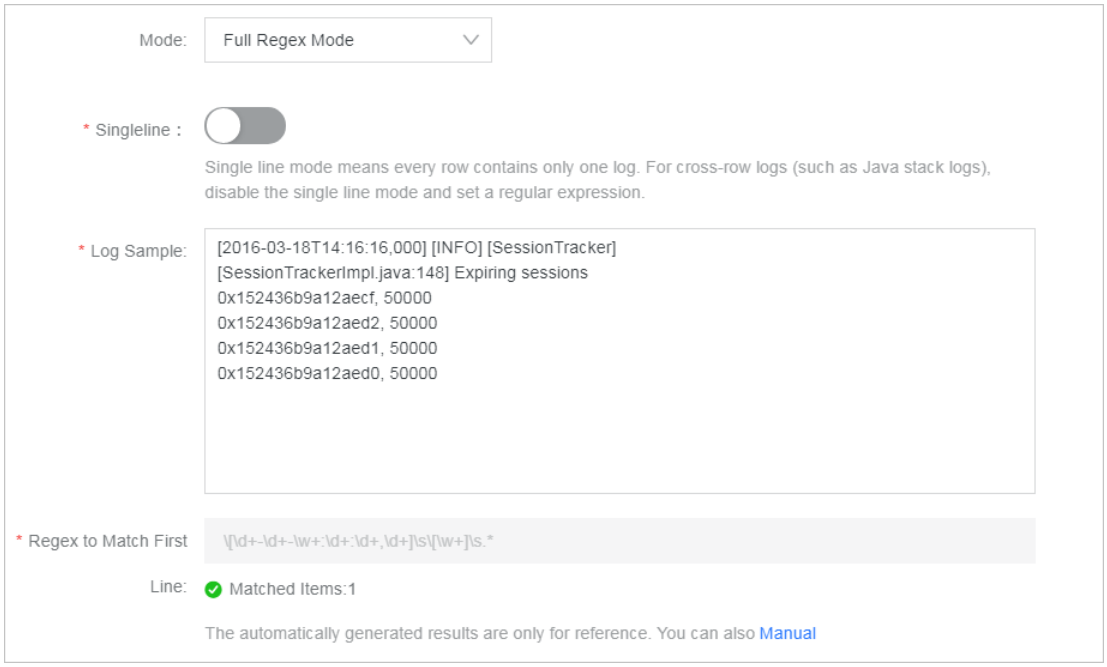
```
10.1.1.1 - - [13/Mar/2016:10:00:10 +0800] "GET / HTTP/1.1" 0.011 180 404 570 "-" "Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1; 360se)"
10.1.1.1 - - [13/Mar/2016:10:00:11 +0800] "GET / HTTP/1.1" 0.011 180 404 570 "-" "Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1; 360se)"
```

For Java applications, a log entry usually spans several lines. Therefore, log entries are separated based on the identifier at the beginning of each log entry. The following example shows a Java application log.

```
[2016-03-18T14:16:16,000] [INFO] [SessionTracker] [SessionTrackerImpl.java:148] Expiring sessions
0x152436b9a12aecf, 50000
0x152436b9a12aed2, 50000
0x152436b9a12aed1, 50000
0x152436b9a12aed0, 50000
```

The preceding Java application log entries each start with a time field. The regular expression that matches these time fields is `[\d+-\d+-\w+:\d+:\d+,\d+]\s.*`. You can enter information in the Log Service console as shown in the following figure.

Full regular expression mode



Extract log fields

To conform to the data models of Log Service, a log contains one or more key-value pairs. If you want to extract specific fields for analysis, you must set a regular expression. If you do not want to process the contents of a log, you can treat the log as a key-value pair.

You can determine whether to extract fields from the preceding NGINX access log.

- Extract fields

  The regular expression is `(\S+)\s-\s-\s\[(\S+)\s[^]]+]\s"(\w+).*` . The extracted fields are `10.1.1.1` , `13/Mar/2016:10:00` , and `GET` .

- Extract all

  The regular expression is `(.*)` . The extracted field is `10.1.1.1 - - [13/Mar/2016:10:00:10 +0800] "GET / HTTP/1.1" 0.011 180 404 570 "-" "Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.1; 360se)"` .

Specify a log time

To conform to the data models of Log Service, a log must have a time field in the Unix timestamp format. You can use the system time when Logtail collects a log or the time in the log contents as the log time.

For the preceding NGINX access log:

- If you extract the time field from the log contents as the log time, the time is `13/Mar/2016:10:00:10` and the time expression is `%d/%b/%Y:%H:%M:%S` .
- If you use the system time when the log was collected as the log time, the log time is converted into a timestamp.

23.3.1.4.10. Configure the time format

Each log in Log Service must have a timestamp that records the log generation time. When you collect logs from log files, Logtail must extract the timestamp string of each log and parse it into a timestamp. Therefore, you need to specify a timestamp format to facilitate parsing.

In Linux, Logtail supports all time formats provided by the strftime() function. If a timestamp string can match one of the time formats that are provided by the strftime() function, Logtail can parse and use the timestamp string.

> **Note**
>
> - The log timestamp is accurate to seconds. Therefore, you need to specify seconds in a time format, without the need for other information such as milliseconds or microseconds.
> - In addition, you need to configure the time field rather than other information.

Common log time formats supported by Logtail

The timestamp strings of logs have diverse formats. To make configuration easier, the following table lists the common log time formats supported by Logtail:

Format	Description	Example
%a	The abbreviation of a day in a week.	Fri
%A	The day in a week.	Friday
%b	The abbreviation of a month.	Jan
%B	The month name.	January
%d	The numerical day in a month. Valid values: 01 to 31.	07 and 31
%h	The abbreviation of a month. The format is equivalent to `%b`.	Jan
%H	The hour in the 24-hour format.	22
%I	The hour in the 12-hour format.	11
%m	The numerical month.	08
%M	The numerical minute. Valid values: 00 to 59.	59
%n	A line break.	Line break
%p	The local time in the a.m. or p.m. format.	AM and PM
%r	The time in the 12-hour format. The format is equivalent to `%I:%M:%S %p`.	11:59:59 AM
%R	The time includes hours and minutes. The format %R is equivalent to `%H:%M`.	23:59
%S	The numerical second. Valid values: 00 to 59.	59
%t	A tab.	Tab
%y	The two-digit numerical year. Valid values: 00 to 99.	04 and 98
%Y	The four-digit numerical year.	2004 and 1998

Format	Description	Example
%C	The numerical century. Valid values: 00 to 99.	16
%e	The numerical day in a month. Valid values: 1 to 31. A single digit is preceded by a space.	7 and 31
%j	The numerical day in a year. Valid values: 001 to 366.	365
%u	The numerical day in a week. Valid values: 1 to 7, in which 1 represents Monday.	2
%U	The numerical week in a year. Sunday is the first day of a week. Valid values: 00 to 53.	23
%V	The numerical week in a year. Monday is the first day of a week. If a week has four or more days that start from January 1, the week is treated as the first week. Otherwise, the next week is treated as the first week. Valid values: 01 to 53.	24
%w	The numerical day in a week. Valid values: 0 to 6, in which 0 represents Sunday.	5
%W	The numerical week in a year. Monday is the first day of a week. Valid values: 00 to 53.	23
%c	The standard date and time.	To specify more information such as the long date and short date, you can use the preceding formats to provide exact expression.
%x	The standard date.	To specify more information such as the long date and short date, you can use the preceding formats to provide exact time expressions.
%X	The standard time.	To specify more information such as the long date and short date, you can use the preceding formats to provide exact expression.
%s	The Unix timestamp.	1476187251

Example

The following table lists the common log time formats, examples, and corresponding time expressions.

Log time format	Example	Time expression
Custom	2017-12-11 15:05:07	%Y-%m-%d %H:%M:%S

Log time format	Example	Time expression
Custom	[2017-12-11 15:05:07.012]	[%Y-%m-%d %H:%M:%S]
RFC822	02 Jan 06 15:04 MST	%d %b %y %H:%M
RFC822Z	02 Jan 06 15:04 -0700	%d %b %y %H:%M
RFC850	Monday, 02-Jan-06 15:04:05 MST	%A, %d-%b-%y %H:%M:%S
RFC1123	Mon, 02 Jan 2006 15:04:05 MST	%A, %d-%b-%y %H:%M:%S
RFC3339	2006-01-02T15:04:05Z07:00	%Y-%m-%dT%H:%M:%S
RFC3339Nano	2006-01-02T15:04:05.999999999Z07:00	%Y-%m-%dT%H:%M:%S

23.3.1.4.11. Import historical logs

Logtail collects incremental logs by default. If you want to import historical logs, use the historical log importing feature of Logtail.

Prerequisites

To collect logs from Linux servers, use Logtail 0.16.15 or later. To collect logs from Windows servers, use Logtail 1.0.0.1 or later. To ensure successful log collection, update Logtail to the latest version.

Context

Logtail collects log files based on events. The system captures events by detecting or polling files for changes at intervals. Additionally, Logtail can load events from local files to trigger log collection. Logtail implements historical log collection based on these local events.

You can import historical log files from the Logtail installation directory. The location of the directory varies based on the operating system.

- Linux: */usr/local/ilogtail*
- Windows:
  - 32-bit: *C:\Program Files\Alibaba\Logtail*
  - 64-bit: *C:\Program Files (x86)\Alibaba\Logtail*

> **Note**
> - The maximum interval between the time a local event is generated and the time the local event is imported is one minute.
> - Loading local configurations is a special action. Therefore, Logtail sends the `LOAD_LOCAL_EVENT_ALARM` alert to your server to notify you of this action.
> - If you want to import a large number of log files, we recommend that you modify the Logtail startup configuration to increase the upper limit of CPU to 2.0 GHz or more and the upper limit of the memory size to 512 MB or more. For more information, see Set Logtail startup parameters.

Procedure

1. Configure log collection.

   If a collection configuration is only used to import historical log files, you can specify a collection directory that does not exist. For more information, see Configure text log collection.

2. Obtain a unique identifier for a collection configuration.

Obtain the unique identifier in the *user_log_config.json* file stored in the installation directory of Logtail. In Linux, use the **grep** command in the directory to query the unique identifier. In Windows, use tools such as Notepad to query the unique identifier.

To query a unique identifier in a Linux operating system, run the following command:

```
grep "##" /usr/local/ilogtail/user_log_config.json | awk '{print $1}'
            "##1.0##log-config-test$multi"
            "##1.0##log-config-test$ecs-test"
            "##1.0##log-config-test$metric_system_test"
            "##1.0##log-config-test$redis-status"
```

3. Add local events.

   Local events are stored in the *local_event.json* file that resides in the installation directory of Logtail. The file is in the JSON format. The syntax is:

```
[
 {
  "config" : "${your_config_unique_id}",
  "dir" : "${your_log_dir}",
  "name" : "${your_log_file_name}"
 },
 {
  ...
 }
 ...
]
```

   - Parameters

Parameter	Description	Example
config	The unique identifier that is obtained in Step 2.	##1.0##log-config-test$ecs-test
dir	The directory where logs are stored. **Note** The directory cannot end with a slash (/).	/data/logs
name	The name of a log file. Wildcards are supported.	For example, access.log.2018-08-08 and access.log*

Note To prevent Logtail from loading invalid JSON files, save local event configurations to a temporary file, edit the configurations in the temporary file, and copy the contents to the *local_event.json* file.

   - Configuration examples

     In a Windows system, you can use tools such as Notepad to add local events to the *local_event.json* file. In a Linux system, add local events as follows:

```
$ cat /usr/local/ilogtail/local_event.json
[
 {
  "config": "##1.0##log-config-test$ecs-test",
  "dir": "/data/log/",
  "name": "access.log.
 },
 {
  "config": "##1.0##log-config-test$ecs-test",
  "dir": "/tmp",
  "name": "access.log.2017-08-09"
 }
]
```

What's next

- Check whether Logtail has loaded configurations

  After you save the `local_event.ison` file, Logtail loads the configuration file to the memory within one minute and clears the contents of the `local_event.json` file.

  To check whether Logtail has read local events, use the following methods:

  - If the contents of the `local_event.json` file are cleared, it indicates that Logtail has read the local events.
  - Check whether the *ilogtail.LOG* file in the Logtail installation directory contains the `process local event` keywords. If the contents of the `local_event.json` are cleared and these keywords cannot be found, the local configuration file may be screened due to invalid contents.

- Check whether the configuration is loaded but no data is collected

  Possible causes are as follows:

  - The configuration is invalid.
  - The local `config` file does not exist.
  - The log file does not exist in the path specified in the collection configuration.
  - The log file has been collected by Logtail.

23.3.1.4.12. Generate a topic

This topic describes how to generate a topic in the Log Service console. After you generate a topic, you can use the topic to group logs. You can specify topics for logs when these logs are written. You can use a topic as a filter when you query logs.

Topic generation modes

You can set a topic when you use Logtail to collect logs or when you use API operations or SDKs to upload logs. The following topic generation modes are available in the Log Service console: **Null - Do not generate topic**, **Server Group Topic Attributes**, and **File Path RegEx**.

- **Null - Do not generate topic**

  When you configure Logtail in the Log Service console to collect text logs, the default topic generation mode is **Null - Do not generate topic**. In this mode, no topic is generated and query logs without specifying a topic.

- **Server Group Topic Attributes**

You can use this mode to identify logs that are generated from multiple servers. Logs from multiple servers can be stored in the same file or directory. To identify these logs based on topics during log collection, you can create server groups and add the servers into different groups. When you create server groups, you must specify a unique **topic attribute** for each server group and set **Topic Generation Mode** to **Server Group Topic Attributes**. After you complete the configuration, apply the Logtail settings to the server groups.

If the **Server Group Topic Attributes** mode is selected, Logtail uploads the topic attribute of each server group as topics to Log Service. When you query logs, you must specify the topic of the target server group as a filter.

- **File Path RegEx**
  - You can use this mode to differentiate between logs that are generated by multiple users or instances. If Log Service stores logs in different directories for different users or instances, duplicate sub-directory names or log file names may exist in these directories. As a result, Log Service cannot identify the source of logs. You can select **File Path RegEx** in the **Topic Generation Mode** field. Enter a regular expression that matches an absolute file path, and set an instance name as a topic.
  - If you select **File Path RegEx**, Logtail uses an instance name as the topic of the logs that Logtail uploads to Log Service. The topic generated varies based on your directory structure and configuration. You must specify an instance name as a topic when you query logs. For example, the following directory structure includes directories that each store logs generated by different users or instances:

    ```
    /logs
     |- /userA/serviceA
      |- service.log
     |- /userB/serviceA
      |- service.log
     |- /userC/serviceA
      |- service.log
    ```

  - If you want to extract multiple separate fields from a file path, use a multi-layer extraction method of `?P<key>`. The value of the key can contain lowercase letters and digits. For example:

    ```
    /home/admin/serviceA/userB/access.log
    \/home\/admin\/(? P<service>[^\/]+)/(? P<user>[^/]+)/. *
    ```

    The following custom tags are created for logs:

    ```
    "__tag__ : service : serviceA"
    "__tag__ : user : userB"
    ```

    > **Note** Logtail 0.16.19 and later are supported.

  - If you specify the */logs* file path and the *service.log* file name in a regular expression, Logtail collects logs from the preceding directories that contain the service.log file and uploads the logs to Log Service. However, Log Service cannot identify the log source based on log contents. You can select **File Path RegEx** in the **Topic Generation Mode** field, and enter the `\/(.*)\/serviceA\/.*` regular expression to extract instance names. After the configuration is complete, the following topics are generated for logs in different directories: userA, userB, and userC. You can specify a topic as a filter to query logs.

    > **Note** You must escape the forward slashes (`/`) in the file path that the regular expression contains.

- **Static topic generation**

  You can select **File Path RegEx** in the **Topic Generation Mode** field, and enter **customized:// + custom topic** in the `Custom RegEx` field.

  > **Note** Logtail 0.16.21 and later are supported.

Set a log topic

1. Configure Logtail in the Log Service console. For more information, see Configure text log collection.

   To set the topic generation mode to **Server Group Topic Attributes**, go to the **Topic** section on the server group creation or modification page.
2. In the Logtail Configuration for Data Import step, click **Advanced Options** and select a **topic generation mode**.

23.3.1.5. Custom plug-ins

Context

Log Service allows you to collect text logs and system logs through Logtail. Logtail supports connections with multiple data sources, such as HTTP or MySQL query results and MySQL binary logs.

You can collect HTTP request data and upload the processing results to Log Service in real time to check service availability check and continuous availability monitoring. You can configure MySQL query results as the data source, and then synchronize incremental data based on custom IDs or time. You can also configure an SQL data source to synchronize MySQL binary logs, subscribe to database changes, and query or analyze logs in real time.

> **Note** This feature is only supported on Linux and must be used together with Logtail. 0.16.0 or later versions. For more information, see Install Logtail in Linux.

配置流程

1. Configure a method that is used to collect logs from the data source.

   Different Logtail configurations for different data sources. Select a Logtail configuration according to your data source.
2. Configure a processing method.

   Logtail provides multiple processing methods for binary logs, MySQL query results, NGINX monitoring data, and HTTP input sources. You can configure multiple processing methods for a single input source. Each input source supports all processing methods. Logtail runs the configured processing methods in sequence.

   For more information, see Configure data processing methods.
3. Apply the configurations to the machine group.

   After you configure the collection and processing methods, apply them to the specified machine group. Then, Logtail automatically applies the configurations and starts data collection.

23.3.1.5.1. Collect MySQL binary logs

Logtail is used as a MySQL slave. It is used to collect binary logs from a MySQL master. Logtail collects binary logs by using a similar method to Alibaba Canal. This improves the efficiency of log collection.

Features

- Allows you to collect incremental data of databases in the form of binary logs to improve performance. Supports MySQL databases such as ApsaraDB RDS for MySQL.
- Supports multiple database filters, such as regular expressions.
- Allows you to set binary log file positions.
- Allows you to record synchronization statuses by using the checkpoint mechanism.

Limits

- MySQL binary logs are available only for Logtail 0.16.0 or later versions that you install on Linux. For more information about how to update Logtail and view Logtail versions, see Install Logtail in Linux.

- Binary logs in the ROW format must be enabled for MySQL databases. By default, binary logs in the ROW format are enabled for RDS instances.

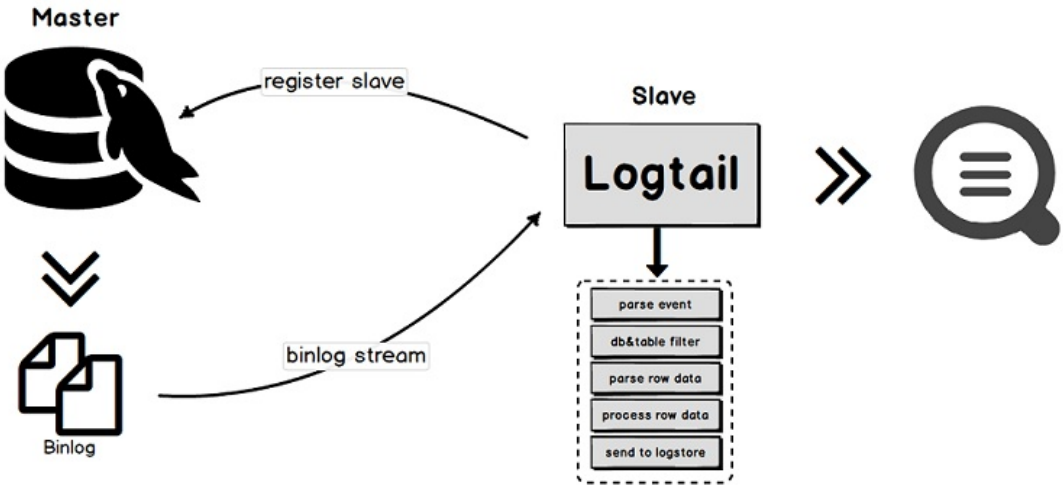
```
# Check whether binary logs are enabled.
mysql> show variables like "log_bin";
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| log_bin       | ON    |
+---------------+-------+
1 row in set (0.02 sec)
# View the format of binary logs.
mysql> show variables like "binlog_format";
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| binlog_format | ROW   |
+---------------+-------+
1 row in set (0.03 sec)
```

- Each server ID must be unique. Make sure that the ID of each slave to be synchronized is unique.
- Limits for RDS databases:
  - Logtail cannot be installed on an RDS instance. You must install Logtail on an ECS instance that can communicate with the destination RDS instance.
  - Secondary RDS databases cannot be used to collect binary logs. You must configure a primary RDS database to collect binary logs.

Implementation

Logtail enables communication between master and slave MySQL servers. The process of how master and slave MySQL servers communicate is provided in the following information:

1. Logtail is used as a MySQL slave. It can also be used to send dump requests to the MySQL master.
2. After the dump requests are received, the MySQL master delivers its binary logs to Logtail in real time.
3. Logtail parses and filters binary logs, and then uploads the results to Log Service.



Scenarios

The MySQL binary logging feature applies to scenarios in which you need to synchronize large amounts of data and meet high performance requirements.

- Query the incremental data of databases in real time.

- Audit operations that are performed on databases.
- Use Log Service to query data, visualize query results, transform data for stream processing, export data to MaxCompute for offline computing, and export log to Object Storage Service (OSS) for long-term storage.

Data reliability

We recommend that you enable the global transaction identifier (GTID) feature of the MySQL server and upgrade Logtail to version 0.16.15 or later. This prevents repeated data collection during a primary/secondary server switchover and ensures data reliability.

- Incomplete data collection: If the network between Logtail and the MySQL server is disconnected for a long period of time, some data may not be collected.

  A MySQL binary log plug-in is used as a MySQL slave to collect binary logs from the master server. Logtail establishes a connection with the master server to obtain data from the server. If the network between Logtail and the master node is disconnected, the master node still generates new binary logs and deletes expired binary logs. After the connection is reestablished and Logtail is reconnected to the master server, Logtail uses the last checkpoint to request binary log data from the master server. However, if the network is disconnected for a long period of time, the data generated after the checkpoint may be deleted. In this case, the recovery mechanism specifies the new point at which Logtail resumes collecting binary logs. The new point is the most recent binary log file position. If the network is disconnected for a long period of time, some data generated between the checkpoint and the new data collection point may not be collected.

- Repeated data collection: If the ordinal numbers of binary logs on the master and slave servers are different and a master/slave switchover occurs, repeated data collection may occur.

  If the MySQL master-slave synchronization is configured, the master server synchronizes the generated binary log data to the slave server. Then, the slave server stores the received binary log data to the local binary log file. If the ordinal numbers of binary logs on the master and slave servers are different, a master/slave switchover occurs. In this case, the mechanism that uses a binary log file name and an offset as the checkpoint causes repeated data collection.

  For example, assume that a data entry ranges from `(binlog.100, 4)` to `(binlog.105, 4)` on the master server, and ranges from `(binlog.1000, 4)` to `(binlog.1005. 4)` on the slave. Logtail has obtained the data from the master server and updated the checkpoint to `(binlog.105, 4)`. In this case, if a master/slave switchover occurs without exception, Logtail continues to obtain binary logs from the new master server based on the local checkpoint `(binlog.105, 4)`. The new master server returns the data entries that range from `(binlog.1000, 4)` to `(binlog.1005, 4)` to Logtail. This is because the ordinal numbers of these data entries on the new master server are greater than the ordinal numbers of data entries requested by Logtail. As a result, log data is repeatedly collected.

Parameter

The type of input sources is `service_canal`.

Parameter	Type	Required	Description
Host	string	No	The IP address of the host where the database resides. Default value: 127.0.0.1.
Port	int	No	The port number that you can use to connect with the database. Default value: 3306.

Parameter	Type	Required	Description

User	string	No	The database username. Default value: root.
			The configured user must have the read permissions on the source database and the MySQL REPLICATION permission. Example:
			`CREATE USER canal IDENTIFIED BY 'canal';`
			`GRANT SELECT, REPLICATION SLAVE, REPLICATION CLIENT ON *.* TO 'canal'@'%';`
			`-- GRANT ALL PRIVILEGES ON *.* TO 'canal'@'%' ;`
			`FLUSH PRIVILEGES;`

Password	string	No	The database password. By default, this parameter is unspecified. If you require a high level of data security, we recommend that you set both the username and the password to xxx. After your configurations are synchronized to the on-premises server, find the Password parameter in the */usr/local/ilogtail/user_log_config.json* file and modify the value. **Note** • After you modify the password, use the **sudo /etc/init.d/ilogtaild stop; sudo /etc/init.d/ilogtaild start** command to restart Logtail. • If you modify the value of the Password parameter on the web and synchronize your configurations to the on-premises server, the configurations on the on-premises server are overwritten. You can change the configurations on the on-premises server later.
ServerID	int	No	The ID of a MySQL slave whose role is assumed by Logtail. Default value: 125. **Note** In a MySQL database, each ID must be unique. Otherwise, synchronization fails.
IncludeTables	String array	Yes	The names of matched tables. Each value contains a database name and a table name, for example, `test_db.test_table`. You must specify a regular expression for the parameter. Logtail does not collect incremental data from tables whose names do not match the regular expression. To collect incremental data from all tables of a database, set the value of the IncludeTables parameter to `.*\\..*`. **Note** If an exact match is required, make sure that the regular expression is prefixed by `^`. In this case, you must also make sure that the regular expression is suffixed by `$`. Example: `^test_db\\.test_table$`.

Parameter	Type	Required	Description
ExcludeTables	String array	No	The names of excluded tables expressed as a regular expression. The name of a table must include the name of the database to which the table belongs, for example, `test_db.test_table`. If a table meets one of the conditions specified in the parameter, the table is not collected. If you do not specify this parameter, incremental data from all tables is collected. **Note** If an exact match is required, make sure that the regular expression is prefixed by `^`. In this case, you must also make sure that the regular expression is suffixed by `$`. Example: `^test_db\\.test_table$`.

StartBinName	string	No	The name of the first binary log file that is collected by Logtail. If you do not specify this parameter, Logtail starts to collect binary log files that are generated from the current time.
			To collect data from a specific location, view the name of the current binary log file and the file offset. Then, set `StartBinName` and `StartBinLogPos` to actual values. Example:
			`# Set StartBinName to mysql-bin.000063 and StartBinLogPos to 0.`
			`mysql> show binary logs;`
			`+------------------+-----------+`
			`| Log_name | File_size |`
			`+------------------+-----------+`
			`| mysql-bin.000063 | 241 |`
			`| mysql-bin.000064 | 241 |`
			`| mysql-bin.000065 | 241 |`
			`| mysql-bin.000066 | 10778 |`
			`+------------------+-----------+`
			`4 rows in set (0.02 sec)`
			Note
			If you set the `StartBinName` parameter, a large amount of traffic is generated during the first collection.

StartBinLogPos	int	No	The offset of the first binary log file that is collected. Default value: 0.
EnableGTID	bool	No	Specifies whether to add GTID. Default value: true. If the value is false, no GTID is added to uploaded data.
EnableInsert	bool	No	Specifies whether to collect log events triggered by INSERT operations. Default value: true. If the value is false, INSERT events are not collected.
EnableUpdate	bool	No	Specifies whether to collect UPDATE events. Default value: true. If the value is false, UPDATE events are not collected.
EnableDelete	bool	No	Specifies whether to collect DELETE events. Default value: true. If the value is false, DELETE events are not collected.

Parameter	Type	Required	Description
EnableDDL	bool	No	Specifies whether to collect data definition language (DDL) events. Default value: false. If the value is false, DDL events are not collected. **Note** This parameter does not support the `IncludeTables` or `ExcludeTables` filtering methods.
Charset	string	No	The encoding method. Default value: `utf-8`.
TextToString	bool	No	Specifies whether to convert data of the text type into a string. Default value: false.
PackValues	bool	No	Specifies whether to encapsulate event data into the JSON format. Default value: false. If the value is false, event data is not encapsulated. If this feature is enabled, Logtail encapsulates event data into the data and old_data fields in the JSON format. The old_data field is available only for ROW_UPDATE events. For example, assume that a table has three fields named c1, c2, and c3. If this feature is disabled, the ROW_INSERT event data contains three fields c1, c2, and c3. If this feature is enabled, c1, c2, and c3 are encapsulated into one data field and the value is `{"c1":"...", "c2": "...", "c3": "..."}`. **Note** This parameter is available only for Logtail V0.16.19 and later.
EnableEventMeta	bool	No	Specifies whether to collect event metadata. Default value: false. If the value is false, event metadata is not collected. The metadata of binary log events includes `event_time`, `event_log_position`, `event_size`, and `event_server_id`. **Note** This parameter is available only for Logtail V0.16.21 and later.

Procedure

Synchronize data from tables whose names do not end with `_inner` in the `user_info` RDS database.

1. Log on to the Log Service console.
2. Select a data source.

   Click **Import Data**. On the **Import Data** page, select **MYSQL BinLog**.
3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a server group.

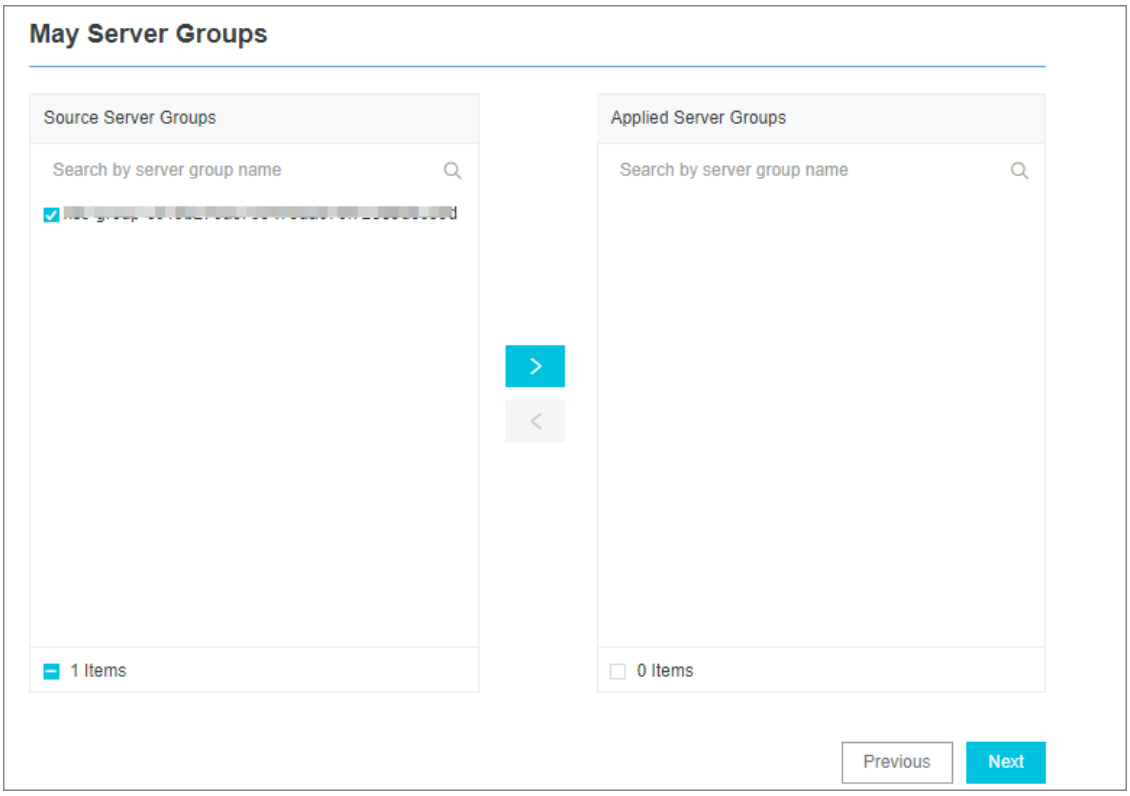
   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.

5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Configure the data source.

   Set the Config Name and Plug-in Config fields.

   In the **Plug-in Config** field, modify the parameter settings in the default configuration template based on your business requirements.

```
{
 "inputs": [
   {
     "type": "service_canal",
     "detail": {
       "Host": "************.mysql.rds.aliyuncs.com",
       "Port": 3306,
       "User" : "root",
       "ServerID" : 56321,
       "Password": "********",
       "IncludeTables": [
         "user_info\\.. *"
       ],
       "ExcludeTables": [
         ". *\\. \\S+_inner"
       ],
       "TextToString" : true,
       "EnableDDL" : true
     }
   }
 ]
}
```

- *inputs*: specifies the collection configurations. This parameter is required. You must configure statements to collect data based on your data source.
- *processors*: specifies the processing method. This parameter is optional. For more information about how to set a processing method, see Configure data processing methods.

7. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

8. (Optional)Modify the configurations on the server.

   If you do not enter the actual URL, username, or password in **Plug-in Config**, you must replace them with actual values after the configurations are synchronized to the server.

   > **Note** If you have entered the actual information, skip this step.

   i. Log on to the server where Logtail is installed, find the `service_canal` keyword in the `/usr/local/ilogtail/user_log_config.json` file, and then set related fields. These fields include `Host`, `User`, and `Password`.

   ii. Run the following command to restart Logtail:

   ```
   sudo /etc/init.d/ilogtaild stop; sudo /etc/init.d/ilogtaild start
   ```

The configurations that are used to collect binary logs are completed. If changes are made to your database, Logtail immediately collects the updated data and uploads the data to Log Service.

> **Note** Logtail collects incremental binary logs. If no data is collected, check whether changes are made to the table in your database after the configurations are updated.

Metadata fields

When you collect binary logs, some metadata is also uploaded. The following table lists the fields of uploaded metadata.

Parameter	Description	Example
host	The name of the host where the database resides.	*********.mysql.rds.aliyuncs.com
_db_	The name of the RDS database.	my-database
table	The name of the table.	my-table
event	The type of the event. Valid values:	row_update , row_insert , and row_delete
_id_	The ID of the current collection. The value starts from 0 and increments by 1 each time a binary log event is collected.	1
gtid	The GTID.	7d2ea78d-b631-11e7-8afb-00163e0eef52:536
filename	The name of the binary log file.	binlog.001
offset	The offset of the binary log file. The value is updated after each COMMIT operation.	12876

Example

After you completed the preceding steps to set a processing method, perform INSERT , UPDATE , and DELETE operations on the SpecialAlarm table in the user_info database. The following information shows the schema, database operations, and sample logs that are collected by Logtail.

- Schema

```
CREATE TABLE `SpecialAlarm` (
`id` int(11) unsigned NOT NULL AUTO_INCREMENT,
`time` datetime NOT NULL,
`alarmtype` varchar(64) NOT NULL,
`ip` varchar(16) NOT NULL,
`count` int(11) unsigned NOT NULL,
PRIMARY KEY (`id`),
KEY `time` (`time`) USING BTREE,
KEY `alarmtype` (`alarmtype`) USING BTREE
) ENGINE=MyISAM AUTO_INCREMENT=1;
```

- Database operations

  Perform the INSERT, DELETE, and UPDATE operations on the database.

```
insert into specialalarm (`time`, `alarmType`, `ip`, `count`) values(now(), "NO_ALARM", "10.10. **.***", 55);
delete from specialalarm where id = 4829235 ;
update specialalarm set ip = "10.11. ***.**" where id = "4829234";
```

  Create an index for zc.specialalarm .

```
ALTER TABLE `zc`.`specialalarm`
ADD INDEX `time_index` (`time` ASC);
```

- Sample logs

  On the data preview or Search & Analysis page, you can view a sample log that corresponds to each operation.

- INSERT statement

```

Query: ALTER TABLE `zc`.`specialalarm`
ADD INDEX `time_index` (`time` ASC)
StatusVars:
```

Usage notes

We recommend that you increase resource limits on Logtail to process traffic surges and prevent data security risks. If the limits are exceeded, Logtail may be forcibly restarted.

You can modify the resource limits in the */usr/local/ilogtail/ilogtail_config.json* file. Then, you can run the **sudo /etc/init.d/ilogtaild stop;sudo /etc/init.d/ilogtaild start** command to restart Logtail.

The following example shows how to set the CPU limit to two and memory limit to 2,048 MB:

```
{
  ...
  "cpu_usage_limit":2,
  "mem_usage_limit":2048,
  ...
}
```

23.3.1.5.2. Collect MySQL query results

This topic describes how to configure Logtail in the Log Service console to collect MySQL query results.

Context

If you want to collect data from a MySQL database, you can install Logtail on a server and connect the server with the database. Then, you can create a Logtail configuration file by executing a custom SQL statement in the Log Service console and deliver the configuration file to Logtail. Logtail can use the custom SQL statement to collect data from the database at regular intervals.

> **Note** This feature applies only to Logtail 0.16.0 and later versions that run on Linux. For more information, see Install Logtail in Linux.

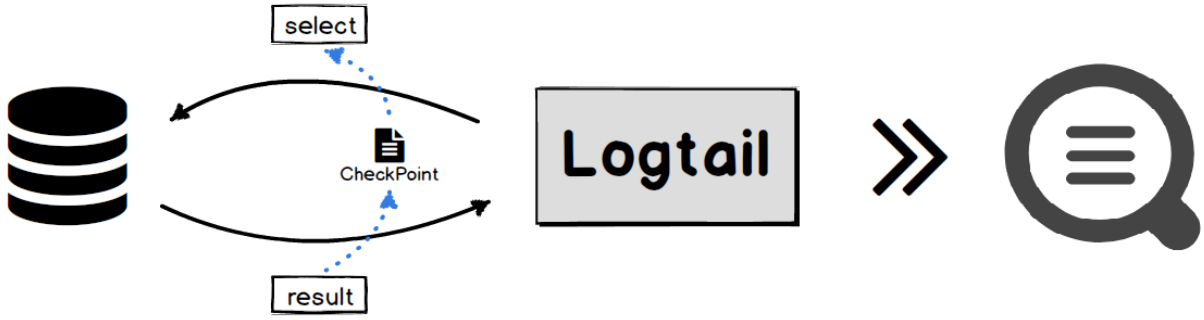
Benefits

Supports MySQL databases such as ApsaraDB RDS for MySQL. When you collect data, you can perform the following operations:

- Paginate query results.
- Set time zones.
- Set timeout periods.
- Store checkpoints.
- Transmit data over the SSL protocol.
- Set the maximum size of data that can be collected at a time.

Implementation

Logtail executes the specified SELECT statement at a regular interval based on the Logtail configurations, and then uploads the query results to Log Service.



When Logtail obtains a query result, Logtail saves the value of the CheckPoint field in the on-premises server. The next time Logtail executes the SELECT statement, Logtail adds the saved value of the CheckPoint field to the SELECT statement. This way, Logtail collects the incremental data of MySQL databases.

Scenarios

- Collect incremental data based on specific marks such as an auto-increment ID or a point in time.
- Customize data synchronization based on specified filtering conditions.

Parameters

The following table describes Logtail parameters. The type of the data source is `service_mysql` .

Parameter	Type	Required	Description
Address	string	No	The address of the MySQL database. Default value: 127.0.0.1:3306.
User	string	No	The username of the MySQL database. Default value: root.
Password	string	No	The password of the MySQL database. By default, this parameter is unspecified.
DialTimeOutMs	int	No	The timeout period for the database connection. Unit: milliseconds. Default value: 5000.
ReadTimeOutMs	int	No	The timeout period for data reading. Unit: milliseconds. Default value: 5000.
StateMent	string	Yes	The SQL statement.
Limit	bool	No	Specifies whether to paginate query results by using the LIMIT clause. Default value: false.

Parameter	Type	Required	Description
PageSize	int	No	The number of log entries to return on each page. You must specify this parameter if you set the Limit parameter to true.
MaxSyncSize	int	No	The maximum number of log entries that are synchronized at a time. Default value: 0. This value indicates that no limit is set for the size of data that can be synchronized at a time.
CheckPoint	bool	No	Specifies whether to use checkpoints during data collection. Default value: false.
CheckPointColumn	string	No	The name of the checkpoint column. You must specify this parameter if you set the CheckPoint parameter to true.
CheckPointColumnType	string	No	The type of the checkpoint column. Valid values: `int` and `time`.
CheckPointStart	string	No	The initial value of the checkpoint.
CheckPointSavePerPage	bool	No	If this parameter is set to true, a checkpoint is saved each time query results are paginated. If this parameter is set to false, a checkpoint is saved after each synchronization.
IntervalMs	int	Yes	The synchronization interval. Unit: milliseconds.

Limits

- We recommend that you paginate query results by specifying the `Limit` parameter. If you set the `Limit` parameter to true, the LIMIT clause is automatically appended to the SQL statement specified by the `StateMent` parameter when you run a query.
- If you set the `CheckPoint` parameter to true, the data that is selected based on the `StateMent` parameter must contain the checkpoint column. In addition, the WHERE clause must contain the checkpoint field. The value of the checkpoint field is a question mark (`?`).

  For example, assume that the checkpoint is "id" and the value of the `StateMent` parameter is `SELECT * from ... where id > ?` .
- If you set the `CheckPoint` parameter to true, you must specify the `CheckPointColumn` , `CheckPointColumnType`

, and `CheckPointStart` parameters.

- The value of `CheckPointColumnType` can only be set to `int` or `time`. If the value is set to `int`, the int64 data type is used for internal storage. If the value is set to `time`, MySQL DATE, DATETIME, and TIME are supported.

Procedure

The following procedure describes how to synchronize incremental data from a MySQL database to Log Service. In this procedure, the logtail.VersionOs field is synchronized every 10 seconds. The value of the count parameter in this field is greater than 0. The value of the initial checkpoint is 2017-09-25 11:00:00. Log entries are paginated and each page contains 100 log entries. The checkpoint of each page is saved.

1. Log on to the Log Service console.
2. Select a data source.

   Click **Import Data**. On the **Import Data** page, select **MYSQL Query Result-Plug-in**.
3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

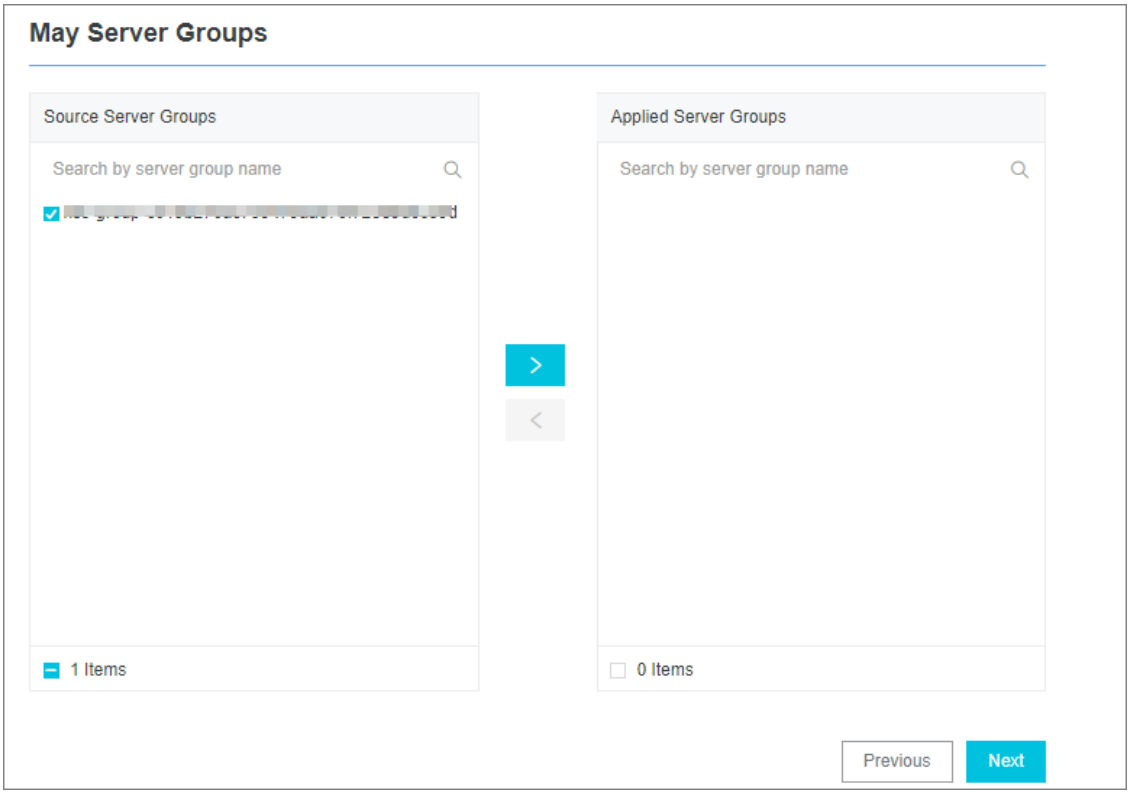
   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a server group.

   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.
5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Configure the data source.
   - In the **Plug-in Config** field, modify the parameter settings in the default configuration template based on your business requirements.
   - `inputs` : specifies the collection configurations. This parameter is required. `processors` : specifies the processing method. This parameter is optional. You must configure statements to collect data based on your data source. You can specify one or more processing methods. For more information, see Configure data processing methods.

   > **Note** If you require a high level of data security, we recommend that you set both the username and the password to xxx. After your configurations are synchronized to the on-premises server, find the Password parameter in the /usr/local/ilogtail/user_log_config.json file and modify the value.

   The following example shows the configurations:

```
{
 "inputs": [
   {
     "type": "service_mysql",
     "detail": {
       "Address": "********:3306",
       "User": "logtail",
       "Password": "********",
       "DataBase": "logtail",
       "Limit": true,
       "PageSize": 100,
       "StateMent": "SELECT * from logtail.VersionOs where time > ?",
       "CheckPoint": true,
       "CheckPointColumn": "time",
       "CheckPointStart": "2017-09-25 11:00:00",
       "CheckPointSavePerPage": true,
       "CheckPointColumnType": "time",
       "IntervalMs": 10000
     }
   }
 ]
}
```

7. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

8. (Optional)Modify the configurations on the server.

   If you do not enter the actual URL, username, or password in the **Specify Data Source** page, you must replace them with actual values after the configurations are synchronized to the server.

   > **Note** If you have entered the actual information, skip this step.

   i. Log on to the server where Logtail is installed, find the `service_mysql` keyword in the `/usr/local/ilogtail/user_log_config.json` file, and then set related fields. These fields include: `Address` , `User` , and `Password` .

   ii. Run the following command to restart Logtail:

```
sudo /etc/init.d/ilogtaild stop; sudo /etc/init.d/ilogtaild start
```

Example

After you configure the processing method, you can view the processed data in the Log Service console. The following information shows the schema and sample logs that are collected by Logtail.

- Schema

```
CREATE TABLE `VersionOs` (
 `id` int(11) unsigned NOT NULL AUTO_INCREMENT COMMENT 'id',
 `time` datetime NOT NULL,
 `version` varchar(10) NOT NULL DEFAULT '',
 `os` varchar(10) NOT NULL,
 `count` int(11) unsigned NOT NULL,
 PRIMARY KEY (`id`),
 KEY `timeindex` (`time`)
)
```

- Sample output

```
"count": "4"
"id: "721097"
"os: "Windows"
"time: "2017-08-25 13:00:00"
"version": "1.3.0"
```

23.3.1.5.3. Collect syslogs

This topic describes how to use the syslog plug-in of Logtail to collect syslogs from a server.

Prerequisites

Logtail 0.16.13 or a later version is installed on the server.

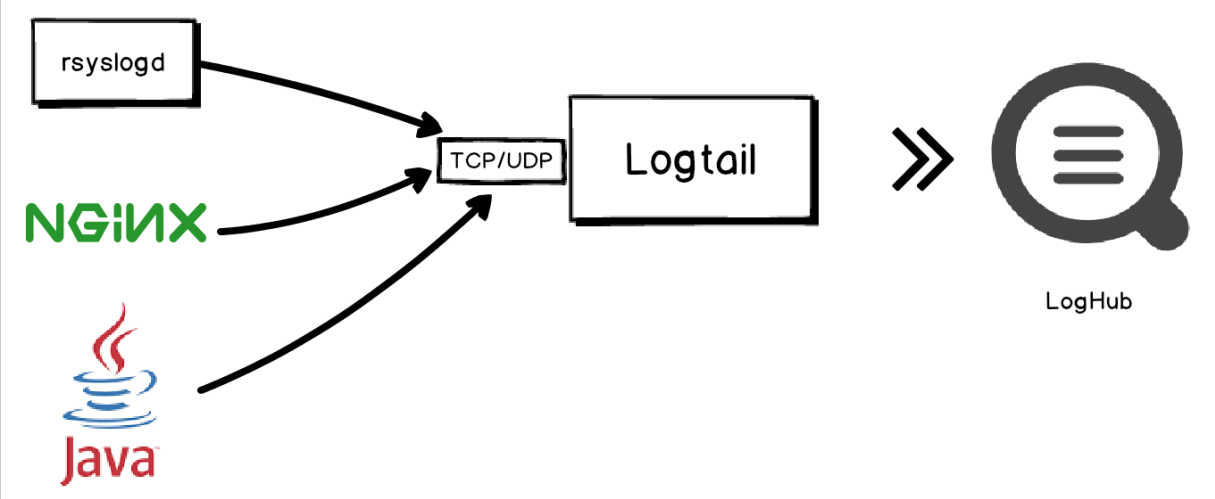
Overview

On a Linux server, local syslogs can be forwarded to the IP address and port of a specified server by using syslog agents such as rsyslog. After you create a Logtail configuration for the specified server, the syslog plug-in of Logtail receives the syslogs over TCP or UDP. In addition, the syslog plug-in parses the received syslogs and extract log fields such as facility, tag (program), severity, and content based on the specified syslog protocol. The syslog protocol can be RFC 3164 or RFC 5424.

> Note
> - Logtail installed on a Windows server does not support the syslog plug-in.
> - You can configure multiple syslog plug-ins for Logtail. For example, you can use both TCP and UDP to listen on 127.0.0.1:9999.

Implementation

After the syslog plug-ins start to listen on a specified IP address and port, Logtail can act as a syslog server to collect syslogs from various data sources. These syslogs include system logs collected by rsyslog, access or error logs forwarded by NGINX, and logs forwarded by syslog clients in languages such as Java.



Logtail parameters

The following table describes Logtail parameters. The type of the input is `service_syslog`.

Parameter	Type	Required	Description
Address	String	No	The protocol, address, and port on which the syslog plug-in listens. The syslog plug-in obtains logs based on the value of this parameter. Format: `[tcp/udp]://[ip]:[port]`. Default value: `tcp://127.0.0.1:9999`. **Note** • The specified protocol, address, and port must be the same as those specified for the forwarding rule in the rsyslog configuration file. • If the server on which Logtail is installed has multiple IP addresses, you can set the IP address to 0.0.0.0. It means that the syslog plug-in listens on all IP addresses of the server.
ParseProtocol	String	No	The protocol that is used to parse logs. This parameter is not specified by default, indicating that logs are not parsed. Valid values: • rfc3164: The RFC 3164 protocol is used to parse logs. • rfc5424: The RFC 5424 protocol is used to parse logs. • auto: The syslog plug-in selects a protocol based on the log content.

Parameter	Type	Required	Description
IgnoreParseFailure	Boolean	No	Specifies whether to ignore a parsing failure. Default value: true. Valid values: • true: Logs that fail to be parsed are included in the returned content field. • false: Logs that fail to be parsed are dropped.

Default fields

Field	Type	Description
hostname	String	The hostname. If a hostname is not provided in the log, the hostname of the current host is obtained.
program	String	The tag field in the protocol.
priority	String	The priority field in the protocol.
facility	String	The facility field in the protocol.
severity	String	The severity field in the protocol.
unixtimestamp	String	The timestamp of the log.
content	String	The log content. If the log fails to be parsed, this field contains the complete content of the log.
_ip_	String	The IP address of the current host.

Configure the plug-in of Logtail to collect syslogs

1. Add a forwarding rule for rsyslog.

   Modify the */etc/rsyslog.conf* rsyslog configuration file on the server from which syslogs are collected. Add a forwarding rule at the end of the configuration file. Then, rsyslog forwards syslogs to the specified IP address and port.

   - If you want to collect syslogs of the server by using Logtail on this server, set the forwarding address to 127.0.0.1 and the port to an idle port.
   - If you want to collect syslogs of the server by using Logtail on a second server (Server B), set the forwarding address to the public IP address of the second server and port to an idle port.

   For example, the following forwarding rule indicates that logs are forwarded to 127.0.0.1:9000 over TCP.

   ```
   *.* @@127.0.0.1:9000
   ```

2. Run the following command to restart rsyslog and validate the log forwarding rule:

   ```
   sudo service rsyslog restart
   ```

3. Log on to the Log Service console.
4. Select the data source **Custom Data Plug-in**.

   You can use one of the following three methods to select a data source:

   - On the homepage of the Log Service console, select a data source in the **Import Data** section.
   - In the **Projects** section, click a project name. On the **Overview** page, click **Import Data**, and then select a data source.
   - On the Logstores tab in the left-side navigation pane, find a Logstore and click the closing angle bracket (>)

in front of the Logstore name. Click the plus sign (+) next to **Data Import**, and then select a data source.

5. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.

6. Create a server group.

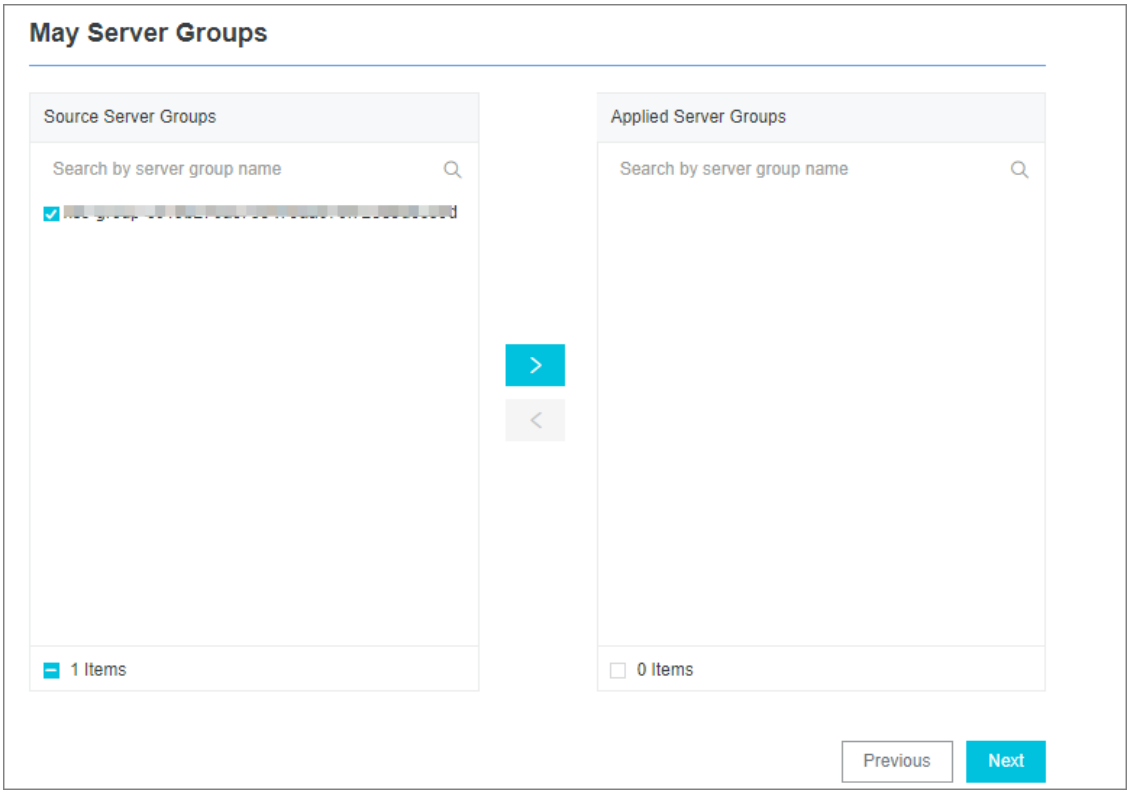
   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.

7. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



8. Configure the data source.

   Set **Config Name** and **Plug-in Config**.

   The `inputs` section is required. It specifies the collection configuration. The `processors` section is optional. It specifies the processing configuration. You must specify a collection statement for the collection configuration based on the data source. You can specify one or more processing methods for the processing configuration. For more information, see Configure data processing methods.

   The following sample code shows how to use UDP and TCP to listen on 127.0.0.1:9000:

```
{
  "inputs": [
    {
      "type": "service_syslog",
      "detail": {
        "Address": "tcp://127.0.0.1:9000",
        "ParseProtocol": "rfc3164"
      }
    },
    {
      "type": "service_syslog",
      "detail": {
        "Address": "udp://127.0.0.1:9001",
        "ParseProtocol": "rfc3164"
      }
    }
  ]
}
```

9. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

Configure the plug-in of Logtail to collect NGINX logs

NGINX access logs can be forwarded to specified addresses and ports over the syslog protocol. To deliver NGINX access logs as syslogs from a server to Log Service, you can create a Logtail configuration and apply it to the server group to which the server belongs.

1. Add a forwarding rule to the *nginx.conf* configuration file on the NGINX server.

   For example, add the following content to the configuration file.

```
http {
  ...
  # Add this line.
  access_log syslog:server=127.0.0.1:9000,facility=local7,tag=nginx,severity=info combined;
  ...
}
```

2. Run the following command to restart the NGINX service and validate the configuration.

```
sudo service nginx restart
```

3. Create a Logtail configuration and apply it to the server group to which the server belongs.

   For more information, see Configure the plug-in of Logtail to collect syslogs.

4. Check whether the Logtail configuration takes effect.

   Run the `curl http://127.0.0.1/test.html` command in shell to generate an access log. If the Logtail configuration takes effect, you can view the log information on the query page of the Log Service console.

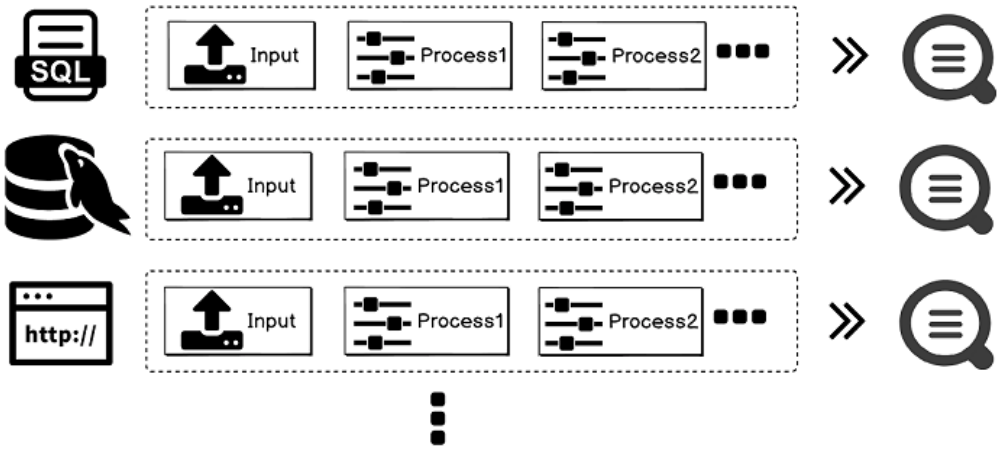
23.3.1.5.4. Configure data processing methods

Logtail allows you to configure plug-ins for data processing. Each plug-in defines a processing method. You can configure one or more processing methods for a data source. Then, Logtail executes the processing methods in sequence. This topic describes the available data processing methods and describes how to configure the methods.

Implementation

The following figure shows how collected data is processed.

Implementation



Plug-in elements

When you configure the data processing methods, you must set the key parameter to `processors` and the value parameter to an array of JSON objects. Each object contains the details of a processing method.

Each object contains the `type` and `detail` fields. The `type` field specifies the type of a processing method. The `detail` field contains configuration details.

```
"processors" : [
    {
      "type" : "processor_anchor",
      "detail" : {
        ...
      }
    },
    {
      "type" : "processor_regex",
      "detail" : {
        ...
      }
    }
  ]
```

Processing methods

The following processing methods are supported:

- Extract log fields by using a regular expression
- Extract log fields by using start and stop keywords
- Extract log fields by using a single-character delimiter
- Extract log fields by using a multi-character delimiter
- Convert an IP address into a geographical location
- Filter log fields by using a regular expression
- Add log fields
- Remove log fileds
- Extract log time (Go)
- Expand log fields (JSON)
- Combine log fields (JSON)

- Rename fields
- Extract log time (Strptime)

You can also create a custom method that includes several of the preceding methods. For more information, see Custom methods.

Extract log fields by using a regular expression

This method extracts the fields that match a specified regular expression.

The type of the plug-in is `processor_regex`.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field to extract by using the regular expression.
Regex	string	Yes	The regular expression. Enclose the value of fields to extract with parentheses `()`.
Keys	String array	Yes	The array of fields to extract, for example, ["key1", "key2" ...].
NoKeyError	bool	No	Specifies whether to report an error if no field matches the regular expression. Default value: false.
NoMatchError	bool	No	Specifies whether to report an error if the specified regular expression does not match logs. Default value: false.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: false. This value specifies that the SourceKey parameter is not returned.
FullMatch	bool	Yes	Specifies whether to extract fields that exactly match the `Regex` parameter. Default value: true. This value specifies that fields that partially match the Regex parameter are extracted.

The following example shows how to extract fields from an access log.

- Input data

```
"content" : "10.200. **. ** - - [10/Aug/2017:14:57:51 +0800] \"POST /PutData?Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=<yourSignature> HTTP/1.1\" 0.024 18204 200 37 \"-\" \"aliyun-sdk-java"
```

- Configurations

```
{
  "type" : "processor_regex",
  "detail" : {"SourceKey" : "content",
    "Regex" : "([\\d\\.] +) \\S+ \\S+ \\[(\\S+) \\S+\\] \"(\\w+) ([^\\\"]*)\" ([\\d\\.]+) (\\d+) (\\d+) (\\d+|-) \"([^\\\"]*)\" \"([^\\\"]*)\" (\\d+)",
    "Keys"  : ["ip", "time", "method", "url", "request_time", "request_length", "status", "length", "ref_url", "browser"],
    "NoKeyError" : true,
    "NoMatchError" : true,
    "KeepSource" : false
  }
}
```

- Output data

```
"ip" : "10.200. **.**"
"time" : "10/Aug/2017:14:57:51"
"method" : "POST"
"url" : "/PutData? Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=<yourSignature>"
"request_time" : "0.024"
"request_length" : "18204"
"status" : "200"
"length" : "27"
"ref_url" : "-"
"browser" : "aliyun-sdk-java"
```

Extract log fields by using start and stop keywords

This method uses the `start` and `stop` keywords to extract fields. You can extract fields from the JSON string between the start and stop keywords. You can also expand the JSON string into other forms.

The type of the plug-in is `processor_anchor`.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field to extract.
Anchors	Array	Yes	The array of anchors. For more information, see the following table.
NoAnchorError	bool	No	Specifies whether to report an error if no specified keyword is found. Default value: false.
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: false.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: false. This value specifies that the SourceKey parameter is not returned.

Anchor fields

Parameter	Type	Required	Description

Parameter	Type	Required	Description
Start	string	Yes	The start keyword. If you do not specify the parameter, Logtail matches the first character of a string.
Stop	string	Yes	The stop keyword. If you do not specify the parameter, Logtail matches the last character of a string.
FieldName	string	Yes	The name of the field to extract.
FieldType	string	Yes	The type of the field to extract. Valid values: `string` and `json`.
ExpondJson	bool	No	Specifies whether to expand JSON strings. Default value: false. This parameter is available only if you specify `json` for the `FieldType` parameter.
ExpondConnecter	string	No	The connector that combines separate field names into a string. Default value: `_`.
MaxExpondDepth	int	No	The maximum depth of JSON expansion. Default value: `0`. This indicates no limit.

The following example shows how to use this method to process input data of multiple types.

- Input data

```
"content" : "time:2017.09.12 20:55:36\tjson:{\"key1\" : \"xx\", \"key2\": false, \"key3\":123.456, \"key4\" : { \"inner1\" : 1, \"inner2\" : false}}"
```

- Configurations

```
{
  "type" : "processor_anchor",
  "detail" : {"SourceKey" : "content",
    "Anchors" : [
      {
        "Start" : "time",
        "Stop" : "\t",
        "FieldName" : "time",
        "FieldType" : "string",
        "ExpondJson" : false
      },
      {
        "Start" : "json:",
        "Stop" : "",
        "FieldName" : "val",
        "FieldType" : "json",
        "ExpondJson" : true
      }
    ]
  }
}
```

- Output data

```
"time" : "2017.09.12 20:55:36"
"val_key1" : "xx"
"val_key2" : "false"
"val_key3" : "123.456"
"value_key4_inner1" : "1"
"value_key4_inner2" : "false"
```

Extract log fields by using a single-character delimiter

This method uses `single-character delimiters` to split logs into several fields. You can enclose delimited fields by using characters that you specify in the Quote parameter.

The type of the plug-in is `processor_split_char`.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field to extract.
SplitSep	string	Yes	The single-character delimiter. You must specify a single character as a delimiter. You can specify a non-printable character such as `\u0001` as a delimiter.
SplitKeys	String array	Yes	The names of the fields that are split, for example, ["key1", "key2"...].
QuoteFlag	bool	No	Specifies whether to use the `Quote` parameter. Default value: false.
Quote	string	No	You must specify a single character. The parameter is available only if you specify true for the `QuoteFlag` parameter. You can specify non-printable characters, such as `\u0001`.
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: false.
NoMatchError	bool	No	Specifies whether to report an error if the specified delimiter is not found. Default value: false.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: false. This value specifies that the SourceKey parameter is not returned.

The following example shows how to use this method to process logs.

- Input data

```
"content" : "10. **. **. **|10/Aug/2017:14:57:51 +0800|POST|PutData?
Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun%202013%2006%3A53
%3A30%20GMT&Topic=raw&Signature=<yourSignature>|0.024|18204|200|37|-|
aliyun-sdk-java"
```

- Configurations

```
{
  "type" : "processor_split_char",
  "detail" : {"SourceKey" : "content",
    "SplitSep" : "|",
    "SplitKeys" : ["ip", "time", "method", "url", "request_time", "request_length", "status", "length", "ref_url", "browser"]
  }
}
```

- Output data

```
"ip" : "10. **. **.**"
"time" : "10/Aug/2017:14:57:51 +0800"
"method" : "POST"
"url" : "/PutData? Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=<yourSignature>"
"request_time" : "0.024"
"request_length" : "18204"
"status" : "200"
"length" : "27"
"ref_url" : "-"
"browser" : "aliyun-sdk-java"
```

Extract log fields by using a multi-character delimiter

Similar to the single-character delimiter method, this method uses multi-character delimiters to split logs into several fields. The Quote parameter is unavailable for this method.

The type of the plug-in is `processor_split_string`.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field to extract.
SplitSep	string	Yes	The multi-character delimiter. You can specify non-printable characters such as `\u0001\u0002`.
SplitKeys	String array	Yes	The names of the fields that are split, for example, ["key1", "key2"...].
PreserveOthers	bool	No	Specifies whether to retain excess fields when the number of split fields exceeds the number of fields defined in the `SplitKeys` parameter. Default value: false.
ExpandOthers	bool	No	Specifies whether to parse excess fields. Default value: false.
ExpandKeyPrefix	string	No	The prefix of the names of excess fields. For example, if you specify `expand_` for the parameter, excess fields are named `expand_1` and `expand_2`.
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: false.

Parameter	Type	Required	Description
NoMatchError	bool	No	Specifies whether to report an error if no multi-character delimiter is found. Default value: false.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: false. The value false specifies that the SourceKey parameter is not returned.

The following example shows how to use this method to process logs.

- Input data

```
"content" : "10. **. **. **|#|10/Aug/2017:14:57:51 +0800|#|POST|#|PutData?
Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun%202013%2006%3A53
%3A30%20GMT&Topic=raw&Signature=<yourSignature>|#|0.024|#|18204|#|200|#|37|#|-|#|
aliyun-sdk-java"
```

- Configurations

```
{
  "type" : "processor_split_string",
  "detail" : {"SourceKey" : "content",
    "SplitSep" : "|#|",
    "SplitKeys" : ["ip", "time", "method", "url", "request_time", "request_length", "status"],
    "PreserveOthers" : true,
    "ExpandOthers" : true,
    "ExpandKeyPrefix" : "expand_"
  }
}
```

- Output data

```
"ip" : "10. **. **.**"
"time" : "10/Aug/2017:14:57:51 +0800"
"method" : "POST"
"url" : "/PutData? Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun%20
2013%2006%3A53%3A30%20GMT&Topic=raw&Signature=<yourSignature>"
"request_time" : "0.024"
"request_length" : "18204"
"status" : "200"
"expand_1" : "27"
"expand_2" : "-"
"expand_3" : "aliyun-sdk-java"
```

Convert an IP address into a geographical location

This method converts IP address into a geographical location, such as a country, province, city, or geographical coordinates.

> **Note** By default, the Logtail installation package does not include GeoIP databases. You must download these databases to your local host and configure the required parameters. We recommend that you download a version of the GeoIP database that includes the `City` database.

The type of the plug-in is `processor_geoip` .

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field whose IP address you want to convert into a geographical location.
DBPath	string	Yes	The absolute path of the GeoIP database. The database format is `MMDB`, for example, `/user/data/GeoLite2-City_20180102/GeoLite2-City.mmdb`.
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: false.
NoMatchError	bool	No	Specifies whether to report an error if the specified IP address is invalid or does not match the IP addresses stored in the library. Default value: false.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: true.
Language	string	No	The language of the GeoIP database. Default value: `zh-CN`. Make sure that your GeoIP database can be displayed in a language that is suitable for your business.

The following example shows how to use this method to convert an IP address into a geographical location.

- Input data

```
"source_ip" : "**. **. **. **"
```

Download a GeoIP database and install the database on the host where Logtail resides. We recommend that you download MaxMind GeoLite2 that includes the city database.

> **Note** Make sure that the database format is MMDB.

- Configurations

```
{
  "type": "processor_geoip",
   "detail": {
      "SourceKey": "ip",
      "NoKeyError": true,
      "NoMatchError": true,
      "KeepSource": true,
      "DBPath" : "/user/local/data/GeoLite2-City_20180102/GeoLite2-City.mmdb"
   }
}
```

- Output result

```
"source_ip_city_" : "**. **. **.**"
"source_ip_province_" : "Zhejiang"
"source_ip_city_" : "Hangzhou"
"source_ip_province_code_" : "ZJ"
"source_ip_country_code_" : "CN"
"source_ip_longitude_" : "120.********"
"source_ip_latitude_" : "30. ********"
```

Filter log fields by using a regular expression

This method uses regular expressions to filter logs. You can specify conditions in the `Include` and `Exclude` parameters.

The type of the plug-in is `processor_filter_regex`.

Parameters

Parameter	Type	Required	Description
Include	The JSON object that includes key-value pairs.	No	Each key includes a log field. Each value includes a regular expression. If the field value matches the regular expression, the log is collected.
Exclude	The JSON object that includes key-value pairs.	No	Each key includes a log field. Each value includes a regular expression. If the field value matches the regular expression, the log is dropped.

Note A log is collected only if the field value matches the regular expression specified in the `Include` parameter and does not match the regular expression specified in the `Exclude` parameter. Otherwise, the log is dropped.

The following example shows how to use this method to process logs.

- Input data
  - Log 1

    ```
    "ip" : "10. **. **.**"
    "method" : "POST"
    ...
    "browser" : "aliyun-sdk-java"
    ```

  - Log 2

    ```
    "ip" : "10. **. **.**"
    "method" : "POST"
    ...
    "browser" : "chrome"
    ```

  - Log 3

    ```
    "ip" : "192.168. *.*"
    "method" : "POST"
    ...
    "browser" : "ali-sls-ilogtail"
    ```

- Configurations

```
{
  "type" : "processor_filter_regex",
   "detail" : {
     "Include" : {
       "ip" : "10\\..*",
       "method" : "POST"
     },
     "Exclude" : {
       "browser" : "aliyun. *"
     }
   }
}
```

- Output data

Log	Matched	Reason
Log 1	No	The match failed because the value of the browser field matches the regular expression specified in the Exclude parameter.
Log 2	Yes	-
Log 3	No	The match failed because the value of the ip field does not match the regular expression specified in the `Include` parameter. The regular expression matches `IP` addresses that start with `10`.

Add log fields

You can use this method to add multiple fields to a log.

The type of the plug-in is `processor_add_fields`.

> **Note** This method is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
Fields	map	No	The JSON object that includes key-value pairs. You can specify multiple key-value pairs in the parameter.
IgnoreIfExist	bool	No	Specifies whether to ignore key-value pairs that have the same keys. Default value: false.

The following example shows how to use this method to add fields to logs.

- Input data

```
"aaa1":"value1"
```

- Configurations

```
{
 "processors":[
  {
   "type":"processor_add_fields",
   "detail":{
    "Fields":{
     "aaa2": "value2",
     "aaa3": "value3"
    }
   }
  }
 ]
}
```

- Output data

```
"aaa1":"value1"
"aaa2":"value2"
"aaa3":"value3"
```

Remove log fileds

You can use this method to remove specific fields from logs.

The type of the plug-in is `processor_drop` .

> **Note** The method is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
DropKeys	array	No	The array that includes a set of strings. You can remove multiple fields from a log.

The following example shows how to remove the `aaa1` and `aaa2` fields from a log.

- Input data

```
"aaa1":"value1"
"aaa2":"value2"
"aaa3":"value3"
```

- Configurations

```
{
 "processors":[
  {
   "type":"processor_drop",
   "detail":{
    "DropKeys": ["aaa1","aaa2"]
   }
  }
 ]
}
```

- Output data

```
"aaa3":"value3"
```

Extract log time (Go)

You can use this method to extract time from a log field and convert the time format.

The type of the plug-in is `processor_gotime`.

> **Note** This plug-in is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the log field from which you want to extract time.
SourceFormat	string	Yes	The time that is parsed in Go.
SourceLocation	int	Yes	The source time zone. If the parameter is not specified, it indicates the time zone of the local host.
DestKey	string	Yes	The destination field.
DestFormat	string	Yes	The destination time format in Go.
DestLocation	int	No	The destination time zone. If the parameter is not specified, it indicates the time zone of the local host.
SetTime	bool	No	Specifies whether to overwrite the original time. Default value: true.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: true.
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: true.
AlarmIfFail	bool	No	Specifies whether to send alerts when extraction failed. Default value: true.

Use `2006-01-02 15:04:05` (UTC +8) of the `s_key` field as the source time. Convert the time into `2006/01/02 15:04:05` (UTC +9) and save the new time in the `d_key` field. The following example shows how to use this method to process logs.

- Input data

```
"s_key":"2019-07-05 19:28:01"
```

- Configurations

```
{
 "processors":[
  {
   "type":"processor_gotime",
   "detail":{
    "SourceKey": "s_key",
    "SourceFormat":"2006-01-02 15:04:05",
    "SourceLocation":8,
    "DestKey":"d_key",
    "DestFormat":"2006/01/02 15:04:05",
    "DestLocation":9,
    "SetTime": true,
    "KeepSource": true,
    "NoKeyError": true,
    "AlarmIfFail": true
   }
  }
 ]
}
```

- Output data

```
"s_key":"2019-07-05 19:28:01"
"d_key":"2019/07/05 20:28:01"
```

Expand log fields (JSON)

You can use this method to expand a log field.

The type of the plug-in is `processor_json`.

> **Note** This plug-in is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field you want to expand.
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: true.
ExpandDepth	int	No	The depth of JSON expansion. The value must be a non-negative integer. Default value: 0. This indicates the depth is not limited. The value n specifies that the number of levels to expand is n.
ExpandConnector	string	No	The delimiter that you use to connect expanded levels. Default value: `_`. You can leave this parameter unspecified.
Prefix	string	No	The prefix that you want to add to the name of each new field after expansion.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: true.

Parameter	Type	Required	Description
UseSourceKeyAsPrefix	bool	No	Specifies whether to retain the name of the source field as the prefix of each new field after expansion. Default value: false.

The following example shows how to use the field expansion (JSON) method to expand the `s_key` field.

- Input data

```
"s_key":"{\"k1\":{\"k2\":{\"k3\":{\"k4\":{\"k51\":\"51\",\"k52\":\"52\"},\"k41\":\"41\"}}}}"
```

- Configurations

```
{
 "processors":[
  {
   "type":"processor_json",
   "detail":{
    "SourceKey": "s_key",
    "NoKeyError":true,
    "ExpandDepth":0,
    "ExpandConnector":"-",
    "Prefix":"j",
    "KeepSource": false,
    "UseSourceKeyAsPrefix": true
   }
  }
 ]
}
```

- Output data

```
"s_key":"{\"k1\":{\"k2\":{\"k3\":{\"k4\":{\"k51\":\"51\",\"k52\":\"52\"},\"k41\":\"41\"}}}}"
"js_key-k1-k2-k3-k4-k51":"51"
"js_key-k1-k2-k3-k4-k52":"52"
"js_key-k1-k2-k3-k41":"41"
```

Combine log fields (JSON)

You can use this method to combine multiple log fields into one field.

The type of the plug-in is `processor_packjson`.

> **Note** This plug-in is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
SourceKeys	array	Yes	The array that includes the names of fields that you want to combine.
DestKey	string	No	The name of the destination field after combination.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: true.

Parameter	Type	Required	Description
AlarmIfIncomplete	bool	No	Specifies whether to send alerts if no source fields exist. Default value: true.

The following example shows how to use the method to combine the `a` and `b` fields into the `d_key` field.

- Input data

```
"a":"1"
"b":"2"
```

- Configurations

```
{
 "processors":[
  {
   "type":"processor_packjson",
   "detail":{
    "SourceKeys":["a","b"],
    "DestKey":"d_key",
    "KeepSource":true,
    "AlarmIfEmpty":true
   }
  }
 ]
}
```

- Output data

```
"a":"1"
"b":"2"
"d_key":"{\"a\":\"1\",\"b\":\"2\"}"
```

Rename fields

You can use this method to rename multiple fields.

The type of the plug-in is `processor_rename`.

> **Note** This plug-in is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
NoKeyError	bool	No	Specifies whether to report an error if no match exists. Default value: true.
SourceKeys	array	Yes	The array that includes the names of fields that you want to rename.
DestKeys	array	Yes	The array that includes the new names of the fields.

The following example shows how to use this method to rename the `aaa1` and `aaa2` fields to `bbb1` and `bbb2` fields.

- Input data

```
"aaa1":"value1"
"aaa2":"value2"
"aaa3":"value3"
```

- Configurations

```
{
 "processors":[
  {
   "type":"processor_rename",
   "detail":{
    "SourceKeys":["aaa1","aaa2"],
    "DestKeys":["bbb1","bbb2"],
    "NoKeyError":true
   }
  }
 ]
}
```

- Output data

```
"bbb1":"value1"
"bbb2":"value2"
"aaa3":"value3"
```

Extract log time (Strptime)

You can use this method to extract time from a log field and parse the time by using the Linux strptime() function.

The type of the plug-in is `processor_strptime`.

> **Note** This plug-in is available for Logtail 0.16.28 or later.

Parameters

Parameter	Type	Required	Description
SourceKey	string	Yes	The name of the field from which you want to extract time.
Format	string	Yes	The time format to parse the time.
AdjustUTCOffset	bool	No	Specifies whether to adjust the time zone. Default value: false.
UTCOffset	int	No	The offset that is used to adjust the time zone. Unit: seconds. For example, if you set the value to 14400, the time zone is changed to UTC+8.
AlarmIfFail	bool	No	Specifies whether to send alerts if a field fails to be extracted.
KeepSource	bool	No	Specifies whether to return the SourceKey parameter. Default value: true.

Parse the value of the `log_time` in the `%Y/%m/%d %H:%M:%S` time format and use the time zone of your local host. The following examples show how to use this method to process logs.

- Example 1: The time zone is UTC +8.

- Input data

```
"log_time":"2016/01/02 12:59:59"
```

- Configurations

```
{
 "processors":[
  {
   "type":"processor_strptime",
   "detail":{
    "SourceKey": "log_time",
    "Format": "%Y/%m/%d %H:%M:%S"
   }
  }
 ]
}
```

- Output data

```
"log_time":"2016/01/02 12:59:59"
Log.Time = 1451710799
```

- Example 2: The time zone is UTC +7.
  - Input data

```
"log_time":"2016/01/02 12:59:59"
```

  - Configurations

```
{
 "processors":[
  {
   "type":"processor_strptime",
   "detail":{
    "SourceKey": "log_time",
    "Format": "%Y/%m/%d %H:%M:%S",
    "AdjustUTCOffset": true,
    "UTCOffset": 25200
   }
  }
 ]
}
```

  - Output data

```
"log_time":"2016/01/02 12:59:59"
Log.Time = 1451714399
```

Custom methods

You can use a combination of multiple processing methods to process logs. The following example shows how to use a single-character delimiter to split a log into several fields and then specify anchor points to extract content from the `detail` field.

- Input data

"content":
"ACCESS|QAS|11. **. **.**|1508729889935|52460dbed4d540b88a973cf5452b1447|1238|appKey=ba,env=pub,requestTime=1508729889913,latency=22ms,
request={appKey:ba,optional:{\\domains\\:\\daily\\,\\version\\:\\v2\\},rawQuery:{\\query\\:\\The route to Location A\\,\\domain\\:\\Navigation\\,\\intent\\:\\navigate\\,\\slots\\:\\to_geo:level3=Location A\\,\\location\\:\\Location B\\},
requestId:52460dbed4d540b88a973cf5452b1447},
response={answers:[],status:SUCCESS}|"

- Configurations

```
"processors" : [
  {
    "type" : "processor_split_char",
    "detail" : {"SourceKey" : "content",
      "SplitSep" : "|",
      "SplitKeys" : ["method", "type", "ip", "time", "req_id", "size", "detail"]
    }
  },
  {
    "type" : "processor_anchor",
    "detail" : "SourceKey" : "detail",
      "Anchors" : [
        {
            "Start" : "appKey=",
          "Stop" : ",env=",
          "FieldName" : "appKey",
          "FieldType" : "string"
        },
        {
          "Start" : ",env",
          "Stop" : ",requestTime=",
          "FieldName" : "env",
          "FieldType" : "string"
        },
        {
          "Start" : ",requestTime=",
          "Stop" : ",latency",
          "FieldName" : "requestTime",
          "FieldType" : "string"
        },
        {
          "Start" : ",latency=",
          "Stop" : ",request=",
          "FieldName" : "latency",
          "FieldType" : "string"
        },
        {
          "Start" : ",request=",
          "Stop" : ",response=",
          "FieldName" : "request",
          "FieldType" : "string"
        },
        {
          "Start" : ",response=",
          "Stop" : "",
          "FieldName" : "response",
          "FieldType" : "json"
        }
      ]
    }
  }
]
```

- Output data

"method" : "ACCESS"
"type" : "QAS"
"ip" : "**. **. **.**"
"time" : "1508729889935"
"req_id" : "52460dbed4d540b88a973cf5452b1447"
"size" : "1238"
"appKey" : "ba"
"env" : "pub"
"requestTime" : "1508729889913"
"latency" : "22ms"
"request" : "{appKey:nui-banma,optional:{\\domains\\:\\daily-faq\\,\\version\\:\\v2\\},rawQuery:{\\query\\:\\\345\216\273\344\271\220\345\261\261\347\232\204\350\267\257\347\272\277\\,\\domain\\:\\\345\257\274\350\210\252\\,\\intent\\:\\navigate\\,\\slots\\:\\to_geo:level3=\344\271\220\345\261\261\\,\\location\\:\\\345\214\227\344\272\254\\},requestId:52460dbed4d540b88a973cf5452b1447}"
"response_answers" : "[]"
"response_status" : "SUCCESS"

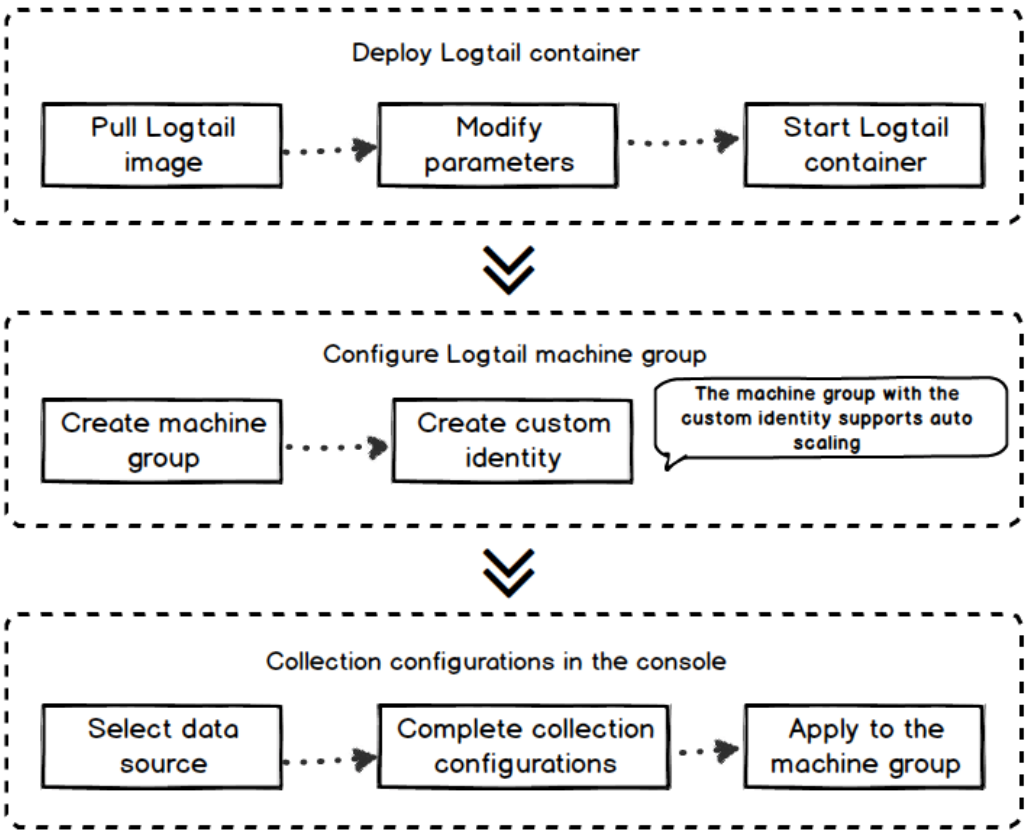
23.3.1.6. Collect container logs

23.3.1.6.1. Collect standard Docker logs

This topic describes how to use Logtail to collect standard Docker logs and upload these logs together with the container metadata to Log Service.

Procedure

Procedure



1. Deploy a Logtail container.

2. Configure a Logtail server group.

   Create a server group with a custom ID in the Log Service console. The container cluster can automatically scale up or down based on data traffic.

3. Create a Logtail configuration.

   Create a Logtail configuration in the Log Service console. The Logtail configuration process is completed in the Log Service console. No local configuration is needed.

Deploy a Logtail container

1. Run the following command to pull the Logtail image.

```
docker pull registry.cn-hangzhou.aliyuncs.com/log-service/logtail
```

2. Start a Logtail container.

   Set the `${your_region_name}`, `${your_aliyun_user_id}`, and `${your_machine_group_user_defined_id}` parameters in the startup template.

```
docker run -d -v /:/logtail_host:ro -v /var/run:/var/run --env
ALIYUN_LOGTAIL_CONFIG=/etc/ilogtail/conf/${your_region_name}/ilogtail_config.json
--env ALIYUN_LOGTAIL_USER_ID=${your_aliyun_user_id} --env
ALIYUN_LOGTAIL_USER_DEFINED_ID=${your_machine_group_user_defined_id} registry.cn-hangzhou.aliyuncs.com/log-service/logtail
```

   Notice Before you set the parameters, you must complete one of the following configurations. Otherwise, the `container text file busy` error may occur when you delete another container.

   - For CentOS 7.4 and later versions, set fs.may_detach_mounts to 1. For more information, see Bug 1468249, Bug 1441737, and Issue 34538.
   - Grant the `privileged` permission to Logtail by adding the `--privileged` flag to the startup parameters. For more information, see Docker run reference.

Parameter	Description
`${your_region_name}`	The region of the project. For more information, see View the information of a project.
`${your_aliyun_user_id}`	The user ID. Set this parameter to the ID of your Alibaba Cloud account, which is a string. For information about how to view the ID, see Step 1 in Configure an account ID for a server.
`${your_machine_group_user_defined_id}`	The custom ID of your server group. For information about how to set the custom ID, see Step 1 in Create a machine group based on a custom ID.

   After you set the parameters, run the following command to start the Logtail container.

```
docker run -d -v /:/logtail_host:ro -v /var/run:/var/run
--env ALIYUN_LOGTAIL_CONFIG=/etc/ilogtail/conf/cn_hangzhou/ilogtail_config.json --env
ALIYUN_LOGTAIL_USER_ID=1654218******--env ALIYUN_LOGTAIL_USER_DEFINED_ID=log-docker-demo registry.cn-hangzhou.aliyuncs.com/log-service/logtail
```

> **Notice**
>
> You can customize the startup parameters of the Logtail container if the following conditions are met:
>
> - The following environment variables exist before you start the Logtail container: `ALIYUN_LOGTAIL_USER_DEFINED_ID`, `ALIYUN_LOGTAIL_USER_ID`, and `ALIYUN_LOGTAIL_CONFIG`.
> - The */var/run* directory is mounted on the */var/run* directory of the Logtail container.
> - To collect container standard output, container logs, or host files, you must mount the root directory on the `/logtail_host` directory of the Logtail container.
> - If an error showing *The parameter is invalid : uuid=none* occurs in the `/usr/local/ilogtail/ilogtail.LOG` Logtail log file, create a file named *product_uuid* on the host. Add a valid UUID such as `169E98C9-ABC0-4A92-B1D2-AA6239C0D261` to the file, and mount the file on the */sys/class/dmi/id/product_uuid* directory of the Logtail container.

Configure a Logtail server group

1. Log on to the Log Service console.
2. Click a project name.
3. In the left-side navigation pane, click the **Server Groups** icon to show the server group list.
4. Click the icon next to Server Groups, and then select **Create Server Group**.

   You can also create a server group when you import data to Log Service.
5. In the dialog box that appears, select **Custom ID** from the Identifier drop-down list. Enter the value of `ALIYUN_LOGTAIL_USER_DEFINED_ID` set in the previous step in the **Custom Identifier** field.

Click OK. One minute later, click the name of the server group in the **Server Groups** list. On the **Server Group Settings** page that appears, you can view the heartbeat status of the Logtail container. For more information, see View the status of a server group.

Create a Logtail configuration

Create a Logtail configuration in the console.

- For more information about Docker logs, see Collect container text logs.
- For more information about Docker standard output, see Collect stdout and stderr logs from containers.
- Host text logs.

  The root directory of a host is mounted on the `/logtail_host` directory of the Logtail container by default. You must add the /logtail_host prefix to the log path. For example, if you want to collect data from the `/home/logs/app_log/` directory of the host, you must set the log path as `/logtail_host/home/logs/app_log/`.

What to do next

- View the status of the Logtail container.

  You can run the `docker exec ${logtail_container_id} /etc/init.d/ilogtaild status` command to view the status of Logtail.
- View the version number, IP address, and startup time of Logtail.

  You can run the `docker exec ${logtail_container_id} cat /usr/local/ilogtail/app_info.json` command to view Logtail information.
- View the operations logs of Logtail.

  The operations logs of Logtail are stored in the `ilogtail.LOG` file in the `/usr/local/ilogtail/` directory. If the log file is rotated and compressed, it is stored as a file named `ilogtail.LOG.x.gz`.

  For example:

```
[root@iZbp17enxc2us3624wexh2Z ilogtail]# docker exec a287de895e40 tail -n 5 /usr/local/ilogtail/ilogtail.LOG
[2018-02-06 08:13:35.721864]  [INFO]  [8]  [build/release64/sls/ilogtail/LogtailPlugin.cpp:104]  logtail plugin Resume: start
[2018-02-06 08:13:35.722135]  [INFO]  [8]  [build/release64/sls/ilogtail/LogtailPlugin.cpp:106]  logtail plugin Resume: success
[2018-02-06 08:13:35.722149]  [INFO]  [8]  [build/release64/sls/ilogtail/EventDispatcher.cpp:369]  start add existed check point events, size:0
[2018-02-06 08:13:35.722155]  [INFO]  [8]  [build/release64/sls/ilogtail/EventDispatcher.cpp:511]  add existed check point events, size:0  cache size:0  event size:0  success count:0
[2018-02-06 08:13:39.725417]  [INFO]  [8]  [build/release64/sls/ilogtail/ConfigManager.cpp:3776]  check container path update flag:0  size:1
```

Ignore the following standard output:

```
start umount useless mount points, /shm$|/merged$|/mqueue$
umount: /logtail_host/var/lib/docker/overlay2/3fd0043af174cb0273c3c7869500fbe2bdb95d13b1e110172ef57fe840c82155/merged: must be superuser to unmount
umount: /logtail_host/var/lib/docker/overlay2/d5b10aa19399992755de1f85d25009528daa749c1bf8c16edff44beab6e69718/merged: must be superuser to unmount
umount: /logtail_host/var/lib/docker/overlay2/5c3125daddacedec29df72ad0c52fac800cd56c6e880dc4e8a640b1e16c22dbe/merged: must be superuser to unmount
...
xargs: umount: exited with status 255; aborting
umount done
start logtail
ilogtail is running
logtail status:
ilogtail is running
```

- Restart Logtail.

  To restart Logtail, use the following sample code:

```
[root@iZbp17enxc2us3624wexh2Z ilogtail]# docker exec a287de895e40 /etc/init.d/ilogtaild stop
kill process Name: ilogtail pid: 7
kill process Name: ilogtail pid: 8
stop success
[root@iZbp17enxc2us3624wexh2Z ilogtail]# docker exec a287de895e40 /etc/init.d/ilogtaild start
ilogtail is running
```

23.3.1.6.2. Collect Kubernetes logs

This topic describes how to install and use Logtail to collect logs from Kubernetes clusters.

Configuration procedure

Perform the following steps to collect logs from Kubernetes clusters:

1. Install the alibaba-log-controller Helm package.
2. Use the Log Service console to manage log collection configurations.

Step 1: Install Logtail

- Install Logtail in an Alibaba Cloud Container Service for Kubernetes cluster.

  If Log Service components are not installed in your cluster, you must manually install the components.

  i. Connect to the Kubernetes cluster by using CloudShell.

  ii. Run the following command in CloudShell to obtain the ID of your Apsara Stack tenant account.

```
echo $ALIBABA_CLOUD_ACCOUNT_ID
```

iii. After you set the `${your_k8s_cluster_id}`, `${your_ali_uid}`, and `${your_k8s_cluster_region_id}` parameters, run the following command:

```
wget https://acs-logging.oss-cn-hangzhou.aliyuncs.com/alicloud-k8s-log-installer.sh -O alicloud-k8s-log-installer.sh; chmod 744 ./alicloud-k8s-log-installer.sh; ./alicloud-k8s-log-installer.sh --cluster-id ${your_k8s_cluster_id} --ali-uid ${your_ali_uid} --region-id ${your_k8s_cluster_region_id}
```

- Install Logtail in a user-created Kubernetes cluster.

> **Notice**
> - The version of the Kubernetes cluster must be 1.8 or later.
> - Helm 2.6.4 or later must be installed.

i. In the Log Service console, create a project whose name starts with `k8s-log-custom-`.

ii. Replace the parameters in the following command based on your business requirements:

```
wget http://logtail-release-cn-hangzhou.oss-cn-hangzhou.aliyuncs.com/kubernetes/alicloud-log-k8s-custom-install.sh; chmod 744 ./alicloud-log-k8s-custom-install.sh; sh ./alicloud-log-k8s-custom-install.sh {your-project-suffix} {region-id} {aliuid} {access-key-id} {access-key-secret}
```

The following table lists the parameters in the preceding command.

Parameter	Description
{your-project-suffix}	The portion of the project name at the end of `k8s-log-custom-`. For example, if you create a project whose name is `k8s-log-custom-xxxx`, set this parameter to `xxxx`.
{regionId}	The ID of the region where the project resides. For more information, see View the information of a project.
{aliuid}	The user ID. Set this parameter to the ID of your Apsara Stack tenant account. **Note** The ID of an Apsara Stack tenant account is a string. For more information about how to obtain the ID, see Configure an account ID for a server.
{access-key-id}	The AccessKey ID of your Apsara Stack tenant account.
{access-key-secret}	The AccessKey secret of your Apsara Stack tenant account.

After Logtail is installed in the Kubernetes cluster, Log Service automatically creates a machine group named `k8s-group-${your_k8s_cluster_id}` for the project.

> **Note**
> - A Logstore named `config-operation-log` is automatically created in the project. Do not delete the Logstore.
> - When you install Logtail in a user-created Kubernetes cluster, Logtail is granted `privileged` permissions by default. This prevents the `container text file busy` error when you delete a pod. For more information, visit Bug 1468249, Bug 1441737, and Issue 34538.

The following example shows a successful installation:

```
[root@iZbp1dsxxxxxqfbiaZ ~]# wget http://logtail-release-cn-hangzhou.oss-cn-hangzhou.aliyuncs.com/kubernetes/alicloud-log-k8s-custom-install.sh; chmod 744 ./alicloud-log-k8s-custom-install.sh; sh ./alicloud-log-k8s-custom-install.sh xxxx cn-hangzhou 165xxxxxxxx050 LTAxxxxxxxxxxx AIxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxe
....
....
....

[INFO] your k8s is using project : k8s-log-custom-xxx, region : cn-hangzhou, aliuid : ***************, accessKeyId : LTA*********
[SUCCESS] install helm package : alibaba-log-controller success.
```

To check the status of each Log Service component in the Kubernetes cluster, run the `helm status alibaba-log-controller` command. If all pods are in the Running state, Logtail is installed.

Log on to the Log Service console to find the project. If you have multiple projects, search for the project by using the `k8s-log` keyword.

Step 2: Configure log collection

Create Logtail configurations for log collection in the console as required.

- For information about how to collect Kubernetes text logs, see Collect container text logs.
- For information about how to collect Kubernetes stdout logs, see Collect stdout and stderr logs from containers.
- Host text logs.

  By default, the root directory of a host is mounted to the `/logtail_host` directory of the Logtail container. You must add the /logtail_host prefix to the log path. For example, if you want to collect data from the `/home/logs/app_log/` directory of the host, you must set the log path to `/logtail_host/home/logs/app_log/` .

Other common commands

- Store logs of multiple clusters in one project

You can collect logs from multiple Kubernetes clusters. If you want to store these logs in the same project, you can specify the same cluster ID for the `${your_k8s_cluster_id}` parameter when you install Log Service components on multiple Kubernetes clusters.

For example, if you have three Kubernetes clusters whose IDs are abc001, abc002, and abc003, specify `abc001` for the `${your_k8s_cluster_id}` parameter when you install Log Service components for each Kubernetes cluster.

> **Notice** This feature is unavailable for Kubernetes clusters that reside in different regions.

- Logtail container logs

  Logtail log files named `ilogtail.LOG` and `logtail_plugin.LOG` are stored in the `/usr/local/ilogtail/` directory of a Logtail container. Ignore the following standard output:

```
start umount useless mount points, /shm$|/merged$|/mqueue$
umount: /logtail_host/var/lib/docker/overlay2/3fd0043af174cb0273c3c7869500fbe2bdb95d13b1e110172ef57fe840c82155/merged: must be superuser to unmount
umount: /logtail_host/var/lib/docker/overlay2/d5b10aa19399992755de1f85d25009528daa749c1bf8c16edff44beab6e69718/merged: must be superuser to unmount
umount: /logtail_host/var/lib/docker/overlay2/5c3125daddacedec29df72ad0c52fac800cd56c6e880dc4e8a640b1e16c22dbe/merged: must be superuser to unmount
......
xargs: umount: exited with status 255; aborting
umount done
start logtail
ilogtail is running
logtail status:
ilogtail is running
```

- View the status of each Log Service component in a Kubernetes cluster

```
helm status alibaba-log-controller
```

- Troubleshoot alibaba-log-controller startup failures

  Make sure that the following conditions are met:

  - Log Service components are installed on the master node of the Kubernetes cluster.
  - The Kubernetes cluster ID that you specified is valid when you install Log Service components.

  If Log Service components fail to be installed because the preceding conditions are not met, run the `helm del --purge alibaba-log-controller` command to delete the installation package and install Log Service components again.

- View the status of Logtail DaemonSet in a Kubernetes cluster

  Run the `kubectl get ds -n kube-system` command.

  > **Note** The default namespace of Logtail is `kube-system`.

- View the version number, IP address, and startup time of Logtail.

  Example:

```
[root@iZbp1dsu6v77zfb40qfbiaZ ~]# kubectl get po -n kube-system | grep logtail
NAME       READY   STATUS   RESTARTS  AGE
logtail-ds-gb92k  1/1     Running  0       2h
logtail-ds-wm7lw  1/1     Running  0       4d
[root@iZbp1dsu6v77zfb40qfbiaZ ~]# kubectl exec logtail-ds-gb92k -n kube-system cat /usr/local/ilogtail/app_info.jso
n
{
  "UUID" : "",
  "hostname" : "logtail-ds-gb92k",
  "instance_id" : "0EBB2B0E-0A3B-11E8-B0CE-0A58AC140402_172.20.4.2_1517810940",
  "ip" : "172.20.4.2",
  "logtail_version" : "0.16.2",
  "os" : "Linux; 3.10.0-693.2.2.el7.x86_64; #1 SMP Tue Sep 12 22:26:13 UTC 2017; x86_64",
  "update_time" : "2018-02-05 06:09:01"
}
```

- View the operational logs of Logtail

  Logtail operational logs are stored in the `ilogtail.LOG` file in the `/usr/local/ilogtail/` directory. If the log file is rotated and compressed, it is stored as a file named `ilogtail.LOG.x.gz`.

  Example:

```
[root@iZbp1dsu6v77zfb40qfbiaZ ~]# kubectl exec logtail-ds-gb92k -n kube-system tail /usr/local/ilogtail/ilogtail.LOG
[2018-02-05 06:09:02.168693] [INFO] [9] [build/release64/sls/ilogtail/LogtailPlugin.cpp:104] logtail plugin Resume:start
[2018-02-05 06:09:02.168807] [INFO] [9] [build/release64/sls/ilogtail/LogtailPlugin.cpp:106] logtail plugin Resume:succe
ss
[2018-02-05 06:09:02.168822] [INFO] [9] [build/release64/sls/ilogtail/EventDispatcher.cpp:369] start add existed check
point events, size:0
[2018-02-05 06:09:02.168827] [INFO] [9] [build/release64/sls/ilogtail/EventDispatcher.cpp:511] add existed check point
events, size:0 cache size:0 event size:0 success count:0
```

- Restart Logtail in a pod

  Example:

```
[root@iZbp1dsu6v77zfb40qfbiaZ ~]# kubectl exec logtail-ds-gb92k -n kube-system /etc/init.d/ilogtaild stop
kill process Name: ilogtail pid: 7
kill process Name: ilogtail pid: 9
stop success
[root@iZbp1dsu6v77zfb40qfbiaZ ~]# kubectl exec logtail-ds-gb92k -n kube-system /etc/init.d/ilogtaild start
ilogtail is running
```

23.3.1.6.3. Collect container text logs

Logtail collects text logs generated in containers and uploads these logs together with the container-related metadata information to Log Service.

Features

Compared with basic log file collection, Docker file collection has the following characteristics:

- Allows you to configure the log path of a container, without the need to consider the mapping between the path and the host.
- Allows you to use labels to specify the containers whose logs are to be collected.
- Allows you to use labels to exclude specific containers.
- Allows you to use environment variables to specify the containers whose logs are to be collected.
- Allows you to use environment variables to exclude specific containers.
- Supports multiline logs such as Java Stack logs.

- Supports automatic labeling for container data.
- Supports automatic labeling for Kubernetes containers.

Limits

- Collection stop policy: When a container is stopped and Logtail detects the `die` event on the container, Logtail stops collecting logs of the container (with a latency of no more than 3 seconds). In this case, if a collection latency occurs, some logs generated before the stop action may be lost.
- Docker storage driver: Only overlay and overlay2 are supported. For other storage drivers, you must mount the log directory to the local host.
- Logtail running mode: Logtail must run in a container and must be deployed based on Logtail deployment solutions.
- Label: refers to the label information in docker inspect. It is not synonymous with labels in Kubernetes.
- Environment: refers to the environment information configured during container startup.

Procedure

1. Deploy and configure the Logtail container.
2. Configure log collection in Log Service.

Logtail deployment and configuration

- Kubernetes

  For more information about Kubernetes log collection, see Logtail deployment solution for collecting Kubernetes logs.

- Management methods for other containers

  For more information about management methods for other containers, such as Swarm and Mesos, see Common deployment solution for collecting Docker logs.

Collection configuration

1. Log on to the Log Service console.
2. Click the **Import Data** button. On the **Import Data** page that appears, select **Docker File**.
3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.

4. Create a server group.

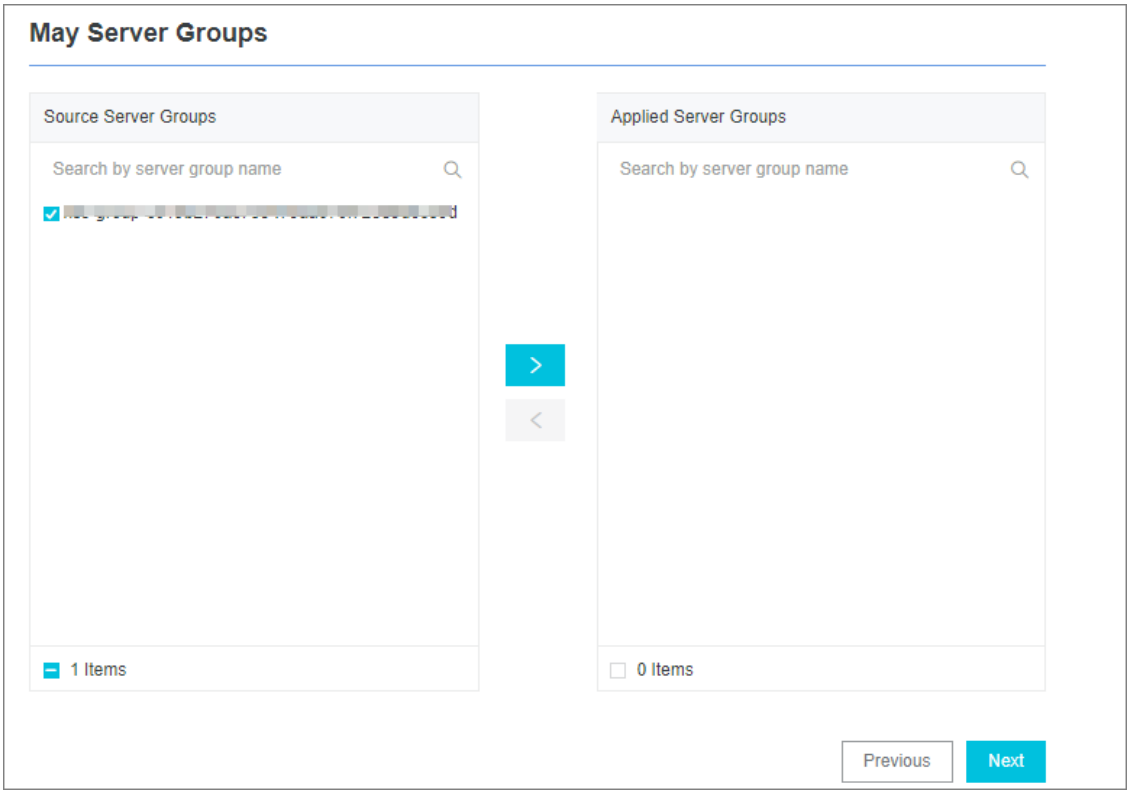
   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.

5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Configure Logtail.

   The following table lists data source-specific parameters. For more information about common parameters, see Configure text log collection.

Parameter	Description
Docker File	This parameter is used to check whether the collected target file is a Docker file.
Label Whitelist	LabelKey is required. If LabelValue is not empty, only containers whose labels contain LabelKey = LabelValue are collected. If LabelValue is empty, all the containers whose labels contain LabelKey are collected. **Note** ◦ Key-value pairs are disjunctive with each other. If the label of a container contains one of the key-value pairs you specify, logs of the container are collected. ◦ Labels refer to Docker labels.
Label Blacklist	LabelKey is required. If LabelValue is not empty, only containers whose labels contain LabelKey = LabelValue are excluded. If LabelValue is empty, all containers whose labels contain LabelKey are excluded. **Note** ◦ Key-value pairs are disjunctive with each other. If the label of a container contains one of the key-value pairs you specify, the container is excluded. ◦ Labels described in this topic refer to the label information in docker inspect.

Parameter	Description
Environment Variable Whitelist	EnvKey is required. If EnvValue is not empty, only containers whose environment variables contain EnvKey = EnvValue are collected. If EnvValue is empty, all containers whose environment variables contain EnvKey are collected. Note ○ Key-value pairs are disjunctive with each other. If the environment variable of a container contains one of the key-value pairs you specify, logs of the container are collected. ○ The environment variable refers to the environment information configured in container startup.
Environment Variable Blacklist	EnvKey is required. If EnvValue is not empty, only containers whose environment variables contain EnvKey = EnvValue are excluded. If EnvValue is empty, all containers whose environment variables contain EnvKey are excluded. Note ○ Key-value pairs are disjunctive with each other. If the environment variable of a container contains one of the key-value pairs you specify, the container is excluded. ○ The environment variable refers to the environment information configured in container startup.

Note

- Labels in whitelist and blacklist are different from those defined in Kubernetes. Labels in this topic refer to the label information in docker inspect.
- A namespace and a container name in Kubernetes can be mapped to Docker labels. LabelKey corresponding to a namespace is `io.kubernetes.pod.namespace`. LabelKey corresponding to a container name is `io.kubernetes.container.name`. For example, the namespace of the pod you created is backend-prod and the container name is worker-server. In this case, you can configure a whitelist label: `io.kubernetes.pod.namespace:backend-prod` or `io.kubernetes.container.name:worker-server`, so that only logs of the container are collected.
- In Kubernetes, we recommend that you only use the `io.kubernetes.pod.namespace` and `io.kubernetes.container.name` labels. In other cases, use an environment variable whitelist or blacklist.

7. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

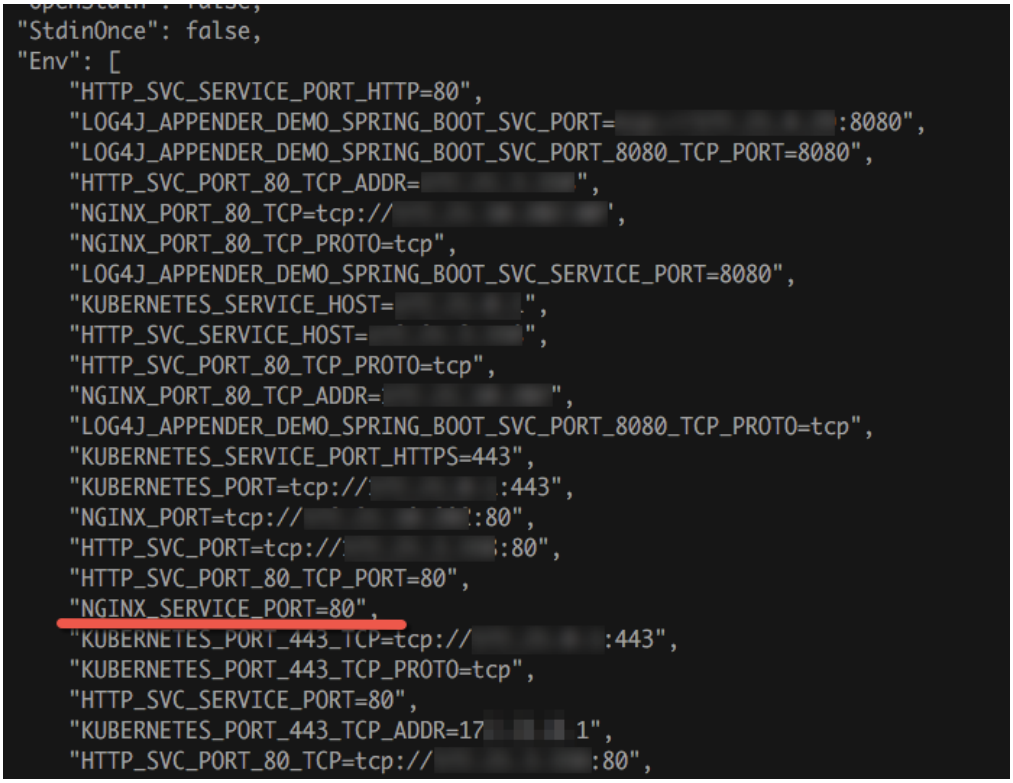
Configuration examples

- Environment configuration

  Collect the logs of the container whose environment variable is `NGINX_PORT_80_TCP_PORT=80` but not `POD_NAMESPACE=kube-system`. The log file path is `/var/log/nginx/access.log` and logs are parsed in simple mode.

  Note The environment variable refers to the environment information configured in container startup.

  Environment configuration example



- Label configuration

  Collect the logs of a container that meets the following conditions: the container label is `io.kubernetes.container.name=nginx`, the log file path is `/var/log/nginx/access.log`, and logs are parsed in simple mode.

  > **Note** Labels refer to Docker labels.

  Label configuration example

Default fields

Each uploaded log of a common Docker container contains the following fields.

Field	Description:
_image_name_	The name of the image.
_container_name_	The name of the container.

Field	Description:
_container_ip_	The IP address of the container.

If a Kubernetes cluster is used, each uploaded log contains the following fields.

Field	Description
_image_name_	The name of the image.
_container_name_	The name of the container.
_pod_name_	The name of the pod.
namespace	The namespace to which the pod belongs.
_pod_uid_	The unique identifier of the pod.
_container_ip_	The IP address of the pod.

23.3.1.6.4. Collect stdout and stderr logs from containers

This topic describes how to use Logtail to collect standard output (stdout) and standard error (stderr) logs from containers. After you collect stdout and stderr logs, you can upload the logs together with the container-related metadata to Log Service.

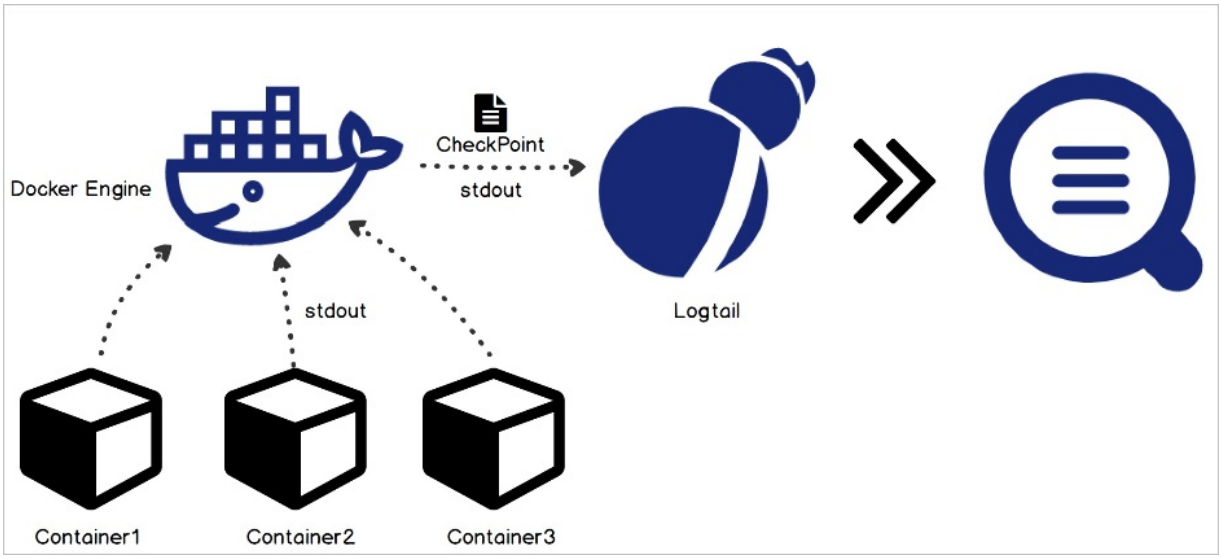
Features

- Collects stdout and xxx logs.
- Labels the containers from which you want to collect stdout and stderr logs.
- Uses tags to exclude specific containers.
- Allows you to use environment variables to specify the containers whose logs are to be collected.
- Allows you to use environment variables to exclude specific containers.
- Supports multiline logs such as Java Stack logs.
- Supports automatic labeling for container data.
- Supports automatic labeling for Kubernetes containers.

Implementation

As shown in the following figure, Logtail communicates with the domain socket of the Docker engine to query containers that run on the Docker engine. Logtail also locates containers from which you want to collect logs based on the specified labels and environment variables. Logtail then uses the docker logs command to collect logs from the specified containers.

When Logtail collects the stdout logs of a container, Logtail records information about log file positions to the checkpoint file at regular intervals. If Logtail is restarted, Logtail collects logs from the last log file position.



Limits

- This feature is available only for Logtail 0.16.0 or later that runs on Linux. For more information about Logtail versions and version updates, see Install Logtail in Linux.
- The domain socket must exist and can access the Docker engine. Otherwise, Logtail cannot access the Docker engine by running the `/var/run/docker.sock` file.
- The last multiline log that you collect must be cached for at least 1,000 seconds. By default, the retention period for a multiline log is 3 seconds. You can specify the period by configuring the `BeginLineTimeoutMs` parameter. The value of the parameter must be a minimum of 1,000 ms. Otherwise, a false positive error may occur.
- Collection stop policy: When a container is stopped and Logtail detects the `die` event on the container, Logtail stops collecting stdout logs of the container. In this case, if a collection latency occurs, some stdout logs that are generated before the stop action may be lost.
- Docker log driver: Only log drivers of the JSON type are supported in the collection of stdout logs.
- Context: By default, a collection configuration is in the same context. If you need to configure different types of containers in different contexts, configure each type separately.
- Data processing: By default, collected logs start with the `content` field. You can apply standard processing methods to these logs. For more information about how to configure one or more processing methods, see Configure data processing methods.
- Label: refers to the label information in docker inspect. It is not related to labels in Kubernetes configurations.
- Environment: refers to environment information that you specified during container startup.

Procedure

1. Deploy and configure Logtail on one or more containers.
2. Create a Logtail configuration and deliver it to Logtail.

Logtail deployment and configuration

- Kubernetes

  For more information about how to collect Kubernetes logs, see Logtail deployment solution for collecting Kubernetes logs.
- Configure Logtail on other containers

For more information about how to configure Logtail on other containers, such as Swarm and Mesos, see Common Logtail deployment solution for collecting Docker logs.

Configure a data source

1. Log on to the Log Service console.
2. Click **Import Data**. On the **Import Data** page that appears, select **Docker Standard Output**.
3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

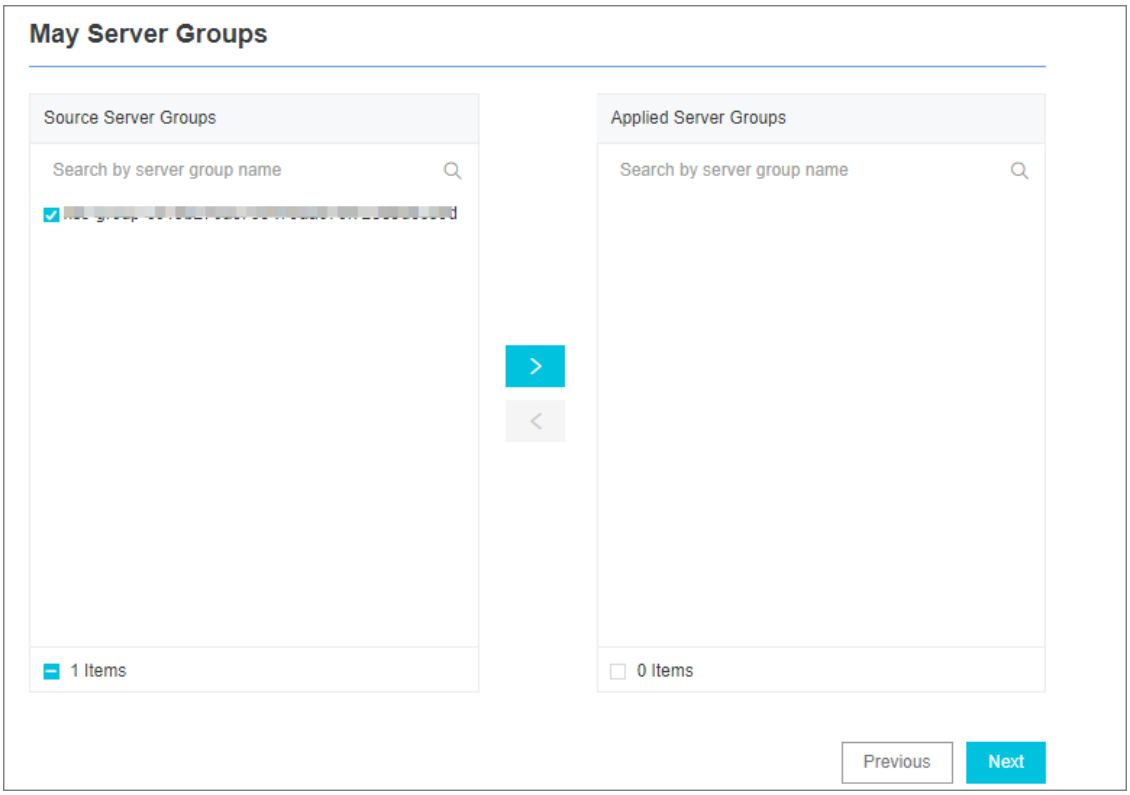
   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a server group.

   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.
5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.



6. Configure a data source.

   In the **Plug-in Config** section, set the required parameters. The following example shows how to set these parameters. For more information, see Parameters.

```
{
 "inputs": [
   {
     "type": "service_docker_stdout",
     "detail": {
       "Stdout": true,
       "Stderr": true,
       "IncludeLabel": {
         "io.kubernetes.container.name": "nginx"
       },
       "ExcludeLabel": {
         "io.kubernetes.container.name": "nginx-ingress-controller"
       },
       "IncludeEnv": {
         "NGINX_SERVICE_PORT": "80"
       },
       "ExcludeEnv": {
         "POD_NAMESPACE": "kube-system"
       }
     }
   }
 ]
}
```

7. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

Parameters

The type of the input source is `service_docker_stdout`.

> **Note** Before Logtail uploads data to Log Service, Logtail can process collected data. For more information about processing methods, see Configure data processing methods.

Parameter	Type	Required	Description
IncludeLabel	JSON text. Key: JSON string. Value: JSON string.	Yes	By default, this parameter is not specified. If the parameter is not specified, Logtail collects logs from all containers. If you set the key field and leave the value field empty, Logtail collects logs from containers whose labels include this key. **Note** • Key-value pairs are disjunctive with each other. If the label of a container matches one of the key-value pairs, logs of the container are collected. • Labels refer to docker labels.

Parameter	Type	Required	Description
ExcludeLabel	JSON text. Key: JSON string. Value: JSON string.	No	This parameter is not specified by default. If the parameter is empty, no containers are excluded. If the key is not empty but the value is empty, the containers whose labels include this key are excluded. **Note** • Key-value pairs are disjunctive with each other. If the label of a container matches one of the key-value pairs, the container is excluded. • Labels described in this topic refer to Docker labels.
IncludeEnv	Map. Key: string. Value: string	No	This parameter is empty by default. If the parameter is empty, logs of all containers are collected. If the key is not empty but the value is empty, logs of the containers whose environment variables include this key are collected. **Note** • Key-value pairs are disjunctive with each other. If the environment variable of a container includes one of the key-value pairs, the container is excluded. • The environment variable refers to the environment information configured in container startup.
ExcludeEnv	Map. Key: string. Value: string	No	This parameter is empty by default. If you leave the parameter empty, no container is excluded. If you set the key and leave the value empty, the containers whose environment variables include this key are excluded. **Note** • Key-value pairs are disjunctive with each other. When the environment variable of a container includes one of the key-value pairs, the container is excluded. • The environment variable refers to the environment information configured in container startup.
Stdout	Boolean	No	If the value of the parameter is false, stdout data is not collected. Default value: true.
Stderr	Boolean	No	Default value: true. If the value of the parameter is false, stderr data is not collected.

Parameter	Type	Required	Description
BeginLineRegex	String	No	This parameter is not specified by default. If the parameter is not empty, the regular expression is used to match the first line of each log. If a line matches this regular expression, this line is assumed as the start of a new log. Otherwise, this line is assumed as part of the previous log.
BeginLineTimeoutMs	Integer	No	The timeout period for the regular expression to match a line. Default value: 3000. Unit: ms. If no new log appears within 3 seconds, the most recent log is uploaded.
BeginLineCheckLength	Integer	No	The length of data for the regular expression to match. Default value: 10×1024. Unit: bytes. You can set this parameter to check whether the beginning part of a line can match the regular expression. This improves matching efficiency.
MaxLogSize	Integer	No	The maximum length of a log. Default value: 512×1024. Unit: bytes. If the length exceeds this value, the log data is uploaded directly without finding the first line of logs.

Note

- Labels defined in IncludeLabel and ExcludeLabel are different from those defined in Kubernetes. Labels in this topic refer to Docker labels.
- A namespace and a container name in Kubernetes can be mapped to Docker labels. The LabelKey parameter corresponding to a namespace is `io.kubernetes.pod.namespace`. The LabelKey parameter corresponding to a container name is `io.kubernetes.container.name`. For example, the namespace of the pod you created is backend-prod and the container name is worker-server. In this case, you can configure a whitelist label: `io.kubernetes.pod.namespace:backend-prod` or `io.kubernetes.container.name:worker-server`, so that only logs of the container are collected.
- In Kubernetes, we recommend that you use the `io.kubernetes.pod.namespace` and `io.kubernetes.container.name` labels. In other cases, use IncludeEnv or ExcludeEnv.

Default fields

- Common Docker containers

  Each uploaded log contains the following fields.

Field	Description:
`_time_`	The data upload time. Example: `2018-02-02T02:18:41.979147844Z`.
`_source_`	The type of the input source. Valid values: stdout and stderr.
`_image_name_`	The name of the image.
`_container_name_`	The name of the container.
`_container_ip_`	The IP address of the container.

- Kubernetes containers

  Each uploaded log contains the following fields.

Field	Description
time	The data upload time. Example: 2018-02-02T02:18:41.979147844Z.
source	The type of input sources. Valid values: stdout and stderr.
_image_name_	The name of the image.
_container_name_	The name of the container.
_pod_name_	The name of the pod.
namespace	The namespace where the pod is located.
_pod_uid_	The unique identifier of the pod.
_container_id_	The IP address of the pod.

Common configuration examples

- Environment configuration

  Collect the logs of the container whose environment variable is NGINX_PORT_80_TCP_PORT=80 but not POD_NAMESPACE=kube-system.

  > **Note** The environment variable refers to the environment information configured in container startup.

  Environment configuration example

  Collection configuration

```
{
  "inputs": [
    {
      "type": "service_docker_stdout",
      "detail": {
        "Stdout": true,
        "Stderr": true,
        "IncludeEnv": {
          "NGINX_PORT_80_TCP_PORT": "80"
        },
        "ExcludeEnv": {
          "POD_NAMESPACE": "kube-system"
        }
      }
    }
  ]
}
```

- Label configuration

  Collect the stdout and stderr logs of the container whose label is `io.kubernetes.container.name=nginx` but not `type=pre`.

  > **Note** Labels refer to Docker labels.

  Label configuration example

```
{
  "inputs": [
    {
      "type": "service_docker_stdout",
      "detail": {
        "Stdout": true,
        "Stderr": true,
        "IncludeLabel": {
          "io.kubernetes.container.name": "nginx"
        },
        "ExcludeLabel": {
          "type": "pre"
        }
      }
    }
  ]
}
```

Example of configuring multiline log collection

Configuring multiline log collection is important for the collection of Java exception stack logs. The following section introduces a standard collection configuration for Java stdout logs.

- Sample log

```
2018-02-03 14:18:41.968  INFO [spring-cloud-monitor] [nio-8080-exec-4] c.g.s.web.controller.DemoController : service start
2018-02-03 14:18:41.969 ERROR [spring-cloud-monitor] [nio-8080-exec-4] c.g.s.web.controller.DemoController : java.lang.NullPointerException
at org.apache.catalina.core.ApplicationFilterChain.internalDoFilter(ApplicationFilterChain.java:193)
at org.apache.catalina.core.ApplicationFilterChain.doFilter(ApplicationFilterChain.java:166)
at org.apache.catalina.core.StandardWrapperValve.invoke(StandardWrapperValve.java:199)
at org.apache.catalina.core.StandardContextValve.invoke(StandardContextValve.java:96)
...
2018-02-03 14:18:41.968  INFO [spring-cloud-monitor] [nio-8080-exec-4] c.g.s.web.controller.DemoController : service start done
```

- Collection configuration

  Collect logs of the container whose label is `app=monitor`. The first line of each log to be collected is of the date type. To improve matching efficiency, only the first 10 bytes of each line are checked.

```
{
"inputs": [
 {
  "detail": {
   "BeginLineCheckLength": 10,
   "BeginLineRegex": "\\d+-\\d+-\\d+. *",
   "IncludeLabel": {
    "app": "monitor"
   }
  },
  "type": "service_docker_stdout"
 }
]
}
```

Process collected data

Logtail can process the collected Docker stdout logs by using a common data processing method. Use a regular expression to extract the time, module, thread, class, and info fields.

- Collection configuration

  Collect logs from a container whose label is `app=monitor`. The first line of each log to be collected is of the date type. To improve matching efficiency, only the first 10 bytes of each line are checked.

```
{
"inputs": [
 {
  "detail": {
   "BeginLineCheckLength": 10,
   "BeginLineRegex": "\\d+-\\d+-\\d+. *",
   "IncludeLabel": {
    "app": "monitor"
   }
  },
  "type": "service_docker_stdout"
 }
],
"processors": [
  {
    "type": "processor_regex",
    "detail": {
      "SourceKey": "content",
      "Regex": "(\\d+-\\d+-\\d+ \\d+:\\d+:\\d+\\.\\d+)\\s+(\\w+)\\s+\\[([^]]+)]\\s+\\[([^]]+)]\\s+:\\s+([\\s\\S]*)",
      "Keys": [
        "time",
        "module",
        "thread",
        "class",
        "info"
      ],
      "NoKeyError": true,
      "NoMatchError": true,
      "KeepSource": false
    }
  }
]
}
```

- Sample output

  After the `2018-02-03 14:18:41.968 INFO [spring-cloud-monitor] [nio-8080-exec-4] c.g.s.web.controller.DemoController : service start done` log is processed, the following output is returned:

```
__tag__:__hostname__:logtail-dfgef
_container_name_:monitor
_image_name_:registry.cn-hangzhou.aliyuncs.xxxxxxxxxxxxxx

_pod_name_:monitor-6f54bd5d74-rtzc7
_pod_uid_:7f012b72-04c7-11e8-84aa-00163f00c369
_source_:stdout
_time_:2018-02-02T14:18:41.979147844Z
time:2018-02-02 02:18:41.968
level:INFO
module:spring-cloud-monitor
thread:nio-8080-exec-4
class:c.g.s.web.controller.DemoController
message:service start done
```

23.3.1.7. Limits

This topic describes the limits of Logtail. These limits apply when you collect files, manage resources, and resolve errors.

Limits on file collection

Item	Description
File encoding	Log files encoded in UTF-8 and GBK are supported. We recommend that you use UTF-8 encoding for better processing performance. If log files are encoded in other formats, errors such as garbled characters and data loss may occur.
Log file size	Unlimited.
Log file rotation	Supported. Both `.log*` and `.log` are supported for file names.
Log collection behavior when log parsing is restricted	When log parsing is restricted, Logtail keeps the log file descriptor (FD) open. If log file rotation occurs multiple times during the restriction, Logtail attempts to keep the log parsing sequence of each rotation. If the number of rotated logs to be parsed exceeds 20, Logtail does not process subsequent log files.
Symbolic link	Monitored directories can be soft links.
Size of a single log entry	The maximum size of a single log entry is 512 KB. If a multi-line log entry is divided by using a regular expression to match the first line, the maximum size of each log entry after division is still 512 KB. If the size of a log entry exceeds 512 KB, the log entry is forcibly separated into multiple parts for collection. For example, if the size of a log entry is 1,025 KB, it will be split into three parts: 512 KB, 512 KB, and 1 KB. These log parts are collected in sequence.
Regular expression	Perl-based regular expressions can be used.
Multiple Logtail configuration files for the same log file	Not supported. We recommend that you collect and store log files to one Logstore, and configure multiple subscriptions. If this feature is required, configure symbolic links for log files to bypass this limit.
File opening behavior	When Logtail collects a log file, Logtail opens the log file. If the log file is not modified for more than 5 minutes and log rotation does not occur, Logtail closes the log file.
First log collection behavior	Logtail collects only incremental log files. If a log file is modified for the first time and the log file size exceeds 1 MB, Logtail collects the logs from the last 1 MB. Otherwise, Logtail collects the logs from the beginning of the log file. If the log file is not modified after the Logtail configuration file is sent to the server where the log file resides, Logtail does not collect the log file.
Non-standard text logs	If a log entry contains \0 in multiple lines, the log entry is truncated at the first \0.

Limits on checkpoints

Item	Description
Checkpoint timeout period	If a log file is not modified for more than 30 days, the checkpoint of the log file is deleted.
Checkpoint storage policy	Checkpoints are saved every 15 minutes and are automatically saved when you exit Logtail.
Checkpoint storage path	By default, checkpoints are stored in the `/tmp/logtail_checkpoint` directory. For more information about how to modify the values of the related parameters, see Set Logtail startup parameters.

Limits on configurations

Item	Description
Configuration update	A custom configuration update requires about 30 seconds to take effect.
Dynamic loading of Logtail configuration files	Supported. The update of a Logtail configuration file does not affect other Logtail configuration files.
Number of Logtail configuration files	Unlimited. However, we recommend that you create a maximum of 100 Logtail configuration files on a server.
Multi-tenant isolation	Logtail configuration files for different tenants are isolated.

Limits on resources and performance metrics

Item	Description
Throughput for log processing	The default traffic of raw logs is limited to 2 MB/s. Data is uploaded after it is encoded and compressed. The compression ratio ranges from 5:1 to 10:1. Logs may be lost if the traffic exceeds the limit. For more information about how to modify the values of the related parameters, see Set Logtail startup parameters.
Maximum processing speed	Single-core processing speed: The maximum processing speed is 100 MB/s for logs in simple mode, 40 MB/s for logs in delimiter mode, and 30 MB/s for logs in JSON mode. By default, the maximum processing speed is 20 MB/s for logs in full regex mode based on the complexity of regular expressions. If multiple processing threads are enabled, the performance can be improved by 1.5 to 3 times.
Number of monitored directories	Logtail limits the depth of monitored directories to reduce the consumption of your resources. If the upper limit is reached, Logtail stops monitoring additional directories and log files. Logtail monitors a maximum of 3,000 directories, including subdirectories.
Number of monitored files	A Logtail configuration file on each server can be used to monitor a maximum of 10,000 files by default. A Logtail client on each server can monitor a maximum of 100,000 files by default. Excessive files are not monitored. If the upper limit is reached, you can perform the following operations: • Improve the depth of the monitored directory in each Logtail configuration file. • Modify the value of the mem_usage_limit parameter to increase the Logtail memory usage threshold. For more information, see Set Logtail startup parameters. You can set a memory usage threshold of 2 GB for Logtail. In this case, the maximum number of files that each Logtail configuration file can be used to monitor is increased to 100,000. The maximum number of files that each Logtail client can monitor is increased to 1,000,000.
Default resources	By default, Logtail consumes up to 40% of CPU usage and 256 MB of memory. If logs are generated at a high speed, you can modify relevant parameters. For more information, see Set Logtail startup parameters.
Processing policy of threshold-crossing resources	If the resources occupied by Logtail exceed the upper limit and this issue lasts for five or more minutes, Logtail is forcibly restarted. The restart may cause data loss or duplication.

Limits on error handling

Item	Description
Network error handling	If a network error occurs, Logtail retries and adjusts the retry interval.
Processing policy of threshold-crossing resources	If the data transmission speed exceeds the quota of the Logstore, Logtail restricts the log collection speed and retries the log collection.
Maximum retry period before timeout	If data fails to be transmitted and the failure lasts for more than six consecutive hours, Logtail discards the data.
Status self-check	Logtail restarts if an exception occurs, for example, an application unexpectedly exits or the resource usage exceeds the quota.

Other limits

Item	Description
Log collection latency	A latency of less than 1 second exists between the time when a log is written to a disk and the time when Logtail collects the log. However, if the log collection speed is restricted, the latency increases.
Log upload policy	Before Logtail uploads logs, it aggregates the logs in the same file. The log upload starts if the number of logs exceeds 2,000, the total size of logs exceeds 2 MB, or the log collection duration exceeds 3 seconds.

23.3.2. Other collection methods

23.3.2.1. WebTracking

This topic describes how to use WebTracking to collect logs from websites that are written in HTML or HTML5, iOS, and Android.

Context

Log Service uses WebTracking to collect logs from websites written in HTML or HTML5, iOS, and Android. You can customize dimensions and metrics.

In the preceding figure, WebTracking allows you to collect user information from various browsers, iOS apps, and Android apps (except for SDK for iOS or Android). For example:

- Browsers, operating systems, and resolutions used by users.
- Browsing history such as preferences on different websites.
- The length of time that users stay on an app and whether the users are active in the app.

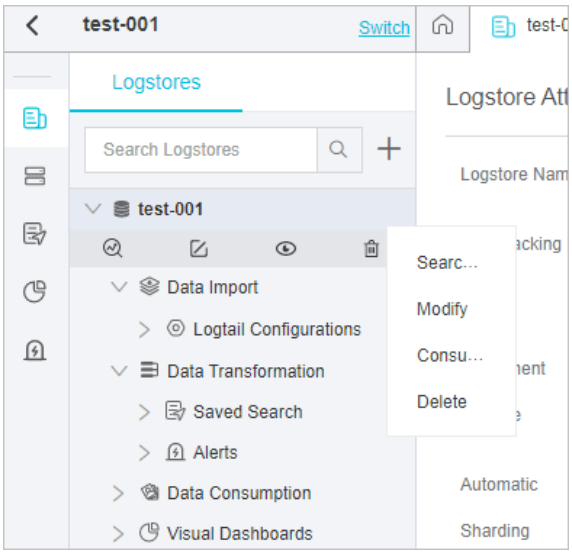
Precautions

- Dirty data may occur due to the use of WebTracking. This occurs because WebTracking allows unauthorized write access from Internet anonymous users to a Logstore.
- GET and POST requests are supported. The size of a request body cannot exceed 16 KB.
- The same limits apply to POST requests and the PutLogs API operation. The maximum number of logs that you can use a POST request to collect at a time is 4,096. The total size of these logs cannot exceed 3 MB.

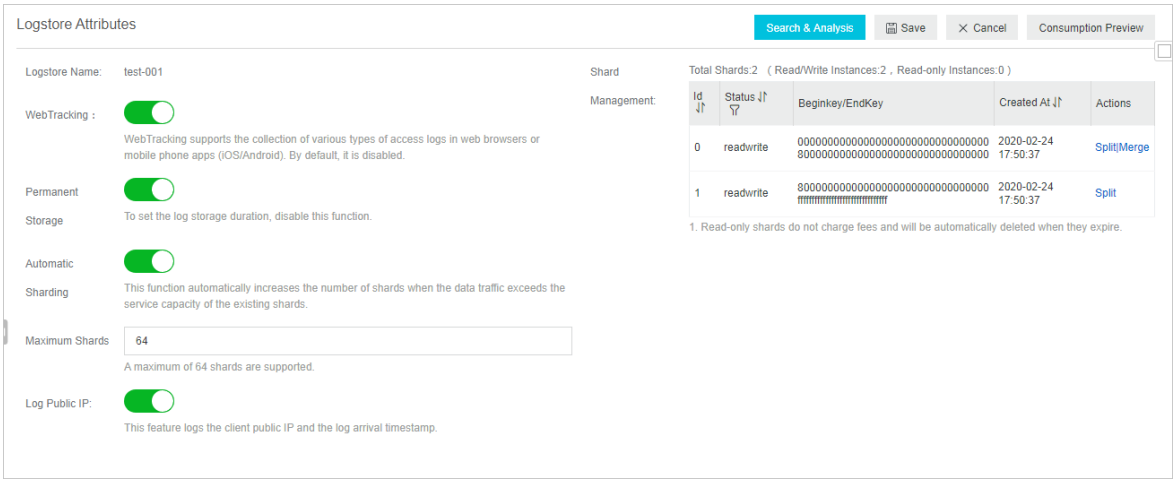
Step 1: Enable WebTracking

Log on to the Log Service console and enable WebTracking.

1. Log on to the Log Service console.
2. Select the target Logstore, go to the **Logstore Attributes** page.
   - Method 1: Click the Modify icon under the name of the Logstore.
   - Method 1: Click the icon next to the name of the Logstore, and select **Modify**.



3. On the **Logstore Attributes** page, click **Modify** in the upper-right corner.
4. Turn on the WebTracking switch.



Use SDK for Java to enable WebTracking

Example:

```
import com.aliyun.openservices.log.Client;
import com.aliyun.openservices.log.common.LogStore;
import com.aliyun.openservices.log.exception.LogException;
public class WebTracking {
 static private String accessId = "your accesskey id";
 static private String accessKey = "your accesskey";
 static private String project = "your project";
 static private String host = "log service data address";
 static private String logStore = "your logstore";
 static private Client client = new Client(host, accessId, accessKey);
 public static void main(String[] args) {
   try {
     //Enable WebTracking on an existing Logstore.
     LogStore logSt = client.GetLogStore(project, logStore).GetLogStore();
     client.UpdateLogStore(project, new LogStore(logStore, logSt.GetTtl(), logSt.GetShardCount(), true));
     //Disable WebTracking.
     //client.UpdateLogStore(project, new LogStore(logStore, logSt.GetTtl(), logSt.GetShardCount(), false));
     //Create a Logstore on which you want to enable WebTracking.
     //client.UpdateLogStore(project, new LogStore(logStore, 1, 1, true));
   }
   catch(LogException e){
     e.printStackTrace();
   }
 }
}
```

Step 2: Collect logs

After you enable WebTracking for a Logstore, you can use the following methods to upload data to the Logstore.

- Use the JavaScript SDK
  i. Copy the *loghub-tracking.js* file to the *web* directory and add the following script to the file.

     Click here to copy the script.

     ```
     <script type="text/javascript" src="loghub-tracking.js" async></script>
     ```

     Note To ensure that a page loads, the script asynchronously sends HTTP requests. If data must be sent several times during the page loading, the newest request overwrites the previous HTTP request. A message showing WebTracking is about to exit appears in the browser. To eliminate the issue, send requests in a synchronous manner. To implement the method, perform the following step.

     Original statement:

     ```
     this.httpRequest_.open("GET", url, true)
     ```

     Replace the original statement with the following statement:

     ```
     this.httpRequest_.open("GET", url, false)
     ```

  ii. Create a tracker.

```
var logger = new window.Tracker('${host}','${project}','${logstore}');
logger.push('customer', 'zhangsan');
logger.push('product', 'iphone 6s');
logger.push('price', 5500);
logger.logger();
logger.push('customer', 'lisi');
logger.push('product', 'ipod');
logger.push('price', 3000);
logger.logger();
```

The following table lists the parameters:

Parameter	Description
${host}	The endpoint of the region where Log Service resides. For more information, see the *Obtain an endpoint topic in the Log Service Developer Guide* .
${project}	The name of the project that you create in Log Service.
${logstore}	The name of the Logstore in the ${project} .

After you run the following code, the following logs appear in Log Service.

```
customer:zhangsan
product:iphone 6s
price:5500
```

```
customer:lisi
product:ipod
price:3000
```

- Use HTTP GET requests

```
curl --request GET 'http://${project}.${host}/logstores/${logstore}/track? APIVersion=0.6.0&key1=val1&key2=val2'
```

The following table lists the parameters.

Parameter	Description
${project}	The name of the project that you create in Log Service.
${host}	The endpoint of the region where Log Service resides.
${logstore}	The name of a Logstore that has WebTracking enabled in the ${project} .
APIVersion=0.6.0	(Required) A reserved parameter.
__topic__=yourtopic	(Optional) A reserved parameter that specifies the topic of the log.
key1=val1, key2=val2	The key-value pairs that you want to upload to Log Service. You can specify multiple pairs. Make sure that the length of each request URL is less than 16 KB.

- Use HTML img tags

```
<img src='http://${project}.${host}/logstores/${logstore}/track.gif? APIVersion=0.6.0&key1=val1&key2=val2'/>
<img src='http://${project}.${host}/logstores/${logstore}/track_ua.gif? APIVersion=0.6.0&key1=val1&key2=val2'/>
```

The parameters that you need to specify are the same as the preceding parameters. In addition to custom parameters that are uploaded by track_ua.gif, Log Service also uses UserAgent and referer fields in the HTTP header as the fields of logs.

23.3.2.2. Use SDKs to collect logs

23.3.2.2.1. Producer Library

The Aliyun LOG Java Producer supports Java applications that run in big data processing scenarios with high concurrency. The library is easy to use and highly customizable.

For more information about the related GitHub project, visit Aliyun LOG Java Producer.

23.3.2.2.2. Log4j Appender

Log4j is an open-source logging framework of Apache. You can use Log4j to write logs to the Log Service console, files, graphical user interface (GUI) components, socket servers, NT kernel loggers, or Unix syslog daemons. You can specify the output format of each log. You can also specify the severity level of each log to implement a fine-grained control on log generation.

Log4j consists of three components: loggers, appenders, and layouts.

- Loggers allow you to specify the severity level of each log.

  Severity levels are sorted into ERROR, WARN, INFO, and DEBUG in descending order of severity.
- Appenders allow you to specify the destination of each log.

  A destination can be the Log Service console or a file.
- Layouts allow you to specify the output format of each log.

  The output format defines how logs are displayed.

To write logs to Log Service, use the Alibaba Cloud Log Log4j Appender. For information about where to download the library and how to use it, see Log4j Appender.

23.3.2.2.3. Logback Appender

Logback was created by the same developer of Log4j. Logback allows you to write logs to multiple destinations. These destinations include the Log Service console, files, graphical user interface (GUI) components, socket servers, NT kernel loggers, and Unix syslog daemons. You can define the output format of each log. If you define the severity level of each log, you can implement a fine-grained control on the log generation process.

You can set the destination of logs to Log Service by using the Aliyun Log Logback Appender. The following example shows the format of logs that are uploaded to Log Service.

```
level: ERROR
location: com.aliyun.openservices.log.logback.example.LogbackAppenderExample.main(LogbackAppenderExample.java
:18)
message: error log
throwable: java.lang.RuntimeException: xxx
thread: main
time: 2018-01-02T03:15+0000
log: 2018-01-02 11:15:29,682 ERROR [main] com.aliyun.openservices.log.logback.example.LogbackAppenderExample: err
or log
__source__: xxx
__topic__: yyy
```

For information about where to download the library and how to use it, see Logback Appender.

23.3.2.2.4. Golang Producer Library

The Aliyun LOG Go Producer Library supports Go applications that run in big data processing scenarios with high concurrency. The library is easy to use and highly customizable. You can use the library to create producers that allow you to resend failed logs. Before Go applications send log data to Log Service, you can use these producers to compress the log data. This improves write performance.

For more information about the related GitHub project, visit Aliyun Log Go Producer.

23.3.2.2.5. Python logging

Configurations

For more information about the configurations that are related to the Python logging module, see Logging configuration.

The Python logging module allows you to configure logging by using code or a configuration file. The following example shows how to configure logging by using the `logging.conf` configuration file.

```
[loggers]
keys=root,sls
[handlers]
keys=consoleHandler, slsHandler
[formatters]
keys=simpleFormatter, rawFormatter
[logger_root]
level=DEBUG
handlers=consoleHandler
[logger_sls]
level=INFO
handlers=consoleHandler, slsHandler
qualname=sls
propagate=0
[handler_consoleHandler]
class=StreamHandler
level=DEBUG
formatter=simpleFormatter
args=(sys.stdout,)
[handler_slsHandler]
class=aliyun.log.QueuedLogHandler
level=INFO
formatter=rawFormatter
args=(os.environ.get('ALIYUN_LOG_SAMPLE_ENDPOINT', ''), os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSID', ''), os.en
viron.get('ALIYUN_LOG_SAMPLE_ACCESSKEY', ''), os.environ.get('ALIYUN_LOG_SAMPLE_TMP_PROJECT', ''), "logstore")
[formatter_simpleFormatter]
format=%(asctime)s - %(name)s - %(levelname)s - %(message)s
[formatter_rawFormatter]
format=%(message)s
```

Two handlers named `root` and `sls` are created. The `sls` handler is an object of the `aliyun.log.QueuedLogHandler` class. The following shows the parameters that are specified for the sls handler. For more information, see Parameters.

```
args=(os.environ.get('ALIYUN_LOG_SAMPLE_ENDPOINT', ''), os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSID', ''), os.en
viron.get('ALIYUN_LOG_SAMPLE_ACCESSKEY', ''), os.environ.get('ALIYUN_LOG_SAMPLE_TMP_PROJECT', ''), "logstore")
```

Note In this case, the `os.environ` function is used to retrieve configurations from environment variables. You can also specify values for these parameters based on your business requirements.

Upload logs

You can use the configuration file to upload logs to Log Service.

```
import logging
import logging.config
# Configurations
logging.config.fileConfig('logging.conf')
logger = logging.getLogger('sls')
# Use the logger
logger.info("test1")
try:
  1/0
except ZeroDivisionError as ex:
  logger.exception(ex)
```

Then, logs are automatically uploaded to Log Service. To use the LogSearch/Analytics feature, you must enable the index feature on the corresponding Logstore.

Configure an index for a Logstore

Enable the index feature on the Logstore that receives logs and configure an index for specific fields. We recommend that you use CLI (Command Line Interface) to configure the index as follows:

```
aliyunlog log update_index --project_name="project1" --logstore_name="logstore1" --index_detail="file:///Users/user1/loghandler_index.json"
```

For more information, see the python_logging_handler_index.json configuration file.

Specify log fields to be collected

The following table lists supported log fields that you can collect. By default, all of the fields are collected.

Field	Description
message	The contents of a log.
record_name	The name of a handler. In the preceding example, the name is `sls`.
level	The output level of a logger, such as INFO and ERROR.
file_path	The full path of a configuration file.
func_name	The name of a function.
line_no	The number of a log line.
module	The name of a module where the function resides.
thread_id	The ID of the thread that runs the function.
thread_name	The name of the thread that runs the function.
process_id	The ID of the process that runs the function.

Field	Description
process_name	The name of the process that runs the function.

You can specify log fields to be collected based on the fields parameter of the `QueuedLogHandler` class. For more information, see aliyun.log.LogFields.

The following example shows how to modify the preceding configuration file and collect several fields, such as module and func_name.

```
[handler_slsHandler]
class=aliyun.log.QueuedLogHandler
level=INFO
formatter=rawFormatter
args=('cn-beijing.log.aliyuncs.com', 'ak_id', 'ak_key', 'project1', "logstore1", 'mytopic', ['level', 'func_name', 'module', 'line_no'] )
```

> **Note**
>
> - The message field is collected regardless of your configurations.
> - To add a prefix and suffix to the names of these fields, use the `buildin_fields_prefix` and `buildin_fields_suffix` parameters. For example, `__level__`.

Configure logging by using a JSON text

You can use a JSON text to create more flexible logging configurations than code does.

```
#encoding: utf8
import logging, logging.config, os
# Configurations
conf = {'version': 1,
    'formatters': {'rawformatter': {'class': 'logging.Formatter',
                    'format': '%(message)s'}
            },
    'handlers': {'sls_handler': {'()':
                    'aliyun.log.QueuedLogHandler',
                    'level': 'INFO',
                    'formatter': 'rawformatter',
                    # custom args:
                    'end_point': os.environ.get('ALIYUN_LOG_SAMPLE_ENDPOINT', ''),
                    'access_key_id': os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSID', ''),
                    'access_key': os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSKEY', ''),
                    'project': 'project1',
                    'log_store': "logstore1"
                    }
            },
    'loggers': {'sls': {'handlers': ['sls_handler', ],
                    'level': 'INFO',
                    'propagate': False}
            }
    }
logging.config.dictConfig(conf)
# Use the logger
logger = logging.getLogger('sls')
logger.info("Hello world")
```

Note To instantiate an object of the `aliyun.log.QueuedLogHandler` class, pass named parameters to the constructor. For more information, see Parameters.

23.3.2.3. Common log formats

23.3.2.3.1. Log4j logs

Log Service allows you to collect Log4j logs.

Collect Log4j logs by using LogHub Log4j Appender

For more information, see Log4j Appender.

Configure Logtail to collect Log4j logs

This topic describes how to configure regular expressions based on the default configuration of Log4j 1 logs. If Log4j 2 is used, you must modify the default configuration to record the complete date information. Log4j logs are sorted into Log4j 1 logs and Log4j 2 logs.

```
<Configuration status="WARN">
 <Appenders>
  <Console name="Console" target="SYSTEM_OUT">
   <PatternLayout pattern="%d{yyyy-MM-dd HH:mm:ss:SSS zzz} [%t] %-5level %logger{36} - %msg%n"/>
  </Console>
 </Appenders>
 <Loggers>
  <Logger name="com.foo.Bar" level="trace">
   <AppenderRef ref="Console"/>
  </Logger>
  <Root level="error">
   <AppenderRef ref="Console"/>
  </Root>
 </Loggers>
</Configuration>
```

For more information about how to configure Logtail to collect Log4j logs, see Python logs. Configure the required parameters based on your network environment and business requirements.

The automatically generated regular expression is based on the sample log and may not be suitable for other logs. Therefore, you must make minor changes to the regular expression after it is automatically generated

The following shows a sample log of the default Log4j format.

```
2013-12-25 19:57:06,954 [10.207.37.161] WARN impl.PermanentTairDaoImpl - Fail to Read Permanent Tair,key:e:47021731
9319741_1,result:com.example.tair.Result@172e3ebc[rc=code=-1, msg=connection error or timeout,value=,flag=0]
```

Regular expression that matches IP addresses that each indicate the start of a line:

```
\d+-\d+-\d+\s. *
```

Regular expression used to extract log information:

```
(\d+-\d+-\d+\s\d+:\d+:\d+,\d+)\s\[([^\]]*)\]\s(\S+)\s+(\S+)\s-\s(. *)
```

Time conversion format:

```
%Y-%m-%d %H:%M:%S
```

The following table lists the extraction results of the sample log.

Key	Value
time	2013-12-25 19:57:06,954
ip	10.207.37.161
level	WARN
class	impl.PermanentTairDaoImpl
message	Fail to Read Permanent Tair,key:e:470217319319741_1,result:com.example.tair.Result@172e3ebc[rc=code=-1, msg=connection error or timeout,value=,flag=0]

23.3.2.3.2. Python logs

The Python logging module provides a general logging system, which can be used by third-party modules or applications.

The Python logging module provides different log levels and logging methods, such as file-based, HTTP GET, HTTP POST, SMTP, and Socket logging. You can also create a custom logging method. The Python logging module works in the same way as the Log4j logging module except for some implementation details. The Python logging module includes the logger, handler, filter, and formatter objects.

Log format

A formatter specifies the output format of logs. To instantiate a formatter, pass two parameters to the constructor. One parameter includes a message format string and the other parameter includes a date format string. The parameters are optional.

Log format:

```
import logging
import logging.handlers
LOG_FILE = 'tst.log'
handler = logging.handlers.RotatingFileHandler(LOG_FILE, maxBytes = 1024*1024, backupCount = 5) # Instantiate the ha
ndler
fmt = '%(asctime)s - %(filename)s:%(lineno)s - %(name)s - %(message)s'
formatter = logging.Formatter(fmt)   # Instantiate the formatter
handler.setFormatter(formatter)      # Add the formatter to the handler
logger = logging.getLogger('tst')    # Obtain a logger named tst
logger.addHandler(handler)           # Add the handler to the logger
logger.setLevel(logging.DEBUG)
logger.info('first info message')
logger.debug('first debug message')
```

Attributes

Formatter attributes are specified in the `%(key)s` format. The following table lists the attributes.

Format	Description
%(name)s	The name of a logger that generates logs.
%(levelno)s	The log output level in the numeric format. Valid values: DEBUG, INFO, WARNING, ERROR, and CRITICAL

Format	Description
%(levelname)s	The log output level in the text format. Valid values: 'DEBUG', 'INFO', 'WARNING', 'ERROR', and 'CRITICAL'.
%(pathname)s	The full path of a source file that contains the logging module.
%(filename)s	The name of the source file.
%(module)s	The name of a module where the statement that you use to generate logs resides.
%(funcName)s	The name of the function that is used to call the log output function.
%(lineno)d	The number of a code line that contains the statement used to call the log output function.
%(created)f	The time when the log was created. The value is a UNIX timestamp representing the number of seconds that have elapsed since January 1, 1970, 00:00:00 (UTC).
%(relativeCreated)d	The interval between the time when a log was created and the time when the logging module was loaded. Unit: milliseconds.
%(asctime)s	The time when the log was created. The value of 2003-07-08 16:49:45,896 is an example of the default format. The number after the comma (,) indicates the number of milliseconds.
%(msecs)d	The time when the log was created. The value is a UNIX timestamp representing the number of milliseconds that have elapsed since January 1, 1970, 00:00:00 (UTC).
%(thread)d	The thread ID.
%(threadName)s	The thread name.
%(process)d	The process ID.
%(message)s	The contents of a log.

Sample logs

Sample log:

```
2015-03-04 23:21:59,682 - log_test.py:16 - tst - first info message
2015-03-04 23:21:59,682 - log_test.py:17 - tst - first debug message
```

Common Python logs and the corresponding regular expressions:

- Sample log:

  ```
  2016-02-19 11:03:13,410 - test.py:19 - tst - first debug message
  ```

  Regular expression:

  ```
  (\d+-\d+-\d+\s\S+)\s+-\s+([^:]+):(\d+)\s+-\s+(\w+)\s+-\s+(. *)
  ```

- Log format

```
%(asctime)s - %(filename)s:%(lineno)s - %(levelno)s %(levelname)s %(pathname)s %(module)s %(funcName)s %(created)f %(thread)d %(threadName)s %(process)d %(name)s - %(message)s
```

Sample log:

```
2016-02-19 11:06:52,514 - test.py:19 - 10 DEBUG test.py test <module> 1455851212.514271 139865996687072 MainThread 20193 tst - first debug message
```

Regular expression:

```
(\d+-\d+-\d+\s\S+)\s-\s([^:]+):(\d+)\s+-\s+(\d+)\s+(\w+)\s+(\S+)\s+(\w+)\s+(\S+)\s+(\S+)\s+(\d+)\s+(\w+)\s+(\d+)\s+(\w+)\s+-\s+(.*)
```

Configure Logtail to collect Python logs

1. Log on to the Log Service console.
2. Click **Import Data**. On the **Import Data** page that appears, select **RegEx-Text Log**.
3. Select a Logstore, and then click Next.

   Select an existing project and Logstore. You can also click **Create Now** to create a project and Logstore. For more information, see Manage a Logstore.

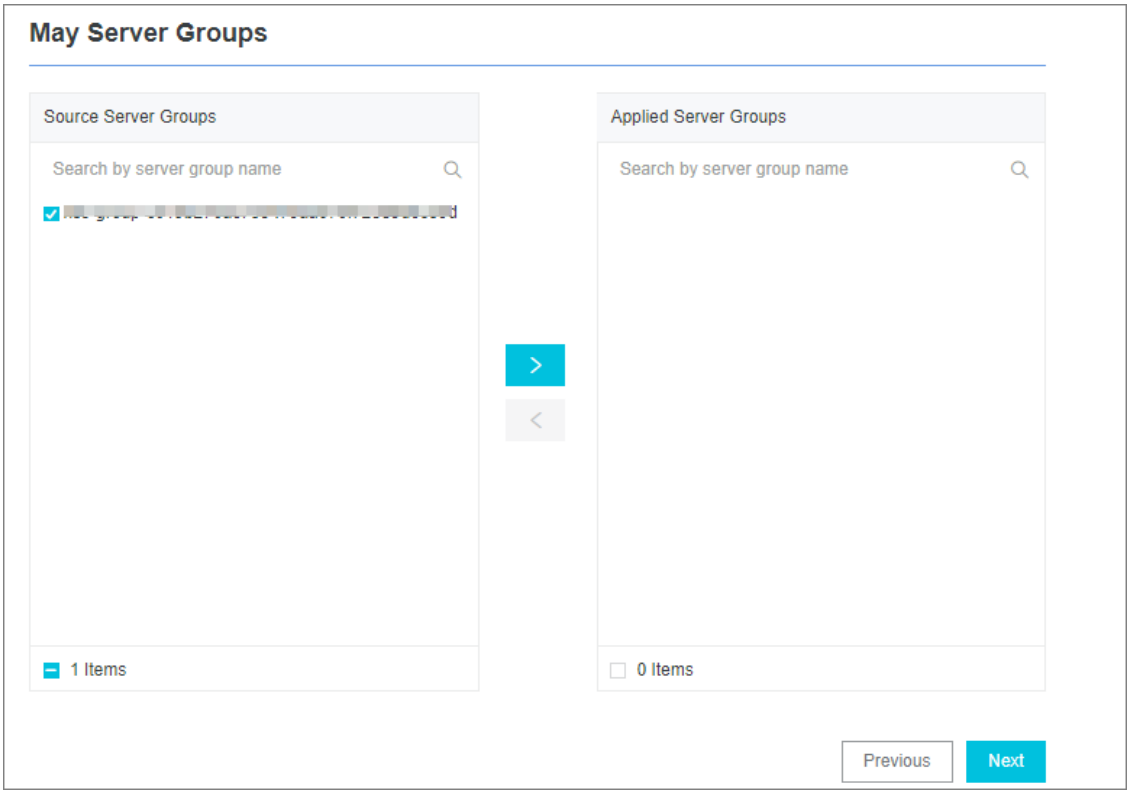
   If you enter the configuration procedure by clicking the plus sign (+) next to **Data Import** under a Logstore on the Logstores tab, the system skips this step.
4. Create a server group.

   Before you create a server group, ensure that Logtail is installed.

   Install Logtail as prompted. For more information, see Install Logtail in Linux or Install Logtail in Windows.

   After you install Logtail, click **Complete Installation** to create a server group. For more information, see Overview. If you have created a server group, click **Use Existing Server Groups** to select the server group.
5. Configure the server group, and then click Next.

   Select a server group and move the group from **Source Server Groups** to **Applied Server Groups**.

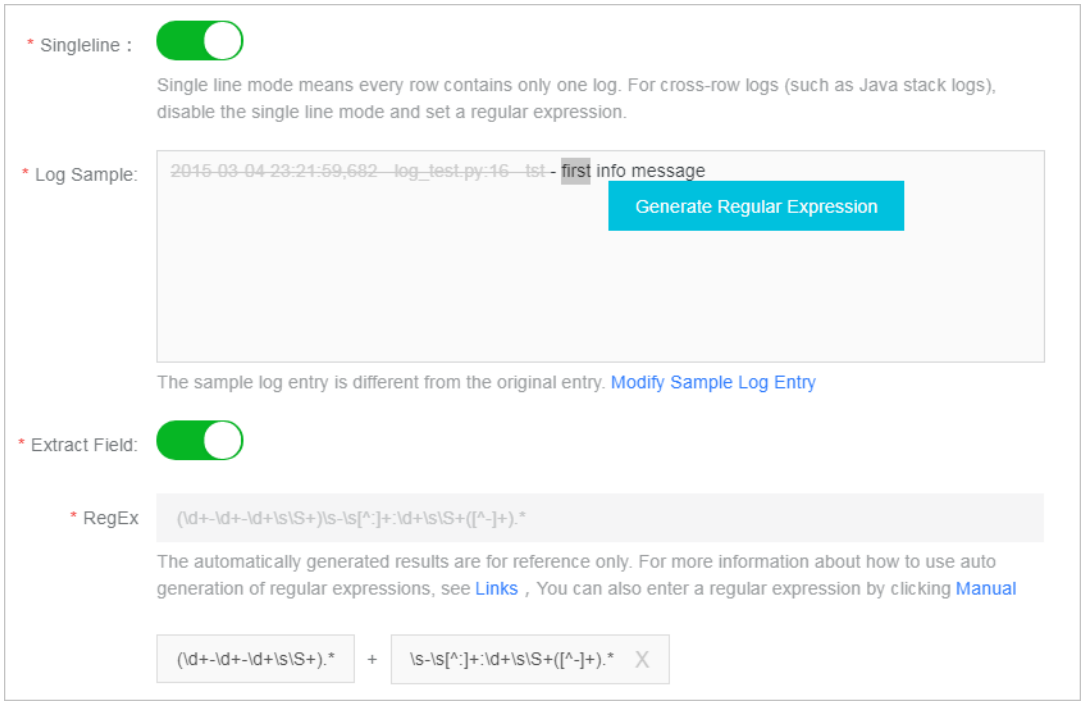


6. Create a Logtail configuration.
   i. Enter a **configuration name** and **log path** and select **Full Regex Mode** in the Mode field.
   ii. Turn on **Singleline**.
   iii. Enter a snippet in the **Log Sample** field.
   iv. Turn on **Extract Field**.

v. Set a regular expression in the **RegEx** field.

a. Select fields to generate a regular expression

If the regular expression that is automatically generated does not match your sample log, you can select fields in the sample log to generate a regular expression. Log Service can automatically parse the highlighted fields of the sample log to generate a regular expression. In the **Log Sample** field, select the required fields, and click **Generate Regular Expression**. The regular expression of the selected field is displayed in the **RegEx** field. To obtain a full regular expression for the sample log, generate regular expressions for each log field.



b. Modify the regular expression

Actual data formats may vary. In this case, click **Manual** under the RegEx field to adjust the regular expression that is automatically generated based on your business requirements. This ensures that the regular expression is suitable for all formats of the collected logs.

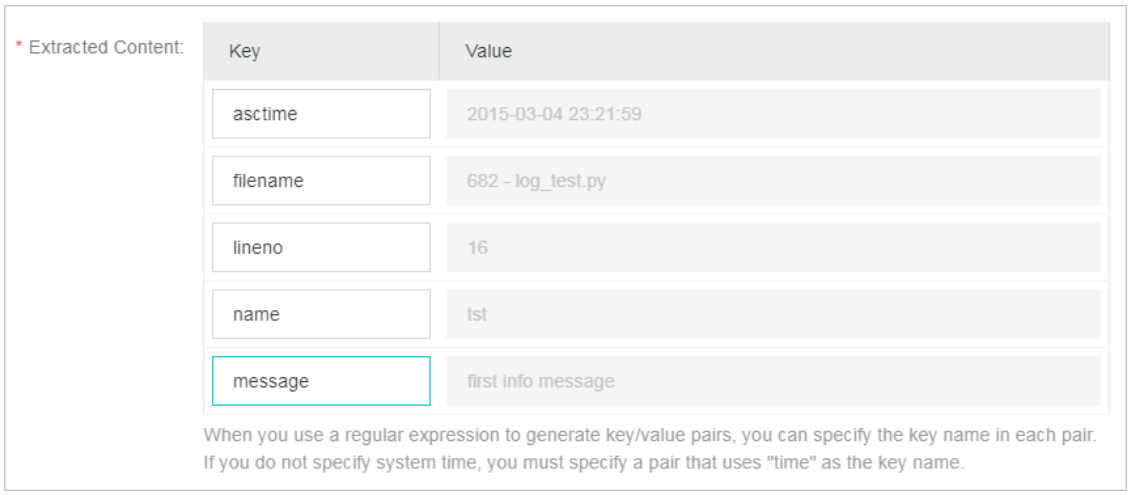
c. Verify the regular expression

After you modify the regular expression, click **Validate** next to the RegEx field. If the regular expression is valid, the extraction results are displayed. If the regular expression is invalid, modify the regular expression again.

vi. Confirm **the extraction results of log fields**.

View the extraction results of log fields and specify keys for the extracted fields.

Specify an informative name for each log field in the extraction results. For example, time as the name for a time field. If you do not use the system time, you must specify the name of a time field in the Value fields and time in the Key field.



7. (Optional)Specify **Advanced Options** and click **Next**.

Specify **Advanced Options** based on your business requirements. We recommend that you do not modify the default settings unless otherwise required.

Parameter	Description
Enable Plug-in Processing	Specifies whether to enable plug-in processing. If you turn on this switch, you can use the plug-in of Logtail to process text logs.
Upload Raw Log	Specifies whether to upload raw logs. If you turn on this switch, raw logs are written to the __raw__ field and uploaded with the parsed logs.
Topic Generation Mode	◦ **Null - Do not generate topic**: This mode is selected by default. In this mode, the topic is set to an empty string and you can query logs without the need to enter a topic. ◦ **Server Group Topic Attributes**: This mode is used to differentiate log data that is generated by different frontend servers. ◦ **File Path RegEx**: If you select this mode, you must enter a value in the **Custom RegEx** field to extract part of the path as the topic. This mode is used to differentiate log data that is generated by users or instances.
Custom RegEx	Specifies a custom regular expression. If you select **File Path RegEx** for **Topic Generation Mode**, you must enter a custom regular expression.
Log File Encoding	◦ utf8: indicates UTF-8 encoding. ◦ gbk: indicates GBK encoding.
Timezone	Specifies the time zone where logs are collected. ◦ System Timezone: This option is selected by default. It indicates that the time zone where logs are collected is the same as the time zone to which the server belongs. ◦ Custom: Select a time zone.

Parameter	Description
Timeout	If a log file is not updated within a specific period of time, Logtail considers the file to be timed out. ○ Never: All log files are continuously monitored and never time out. ○ 30 Minute Timeout: If a log file is not updated within 30 minutes, Logtail considers the log file to be timed out and no longer monitors the file.
Filter Configuration	Only logs that **meet all filter conditions** are collected. Examples: ○ Collect logs that meet a condition: Set the condition to `Key:level Regex:WARNING|ERROR`. It indicates that only logs with the severity level of WARNING or ERROR are collected. ○ Filter logs that do not meet a condition: ■ Set the condition to `Key:level Regex:^(?!. *(INFO|DEBUG)). *`. It indicates that logs with the severity level of INFO or DEBUG are not collected. ■ Set the condition to `Key:url Regex:. *^(?!.*(healthcheck)). *`. It indicates that logs whose URL contains the keyword healthcheck are not collected. For example, logs in which the key is url and the value is `/inner/healthcheck/jiankong.html` are not collected.

8. Configure an index.

   Configure an index based on your business requirements. For more information, see Enable the index feature and configure indexes for a Logstore.

After the configuration is complete, apply the settings to the server group to collect Python logs.

23.3.2.3.3. Node.js logs

Node.js logs are displayed in the Log Service console by default. This impedes data collection and troubleshooting. You can use the log4js function to write logs into files and customize the log format. This facilitates data collection and consolidation.

Example:

```
var log4js = require('log4js');
log4js.configure({
 appenders: [
  {
   type: 'file', //Output to a file
   filename: 'logs/access.log',
   maxLogSize: 1024,
   backups:3,
   category: 'normal'
  }
 ]
});
var logger = log4js.getLogger('normal');
logger.setLevel('INFO');
logger.info("this is a info msg");
logger.error("this is a err msg");
```

Log format

After logs are written to text files by using the log4js function, these logs are displayed in the following format:

```
[2016-02-24 17:42:38.946] [INFO] normal - this is a info msg
[2016-02-24 17:42:38.951] [ERROR] normal - this is a err msg
```

The log4js function defines six log severity levels. They are TRACE, DEBUG, INFO, WARN, ERROR, and FATAL in ascending order of severity.

Use Logtail to collect Node.js logs

For more information about how to configure Logtail to collect Python logs, see Python logs. Use configurations based on your network environment and business requirements.

The automatically generated regular expression is based on the sample log and may not apply to other logs. Therefore, you must make minor changes to the regular expression after it is generated. You can use the following sample Node.js logs to configure appropriate regular expressions for your logs.

Sample Node.js logs:

- Example 1
  - Sample log

    ```
    [2016-02-24 17:42:38.946] [INFO] normal - this is a info msg
    ```

  - Regular expression:

    ```
    \[([^]]+)]\s\[([^\]]+)]\s(\w+)\s-(. *)
    ```

  - Extracted fields:

    `time` , `level` , `loggerName` , and `message`

- Example 2
  - Sample log

    ```
    [2016-01-31 12:02:25.844] [INFO] access - 42.120.73.203 - - "GET /user/projects/ali_sls_log? ignoreError=true HTTP/1.1" 304 - "http://
    aliyun.com/" "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_10_3) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/48.0.2564.97 Safari/537.36"
    ```

  - Regular expression:

    ```
    \[([^]]+)]\s\[(\w+)]\s(\w+)\s-\s(\S+)\s-\s-\s"([^"]+)"\s(\d+)[^"]+("[^"]+)"\s"([^"]+). *
    ```

  - Extracted fields:

    `time` , `level` , `loggerName` , `ip` , `request` , `status` , `referer` , and `user_agent`

23.3.2.3.4. WordPress logs

This topic describes the format of WordPress logs and extraction results of a sample log.

Log format

Sample log:

```
172.64.0.2 - - [07/Jan/2016:21:06:39 +0800] "GET /wp-admin/js/password-strength-meter.min.js? ver=4.4 HTTP/1.0" 200 776 "http://wordpress.c4a1a0aecdb1943169555231dcc4adfb7.cn-hangzhou.alicontainer.com/wp-admin/install.php" "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_10_5) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/47.0.2526.106 Safari/537.36"
```

Configure Logtail to collect WordPress logs

Configurations required to collect WordPress logs:

- Regular expression that matches IP addresses that each indicate the start of a line

```
\d+\.\d+\.\d+\.\d+\s-\s. *
```

- Regular expression used to extract information from the log:

```
(\S+) - - \[([^\]]*)] "(\S+) ([^"]+)" (\S+) (\S+) "([^"]+)" "([^"]+)"
```

- Time conversion format:

```
%d/%b/%Y:%H:%M:%S
```

- Results after Logtail extracts information from the sample log

Key	Value
ip	10.10.10.1
time	07/Jan/2016:21:06:39 +0800
method	GET
url	/wp-admin/js/password-strength-meter.min.js? ver=4.4 HTTP/1.0
status	200
length	776
ref	http://wordpress.c4a1a0aecdb1943169555231dcc4adfb7.cn-hangzhou.alicontainer.com/wp-admin/install.php
user-agent	Mozilla/5.0 (Macintosh; Intel Mac OS X 10_10_5) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/47.0.2526.106 Safari/537.36

23.3.2.3.5. Unity3D logs

Log Service can use the WebTracking feature to collect Unity3D logs. The following example shows how to collect *Unity logs* of the debug type.

Context

Unity3D is a cross-platform game engine developed by Unity Technologies. The engine allows you to create 3D video games, VR buildings, real-time 3D animation, and other interactive content.

Procedure

1. Enable the WebTracking feature.

   For more information about how to enable this feature, see WebTracking.

2. Create a Unity3D LogHandler.

   In a Unity editor, create a C# file named *LogOutputHandler.cs*, add the following code, and modify the following variables.

   - project: specifies the name of the project.
   - logstore: specifies the name of the Logstore.
   - serviceAddr: specifies the endpoint of the project.

     For more information about serviceAddr, see View the information of a project.

```
using UnityEngine;
using System.Collections;
public class LogOutputHandler : MonoBehaviour
{
  //Register the HandleLog function on scene start to fire on debug.log events
  public void OnEnable()
  {
    Application.logMessageReceived += HandleLog;
  }
  //Remove callback when object goes out of scope
  public void OnDisable()
  {
    Application.logMessageReceived -= HandleLog;
  }
  string project = "your project name";
  string logstore = "your logstore name";
  string serviceAddr = "http address of your log service project";
  //Capture debug.log output, send logs to Loggly
  public void HandleLog(string logString, string stackTrace, LogType type)
  {
    string parameters = "";
    parameters += "Level=" + WWW.EscapeURL(type.ToString());
    parameters += "&";
    parameters += "Message=" + WWW.EscapeURL(logString);
    parameters += "&";
    parameters += "Stack_Trace=" + WWW.EscapeURL(stackTrace);
    parameters += "&";
    //Add any User, Game, or Device MetaData that would be useful to finding issues later
    parameters += "Device_Model=" + WWW.EscapeURL(SystemInfo.deviceModel);
    string url = "http://" + project + "." + serviceAddr + "/logstores/" + logstore + "/track? APIVersion=0.6.0&" + param
eters;
    StartCoroutine(SendData(url));
  }
  public IEnumerator SendData(string url)
  {
    WWW sendLog = new WWW(url);
    yield return sendLog;
  }
}
```

The preceding code allows you to send logs to Log Service in an asynchronous manner. In the code, you can specify more fields you want to collect.

3. Generate Unity logs.

   In the project, create a C# file named *LogglyTest.cs* and add the following code.

```
using UnityEngine;
using System.Collections.Generic;
public class LogglyTest : MonoBehaviour {
  void Start () {
    Debug.Log ("Hello world");
  }
}
```

4. View logs in the console.

   After you complete the preceding steps, run the Unity application. In the Log Service console, view logs that are sent to Log Service.

The preceding code shows how to use *Debug.Log*, *Debug.LogError*, and *Debug.LogException* methods to collect logs. Unity provides Component Object Model (COM)-based exception handling and log handling APIs. These APIs allow you to easily collect device details of clients.

23.4. Query and analysis

23.4.1. Overview

Log Service provides the LogSearch/Analytics feature that you can use to query and analyze a large number of logs. If you do not enable indexes, raw data is consumed in sequence based on shards. The procedure is similar to the sequential consumption of Kafka messages. If you enable indexes, you can query logs and perform statistical analysis on query results in addition to consuming logs in sequence.

Benefits

- Real-time: Logs can be analyzed immediately after they are written.
- Fast:
  - Query: Billions of data records can be processed and queried within one second. Each search statement has a maximum of five conditions specified.
  - Analysis: Hundreds of millions of data records can be aggregated and analyzed within one second. Each query has a maximum of five aggregate functions and a GROUP BY clause specified.
- Flexible: Query and analysis conditions can be changed as required and the results are returned in real time.
- All-in-one: Reports and dashboards are available in the console for quick analysis. In addition to these features, Log Service can work together with Grafana, DataV, Jaeger, and other services. It also supports RESTful APIs, Java Database Connectivity (JDBC) APIs, and other APIs.

Indexing

Indexes refer to a data structure that you can use to sort the values of one or more columns of logs. Indexes allow you to obtain the required information in a timely manner from logs that Log Service collects. Before you use the LogSearch/Analytics feature, you must collect logs and Enable the index feature and configure indexes for a Logstore on the collected logs.

In Log Service, indexes are sorted into **full-text indexes** and **field-specific indexes**.

- **Full-text index**: Indexing is enabled for the full contents of a log. The values of all fields in a log are queried by default. The log can be queried if one of the fields matches the search term.
- **Field-specific index**: You can configure a field-specific index for a key. Then, you can query logs based on specific keys to narrow the query scope.

To use **field-specific indexes**, you must specify the data type for a field. Available data types for fields in Log Service include Text, JSON, Long, and Double. For more information about Overview.

Query methods

- Console

  In the Log Service console, you can query logs by specifying time ranges and search statements. For more information about the procedure and search statements, see Query logs and Query syntax.

- API

  To query logs, you can call the GetLogs and GetHistograms API operations of the Log Service API.

> **Note** Before you query logs, make sure that you collect logs and Enable the index feature and configure indexes for a Logstore.

Search and analysis statements

To apply real-time LogSearch/Analytics to collected logs, you must specify query statements. Each query statement includes the search section and the analytics section. Separate the sections with a vertical bar (|).

```
$Search |$Analytics
```

Statement	Required	Description
Search	No	A search statement contains search conditions. These conditions include keywords, fuzzy keywords, values, ranges, and combined conditions. If you leave the statement empty or specify an asterisk (*) for the statement, it indicates that no condition is specified and all data is returned. For more information, see Query syntax.
Analytics	No	You can use an analytics statement to aggregate or analyze data based on query results. If you leave the statement empty, it indicates that no analytics is required and all query results are returned. For more information, see Real-time analysis.

Precautions

You may query a large number of logs. For example, if the number of logs to be queried is more than 1,000,000,000, Log Service may fail to return all results. Log Service returns a partial result set and notifies you that the returned data set includes partial results.

Query results are cached every 15 minutes. If a partial result set is matched in the cache, Log Service continues to scan logs that are not cached. Log Service combines query results of the current query with results of cached results.

Therefore, Log Service enables you to obtain results by calling the API operation multiple times with the same parameters.

23.4.2. Real-time analysis

Log Service supports SQL-like aggregate calculation. This feature integrates search statements with SQL aggregate functions to calculate query results.

Sample statement:

```
status>200 |select avg(latency),max(latency) ,count(1) as c GROUP BY  method  ORDER BY c DESC  LIMIT 20
```

Basic syntax:

```
[search query] | [sql query]
```

Separate a search statement and a calculation statement with a vertical bar (|). You can use the search statement to query logs and obtain the required results. Then, use the calculation statement for further aggregation. The search query syntax is specific to Log Service. For more information, see Query syntax.

Prerequisites

To use the statistical analysis feature, click **Index Attributes**. Turn on the **Enable Analytics** switch for the required field. For more information, see Enable the index feature and configure indexes for a Logstore.

- If you turn off the switch, Log Service calculates up to 10,000 rows of data in each shard along with high latency

of calculation.

- If you turn on the switch, Log Service analyzes data in seconds.
- The update applies only to new data.
- No extra fee is incurred for the update.

Supported SQL syntax

Log Service supports the following SQL syntax. For more information about a specific topic, click the corresponding link.

- Aggregate functions that are available for SELECT statements include:
  - General aggregate functions
  - Security check functions
  - Map functions
  - Approximate functions
  - Mathematical statistics functions
  - Mathematical calculation functions
  - String functions
  - Date and time functions
  - URL functions
  - Regular expression functions
  - JSON functions
  - Type conversion functions
  - IP functions
  - Array functions
  - Binary string functions
  - Bitwise operations
  - Interval-valued comparison and periodicity-valued comparison functions
  - Comparison functions and operators
  - Lambda functions
  - Logical functions
  - Geospatial functions
  - Geography functions
  - Machine learning functions
- GROUP BY syntax
- Window functions
- HAVING syntax
- ORDER BY syntax
- LIMIT syntax
- Syntax for CASE statements and if() functions
- UNNEST function
- Field aliases
- Nested subqueries

Precautions

Before you use SQL statements, note the following items:

- You do not need to specify FROM and WHERE clauses for SQL statements. By default, Log Service queries logs

from the current Logstore, and each WHERE clause is specified in the [search query] section.

- The supported clauses include SELECT, GROUP BY, ORDER BY [ASC,DESC], LIMIT, and HAVING.

> **Note** By default, only the first 10 results are returned. If you want to return more results, add a LIMIT clause to the statement. For example, `* | select count(1) as c, ip group by ip order by c desc limit 100`.

Built-in fields

Log Service has multiple built-in fields for statistical analysis. A built-in field is automatically added to a valid column that you create.

Field	Type	Description
`__time__`	Bigint	The time when a log was created.
`__source__`	Varchar	The source IP address of a log. When you query logs, the name of the field is source. If you specify the field for an SQL statement, you must add two underscores (_) at both the start and end of source.
`__topic__`	Varchar	The topic of a log.

Limits

- Maximum number of Logstores from which you can query logs at the same time is 15.
- Maximum length for a field value of the varchar type is 2,048. Extra data will be truncated.
- By default, up to 100 lines of a log file are returned and pagination is not supported. If you want to return more lines, use LIMIT syntax.

Example

Calculate the hourly PV and UV, and the user request of the highest latency.

```
*|select date_trunc('hour',from_unixtime(__time__)) as time,
  count(1) as pv,
  approx_distinct(userid)  as uv,
  max_by(url,latency) as top_latency_url,
  max(latency,10) as top_10_latency
  group by  1
  order by time
```

23.4.3. Enable the indexing feature and configure indexes for a Logstore

This topic describes how to enable the indexing feature and configure indexes for a Logstore.

Context

Before you can query logs that are stored in a Logstore, you must enable the indexing feature and configure indexes for the Logstore. We recommend that you configure indexes for your Logstores based on your business requirements.

> **Note** After you enable the indexing feature, the indexes occupy extra storage space and transferring the indexes occupies extra bandwidth.

When you collect a log entry, Log Service adds the relevant information (such as the source and time fields) to the log entry as key-value pairs. These fields are reserved in Log Service. If you enable the indexing feature for a Logstore and configure indexes for fields in the Logstore, the indexing and analytics features are automatically enabled for these fields.

Reserved fields in Log Service

Field	Description
__topic__	The topic of a log entry. If you specify a topic for a log entry, Log Service adds the topic field to the log entry. The key of the field is __topic__ and the value of the field is the log topic. For more information, see **Specify a log topic**.
__source__	The source of a log entry. The source device that generates the log entry.
__time__	The time when a log entry is written to the Logstore by using an SDK.

> **Note** If the values of the __topic__ and __source__ fields are null, the keywords that you use to query the two fields must exactly match the field values.

Procedure

1. Log on to the Log Service console.
2. In the Projects section, click the target project.
3. Find the target Logstore, and choose > **Search & Analysis**.
4. On the page that appears, click **Enable** in the upper-right corner.

   > **Note** If you have created indexes for the Logstore, choose **Index Attributes** > **Modify** to modify the indexes.

5. Configure the indexes.

   > **Note** If you enable a full-text index and a field-specific index at the same time, the field-specific index takes precedence over the full-text index.

   Index types

Index type	Description
Full text index	An index is created in the text format for all fields. You can search for key-value pairs that are included in these fields. For fields of the LONG type, you must specify the key name of a field when you query a value of the field. For fields of the other types, you do not need to specify a key name in queries.

Index type	Description
Field-specific index	After you configure a field-specific index, you must specify the name of a key when you query logs. If you configure the field-specific index on a field, the field-specific index takes effect when you query logs. The full-text index does not take effect. Available data types that you can specify for fields include: ○ Query text data ○ JSON indexes ○ Numeric (LONG and DOUBLE)

- Configure a full-text index.

  After you configure a full-text index for a Logstore, the values of all fields in the Logstore are queried by default.

Parameter	Description	Example value
Full Text Index	If you turn on the switch, Log Service traverses the values of all fields in a log entry. If the value of one of the fields matches the keyword, the log entry is returned.	-
Case Sensitive	Specifies whether queries are case-sensitive. ■ If you turn off the switch, queries are not case-sensitive. For example, if you search for internalError, you can use either INTERNALERROR or internalerror as the keyword. ■ If you turn on the switch, queries are case-sensitive. For example, if you search for internalError, you can use only internalError as the keyword.	-
Include Chinese	Specifies whether to differentiate the Chinese content and English content. ■ If you turn on the switch, Log Service separates the Chinese content based on the Chinese semantics and English content based on the specified delimiters. ■ If you turn off the switch, the content of a log entry is separated by the specified delimiters.	-
Delimiter	The delimiters that you use to separate the content of a log entry into multiple keywords. For example, the content of a log entry is `a,b;c;D-F`. You can specify commas (,), semicolons (;), and hyphens (-) as delimiters to delimit the log content. Then you can use the five letters a, b, c, D, and F as keywords to match the log entry.	`, '";=()[]{}? @&<>/:\n\t`

- Configure a field-specific index.

  You can specify fields to be indexed. Field-specific indexes allow you to query log data based on the values of specific fields. This narrows down the query scope.

Parameter	Description	Example value
Key Name	The name of a log field. **Note** ■ If you want to configure an index for fields of the tag type, such as fields that include public IP addresses or UNIX timestamps, you must set the value of the **Key Name** parameter in the `__tag__:key` format, for example, `__tag__:__receive_time__`. ■ Indexes of the numeric types are unavailable for tag fields. You must select text in the **Type** field for all tag fields.	`_address_`
Type	The type of a field. Valid values: ■ **text**: The data type of the field is TEXT. ■ **long**: The data type of the field is LONG. You must specify a numeric range to query log data. ■ **double**: The data type of the field is DOUBLE. You must specify a numeric range to query log data. ■ **json**: The data type of the field is JSON. **Note** The **Case Sensitive**, **Include Chinese**, and **Delimiter** parameters are unavailable for fields of numeric types (LONG and DOUBLE).	-
Alias	The alias of a column. Aliases are applied only to SQL statistics. Original names are applied when you store and query log data in Log Service. For more information, see Field aliases.	`address`
Case Sensitive	Specifies whether queries are case-sensitive. ■ If you turn off the switch, queries are not case-sensitive. For example, if you search for internalError, you can use either INTERNALERROR or internalerror as the keyword. ■ If you turn on the switch, queries are case-sensitive. For example, if you search for internalError, you can use only internalError as the keyword.	-
Delimiter	The delimiters that you use to separate the content of a log entry into multiple keywords. For example, the content of a log entry is `a,b;c;D-F`. You can specify commas (,), semicolons (;), and hyphens (-) as delimiters to delimit the log content. Then you can use the five letters a, b, c, D, and F as keywords to match the log entry.	`, '";=()[]{}? @&<>/:\n\t`

Parameter	Description	Example value
Include Chinese	Specifies whether to differentiate the Chinese content and English content. ■ If you turn on the switch, Log Service separates the Chinese content based on the Chinese semantics and English content based on the specified delimiters. ■ If you turn off the switch, the content of a log entry is separated by the specified delimiters.	-
Enable Analytics	Specifies whether to enable the analytics feature. The switch is turned on by default. After you turn on the switch, you can use search and analytic statements to obtain statistical results.	-

6. Click **OK**.

> **Note**
> - The index configurations take effect within one minute.
> - After an index is enabled or modified, the updates on the index apply only to new data that is written to Log Service.

23.4.4. Query logs

This topic describes how to query logs in a Logstore. After you enable and configure the index of the Logstore, you can query and analyze logs in a Logstore in real time.

Prerequisites

- Logs are collected and stored in a Logstore.
- Indexes are enabled and configured. For more information, see Enable the index feature and configure indexes for a Logstore.

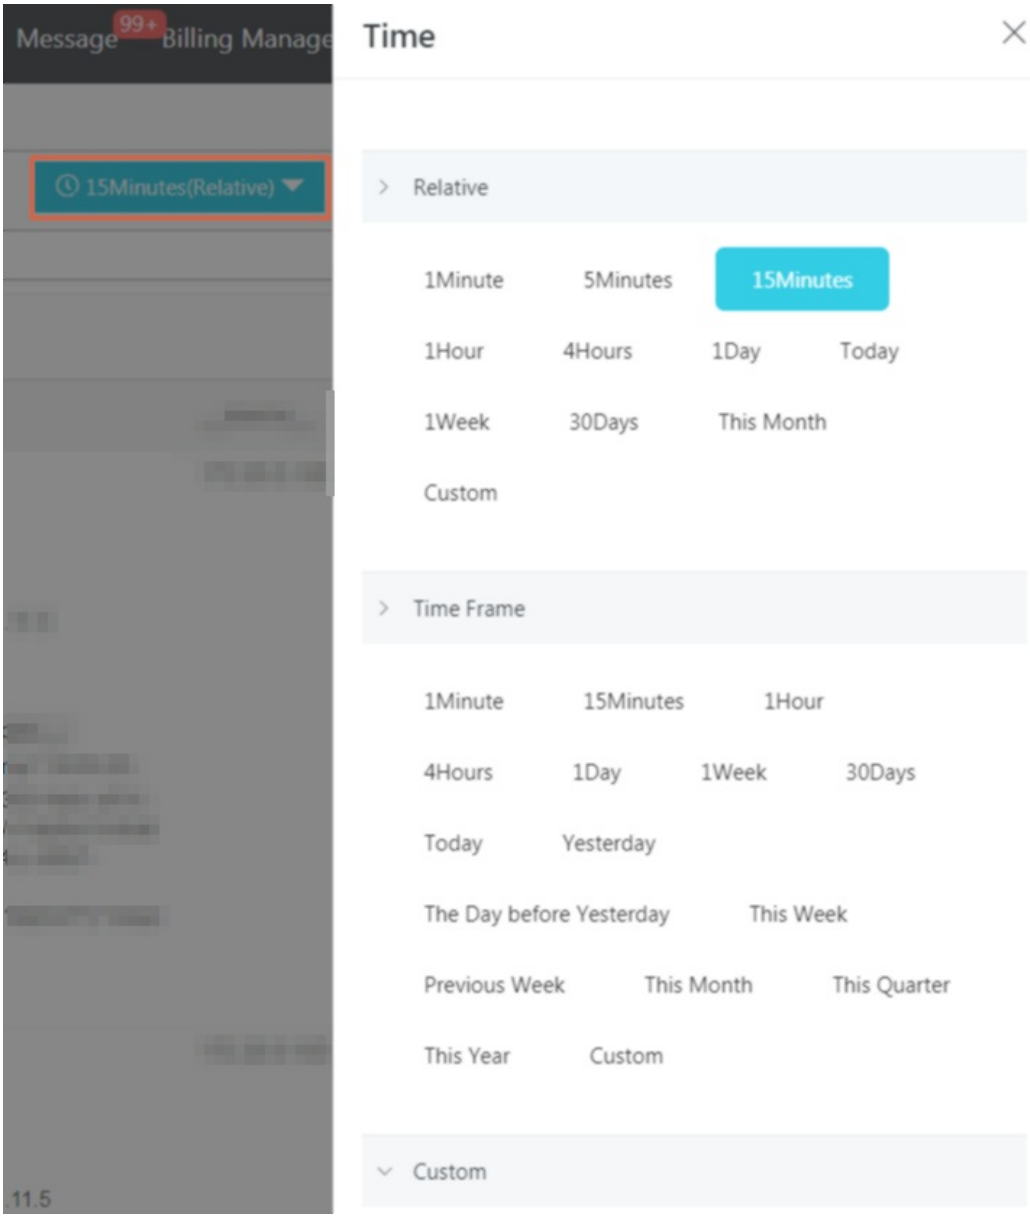
Procedure

1. Log on to the Log Service console.
2. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
3. Enter a query statement in the search box.

   A query statement consists of a search statement and an analytic statement. The syntax is `search statement|analytic statement`. For more information, see Search and analysis statements.
4. On the Search & Analysis page, select **15 Minutes** in the Relative section to set the time range for the query.

   You can select a relative time, time frame, or a custom time range.

   > **Note** The query results may contain logs that are generated 1 minute earlier or later than the specified time period.



5. Click **Query & Analyze** to view the query results.

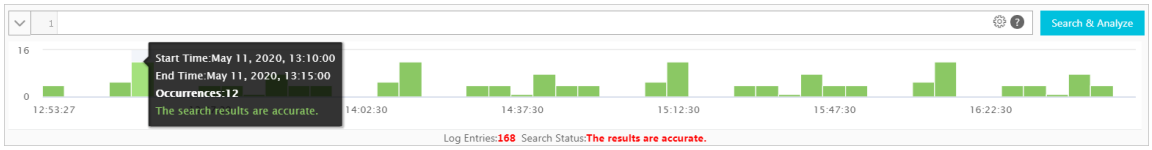
   Log Service illustrates query results on log distribution histograms, Raw Logs tab, or statistical graphs.

   > **Note** 100 results are returned by default. For information about how to retrieve more results, see LIMIT syntax.

   - Log distribution histogram

     The log distribution histogram shows the distribution of query results across different time ranges.

     - Move the pointer over a green block to view a time range and the number of logs obtained within the time range.
     - Click a data block to view finer-grained log distribution. You can also view the query results on the **Raw Logs** tab.



- Raw Logs tab

  On the **Raw Logs** tab, view logs that match your search conditions.

  - Quick analysis: Use this feature to analyze the distribution of values for a specific field within a period of time. For more information, see Quick analysis.
  - Log download: Click the download icon in the upper-right corner of the tab, select a time range, and then click **OK**.
  - Column settings: Click **Column Settings** in the upper-right corner of the tab, select the required fields and click **Add** to add the fields. Then, the columns that correspond to the fields appear on the tab. The field names are also column names. The columns list the field values.

    > **Note** To view the log contents on the tab, select **Content**.

  - Content column settings: If the content of a field exceeds 3,000 characters, extra characters will be hidden. In this case, the message "The character string is too long and has been truncated" will be displayed before the Key field. Click **Display Content Column**. In the dialog box that appears, set the **Key-Value Arrangement** and **Truncate Character String** parameters.

    > **Note** If the content limit is set to 10,000 characters, no delimiter will be specified for extra characters.

Parameter		Description
Key-Value Pair Arrangement		You can set this parameter to **New Line** or **Full Line**.
Truncate Character String	**Key**	If a field value contains more than 3,000 characters, the field value is truncated. However, this parameter remains unspecified if no field value exceeds 3,000 characters. The value of this parameter is the key of the truncated value.
	Status	This parameter determines whether to enable the value truncation feature. By default, the feature is enabled. ■ **Enable**: If the value in a key-value pair exceeds the specified **Truncate Step**, extra characters will be truncated. You can click the Show button at the end of the value to show the truncated characters. The increment per click is the specified truncate step. ■ **Disable**: If the value in the key-value pair exceeds the specified **Truncate Step**, extra characters will not be truncated.
	Truncate Step	This parameter specifies the maximum number of characters that a field value shows by default. The parameter also specifies the number of extra characters that you displayed each time you click the Show button. Valid values: 500 to 10000. Default value: 3000.

- Graph

If you enable the Analytics feature on the Search & Analysis page and use search and analytic statements to query logs, you can view the analytical results on the **Graph** tab.

- Graphs of multiple types are provided in Log Service, including tables, line charts, and bar charts. You can select a graph to show the required analytical results. For more information, see Graphs.
- Log Service allows you to create dashboards for real-time data analysis. For more information, see Create and delete a dashboard. Click **Add to New Dashboard** to save a common chart as query statements to a dashboard.
- Drill-down analysis allows you to move to deeper data layers, which reveals more detailed information. You can set the drill-down parameters and add the chart to the dashboard. Then, you can click the values in the chart to view the analysis results from more dimensions. For more information, see Drill-down analysis.

You can also click **Save Search** or **Save as Alarm** on the Search & Analysis page to use the saved search and alarm features. For more information, see Save a query statement as a search and Configure an alert.

23.4.5. Export logs

You can export logs on the current page to a CSV file and save the file to your localhost.

Procedure

1. Log on to the Log Service console.
2. Click a project name.
3. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
4. Click the icon next to the **Raw Logs** tab.
5. In the **Download Log** dialog box, select **Download Log in Current Page**.
6. Click **OK** to export logs of the current page to a .CSV file and save the file to the localhost.

23.4.6. Index data type

23.4.6.1. Overview

Log Service allows you to use full-text indexes or field-specific indexes to query collected logs. If you set a full-text index for a log, the value is the entire log. If you set a field-specific index for a log, you can specify a data type for each key.

Date types

The following table lists the supported data types.

Query type	Data type (index)	Description	Example
Basic query	Text	The text type. You can use keywords and fuzzy matches to query logs.	`uri:"login*" method:"post"`
	Long	The numeric type. You can specify numeric ranges to query logs.	`status>200 and status in [200, 500]`
	Double	The floating-point type.	`price>28.95 and t in [20.0, 37]`

Query type	Data type (index)	Description	Example
Combined query	JSON	Indicates that the index is a JSON field that supports nested queries. By default, the data type of the field is text. You can set indexes of the Text, Long, and Double types for the b elements at layer a in the a.b path format. The fields adopt the configured types.	level0.key>29.95 level0.key2:"action"
	Text	Indicates that the full contents of the log are queried as text.	error and "login fail"

Query examples

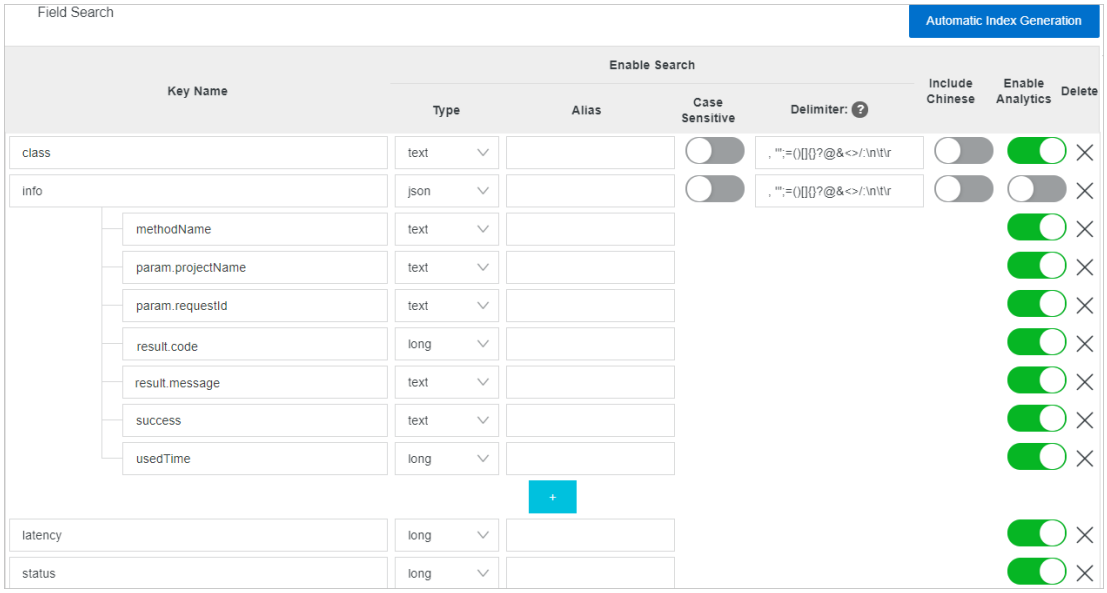
The following table lists the keys included in the sample log.

No.	Key	Type
0	time	N/A
1	class	text
2	status	long
3	latency	double
4	message	json

```
0. time:2018-01-01 12:00:00
 1. class:central-log
 2. status:200
 3. latency:68.75
 4. message:
 {
   "methodName": "getProjectInfo",
   "success": true,
   "remoteAddress": "1.1.1.1:11111",
   "usedTime": 48,
   "param": {
        "projectName": "ali-log-test-project",
        "requestId": "d3f0c96a-51b0-4166-a850-f4175dde7323"
   },
   "result": {
     "message": "successful",
     "code": "200",
     "data": {
       "clusterRegion": "ap-southeast-1",
       "ProjectName": "ali-log-test-project",
       "CreateTime": "2017-06-08 20:22:41"
     },
     "success": true
   }
 }
```

You can set an index as follows.

Set an index



In the preceding figure,

- ① specifies that Log Service can query data of the string and Boolean types in JSON fields.
- ② specifies that Log Service can query data of the long type.
- ③ enables SQL analysis for specified fields.

Example

1. Query data of the string and Boolean types
   - You do not need to configure JSON fields.
   - JSON maps and arrays are automatically expanded and can contain nested fields. Separate multiple levels with periods (.). .

   ```
   class : cental*
   message.traceInfo.requestId : 92.137_1518139699935_5599
   message.param.projectName : ali-log-test-project
   message.success : true
   ```

2. Query data of the double and long types

   Each JSON field must be specified separately and cannot be contained in a JSON array.

   ```
   latency>40
   message.usedTime > 40
   ```

3. Combined query

   ```
   class : cental* and message.usedTime > 40 not message.param.projectName:ali-log-test-project
   ```

23.4.6.2. Query text data

This topic describes how to query text data.

Similar to search engines, Log Service queries text data based on terms. Therefore, you must set the Delimiter, Case Sensitive fields.

Configurations

- Case sensitivity

You can specify whether log queries are case-sensitive. For example, you want to query logs by using a search term named `internalError`.

- *false* specifies a case-insensitive query. Both `INTERNALERROR` and `internalerror` can be the keywords.
- *true* specifies a case-sensitive query. Only the `internalError` can be the keyword.

- Delimiter

  You can use delimiters to split a search term into multiple keywords.

  For example, you want to query logs by using the following search term.

  ```
  /url/pic/abc.gif
  ```

  - If no delimiter is set, the entire `/url/pic/abc.gif` string is treated as a keyword. You must use the entire string as a keyword or a fuzzy string named `/url/pic/*` to query logs.
  - If the delimiter is set to `/`, the search term is split into three words: `url`, `pic`, and `abc.gif`. You can use one of these words or a fuzzy word to query logs. For example, `url`, `abc.gif`, or `pi*`. You can also use the `/url/pic/abc.gif` string as a search term to query logs. However, the search term is split into three keywords named `url, pic, and abc.gif`.
  - If the delimiter is set to `/.`, the search term is split into four keywords named `url`, `pic`, `abc`, and `gif`.

  > **Note** You can extend query ranges by setting appropriate delimiters.

- Full-text index

  By default, full-text indexes treat each log except for the time field as text data. You do not need to specify any keys for a full-text index. For example, the following log includes the time field, status field, level field, and message field.

  ```
  [20180102 12:00:00] 200,error,some thing is error in this field
  ```

  - `time:2018-01-02 12:00:00`
  - `level:"error"`
  - `status:200`
  - `message:" some thing is error in this field"`

  > **Note**
  > - Prefixes are not required for full-text indexes. If you set the search term to error, the level and message fields that include error match the search term.
  > - You must set delimiters for full-text indexes. For example, if you set a space ( ) as a delimiter, the `status:200` string is a search term. If you set a colon (:) as a delimiter, the search term is split into two keywords named `status` and `200`.
  > - Numbers are treated as text data. For example, you can use 200 to query logs. Values in the time field are not treated as text data.
  > - You can query logs by using keys such as `status`.

23.4.6.3. Numeric type

When you configure indexes, you can set the data type of a key to number. To query logs, you can specify a numeric range for the key.

Configurations

Supported types: `long` (long integers) and `double` (decimals). After you set the data type of a key to number, you must specify a numeric range for the key to query logs.

Query examples

To specify a numeric range from 1000 to 2000 (excluding 1000) for a key of the long type, you can use the following methods:

- Query syntax for numbers. For example:

```
longKey > 1000 and longKey <= 2000
```

- Query grammar for numeric ranges. For example:

```
longKey in (1000 2000]
```

For more information about query syntax, see Query syntax.

23.4.6.4. JSON indexes

Log Service can query and analyze logs in the JSON format. You can set the data type of indexes to JSON.

JSON texts include data of multiple types, including string, Boolean, number, array, and map. JSON-formatted data is self-parsed and flexible. You can use JSON-formatted data in various scenarios. In most cases, variable log fields are recorded in the JSON format. For example, HTTP request and response parameters are recorded in a log in the JSON format.

Log Service allows you to set the data type of index fields to JSON so that you can query and analyze logs in the JSON format.

Configurations

- Log Service can parse JSON-formatted fields and generate indexes for all the fields of the text and Boolean types.

```
json_string.key_map.key_text : test_value
json_string.key_map.key_bool : true
```

- To query fields of the double or long type that is not in a JSON array, you can specify a JSON path.

```
Set the data type of the key_map.key_long field to long.
Search condition: json_string.key_map.key_long > 50
```

- To query fields of the text, double, or long type that is not in a JSON array, you can enable the Analytics feature and use SQL statements to analyze these fields.

```
json_string.key_map.key_long > 10 | select count(*) as c ,
  "json_string.key_map.key_text" group by
  "json_string.key_map.key_text"
```

> **Note**
>
> - JSON objects and JSON arrays are not supported.
> - Fields cannot be contained in JSON arrays.
> - Fields of the Boolean type can be converted into the text type.
> - To query and analyze logs, JSON-formatted fields must be enclosed with double quotation marks (" ").

- Log Service cannot parse invalid JSON-formatted data.

  Log Service does not stop parsing logs until it detects an invalid field.

  In the following example, data after the key_3 field is truncated and lost in the following text. Log Service can parse the json_string.key_map.key_2 field and the contents before this field.

```
"json_string":
{
   "key_1" : "value_1",
   "key_map" :
   {
       "key_2" : "value_2",
       "key_3" : "valu
```

Query syntax

To query a specific key, you must add the JSON parent path to the query statement as the prefix of the key. The query syntax for the fields of the text and numeric types is the same for both JSON-formatted data and other data. For more information, see Query syntax.

Query example

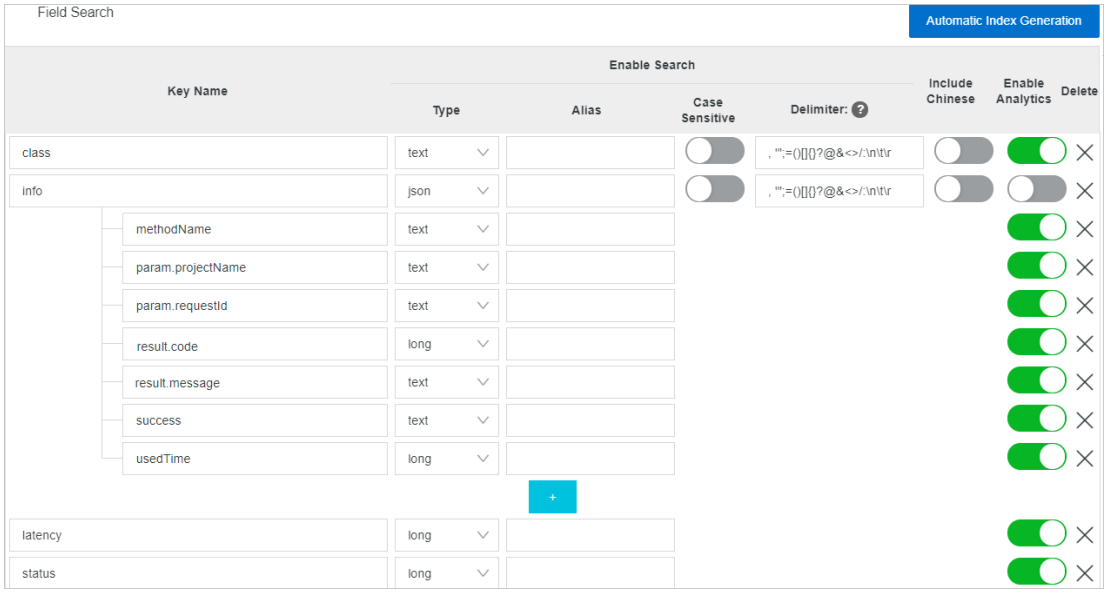
The following table lists the keys included in the sample log. The data type of the `message` key is JSON.

Number	Key	Type
0	time	N/A
1	class	text
2	status	long
3	latency	double
4	message	json

```
0. time:2018-01-01 12:00:00
 1. class:central-log
 2. status:200
 3. latency:68.75
 4. message:
{
   "methodName": "getProjectInfo",
   "success": true,
   "remoteAddress": "1.1.1.1:11111",
   "usedTime": 48,
   "param": {
       "projectName": "ali-log-test-project",
       "requestId": "d3f0c96a-51b0-4166-a850-f4175dde7323"
   },
   "result": {
     "message": "successful",
     "code": "200",
     "data": {
       "clusterRegion": "ap-southeast-1",
       "ProjectName": "ali-log-test-project",
       "CreateTime": "2017-06-08 20:22:41"
     },
     "success": true
   }
}
```

You can set indexes for the log as follows:

Set an index



In the preceding figure:

- ① specifies that Log Service can query data of the string and Boolean types in JSON fields.
- ② specifies that Log Service can query data of the long type.
- ③ enables SQL analysis for specified fields.

Examples

1. Query data of the string and Boolean types

   > **Note**
   > - You do not need to configure JSON fields.
   > - JSON maps and arrays are automatically expanded and can include hierarchical levels. Separate multiple levels with periods (.) .

   ```
   message.traceInfo.requestId : 92.137_1518139699935_5599
   message.param.projectName : ali-log-test-project
   message.success : true
   message.result.data.ProjectStatus : Normal
   ```

2. Query fields of the double and long types

   > **Note** Each JSON field must be configured and cannot be contained in an array.

   ```
   message.usedTime > 40
   ```

3. Use SQL statements to analyze fields

   > **Note**
   > - Each JSON field must be configured and cannot be contained in an array.
   > - Each field to be queried must be enclosed with double quotation marks (" ") or be configured with an alias.

   ```
   * | select avg("message.usedTime") as avg_time ,
   "message.methodName" group by "message.methodName"
   ```

23.4.7. Query syntax and functions

23.4.7.1. Search syntax

This topic describes the search syntax that is used in Log Service.

Search types

After you enable and configure the index feature of a Logstore, you can enter a search statement on the search and analysis page to query logs.

A query statement consists of two sub-statements in sequence: a search statement and an analytic statement. A search statement specifies one or more search conditions and returns the log entries that match the search conditions. You can execute a search statement to perform a full-text search or field-specific search.

- Full-text search

  During full-text search, a log entry is considered a key-value pair. The value in the key-value pair indicates the content of the log entry. A full-text search statement returns the log entries that include or exclude the specified keywords.

  Full-text search is divided into basic full-text search, phrase search, and wildcard-based search.

  - Basic full-text search: You can specify keywords and operators in search conditions of a search statement. You can then execute the search statement to query the log entries that match the search conditions.

    For example, the `a and b` statement returns the log entries that include the `a` and `b` keywords.
  - Phrase search: A phrase is a string that is enclosed in double quotation marks (""). Substrings in a phrase are separated by space characters. Each substring is a keyword.

    For example, the `"http error"` statement returns the log entries that contain the http and error keywords. This statement is equivalent to `http and error`.
  - Wildcard-based search: You can use an asterisk (`*`) or a question mark (`?`) as a wildcard character in a keyword. Each keyword that includes wildcards can contain 1 to 64 characters in length and cannot start with a wildcard character. If a search condition contains a keyword that includes a wildcard character, Log Service returns a maximum of 100 log entries and each log entry contains a word that matches the keyword pattern.

    For example, if you execute the `addr?` statement, Log Service returns a maximum of 100 log entries and each log entry contains a word that is prefixed with `addr`.

    When you use wildcard-based search, note the following information:

    - A keyword cannot start with an asterisk (`*`) or a question mark (`?`).
    - The more accurate the keyword is, the more accurate the search results will be.
    - Wildcard-based search is not supported for a keyword that contains more than 64 characters in length.
    - A search statement returns a maximum of 100 log entries that match the search conditions.

- Field-specific search

  After you configure the field index, you can search log entries based on the keys and values of the fields in the field index. For a field of the DOUBLE or LONG type, you can specify a value range for search. For example, the `Latency>5000 and Method:Get* and not Status:200` statement returns the log entries that meet the following conditions: The value of the `Latency` field is greater than 5000, the value of the `Method` field is prefixed with `Get`, and the value of the `Status` field is not 200.

  You can perform a basic query or combined query, depending on the data types of the fields in the field index. For more information, see Overview.

Additional considerations

- If you execute a search statement to perform both full-text search and field-specific search and you set different delimiters for the two search types, the delimiter that is set for field-specific search is used.

- You must set the data type of a field to DOUBLE or LONG before you specify a value range to search the field. If the data type of a field is not DOUBLE or LONG or the value range syntax is incorrect, the field-specific search condition is considered a full-text search condition. In this case, unexpected search results may be returned.
- If you change the data type of a field from TEXT to DOUBLE or LONG, only the equal-to operator (`=`) can be used to search for the log entries that are collected before the change.

Operators

The following table lists the operators that are supported by search statements.

Operator	Description
and	A binary operator. The syntax is `query1 and query2`. It indicates the intersection of the search results of `query1` and `query2`. The default operator between keywords is `and`.
or	A binary operator. The syntax is `query1 or query2`. It indicates the union of the search results of `query1` and `query2`.
not	A binary operator. The syntax is `query1 not query2`. It indicates that the log entries that match `query1` but do not match `query2` are returned. The syntax is equivalent to `query1-query2`. You can also use the `not query1` syntax. It indicates that the log entries that do not match `query1` are returned.
(,)	The operator that merges one or more sub-conditions into one search condition. The search based on a sub-condition that is enclosed in parentheses () is performed first.
:	The operator that is used to specify a pattern of key-value pairs. The syntax is `term1:term2`. If the key or value contains reserved characters such as spaces and colons (:), use double quotation marks (`""`) to enclose the entire key or value.
"	The operator that converts another operator into a common character. All terms enclosed in double quotation marks ("") are considered keywords rather than operators. In a field-specific search statement, you can enclose the entire key or value in double quotation marks.
\	The operator that escapes a double quotation mark. The escaped double quotation mark is considered a symbol instead of an operator. Example: `"\""`.
|	The pipeline operator that is used to chain a search statement and an analytic statement. The analytic statement that follows the pipeline operator is executed based on the result of the search statement that the pipeline operator follows. Example: `query1 | select count(1)`.
count	The count operator that is used to summarize the number of log entries.
*	The wildcard character that is used to replace zero or more characters. For example, the `que*` statement returns the log entries with a word that is prefixed with `que`. **Note** A wildcard-based search statement returns a maximum of 100 log entries that match the search condition.
?	The wildcard character that replaces a single character. The `qu?ry` statement returns the log entries with a word that is prefixed with `qu`, is suffixed with `ry`, and contains a character in between.

Operator	Description
__topic__	The operator that specifies zero or more topics from which to query log entries. Example: __topic__:mytopicname .
__tag__	The operator that specifies a tag value of a tag key to query. Example: __tag__:tagkey:tagvalue .
source	The operator that specifies the IP address of a log source whose log entries you want to query. Example: source:127.0.0.1 .
>	The greater-than operator. You can use this operator to query the log entries whose value of a field is greater than a specified number. Example: latency > 100 .
>=	The greater-than-or-equal-to operator. You can use this operator to query the log entries whose value of a field is greater than or equal to a specified number. Example: latency >= 100 .
<	The less-than operator. You can use this operator to query the log entries whose value of a field is less than a specified number. Example: latency < 100 .
<=	The less-than-or-equal-to operator. You can use this operator to query the log entries whose value of a field is less than or equal to a specified number. Example: latency <= 100 .
=	The equal-to operator. You can use this operator to query the log entries whose value of a field is equal to a specified number. Example: latency = 100 .
in	The operator that is used to query the log entries whose value of a field falls in a specified range. Brackets [] indicate closed intervals and parentheses () indicate open intervals. The beginning number and ending number of the range are enclosed in brackets or parentheses and separated by one or more space characters. The in operator must be in lowercase. Example: latency in [100 200] or latency in (100 200] .

Note

- All operators except the in operator are case-insensitive.
- You can use the following operators, which are sorted in descending order of precedence: : , " , () , and , not , and or .
- Log Service uses the following operators: sort , asc , desc , group by , avg , sum , min , max , and limit . If you need to use these operators as keywords, enclose them in double quotation marks ("").

Search statement examples

Expected search result	Search statement
Log entries that contain a and b	a and b or a b
Log entries that contain a or b	a or b
Log entries that contain a but do not contain b	a not b
Log entries that do not contain a	not a
Log entries that contain a and b but do not contain c	a and b not c

Expected search result	Search statement
Log entries that contain a or b and contain c	`(a or b ) and c`
Log entries that contain a or b but do not contain c	`(a or b ) not c`
Log entries that contain a and b and may contain c	`a and b or c`
Log entries whose FILE field contains apsara	`FILE:apsara`
Log entries whose FILE field contains apsara and shennong	`FILE:"apsara shennong"` , `FILE:apsara FILE: shennong` , or `FILE:apsara and FILE:shennong`
Log entries that contain the following keyword: and	`and`
Log entries whose FILE field contains apsara or shennong	`FILE:apsara or FILE:shennong`
Log entries whose file info field contains apsara	`"file info":apsara`
Log entries that contain double quotation mark (")	`\"`
Log entries with words that are prefixed with shen	`shen*`
Log entries whose FILE field is prefixed with shen	`FILE:shen*`
Log entries whose value of the FILE field is shen*	`FILE: "shen*"`
Log entries with words that are prefixed shen, are suffixed with ong, and contain a single character in between	`shen?ong`
Log entries with words that are prefixed with shen and words that are prefixed with aps	`shen* and aps*`
Log entries of topic1 and topic2	`__topic__:topic1 or __topic__ : topic2`
Log entries with a tag whose key is tagkey1 and value is tagvalue2	`__tag__ : tagkey1 : tagvalue2`
Log entries whose value of the latency field is greater than or equal to 100 and less than 200	`latency>= 100 and latency < 200` or `latency in [100 200)`
Log entries whose value of the latency field is greater than 100	`latency > 100`
Log entries that do not contain spider and whose http_referer field does not contain opx	`not spider not bot not http_referer:opx`
Log entries whose cdnIP field is not empty	`not cdnIP:""`
Log entries that do not contain the cdnIP field	`not cdnIP:*`
Log entries that contain the cdnIP field	`cdnIP:*`
Log entries that contain a specified URL	`* | select * where url = 'www.xxxxx.com'`

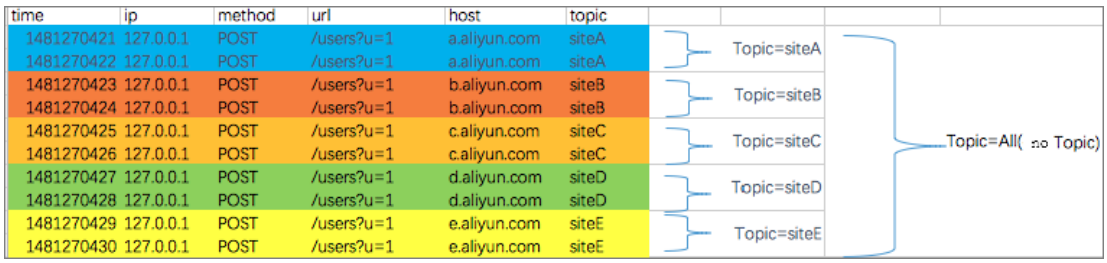
Topic-specific search

Each Logstore is divided into one or more topics. You can divide a Logstore into multiple topics if you need level-2 categories of log entries. When you query logs, you can specify topics to increase efficiency.

In a search statement, you can specify one or more topics to query. If no topic is specified, log entries are queried from all topics.

For example, you can classify log entries into multiple topics based on domain names.

Log topics



Syntax of topic-specific search:

- In a search statement, you can specify one or more topics to query. If no topic is specified, log entries are queried from all topics.
- The topic-specific search syntax is `__topic__:topicName`. You can also specify a topic in a URL.
- You can query log entries from multiple topics. For example, the `__topic__:topic1 or __topic__:topic2` statement returns the log entries in topic1 and topic2.

23.4.7.2. LiveTail

This topic describes how to use LiveTail to monitor and analyze log data. LiveTail is an interactive feature provided in the Log Service console to monitor and extract key log data in real time.

Prerequisites

- LiveTail is available only after logs are collected.
- LiveTail can only monitor and extract log data collected by Logtail.

Context

In online O&M scenarios, you often need to monitor collected log data in real time and extract key information from the latest log data to locate error causes. In traditional O&M, you must run the `tail -f` command on servers to monitor log files in real time. To easily obtain the required real-time log information, you can include the `grep` or `grep -v` command to filter log entries by keyword. To simplify online O&M, Log Service provides LiveTail in the console to monitor and analyze online log data in real time.

Benefits

- Monitors real-time log information and filters log data by keyword.
- Logs collected based on the log collection configurations are identified by index.
- Log fields are delimited. This allows you to query contextual logs that contain delimiters.
- Log files can be tracked based on a single log entry and monitored in real time without the need to connect to online servers.

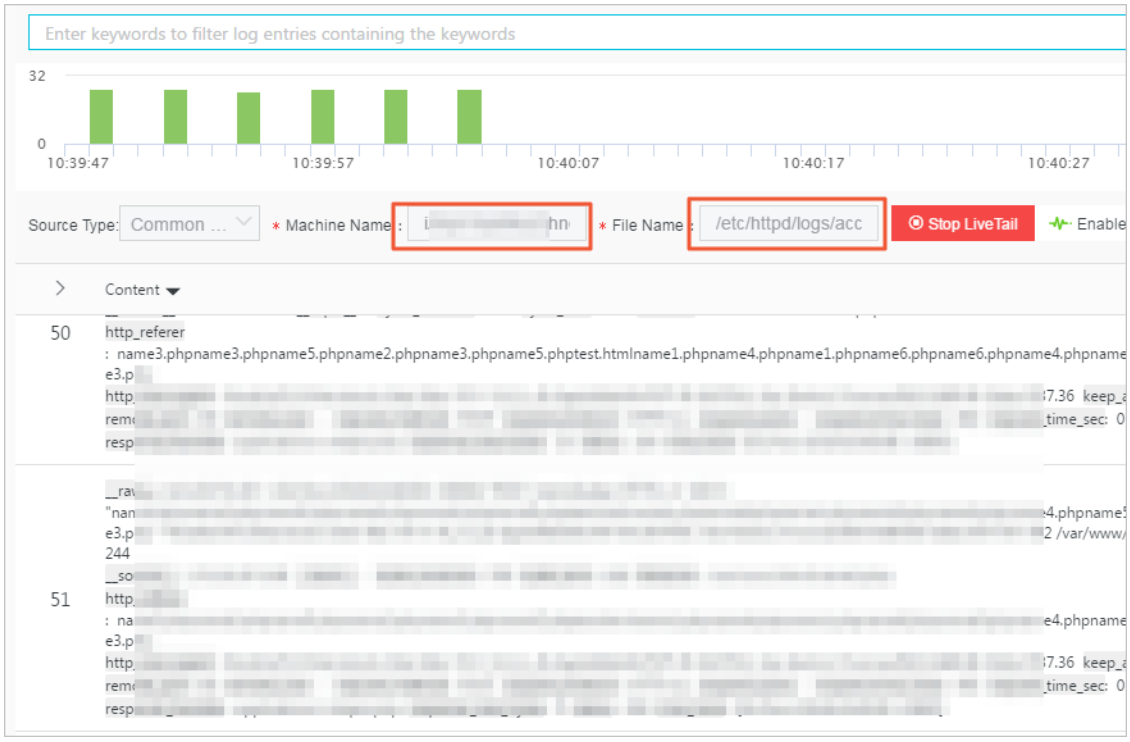
Use LiveTail to monitor logs in a Logstore in real time

1. Log on to the Log Service console.
2. In the Projects section, click the target project.
3. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
4. (Optional)Start LiveTail.

i. On the **Raw Logs** tab, click the icon next to the sequence number of the specified raw log entry, and then select **LiveTail**.

The system starts LiveTail and starts timing. The **Source Type**, **Machine Name**, and **File Name** fields are automatically filled in based on the specified raw log entry.

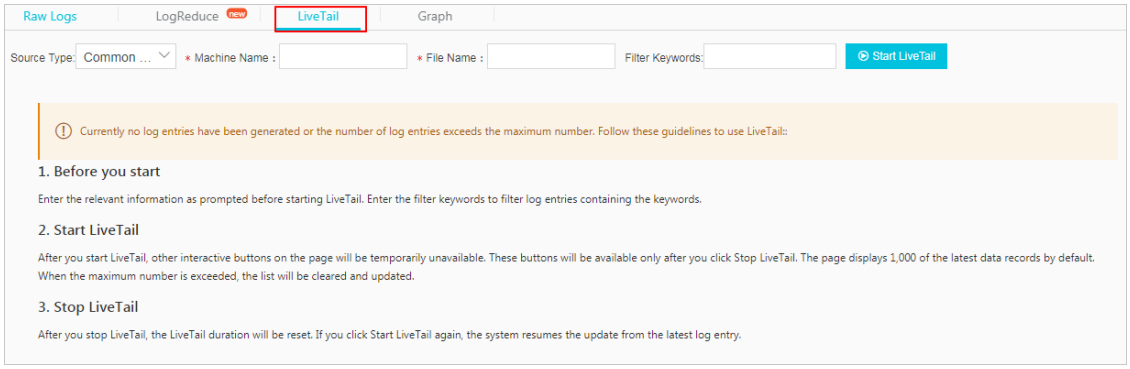
After LiveTail is started, log data collected by Logtail is displayed in order on the page in real time. The latest log data is displayed at the bottom of the page by default. You can view the latest log data without the need to drag the scroll bar. Up to 1,000 log entries can be displayed on the page. If more than 1,000 log entries are collected, the page is automatically refreshed to show the latest 1,000 log entries.



ii. (Optional)You can also enter keywords in the search box to display log entries that contain the keywords in the monitoring list. By filtering log entries that contain the keyword, you can monitor specific log entries in real time.

5. Customize LiveTail.

i. On the Search & Analysis page, click the **LiveTail** tab.



ii. Configure LiveTail.

Parameter	Required	Description
Source Type	Yes	The source of log entries. Valid values: ■ Physical servers ■ Kubernetes containers ■ Docker
Machine Name	Yes	The name of the server from which log entries are collected.
File Name	Yes	The full path and name of the log file.
Filter Keywords	No	A keyword. After you set a keyword, only log entries that contain the keyword are displayed in the log monitoring list.

iii. Click **Start LiveTail**.

After LiveTail is started, log data collected by Logtail is displayed in order on the page in real time. The latest log data is displayed at the bottom of the page by default. You can view the latest log data without the need to drag the scroll bar. Up to 1,000 log entries can be displayed on the page. When more than 1,000 log entries are collected, the page is refreshed to show the latest 1,000 log entries.

6. To analyze logs during real-time log monitoring, click **Stop LiveTail**.

After you stop LiveTail, the LiveTail timing and the real-time log data update also stop.

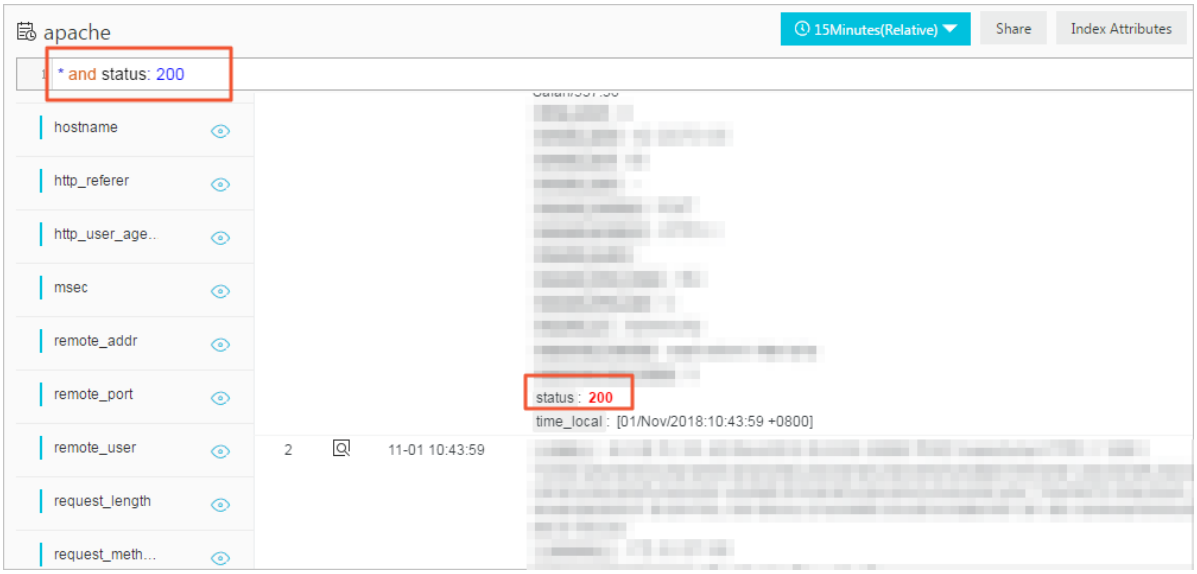
Log Service provides multiple methods to analyze exceptions that are found during log monitoring. For more information, see Use LiveTail to analyze logs.

Use LiveTail to analyze logs

After you stop LiveTail, real-time log updates in the log monitoring list also stop. You can analyze and fix errors that are found during log monitoring.

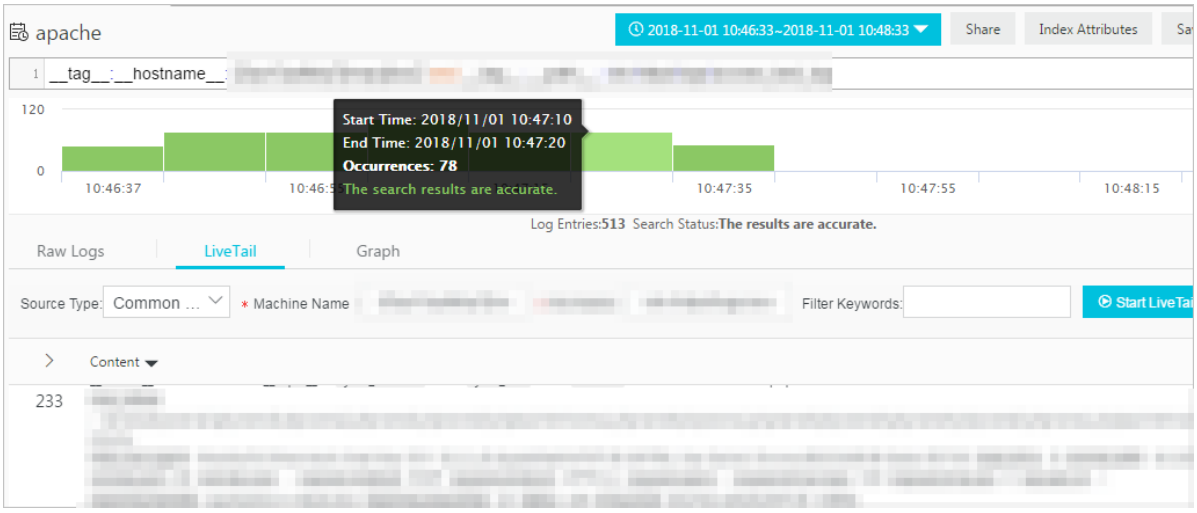
- View log entries that contain specified fields

Log fields are delimited. You can click the value of the specified exception field on the **LiveTail** tab. Then, you are automatically forwarded to the **Raw logs** tab and the value of the exception field is used as a keyword to filter all log entries that contain the field and the keyword. You can also analyze log entries that contain the keyword based on contextual queries and statistical charts.



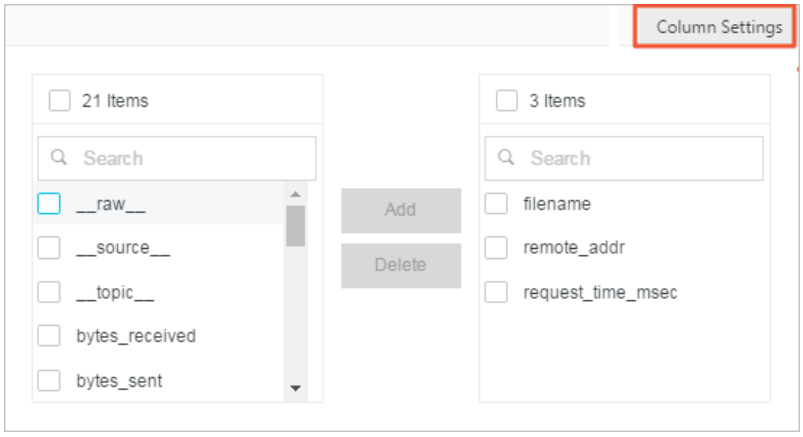
- Narrow down the time range of a log query based on the log distribution histogram

  After LiveTail is started, the log distribution histogram is updated at the same time. If you find a distribution exception (for example, a big increase in the number of log entries) in a time range, you can click the corresponding green rectangle to narrow down the time range of the log query. The timeline of the raw logs is associated with the timeline that you click on the LiveTail tab. You can view all relevant raw logs and log distribution details during this time range.



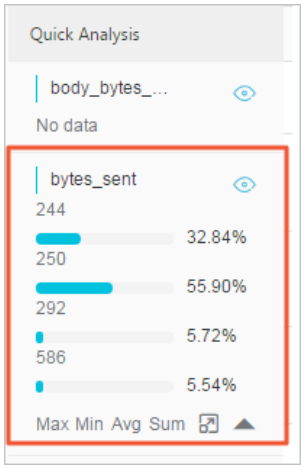
- Highlight key information based on column settings

  On the **LiveTail** tab, click **Column Settings** in the upper-right corner of the log monitoring list. Then, you can specify a field as a separate column to highlight relevant data.



- Analyze log data

  On the **LiveTail** tab, click the arrow in the upper-left corner of the log monitoring list to show the Quick Analysis pane. The time range for quick analysis starts from the time when LiveTail is started and ends at the time when LiveTail is stopped. The quick analysis provided on the LiveTail tab is the same as that provided on the Raw Logs tab. For more information, see Quick analysis.



23.4.7.3. LogReduce

This topic describes how to use LogReduce to group log data in Log Service. The LogReduce feature groups similar log entries by detecting same log patterns during text log collection.

Context

The LogReduce feature allows you to group text logs of multiple formats. You can locate errors, detect anomalies, roll back versions, and perform other O&M operations in DevOps scenarios. You can also detect network intrusions to ensure data security. In addition, you can save the log grouping result to a dashboard as an analysis chart, and then view the grouped data in real time.

Benefits

- Various formats of logs such as Log4j logs, JSON-formatted logs, and syslog logs can be grouped.
- Hundreds of millions of log entries can be grouped in seconds.
- Log entries can be grouped in any pattern.
- Raw log entries can be retrieved based on the signature of log entries grouped in a pattern.
- The number of log entries grouped in a log pattern in different time ranges can be compared.
- The precision of log grouping can be adjusted based on your needs.

Billing method

After the LogReduce feature is enabled, the size of indexes increases by 10% of the raw log size. For example, if the size of raw log data is 100 GB per day, the size of log indexes increases by 10 GB.

Raw log size	Index percentage	Size of indexes generated by LogReduce	Index size
100 GB	20% (20 GB)	100 × 10%	30 GB
100 GB	40% (40 GB)	100 × 10%	50 GB
100 GB	100% (100 GB)	100 × 10%	110 GB

Enable LogReduce of a Logstore

The LogReduce feature is disabled by default.

1. Log on to the Log Service console.
2. Click the target project in the Projects section.
3. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
4. Configure an index.
   - If you have enabled the index feature and configured indexes for the Logstore, choose **Index Attributes > Modify**.
   - If you have not enabled the index feature, click **Enable**.
5. Set the index attributes and turn on the **LogReduce** switch. Click **OK**.

   After LogReduce is enabled, Log Service groups log data that has been collected. Then, you can perform the following operations:
   - View log grouping results and raw logs
   - Adjust the precision of log grouping
   - Compare the number of log entries grouped in different time ranges

View log grouping results and raw logs

1. On the Search & Analysis page, enter a search and analytic statement in the search box, and then click **Search & Analytics**.

   You can use keywords to filter grouped log entries.

   > **Note** SQL statements are not supported. This means analysis results cannot be grouped.

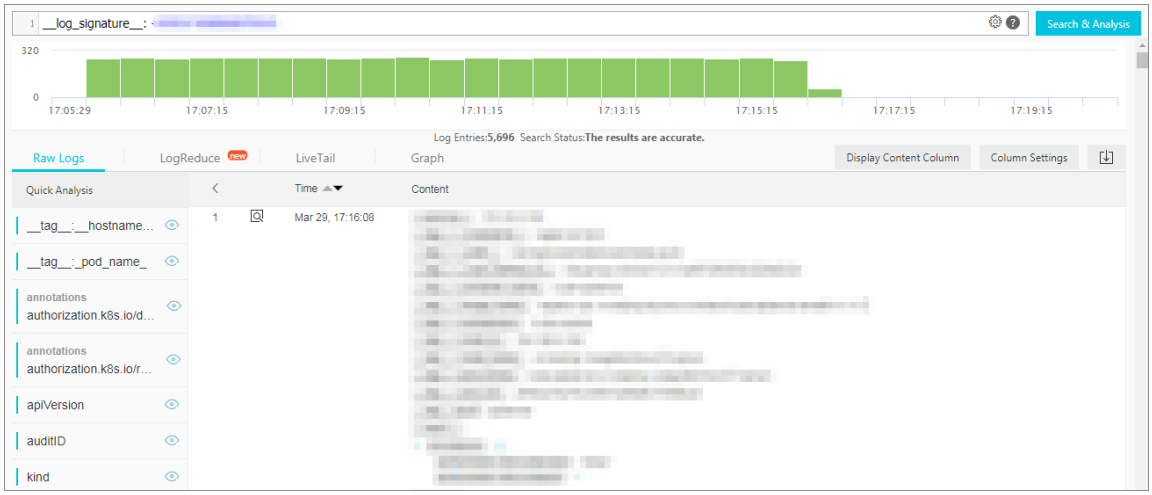
2. Click the **LogReduce** tab to view the log grouping result.

   The filtered log grouping result is displayed on the **LogReduce** tab.

Item	Description
Number	The sequence number of a log group.
Count	The number of log entries in a log group.
Pattern	The log pattern. Each log group has one or more sub-patterns.

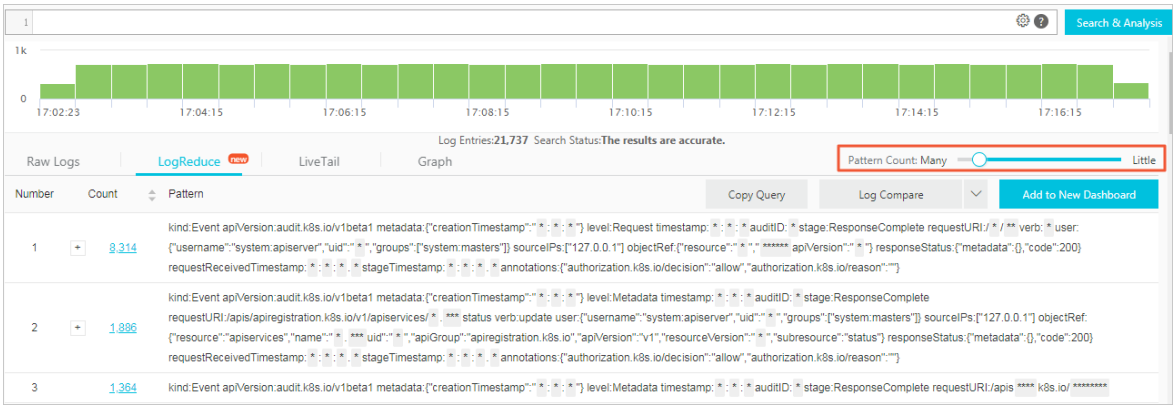
   - Move the pointer over a value in the **Count** column to view the sub-patterns of the corresponding log group and the percentage of each sub-pattern in the log group. You can also click the plus sign (+) before the count value to expand the sub-pattern list.

- Click a count value to view the raw log entries of the corresponding log group.



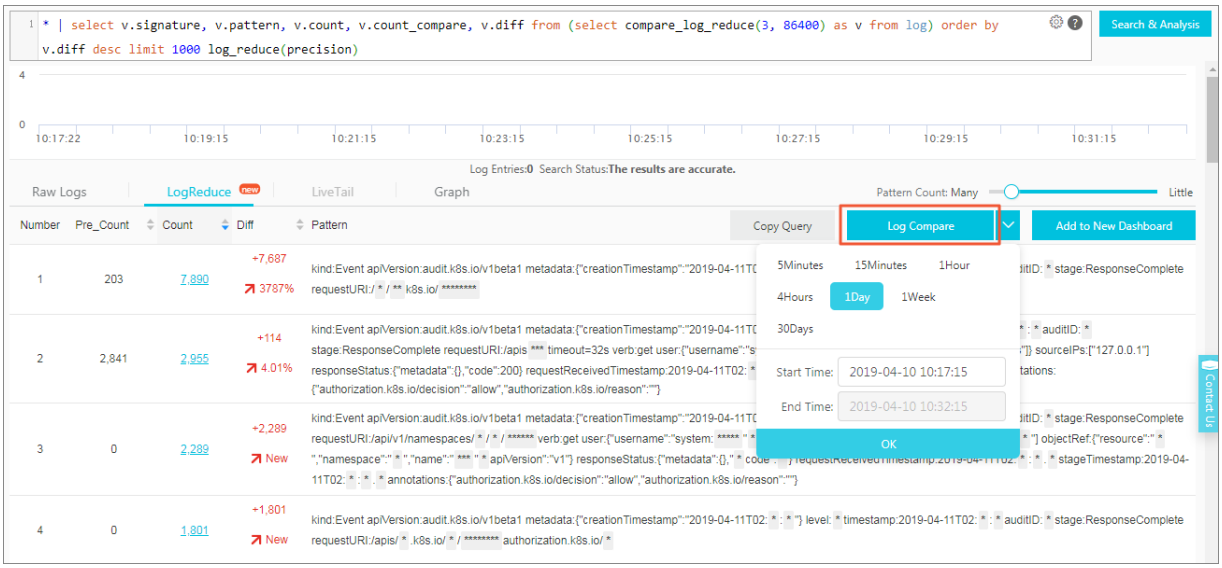
Adjust the precision of log grouping

1. On the Search & Analysis page, click the **LogReduce** tab.
2. In the upper-right corner of the tab, drag the **Pattern Count** slider to adjust the precision of log grouping.
   - If you drag the slider towards **Many**, you can obtain a more precise log grouping result with more detailed patterns.
   - If you drag the slider towards **Little**, you can obtain a less precise log grouping result with less detailed patterns.



Compare the number of log entries grouped in different time ranges

Click **Log Compare** on the **LogReduce** tab, select a time range, and then click **OK**.



Item	Description
Number	The sequence number of a log group.
Pre_Count	The number of log entries grouped by the current pattern in the previous time range.
Count	The number of log entries grouped by the current pattern in the current time range.
Diff	The difference between the Pre_Count value and Count value.
Pattern	The pattern of a log group.

SQL statement examples:

- Obtain a log grouping result.
  - SQL statement:

    ```
    * | select a.pattern, a.count,a.signature, a.origin_signatures from (select log_reduce(3) as a from log) limit 1000
    ```

    > **Note** When you view the log grouping result in the Log Service console, you can click **Copy Query** to obtain the relevant SQL statement.

  - Input parameter: log_reduce (precision)

    precision: an integer from 1 to 16 that can be set as the log grouping precision. A smaller value indicates a higher precision and more patterns. The default value is 3.

  - Returned fields:
    - pattern: the sub-patterns of log entries in a log group.
    - count: the number of log entries in a log group.
    - signature: the log pattern of a log group.
    - origin_signatures: the original signature of a log group. You can use this field to query raw log entries of the log group.
- Compare the number of log entries grouped in different time ranges.

- SQL statement:

```
* | select v.pattern, v.signature, v.count, v.count_compare, v.diff from (select compare_log_reduce(3, 86400) as v from log) order by v.diff desc limit 1000
```

> **Note** After you click **Log Compare** in the Log Service console, you can click **Copy Query** to obtain the SQL statement.

- Input parameters: compare_log_reduce(precision, compare_interval)
  - precision: an integer from 1 to 16 that can be set as the log grouping precision. A smaller value indicates a higher precision and more patterns. The default value is 3.
  - compare_interval: the number of seconds between when the previous log entries and the current log entries were generated. The value of this parameter must be a positive integer.
- Returned fields:
  - pattern: the sub-patterns of log entries in a log group.
  - signature: the log pattern of a log group.
  - count: the number of log entries in a log group.
  - count_compare: the number of log entries for a same-pattern log group within the specified time range.
  - Diff: the difference between the values of the count field and the count_compare field.

23.4.7.4. Contextual query

This topic describes the contextual query feature provided in the Log Service console. You can use this feature to query the full context of the log file where specified log entries are obtained.

Prerequisites

The index feature is enabled.

Context

The contextual query feature identifies the server and file where a specified log entry resides. It then queries several log entries before and after the log entry in the original log file. This helps you locate errors during troubleshooting.

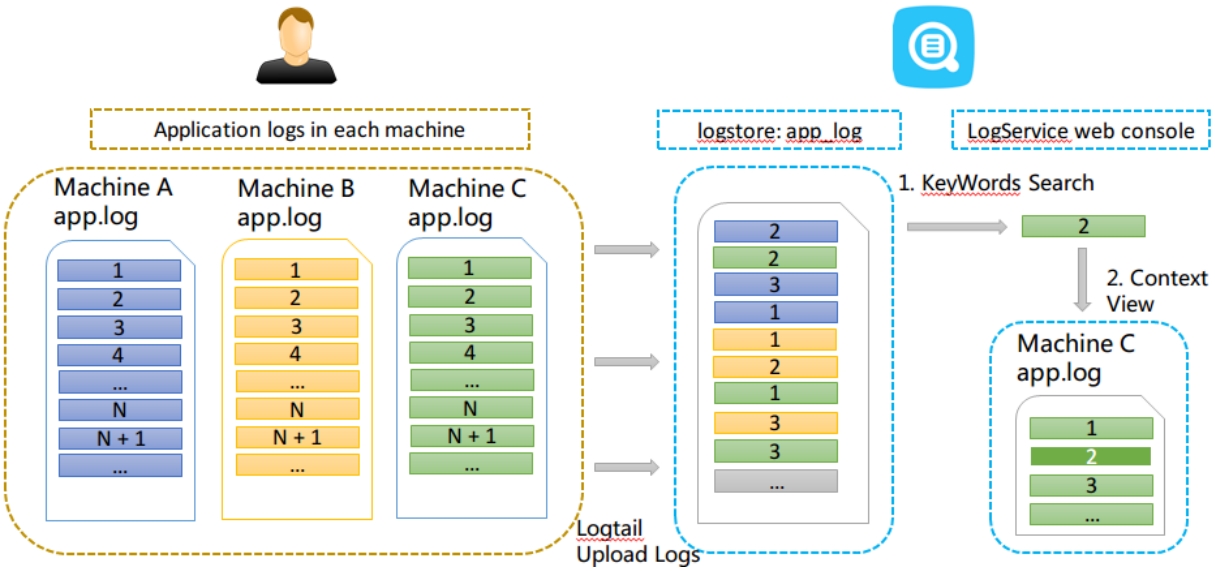
Scenarios

For example, a transaction on an O2O takeout website is logged in an application log file on a server as follows: **User logon** > **Browse products** > **Select an item** > **Add to a shopping cart** > **Place an order** > **Payment** > **Deduction** > **Generate an order**.

If the order fails, the O&M personnel must locate the cause at the earliest opportunity. In traditional contextual queries, the O&M personnel must be authorized before logging on to each server where the application is deployed. Then, the O&M personnel must use the order ID as a keyword to search application log files to locate the cause of the failure.

In Log Service, the O&M personnel can perform the following steps to locate the cause of the failure:

1. Install Logtail on servers. Then log on to the Log Service console to add the servers to machine groups and configure log collection. After the configurations are complete, Logtail starts to upload incremental logs.
2. On the search and analysis page of the Log Service console, specify the time range and find the error log entry based on the order ID.
3. Based on the error log entry, page up until you find log entries related to the error log entry. For example, you may want to find a log entry that records a credit card payment failure.



Note The contextual query feature does not support syslog.

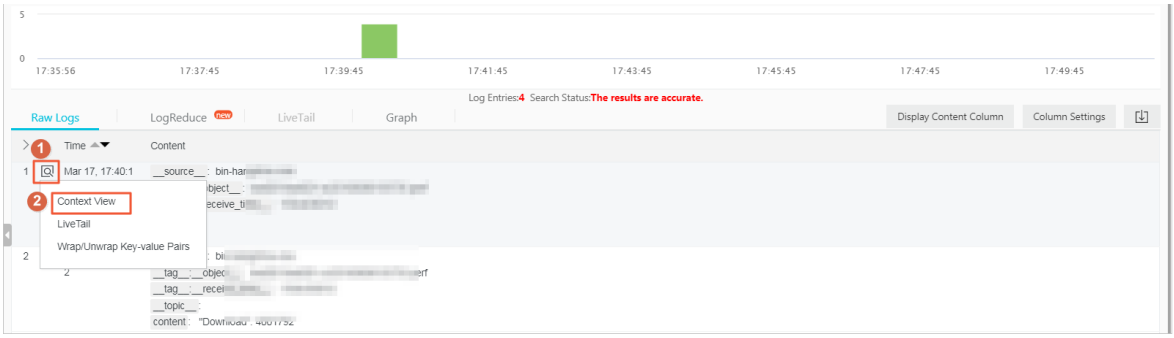
Benefits

- Intrusions into applications or changes to log file formats are avoided.
- You can view contextual log entries of a specified log entry in a log file on a server that has been registered in the Log Service console. This helps you avoid logging on to each server to search for logs that you want.
- You can specify the time range based on the time when an event occurs to locate suspicious log entries. Then you can perform a contextual query in the Log Service console. This improves troubleshooting efficiency.
- Data loss caused by log file rotation or insufficient storage space is avoided. You can view historical log data in the Log Service console at any time.

Procedure

1. Log on to the Log Service console.
2. Click the target project in the Projects section.
3. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
4. Enter a search and analytic statement, select a time range, and then click **Search & Analytics**.

   On the query results page, if the **Context View** icon is available in the drop-down list of the icon to the left of a log entry, the log entry supports contextual query.



5. Click the icon to the left of a log entry, and select **Context View** from the drop-down list. On the page that appears, view the contextual log entries of the selected log entry.
6. Scroll up and down to view more contextual log entries. To view earlier or later contextual log entries, click

Old or **New**.

23.4.7.5. Saved search

This topic describes how to save a search and analytic statement as a saved search for a Logstore. The saved search feature allows you to search and analyze log data in an efficient way.

Prerequisites

The index feature is enabled and configured.

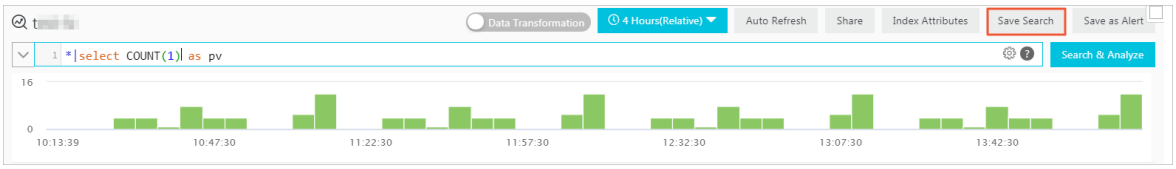
Context

If you need to frequently run a search and analytic statement, you can save the statement as a saved search. In later queries, you can click the name of the saved search on the left side of the search page to run the statement and view the result. You can also use the saved search in alert configurations. Log Service periodically runs the search and analytic statement and sends an alert if a query result meets the trigger condition.

If you want to select **Open Saved Search** in the Event Action field when you configure drill-down analysis, you must preset a saved search and set a **placeholder** in the query statement. For more information, see Drill-down analysis.

Procedure

1. Log on to the Log Service console.
2. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
3. Enter a search and analytic statement in the search box, set a time range, and then click **Search & Analyze**.
4. Click **Save Search** in the upper-right corner of the page.



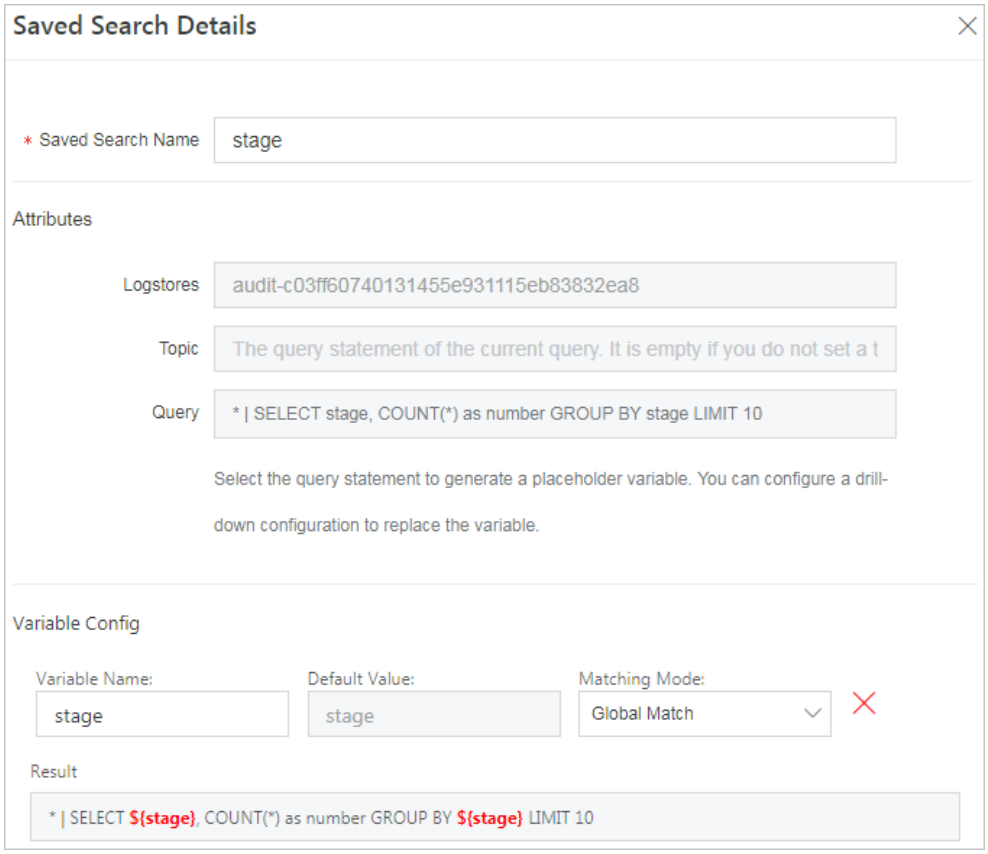
5. Configure the saved search.
   i. Enter a **Saved Search Name**.
      - The name can contain only lowercase letters, digits, hyphens (-), and underscores (_).
      - The name must start and end with a lowercase letter or digit.
      - The name must be 3 to 63 characters in length.
   ii. Check the values of the **Logstores**, **Topic**, and **Query** parameters.

      If the values of the **Logstores** and **Topic** parameters do not meet your requirements, follow these steps: Return to the Logstores page. On this page, find and click the name of the target Logstore. On the page that appears, enter the search and analytic statement in the Search & Analyze search box, and then click **Save Search** again.

iii. (Optional)Select a part of the query statement, and then click **Generate Variable**.

The generated variable is a placeholder variable. You can set the placeholder name in the **Variable Name** field. The selected characters are displayed in the **Default Value** field.

> **Note** If you use this saved search for drill-down analysis in another chart where the **variable** is the same as the **Variable Name**, the **Default Value** is replaced with the chart value that you click to trigger the drill-down event. The search and analytic statement with the replaced chart value is executed. For more information, see Drill-down analysis.

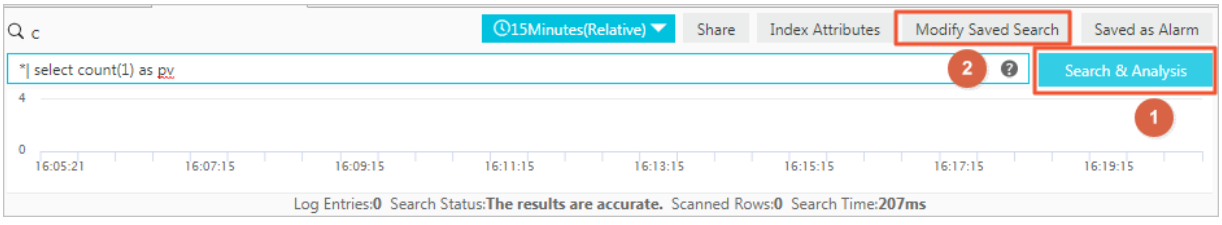


6. Click **OK**.

What's next

To modify a saved search, perform the following operations:

Enter a new search and analytic statement, click **Search & Analytics** to run the statement, and then click **Modify Saved Search**.



23.4.7.6. Quick analysis

This topic describes the quick analysis feature of Log Service. You can use this feature to query log data with one click. This feature allows you to analyze the distribution of a field in a specified time range and reduce the query cost of key data.

Features

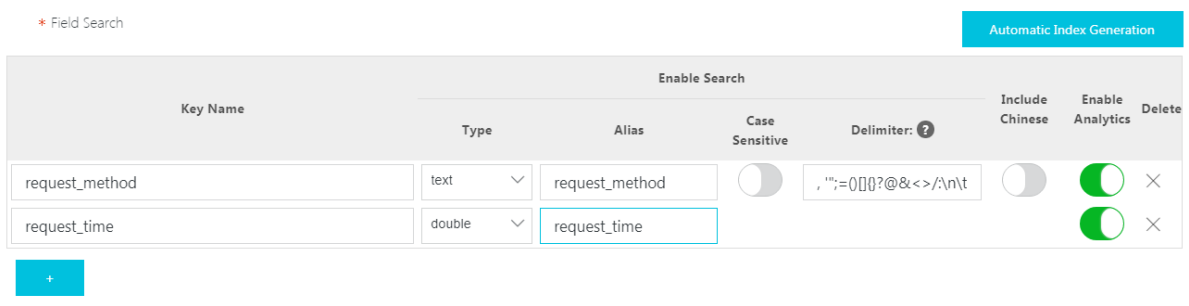
- Groups the first 100,000 values of a `text` field and provides statistics for the top 10 groups.
- Generates `approx_distinct` statements for `text` fields.
- Allows you to perform histogram-based statistics for the approximate distribution of `long` or `double` fields.
- Allows you to search for the maximum, minimum, and average of `long` or `double` fields and calculate the sum of the fields.
- Generates a query statement based on the quick analysis feature.

Prerequisites

Field indexes are configured.

- Indexes are configured for the fields that you need to search and analyze. For more information about how to enable the indexing feature, see Enable the index feature and configure indexes for a Logstore.
- The name of a field is specified as the `key`. The data type, alias, and delimiter of the field are configured.

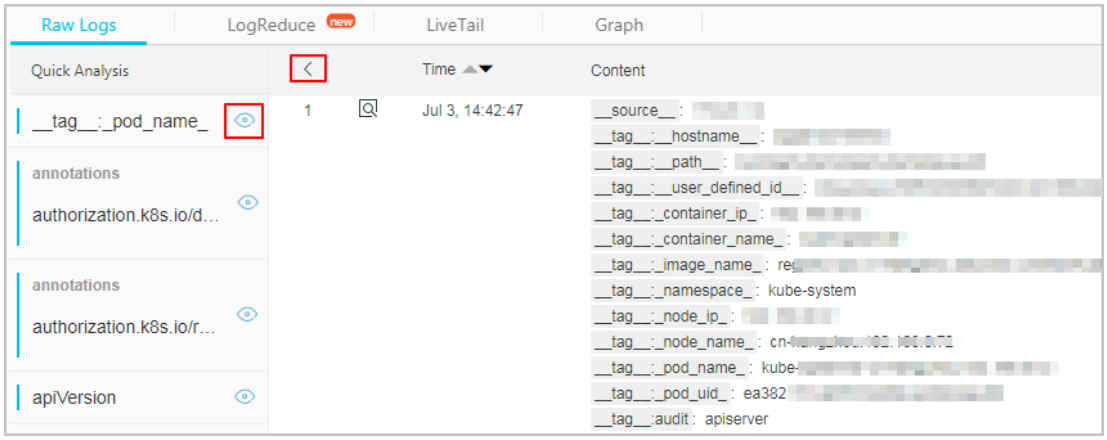
  For example, if a log entry contains the `request_method` and `request_time` fields, you can configure indexes for the two fields, as shown in the following figure.



Instructions

After you configure indexes for specified fields, you can go to the Search & Analysis page and click the **Raw Logs** tab to view the specified fields. The fields are listed in the **Quick Analysis** pane on the left of the raw log entries. You can click the icon above the serial number to hide the Quick Analysis pane. You can also click the **Eye** icon to perform quick analysis based on the **Current Time Zone** and **Current Search** conditions.

Quick analysis



Data of the text type

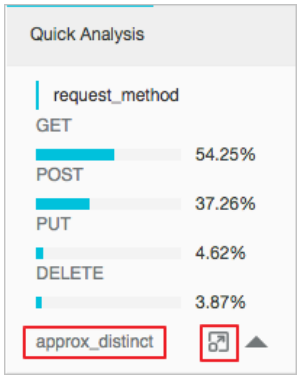
- Group and analyze log data

  Click the **Eye** icon next to a **text** field to group the first 100,000 field values and return the percentages of the top 10 groups.

The following statement is used:

```
$Search | select ${keyName} , pv, pv *1.0/sum(pv) over() as percentage from( select count(1) as pv , "${keyName}" from (select "${keyName}" from log limit 100000) group by "${keyName}" order by pv desc) order by pv desc limit 10
```

The following figure shows the grouping and analytics result of the `request_method` field. `GET` requests account for the majority of requests.



- Calculate the number of unique values in a field

  Under the target fields in the **Quick Analysis** pane, click **Count Distinct Values** to calculate the number of unique values in the `${keyName}` field.

- Fill the Search & Analyze search box with the grouping and analytics statement

  Click the **Count Distinct Values** button on the right of the icon. The Search & Analyze search box is filled with the grouping and analytics statement. You can edit the statement.

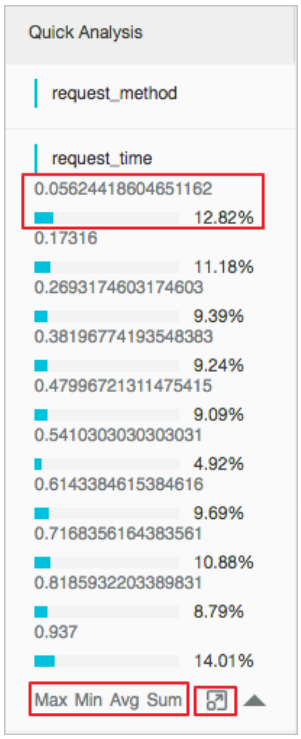
Data of the long and double types

- Display approximate distribution by using histograms

  The number of `long and double` field values is large. The preceding grouping and analytics method is not suitable for the long and double data types. You can use the following statement to divide field values into 10 groups and display the approximate distribution of the values in a histogram:

  ```
  $Search | select numeric_histogram(10, ${keyName})
  ```

The following figure shows the approximate distribution of the values in the `request_time` field. The largest percentage of request time is distributed around 0.059 seconds.



- Perform quick analysis by using the `Max`, `Min`, `Avg`, and `Sum` functions

  You can click `Max` under a field to search for the maximum value, `Min` to search for the minimum value, `Avg` to calculate the average value, and `Sum` to calculate the sum of the values.

- Fill the Search & Analyze search box with the query statement of the histogram approximate distribution

  Click the icon next to `Sum`. The Search & Analyze search box is filled with the query statement of the histogram approximate distribution. You can edit the statement.

23.4.8. Analysis grammar

23.4.8.1. General aggregate functions

This topic describes the syntax and examples of general aggregate functions.

The search and analytics feature of Log Service allows you to use general aggregate functions for log analysis. The following table describes the supported general aggregate functions.

Function	Description	Example
`arbitrary(x)`	Returns a random value from among the values in the x field.	`latency > 100 | select arbitrary(method)`
`avg(x)`	Returns the arithmetic mean of all values in the x field.	`latency > 100 | select avg(latency)`
`checksum(x)`	Returns a Base64-encoded checksum of the values of the x field.	`latency > 100 | select checksum(method)`
`count(*)`	Calculates the number of values of a field.	-

Function	Description	Example
count(x)	Counts the number of non-null values of the x field.	latency > 100 | select count(method)
count(digit)	Counts the number of values of a field. The count(digit) function is equivalent to the count(1) and count(*) functions.	-
count_if(x)	Returns the number of the occurrences of the TRUE value.	latency > 100 | select count_if(url like '%abc')
geometric_mean(x)	Returns the geometric mean of the values in the x field.	latency > 100 | select geometric_mean(latency)
max_by(x,y)	Returns the value of the x field that corresponds to the maximum value of the y field.	* | select min_by(method,latency,3) : queries the method that corresponds to the maximum latency.
max_by(x,y,n)	Returns n values of the x field that corresponds to the n largest value of the y field.	* | select min_by(method,latency,3) : queries the three methods that corresponds to the three maximum latencies.
min_by(x,y)	Returns the value of the x field that corresponds to the smallest value of the y field.	* | select min_by(x,y) : queries the method that corresponds to the minimum latency.
min_by(x,y,n)	Returns n values of the x field that corresponds to the n smallest values of the y field.	* | select min_by(method,latency,3) : queries the three methods that corresponds to the three minimum latencies.
max(x)	Returns the maximum value among all values in the x field.	latency > 100| select max(inflow)
min(x)	Returns the minimum value among all values in the x field.	latency > 100| select min(inflow)
sum(x)	Returns the sum among all values in the x field.	latency > 10 | select sum(inflow)
bitwise_and_agg(x)	Returns the bitwise AND of all values in the x field in two's complement representation.	-
bitwise_or_agg(x)	Returns the bitwise OR of all values in the x field in two's complement representation.	-

23.4.8.2. Security check functions

Security check functions in Log Services are designed based on the globally shared WhiteHat Security asset library. This topic describes security check functions that you can use to check whether an IP address, domain name, or URL in logs is secure.

Scenarios

- O&M personnel of enterprises and institutions in Internet, gaming, information, and other industries that require robust O&M services can use security check functions to identify suspicious requests or attacks. They can also use the functions to implement in-depth analysis and defend against potential attacks.
- O&M personnel of enterprises and institutions in banking, securities, e-commerce, and other industries that require strong protection for internal assets can use security check functions to identify requests to suspicious websites and downloads initiated by trojans. Then the O&M personnel can take immediate actions to prevent potential losses.

Features

- Reliability: built upon the globally shared WhiteHat Security asset library that is updated in a timely manner.
- Efficiency: capable of screening millions of IP addresses, domain names, and URLs within seconds.
- Ease of use: supports the analysis of network logs by using the security_check_ip, security_check_domain, and security_check_url functions.
- Flexibility: supports interactive queries, report creation, and alert configurations and subsequent actions.

Functions

Function	Description	Example
security_check_ip	Checks whether an IP address is secure. • The value 1 indicates that the specified IP address is suspicious. • The value 0 indicates that the specified IP address is secure.	`select security_check_ip(real_client_ip)`
security_check_domain	Checks whether a domain name is secure. • The value 1 indicates that the specified domain name is suspicious. • The value 0 indicates that the specified domain name is secure.	`select security_check_domain(site)`
security_check_url	Checks whether a URL is secure. • The value 1 indicates that the specified URL is suspicious. • The value 0 indicates that the specified URL is secure.	`select security_check_domain(concat(host, url))`

Examples

- Check external suspicious requests and generate reports

  For example, an e-commerce enterprise collects logs from its NGINX servers and wants to scan suspicious client IP addresses. To do this, the enterprise can pass the ClientIP field in logs that are collected from the NGINX servers to the `security_check_ip` function and filter out IP addresses associated with the returned value 1. Then the enterprise can query the countries where the IP addresses are located and ISPs to which the IP addresses belong.

  SQL statement for this scenario:

  ```
  * | select ClientIP, ip_to_country(ClientIP) as country, ip_to_provider(ClientIP) as provider, count(1) as PV where security_check_ip(ClientIP) = 1 group by ClientIP order by PV desc
  ```

  Display the ISPs and countries in a map.

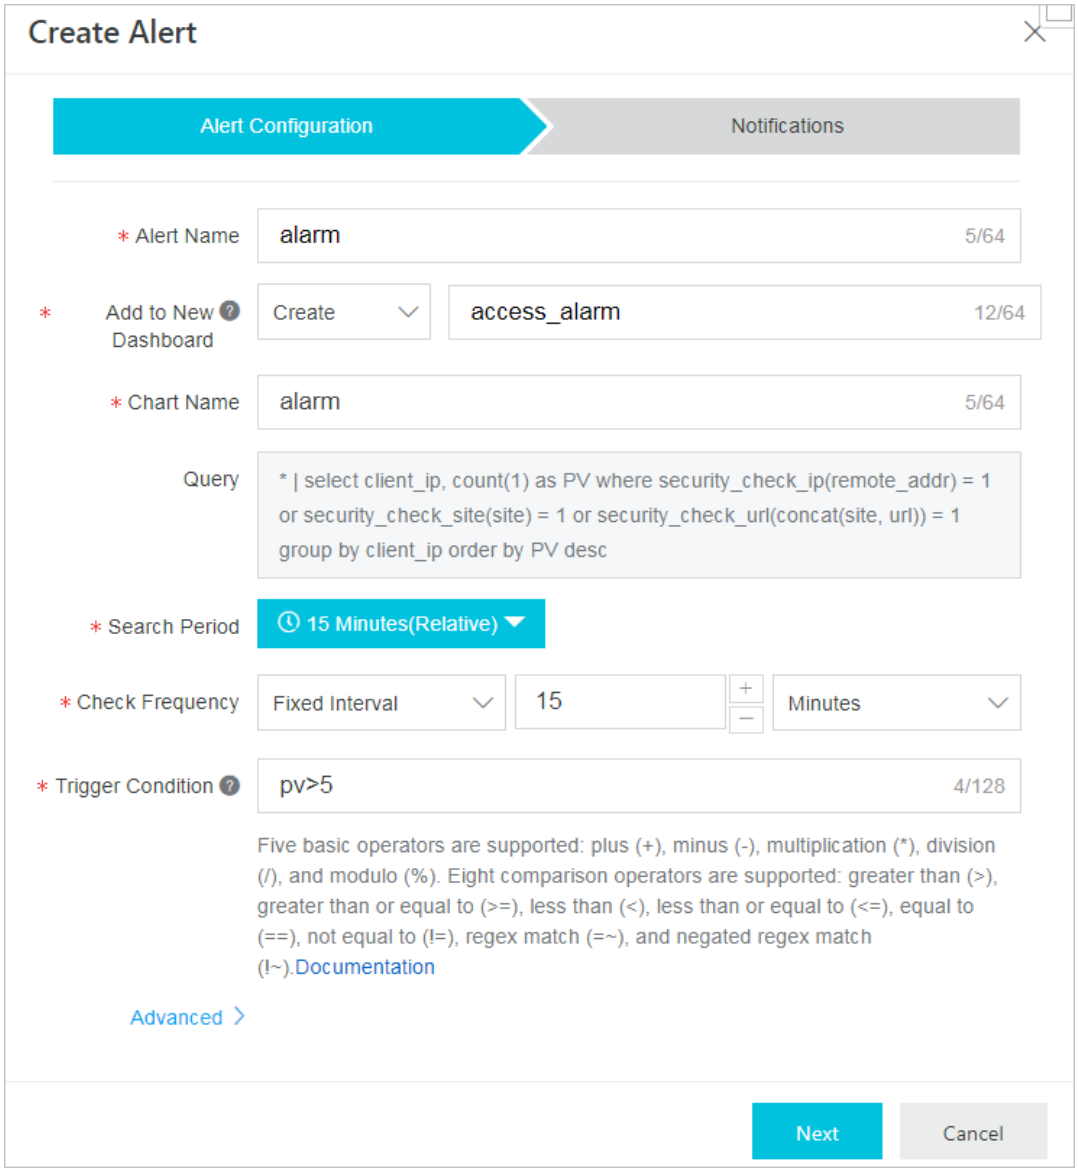
client_ip	country	provider	PV
180 3	CN		3
103	CN		3
180 7	CN		1

- Check internal suspicious requests and send alerts

  For example, a securities operator collects logs of its internal devices that access the Internet through gateways. To check requests to suspicious websites, the operator can run the following statement:

  ```
  * | select client_ip, count(1) as PV where security_check_ip(remote_addr) = 1 or security_check_site(site) = 1 or security_check_url(concat(site, url)) = 1 group by client_ip order by PV desc
  ```

  The operator can save this statement as a saved search and configure an alert. An alert is triggered when a client frequently accesses suspicious websites. The statement in the alert can be configured to run every five minutes to check if a client has frequently (more than five times) accessed suspicious websites in the past one hour. The following figure shows the configurations of an alert.



23.4.8.3. Map functions

This topic describes the syntax and examples of map functions.

The following table describes the supported map functions.

Function	Description	Example
Subscript operator []	Retrieves the value corresponding to a specified key from a map.	-
histogram(x)	Groups the values of the parameter x and calculates the number of occurrences of each value. The syntax is equivalent to `select count group by x`. **Note** The returned data is in the JSON format.	The statement `latency > 10 | select histogram(status)` is equivalent to the statement `latency > 10 | select count(1) group by status`.
histogram_u(x)	Groups the values of the parameter x and calculates the number of occurrences of each value. **Note** The returned data is in the format of multiple rows and columns.	The statement `latency > 10 | select histogram_u(status)` is equivalent to the statement `latency > 10 | select count(1) group by status`.
map_agg(Key,Value)	Returns a random value of the key in the format of a map that consists of key-value pairs.	`latency > 100 | select map_agg(method,latency)`
multimap_agg(Key,Value)	Returns all values of the key in the format of a map that consists of key-value pairs.	`latency > 100 | select multimap_agg(method,latency)`
cardinality(x) → bigint	Returns the cardinality of the map x.	-
element_at(map `<K, V>`, key) → V	Returns the value for the specified key.	-
map() → map `<unknown, unknown>`	Returns an empty map.	-
map(array `<K>`, array `<V>`) → map `<K,V>`	Returns a map where each key-value pair consists of two elements from two separate arrays.	`SELECT map(ARRAY[1,3], ARRAY[2,4]);` - {1 -> 2, 3 -> 4}
map_from_entries(array `<row<K, V>>`) → map `<K,V>`	Converts a multi-dimensional array to a map.	`SELECT map_from_entries(ARRAY[(1, 'x'), (2, 'y')]);` - {1 -> 'x', 2 -> 'y'}

Function	Description	Example
map_concat(map1 <K, V> , map2 <K. V> , ..., mapN <K, V>) → map <K,V>	Returns a map that is the union of all specified maps. If a key is found in multiple specified maps, the value of the key in the returned map is the value of the key that occurs in the last specified map.	-
map_filter(map <K, V> , function) → map <K,V>	For more information, see the map_filter function in Lambda functions.	-
map_keys(x <K, V>) → array <K>	Returns an array of keys in the specified map.	-
map_values(x <K, V>) → array <V>	Returns an array of values in the specified map.	-

23.4.8.4. Approximate functions

This topic describes the syntax and examples of approximate functions that Log Service supports for log analysis.

The following table describes the supported approximate functions.

Function	Description	Example
approx_distinct(x)	Returns the approximate number of distinct values of the x field.	-
approx_percentile(x,percentage)	Returns the value located at the specified approximate percentage among the sorted values of the x field.	approx_percentile(x,0.5) : returns the median among the sorted values of the x field.
approx_percentile(x, percentages)	Returns values located at multiple specified approximate percentages among the sorted values of the x field. This function works in a similar manner to the approx_percentile(x,percentage) function.	approx_percentile(x,array[0.1,0.2])
numeric_histogram(buckets, Value)	Distributes all values of the *Value* field into multiple buckets. The *buckets* parameter specifies the number of buckets. The key of every bucket and the number of values in a bucket are returned. This function is equivalent to select count group by . Note The response is in the JSON format.	method:POST | select numeric_histogram(10,latency) : distributes the latencies of POST requests into 10 buckets and calculates the number of latencies in each bucket.

Function	Description	Example
`numeric_histogram_u(buckets, Value)`	Distribute all values of the *Value* field into multiple buckets. The *buckets* parameter specifies the number of buckets. The key of every bucket and the number of values in a bucket are returned. This function is equivalent to `select count group by` . **Note** The returned data is in the format of multiple rows and columns.	`method:POST | select numeric_histogram(10,latency)` : distributes the latency data of POST requests into 10 buckets and calculates the number of latency data in each bucket.

Note The number of values in every bucket is evenly distributed. It is returned along with the average value of all values in a bucket.

23.4.8.5. Mathematical statistics functions

This topic describes the syntax and examples of mathematical statistics functions.

The search and analytics feature of Log Service allows you to use mathematical statistics functions for log analysis. The following table describes the supported mathematical statistics functions.

Function	Description	Example
`corr(y, x)`	Returns the correlation coefficient of input values. The result ranges from 0 to 1.	`latency>100| select corr(latency,request_size)`
`covar_pop(y, x)`	Returns the population covariance of input values.	`latency>100| select covar_pop(request_size,latency)`
`covar_samp(y, x)`	Returns the sample covariance of input values.	`latency>100| select covar_samp(request_size,latency)`
`regr_intercept(y, x)`	Returns the linear regression intercept of input values. y is the dependent value. x is the independent value.	`latency>100| select regr_intercept(request_size,latency)`
`regr_slope(y,x)`	Returns the linear regression slope of input values. y is the dependent value. x is the independent value.	`latency>100| select regr_slope(request_size,latency)`
`stddev(x)` or `stddev_samp(x)`	Returns the sample standard deviation of the values in the x field.	`latency>100| select stddev(latency)`
`stddev_pop(x)`	Returns the population standard deviation of the values in the x field.	`latency>100| select stddev_pop(latency)`
`variance(x)` or `var_samp(x)`	Returns the sample variance of the values in the x field.	`latency>100| select variance(latency)`

Function	Description	Example
var_pop(x)	Returns the population variance of the values in the x field.	latency>100| select variance(latency)

23.4.8.6. Mathematical calculation functions

This topic describes the syntax and examples of mathematical calculation functions.

By including mathematical calculation functions in SQL statements, you can perform mathematical calculation on log query results.

Mathematical operators

Mathematical operators include the plus sign (+), minus sign (-), multiplication sign (*), division sign (/), and percent sign (%). These operators can be used in SELECT statements.

Example:

```
*|select avg(latency)/100 , sum(latency)/count(1)
```

Mathematical calculation functions

Log Service supports the following mathematical calculation functions.

Function	Description
abs(x)	Returns the absolute values of the values in the x field.
cbrt(x)	Returns the cube roots of the values in the x field.
ceiling(x)	Returns the rounded-up nearest integers of the values in the x field.
cosine_similarity(x,y)	Returns the cosine similarity between the sparse vectors x and y.
degrees	Converts angles in radians to degrees.
e()	Returns the Euler's number.
exp(x)	Returns Euler's number raised to the power of the values in the x field.
floor(x)	Returns the rounded-down nearest integers of the values in the x field.
from_base(string,radix)	Returns the radix number representation of a string.
ln(x)	Returns the natural logarithm of x.
log2(x)	Returns the base 2 logarithm of x.
log10(x)	Returns the base 10 logarithm of x.
log(x,b)	Returns the base b logarithm of x.
pi()	Returns the constant Pi.

Function	Description
pow(x,b)	Returns x raised to the power of b.
radians(x)	Converts angle x in degrees to radians.
rand()	Returns a random number.
random(0,n)	Returns a random number from 0 to n (exclusive).
round(x)	Returns x rounded to the nearest integer.
round(x,y)	Returns x rounded to y decimal places. For example, round(1.012345,2) = 1.01.
sqrt(x)	Returns the square root of x.
to_base(x,radix)	Returns the radix number representation of x.
truncate(x)	Returns x rounded to integer by dropping digits after the decimal point.
acos(x)	Returns the arc cosine of x.
asin(x)	Returns the arc sine of x.
atan(x)	Returns the arc tangent of x.
atan2(y,x)	Returns the arc tangent of y/x.
cos(x)	Returns the cosine of x.
sin(x)	Returns the sine of x.
cosh(x)	Returns the hyperbolic cosine of x.
tan(x)	Returns the tangent of x.
tanh(x)	Returns the hyperbolic tangent of x.
infinity()	Returns the value representing positive infinity.
is_infinity(x)	Determines whether x is infinite.
is_finity(x)	Determines whether x is finite.
is_nan(x)	Determines whether x is not-a-number.

23.4.8.7. String functions

This topic describes string functions that Log Service supports for log data search and analytics.

This following table lists the functions and their descriptions.

Function	Description
chr(x)	Converts an integer to an ASCII character. For example, the result of `chr(65)` is `A`.

Function	Description
codepoint (x)	Converts an ASCII character to a code point of the integer type. For example, the result of codepoint('A') is 65.
length(x)	Returns the length of a string.
levenshtein_distance(string1, string2)	Returns the Levenshtein distance of string1 and string2.
lower(string)	Converts all uppercase characters in a string into lowercase characters.
lpad(string, size, padstring)	Pads a string to the specified size. If the length of the string is shorter than the specified size, padstring is used to left pad the string. If the length of the string is longer than the specified size, the string is truncated with the specified size.
rpad(string, size, padstring)	Right pads a string with the specified padding. The implementation is similar to that of the lpad function.
ltrim(string)	Removes whitespace characters from the left side of a string.
replace(string, search)	Removes all occurrences of a substring search from a string.
replace(string, search,rep)	Replaces all occurrences of a substring search in a string with another substring rep.
reverse(string)	Reverses a string.
rtrim(string)	Removes whitespace characters from the right side of a string.
split(string,delimeter,limit)	Splits a string based on the specified delimiter and returns an array with the maximum number of elements at limit. The index of the first element in the array is 1.
split_part(string,delimeter,offset)	Splits a string based on a delimiter into an array of substrings and returns the element with the index specified by the offset parameter.
split_to_map(string, entryDelimiter, keyValueDelimiter) → map<varchar, varchar>	Splits a string based on the entryDelemiter into multiple entries, each of which is then split based on the keyValueDelimiter into a key and value. This function returns a map.
position(substring IN string)	Returns the position of the first occurrence of the specified substring in a string.
strpos(string, substring)	Returns the position of the first occurrence of the specified substring in a string. Positions start with 1. If the substring is found, 0 is returned.
substr(string, start)	Returns a substring from the start position. Positions start with 1.

Function	Description
substr(string, start, length)	Returns a substring of a specified length from start position. Positions start with 1. The length parameter specifies the length of the substring returned.
trim(string)	Removes leading and trailing whitespace characters from a string.
upper(string)	Converts all lowercase characters in a string into uppercase characters.
concat(string,string...)	Concatenates multiple strings into a single string.
hamming_distance (string1,string2)	Returns the Hamming distance of string1 and string2.

Note Strings must be enclosed in single quotation marks ('). Double quotation marks (") are used to enclose field names. For example, a='abc' indicates field a = string 'abc' , and "a"="abc" indicates field a = field abc .

23.4.8.8. Date and time functions

This topic describes the available time functions, date functions, interval functions, and a time series padding function in Log Service. You can use these functions when you analyze data.

Date and time data types

- Unix timestamp: specifies the number of seconds that have elapsed since 1970-01-01 00:00:00 UTC. The value is in the format of an integer. For example, 1512374067 indicates Mon Dec 4 15:54:27 CST 2017 . The __time__ field in every log entry is of this type.
- Timestamp: specifies the date and time in the format of a string. For example, 2017-11-01 13:30:00 .

Date functions

The following table lists the commonly used date functions that are supported in Log Service.

Function	Description	Example
current_date	Returns the current date.	latency>100| select current_date
current_time	Returns the current time.	latency>100| select current_time
current_timestamp	Returns the current timestamp. This function is equivalent to the combination of the current_date and current_time functions.	latency>100| select current_timestamp
current_timezone()	Returns the current time zone.	latency>100| select current_timezone()
from_iso8601_timestamp(string)	Parses an ISO 8601 formatted string into a timestamp that specifies the time zone.	latency>100| select from_iso8601_timestamp(iso8601)
from_iso8601_date(string)	Parses an ISO 8601 formatted string into a date.	latency>100| select from_iso8601_date(iso8601)

Function	Description	Example
from_unixtime(unixtime)	Parses a Unix timestamp into a timestamp.	latency>100| select from_unixtime(1494985275)
from_unixtime(unixtime,string)	Parses a Unix timestamp into a timestamp based on the time zone that is specified by the string parameter.	latency>100| select from_unixtime(1494985275,'Asia/Shanghai')
localtime	Returns the local time.	latency>100| select localtime
localtimestamp	Returns the local timestamp.	latency>100| select localtimestamp
now()	Returns the current date and time. This function is equivalent to the current_timestamp function.	N/A
to_unixtime(timestamp)	Parses a timestamp into a Unix timestamp.	*| select to_unixtime('2017-05-17 09:45:00.848 Asia/Shanghai')

Time functions

The following table lists the time functions that you can use in Log Service to parse time in the formats supported in MySQL, such as %a, %b, and %y.

Function	Description	Example
date_format(timestamp, format)	Formats a timestamp in the specified format.	latency>100 | select date_format(date_parse('2017-05-17 09:45:00','%Y-%m-%d %H:%i:%S'), '%Y-%m-%d')
date_parse(string, format)	Parses a formatted string into a timestamp.	latency>100 | select date_format(date_parse(time,'%Y-%m-%d %H:%i:%S'), '%Y-%m-%d')

Formats

Format	Description
%a	The week day in abbreviation, such as Sun and Sat.
%b	The month in abbreviation, such as Jan and Dec.
%c	The month in the numeric format. Valid values: 1 to 12.
%D	The day of the month with a suffix, such as 0th, 1st, 2nd, and 3rd.
%d	The day of the month in the numeric format. Valid values: 01 to 31.
%e	The day of the month in the numeric format. Valid values: 1 to 31.
%H	The hour that applies the 24-hour clock convention. Valid values: 00 to 23.
%h	The hour that applies the 12-hour clock convention. Valid values: 01 to 12.
%I	The hour that applies the 12-hour clock convention. Valid values: 1 to 12.

Format	Description
%i	The minute in the numeric format. Valid values: 00 to 59.
%j	The day of the year. Valid values: 001 to 366.
%k	The hour. Valid values: 0 to 23.
%l	The hour. Valid values: 1 to 12.
%M	The month. Valid values: January to December.
%m	The month in the numeric format. Valid values: 01 to 12.
%p	The abbreviation that indicates the morning or afternoon. Valid values: a.m. and p.m..
%r	The time that applies the 12-hour clock convention: `hh:mm:ss AM/PM` .
%S	The second. Valid values: 00 to 59.
%s	The second. Valid values: 00 to 59.
%T	The time that applies the 24-hour clock convention, formatted in `hh:mm:ss` .
%U	The week of the year. Sunday is the first day of a week. Valid values: 00 to 53.
%u	The week of the year. Monday is the first day of a week. Valid values: 00 to 53.
%V	The week of the year. Sunday is the first day of a week. This format is used together with %X. Valid values: 01 to 53.
%v	The week of the year. Monday is the first day of a week. This format is used in combination with %x. Valid values: 01 to 53.
%W	The day of the week. Valid values: Sunday to Saturday.
%w	The day of the week. Valid values: 0 to 6. The value 0 indicates Sunday.
%Y	The year in the 4-digit format.
%y	The year in the 2-digit format.
%%	Escapes the second percent sign (%).

Truncation functions

Log Service supports a truncation function, which can truncate a time by the second, minute, hour, day, month, or year. Typically, this function is used for time-based analytics.

- Syntax

  ```
  date_trunc(unit, x)
  ```

- Parameters

  The value of the x parameter can be a timestamp or Unix timestamp.

  The following table lists the values of the unit parameter and the responses when the x parameter is set to `2001-08-22 03:04:05.000` .

Unit	Response
second	2001-08-22 03:04:05.000
minute	2001-08-22 03:04:00.000
hour	2001-08-22 03:00:00.000
day	2001-08-22 00:00:00.000
week	2001-08-20 00:00:00.000
month	2001-08-01 00:00:00.000
quarter	2001-07-01 00:00:00.000
year	2001-01-01 00:00:00.000

- Example

  The date_trunc function is applicable only to analytics at a fixed time interval. To implement analytics at a flexible interval, for example, every 5 minutes, you need to use a GROUP BY clause according to the mathematical modulus method.

  ```
  * | SELECT count(1) as pv, __time__ - __time__ % 300 as minute5 group by minute5 limit 100
  ```

  In the preceding statement, `%300` indicates that modulo and truncation are performed every 5 minutes.

  The following example shows how to use the date_trunc function:

  ```
  *|select date_trunc('minute', __time__) as t,
      truncate(avg(latency)),
      current_date
      group by t
      order by t desc
      limit 60
  ```

Interval functions

Interval functions perform interval-related calculation. For example, you can use interval functions to add or subtract an interval based on a date, or calculate the interval between two dates.

Function	Description	Example
`date_add(unit, value, timestamp)`	Adds an interval `value` of the `unit` type to a `timestamp`. To subtract an interval, use a negative `value`.	`date_add('day', -7, '2018-08-09 00:00:00')`: indicates seven days before August 9.
`date_diff(unit, timestamp1, timestamp2)`	Returns the time difference between `timestamp1` and `timestamp2` expressed in terms of `unit`.	`date_diff('day', '2018-08-02 00:00:00', '2018-08-09 00:00:00') = 7`

The following table lists the values of the unit parameter that are supported by the interval functions.

Value	Description
millisecond	The millisecond.

Value	Description
second	The second.
minute	The minute.
hour	The hour.
day	The day.
week	The week.
month	The month.
quarter	The quarter, namely, three months.
year	The year.

Time series padding function

The time series padding function is used to pad time series and corresponding data.

> **Note** This function must be used in combination with the `group by time order by time` clause. When used together, the `order by` clause does not support the `desc` sorting method.

- Syntax

```
time_series(time_column, window, format, padding_data)
```

- Parameters

Parameter	Description
time_column	The name of the time field in a log entry. The default field name is `__time__`. The field value is of the LONG or TIMESTAMP type.
window	The time window for a data query. It is composed of a number and a unit. Unit: s (seconds), m (minutes), H (hours), and d (days). For example, 2h, 5m, or 3d.
format	The MySQL time format displayed.
padding_data	The content to be added for a time point. Valid values: ○ 0: adds 0. ○ null: adds null. ○ last: adds the value corresponding to the last time point. ○ next: adds the value corresponding to the next time point. ○ avg: adds the average value of the last and next values.

- Example

  The following statement is used to format data every 2 hours:

```
* | select time_series(__time__, '2h', '%Y-%m-%d %H:%i:%s', '0')  as stamp, count(*) as num from log group by stamp order by stamp
```

23.4.8.9. URL functions

This topic describes the syntax of URL functions and provides examples.

URL functions extract fields from standard URLs. A standard URL is described as follows:

```
[protocol:][//host[:port]][path][? query][#fragment]
```

Common URL functions

Function	Description	Example	
		Statement	Response
`url_extract_fragment(url)`	Extracts the fragment identifier from a URL and returns the fragment identifier of the VARCHAR type.	`*| select url_extract_fragment('https://sls.console.aliyun.com/#/project/dashboard-demo/categoryList')`	`/project/dashboard-demo/categoryList`
`url_extract_host(url)`	Extracts the host information from a URL and returns the host information of the VARCHAR type.	`*|select url_extract_host('http://www.aliyun.com/product/sls')`	`www.aliyun.com`
`url_extract_parameter(url, name)`	Extracts the value of the name parameter in the query from a URL and returns the value of the VARCHAR type.	`*|select url_extract_parameter('http://www.aliyun.com/product/sls?userid=testuser','userid')`	`testuser`
`url_extract_path(url)`	Extracts the path from a URL and returns the path of the VARCHAR type.	`*|select url_extract_path('http://www.aliyun.com/product/sls?userid=testuser')`	`/product/sls`
`url_extract_port(url)`	Extracts the port number from a URL and returns the port number of the BIGINT type.	`*|select url_extract_port('http://www.aliyun.com:80/product/sls?userid=testuser')`	`80`
`url_extract_protocol(url)`	Extracts the protocol from a URL and returns the protocol of the VARCHAR type.	`*|select url_extract_protocol('http://www.aliyun.com:80/product/sls?userid=testuser')`	`http`
`url_extract_query(url)`	Extracts the query string from a URL and returns the query string of the VARCHAR type.	`*|select url_extract_query('http://www.aliyun.com:80/product/sls?userid=testuser')`	`userid=testuser`
`url_encode(value)`	Encodes a URL.	`*|select url_encode('http://www.aliyun.com:80/product/sls?userid=testuser')`	`http%3a%2f%2fwww.aliyun.com%3a80%2fproduct%2fsls%3fuserid%3dtestuser`

Function	Description	Example	
		Statement	Response
url_decode(value)	Decodes a URL.	*|select url_decode('http%3a%2f%2fwww.aliyun.com%3a80%2fproduct%2fsls%3fuserid%3dtestuser')	http://www.aliyun.com:80/product/sls?userid=testuser

23.4.8.10. Regular expression functions

This topic describes the available regular expression functions. You can use these functions when you query and analyze data in Log Service.

A regular expression function parses a string and returns the required substrings.

The following table lists common regular expression functions.

Function	Description	Example
regexp_extract_all(string, pattern)	Returns an array where each element is a substring that matches the regular expression. These substrings derive from the specified string.	The returned result of *| SELECT regexp_extract_all('5a 67b 890m', '\d+') is ['5','67','890']. The returned result of *|SELECT regexp_extract_all('5a 67a 890m', '(\d+)a') is ['5a','67a'].
regexp_extract_all(string, pattern, group)	Returns an array where each element is a part of a substring that matches the regular expression. This part is the content in the group parameter value of the () of a substring that derives from the specified string.	The returned result of *| SELECT regexp_extract_all('5a 67a 890m', '(\d+)a',1) is ['5','67'].
regexp_extract(string, pattern)	Returns the first substring of the specified string that matches the regular expression.	The returned result of *|SELECT regexp_extract('5a 67b 890m', '\d+') is '5'.
regexp_extract(string, pattern,group)	Returns a part of the first substring that matches the regular expression. This part is the content in the group parameter value of the () of the substring that derives from the specified string.	The returned result of *|SELECT regexp_extract('5a 67b 890m', '(\d+)([a-z]+)',2) is 'a'.
regexp_like(string, pattern)	Returns a Boolean value. If the string and its substrings cannot match the regular expression, the value False is returned.	The returned result of *|SELECT regexp_like('5a 67b 890m', '\d+m') is True.
regexp_replace(string, pattern, replacement)	Replaces the substrings of the specified string that match the regular expression with the value of the replacement parameter.	The returned result of *|SELECT regexp_replace('5a 67b 890m', '\d+','a') is 'aa ab am'.

Function	Description	Example
regexp_replace(string, pattern)	Removes the substrings of the specified string that match the regular expression. This function is equivalent to regexp_replace(string,pattern,'') .	The returned result of *|SELECT regexp_replace('5a 67b 890m', '\d+') is 'a b m' .
regexp_split(string, pattern)	Returns an array where each element is a substring of the specified string that is split based on the regular expression.	The returned result of *|SELECT regexp_split('5a 67b 890m', '\d+') is ['a','b','m'] .

23.4.8.11. JSON functions

JSON functions can convert a string into a JSON type and extract JSON fields. The two major JSON data types are map and array. If a string cannot be converted to a value of the JSON type, null value is returned.

For information about how to expand JSON data into multiple rows, see UNNEST function.

The following table lists the JSON functions that Log Service supports:

Function	Description	Example
json_parse(string)	Converts a string to a JSON-formatted data.	SELECT json_parse('[1, 2, 3]') : returns a JSON array.
json_format(json)	Converts JSON-formatted data to a string.	SELECT json_format(json_parse('[1, 2, 3]')) : returns a string.
json_array_contains(json, value)	Determines whether a value exists in a JSON array or in a string that contains a JSON array.	SELECT json_array_contains(json_parse('[1, 2, 3]'), 2) or SELECT json_array_contains('[1, 2, 3]', 2)
json_array_get(json_array, index)	Retrieves the element at the specified index in the JSON array. This function is equivalent to json_array_contains .	SELECT json_array_get('["a", "b", "c"]', 0): returns 'a'
json_array_length(json)	Returns the length of the JSON array.	SELECT json_array_length('[1, 2, 3]'): returns 3
json_extract(json, json_path)	Extracts a value from a JSON object and returns a JSON object. The json_path expression works in a similar manner to $.store.book[0].title .	SELECT json_extract(json, '$.store.book')
json_extract_scalar(json, json_path)	Returns a string. This function works in a similar manner to json_extract).	N/A
json_size(json,json_path)	Retrieves the length of a JSON object or array.	SELECT json_size('[1, 2, 3]'): returns 3.

23.4.8.12. Type conversion functions

Type conversion functions convert the data type of a specified value or column in a query.

You can use the index attribute feature of Log Service to set the data type of a field to LONG, DOUBLE, TEXT, or JSON. You can also query fields of various data types, including BIGINT, DOUBLE, VARCHAR, and TIMESTAMP. To query fields of a specific data type, you can use type conversion functions to convert the data type configured in an index into the data type that you use in a query.

Syntax

> **Note** We recommend that you use the try_cast() function if a log contains dirty data. Otherwise, a query may fail due to the dirty data.

- Convert the data type of a column of values or a specific value into the specified type in a query. If the data type of a value fails to be converted, the query is terminated.

```
cast([key|value] AS type)
```

- Convert the data type of a column of values or a specific value into the specified type in a query. If the data type of a value fails to be converted, NULL is returned for the value, and the query continues.

```
try_cast([key|value] AS type)
```

Parameter	Description
key	The key of a field whose value data type is to be converted.
value	The field value whose data type is to be converted into the specified type.

Example

- To convert the numeric value 123 to a value of the VARCHAR type, use the following statement:

```
cast(123 AS varchar)
```

- To convert the data type of the uid field values to the VARCHAR type, use the following statement:

```
cast(uid AS varchar)
```

23.4.8.13. IP functions

This topic describes the syntax of IP functions and provides examples.

IP functions can identify whether an IP address is an intranet or Internet IP address. IP functions can also identify the country, province, and city where an IP address resides. For information about geohash functions, see Geography functions.

Function	Description	Example
`ip_to_domain(ip)`	Identifies whether an IP address is an intranet or Internet IP address. This function returns intranet or internet.	`SELECT ip_to_domain(ip)`
`ip_to_country(ip)`	Identifies the country where an IP address resides.	`SELECT ip_to_country(ip)`

Function	Description	Example
ip_to_province(ip)	Identifies the province where an IP address resides.	SELECT ip_to_province(ip)
ip_to_city(ip)	Identifies the city where an IP address resides.	SELECT ip_to_city(ip)
ip_to_geo(ip)	Identifies the longitude and latitude of the city where an IP address resides. The result is returned in the format of latitude, longitude.	SELECT ip_to_geo(ip)
ip_to_city_geo(ip)	Identifies the longitude and latitude of the city where an IP address resides. Each city has only one longitude and latitude. The result is returned in the format of latitude, longitude.	SELECT ip_to_city_geo(ip)
ip_to_provider(ip)	Identifies the network service provider that assigns an IP address.	SELECT ip_to_provider(ip)
ip_to_country(ip,'en')	Identifies the country where an IP address resides. The function returns a country code.	SELECT ip_to_country(ip,'en')
ip_to_country_code(ip)	Identifies the country where an IP address resides. The function returns a country code.	SELECT ip_to_country_code(ip)
ip_to_province(ip,'en')	Identifies the province where an IP address resides.	SELECT ip_to_province(ip,'en')
ip_to_city(ip,'en')	Identifies the city where an IP address resides.	SELECT ip_to_city(ip,'en')

Example

- To query the number of requests that are not sent from an intranet, run the following statement:

```
* | SELECT count(1) where ip_to_domain(ip)! ='intranet'
```

- To query the top 10 provinces from which requests are sent, run the following statement:

```
* | SELECT count(1) as pv, ip_to_province(ip) as province GROUP BY province order by pv desc limit 10
```

  Sample response

```
[
  {
    "__source__": "",
    "__time__": "1512353137",
    "province": "Zhejiang",
    "pv": "4045"
  },{
    "__source__": "",
    "__time__": "1512353137",
    "province": "Shanghai",
    "pv": "3727"
  },{
    "__source__": "",
    "__time__": "1512353137",
    "province": "Beijing",
    "pv": "954"
  },{
    "__source__": "",
    "__time__": "1512353137",
    "province": "intranet IP address",
    "pv": "698"
  },{
    "__source__": "",
    "__time__": "1512353137",
    "province": "Guangdong",
    "pv": "472"
  },{
    "__source__": "",
    "__time__": "1512353137",
    "province": "Fujian",
    "pv": "71"
  }
]
```

The response contains an intranet IP address. You can use the SELECT statement to filter requests that are sent from the IP address.

- To query the top 10 provinces from which intranet requests are sent, run the following statement:

```
* | SELECT count(1) as pv, ip_to_province(ip) as province WHERE ip_to_domain(ip) != 'intranet' GROUP BY province ORDER BY pv desc limit 10
```

- To query the average request latency, the maximum request latency, and the request with the maximum latency from each country, run the following statement:

```
* | SELECT AVG(latency),MAX(latency),MAX_BY(requestId, latency) ,ip_to_country(ip) as country group by country limit 100
```

- To query the average latency of requests supported by each network service provider, run the following statement:

```
* | SELECT AVG(latency) , ip_to_provider(ip) as provider group by provider limit 100
```

- To query the longitude and latitude of the city to which an IP address belongs and show the city on a map, run the following statement:

```
* | SELECT count(1) as pv , ip_to_geo(ip) as geo group by geo order by pv desc
```

The following table shows the format of the result.

pv	geo
100	35.3284,-80.7459

23.4.8.14. GROUP BY syntax

This topic describes the GROUP BY syntax.

GROUP BY statements support multiple columns. A GROUP BY statement allows you to specify a column alias in a SELECT statement to as the corresponding KEY.

Example:

```
method:PostLogstoreLogs |select avg(latency),projectName,date_trunc('hour',__time__) as hour  group by projectName,hour
```

The hour alias indicates the third SELECT column `date_trunc('hour',__time__)` . This improves the performance of complicated queries.

The GROUP BY statement supports the GROUPING SETS, CUBE, and ROLLUP clauses.

Example:

```
method:PostLogstoreLogs |select avg(latency)  group by cube(projectName,logstore)
method:PostLogstoreLogs |select avg(latency)  group by GROUPING SETS ( ( projectName,logstore), (projectName,method))
method:PostLogstoreLogs |select avg(latency)  group by rollup(projectName,logstore)
```

Examples

- Use GROUP BY based on time

  Each log has a built-in time column named `__time__` . When the analytics feature is enabled on one of the columns, the statistics of the time column are included.

  The `date_trunc` function can truncate the time column to minute, hour, day, month, and year. The `date_trunc` function accepts an aligned unit and a column of the Unix timestamp type, such as `__time__` .

  - PV statistics per hour and per minute

    ```
    * | SELECT count(1) as pv , date_trunc('hour',__time__) as hour group by hour order by hour limit 100
    * | SELECT count(1) as pv , date_trunc('minute',__time__) as minute group by minute order by minute limit 100
    ```

    > **Note** 100 specifies that up to 100 rows can be retrieved. If a LIMIT clause is not specified, up to 10 rows of data are retrieved by default.

  - date_trunc functions are available only for statistics at a fixed time interval. For statistics based on flexible time dimensions, for example, every 5 minutes, run a GROUP BY statement based on the mathematical modulus method.

    ```
    * | SELECT count(1) as pv, __time__ - __time__% 300 as minute5 group by minute5 limit 100
    ```

    In the preceding statement, `%300` indicates that the time is truncated in mod every 5 minutes.

- Retrieve non-aggregation columns from a GROUP BY statement

  In standard SQL, if a GROUP BY statement is used during the SELECT operation, Log Service selects only the raw data of the column specified in the GROUP BY statement or performs aggregation on any columns.

  For example, the following statement is invalid. Log Service cannot determine which row of b to return during the GROUP BY operation based on a, because b is not a GROUP BY column.

```
*|select a, b , count(c) group by a
```

Instead, you can use the `arbitrary()` function to return b.

```
*|select a, arbitrary(b), count(c) group by a
```

23.4.8.15. Window functions

This topic describes the syntax for window functions.

Window functions are used to perform calculations across rows of a log. Common SQL aggregate functions calculate the results of only one row or aggregate all rows into one row for calculation. Window functions support cross-row calculation and fill the calculation results in each row.

Syntax for window functions is

```
SELECT key1, key2, value,
    rank() OVER (PARTITION BY key2
            ORDER BY value DESC) AS rnk
FROM orders
ORDER BY key1,rnk
```

The important part is

```
rank() OVER (PARTITION BY  KEY1 ORDER BY KEY2 DESC)
```

rank() is an aggregate function. You can use any functions in analysis syntax or the function listed in this topic. PARTITION BY indicates the buckets based on which values are calculated.

Special aggregate functions used in windows

Function	Description
rank()	Returns the rank of a value within a group of values. The rank is one plus the number of preceding rows that are not peers of the current row.
row_number()	Returns a unique, sequential number for each row.
first_value(x)	Returns the first value of the window. In most cases, the function is used to obtain the maximum value after the values of the window are sorted.
last_value(x)	Returns the last value of the window. In most cases, the function is used to obtain the minimum value after the values of the window are sorted.
nth_value(x, offset)	Returns the value at the specified offset from the beginning of the window.
lead(x,offset,defaut_value)	Returns the value at offset rows after the current row in the window. If the target row does not exist, the default_value is returned.
lag(x,offset,defaut_value)	Returns the value at offset rows after the current row in the window. If the target row does not exist, the default_value is returned.

Example

- Rank the salaries of employees in their respective departments

```
* | select department, persionId, sallary , rank() over(PARTITION BY department order by sallary desc) as sallary_rank
order by department,sallary_rank
```

Results

department	persionId	sallary	sallary_rank
dev	john	9000	1
dev	Smith	8000	2
dev	Snow	7000	3
dev	Achilles	6000	4
Marketing	Blan Stark	9000	1
Marketing	Rob Stark	8000	2
Marketing	Sansa Stark	7000	3

- Calculate the salaries of employees as percentages in their respective departments

```
* | select department, persionId, sallary *1.0 / sum(sallary) over(PARTITION BY department ) as sallary_percentage
```

Results

department	persionId	sallary	sallary_percentage
dev	john	9,000	0.3
dev	Smith	8,000	0.26
dev	Snow	7000	0.23
dev	Achilles	6000	0.2
Marketing	Blan Stark	9000	0.375
Marketing	Rob Stark	8000	0.333
Marketing	Sansa Stark	7000	0.29

- Calculate the daily UV increase over the previous day

```
* | select day ,uv, uv *1.0 /(lag(uv,1,0) over() ) as diff_percentage from
(
select approx_distinct(ip) as uv, date_trunc('day',__time__) as day from log group by day order by day asc
)
```

Results

day	uv	diff_percentage
2017-12-01 00:00:00	100	null

day	uv	diff_percentage
2017-12-02 00:00:00	125	1.25
2017-12-03 00:00:00	1,500	1.2
2017-12-04 00:00:00	175	1.16
2017-12-05 00:00:00	2,000	1.14
2017-12-06 00:00:00	225	1.125
2017-12-07 00:00:00	250	1.11

23.4.8.16. HAVING syntax

This topic describes the HAVING syntax.

The LogSearch/Analytics feature of Log Service supports the standard SQL HAVING clause. The HAVING clause is used with the GROUP BY statement to filter GROUP BY results.

Example:

```
method :PostLogstoreLogs |select avg(latency),projectName group by projectName  HAVING avg(latency) > 100
```

Difference between HAVING and WHERE clauses

The HAVING clause is used to filter the aggregation and calculation results after you run the GROUP BY statement. The WHERE clause is used to filter the raw data during the aggregation calculation.

Example

Calculate the average rainfall of each province where the temperature is higher than 10°C, and only show the provinces with average rainfall greater than 100 mL in the final results:

```
* | select avg(rain) ,province where temperature > 10 group by province having avg(rain) > 100
```

23.4.8.17. ORDER BY syntax

This topic describes the ORDER BY syntax.

The ORDER BY keyword is used to sort output results. You can sort output results based on only one column.

- Syntax format

  ```
  order by column name [desc|asc]
  ```

- Example

  ```
  method :PostLogstoreLogs |select avg(latency) as avg_latency,projectName group by projectName
  HAVING avg(latency) > 5700000
  order by avg_latency desc
  ```

23.4.8.18. LIMIT syntax

The LIMIT clause is used to limit the number of returned rows.

Syntax formats

Log Service supports the following LIMIT syntax formats:

- Reads only the first N rows:

```
limit N
```

- Reads N rows starting from the S-th row:

```
limit S , N
```

> Note
> - If you use the LIMIT clause to paginate results, the final results rather than the intermediate results of the SQL query are obtained.
> - You cannot apply the LIMIT clause to subqueries. For example, the following statement is not supported:
>
> ```
> * | select count(1) from ( select distinct(url) from limit 0,1000)
> ```
>
> - If you use the LIMIT clause for pagination, the offset value cannot exceed 1,000,000. For example, in the `limit S , N` clause, the sum of S and N cannot exceed 1,000,000, and the value of N cannot exceed 10,000.

Example

- To obtain the first 100 rows of results, run the following statement.

```
* | select distinct(url) from log limit 100
```

- To obtain a total of 1,000 results from row 0 to row 999, run the following statement.

```
* | select distinct(url) from log limit 0,1000
```

- To obtain a total of 1,000 results from row 1,000 to row 1,999, run the following statement:

```
* | select distinct(url) from log limit 1000,1000
```

23.4.8.19. Syntax for CASE statements and if() functions

This topic describes the syntax for CASE statements and if() functions.

CASE statements are used to classify continuous data. For example, you can use the following CASE statement to extract information from http_user_agent and classify the information into two types: Android and iOS.

```
SELECT
CASE
WHEN http_user_agent like '%android%' then 'android'
WHEN http_user_agent like '%ios%' then 'ios'
ELSE 'unknown' END
as http_user_agent,
  count(1) as pv
  group by  http_user_agent
```

Examples

- Calculate the ratio of requests whose status code is 200 to all requests

```
* | SELECT
 sum(
 CASE
 WHEN status =200 then 1
 ELSE 0 end
 ) *1.0 / count(1) as status_200_percentage
```

- Calculate the distribution of latencies

```
* | SELECT `
 CASE
 WHEN latency < 10 then 's10'
 WHEN latency < 100 then 's100'
 WHEN latency < 1000 then 's1000'
 WHEN latency < 10000 then 's10000'
 else 's_large' end
 as latency_slot,
 count(1) as pv
 group by latency_slot
```

Syntax for if() functions

An if() function works in the same way as a CASE statement does.

```
CASE
   WHEN condition THEN true_value
   [ ELSE false_value ]
 END
```

- if(condition, true_value)

  If the condition is true, the true_value column is returned. Otherwise, null is returned.

- if(condition, true_value, false_value)

  If the condition is true, the true_value column is returned. Otherwise, the false_value column is returned.

Syntax for coalesce() functions

A coalesce() function returns the first non-null value from multiple columns.

```
COALESCE (value1, value2 [,...])
```

Syntax for the nullif() function

If value1 is equal to value2, null is returned. Otherwise, value1 is returned.

```
nullif(value1, value2)
```

Syntax for the try() function

The try() function catches underlying exceptions, such as division by zero errors, and returns null.

```
try(expression)
```

23.4.8.20. Nested subqueries

This describes how to use nested subqueries when you query logs.

You can use nested queries to perform more complicated queries.

Nested queries differ from non-nested queries in the need for specifying the FROM clause in the SQL statement. You must specify the `from log` keyword in each SQL statement to read raw data from logs.

Example:

```
* | select sum(pv) from
(
select count(1) as pv from log group by method
)
```

23.4.8.21. Array functions

This topic describes the syntax of array functions. It also provides examples that show how to use these functions.

Function	Description	Example
Subscript operator []	The subscript operator [] is used to obtain an element in the array.	N/A
array_distinct	Returns the distinct elements in the array.	N/A
array_intersect(x, y)	Returns the intersection of the x and y arrays.	N/A
array_union(x, y) → array	Returns the union of the x and y arrays.	N/A
array_except(x, y) → array	Returns the subtraction of the x and y arrays.	N/A
array_join(x, delimiter, null_replacement) → varchar	Joins string arrays with the delimiter into a string and replaces null values with null_replacement. **Note** The maximum size of the returned result of this array_join function is 1 KB. If the returned result exceeds 1 KB, the extra data will be truncated.	N/A
array_max(x) → x	Returns the maximum value in the x array.	N/A
array_min(x) → x	Returns the minimum value in the x array.	N/A
array_position(x, element) → bigint	Returns the subscript of the element in the x array. The subscript starts from 1. The value 0 is returned if no subscript is found.	N/A
array_remove(x, element) → array	Removes the element from the array.	N/A
array_sort(x) → array	Sorts the array and moves null values to the end.	N/A

Function	Description	Example
cardinality(x) → bigint	Returns the array size.	N/A
concat(array1, array2, ..., arrayN) → array	Concatenates arrays.	N/A
contains(x, element) → boolean	Returns true if the x array contains the specified element.	N/A
filter(array, function) → array	For more information about this Lambda function, see the filter() function in Lambda functions.	N/A
flatten(x) → array	Flattens an array(array(T)) to an array(T) by concatenating the contained arrays.	N/A
reduce(array, initialState, inputFunction, outputFunction) → x	For more information, see the reduce() function in Lambda functions.	N/A
reverse(x) → array	Returns an array that has the reversed order of the x array.	N/A
sequence(start, stop) → array	Generates a sequence of elements from start to stop. The difference between elements is 1.	N/A
sequence(start, stop, step) → array	Generates a sequence of elements from start to stop. The difference between elements is step.	N/A
sequence(start, stop, step) → array	Generates a sequence of timestamps from start to stop. The difference between timestamps is step. The type of step can be either INTERVAL DAY TO SECOND or INTERVAL YEAR TO MONTH.	N/A
shuffle(x) → array	Shuffles the array.	N/A
slice(x, start, length) → array	Returns a subset of the x array starting from the start value with the specified length.	N/A
transform(array, function) → array	For more information, see the transform() function in Lambda functions.	N/A
zip(array1, array2[, ...]) → array	Merges the specified arrays. The M-th element of the N-th argument will be the N-th field of the M-th output element.	SELECT zip(ARRAY[1, 2], ARRAY['1b', null, '3b']); -- [ROW(1, '1b'), ROW(2, null), ROW(null, '3b')]
zip_with(array1, array2, function) → array	For more information, see the zip_with() function in Lambda functions.	N/A

Function	Description	Example
array_agg (key)	An aggregate function that returns an array from values in the key column.	* | select array_agg(key)
array_transpose(array[array[*x*,*y*,*z*], array[*a*,*b*,*c*]])	Returns a new matrix by transposing the values of the previous matrix from rows to columns.	N/A

23.4.8.22. Binary string functions

This topic describes the syntax of binary string functions. It also provides examples that show how to use these functions.

Data of the VARBINARY type is different from data of the VARCHAR type.

Function	Description
Concatenation operator (||)	The result of `a || b` is `ab`.
length(binary) → bigint	Returns the length in binary.
concat(binary1, ..., binaryN) → varbinary	Connects the binary strings, which is equivalent to ||.
to_base64(binary) → varchar	Converts a binary string to a Base64 string.
from_base64(string) → varbinary	Converts a Base64 string to a binary string.
to_base64url(binary) → varchar	Converts a string to a URL-safe Base64 string.
from_base64url(string) → varbinary	Converts a URL-safe Base64 string to a binary string.
to_hex(binary) → varchar	Converts a binary string to a hexadecimal string.
from_hex(string) → varbinary	Converts a hexadecimal string to a binary string.
to_big_endian_64(bigint) → varbinary	Convert a number to a binary string in big endian mode.
from_big_endian_64(binary) → bigint	Converts a binary string in big endian mode to a number.
md5(binary) → varbinary	Calculates the MD5 value of a binary string.
sha1(binary) → varbinary	Calculates the SHA1 value of a binary string.
sha256(binary) → varbinary	Calculates the SHA256 hash value of a binary string.
sha512(binary) → varbinary	Calculate the SHA512 value of a binary string.
xxhash64(binary) → varbinary	Calculates the xxhash64 value of a binary string.

23.4.8.23. Bitwise operations

This topic describes the syntax for bitwise operations. It also provides examples that show how to use these operations.

Function	Description	Example
bit_count(x, bits) → bigint	Count the number of 1 in the binary expression of x.	SELECT bit_count(9, 64); — 2 SELECT bit_count(9, 8); — 2 SELECT bit_count(-7, 64); — 62 SELECT bit_count(-7, 8); — 6
bitwise_and(x, y) → bigint	Perform the AND operation on x and y in the binary form.	N/A
bitwise_not(x) → bigint	Calculate the opposite values of all bits of x in the binary form.	N/A
bitwise_or(x, y) → bigint	Perform the OR operation on x and y in the binary form.	N/A
bitwise_xor(x, y) → bigint	Perform the XOR operation on x and y in the binary form.	N/A

23.4.8.24. Interval-valued comparison and periodicity-valued comparison functions

Log Service allows you to use interval-valued comparison and periodicity-valued comparison functions to query and analyze log data.

You can use the functions to compare the value for one period with that for a previous period.

Function	Description	Example
compare(value, time_window)	This function compares the value calculated for the current period with that calculated for the period before time_window. The data type of the values to be compared is Double or Long. The time_window parameter is measured in seconds. This function returns an array. Possible return values include the value for the current period, the value for the period before time_window, and the ratio of the current value to the value before time_window.	*|select compare(pv , 86400) from (select count(1) as pv from log)

Function	Description	Example
`compare(value, time_window1, time_window2)`	This function compares the current value with the values for periods before time_window1 and time_window2. The comparison results are in the JSON array format, where the values must be returned in the following order: [current value, value before time_window1, value before time_window2, current value/value before time_window1, current value/value before time_window2].	`* | select compare(pv, 86400, 172800) from ( select count(1) as pv from log)`
`compare(value, time_window1, time_window2, time_window3)`	This function compares the value for the current period with the values for periods before time_window1, time_window2, and time_window3. The comparison results are in the JSON array format, where the values must be returned in the following order: [current value, value before time_window1, value before time_window2, value before time_window3, current value/value before time_window1, current value/value before time_window2, current value/value before time_window3].	`* | select compare(pv, 86400, 172800,604800) from ( select count(1) as pv from log)`
`ts_compare(value, time_window)`	This function compares the value for the current period with the values for periods before `time_window1` and `time_window2` and returns a JSON array. The comparison results are in the JSON array format, where the values must be returned in the following order: [current value, value before time_window1, current value/value before time_window1, Unix timestamp that indicates the start time of the previous period]. This function is used to compare time series values. You must specify the GROUP BY keyword for the time column in SQL statements.	For example, `* | select t, ts_compare(pv, 86400 ) as d from(select date_trunc('minute', time ) as t, count(1) as pv from log group by t order by t ) group by t` specifies that the function compares the calculation result of every minute in the current period with that of every minute in the last period. The comparison result is `d: [1251.0,1264.0, 0.9897151898734177, 1539843780.0,1539757380.0]t:2018-10-19 14:23:00.000` .

Examples

- Calculate the ratio of the PV for an hour on a day to that for the same time period on a previous day.

  The start time is 2018-07-25 14:00:00, and the end time is 2018-07-25 15:00:00.

  Statement for query and analysis:

  ```
  * | select compare( pv , 86400) from (select count(1) as pv from log)
  ```

  In the preceding statement, 86400 indicates 86,400 seconds before the current period.

  Return results:

```
[9.0,19.0,0.47368421052631579]
```

In the preceding results,

- 9.0 is the PV for the period from 2018-07-25 14:00:00 to 2018-07-25 15:00:00.
- 19.0 is the PV for the period from 2018-07-24 14:00:00 to 2018-07-24 15:00:00.
- 0.47368421052631579 is the ratio of the PV for the current period to that for a previous period.

If you want to expand the array into three columns of numbers, the analysis statement is

```
* | select diff[1],diff[2],diff[3] from(select compare( pv , 86400) as diff from (select count(1) as pv from log))
```

- Calculate the PV ratio for every minute of the current hour to that in the same time period as the day before, and output the results in a line chart.
  i. Calculate the PV ratio for every minute of the current hour to that in the same time period as the day before. The start time is 2018-07-25 14:00:00, and the end time is 2018-07-25 15:00:00.

  Statement for query and analysis:

  ```
  *| select t, compare( pv , 86400) as diff from (select count(1) as pv, date_format(from_unixtime(__time__), '%H:%i') as t from log group by t) group by t order by t
  ```

  Return results:

t	diff
14:00	[9520.0,7606.0,1.2516434393899554]
14:01	[8596.0,8553.0,1.0050274757395066]
14:02	[8722.0,8435.0,1.0340248962655603]
14:03	[7499.0,5912.0,1.2684370771312586]

  In the preceding table, t indicates the time in the format of `Hour:Minute`. The contents of the diff column are included in an array that contains the following values:

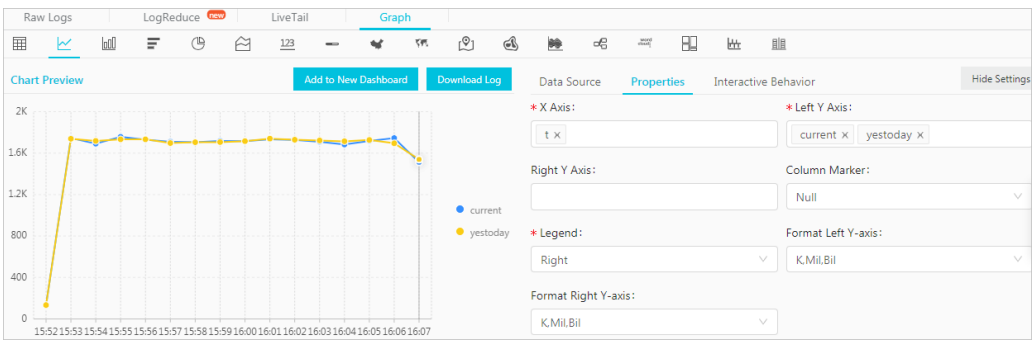
  - The PV value of the current period.
  - The PV value of the previous period.
  - The ratio of the PV value for the current period to that for the previous period.

  ii. To show the query results in a line chart, use the following statement:

  ```
  *|select t, diff[1] as current, diff[2] as yestoday, diff[3] as percentage from(select t, compare( pv , 86400) as diff from (select count(1) as pv, date_format(from_unixtime(__time__), '%H:%i') as t from log group by t) group by t order by t)
  ```

  The two lines indicate the PV values of a day and the day before.

  Line chart



23.4.8.25. Comparison functions and operators

This topic describes the comparison functions and operators in Log Service. You can use these functions and operators to query and analyze log data.

Comparison functions and operators

A comparison function compares two parameter values of any comparable data types, such as INTEGER, BIGINT, DOUBLE, and TEXT.

Comparison operators

A comparison operator is used to compare two values. If the statement is true, TRUE is returned. Otherwise, FALSE is returned.

Operator	Description
<	Less than
>	Greater than
<=	Less than or equal to
>=	Greater than or equal to
=	Equal to
<>	Not equal to
! =	Not equal to

Range operator BETWEEN

The BETWEEN operator determines whether a value falls in a specified closed interval.

- If the value falls in the specified closed interval, TRUE is returned. Otherwise, FALSE is returned.

  Example: `SELECT 3 BETWEEN 2 AND 6;`. The statement is true, and TRUE is returned.

  The preceding statement is equivalent to `SELECT 3 >= 2 AND 3 <= 6;`.
- The BETWEEN operator can be put behind the NOT operator to test whether a value falls out of a specified closed interval.

  Example: `SELECT 3 NOT BETWEEN 2 AND 6;`. The statement is false, and FALSE is returned.

  The preceding statement is equivalent to `SELECT 3 < 2 OR 3 > 6;`.
- If any of the three values is NULL, NULL is returned.

IS NULL and IS NOT NULL

The IS NULL and IS NOT NULL operators test whether a value is NULL.

IS DISTINCT FROM and IS NOT DISTINCT FROM

These operators are similar to the EQUAL TO and NOT EQUAL TO operators. However, IS DISTINCT FROM and IS NOT DISTINCT FROM can determine whether a NULL value exists.

Examples:

```
SELECT NULL IS DISTINCT FROM NULL; -- false
SELECT NULL IS NOT DISTINCT FROM NULL; -- true
```

The DISTINCT operator compares parameter values under multiple conditions, as described in the following table.

a	b	a = b	a <> b	a DISTINCT b	a NOT DISTINCT b
1	1	TRUE	FALSE	FALSE	TRUE
1	2	FALSE	TRUE	TRUE	FALSE
1	NULL	NULL	NULL	TRUE	FALSE
NULL	NULL	NULL	NULL	FALSE	TRUE

GREATEST and LEAST

These operators are used to obtain the maximum or minimum value from a row of field values.

Example:

```
select greatest(1,2,3) -- Returns 3.
```

Quantified comparison predicates: ALL, ANY, and SOME

The ALL, ANY, and SOME quantifiers can be used to determine whether a parameter value meets specified conditions.

- ALL is used to determine whether a parameter value meets all conditions. If the statement is true, TRUE is returned. Otherwise, FALSE is returned.
- ANY is used to determine whether a parameter value meets a condition. If the statement is true, TRUE is returned. Otherwise, FALSE is returned.
- SOME is used to determine whether a parameter value meets a condition. SOME is equivalent to ANY.
- ALL, ANY, and SOME must immediately follow comparison operators.

ALL and ANY support comparison under multiple conditions, as described in the following table.

Expression	Description
A = ALL (...)	Returns TRUE if A matches all values.
A <> ALL (...)	Returns TRUE if A does not match a value.
A < ALL (...)	Returns TRUE if A is smaller than the smallest value.
A = ANY (...)	Returns TRUE if A is equal to a value. This statement is equivalent to A IN (...).
A <> ANY (...)	Returns TRUE if A does not match a value.
A < ANY (...)	Returns TRUE if A is smaller than the largest value.

Examples:

```
SELECT 'hello' = ANY (VALUES 'hello', 'world'); -- true
SELECT 21 < ALL (VALUES 19, 20, 21); -- false
SELECT 42 >= SOME (SELECT 41 UNION ALL SELECT 42 UNION ALL SELECT 43); -- true
```

23.4.8.26. Lambda functions

This topic describes Lambda functions and provides some examples. You can use Lambda functions to analyze log data in Log Service

Lambda expressions

Lambda expressions use the arrow operator `->`.

Examples:

```
x -> x + 1
(x, y) -> x + y
x -> regexp_like(x, 'a+')
x -> x[1] / x[2]
x -> IF(x > 0, x, -x)
x -> COALESCE(x, 0)
x -> CAST(x AS JSON)
x -> x + TRY(1 / 0)
```

Most MySQL expressions can be used in Lambda functions.

filter(array<T>, function<T, boolean>) → ARRAY<T>

Returns an array whose elements are filtered from the specified array based on the Lambda expression.

Examples:

```
SELECT filter(ARRAY [], x -> true); -- []
SELECT filter(ARRAY [5, -6, NULL, 7], x -> x > 0); -- [5, 7]
SELECT filter(ARRAY [5, NULL, 7, NULL], x -> x IS NOT NULL); -- [5, 7]
```

map_filter(map<K, V>, function<K, V, boolean>) → MAP<K,V>

Returns a map whose elements are filtered based on the Lambda expression. The map is generated from the map function.

Examples:

```
SELECT map_filter(MAP(ARRAY[], ARRAY[]), (k, v) -> true); -- {}
SELECT map_filter(MAP(ARRAY[10, 20, 30], ARRAY['a', NULL, 'c']), (k, v) -> v IS NOT NULL); -- {10 -> a, 30 -> c}
SELECT map_filter(MAP(ARRAY['k1', 'k2', 'k3'], ARRAY[20, 3, 15]), (k, v) -> v > 10); -- {k1 -> 20, k3 -> 15}
```

reduce(array<T>, initialState S, inputFunction<S, T, S>, outputFunction<S, R>) → R

The reduce function starts from the initial state, traverses each element in the array, and then calls inputFunction(S,T) to generate a new state. After all the elements in the array are traversed and the final state is generated, the reduce function calls outputFunction to assign the final state value to the result R and output the result. The procedure is described as follows:

1. Start from the initial state S.
2. Traverse each element T.
3. Calculate inputFunction(S,T) to generate a new state S.
4. Repeat steps 2 and 3 until the last element is traversed and has a new state.
5. Turn the final state S into the final result R.

Examples:

```
SELECT reduce(ARRAY [], 0, (s, x) -> s + x, s -> s); -- 0
SELECT reduce(ARRAY [5, 20, 50], 0, (s, x) -> s + x, s -> s); -- 75
SELECT reduce(ARRAY [5, 20, NULL, 50], 0, (s, x) -> s + x, s -> s); -- NULL
SELECT reduce(ARRAY [5, 20, NULL, 50], 0, (s, x) -> s + COALESCE(x, 0), s -> s); -- 75
SELECT reduce(ARRAY [5, 20, NULL, 50], 0, (s, x) -> IF(x IS NULL, s, s + x), s -> s); -- 75
SELECT reduce(ARRAY [2147483647, 1], CAST (0 AS BIGINT), (s, x) -> s + x, s -> s); -- 2147483648
SELECT reduce(ARRAY [5, 6, 10, 20], -- calculates arithmetic average: 10.25
       CAST(ROW(0.0, 0) AS ROW(sum DOUBLE, count INTEGER)),
       (s, x) -> CAST(ROW(x + s.sum, s.count + 1) AS ROW(sum DOUBLE, count INTEGER)),
       s -> IF(s.count = 0, NULL, s.sum / s.count));
```

transform(array<T>, function<T, U>) → ARRAY<U>

This Lambda function traverses each element in an array to generate a new result U.

Examples:

```
SELECT transform(ARRAY [], x -> x + 1); -- []
SELECT transform(ARRAY [5, 6], x -> x + 1); -- [6, 7] -- Increments each element by 1.
SELECT transform(ARRAY [5, NULL, 6], x -> COALESCE(x, 0) + 1); -- [6, 1, 7]
SELECT transform(ARRAY ['x', 'abc', 'z'], x -> x || '0'); -- ['x0', 'abc0', 'z0']
SELECT transform(ARRAY [ARRAY [1, NULL, 2], ARRAY[3, NULL]], a -> filter(a, x -> x IS NOT NULL)); -- [[1, 2], [3]]
```

zip_with(array<T>, array<U>, function<T, U, R>) → array<R>

This Lambda function merges two arrays and generates the element R in the new array based on element T and element U.

Examples:

```
SELECT zip_with(ARRAY[1, 3, 5], ARRAY['a', 'b', 'c'], (x, y) -> (y, x)) --Transposes the elements of the two arrays to generate a new array. Result: [['a', 1], ['b', 3],['c', 5]]
SELECT zip_with(ARRAY[1, 2], ARRAY[3, 4], (x, y) -> x + y); -- Result: [4, 6]
SELECT zip_with(ARRAY['a', 'b', 'c'], ARRAY['d', 'e', 'f'], (x, y) -> concat(x, y)) -- Concatenates the elements of the two arrays to generate a new string. Result: ['ad', 'be', 'cf']
```

23.4.8.27. Logical functions

This topic describes the available logical functions in Log Service. You can use these functions to query and analyze log data.

Logical operators

Operator	Description	Example
AND	The result is TRUE if both values are TRUE.	a AND b
OR	The result is TRUE if either value is TRUE.	a OR b
NOT	The result is TRUE if the value is FALSE.	NOT a

Effect of NULL on logical operators

The following tables list the truth values when the values of a and b are TRUE, FALSE, and NULL, respectively.

Truth table 1

a	b	a AND b	a OR b
TRUE	TRUE	TRUE	TRUE
TRUE	FALSE	FALSE	TRUE
TRUE	NULL	NULL	TRUE
FALSE	TRUE	FALSE	TRUE
FALSE	FALSE	FALSE	FALSE
FALSE	NULL	FALSE	NULL
NULL	TRUE	NULL	TRUE
NULL	FALSE	FALSE	NULL
NULL	NULL	NULL	NULL

Truth table 2

a	NOT a
TRUE	FALSE
FALSE	TRUE
NULL	NULL

23.4.8.28. Field aliases

This topic describes how to specify an alias for a field and provides some examples.

A field name in an SQL statement must start with letters and contain digits and underscores (_).

If you have configured a field name that does not conform to the SQL standard (such as User-Agent), you must specify an alias for the field on the field index configuration page. The alias takes effect only for the duration of the SQL statement. The data is still stored under the original field name. You must specify the original name when you perform a search.

You can also specify an alias for a field in an SQL statement if the original name is long.

Sample aliases

Original field name	Alias
User-Agent	ua
User.Agent	ua
123	col
abceefghijklmnopqrstuvw	a

23.4.8.29. JOIN operations between Logstores and Relational Database Service (RDS) tables

This topic describes how to join Logstores in Log Service with RDS tables for queries and store the query results in RDS tables.

Procedure

1. Create a VPC.

   Create an RDS instance and specify the VPC to host the RDS instance. Then the VPC ID and the RDS instance ID are obtained.

2. Configure a whitelist for the RDS instance.

   Add the following CIDR blocks to the whitelist: `100.104.0.0/16`, `11.194.0.0/16`, and `11.201.0.0/16`

3. Create an external store

   Run the following statement to create an external store. Replace the parameter values based on your business needs.

```
{
"externalStoreName":"storeName",
"storeType":"rds-vpc",
"parameter":
 {
 "region":"cn-qingdao",
 "vpc-id":"vpc-m5eq4irc1pucp*******"
 "instance-id":"i-m5eeo2whsn*******"
 "host":"localhost",
 "port":"3306",
 "username":"root",
 "password":"*****",
 "db":"scmc"
 "table":"join_meta"
 }
}
```

   Parameters

Parameter	Description
region	The region where your RDS instance resides.
vpc-id	The ID of the VPC where your RDS instance resides.
instance-id	The ID of the RDS instance.
host	The ID of the ECS instance that is used to access the RDS instance.
port	The port of the ECS instance that is used to access the RDS instance.
username	The username that is used to log on to the RDS instance.
password	The password that is used to log on to the RDS instance.

Parameter	Description
db	The name of the database.
table	The name of the table with which the Logstore is joined.

> **Note** You can join a Logstore with an RDS table that resides only in the China (Beijing), China (Qingdao), and China (Hangzhou) regions.

4. JOIN query.

   Log on to the Log Service console. In the **Search & Analyze** search box, run a JOIN statement.

   Supported JOIN syntax:

   - INNER JOIN
   - LEFT JOIN
   - RIGHT JOIN
   - FULL JOIN

   ```
   [ INNER ] JOIN
   LEFT [ OUTER ] JOIN
   RIGHT [ OUTER ] JOIN
   FULL [ OUTER ] JOIN
   ```

   > **Note**
   > - You can join Logstores only to external tables.
   > - In the JOIN statement, you must first specify a Logstore before specifying an external store.
   > - You must specify the name of the external store instead of the name of an RDS table. The external store name automatically changes into the combination of the RDS database name and the name of the RDS table that you want to join with the Logstore.

   Sample JOIN statement:

   ```
   method:postlogstorelogs | select count(1) , histogram(logstore) from log  l join join_meta m on l.projectid = cast( m.ikey as varchar)
   ```

5. Store the query results to the RDS table.

   You can use the INSERT statement to insert the query results into the RDS table.

   ```
   method:postlogstorelogs | insert into method_output  select cast(methodasvarchar(65535)),count(1)fromloggr oupbymethod
   ```

Sample Python script:

```
# encoding: utf-8
from __future__ import print_function
from aliyun.log import *
from aliyun.log.util import base64_encodestring
from random import randint
import time
import os
from datetime import datetime
  endpoint = os.environ.get('ALIYUN_LOG_SAMPLE_ENDPOINT', 'cn-chengdu.log.aliyuncs.com')
  accessKeyId = os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSID', '')
  accessKey = os.environ.get('ALIYUN_LOG_SAMPLE_ACCESSKEY', '')
  logstore = os.environ.get('ALIYUN_LOG_SAMPLE_LOGSTORE', '')
  project = "ali-yunlei-chengdu"
  client = LogClient(endpoint, accessKeyId, accessKey, token)
## Create an external store
  res = client.create_external_store(project,ExternalStoreConfig("rds_store","region","rds-vpc","vpc id","instance-id","
instance-ip","port","username","password","db","table"));
  res.log_print()
  ## Obtain external store details
  res = client.get_external_store(project,"rds_store");
  res.log_print()
  res = client.list_external_store(project,"");
  res.log_print();
  # Perform the JOIN operation.
  req = GetLogStoreLogsRequest(project,logstore,From,To,"","select count(1) from "+ logstore +" s join meta m on s.p
rojectid = cast(m.ikey as varchar)");
  res = client.get_logs(req)
  res.log_print();
   # Store query results to the RDS table
  req = GetLogStoreLogsRequest(project,logstore,From,To,"," insert into rds_store select count(1) from "+ logstore );
  res = client.get_logs(req)
  res.log_print();
```

23.4.8.30. Geospatial functions

This topic describes the available geospatial functions in Log Service. You can use these functions to query and analyze log data.

Concept of geometry

Geospatial functions support geometries in the well-known text (WKT) format.

Geometry formats

Geometry	WKT format
Point	POINT (0 0)
LineString	LINESTRING (0 0, 1 1, 1 2)
Polygon	POLYGON ((0 0, 4 0, 4 4, 0 4, 0 0), (1 1, 2 1, 2 2, 1 2, 1 1))
MultiPoint	MULTIPOINT (0 0, 1 2)
MultiLineString	MULTILINESTRING ((0 0, 1 1, 1 2), (2 3, 3 2, 5 4))
MultiPolygon	MULTIPOLYGON (((0 0, 4 0, 4 4, 0 4, 0 0), (1 1, 2 1, 2 2, 1 2, 1 1)), ((-1 -1, -1 -2,

Geometry	WKT format
GeometryCollection	`GEOMETRYCOLLECTION (POINT(2 3), LINESTRING (2 3, 3 4))`

Constructors

Constructor description

Function	Description
ST_Point(double, double) → Point	Returns a geometry point instance with the specified coordinate values.
ST_LineFromText(varchar) → LineString	Returns a geometry LineString instance from a WKT representation.
ST_Polygon(varchar) → Polygon	Returns a geometry polygon instance from a WKT representation.
ST_GeometryFromText(varchar) → Geometry	Returns a geometry instance from a WKT representation.
ST_AsText(Geometry) → varchar	Returns the WKT representation of a geometry.

Operations

Function	Description
ST_Boundary(Geometry) → Geometry	Returns the closure of the combinatorial boundary of a geometry.
ST_Buffer(Geometry, distance) → Geometry	Returns the geometry that represents all points whose distance from the specified geometry is shorter than or equal to the specified distance.
ST_Difference(Geometry, Geometry) → Geometry	Returns the geometry value that represents the point set difference of the specified geometries.
ST_Envelope(Geometry) → Geometry	Returns the bounding rectangular polygon of a geometry.
ST_ExteriorRing(Geometry) → Geometry	Returns a line string that represents the exterior ring of the input polygon.
ST_Intersection(Geometry, Geometry) → Geometry	Returns the geometry value that represents the point set intersection of two geometries.
ST_SymDifference(Geometry, Geometry) → Geometry	Returns the geometry value that represents the point set symmetric difference of two geometries.

Relationship tests

Function	Description

Function	Description
ST_Contains(Geometry, Geometry) → boolean	Returns True if and only if no points of the second geometry lie in the exterior of the first geometry, and at least one point of the interior of the first geometry lies in the interior of the second geometry. Returns False if points of the second geometry are on the boundary of the first geometry.
ST_Crosses(Geometry, Geometry) → boolean	Returns True if the specified geometries share some, but not all, interior points in common.
ST_Disjoint(Geometry, Geometry) → boolean	Returns True if the specified geometries do not spatially intersect.
ST_Equals(Geometry, Geometry) → boolean	Returns True if the specified geometries represent the same geometry.
ST_Intersects(Geometry, Geometry) → boolean	Returns True if the specified geometries spatially intersect in two dimensions.
ST_Overlaps(Geometry, Geometry) → boolean	Returns True if the specified geometries share space in the same dimension, but are not completely contained by each other.
ST_Relate(Geometry, Geometry) → boolean	Returns True if the first geometry is spatially related to the second geometry.
ST_Touches(Geometry, Geometry) → boolean	Returns True if the specified geometries have at least one point in common, but their interiors do not intersect.
ST_Within(Geometry, Geometry) → boolean	Returns True if the first geometry is completely inside the second geometry. Returns False if the two geometries have points in common at the boundaries.

Accessors

Function	Description
ST_Area(Geometry) → double	Returns the two-dimensional Euclidean area of a geometry.
ST_Centroid(Geometry) → Geometry	Returns the point value that is the mathematical centroid of a geometry.
ST_CoordDim(Geometry) → bigint	Returns the coordinate dimension of a geometry.
ST_Dimension(Geometry) → bigint	Returns the inherent dimension of a geometry object, which must be less than or equal to the coordinate dimension.
ST_Distance(Geometry, Geometry) → double	Returns the minimum two-dimensional Cartesian distance (based on spatial ref) between two geometries in projected units.
ST_IsClosed(Geometry) → boolean	Returns True if the start and end points of the linestring are coincident.

Function	Description
ST_IsEmpty(Geometry) → boolean	Returns True if the specified geometry is an empty geometry, such as geometry collection, polygon, and point.
ST_IsRing(Geometry) → boolean	Returns True if and only if the line is closed and simple.
ST_Length(Geometry) → double	Returns the length of a LineString or multi-LineString by using Euclidean measurement on a two-dimensional plane (based on spatial ref) in projected units.
ST_XMax(Geometry) → double	Returns the X maximum of the bounding box of the geometry.
ST_YMax(Geometry) → double	Returns the Y maximum of the bounding box of the geometry.
T_XMin(Geometry) → double	Returns the X minimum of the bounding box of the geometry.
ST_YMin(Geometry) → double	Returns the Y minimum of the bounding box of the geometry.
ST_StartPoint(Geometry) → point	Returns the first point of a geometry LineString instance.
ST_EndPoint(Geometry) → point	Returns the last point of a geometry LineString instance.
ST_X(Point) → double	Returns the X coordinate of a point.
ST_Y(Point) → double	Returns the Y coordinate of a point.
ST_NumPoints(Geometry) → bigint	Returns the number of points in a geometry.
ST_NumInteriorRing(Geometry) → bigint	Returns the cardinality of the collection of interior rings of a polygon.

23.4.8.31. Geography functions

This topic describes the syntax of geography functions and provides some examples.

For information about functions that identify the country, province, city, ISP, and the longitude and latitude of a specified IP address, see IP functions.

Geography functions

Function	Description	Example
geohash(string)	Returns the geohash value of the specified geographical location. The geographical location is represented by a string in the format of "latitude, longitude". The values for latitude and longitude are separated by a comma.	`select geohash('34.1,120.6')= 'wwjcbrdnzs'`

Function	Description	Example
geohash(lat,lon)	Returns the geohash value of the specified geographical location. The geographical location is represented by two parameters that indicate the latitude and longitude.	`select geohash(34.1,120.6)= 'wwjcbrdnzs'`

23.4.8.32. JOIN syntax

The JOIN operation joins multiple tables by using one or more fields in the tables. You can join a Logstore created in Log Service with the Logstore itself, with another Logstore, or with an RDS table. This topic describes how to join different Logstores.

Procedure

1. Download the latest version of the SDK for Python.
2. Call the GetProjectLogs operation to query logs.

Sample SDK

```
#! /usr/bin/env python
#encoding: utf-8
import time,sys,os
from aliyun.log.logexception import LogException
from aliyun.log.logitem import LogItem
from aliyun.log.logclient import LogClient
from aliyun.log.getlogsrequest import GetLogsRequest
from aliyun.log.getlogsrequest import GetProjectLogsRequest
from aliyun.log.putlogsrequest import PutLogsRequest
from aliyun.log.listtopicsrequest import ListTopicsRequest
from aliyun.log.listlogstoresrequest import ListLogstoresRequest
from aliyun.log.gethistogramsrequest import GetHistogramsRequest
from aliyun.log.index_config import *
from aliyun.log.logtail_config_detail import *
from aliyun.log.machine_group_detail import *
from aliyun.log.acl_config import *
if __name__=='__main__':
  token = None
  endpoint = "http://cn-hangzhou.log.aliyuncs.com"
  accessKeyId  = 'LTAIvKy7U'
  accessKey='6gXLNTLyCfdsfwrewrfhdskfdsfuiwu'
  client = LogClient(endpoint, accessKeyId, accessKey,token)
  logstore = "meta"
  # In the query statements, specify two Logstores, the query time ranges of both Logstores, and the key that you want t
o use to join the two Logstores.
  req = GetProjectLogsRequest(project,"select count(1) from sls_operation_log  s join  meta m on s.__date__ >'2018-04-1
0 00:00:00' and s.__date__ < '2018-04-11 00:00:00' and m.__date__ >'2018-04-23 00:00:00' and m.__date__ <'2018-04-24 00
:00:00' and s.projectid = cast(m.ikey as varchar)");
  res = client.get_project_logs(req)
  res.log_print();
  exit(0)
```

> **Note** For more information about the JOIN syntax and examples, see Join.

23.4.8.33. UNNEST function

This topic describes the UNNEST function.

Scenarios

Log data is typically stored as primitive data types, such as string or number. In certain scenarios, log data may include complex data types, such as arrays, maps, and JSON objects. The UNNEST function can be used to transform complex data types into rows of primitive data types. This simplifies query and analysis.

Example:

```
__source__: 1.1.1.1
__tag__:__hostname__: vm-req-170103232316569850-tianchi111932.tc
__topic__: TestTopic_4
array_column: [1,2,3]
double_column: 1.23
map_column: {"a":1,"b":2}
text_column: Product
```

The values of the `array_column` field are arrays. To obtain the sum of elements of all `array_column` field values, you must traverse all elements of every array.

UNNEST function

Syntax	Description
`unnest( array) as table_alias(column_name)`	Expands an array into multiple rows. The column name of these rows is `column_name`.
`unnest(map) as table(key_name, value_name)`	Expands a map into multiple rows. `kev name` specifies the column name of the keys, and `value_name` specifies the column name of the values.

Note The UNNEST function is used to expand arrays or maps. If you want to expand a string, you must transform the string into a JSON object, and then convert the JSON object into an array or map. To do this, you can use the `cast(json_parse(array_column) as array(bigint))` function.

Traverse every element of an array

Expands an array into multiple rows by using the following SQL SELECT statement:

```
* | select  array_column, a  from log, unnest( cast( json_parse(array_column)  as array(bigint) ) ) as  t(a)
```

The UNNEST function `unnest( cast( json_parse(array_column) as array(bigint) ) ) as t(a)` expands the array into multiple rows. The rows are stored in a derived table referenced as t, with the column referenced as a.

- Calculate the sum of the elements in an array:

  ```
  * | select  sum(a)  from log, unnest( cast( json_parse(array_column)  as array(bigint) ) ) as  t(a)
  ```

- Perform a GROUP BY operation on all elements of an array:

  ```
  * | select  a, count(1)  from log, unnest( cast( json_parse(array_column)  as array(bigint) ) ) as  t(a)  group by a
  ```

Traverse every key and value of a map

- Traverse every key and value of a map:

```
* | select map_column , a,b from log, unnest( cast( json_parse(map_column) as map(varchar, bigint) ) ) as t(a,b)
```

- Perform a GROUP BY operation on all keys of a map:

```
* | select key, sum(value) from log, unnest( cast( json_parse(map_column) as map(varchar, bigint) ) ) as t(key,valu
e) GROUP BY key
```

Visualize the query results of the histogram and numeric_histogram functions.

- histogram

  The histogram function works in a similar manner to the count group by syntax. For more information about the histogram function, see Map functions.

  In most cases, the histogram function returns a JSON object. The following is an example:

```
* | select histogram(method)
```

  You can use the UNNEST function to expand JSON data into multiple rows. Then the data can be visualized. The following is an example:

```
* | select key , value from( select histogram(method) as his from log) , unnest(his ) as t(key,value)
```

- numeric_histogram

  The numeric_histogram function assigns a column of numeric values into multiple bins. This function is equivalent to a GROUP BY operation that is performed on a numeric value column. For more information about the syntax of the numeric_histogram function, see Approximate functions.

```
* | select numeric_histogram(10,Latency)
```

  Use the following SELECT statement to visualize the result:

```
* | select key,value from(select numeric_histogram(10,Latency) as his from log) , unnest(his) as t(key,value)
```

23.4.9. Machine learning syntax and functions

23.4.9.1. Overview

The machine learning feature of Log Service supports multiple algorithms and calling methods. You can use SELECT statements and machine learning functions to analyze the characteristics of a field or fields within a period of time.

Log Service offers multiple time series analysis algorithms to help you implement time series prediction, time series anomaly detection, time series decomposition, and multi-time series clustering. The algorithms are compatible with standard SQL statements. This greatly simplifies the use of the algorithms and improves the troubleshooting efficiency.

Features

- Supports various smooth operations on single-time series data.
- Supports algorithms related to the prediction, anomaly detection, change point detection, inflection point detection, and multi-period estimation of single-time series data.
- Supports decomposition operations on single-time series data.
- Supports various clustering algorithms of multi-time series data.
- Supports multi-field pattern mining (based on the sequence of numeric data or text).

Limits

- The specified time series data must be sampled based on the same interval.
- The specified time series data cannot contain data repeatedly sampled from the same time point.

Item	Description
Processing capacity of time-series data	Data can be collected from a maximum of 150,000 consecutive time points. If the data volume exceeds the processing capacity, you must aggregate the data or reduce the sampling amount.
Clustering capacity of the density-based clustering algorithm	A maximum of 5,000 time series curves, each of which cannot contain more than 1,440 time points.
Clustering capacity of the hierarchical clustering algorithm	A maximum of 2,000 time series curves, each of which cannot contain more than 1,440 time points.

Machine learning functions

Type	Function	Description
Smooth functions	ts_smooth_simple	Uses the Holt Winters algorithm to smooth time series data.
	ts_smooth_fir	Uses the finite impulse response (FIR) filter to smooth time series data.
	ts_smooth_iir	Uses the infinite impulse response (IIR) filter to smooth time series data.
Multi-period estimation functions	ts_period_detect	Forecasts time series data by period.
Change point detection functions	ts_cp_detect	Finds intervals with different statistical characteristics from time series data. The interval endpoints are change points.
	ts_breakout_detect	Finds the time points when statistics steeply increases or decreases from time series data.
Maximum value detection function	ts_find_peaks	Finds the local maximum value of time series data in a specified window.
Prediction and anomaly detection functions	ts_predicate_simple	Uses default parameters to model time series data and performs simple time series prediction and anomaly detection.
	ts_predicate_ar	Uses an autoregressive (AR) model to model time series data and performs simple time series prediction and anomaly detection.
	ts_predicate_arma	Uses an autoregressive moving average (ARMA) model to model time series data and performs simple time series prediction and anomaly detection.
	ts_predicate_arima	Uses an autoregressive integrated moving average (ARIMA) model to model time series data and performs simple time series prediction and anomaly detection.
	ts_regression_predict	Accurately predicts the trend for a single periodic time series with a certain tendency.

Type	Function	Description
Time series decomposition function	ts_decompose	Uses the Seasonal and Trend decomposition using Loess (STL) algorithm to decompose time series data.
Time series clustering functions	ts_density_cluster	Uses a density-based clustering method to cluster multiple pieces of time series data.
	ts_hierarchical_cluster	Uses a hierarchical clustering method to cluster multiple pieces of time series data.
	ts_similar_instance	Queries curves that are similar to a specified curve.
Frequent pattern statistics function	pattern_stat	Mines representative combinations of attributes among the given multi-attribute field samples to obtain the frequent pattern in statistical patterns.
Differential pattern statistics function	pattern_diff	Finds the pattern that causes differences between two collections under specified conditions.
Root cause analysis function	rca_kpi_search	When a time series metric is abnormal, you can use the root cause analysis function to analyze the dimension attributes that result in the abnormal metric in a timely manner.
Correlation analysis functions	ts_association_analysis	Quickly finds the metrics that are correlated with a specified metric among multiple observed metrics in the system.
ts_similar	Quickly finds the metrics that are correlated with specified time series data among multiple observed metrics in the system.	
Kernel density estimation function	kernel_density_estimation	Uses the smooth peak function to fit the observed data points, thus simulating the real probability distribution curve.

23.4.9.2. Smooth functions

This topic describes the smooth functions that you can use to smooth and filter specified time series curves. Filtering is the first step to discover the shapes of time series curves.

Functions

Function	Description
ts_smooth_simple	Uses the Holt-Winters algorithm to filter time series data. This function is the default smooth function.
ts_smooth_fir	Uses a finite impulse response (FIR) filter to filter time series data.
ts_smooth_iir	Uses an infinite impulse response (IIR) filter to filter time series data.

ts_smooth_simple

- Syntax:

```
select ts_smooth_simple(x, y)
```

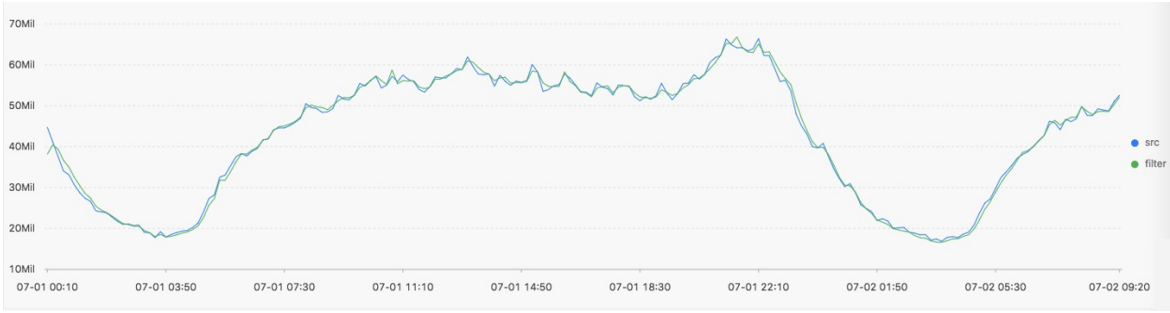
- The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	The Unix timestamp of the time series data. Unit: seconds.
y	The sequence of numeric data at each specified time point.	-

- Example
  - The search and analytic statement is shown as follows:

```
* | select ts_smooth_simple(stamp, value) from ( select __time__ - __time__ % 120 as stamp, avg(v) as value from log GROUP BY stamp order by stamp )
```

  - The following figure shows the response.



- The following table lists the display items.

Item		Description
Horizontal axis	unixtime	The Unix timestamp of time series data. Unit: seconds.
Vertical axis	src	The unfiltered data.
	filter	The filtered data.

ts_smooth_fir

- Syntax:
  - If you cannot determine filter parameters, use built-in window parameters in the following statement:

```
select ts_smooth_fir(x, y,winType,winSize)
```

  - If you can determine filter parameters, you can specify the parameters as needed in the following statement:

```
select ts_smooth_fir(x, y,array[])
```

- The following table lists the parameters of the function.

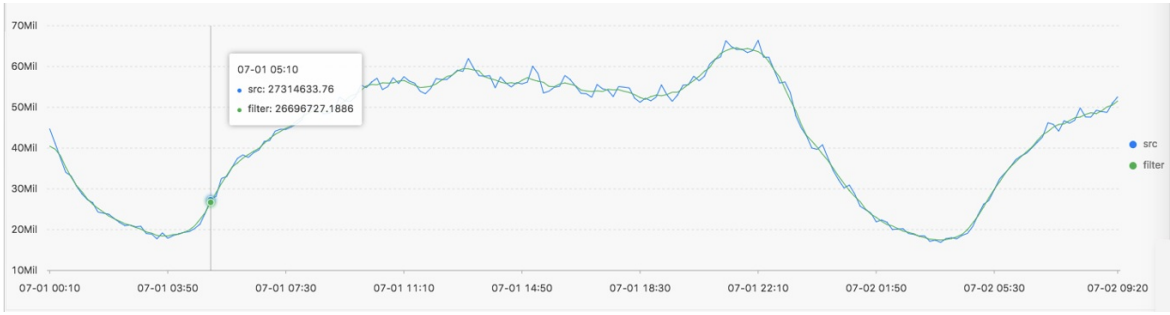
Parameter	Description	Value

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	-
winType	The type of window used for filtering.	Valid values: ○ rectangle: rectangle window. ○ hanning: hanning window ○ hamming: hamming window. ○ blackman: blackman window. **Note** We recommend that you select the rectangle window for better display effects.
winSize	The length of the filtering window.	The value is of the LONG type. Valid values: 2 to 15.
array[]	The parameter used for FIR filtering.	The value is an array where the sum of elements is 1. For example, array[0.2, 0.4, 0.3, 0.1].

- Example 1
  - The search and analytic statement is shown as follows:

```
* | select ts_smooth_fir(stamp, value, 'rectangle', 4) from ( select __time__ - __time__ % 120 as stamp, avg(v) as value from log GROUP BY stamp order by stamp )
```

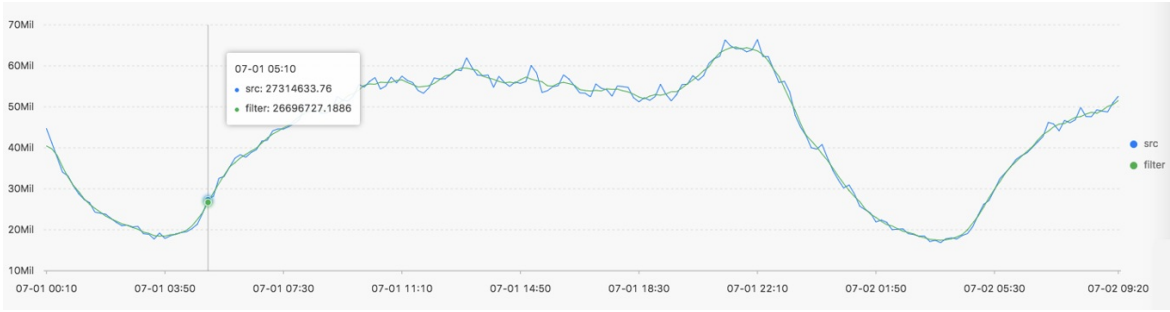
  - The following figure shows the response.



- Example 2
  - The search and analytic statement is shown as follows:

```
* | select ts_smooth_fir(stamp, value, array[0.2, 0.4, 0.3, 0.1]) from ( select __time__ - __time__ % 120 as stamp, avg(v) as value from log GROUP BY stamp order by stamp )
```

- The following figure shows the response.



- The following table lists the display items.

Item		Description
Horizontal axis	unixtime	The Unix timestamp of the time series data. Unit: seconds.
Vertical axis	src	The unfiltered data.
	filter	The filtered data.

ts_smooth_iir

- Syntax:

```
select ts_smooth_iir(x, y, array[], array[] )
```

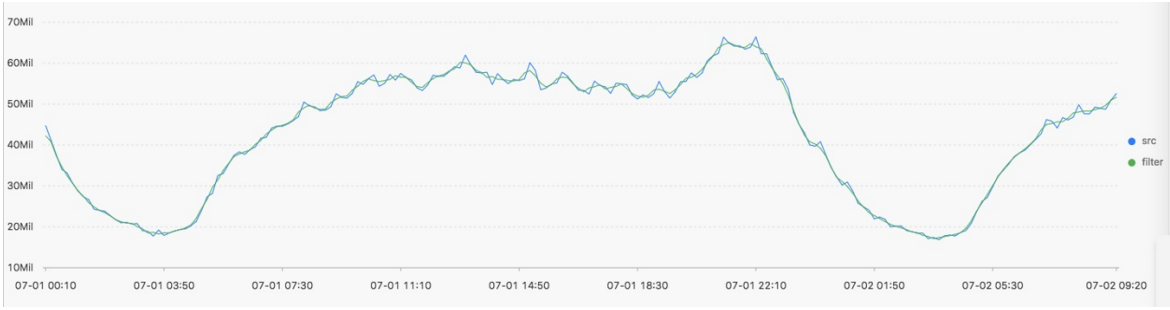
- The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	-
array[]	The parameter used for IIR filtering in terms of x_i .	The value is an array where the sum of elements is 1. The length of the array ranges from 2 to 15. For example, array[0.2, 0.4, 0.3, 0.1].
array[]	The parameter used for IIR filtering in terms of y_{i-1} .	The value is an array where the sum of elements is 1. The length of the array ranges from 2 to 15. For example, array[0.2, 0.4, 0.3, 0.1].

- Example
  - The search and analytic statement is shown as follows:

```
* | select ts_smooth_iir(stamp, value, array[0.2, 0.4, 0.3, 0.1], array[0.4, 0.3, 0.3]) from ( select __time__ - __time__ % 120 as stamp, avg(v) as value from log GROUP BY stamp order by stamp )
```

- The following figure shows the response.



- The following table lists the display items.

Item		Description
Horizontal axis	unixtime	The Unix timestamp of the time series data. Unit: seconds.
Vertical axis	src	The unfiltered data.
	filter	The filtered data.

23.4.9.3. Multi-period estimation functions

This topic describes the multi-period estimation functions that are supported by Log Service. You can use the functions to estimate the periods of time series data in different time intervals. You can also extract the periods by performing a series of operations such as Fourier transform (FT).

Functions

Function	Description
ts_period_detect	Estimates the periods of time series data that is distributed in different time intervals.
ts_period_classify	Uses FT to calculate the periodicity of specified time series curves. This function can be used to identify periodic curves.

ts_period_detect

Syntax:

```
select ts_period_detect(x,y,minPeriod,maxPeriod)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The points in time along the horizontal axis are sorted in ascending order.	Each point is a UNIX timestamp. Unit: seconds.
y	The sequence of numeric data at each specified point in time.	-

Parameter	Description	Value
minPeriod	The ratio of the minimum length of the estimated period to the total length of the time series data.	The value must be a decimal number. Value range: (0, 1].
maxPeriod	The ratio of the maximum length of the estimated period to the total length of the time series data. **Note** The value of the *maxPeriod* parameter must be greater than the value of the *minPeriod* parameter.	The parameter value must be a decimal number. Value range: (0, 1].

Example:

- Query statement

```
* | select ts_period_detect(stamp, value, 0.2, 1.0) from ( select __time__ - __time__ % 120 as stamp, avg(v) as value fro
m log GROUP BY stamp order by stamp )
```

- Result

The following table lists the display items.

Display item	Description
period_id	An array with a length of 1. The element in the array indicates the sequence number of the period. The array [0] indicates the original time series curve.
time_series	The sequence of timestamps.
data_series	The sequence of data at each timestamp. • If the value of period_id is 0, the returned data is the original time series data. • If the value of period_id is not 0, the data returned is filtered time series data.

ts_period_classify

Syntax:

```
select ts_period_classify(stamp,value,instanceName)
```

The following table lists the parameters.

Parameter	Description	Value

Parameter	Description	Value
stamp	The time sequence. The points in time along the horizontal axis are sorted in ascending order.	Each point in time is a UINX timestamp. Unit: seconds.
value	The sequence of numeric data at each specified point in time.	-
instanceName	The name of the time series curve.	-

Example:

- The following query statement is executed:

```
* and h : nu2h05202.nu8 | select ts_period_classify(stamp, value, name) from log
```

- Query result

line_name	prob	type
asg-2zz6jn6zf5ewg188pg5	1.0	-1.0
asg-bp1j8snc92p6v5pptgpj	0.07203669207039314	0.0
asg-wz99hse7u4ubopo5dt9o	0.0	0.0
asg-bp18oqni0gq96vy85te4	0.05590892692207093	0.0

The following table lists the display items.

Display item	Description
line_name	An array with a length of 1. The element in the array indicates the sequence number of the period. The array [0] indicates the original time series curve.
prob	The ratio of the primary period length to the length of the time series curve. Value range: [0, 1]. You can set the value to 0.15 when you perform a test.
type	The type of the curve. Valid values: -1, -2, and 0. • The value -1 indicates that the length of the time series curve is too short (less than 64 points). • The value -2 indicates the time series curve has a high fault rate (the fault rate exceeds 20%). • The value 0 indicates the time series curve is periodic.

23.4.9.4. Change point detection functions

This topic describes the change point detection functions in Log Service. You can use the functions to detect the change points in time series data.

The change point detection functions can detect the following two kinds of change points:

- Statistics feature changes within a specified period of time
- Anomalies in time series data

Functions

Function	Description
ts_cp_detect	Finds intervals in which data has different statistics features. The interval endpoints are change points.
ts_breakout_detect	Finds the time points at which data experiences dramatic changes.

ts_cp_detect

Syntax:

- If you cannot specify an appropriate time window size, use the following syntax. The default window size used in the function is 10.

```
select ts_cp_detect(x, y, samplePeriod)
```

- To adjust the effect specific to your business environment, you can specify the minSize parameter in the following function.

```
select ts_cp_detect(x, y, minSize)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	-
minSize	The minimum length of time series data in a continuous interval.	The minimum value is 3 and the maximum value cannot exceed ten percent of the length of the specified time series data.

Example:

- The search and analytic statement is shown as follows:

```
* | select ts_cp_detect(stamp, value, 3) from (select __time__ - __time__ % 10 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

- The following figure shows the response.

The following table lists the display items.

Display item		Description
Horizontal axis	unixtime	The Unix timestamp of time series data, measured in seconds, for example, 1537071480.

Display item		Description
Vertical axis	src	The unfiltered data, such as 1956092.7647745228.
	prob	The probability that a time point is a change point. Valid values: 0 to 1.

ts_breakout_detect

Syntax:

```
select ts_breakout_detect(x, y, winSize)
```

The following table lists the parameters of the function.

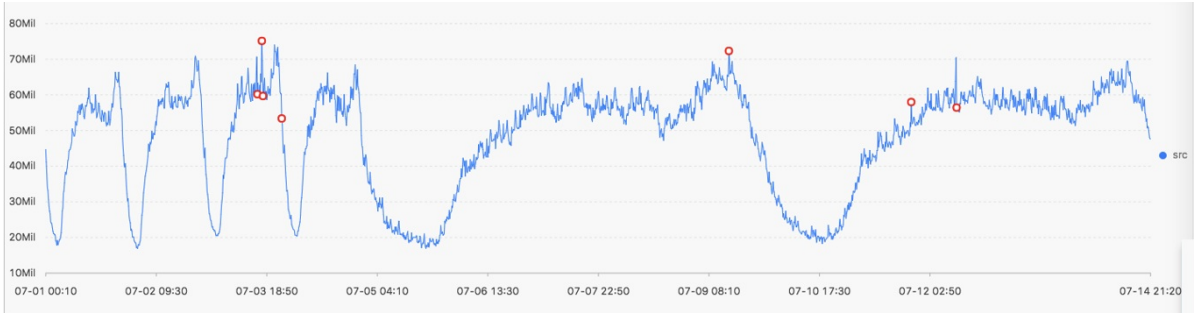
Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	-
winSize	The minimum length of time series data in a continuous interval.	The minimum value is 3 and the maximum value cannot exceed ten percent of the length of the specified time series data.

Example:

- The search and analytic statement is shown as follows:

```
* | select ts_breakout_detect(stamp, value, 3) from (select __time__ - __time__ % 10 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

- The following figure shows the response.



The following table lists the display items.

Display item		Description
Horizontal axis	unixtime	The Unix timestamp of time series data, measured in seconds, for example, 1537071480.
Vertical axis	src	The unfiltered data, such as 1956092.7647745228.
	prob	The probability that a time point is a change point. Valid values: 0 to 1.

23.4.9.5. Maximum value detection function

This topic describes the available maximum value detection function in Log Service. You can use the functions to find the local maximum value of time series data in a specified window.

ts_find_peaks

Syntax:

```
select ts_find_peaks(x, y, winSize)
```

The following table lists the parameters of the function.

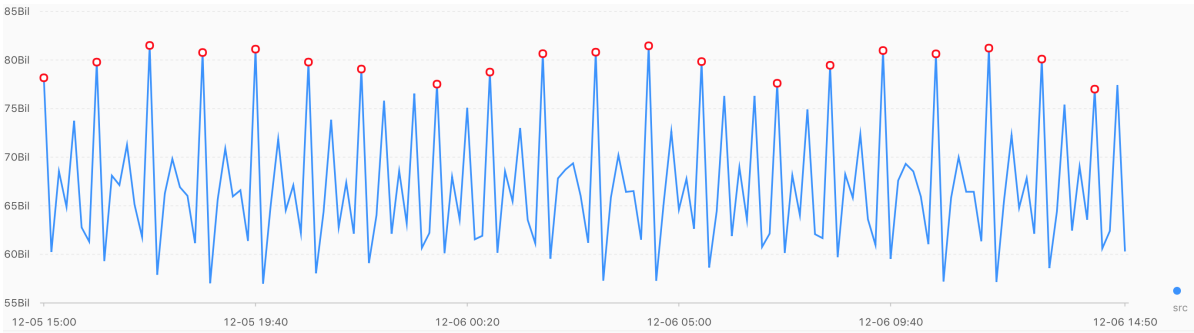
Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	-
winSize	The minimum length of the detection window.	The value of the parameter is of the LONG type, ranging from 1 to the length of time series data. We recommend that you set this parameter to ten percent of the actual data length.

Example:

- The search and analytic statement is shown as follows:

```
* and h : nu2h05202.nu8 and m: NET | select ts_find_peaks(stamp, value, 30) from (select __time__ - __time__ % 10 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

- The following figure shows the response.



The following table lists the display items.

Display item		Description
Horizontal axis	unixtime	The Unix timestamp of time series data, measured in seconds, for example, 1537071480.
	src	The unfiltered data, such as 1956092.7647745228.

Display item Vertical axis		Description
	peak_flag	Indicates whether the numeric value at the time point is the maximum value. Valid values: 1.0 and 0.0. • 1.0: The numeric value at the time point is the maximum value. • 0.0: The numeric value at the time point is not the maximum value.

23.4.9.6. Prediction and anomaly detection functions

Prediction and anomaly detection functions predict the trend of time series curves and identify the Ksigma and quantiles of the errors between a predicted curve and an actual curve. You can use the functions to detect anomalies.

Functions

Function	Description
ts_predicate_simple	Uses default parameters to model time series data and performs prediction and anomaly detection on time series data.
ts_predicate_ar	Uses an autoregressive (AR) model to model time series data and performs prediction and anomaly detection on time series data.
ts_predicate_arma	Uses an autoregressive moving average (ARMA) model to model time series data and performs prediction and anomaly detection on time series data.
ts_predicate_arima	Uses an autoregressive integrated moving average (ARIMA) model to model time series data and performs prediction and anomaly detection on time series data.
ts_regression_predict	Accurately predicts the trend for a periodic time series curve. Scenario: This function can be used to predict metering data, network traffic, financial data, and different business data that follows certain rules.
ts_anomaly_filter	Filters the anomalies detected from multiple time series curves based on the custom anomaly mode. The anomalies are detected during the anomaly detection. This function helps you find abnormal curves in a timely manner.

ts_predicate_simple

Syntax:

```
select ts_predicate_simple(x, y, nPred, isSmooth)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	N/A

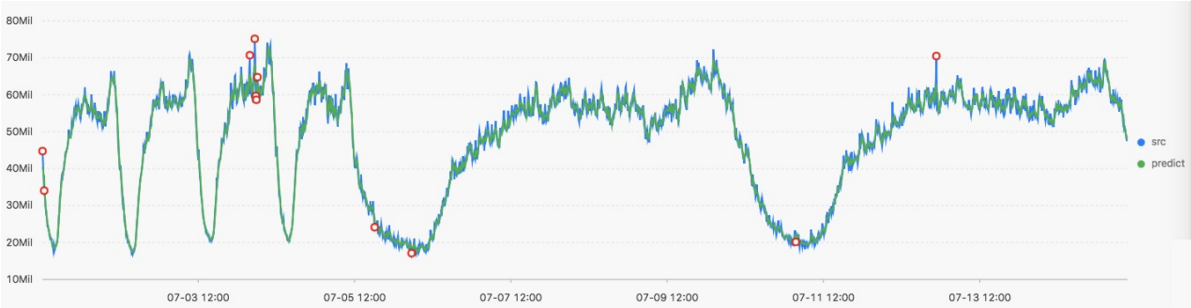
Parameter	Description	Value
nPred	The number of points for prediction.	The value is of the LONG data type and must be equal to or greater than 1.
isSmooth	Specifies whether to filter the raw data.	The value is of the Boolean type. The default value is True, which indicates to filter raw data.

Example:

- A search and analytic statement is shown as follows:

```
* | select ts_predicate_simple(stamp, value, 6) from (select __time__ - __time__ % 60 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

- The following figure shows the response.



The following table lists the display items.

Display item		Description
Horizontal axis	unixtime	The Unix timestamp of the data. Unit: seconds.
Vertical axis	src	The raw data.
	predict	The predicted data.
	upper	The upper limit of the prediction. The confidence level is 0.85. This value cannot be modified.
	lower	The lower limit of the prediction. The confidence level is 0.85. This value cannot be modified.
	anomaly_prob	The probability that the point is an anomaly. Valid values: [0, 1].

ts_predicate_ar

Syntax:

```
select ts_predicate_ar(x, y, p, nPred, isSmooth)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.

Parameter	Description	Value
y	The sequence of numeric data at each specified time point.	N/A
p	The order of the AR model.	The value is of the LONG data type. Valid values: [2, 8].
nPred	The number of points for prediction.	The value is of the LONG data type. Valid values: [1, 5 × *p*].
isSmooth	Specifies whether to filter the raw data.	The value is of the Boolean type. The default value is true, which indicates to filter raw data.

An example search and analytic statement is shown as follows:

```
* | select ts_predicate_ar(stamp, value, 3, 4) from (select __time__ - __time__ % 60 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

Note The response is similar to that of the ts_predicate_simple function. For more information, see the response of the ts_predicate_simple function.

ts_predicate_arma

Syntax:

```
select ts_predicate_arma(x, y, p, q, nPred, isSmooth)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	N/A
p	The order of the AR model.	The value is of the LONG data type. Valid values: [2, 100].
q	The order of the ARMA model.	The value is of the LONG data type. Valid values: [2, 8].
nPred	The number of points for prediction.	The value is of the LONG data type. Valid values: [*p*, 5p].
isSmooth	Specifies whether to filter the raw data.	The value is of the Boolean type. The default value is true, which indicates to filter raw data.

An example search and analytic statement is shown as follows:

```
* | select ts_predicate_arma(stamp, value, 3, 2, 4) from (select __time__ - __time__ % 60 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

> **Note** The response is similar to that of the ts_predicate_simple function. For more information, see the response of the ts_predicate_simple function.

ts_predicate_arima

Syntax:

```
select ts_predicate_arima(x,y, p, d, q, nPred, isSmooth)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	N/A
p	The order of the AR model.	The value is of the LONG data type. Valid values: [2, 8].
d	The order of the ARIMA model.	The value is of the LONG data type. Valid values: [1, 3].
q	The order of the ARMA model.	The value is of the LONG data type. Valid values: [2, 8].
nPred	The number of points for prediction.	The value is of the LONG type. Valid values: [*p*, 5p].
isSmooth	Specifies whether to filter the raw data.	The value is of the Boolean type. The default value is True, which indicates to filter raw data.

An example search and analytic statement is shown as follows:

```
* | select ts_predicate_arima(stamp, value, 3, 1, 2, 4) from (select __time__ - __time__ % 60 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

> **Note** The response is similar to that of the ts_predicate_simple function. For more information, see the response of the ts_predicate_simple function.

ts_regression_predict

Syntax:

```
select ts_regression_predict(x, y, nPred, algotype,processType)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.

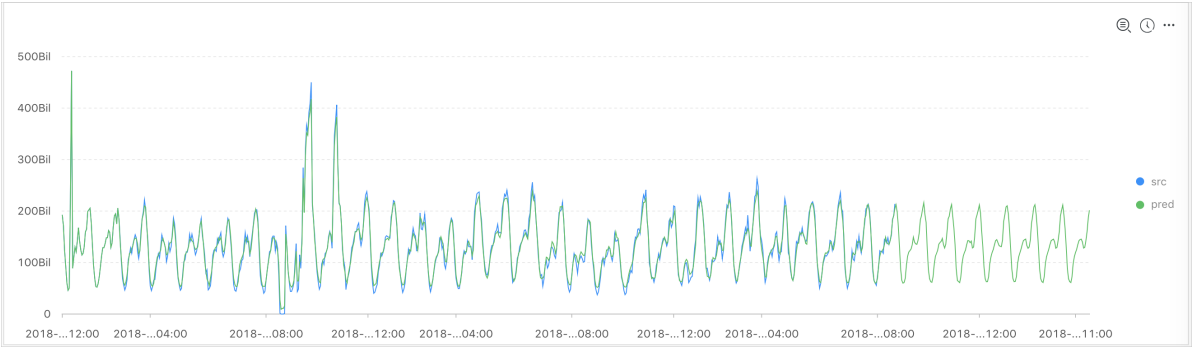
Parameter	Description	Value
y	The sequence of numeric data at each specified time point.	N/A
nPred	The number of points for prediction.	The value is of the LONG data type. Valid values: [1, 500].
algotype	The algorithm type for prediction.	Valid values: • origin: uses the Gradient Boosted Regression Tree (GBRT) algorithm for prediction. • forest: uses the GBRT algorithm for prediction based on the trend component decomposed by Seasonal and Trend decomposition using Loess (STL), and then uses the additive model to sum up the decomposed components and obtains the predicted data. • linear: uses the Linear Regression algorithm for prediction based on the trend components decomposed by STL, and then uses the additive model to sum up the decomposed components and obtains the predicted data.
processType	Specifies whether to preprocess the data.	Valid values: • 0: no additional data preprocessing is performed. • 1: removes abnormal data before prediction.

Example:

- A search and analytic statement is shown as follows:

```
* and h : nu2h05202.nu8 and m: NET | select ts_regression_predict(stamp, value, 200, 'origin') from (select __time__ - __time__ % 60 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

- The following figure shows the response.



The following table lists the display items.

Display item		Description
Horizontal axis	unixtime	The Unix timestamp of the data. Unit: seconds.
Vertical axis	src	The raw data.
	predict	The predicted data.

ts_anomaly_filter

Syntax:

```
select ts_anomaly_filter(lineName, ts, ds, preds, probs, nWatch, anomalyType)
```

The following table lists the parameters of the function.

Parameter	Description	Value
lineName	The name of each curve. The value is of the VARCHAR data type.	N/A
ts	The time sequence of the curve, which indicates the time of the current curve. The parameter value is an array of time points of the DOUBLE data type sorted in the ascending order.	N/A
ds	The actual value sequence of the curve. The parameter value is an array of data points with the same length as the ts parameter value.	N/A
preds	The predicted value sequence of the curve. The parameter value is an array of data points with the same length as the ts parameter value.	N/A
probs	The sequence of anomaly detection results of the curve. The parameter value is an array of data points with the same length as the ts parameter value.	N/A
nWatch	The number of the recently observed actual values on the curve. The value is of the LONG data type. The value must be smaller than the number of time points on the curve.	N/A
anomalyType	The type of anomaly to be filtered. The value is of the LONG data type.	Valid values: • 0: all anomalies. • 1: positive anomalies. • -1: negative anomalies.

Example:

- A search and analytic statement is shown as follows:

```
* | select res.name, res.ts, res.ds, res.preds, res.probs
  from (
    select ts_anomaly_filter(name, ts, ds, preds, probs, cast(5 as bigint), cast(1 as bigint)) as res
   from (
    select name, res[1] as ts, res[2] as ds, res[3] as preds, res[4] as uppers, res[5] as lowers, res[6] as probs
  from (
    select name, array_transpose(ts_predicate_ar(stamp, value, 10)) as res
    from (
     select name, stamp, value from log where name like '%asg-%') group by name)) );
```

- The following figure shows the response.

```
| name                | ts                                                                | ds       | preds    | probs     |
| --------------------- | ------------------------------------------------------------------ | ---------- | --------- | ---------- |
| asg-bp1hylzdi2wx7civ0ivk | [1.5513696E9, 1.5513732E9, 1.5513768E9, 1.5513804E9] | [1,2,3,NaN] | [1,2,3,4] | [0,0,1,NaN] |
```

23.4.9.7. Time series decomposition function

The time series decomposition function decomposes time series curves into curves that reveal the trend and periodicity of curves.

ts_decompose

Syntax:

```
select ts_decompose(x, y)
```

The following table lists the parameters of the function.

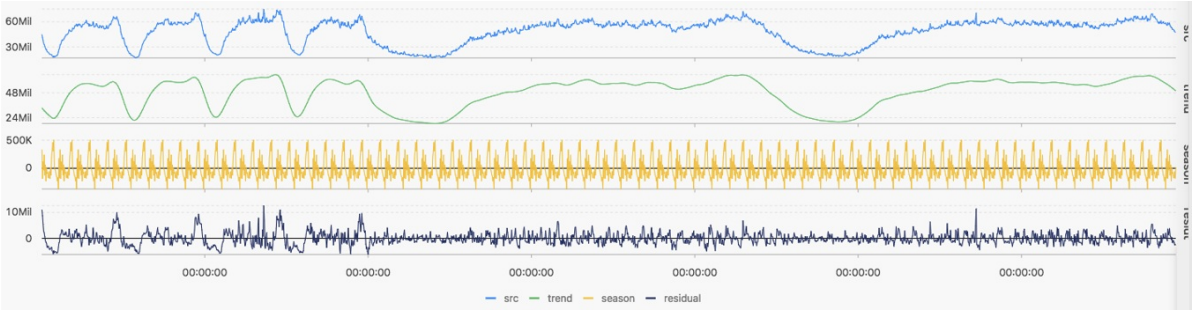
Parameter	Description	Value
x	The time sequence. The time points along the x axis are sorted in the ascending order.	Each time point is a Unix timestamp. Unit: seconds.
y	The sequence of numeric data at each specified time point.	N/A

Example:

- A search and analytic statement is shown as follows:

```
* | select ts_decompose(stamp, value) from (select __time__ - __time__ % 60 as stamp, avg(v) as value from log GROUP BY stamp order by stamp)
```

- The following figure shows the response.



The following table lists the display items.

Display item		Description
Horizontal axis	unixtime	The Unix timestamp of the data. Unit: seconds.
Vertical axis	src	The raw time series data.
	trend	The decomposed data that indicates the trend of the time series data.
	season	The decomposed data that indicates the periodicity of the time series data.

Display item		Description
	residual	The residual data decomposed from the time series data.

23.4.9.8. Time series clustering functions

You can use time series clustering functions to cluster multiple time series and obtain different curve shapes. Then, you can find the cluster center and identify curves with shapes that are different from other curve shapes in the cluster in a timely manner.

Functions

Function	Description
ts_density_cluster	Uses a density-based clustering method to cluster multiple time series.
ts_hierarchical_cluster	Uses a hierarchical clustering method to cluster multiple time series.
ts_similar_instance	Queries time series curves that are similar to a specified time series curve.

ts_density_cluster

Syntax:

```
select ts_density_cluster(x, y, z)
```

The following table lists the parameters of the function.

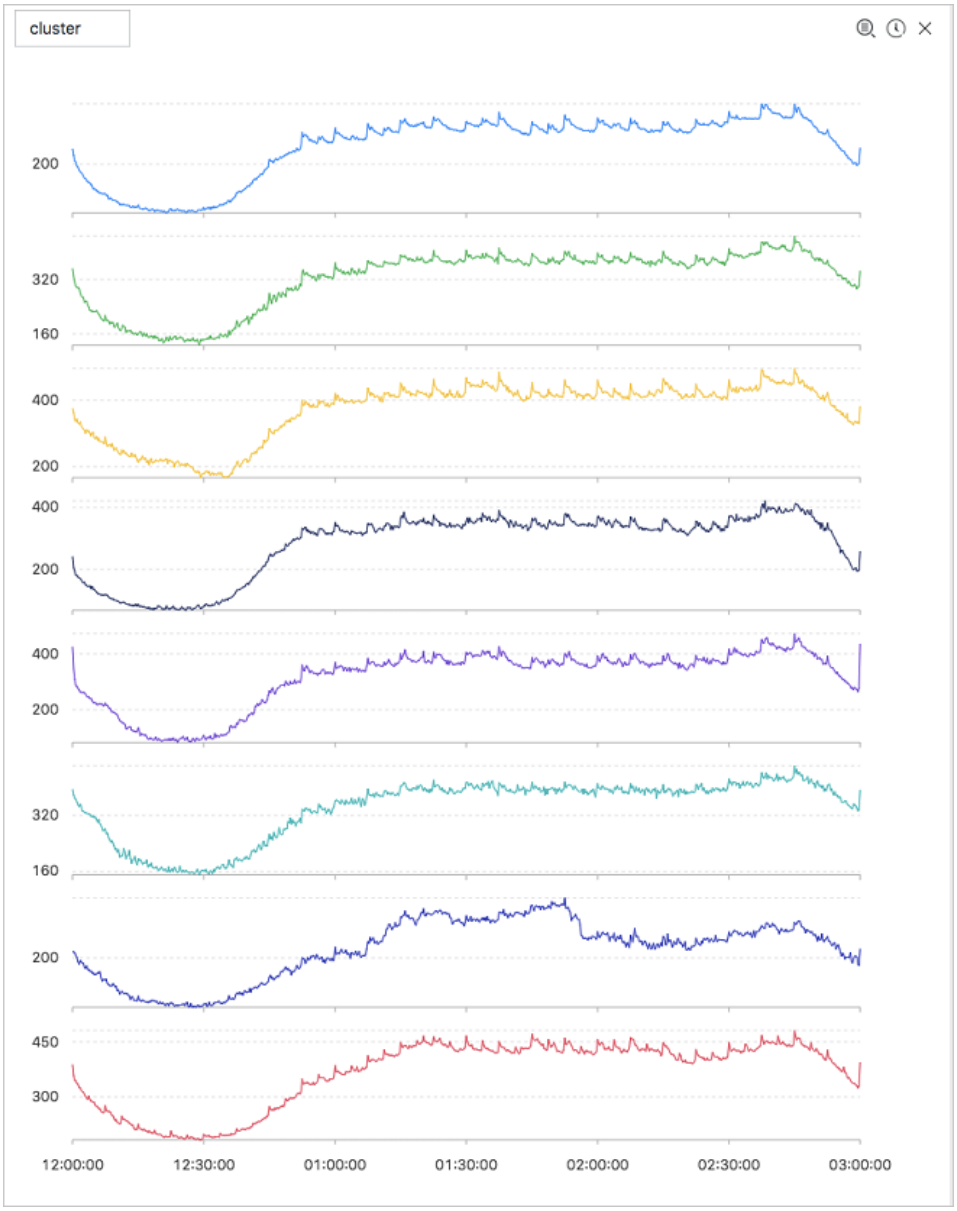
Parameter	Description	Value
x	The time sequence. The points in time along the horizontal axis are sorted in ascending order.	Each point in time is a UNIX timestamp. Unit: seconds.
y	The sequence of numeric data that corresponds to a specified point in time.	-
z	The name of the curve corresponding to the data at a specified point in time.	The value is of the string type, for example, machine01.cpu_usr.

Example

- The query statement:

```
* and (h: "machine_01" OR h: "machine_02" OR h : "machine_03") | select ts_density_cluster(stamp, metric_value,metric_name ) from ( select __time__ - __time__ % 600 as stamp, avg(v) as metric_value, h as metric_name from log GROUP BY stamp, metric_name order BY metric_name, stamp )
```

- Output result



The following table lists the display items.

Display item	Description
cluster_id	The category of the cluster. The value -1 indicates that the cluster is not categorized in any cluster center.
rate	The proportion of instances in the cluster.
time_series	The timestamp sequence of the cluster center.
data_series	The data sequence of the cluster center.
instance_names	The instances that are included in the cluster center.
sim_instance	The name of an instance in the cluster.

ts_hierarchical_cluster

Syntax:

```
select ts_hierarchical_cluster(x, y, z)
```

The following table lists the parameters of the function.

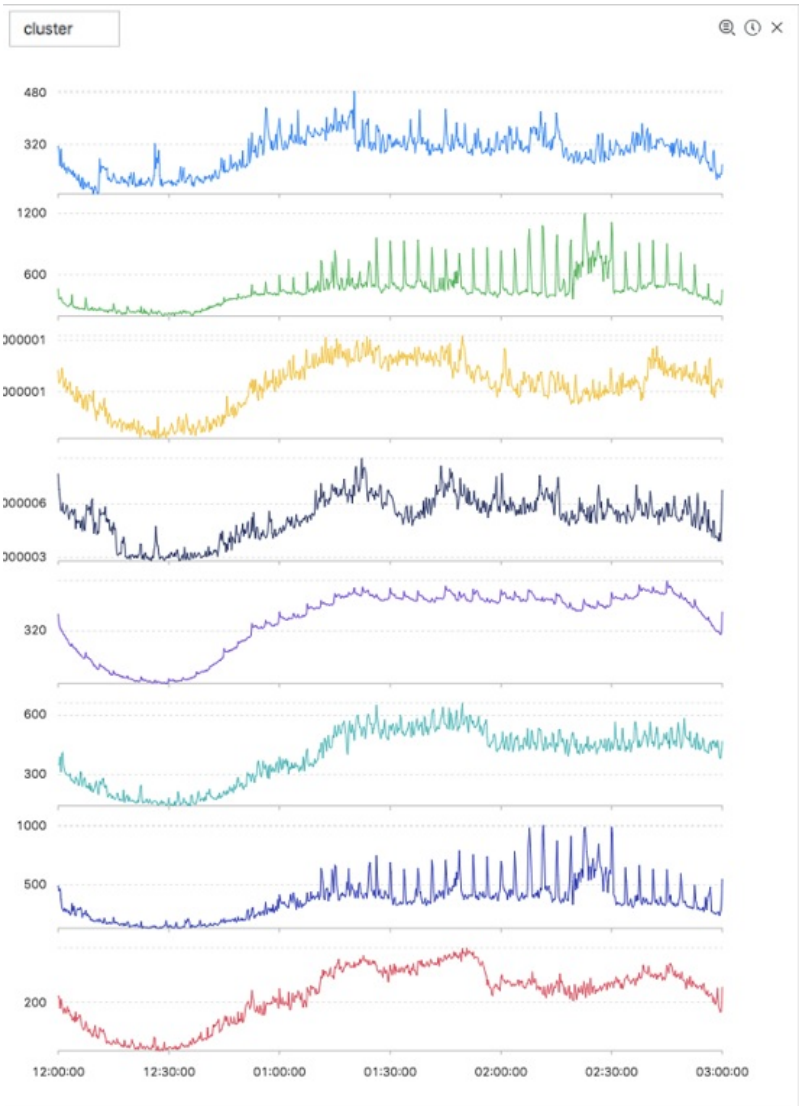
Parameter	Description	Value
x	The time sequence. The points in time along the horizontal axis are sorted in ascending order.	Each point in time is a UNIX timestamp. Unit: seconds.
y	The sequence of numeric data that corresponds to a specified point in time.	-
z	The name of the curve corresponding to the data at a specified point in time.	The value is of the string type, for example, machine01.cpu_usr.

Examples

- The query statement:

```
* and (h: "machine_01" OR h: "machine_02" OR h : "machine_03") | select ts_hierarchical_cluster(stamp, metric_value, metric_name) from ( select __time__ - __time__ % 600 as stamp, avg(v) as metric_value, h as metric_name from log GROUP BY stamp, metric_name order BY metric_name, stamp )
```

- Output result



The following table lists the display items.

Display item	Description
cluster_id	The category of the cluster. The value -1 indicates that the cluster is not categorized in any cluster center.
rate	The proportion of instances in the cluster.
time_series	The timestamp sequence of the cluster center.
data_series	The data sequence of the cluster center.
instance_names	The instances that are included in the cluster center.
sim_instance	The name of an instance in the cluster.

ts_similar_instance

Syntax:

```
select ts_similar_instance(x, y, z, instance_name, topK, metricType)
```

The following table lists the parameters of the function.

Parameter	Description	Value
x	The time sequence. The points in time along the horizontal axis are sorted in ascending order.	Each point in time is a UNIX timestamp. Unit: seconds.
y	The sequence of numeric data that corresponds to a specified point in time.	-
z	The name of the curve corresponding to the data at a specified point in time.	The value is of the string type, for example, machine01.cpu_usr.
instance_name	The name of a specified curve to be queried.	The value is of the string type, for example, machine01.cpu_usr. **Note** The curve to be queried must be an existing one.
topK	The maximum number of curves that are similar to the specified curve can be returned.	-
metricType	`{'shape', 'manhattan', 'euclidean'}`. The metric used to measure the similarity between time series curves.	-

The query statement:

```
* and m: NET and m: Tcp and (h: "nu4e01524.nu8" OR h: "nu2i10267.nu8" OR h : "nu4q10466.nu8") | select ts_similar_instance(stamp, metric_value, metric_name, 'nu4e01524.nu8' ) from ( select __time__ - __time__ % 600 as stamp, sum(v) as metric_value, h as metric_name from log GROUP BY stamp, metric_name order BY metric_name, stamp )
```

The following table lists the display items.

Display item	Description
instance_name	The list of metrics that are similar to the specified metric.
time_series	The timestamp sequence of the cluster center.
data_series	The data sequence of the cluster center.

23.4.9.9. Frequent pattern statistics function

The frequent pattern statistics function combines representative attributes in a specified multi-attribute field sample.

pattern_stat

Syntax:

```
select pattern_stat(array[col1, col2, col3], array['col1_name', 'col2_name', 'col3_name'], array[col5, col6], array['col5_name', 'col6_name'], support_score, sample_ratio)
```

The following table lists the parameters of the function.

Parameter	Description	Value
array[col1, col2, col3]	A column of character values.	An array of values, for example, array[clientIP, sourceIP, path, logstore].
array['col1_name', 'col2_name', 'col3_name']	The field names of the character values.	An array of field names, for example, array['clientIP', 'sourceIP', 'path', 'logstore'].
array[col5, col6]	A column of numeric values.	An array of values, for example, array[Inflow, OutFlow].
array['col5_name', 'col6_name']	The field names of the numeric values.	An array of field names, for example, array['Inflow', 'OutFlow'].
support_score	The support ratio of samples for pattern mining.	The value is of the DOUBLE data type. Value range: (0,1].
sample_ratio	The sampling ratio. The default value is 0.1, which indicates that only 10% of the total samples are used.	The value is of the DOUBLE data type. Value range: (0,1].

Example:

- Query statement

```
* | select pattern_stat(array[ Category, ClientIP, ProjectName, LogStore, Method, Source, UserAgent ], array[ 'Category', 'ClientIP', 'ProjectName', 'LogStore', 'Method', 'Source', 'UserAgent' ], array[ InFlow, OutFlow ], array[ 'InFlow', 'OutFlow' ], 0.45, 0.3) limit 1000
```

- Display item

Display item	Description
count	The number of samples in the current pattern.
support_score	The score of the current pattern. The score indicates the degree to which the current pattern is supported.
pattern	The content of the pattern. The pattern is organized in the format that is defined by the query conditions.

23.4.9.10. Differential pattern statistics function

The differential pattern statistics function analyzes differential patterns of specified multi-field samples based on the specified condition. It helps you identify the causes of the differences under the current condition in a timely manner.

pattern_diff

Syntax:

```
select pattern_diff(array_char_value, array_char_name, array_numeric_value, array_numeric_name, condition, supportScore,posSampleRatio,negSampleRatio )
```

The following table lists the parameters of the function.

Parameter	Description	Value
array_char_value	A column of values of the character data type.	An array of values, for example, array[clientIP, sourceIP, path, logstore].
array_char_name	The field names of the values of the character data type.	An array of field names, for example, array['clientIP', 'sourceIP', 'path', 'logstore'].
array_numeric_value	A column of values of the numeric data type.	An array of values, for example, array[Inflow, OutFlow].
array_numeric_name	The field names of the values of the numeric data type.	An array of field names, for example, array[originflow', 'OutFlow'].
condition	The condition for filtering data. The value True indicates positive samples, and the value False indicates negative samples.	For example, Latency <= 300.
supportScore	The support ratio of positive and negative samples for pattern mining.	The value is of the DOUBLE data type. Valid values: (0,1].
posSampleRatio	The sampling ratio of positive samples. The default value is 0.5, indicating that 50% of positive samples are collected.	The value is of the DOUBLE data type. Valid values: (0,1].
negSampleRatio	The sampling ratio of negative samples. The default value is 0.5, indicating that 50% of positive samples are collected.	The value is of the DOUBLE data type. Valid values: (0,1].

Example:

- A search and analytic statement is shown as follows:

```
* | select pattern_diff(array[ Category, ClientIP, ProjectName, LogStore, Method, Source, UserAgent ], array[ 'Category', 'ClientIP', 'ProjectName', 'LogStore', 'Method', 'Source', 'UserAgent' ], array[ InFlow, OutFlow ], array[ 'InFlow', 'OutFlow' ], Latency > 300, 0.2, 0.1, 1.0) limit 1000
```

- Display item

Display item	Description
possupport	The support ratio of positive samples for the mined patterns.
posconfidence	The confidence level of the mined patterns in positive samples.
negsupport	The support ratio of negative samples for the mined patterns.
diffpattern	The content of the mined patterns.

23.4.9.11. Root cause analysis function

Log Service provides the alert and analytics features that help you quickly analyze data and locate anomalies of specific subdimensions of a metric. You can use the root cause analysis function to analyze the subdimension attributes that result in anomalies of the monitoring metric.

rca_kpi_search

Syntax

```
select rca_kpi_search(varchar_array, name_array, real, forecast, level)
```

The following table lists the parameters of the function.

Parameter	Description	Value
varchar_array	The subdimension attributes.	The parameter value is formatted in an array, for example, array[col1, col2, col3].
name_array	The subdimension attribute names.	The parameter value is formatted in an array, for example, array['col1', 'col2', 'col3'].
real	The actual value of each subdimension attribute specified by the varchar_array parameter.	The parameter value is of the DOUBLE data type. Valid values: all real numbers.
forecast	The predicted value of each subdimension attribute specified by the varchar_array parameter.	The parameter value is of the DOUBLE data type. Valid values: all real numbers.
level	The number of subdimension attributes identified in the returned root cause set. The value 0 indicates that all root causes that are found are returned.	The parameter value is of the LONG data type. Valid values: [0, number of analyzed subdimensions]. The number of analyzed subdimensions is the length of the array specified by the varchar_array parameter.

Example:

- The search and analytic statement is shown as follows:

  Use a subquery to obtain the actual value and predicted value of each subdimension attribute, and then call the rca_kpi_search function to analyze the root causes of anomalies.

```
* not Status:200 |
select rca_kpi_search(
 array[ ProjectName, LogStore, UserAgent, Method ],
 array[ 'ProjectName', 'LogStore', 'UserAgent', 'Method' ], real, forecast, 1)
from (
select ProjectName, LogStore, UserAgent, Method,
 sum(case when time < 1552436040 then real else 0 end) * 1.0 / sum(case when time < 1552436040
then 1 else 0 end) as forecast,
 sum(case when time >=1552436040 then real else 0 end) *1.0 / sum(case when time >= 1552436040
then 1 else 0 end) as real
 from (
select __time__ - __time__ % 60 as time, ProjectName, LogStore, UserAgent, Method, COUNT(*) as real
from log GROUP by time, ProjectName, LogStore, UserAgent, Method )
GROUP BY ProjectName, LogStore, UserAgent, Method limit 100000000)
```

- The following figure shows the response.

The following figure shows the structured response.

```
{
  "rcSets": [
    {
      "rcItems": [
        {
          "kpi": [("attr": "xxx", "val": "xxx")],
          "nleaf": 100,
          "change": 0.524543,
          "score": 0.1454543
        }
      ]
    }
  ]
}
```

The following table lists the display items.

Display item	Description
rcSets	The root cause sets. Each value of this parameter is an array.
rcItems	A specific root cause set.
kpi	A specific item in the root cause set. Each item is formatted in an array where each element is a JSON object. The attr parameter indicates the subdimension name, and the val parameter indicates the attribute name under the subdimension.
nleaf	The number of leaf nodes that an item (KPI) in the root cause set covers in the original data. **Note** Leaf node: the log entry that contains the finest-grained attribute information.
change	The ratio of anomalies of leaf nodes in a KPI to the total anomalies in the root cause set that occurred at the same time point.
score	The abnormality score of the current KPI. Valid values: [0, 1].

The response is formatted in a JSON object as follows:

```
{
 "rcSets": [
 {
  "rcItems": [
  {
   "kpi": [
   {
    "attr": "country",
    "val": "*"
   },
   {
    "attr": "province",
    "val": "*"
   },
   {
    "attr": "provider",
    "val": "*"
   },
   {
    "attr": "domain",
    "val": "download.huya.com"
   },
   {
    "attr": "method",
    "val": "*"
   }
   ],
   "nleaf": 119,
   "change": 0.3180687806279939,
   "score": 0.14436007709620113
  }
  ]
 }
 ]
}
```

23.4.9.12. Correlation analysis functions

You can use a correlation analysis function to find the metrics that are correlated with a specified metric or time series data among multiple observed metrics in the system.

Functions

Function	Description
ts_association_analysis	Quickly finds the metrics that are correlated with a specified metric among multiple observed metrics in the system.
ts_similar	Quickly finds the metrics that are correlated with specified time series data among multiple observed metrics in the system.

ts_association_analysis

Syntax

```
select ts_association_analysis(stamp, params, names, indexName, threshold)
```

The following table lists the parameters of the function.

Parameter	Description	Value
stamp	The Unix timestamp of the LONG data type.	-
params	The metrics to be analyzed, formatted in an array where each element is of the DOUBLE data type.	The parameter value is formatted in an array where each element is of the DOUBLE data type. For example, Latency, QPS, and NetFlow.
names	The names of the metrics to be analyzed.	The parameter value is formatted in an array where each element is of the VARCHAR data type. For example, Latency, QPS, and NetFlow.
indexName	The name of the target metric.	The parameter value is of the VARCHAR data type, for example, Latency.
threshold	The threshold of correlation between the metrics to be analyzed and the target metric.	The parameter value is of the DOUBLE data type. Valid values: [0, 1].

Response

- name: the name of the metric that meets the specified correlation condition with the target metric.
- score: the value of correlation between the returned metric and the target metric. Valid values: [0, 1].

Sample statement

```
* | select ts_association_analysis(
        time,
        array[inflow, outflow, latency, status],
        array['inflow', 'outflow', 'latency', 'status'],
        'latency',
        0.1) from log;
```

Sample response

```
| results          |
| ---------------------- |
| ['latency', '1.0']   |
| ['outflow', '0.6265'] |
| ['status', '0.2270'] |
```

ts_similar

Syntax 1

```
select ts_similar(stamp, value, ts, ds)
select ts_similar(stamp, value, ts, ds, metricType)
```

The following table lists the parameters of the function.

Parameter	Description	Value
stamp	The Unix timestamp of the LONG data type.	-
value	The value of the metric to be analyzed. The parameter value is of the DOUBLE data type.	-
ts	The time sequence of the specified time series curve. The parameter value is formatted in an array where each element is of the DOUBLE data type.	-
ds	The sequence of numeric data of the specified time series curve.	-
metricType	The type of correlation between the measured curves. The parameter value is of the VARCHAR data type.	Valid values: SHAPE, RMSE, PEARSON, SPEARMAN, R2, and KENDALL

Syntax 2

```
select ts_similar(stamp, value, startStamp, endStamp, step, ds)
select ts_similar(stamp, value, startStamp, endStamp, step, ds, metricType )
```

The following table lists the parameters of the function.

Parameter	Description	Value
stamp	The Unix timestamp of the LONG data type.	-
value	The value of the metric to be analyzed. This parameter is of the DOUBLE data type.	-
startStamp	The start timestamp of the specified time series curve. The parameter value is of the LONG data type.	-
endStamp	The end timestamp of the specified time series curve. The parameter value is of the LONG data type.	-
step	The time interval between two adjacent data points in a time series. The parameter value is of the LONG data type.	-
ds	The sequence of numeric data of the specified time series curve. The parameter is formatted in an array where each element is of the DOUBLE data type.	-

Parameter	Description	Value
metricType	The type of correlation between the measured curves. The parameter value is of the VARCHAR data type.	Valid values: SHAPE, RMSE, PEARSON, SPEARMAN, R2, and KENDALL

- Response

  score: the correlation between the analyzed metric and the specified time series curve. Valid values: [-1, 1].

- Sample statement

```
* | select vhost, metric, ts_similar(time, value, 1560911040, 1560911065, 5, array[5.1,4.0,3.3,5.6,4.0,7.2], 'PEARSON') fro
m log group by vhost, metric;
```

- Sample response

```
| vhost | metric       | score              |
| ------ | ------------- | ------------------- |
| vhost1 | redolog      | -0.3519082537204182 |
| vhost1 | kv_qps       | -0.15922168009772697 |
| vhost1 | file_meta_write | NaN              |
```

23.4.9.13. Kernel density estimation function

Kernel density estimation (KDE) is a non-parametric way to estimate the probability density function of a random variable.

The Kernel density estimation function uses the smooth peak function to fit the observed data points. In this way, the function simulates the real probability distribution curve.

- Syntax

```
select kernel_density_estimation(bigint stamp, double value, varchar kernelType)
```

- Parameters

Parameter	Description
stamp	The Unix timestamp of observed data. Unit: second.
value	The observed value.
kernelType	○ box: rectangle window. ○ epanechniov: Epanechnikov curve. ○ gausener: Gaussian curve.

- Response

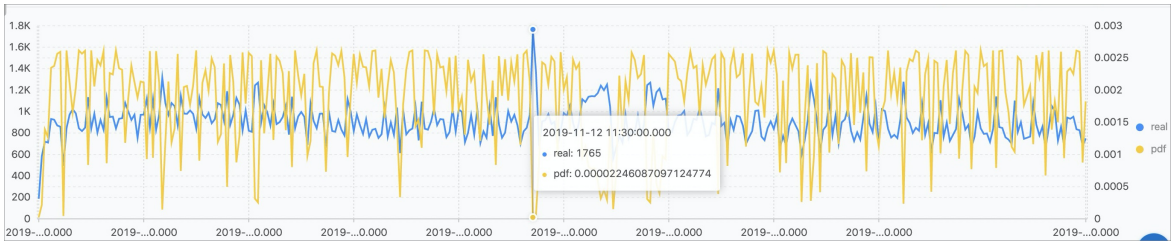
Display item	Description
unixtime	The Unix timestamp of observed data.
real	The observed value.
pdf	The probability of each observed data point.

- Example

- Sample statement

```
* |
select
  date_trunc('second', cast(t1[1] as bigint)) as time, t1[2] as real, t1[3] as pdf from (
    select kernel_density_estimation(time, num, 'gaussian') as res from (
      select __time__ - __time__ % 10 as time, COUNT(*) * 1.0 as num from log group by time order by time)
    ), unnest(res) as t(t1)  limit 1000
```

- Response



23.4.10. Advanced analysis

23.4.10.1. Optimize queries

This topic describes how to optimize queries to improve query efficiency.

You can use the following methods to optimize queries:

- Increase the number of shards.
- Reduce the query time range and data volume.
- Repeat queries multiple times.
- Optimize the SQL statement for queries.

Increase the number of shards

More shards represent more computing resources and faster computing speed. You can increase the number of shards to ensure that the average number of log entries to be scanned in each shard does not exceed 50 million. You can increase the number of shards by splitting shards. For more information, see Split a shard.

> **Note** Splitting shards incurs more fees and only accelerates queries of new data. Existing data is still stored in old shards.

Reduce the query time range and data volume

- The larger the time range, the slower the query. If you query data within a year or a month, data is computed by day. To facilitate computing, you can reduce the query time range.
- The larger the data volume, the slower the query. Reduce the amount of data to be queried as much as possible.

Repeat queries multiple times

If you find that the result of a query is inaccurate, you can repeat the query multiple times. The underlying acceleration mechanism ensures that each query uses the previous query result to analyze data. In this way, multiple queries make the query result more accurate.

Optimize the SQL statement for queries

A time-consuming query statement has the following characteristics:

- Performs the GROUP BY operation on string-type columns.
- Performs the GROUP BY operation on more than five fields.
- Includes operations that generates strings.

You can use the following methods to optimize a query statement:

- Avoid operations that generate strings if possible.
  - If you use the date_format function to generate a formatted timestamp, the query is inefficient.

    ```
    * | select date_format(from_unixtime(__time__) , '%H_%i') as t, count(1) group by t
    ```

  - If you use the substr() function, strings are generated. We recommend that you use the date_trunc or time_series function in a query statement.
- Avoid performing the GROUP BY operation on string-formatted columns if possible.

  Performing the GROUP BY operation on strings may result in a large number of hash calculations, which account for more than 50% of total calculations. Examples:

  ```
  * | select count(1) as pv , date_trunc('hour',__time__) as time group by time
  * | select count(1) as pv , from_unixtime(__time__-__time__%3600) as time group by __time__-__time__%3600
  ```

  Both query 1 and query 2 count the number of log entries per hour. However, query 1 converts the time into a string, for example, 2017-12-12 00:00:00, and then performs the GROUP BY operation on this string. Query 2 calculates the on-the-hour time value, performs the GROUP BY operation on the result, and then converts the value into a string. Query 1 is less efficient than query 2 because query 1 needs to hash strings.
- List fields alphabetically based on the initial letter when performing the GROUP BY operation on multiple columns.

  For example, you need to query 100 million users who are from 13 provinces.

  ```
  Fast: * | select province,uid,count(1)groupby province,uid
  Slow: * | select province,uid,count(1)groupby uid,province
  ```

- Use estimating functions.

  Estimating functions provide stronger performance than accurate calculation. In estimation, accuracy is compromised to an acceptable extent for fast calculation.

  ```
  Fast: * |select approx_distinct(ip)
  Slow: * | select count(distinct(ip))
  ```

- Specify only required columns in the SQL statement if possible.

  You can specify all columns in the search statement. In the SQL statement, specify only required columns if possible. This will speed up calculation.

  ```
  Fast: * |select a,b c
  Slow: * |select *
  ```

- Place columns that do not need to be grouped in an aggregate function if possible.

  For example, a user ID is associated with a username. Therefore, you can execute the Group By operation on user IDs to analyze data.

  ```
  Fast: * | select userid, arbitrary(username), count(1)groupby userid
  Slow: * | select userid, username, count(1)groupby userid,username
  ```

- Avoid using the IN operator if possible.

  If possible, avoid using the IN clause in SQL statements. Instead, use the OR clause.

```
Fast: key : a or key :b or key:c | select count(1)
Slow: * | select count(1) where key in ('a','b')
```

23.4.10.2. Use cases

This topic provides some use cases of log data analysis.

Trigger an alert when the error rate exceeds 40% over the last 5 minutes

Calculate the percentage of 500 Internal Server Error every minute. An alert is triggered when the error rate exceeds 40% over the last 5 minutes.

```
status:500 | select __topic__, max_by(error_count,window_time)/1.0/sum(error_count) as error_ratio, sum(error_count) as total_error from (
select __topic__, count(*) as error_count , __time__ - __time__ % 300 as window_time from log group by __topic__, window_time
)
group by __topic__ having max_by(error_count,window_time)/1.0/sum(error_count) > 0.4 and sum(error_count) > 500 order by total_error desc limit 100
```

Calculate the amount of transferred data and configure alerts

Calculate the amount of transferred data every minute. An alert is triggered when transferred data plunges. Transferred data counted in the last minute does not cover a full minute. The `(max(time) - min(time))` clause is used for normalization to count the average traffic per minute.

```
* | SELECT SUM(inflow) / (max(__time__) - min(__time__)) as inflow_per_minute, date_trunc('minute',__time__) as minute group by minute
```

Calculate the average latency of traffic data in different sizes

Distribute traffic data to multiple bins based on the data size and calculate the average latency of the data in the bins.

```
* | select avg(latency) as latency , case when originSize < 5000 then 's1' when originSize < 20000 then 's2' when originSize < 500000 then 's3' when originSize < 100000000 then 's4' else 's5' end as os group by os
```

Retrieve the percentages of different results

List the number and the percentage of each result for different departments. This query includes subqueries and window functions. The `sum(c) over()` clause indicates the sum of values in all rows.

```
* | select department, c*1.0/ sum(c) over () from(select count(1) as c, department from log group by department)
```

Count the number of log entries that meet the query condition

To count the number of URLs based on their characteristics, you can use the CASE WHEN clause or the COUNT_IF clause. The latter clause is simpler.

```
* | select count_if(uri like '%login') as login_num, count_if(uri like '%register') as register_num, date_format(date_trunc('minute', __time__), '%m-%d %H:%i') as time group by time order by time limit 100
```

23.4.10.3. Time field conversion examples

During search and analytics, you often need to process time fields in log data, such as converting a timestamp to another time format. This topic uses some examples to describe how to convert time fields.

A log entry may include multiple time fields, for example:

- `__time__`: the time that you specify when you use the API or SDK to write log data. This field can be used for log data shipping, search, and analytics.
- Original time field in log data: the field that records the time when the log data is generated. This field is in raw logs.

Time fields in different formats are difficult to read. To simplify the read process, you can convert the time format during search and analytics. For example, you can perform the following conversions:

1. Convert __time__ to a timestamp
2. Display __time__ in a specified format
3. Convert a timestamp to a specified format

Convert __time__ to a timestamp

You can use the from_unixtime function to convert the `__time__` field to a timestamp.

```
* | select from_unixtime(__time__)
```

Display __time__ in a specified format

To display the `__time__` field in the format of `YYYY-MM-DD HH:MM:SS`, you can use the date_format function.

```
* | select date_format(__time__, '%Y-%m-%d %H:%i:%S')
```

Convert the time in a log to a specified format

To convert the time field in a log to the specified format (`YYYY-MM-DD HH:MM:SS`) and perform the GROUP BY operation on the `YYYY-MM-DD` part, you can use the date_format function.

- Sample log entry

```
__topic__:
body_byte_sent: 307
hostname: www.host1.com
http_user_agent: Mozilla/5.0 (iPhone; CPU iPhone OS 10_3_3 like Mac OS X) AppleWebKit/603.3.8 (KHTML, like Gecko) Mobile/14G60 QQ/7.1.8.452 V1_IPH_SQ_7.1.8_1_APP_A Pixel/750 Core/UIWebView NetType/WIFI QBWebViewType/1
method: GET
referer: www.host0.com
remote_addr: 36.63.1.23

```

- Example SQL statement

```
* | select date_format (date_parse(time,'%Y-%m-%d %H:%i:%S'), '%Y-%m-%d') as day, count(1) as uv group by day order by day asc
```

23.4.11. Visual analysis

23.4.11.1. Analysis graph

23.4.11.1.1. Overview

All search and analytics results can be rendered by using visualized charts.

Prerequisites

- The index feature is enabled and configured. The analytics switches are turned on. For more information, see Enable the index feature and configure indexes for a Logstore.
- An analytic statement is included in a query statement. You cannot use charts to show query results if you do not include an analytic statement in your query statement.

Precautions

When multiple search and analytic statements are being executed in sequence, the **Value Column**, **X Axis**, or **Y Axis** information cannot automatically change based on the search and analytic statement. The X and Y axis information may remain the same as the last search and analytic statement. If this happens, the query results of the current search and analytic statement cannot be automatically displayed in a chart. If the following messages are returned, configure parameters on the **Properties** tab based on the current search and analytic statement:

- The currently selected dimensions are not in the queried results. Check and configure the attributes.
- X-Axis or Y-Axis is not available. Check and configure the attributes.

Chart configurations

On the **Graph** tab, various charts are provided to show query results. You can select a type of chart from the chart bar to show results.

- On the **Graph** tab, you can view the **Chart Preview** and **Data Preview** of query results of the current search and analytic statement. **Chart Preview** is the preview of the query results that are displayed in the specified type of chart. **Data Preview** displays the query results in a table.
- On the **Graph** tab on the right, you can configure the following chart properties:
  - **Data Source**: used to set placeholder variables. For example, you configure the drill-down event of Chart A to redirect to the dashboard where Chart B is located. The placeholder variable you configured for Chart B is the same as the variable that you click to trigger the drill-down event. Then the placeholder variable is replaced with the variable you click to trigger the drill-down event and the search and analytic statement of Chart B is executed. For more information, see Drill-down analysis.

    This feature is applicable to scenarios where you configure drill-down events to redirect to targeted dashboards.
  - **Properties**: used to configure the display properties of a chart, including the X axis, left and right Y axes, margins, font size and other properties. The properties vary with different type of charts.

    This feature is applicable to all search and analytics scenarios.
  - **Interactive Behavior**: used to configure drill-down events for a chart. After you configure a drill-down event for the chart, you can click the variable value in the chart to trigger the specified drill-down event. For more information, see Drill-down analysis.

    This feature is applicable to triggering drill-down events for charts.

23.4.11.1.2. Display query results on a table

Tables are used to sort and display data for quick reference and analysis. All query results that match specified query statements can be rendered into visualized charts. By default, the query results are displayed in a table.

Components

- Table header
- Row
- Column

Where:

- The number of columns can be specified by using a `SELECT` statement.
- The number of rows is calculated based on the number of log entries in a specified time range. The default clause is `LIMIT 100`.

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, data is displayed in a table by default. You do not need to click the  icon.
3. On the **Properties** tab, configure the properties of the table.

Properties

Parameter	Description
Items per Page	The number of log entries to return on each page.
Zebra Striping	Specifies whether to display the query results in a zebra-striped table.
Transpose Rows and Columns	Specifies whether to transpose rows and columns.
Hide Reserved Fields	Specifies whether to hide reserved fields.
Disable Sorting	Specifies whether to disable the sorting feature.
Disable Search	Specifies whether to disable the search feature.
Highlight Settings	The rules for highlighting rows or columns that conform to specified rules.

23.4.11.1.3. Display query results on a line chart

A line chart is used to analyze the value changes of fields based on an ordered data type. In most cases, this analysis is based on a specified time range.

You can use a line chart to analyze the following change characteristics of field values over a specified period:

- Increment or decrement
- Increment or decrement rate
- Increment or decrement pattern, for example, periodicity
- Peak value and trough value

Line charts are used to analyze field value changes over a time period. You can also use a line chart to analyze the value changes of multiple fields in multiple lines over the same time period. Then, you can analyze the relationships between the different fields. For example, the values of multiple fields can display positive, negative, or inverse trends.

Components

- X-axis
- Left Y-axis
- Right Y-axis (optional)
- Data point
- Line of trend change

- Legend

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the line chart.

> **Note** In a line chart, each line must contain more than two data points. Otherwise, the data trend cannot be analyzed. We recommend that you select five or fewer lines in a line chart.

Properties

Parameter	Description
X Axis	The sequential data. In most cases, time series is selected.
Left Y Axis	The numeric data. You can select one or more fields for the left Y-axis.
Right Y Axis	The numeric data. You can select one or more fields for the right Y-axis. The layer of the right Y-axis is higher than that of the left Y-axis.
Column Marker	The column on the left or right Y-axis. The column is selected as a histogram.
Legend	The position where the legend is located in the chart. Valid values: Top, Bottom, Left, and Right.
Format Left Y-axis	The format in which data selected for the left Y-axis and right Y-axis is displayed.
Format Right Y-axis	
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

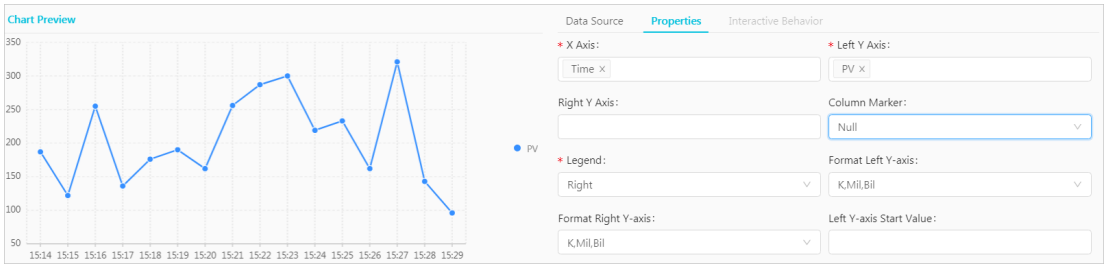
Example of a line chart

To query the page views (PVs) of the IP address `10.0.192.0` in the last 24 hours, execute the following query statement:

```
remote_addr: 10.0.192.0 | select date_format(date_trunc('hour', __time__), '%m-%d %H:%i')
as time, count(1) as PV group by time order by time limit 1000
```

Select `time` for the X-axis, `PV` for the left Y-axis, and Bottom for Legend. Adjust the margins based on your business requirements.

Line chart



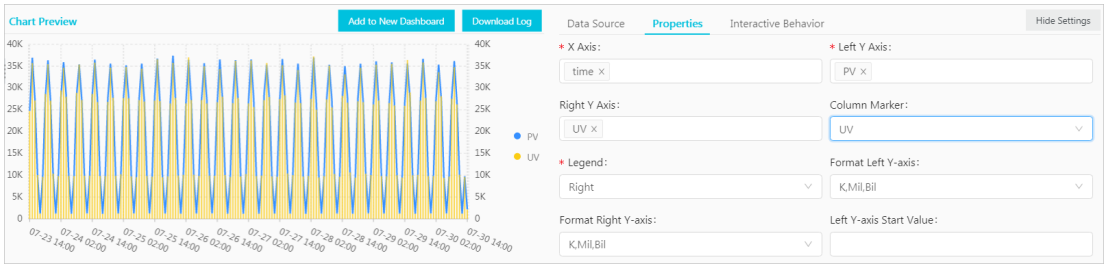
Example of a dual Y-axis line chart

To query the PVs and unique visitors (UVs) in the last 24 hours, execute the following query statement:

```
* | select date_format(date_trunc('hour', __time__), '%m-%d %H:%i') as time, count(1) as PV, approx_distinct(remote_addr) as UV group by time order by time limit 1000
```

Select `time` for the X-axis, `PV` for the left Y-axis, `UV` for the right Y-axis, and `PV` for Column Marker.

Dual Y-axis line chart



23.4.11.1.4. Display query results on a column chart

A column chart uses vertical or horizontal bars to present categorical values. Compared with a line chart, a column chart does not display ordered data, but provides a method to count the number of values in each category.

Components

- X-axis (horizontal)
- Y-axis (vertical)
- Rectangular bar
- Legend

By default, column charts in Log Service use vertical bars. Each rectangular bar has a fixed width and a variable height that indicates a value. You can use a grouped column chart to display the data if multiple columns of data are mapped to the Y-axis.

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the column chart.

> **Note** Column charts can be used to display query results if the number of returned log entries is less than 20. You can use a `LIMIT` clause to control the number of rectangular bars. Analysis results may not be clearly displayed if the chart contains a large number of rectangular bars. In addition, we recommend that you select less than five fields for the Y-axis.

Properties

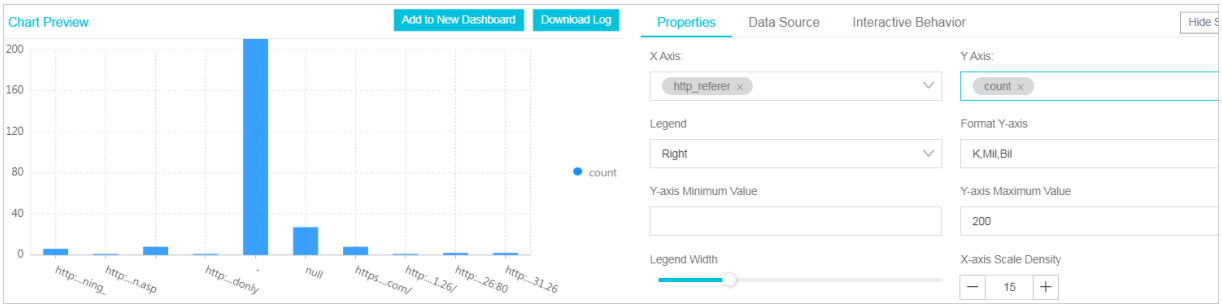
Parameter	Description
X Axis	The categorical data.
Y Axis	The numeric data. You can select one or more fields for the Y-axis.
Legend	The position where the legend is located in the chart. Valid values: Top, Bottom, Left, and Right.
Format	The format in which data is displayed on the Y-axis.
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

Example of a simple column chart

To query the number of visits for each `http_referer` in the specified time range, execute the following query statement:

```
* | select  http_referer, count(1) as count group by http_referer
```

Select `http_referer` for X-axis and `count` for Y-axis.

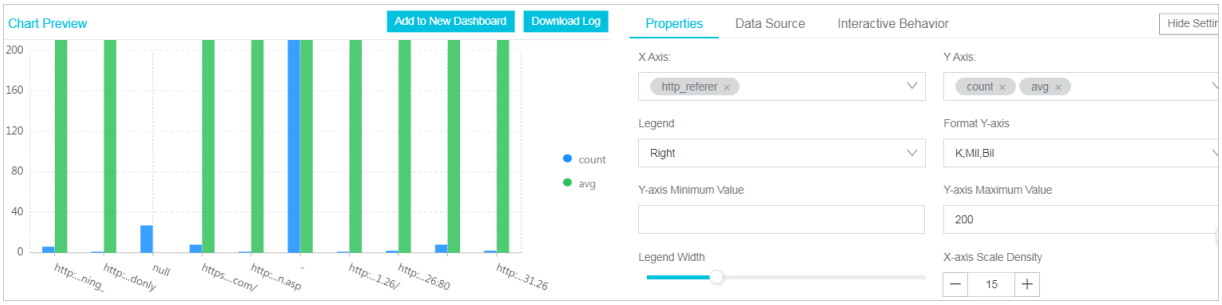


Example of a grouped column chart

To query the number of requests and the average bytes for each `http_referer` in the specified time range, execute the following statement:

```
* | select  http_referer, count(1) as count, avg(body_bytes_sent) as avg group by http_referer
```

Select `http_referer` for X-axis. Select `count` and `avg` for Y-axis.



23.4.11.1.5. Display query results on a bar chart

A bar chart is a horizontal column chart that is used to analyze the top N values of fields. A bar chart is configured in a similar way to a column chart.

Components

- X-axis (vertical)
- Y-axis (horizontal)
- Rectangular bar
- Legend

Each rectangular bar has a fixed height and a variable width. The variable width indicates a value. You can use a grouped bar chart to display the data if multiple columns of data are mapped to the Y-axis.

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, click the  icon.
3. On the **Properties** tab, configure the properties of the bar chart.

> **Note**
>
> - Bar charts can be used to display query results if 20 or fewer log entries are returned. You can use the `LIMIT` clause to control the number of rectangular bars. Analysis results may not be clearly displayed if the chart contains a large number of rectangular bars. You can use the `ORDER BY` clause to analyze the top N values of fields. We recommend that you map less than five columns of data to the Y-axis.
> - You can use a grouped bar chart to display query results. However, the values represented by each rectangular bar in a group must be positively or negatively associated with each other.

Properties

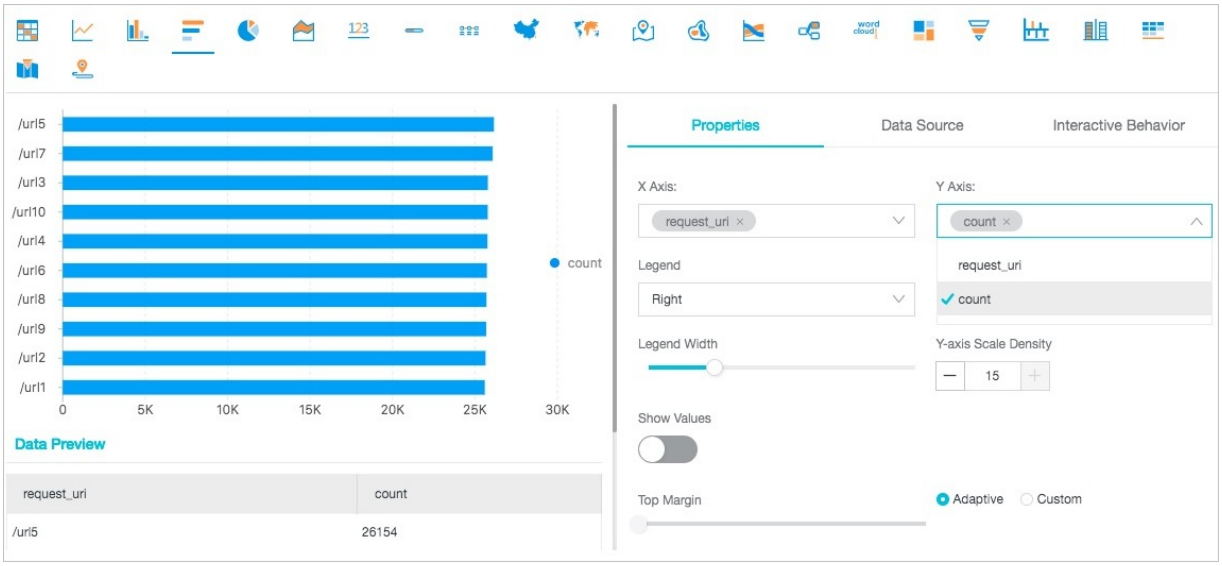
Parameters

Parameter	Description
X Axis	The categorical data.
Y Axis	The numeric data. You can select one or more fields for the Y-axis.
Legend	The position where the legend is located in the chart. Valid values: Top, Bottom, Left, and Right.
Format X-axis	The format in which data is displayed on the X-axis.
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

Examples

To analyze the top 10 visited request URIs (`request_uri`), execute the following query statement:

```
* | select  request_uri, count(1) as count group by request_uri order by count desc limit 10
```



23.4.11.1.6. Display query results on a pie chart

A pie chart is used to indicate the percentages of different data types and compare different data types based on the arc length of each slice.

Components

- Segment
- Percentage in the text format
- Legend

Types

Log Service provides three types of pie charts: a standard pie chart, donut chart, and polar area chart.

- Standard pie chart

  A standard pie chart is divided into multiple segments based on the percentages of various field values. The entire chart displays all field values. Each segment displays the percentage and the numeric value of a field. The sum of percentages from all segments is equal to 100%.

- Donut chart

  A donut chart is a standard pie chart with a hollow center. A donut chart has the following benefits:

  - In addition to the information that a standard pie chart displays, a donut chart displays the total number of occurrences of all field values.
  - You can view the differences between the number of occurrences of the same value in two charts based on the ring length. This is more intuitive than comparing two standard pie charts.

- Polar area chart

  A polar area chart is a column chart in the polar coordinate system. Each category of field values is represented by a segment with the same radian. The radius of a segment indicates the number of occurrences of a field value. Compared with a standard pie chart, a polar area chart has the following benefits:

  - Standard pie charts are suitable to display query results if 10 or fewer log entries are returned. Polar area charts are suitable for displaying query results if the number of returned log entries ranges from 10 to 30.
  - The area is the square of a radius. Therefore, the display of the polar area chart enlarges the differences among multiple types of data. This is best suited for a comparison of similar values.
  - A circle can be used to display a periodic pattern. Therefore, you can use a polar area chart to analyze value change characteristics in specified periods, such as weeks and months.

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, click the  icon.
3. On the **Properties** tab, configure the properties of the pie chart.

> **Note**
> - Donut charts and standard pie charts can be used to display query results if less than 10 log entries are returned. You can use a `LIMIT` clause to control the number of segments. Analysis results may not be clearly displayed if the chart contains a large number of segments of different colors.
> - We recommend that you use a polar area chart or column chart if the number of returned log entries exceeds 10.

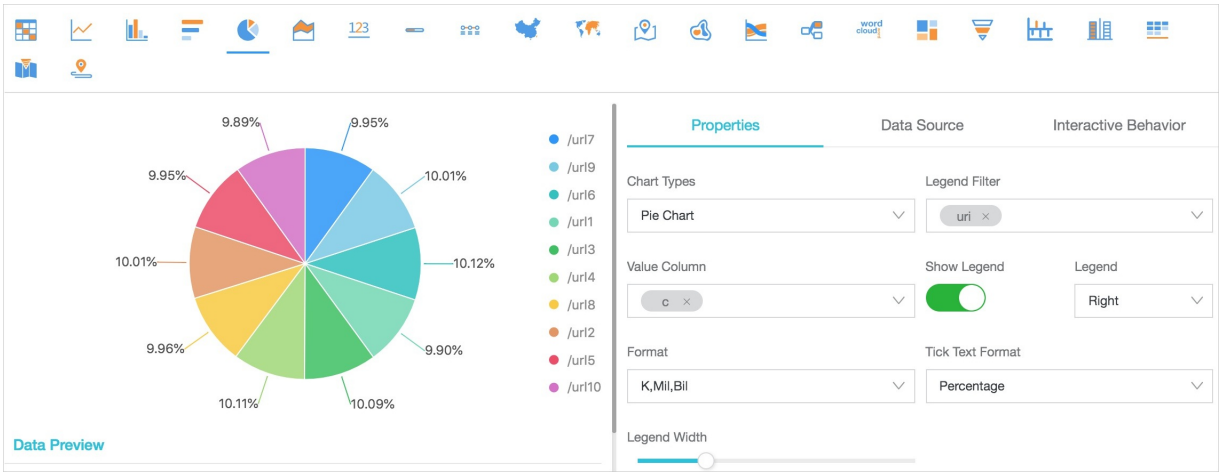
Properties

Parameter	Description
Chart Types	The type of the chart. Valid values: Pie Chart, Donut Chart, and Polar Area Chart. Default value: Pie Chart.
Legend Filter	The categorical data.
Value Column	The values that correspond to different types of data.
Show Legend	Specifies whether to show the legend.
Legend	The position where the legend is located in the chart. Valid values: Top, Bottom, Left, and Right. You can configure this parameter only after you turn on the Show Legend switch.
Format	The format in which data is displayed.
Tick Text Format	The format of the tick.
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

Example of a standard pie chart

To analyze the percentages of the `request_uri` field values, execute the following query statement:

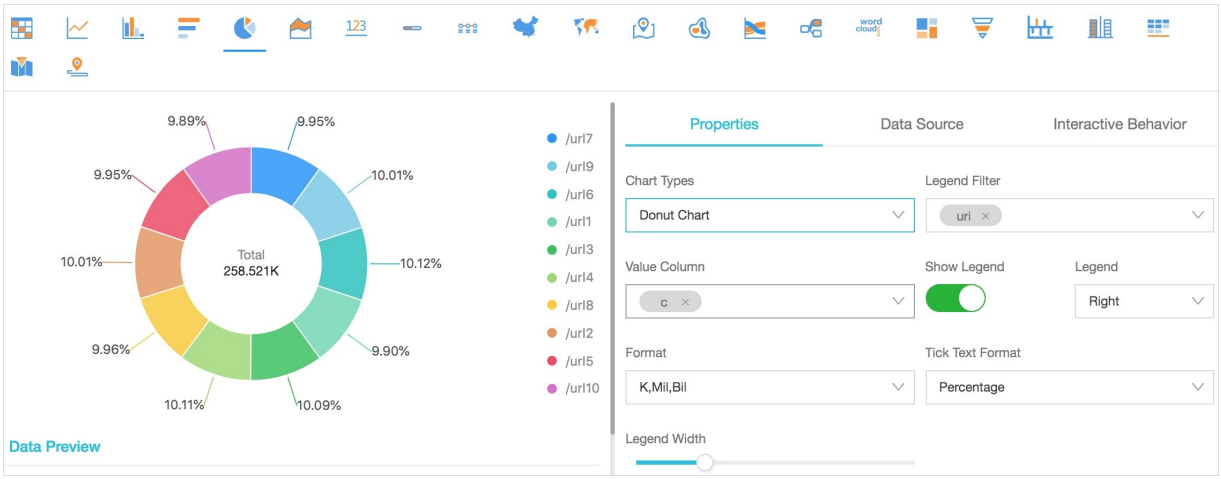
```
* | select requestURI as uri , count(1) as c group by uri limit 10
```



Example of a donut chart

To analyze the percentages of the `request_uri` field values, execute the following query statement:

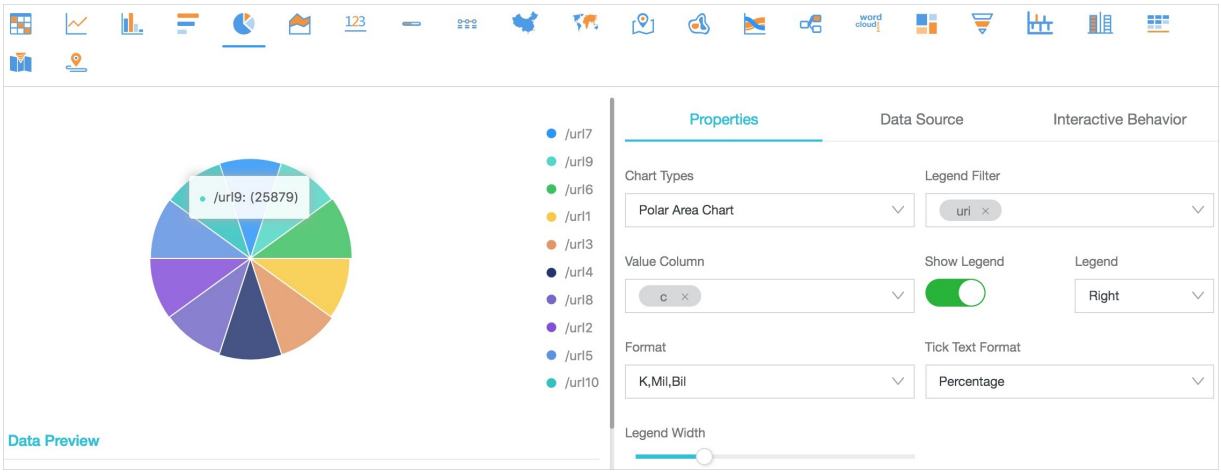
```
* | select requestURI as uri , count(1) as c group by uri limit 10
```



Example of a polar area chart

To analyze the percentages of the `request_uri` field values, execute the following query statement:

```
* | select requestURI as uri , count(1) as c group by uri limit 10
```



23.4.11.1.7. Display query results on an area chart

An area chart is built based on a line chart. The colored section between a line and the axis is an area. The color is used to highlight the trend. Similar to a line chart, an area chart shows the numeric value changes over a specified time period to highlight the overall data trend. Both the line chart and the area chart display the trend and relationship between numeric values instead of displaying specific values.

Components

- X-axis (horizontal)
- Y-axis (vertical)
- Area segment

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the area chart.

> **Note** In an area chart, a single area segment must contain more than two data points. Otherwise, the data trend cannot be analyzed. We recommend that you select five or fewer area segments in an area chart.

Properties

Parameter	Description
X Axis	The sequential data. In most cases, time series is selected.
Y Axis	The numeric data. You can select one or more fields for the Y-axis.
Legend	The position where the legend is located in the chart. Valid values: Top, Bottom, Left, and Right.
Format	The format in which data is displayed.

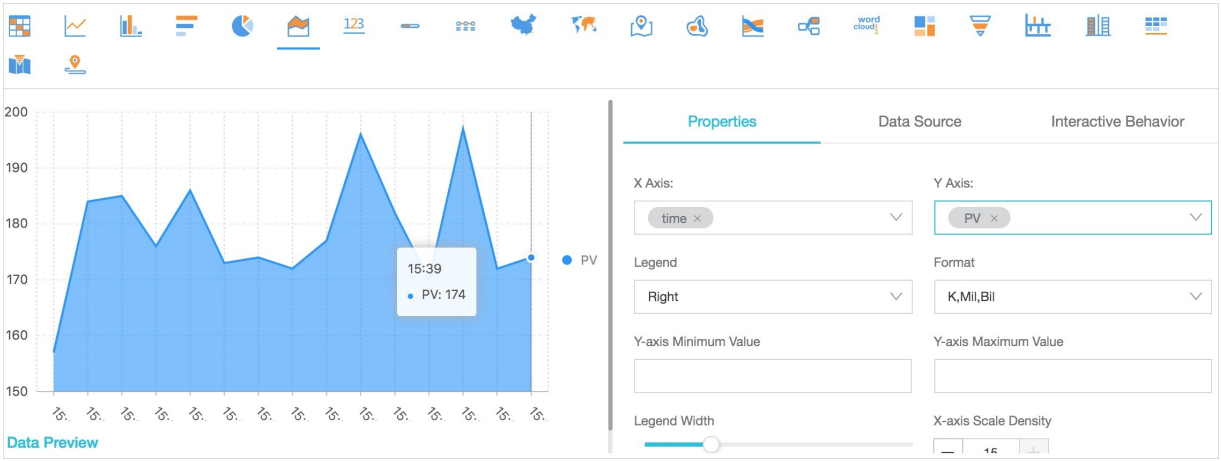
Parameter	Description
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

Example of a simple area chart

To query the page views (PVs) of the IP address `10.0.192.0` in the last 24 hours, execute the following query statement:

```
remote_addr: 10.0.192.0 | select date_format(date_trunc('hour', __time__), '%m-%d %H:%i') as time, count(1) as PV group by time order by time limit 1000
```

Select `time` for the X-axis and `PV` for the Y-axis.



Example of a cascade chart

```
* | select date_format(date_trunc('hour', __time__), '%m-%d %H:%i') as time, count(1) as PV, approx_distinct(remote_addr) as UV group by time order by time limit 1000
```

Select `time` for the X-axis. Select `PV` and `UV` for the Y-axis.

23.4.11.1.8. Display query results on a single value chart

A single value chart displays a single value.

Single value charts have the following types:

- Rectangle Frame: shows a general value.
- Dial: shows the difference between the current value and the specified threshold value.
- Compare Numb Chart: shows the SQL query results of interval-valued comparison and periodicity-valued comparison functions. For more information about the analytic syntax, see Interval-valued comparison and periodicity-valued comparison functions.

Rectangle Frame is selected by default. A rectangle frame is the most basic method to display data at a specified point. In most cases, it is used to show the key information at a specified point in time. To display a proportional metric, you can select Dial.

Components

- Numeric value
- Chart type

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, click the 123 icon.
3. On the **Properties** tab, configure the properties of the single value chart.

> **Note** Log Service normalizes data in numeric value-based charts. For example, `230000` is normalized to `230K`. You can include Mathematical calculation functions in query statements to customize numeric formats.

Properties

- The following table lists the parameters of a rectangle frame.

Parameter	Description
Chart Types	The type of the chart. Select Rectangle Frame.
Value Column	The value displayed in the chart. By default, data in the first row of the specified column is displayed.
Unit	The unit of data.
Unit Font Size	The font size of the unit. You can drag the slider to adjust the font size. Valid values: 10 to 100. Unit: pixels.
Description	The description of the value.
Description Font Size	The font size of the value description. You can drag the slider to adjust the font size. Valid values: 10 to 100. Unit: pixels.
Format	The format in which data is displayed.
Font Size	The font size of the value. You can drag the slider to adjust the font size. Valid values: 10 to 100. Unit: pixels.
Font Color	The color of the value, unit, and description in the chart. You can use the default color or select a color.

Parameter	Description
Background Color	The color of the background. You can use the default color or select another color.

- The following table describes the parameters of a dial.

Parameter	Description
Chart Types	The type of the chart. Select **Dial** to display query results on a dial.
Actual Value	The actual value in the chart. By default, data in the first row of the specified column is displayed.
Unit	The unit of the value on the dial.
Font Size	The font size of the value and unit. Valid values: 10 to 100. Unit: pixels.
Description	The description of the value.
Description Font Size	The font size of the value description. You can drag the slider to adjust the font size. Valid values: 10 to 100. Unit: pixels.
Dial Maximum	The maximum value of the scale in the dial. Default value: 100.
Maximum Value Column	The maximum value in the specified column. If you turn on the Use Query Results switch, **Dial Maximum** is replaced by Maximum Value Column. Then, you can select the maximum value from query results for this parameter.
Use Query Results	If you turn on the Use Query Results switch, Dial Maximum is replaced by Maximum Value Column. Then, you can select the maximum value from query results for this parameter.
Format	The format in which data is displayed.
Colored Regions	The number of segments that divide the dial. Each segment is displayed in a different color. Valid values: 2, 3, 4, and 5. Default value: 3.
Region Max Value	The maximum value of the scale in each colored segment of the dial. By default, the maximum value in the last segment is the maximum value on the dial. You do not need to specify this value. **Note** A dial is evenly divided into three colored segments by default. If you change the value of **Colored Regions**, Region Max Value is not automatically adjusted. You can manually set the maximum value for each colored segment based on your business requirements.
Font Color	The color of the value on the dial.
Region	The colored segments that divide the dial. A dial is evenly divided into three segments by default. The segments are displayed in blue, yellow, and red. If you set **Colored Regions** to a value greater than 3, the added segments are displayed in blue by default. You can change the color of each segment.

Parameter	Description
Show Title	Specifies whether to display the title of a dial when you add the dial to a dashboard. The **Show Title** feature can show or hide the title of the dial on the dashboard page. This switch is turned off by default. If you turn on the Show Title switch, the title of the dial is not displayed on the current page. You must create or modify a dashboard and view the title on the dashboard page.

- The following table lists the parameters of a compare numb chart.

Parameter	Description
Chart Types	The type of the single value chart. If you select Compare Numb Chart, query results are displayed on a compare numb chart.
Show Value	The value that is displayed in the center of the compare numb chart. In most cases, this value is set to the statistical result that is calculated by the related comparison function in the specified time range.
Compare Value	The value that is compared with the threshold. Set the value to the result of the comparison between the statistical results calculated by the related comparison function in the specified time range and the previously specified time range.
Font Size	The font size of the show value. Valid values: 10 to 100. Unit: pixels.
Unit	The unit of the show value.
Unit Font Size	The font size of the unit for the show value. Valid values: 10 to 100. Unit: pixels.
Compare Unit	The unit of the compare value.
Compare Font Size	The font size of the compare value and unit. Valid values: 10 to 100. Unit: pixels.
Description	The description of the show value and its growth trend.
Description Font Size	The font size of the description. Valid values: 10 to 100. Unit: pixels.
Trend Comparison Threshold	The value that is used to measure the variation trend of the compare value. For example, the compare value is -1. ◦ If you set **Trend Comparison Threshold** to 0, a down arrow that indicates a value decrease is displayed on the page. ◦ If you set **Trend Comparison Threshold** to -1, it indicates that the value remains unchanged. The system does not display the trend on the page. ◦ If you set **Trend Comparison Threshold** to -2, an up arrow that indicates a value increase is displayed on the page.
Format	The format in which data is displayed.
Font Color	The color of the show value and its description.
Growth Font Color	The font color of the compare value that is greater than the threshold.

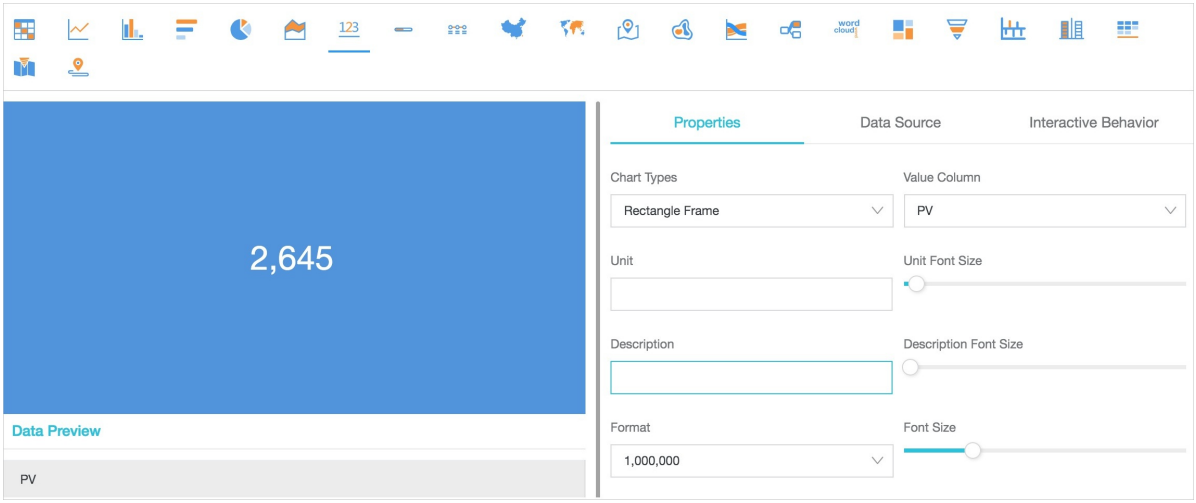
Parameter	Description
Growth Background Color	The background color displayed when the compare value is greater than the threshold.
Decrease Font Color	The font color displayed when the compare value is less than the threshold.
Decrease Background Color	The background color displayed when the compare value is less than the threshold.
Equal Background Color	The background color displayed when the compare value is equal to the threshold.

Examples

To view the number of access requests, execute the following query statements:

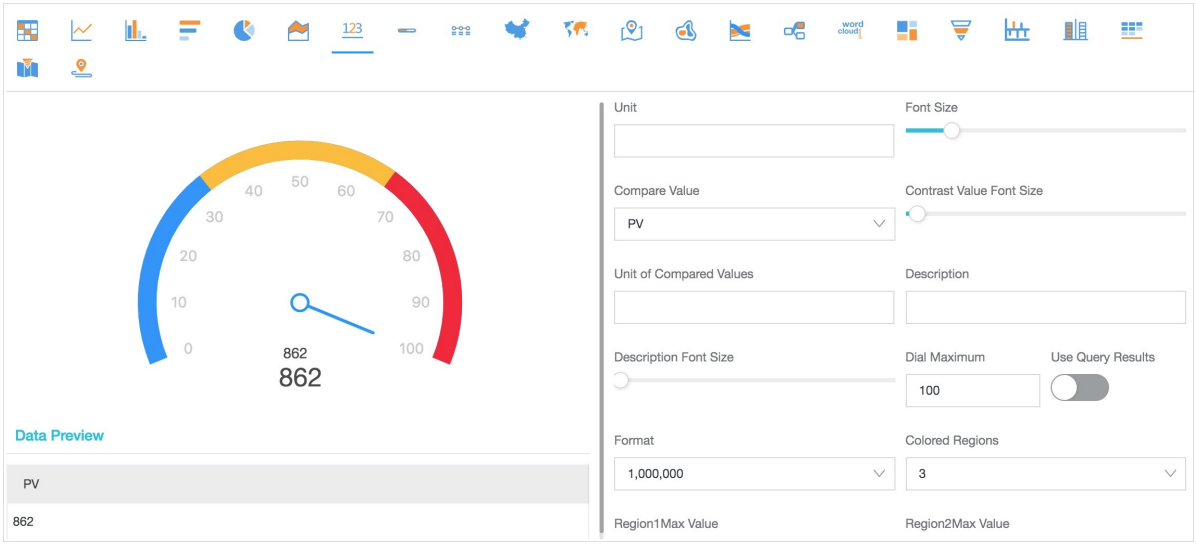
- Rectangle frame

```
* | select count(1) as pv
```



- Dial

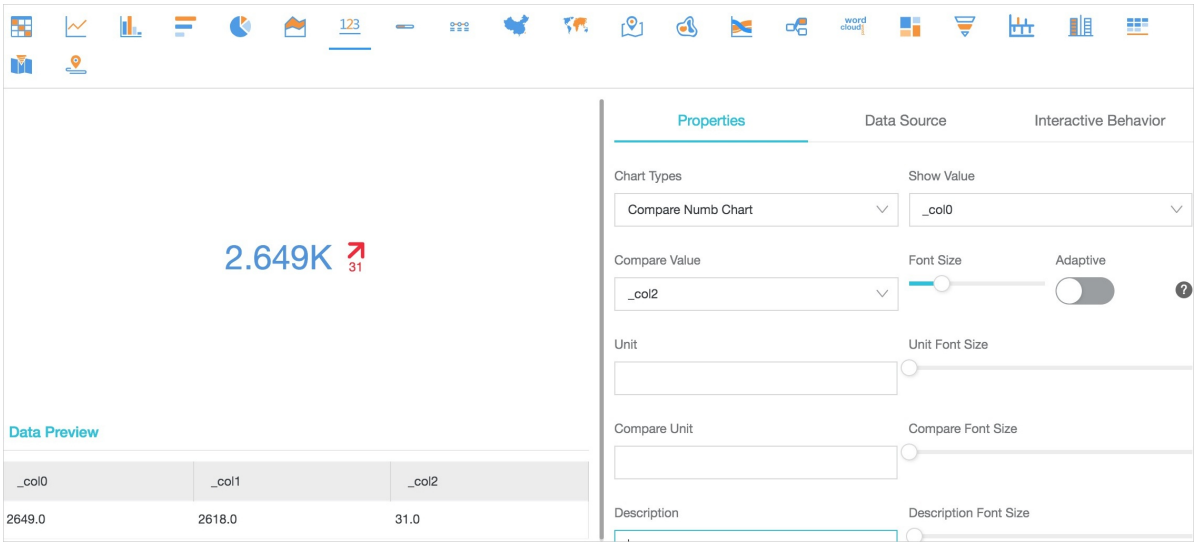
```
* | select count(1) as pv
```



- Compare numb chart

  To view and compare the access requests for today and yesterday, execute the following query statement:

```
* | select diff[1],diff[2], diff[1]-diff[2] from (select compare( pv , 86400) as diff from (select count(1) as pv from log))
```



23.4.11.1.9. Display query results on a progress bar

The progress bar shows the percentage of the actual value of a field to the maximum value of the field. You can configure the properties of the progress bar to adjust its style and set display rules.

Components

- Actual value
- Unit (optional)
- Total value

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, click to select the progress bar.
3. Configure the properties of the progress bar.

Properties

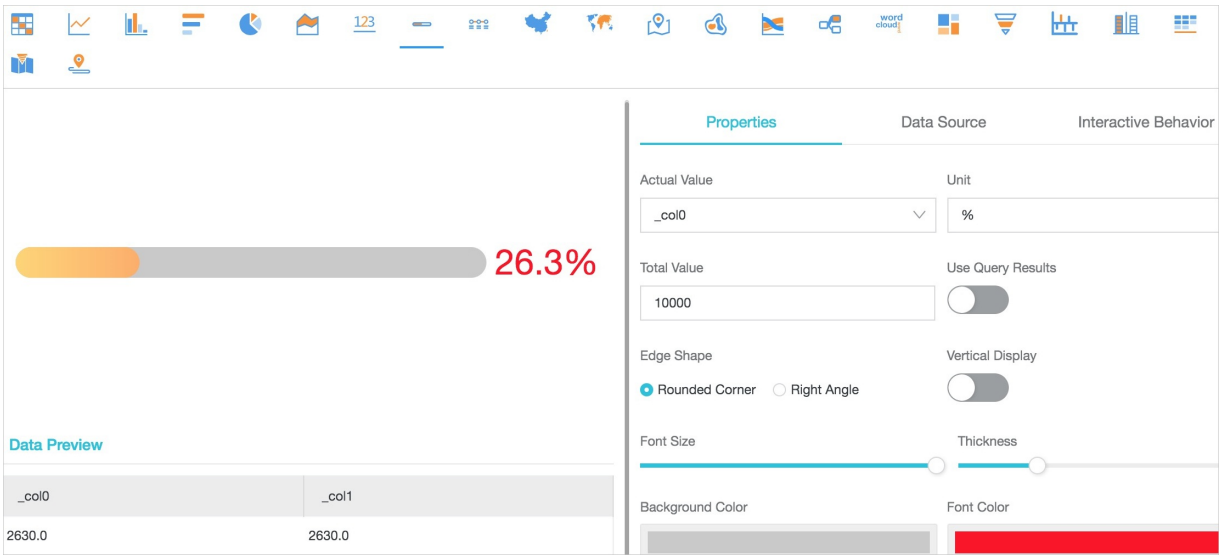
Parameter	Description
Actual Value	The actual value in the chart. By default, data in the first row of the specified column is displayed.
Unit	The unit of the value in the progress bar.
Total Value	The maximum value indicated by the progress bar. Default value: 100.

Parameter	Description
Maximum Value Column	The maximum value in the specified column. If you turn on the **Use Query Results** switch, **Total Value** is replaced by **Maximum Value Column**. Then, you can select the maximum value from the query results for this parameter.
Use Query Results	If you turn on the Use Query Results switch, Total Value is replaced by Maximum Value Column. Then, you can select the maximum value from the query results for this parameter.
Edge Shape	The edge shape of the progress bar.
Vertical Display	Specifies whether to display the progress bar in vertical display mode.
Font Size	The font size of the value in the progress bar.
Thickness	The thickness of the progress bar.
Background Color	The background color of the progress bar.
Font color	The font color of the value in the progress bar.
Default Color	The default color of the progress bar.
Color Display Mode	The display mode of the progress bar.
Start Color	The start color of the progress bar. This parameter is available if **Gradient** is selected for **Color Display Mode**.
End Color	The end color of the progress bar. This parameter is available if **Gradient** is selected for **Color Display Mode**.
Display Color	The display color of the progress bar. This parameter is available if **Display by Rule** is selected for **Color Display Mode**. **Note** The value of **Actual Value** is compared with that of **Threshold** based on the condition specified by **Operator**. If the actual value matches the condition specified by **Operator**, the progress bar is displayed in the color specified by Display Color. Otherwise, the progress bar is displayed in the default color.
Operator	The condition that is used to specify the color of the progress bar. This parameter is available if **Display by Rule** is selected for **Color Display Mode**.
Threshold	The threshold that is used to specify the color of the progress bar. This parameter is available if **Display by Rule** is selected for **Color Display Mode**.

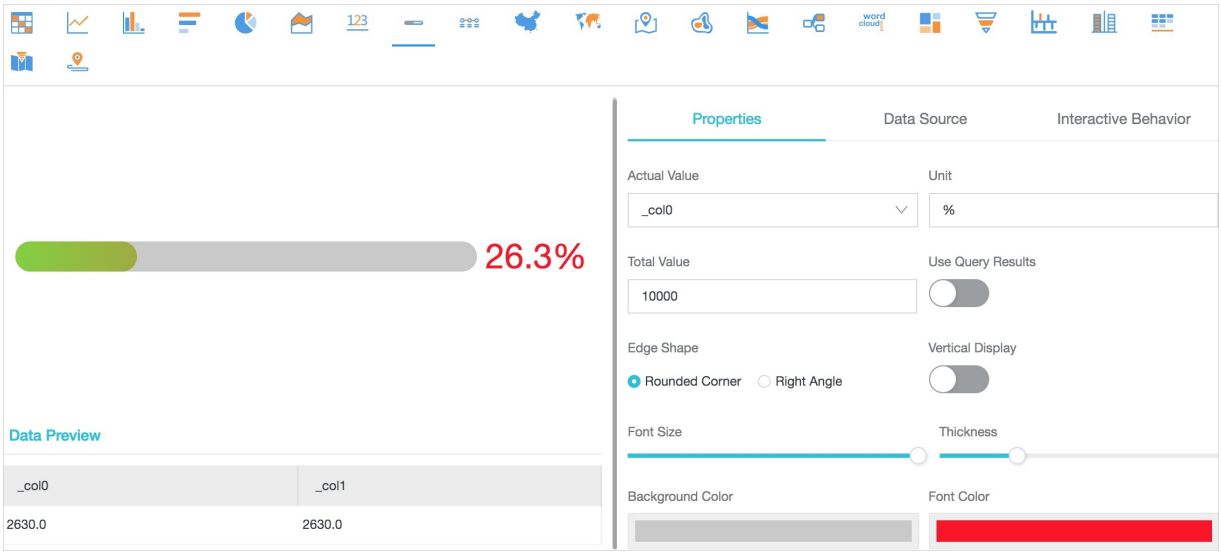
Examples

To view the percentage of a metric or the proportion of data, you can execute the following query statement:

```
* | select diff[1],diff[2] from (select compare( pv , 86400) as diff from (select count(1) as pv from log))
```



If you select **Display by Rule** for Color Display Mode, colors are dynamically displayed based on the specified rule. If the conditions of a rule are not matched, the default color is displayed.



23.4.11.1.10. Display query results on a map

You can color and mark a map to display geographic data. Log Service provides three types of maps: map of China, world map, and AMap. The display modes of an AMap include the anchor point and heat map. You can include specific functions in query statements to display analysis results as maps.

Components

- Map canvas
- Color area

Properties

Parameter	Description

Parameter	Description
Location information	The location information that is recorded in logs. The information is displayed in one of the following dimensions based on the map type: • Provinces (Map of China) • Country (World Map) • Longitude/Latitude (AMap)
Value Column	The data volume of the location information.

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
   - To display query results on a map of China, include the `ip_to_province` function in a query statement.
   - To display query results on a world map, include the `ip_to_country` function in a query statement.
   - To display query results on an AMap, include the `ip_to_geo` function in a query statement.
2. On the **Graph** tab, click the icon.
3. Configure the properties of the map.

Map of China

To display query results on a map of China, you can execute the following query statement that includes the `ip_to_province` function:

- SQL statement

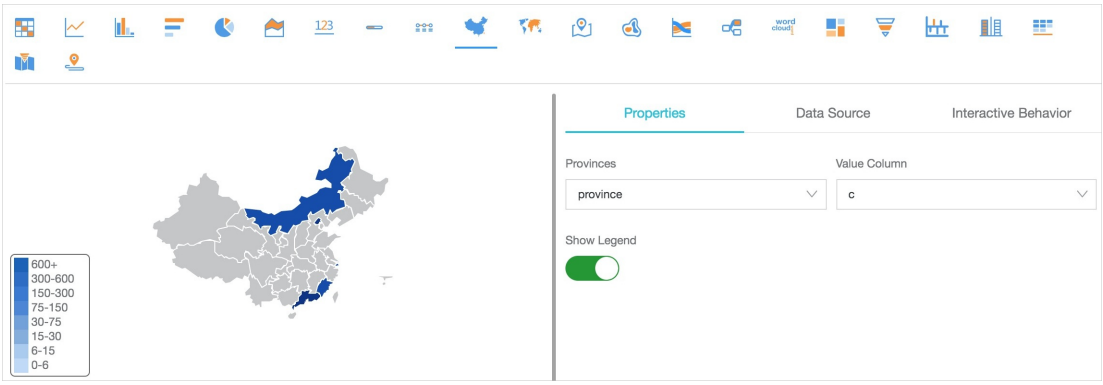
```
* | select ip_to_province(remote_addr) as address, count(1) as count group by address order by count desc limit 10
```

- Dataset

address	count
Guangdong	163
Zhejiang	110
Fujian	107
Beijing	89
Chongqing	28
Heilongjiang	19

Select address for *Provinces* and count for *Value Column*.

Map of China



World Map

To display query results in a world map, you can execute the following query statement that includes the `ip_to_country` function:

- SQL statement

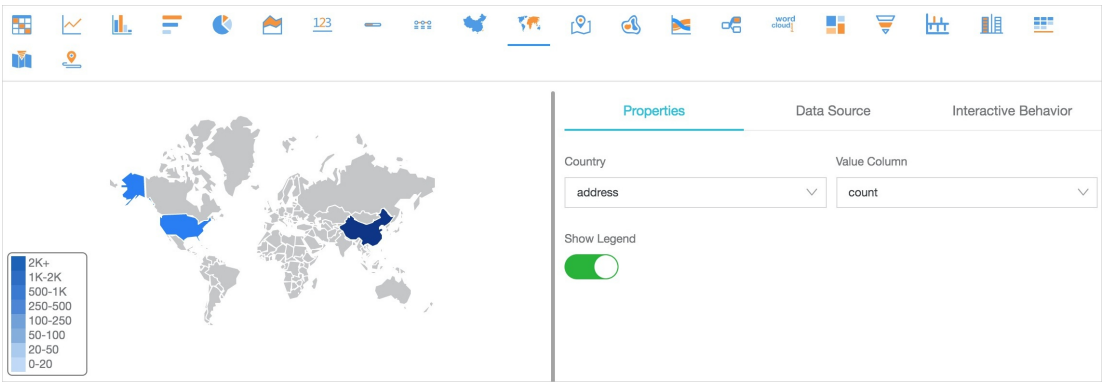
```
* | select ip_to_country(remote_addr) as address, count(1) as count group by address order by count desc limit 10
```

- Dataset

address	count
China	8354
United States	142

Select address for *Country* and count for *Value Column*.

World Map



AMap

To display query results on an AMap, you can execute the following query statement that includes the `ip_to_geo` function. The address column in the dataset contains the latitude and longitude values, which are separated by a comma (,). If the longitude and latitude values are contained in two separate columns named lng and lat, you can use the `concat('lat', ',', lng')` function to combine the two columns into one column.

- SQL statement

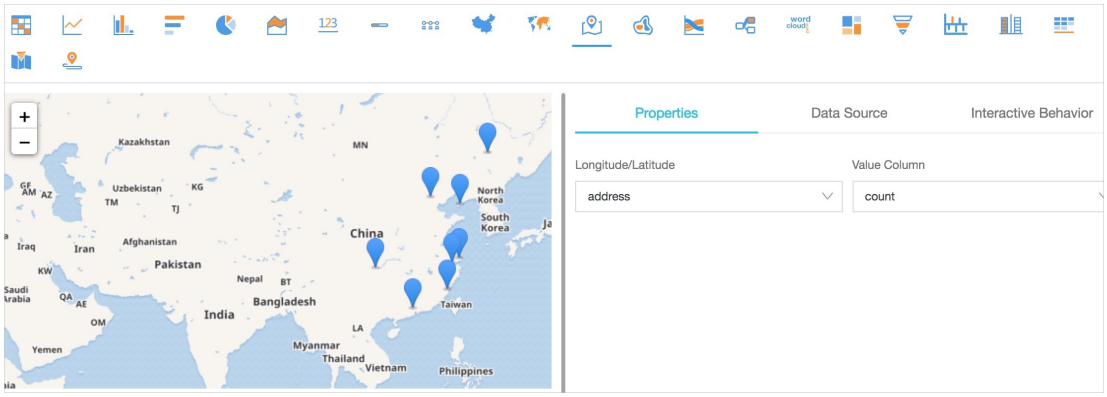
```
* | select ip_to_geo(remote_addr) as address, count(1) as count group by address order by count desc limit 10
```

- Dataset

address	count
39.9289,116.388	771
39.1422,117.177	724
29.5628,106.553	651
30.2936,120.161420	577
26.0614,119.306	545
34.2583,108.929	486

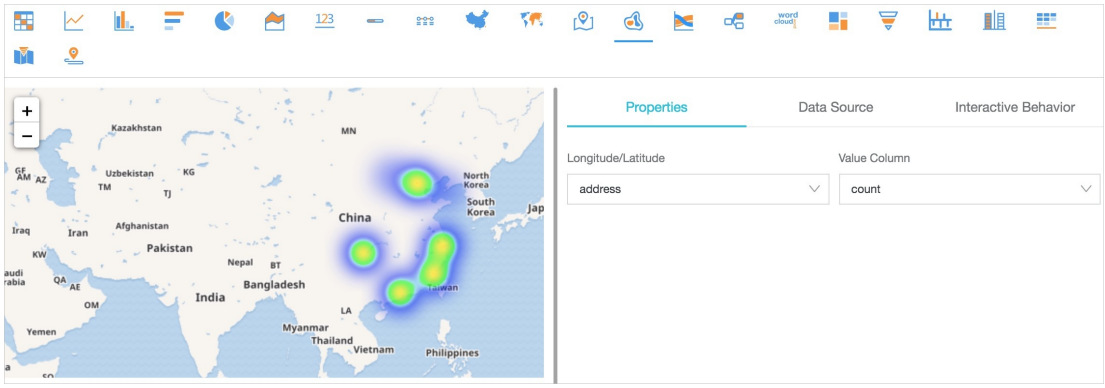
Select address for *Longitude/Latitude* and count for *Value Column*.

AMap: Anchor points



By default, the display mode of the anchor points is returned. If the anchor points are densely distributed on the map, you can switch the display mode to heat map.

AMap: Heat map



23.4.11.1.11. Flow chart

The flow chart, also known as ThemeRiver, is a stacked area chart around a central axis. The banded branches with different colors indicate different categorical data. The band width indicates the numeric value. The time information of the data is mapped to the X-axis by default. A flow chart can display the data of three parameters.

You can select the line chart or column chart for the Chart Types parameter. The column chart is stacked by default. Each category of data starts from the top of the last column of categorical data.

Components

- X-axis (horizontal)
- Y-axis (vertical)
- Band

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the flow chart.

Properties

Parameter	Description
Chart Types	The type of the chart. Valid values: Line Chart, Area Chart, and Column Chart. Default value: Line Chart.
X Axis	The sequential data. In most cases, time series is selected.
Y Axis	The numeric data. You can configure one or more fields on the Y-axis.
Aggregate Column	The field information required to be aggregated as the third point for comparison.
Legend	The position where the legend is located in the chart. Valid values: Top, Bottom, Left, and Right.
Format	The format in which data is displayed.
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

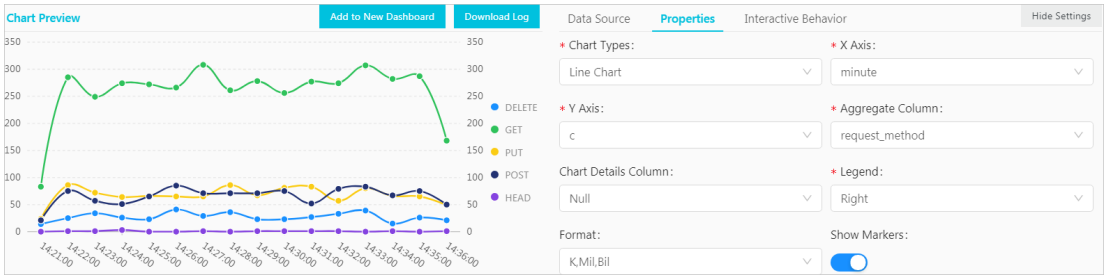
Examples

The flow chart is suitable to display data of three parameters, including the time, categories, and numeric values. In this example, you can execute the following query statement:

```
* | select date_format(from_unixtime(__time__ - __time__% 60), '%H:%i:%S') as minute, count(1) as c, request_method group by minute, request_method order by minute asc limit 100000
```

Select `minute` for the X-axis, `c` for the Y-axis, and `request_method` for Aggregate Column.

Flow chart



23.4.11.1.12. Display query results in a Sankey diagram

A Sankey diagram is a specific type of flow chart. It is used to describe the flow from one set of values to another set of values.

Sankey diagrams are applicable to scenarios such as network traffic flows. A Sankey diagram contains the values of three fields: `source`, `target`, and `value`. The `source` and `target` fields describe the source and target nodes and the `value` field describes the flows from the `source` node to the `target` node.

Features

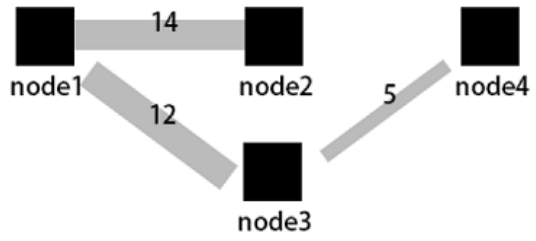
A Sankey diagram has the following features:

- The start flow is equal to the end flow. The overall width of all main edges is equal to the total sum of all branch edges. This allows you to manage and maintain a balanced flow of all traffic.
- The edge width in a row represents the traffic distribution in a specific status. The edge width in a row represents the distribution of traffic.
- The width of an edge between two nodes represents the flow volume of a status.

The following table lists the data that can be displayed in a Sankey diagram.

source	target	value
node1	node2	14
node1	node3	12
node3	node4	5
...	...	...

The following figure shows the data relationships in a Sankey diagram.



Components

- Node
- Edge

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the Sankey diagram.

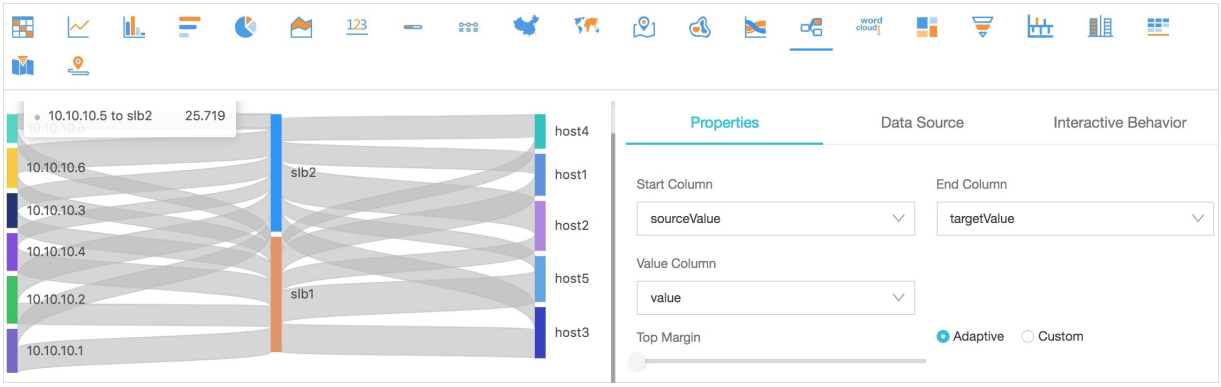
Properties

Parameter	Description
Start Column	The start node.
End Column	The end node.
Value Column	The value that indicates the flow volume from the start node to the end node.
Margin	The distance between an axis and the borders of the chart. Valid values: **Top Margin**, **Bottom Margin**, **Right Margin**, and **Left Margin**.

Example of a Sankey diagram

If a log entry contains the `source`, `target`, and `value` fields, you can use a Nested subqueries statement to obtain the sum of all `steamValue` values.

```
* | select sourceValue, targetValue, sum(streamValue) as streamValue from (select sourceValue, targetValue,
 streamValue, __time__ from log group by  sourceValue, targetValue, streamValue, __time__ order by __time__ desc) gro
up by sourceValue,
 targetValue
```



23.4.11.1.13. Display query results on a word cloud

A word cloud visualizes text data. It is a cloud-like and colored image that consists of words. You can use a word cloud to display a large amount of text data. The font size or color of a word indicates the significance of the word. This allows you to identify the most significant words in an efficient way.

Components

The words in a word cloud are sorted.

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, click the icon.
3. On the **Properties** tab, configure the properties of the word cloud.

Properties

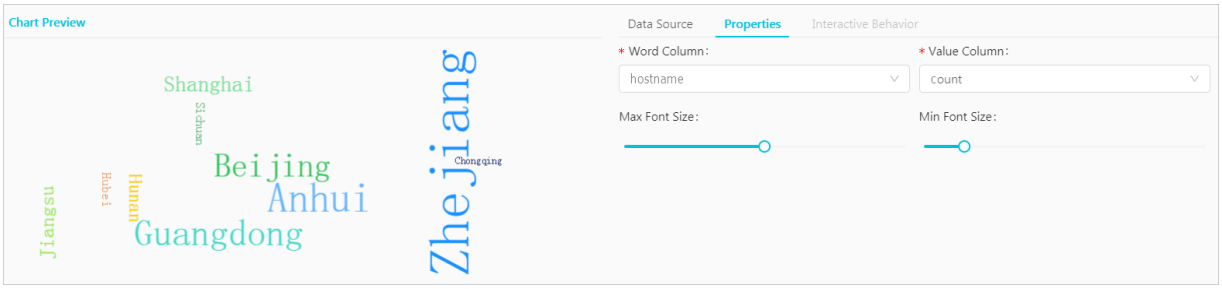
Parameter	Description
Word Column	The words to be displayed.
Value Column	The numeric value that corresponds to a word.
Font Size	The font size of a word. • The minimum font size ranges from 10 pixels to 24 pixels. • The maximum font size ranges from 50 pixels to 80 pixels.

Examples

To query the distribution of hostnames in NGINX logs, execute the following query statement:

```
* | select domain, count(1) as count group by domainorder by count desc limit 1000
```

Select `hostname` for Word Column and `count` for Value Column.



23.4.11.1.14. Display query results on a treemap chart

A treemap chart includes multiple rectangles that represent the data volume. A larger rectangle area represents a larger proportion of the categorical data.

Components

Sorted rectangles

Procedure

1. On the Search & Analysis page, enter a query statement in the search box, specify a time range, and then click **Search & Analyze**.
2. On the **Graph** tab, click the  icon.
3. On the **Properties** tab, configure the properties of the treemap chart.

Properties

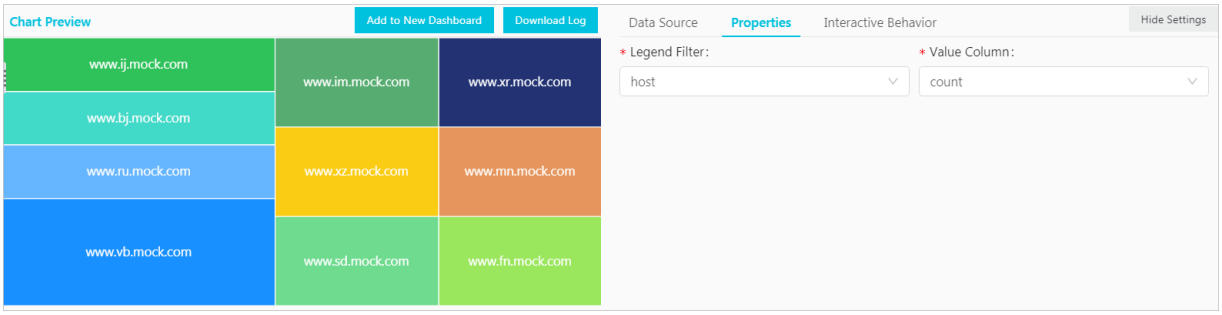
Parameter	Description
Legend Filter	The field that includes categorical data.
Value Column	The numeric value of a field. A greater field value represents a larger rectangle area.

Examples

To query the distribution of hostnames in NGINX logs, execute the following query statement:

```
* | select hostname, count(1) as count group by hostname order by count desc limit 1000
```

Select **hostname** for `Legend Filter` and **count** for `Value Column`.



23.4.11.2. Dashboard

23.4.11.2.1. Overview

A dashboard provided by Log Service is a platform where you can analyze data in real time. You can add multiple charts to a dashboard for data analysis. Each chart is a visualized search and analytic statement.

A dashboard allows you to view the charts of multiple search and analytic statements at one time. When you open or refresh the dashboard, the statements of the charts run automatically.

After you add a chart to a dashboard, you can configure Drill-down analysis for the chart. Then you can click the chart on the dashboard to further analyze data and obtain more fine-grained analysis results.

Limits

- You can create a maximum of 50 dashboards for a project.
- Each dashboard can contain a maximum of 50 analysis charts.

Features

A dashboard has two modes: display mode and edit mode.

- Configure the display mode of a dashboard

  In the display mode, you can configure multiple display settings on the dashboard page.

  - Dashboard: You can specify the time range, the automatic refresh interval, full screen, and the display mode of the title for the dashboard, configure alerts for all charts on the dashboard, and filter chart data based on the Configure and use a filter on a dashboard of a Logstore.
  - Chart: You can view the analysis details of a specified chart, specify the time range and configure alerts for the chart, download logs and the chart, and check whether drill-down analysis is configured for the chart.

- Edit mode

  In the edit mode, you can change the configurations of the dashboard and charts.

  - Dashboard: You can use a dashboard as a canvas and add Markdown chart, custom charts, text, icons, and other chart elements to the dashboard. You can also add lines between chart elements that are self-adaptive to the positions of the charts. You can also add Configure and use a filter on a dashboard of a Logstore, which can be used to filter chart data in the display mode. In addition, you can configure display gridlines to help arrange chart elements such as icons in an orderly manner.
  - Chart: You can also edit a chart on the dashboard. You can modify the statement, properties, and interactive behavior such as drill-down analysis of the chart.

23.4.11.2.2. Create and delete a dashboard

This topic describes how to create and delete a dashboard in a Logstore. In the Log Service console, you can run a query statement and visualize the query result in a chart. After you complete the configurations of the chart, you can add the chart to a dashboard. Each dashboard can display up to 50 charts, which support multiple formats and custom settings.

Prerequisites

The indexing feature of the Logstore is enabled and configured. For more information, see Enable the index feature and configure indexes for a Logstore.

Create a dashboard

1. Log on to the Log Service console.
2. Click a project name.
3. Click the icon next to the name of the Logstore, and then select **Search & Analysis**.
4. Enter a query statement in the search box, and then click **Search & Analyze**.
5. On the **Graph** tab that appears, configure the chart properties on the **Properties** tab.
6. (Optional)Set a placeholder variable.

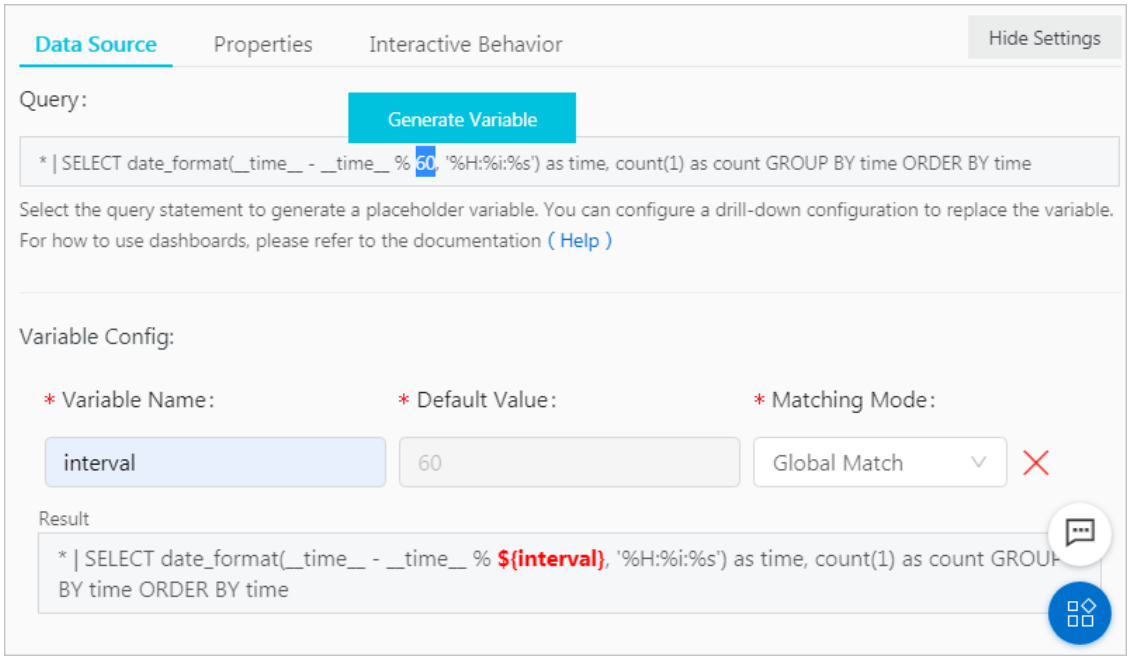
   For example, you have configured a drill-down event for another chart. This drill-down event redirects you to the current dashboard. You have also specified a placeholder variable for the query statement of the preceding chart. When you click a chart value to trigger the drill-down event, you are redirected to the current dashboard. The placeholder variable is replaced by the chart value and the current dashboard is refreshed by the new query statement. For more information, see Drill-down analysis.

   i. Click the **Data Source** tab, and then select a part of the query statement in the **Query** field.

   ii. Click **Generate Variable** to generate a placeholder variable.

iii. Set the parameters in the **Variable Config** section.

Parameter	Description
Variable Name	The name of the placeholder variable. If the name of the placeholder variable is the same as the variable specified in the chart, the placeholder variable is replaced with the chart value when the drill-down event is triggered.
Default Value	The default value of the placeholder variable in the current dashboard.
Matching mode	You can select Global Match or Exact Match.
Result	The query statement that contains the specified variable.



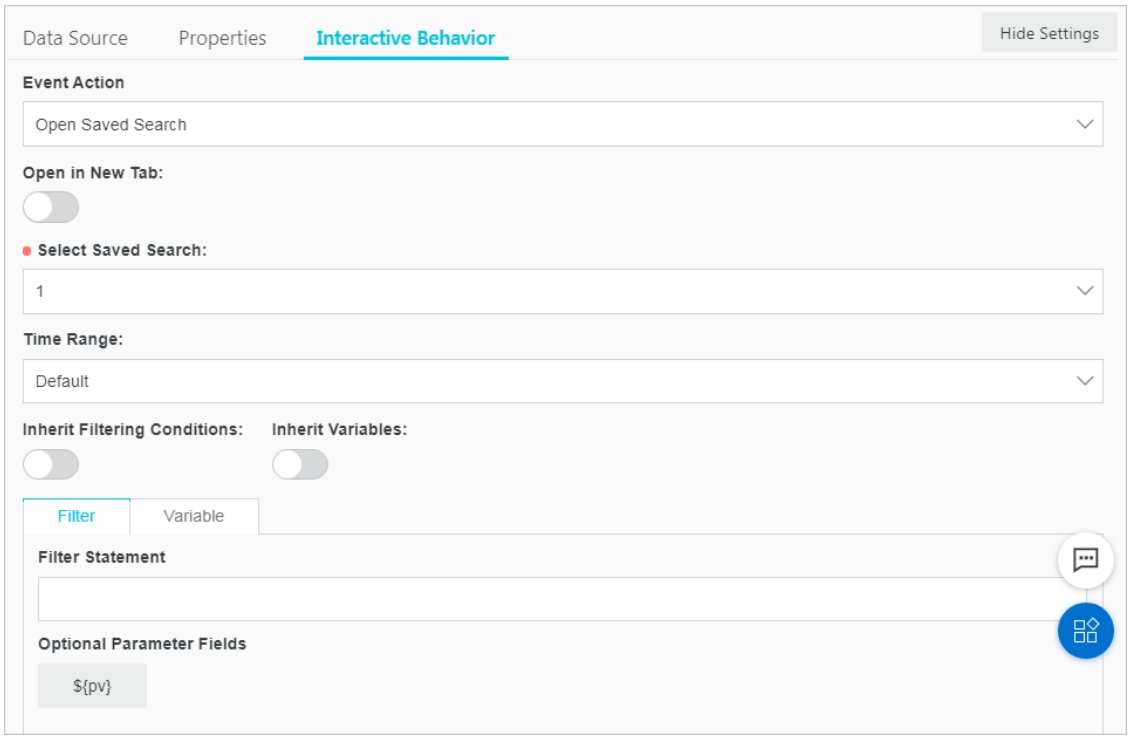
7. Configure a drill-down event.

   After you configure a drill-down event, you can click the chart on the dashboard for a more detailed analysis. For example, you can be redirected to another dashboard or a saved search. For more information, see Drill-down analysis.

   i. Click the **Interactive Behavior** tab.

   ii. Select an **Event Action**.

iii. Set the parameters of the selected event action.



8. Click **Add to New Dashboard** and specify the dashboard name and chart name.

Parameter	Description
Operation	◦ **Add to Existing Dashboard**: Add the chart to an existing dashboard. ◦ **Create Dashboard**: Create a dashboard and then add the chart to the dashboard.
Dashboards	Select an existing dashboard name. **Note** This parameter is required only when you set the **Operation** parameter to **Add to Existing Dashboard**.
Dashboard Name	Enter a dashboard name. **Note** This parameter is required only when you set the **Operation** parameter to **Create Dashboard**.
Chart Name	Enter a name for the current chart. The chart name is displayed as the chart title in the dashboard.

9. Click **OK**.

You can add multiple charts to a dashboard.

Delete a dashboard

You can delete a dashboard if you no longer need it. However, you cannot recover a deleted dashboard.

1. Log on to the Log Service console, and then click the destination project name.

2. In the left-side navigation pane, click the **Dashboard** icon.
3. Click the icon next to the dashboard that you want to delete, and then select **Delete**.

23.4.11.2.3. Configure the display mode of a dashboard

This topic describes how to configure the display mode of a dashboard. By default, you can view all charts in a dashboard in the display mode. When you configure the display mode, you can add chart elements, enable automatic refresh, and set the title display mode.

Set a query time range for a dashboard of a Logstore

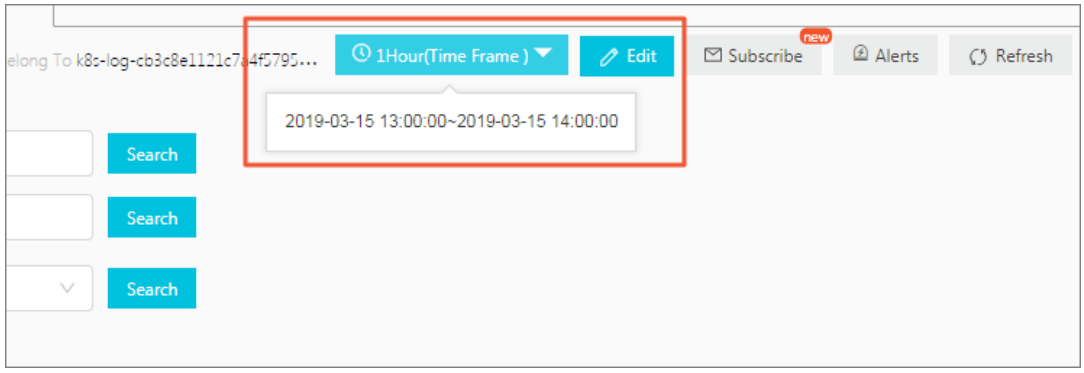
By default, all charts in a dashboard use the query time range that is set for the dashboard. For more information about how to set a query time range for a single chart, see Set a query time range for a chart.

> **Note** On the dashboard page, you can click **Time Range** to specify a time range for a query. The specified query time range is used only for the current query. The next time you open the dashboard, the system will display the analysis results in the default query time range.

1. Log on to the Log Service console.
2. Click a project name.
3. In the left-side navigation pane, click the **Dashboard** icon.
4. Click the icon next to the dashboard, and then select **Details** from the drop-down list.
5. Click **Time Range** to set a time range.

   You can set one of the following time ranges:

   - Relative: queries log data obtained in a time range of 1 minute, 5 minutes, 15 minutes, or other time ranges that end with the current time, accurate to the second. For example, if the current time is 19:20:31 and you select 1Hour as the relative time, the charts on the dashboard display the analysis results of the log data queried from 18:20:31 to 19:20:31.
   - Time Frame: If you select or customize a time range less than one hour (for example, 1 minute, 5 minutes, and 15 minutes), log data obtained in the time range that ends with the current time is queried, accurate to the minute. If you select or customize a time range greater than one hour, log data obtained on the hour before the current time is queried. For example, if the current time is 19:20:31 and you select 1Hour as the time frame, the charts on the dashboard display the analysis results of the log data queried from 18:00:00 to 19:00:00.
   - Custom: queries log data obtained in a specified time range.
6. Move the pointer over the **Time Range** button to confirm the specified time range.



Switch to the edit mode

Click **Edit** to switch to the edit mode of the dashboard. In the edit mode, you can add Markdown chart, custom charts, text, icons, and other chart elements to the dashboard. For more information, see Edit mode.

Set alerts

On the dashboard page, choose **Alerts > Create** to create an alert. Choose **Alerts > Modify** to modify an alert. An alert must be associated with one or more charts.

For more information, see Configure alerts.

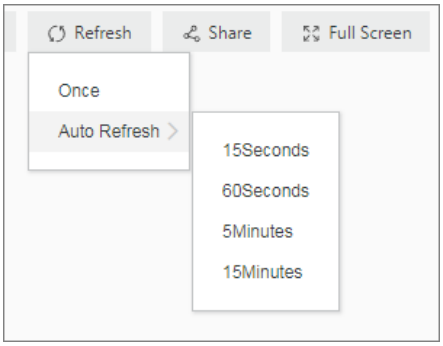
Set a refresh method

You can manually refresh the dashboard, or set an automatic refresh interval for the dashboard.

- To manually refresh the dashboard, choose **Refresh > Once**.
- To set an automatic refresh interval for the dashboard, choose **Refresh > Auto Refresh**, and then select an interval.

  The **Auto Refresh** interval can be 15 seconds, 60 seconds, 5 minutes, or 15 minutes.

> **Note** If your browser is inactive, the automatic refresh interval may be inaccurate.



Share a dashboard

To share a dashboard with authorized users, click **Share** to copy the link of the dashboard page and then send the link to the users. The shared dashboard page uses the settings of the dashboard at the time of sharing. The settings include the time range of charts and chart title format.

> **Note** Before you share the dashboard with other users, you must grant relevant permissions to them.

Display a dashboard in full screen

Click **Full Screen**. Then the charts on a dashboard are displayed in full screen.

Set the chart title format

On the dashboard page, click **Title Configuration**. Available title formats include:

- Single-line Title and Time Display
- Title Only
- Time Only

Reset the query time range

To restore the default query time ranges of all charts on the dashboard, click **Reset Time**.

Select chart view

- View analysis details of a chart

To view analysis details of a chart, move the pointer over the More icon in the upper-right corner of the chart, and then select **View Analysis Details**. The corresponding Search & Analysis page appears, showing the query statement and property settings.

- Set the query time range for a chart

  To set the query time range for a chart, move the pointer over the More icon in the upper-right corner of the chart, and then select **Select Time Range**. The settings are valid only for the current chart.

- Set an alert for a chart

  To set an alert for a chart, move the pointer over the More icon in the upper-right corner of the chart, and then select **Create Alert**. For more information, see Configure alerts.

- Download log analysis results of a chart

  To download analysis results of a chart, move the pointer over the More icon in the upper-right corner of the chart, and then select **Download Log**.

- Download a chart

  To download a chart, move the pointer over the More icon in the upper-right corner of the chart, and then select **Download Chart**.

- Check whether a drill-down event is configured for a chart

  To check whether a drill-down event is configured for a chart, move the pointer over the More icon in the upper-right corner of the chart. Then, check the color of the hand icon at the bottom of the shortcut menu. If the icon is red, a drill-down event is configured for the chart. If the icon is gray, no drill-down event is configured for the chart.

> **Note** Different charts in a dashboard have different shortcut menus. For example, you cannot use the shortcut menu of a custom chart or Markdown chart to view analysis details because they are not analysis charts.

23.4.11.2.4. Edit mode

You can click the Edit button on the dashboard page to enter the edit mode. Then you can change the configurations of the dashboard and charts on the dashboard.

- Dashboard:
  - You can modify the dashboard name in the upper-left corner of the page.
  - You can use a dashboard as a canvas and add Markdown chart, custom charts, text, icons, and other chart elements to the dashboard.
  - You can add lines between chart elements. The lines are adaptive to the positions of the charts.
  - You can add a filter to the dashboard. Then you can filter chart data in the display mode. For more information, see Configure and use a filter on a dashboard of a Logstore.
  - In addition, you can configure display grid lines to arrange chart elements such as icons in order.
  - You can use the menu bar to manage the chart property settings on the dashboard. For example, you can perform the add, delete, and cancel operations on a chart. You can also configure the size and location of a chart and move a chart to the top or bottom of the dashboard.
- Chart: You can edit a chart on the dashboard. For example, you can modify the statement, properties, and interactive behavior such as drill-down analysis of a chart.

> **Note** All changes to the dashboard take effect only after you click **Save** in the upper-right corner of the page.

Chart elements

In the edit mode of a dashboard, you can add the following chart elements:

- Common icons

  Log Service allows you to display common icons on a dashboard page. You can drag an icon from the menu bar and drop the icon to a specified position.

- Text

  You can drag the text icon from the menu bar and drop the icon to a specified position. Double-click the text box to modify the text.

- Markdown chart

  You can add a Markdown chart to a dashboard and edit the chart with the Markdown syntax.

  Drag the Markdown icon from the menu bar and drop the icon to a specified position. Select **Edit** from the More icon. Then you can set the Markdown content.

- Filter

  You can add a filter to a dashboard. Then you can add search conditions or replace placeholder variables in query statements.

  Click the filter icon in the dashboard menu bar. On the page that appears, configure the filter based on your needs. By default, the filter is in the upper-left corner of the dashboard page. To modify the settings of a filter, you can select **Edit** on the More icon in the upper-right corner of the page.

- Customize SVG

  You can upload a Scalable Vector Graphics (SVG) file to a dashboard. Click the SVG icon in the menu bar. On the page that appears, click the box or drag an SVG file to the box to upload the file.

  > **Note** The size of an SVG file cannot exceed 10 KB.

- Customize image's HTTP link

  You can upload the HTTP link of an image to a dashboard. Click the Customize image's HTTP link icon in the menu bar. On the page that appears, enter the HTTP link of an image and click **OK**.

Layout

In the edit mode, all charts and chart elements are placed on a canvas. You can drag and scale each chart, except for the lines. The horizontal width of a chart is up to 1,000 units. Each unit is equal to `current browser width/1,000`. The vertical height is unlimited and each unit is equal to 1 pixel. Before you arrange a chart on the dashboard, you can click **Display gridlines** to better arrange the position of the chart and the spacing between charts.

You can perform the following operations to arrange a chart on the dashboard:

- Adjust the position of a chart
  - You can drag a chart and drop the chart to a specified position.
  - After you specify a chart, you can click **L** and **T** to adjust the chart position.
- Adjust the width and height of a chart
  - After you specify a chart, you can drag the chart in the lower-right corner to resize the chart.
  - After you specify a chart, you can also specify the **W** and **H** parameters to resize the chart.
- Add lines to connect charts

  You can add a directional line between two charts. When you adjust the position and size of the charts, the line automatically moves to display the relative position between the two charts.

  After you select a chart, four squares appear on the border of the chart. These squares indicate the starting point of the connection line. Press and hold one square, and the area where the end point of the connection line is automatically displayed. Move the pointer to this position to connect the two charts.

- You can move a chart to the top or bottom of the dashboard. After you select a chart, you can use the menu bar to move the chart to the top or bottom.

Chart configurations

In the edit mode of a dashboard, you can perform the following operations on chart elements:

- Edit: modifies the query statement, properties, and interactive behavior such as drill-down analysis of a chart.
  i. In the upper-right corner of the dashboard page, click **Edit**.
  ii. Find the target chart and choose > **Edit**.
  iii. Modify the query statement of the chart, **Properties**, **Data Source**, or **Interactive Behavior**.
  iv. Click **Preview**, and then click **OK**.
  v. In the upper-right corner of the dashboard page, click **Save**.
- Copy: creates a copy of the specified chart and retains all configurations.
  i. In the upper-right corner of the dashboard page, click **Edit**.
  ii. Find the target chart and choose > **Copy**.
  iii. Drag the chart copy and drop it to a specified position, and then set the top margin, left margin, and size of the copy.
  iv. In the upper-right corner of the dashboard page, click **Save**.
- Delete: deletes the specified chart from the dashboard.
  i. In the upper-right corner of the dashboard page, click **Edit**.
  ii. Find the target chart and choose > **Delete**.
  iii. In the upper-right corner of the dashboard page, click **Save**.

23.4.11.2.5. Drill-down analysis

This topic describes how to configure drill-down analysis for a chart of a Logstore. When you add a chart to a dashboard, you can modify the configurations in the drill-down list to obtain deeper data analysis results.

Prerequisites

- The index feature of the Logstore is enabled and configured. For more information, see Enable the index feature and configure indexes for a Logstore.
- A saved search, a dashboard, and a custom link to which you want to be redirected are configured.
- A placeholder variable is specified in the saved search or the query statement of a chart added to a dashboard to which you are redirected if you want to add a variable. For more information, see Saved search and Create and delete a dashboard.

Context

Drilling is essential for data analysis. This feature allows you to analyze data in a fine-grained or coarse-grained way. This feature includes drill-up and drill-down analysis. You can implement drill-down analysis to gain a deeper insight into data and make a better decision.

Log Service supports drill-down analysis of the following charts: tables, line charts, column charts, bar charts, pie charts, individual value plots, area charts, and treemap charts.

Procedure

1. Log on to the Log Service console.
2. Click the target project name.

3. Click the icon next to the name of the Logstore, and then select **Search & Analysis** from the drop-down list.
4. Enter a query statement in the search box, set a time range, and then click **Search & Analyze**.
5. On the **Graph** tab that appears, select a **chart type**, and then configure the parameters on the **Properties** tab of the chart.
6. Click the **Interactive Behavior** tab. On this tab, configure the **Event Action** for drill-down analysis.
   - **Disable**: disables drill-down analysis.
   - **Open Logstore**: sets the drill-down event to open a Logstore.

     If you configure a filter statement on the Interactive Behavior tab, the filter statement automatically fills the Search & Analyze search box of the redirected Logstore page when you click a value on the chart.

Parameter	Description
Select Logstore	The name of the Logstore to which you want to be redirected.
Open in New Tab	If you turn on this switch, the specified Logstore is opened on a new tab when the interactive behavior is triggered.
Time Range	The query time range of the Logstore to which you are redirected. Valid values: ■ **Default**: The default time range (15 minutes, accurate to the second) is used for a query statement of the redirected Logstore. ■ **Inherit table time**: The time range that a statement queries in the redirected Logstore is the time range specified for the chart when the event is triggered. ■ Relative: The time range that a statement queries in the redirected Logstore is accurate to the second. ■ Time Frame: The time range that a statement queries in the redirected Logstore is accurate to the minute, hour, or day. Default value: **Default**.
Inherit Filtering Conditions	If you turn on the **Inherit Filtering Conditions** switch, the filtering conditions added to the dashboard are synchronized to a query statement of the specified Logstore. The filtering conditions are added before the query statement by using the logical `AND` operator.
Filter	Enter a **Filter Statement** on the **Filter** tab. The filter statement can contain the **Optional Parameter Fields**. If you configure a filter statement on the **Filter** tab, the **filter statement** automatically fills the Search & Analyze search box of the redirected Logstore page when you click a chart value on the dashboard.

   - **Open Saved Search**: sets the drill-down event to execute a saved search.

     You can configure variables and a filter statement for a chart at the same time. When you click a value on the chart:

     ■ If you configure a variable for the chart, the variable value that you click replaces the placeholder variable that you have configured for the saved search and the saved search is executed for drill-down analysis.

     ■ If you configure a filter statement, the filter statement is added to the saved search to which you are redirected.

Parameter	Description

Parameter	Description
Select Saved Search	The name of the saved search to which you want to be redirected. For more information about how to configure a saved search, see Saved search.
Open in New Tab	If you turn on this switch, the specified saved search is opened on a new tab when the interactive behavior is triggered.
Time Range	The time range of the saved search to which you want to be redirected. Valid values: ■ **Default**: The default time range (15 minutes, accurate to the second) is used for the saved search to which you are redirected. ■ **Inherit table time**: The time range of the saved search is the query time range of the chart that you configure on the dashboard. ■ Relative: The time range of the saved search is accurate to the second. ■ Time Frame: The time range of the saved search is accurate to the minute, hour, or day. Default value: **Default**.
Inherit Filtering Conditions	If you turn on the **Inherit Filtering Conditions** switch, the filtering conditions added on the dashboard are synchronized to the saved search of the specified Logstore. The filtering conditions are added before the saved search by using the logical `AND` operator.
Filter	Click the **Filter** tab, and then enter a **Filter Statement**. The filter statement can contain the **Optional Parameter Fields**. If you configure a filter statement on the **Filter** tab, the **Filter Statement** is added to the saved search when you click a chart value on the dashboard.
Variable	Click the **Variable** tab, click **Add Variable**, and then set the following parameters: ■ **Replace Variable Name**: the variable that triggers the drill-down event. When you click this variable, you are redirected to the specified saved search. ■ **Replace the value in the column**: the column where the value that you want to replace data with is located. To process multiple columns, you can specify the current column and other columns. The current column is the column on which you want to perform drill-down analysis. Specify the current column in the **Replace the value in the column** field. Other columns can be the fields in the chart for which you configure drill-down analysis. If the variable name of the saved search is the same as the added variable, the variable of the saved search is replaced with the chart value that triggers the drill-down event. This helps you use the saved search for analysis in an efficient way. **Note** ■ If you add a variable for drill-down analysis, you must first configure a placeholder variable for the saved search to which you want to be redirected. ■ You can add up to five placeholder variables for a saved search.

- **Open Dashboard**: sets the drill-down event to open a dashboard.

Analysis charts on a dashboard are visualized query results. When you click a chart value on the source dashboard:

- If you configure a variable for the chart and set a placeholder variable for the chart on the destination dashboard to which you want to be redirected, the placeholder variable is replaced with the chart value that you click.
- If you configure a filter statement, the filter statement is added to the query statement of the chart on the destination dashboard.

Parameter	Description
Select Dashboard	The name of the dashboard to which you want to be redirected. For more information, see Create and delete a dashboard.
Open in New Tab	If you turn on this switch, the specified dashboard is opened on a new tab when interactive behavior is triggered.
Time Range	Set the time range for the dashboard to which you want to be redirected. Valid values: ■ **Default**: After you are redirected to the dashboard by clicking a chart value on the current dashboard, the selected dashboard uses its original time range. ■ **Inherit table time**: After you are redirected to the selected dashboard, the time range of the chart on the selected dashboard is the time range of the chart specified on the source dashboard when the event is triggered. ■ Relative: After you are redirected to the selected dashboard, set the time range of the selected dashboard to the specified relative time. ■ Time Frame: After you are redirected to the selected dashboard set the time range of the selected dashboard to the specified time frame. Default value: **Default**.
Inherit Filtering Conditions	If you turn on the **Inherit Filtering Conditions** switch, the filtering conditions added on the current dashboard are synchronized to the dashboard to which you are redirected. The filtering conditions are added before the query statement by using the logical `AND` operator.
Filter	Click the **Filter** tab, and then enter a **Filter Statement**. The filter statement can contain the **Optional Parameter Fields**. If you have set the **Filter**, a filtering condition is added to the selected dashboard when you click a chart value on the current dashboard. The filtering condition is the specified **Filter Statement**.

Parameter	Description
Variable	Click the **Variable** tab, click **Add Variable**, and then set the following parameters: ■ **Replace Variable Name**: the variable that triggers drill-down analysis. When you click this variable, you are redirected to the selected dashboard. ■ **Replace the value in the column**: the column where the value that you want to replace data with is located. To process multiple columns, you can specify the **Default Column** and other columns. The **Default Column** is the current column on which you want to perform drill-down analysis. Other columns can be fields in the chart for which you configure drill-down analysis. If the variable in the query statement of the chart on the selected dashboard is the same as the added variable, the variable is replaced with the chart value that triggers the drill-down event. This changes the query statement of the chart on the selected dashboard. **Note** ■ If you add a variable for drill-down analysis, you must first configure a placeholder in the query statement for the selected dashboard to which you want to be redirected. ■ You can add up to five variables.

- **Custom HTTP Link**: sets the drill-down event to open a custom HTTP link.

  The path in the HTTP link is the path of the destination file in the server. When you add optional parameter fields to the path and click the chart value on the dashboard, the added parameter fields are replaced with the chart value. At the same time, you are redirected to the new HTTP link.

Parameter	Description
Enter Link	The destination address to which you want to be redirected.
Optional Parameter Fields	By clicking an optional parameter variable, you can replace a part of the HTTP link with the chart value that triggers a drill-down event.

7. Click **Add to New Dashboard** and set the dashboard name and chart name.

Example

You want to store collected NGINX access logs in a Logstore named accesslog, display the relevant analysis results on a dashboard named RequestMethod, and display the page view (PV) changes over time on a dashboard named destination_drilldown. You can configure drill-down analysis for the table of request methods, add the table to the RequestMethod dashboard, and then configure the drill-down event that redirects you to the destination_drilldown dashboard. When you click a request method on the table on the RequestMethod dashboard, you are redirected to the destination_drilldown dashboard. Then you can view the PV changes on the dashboard.

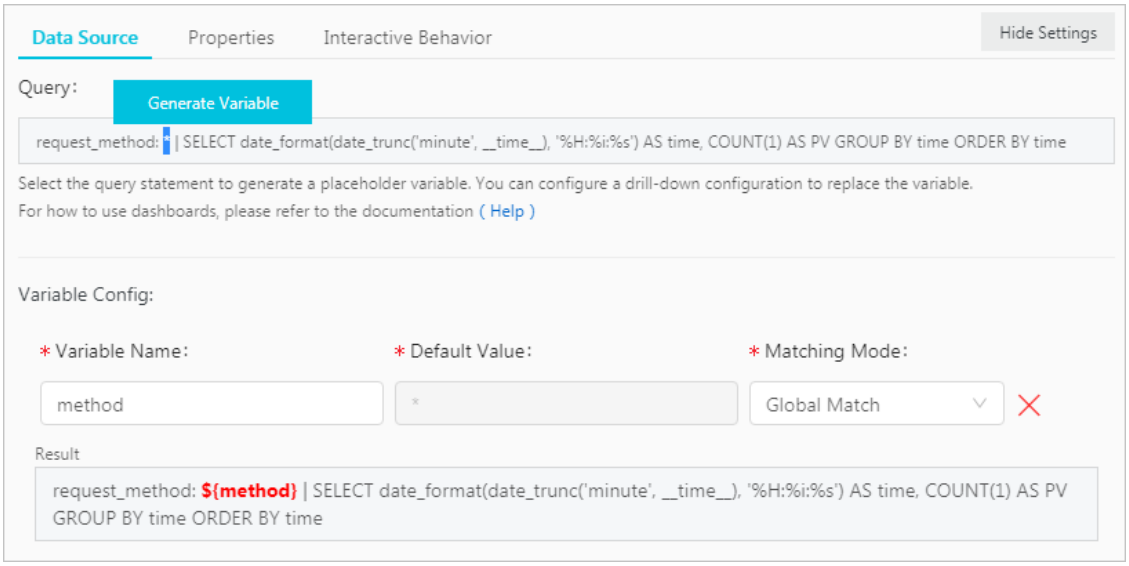
1. Set the dashboard to which you want to be redirected.
   i. Filter log data by request method and analyze how the PV of each request method changes over time.

      The query statement is shown as follows:

      ```
      request_method: * | SELECT date_format(date_trunc('minute', __time__), '%H:%i:%s') AS time, COUNT(1) AS PV GROUP BY time ORDER BY time
      ```

ii. Use a line chart to display the query result and add the line chart to the dashboard named destination_drilldown.

Before you add the line chart to the dashboard, specify the asterisk (*) to generate a placeholder variable and set the variable name to method. If the variable name of another chart for which you configure drill-down analysis is method, when you click the variable value on the chart to trigger drill-down analysis, the asterisk (*) is replaced with the value that you click and the query statement of the line chart is performed.



2. Configure drill-down analysis for a chart and add the chart to the dashboard.

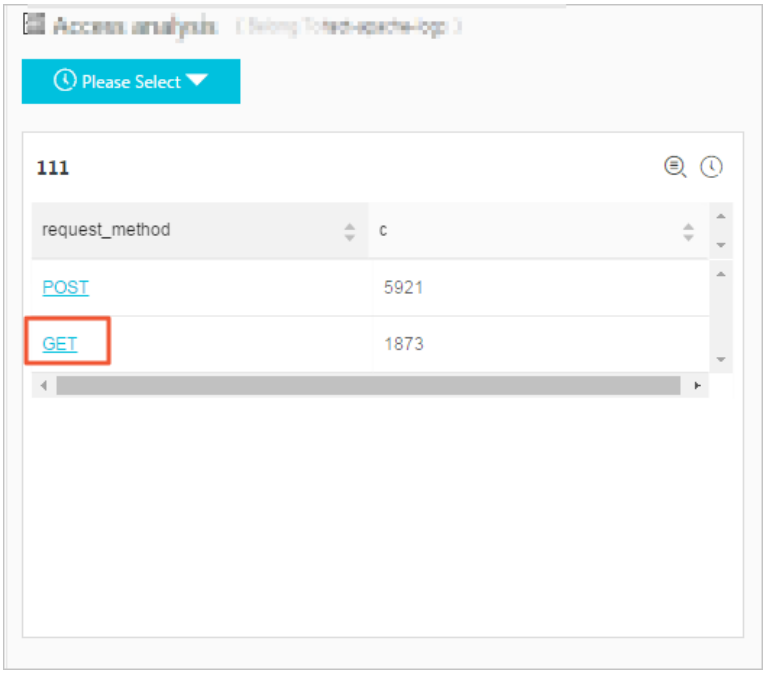
i. On the Search & Analysis page, enter a SQL statement to query the number of NGINX access log entries of each request method, and display the result in a table.

The query statement is shown as follows:

```
*|SELECT request_method, COUNT(1) AS c GROUP BY request_method ORDER BY c DESC LIMIT 10
```

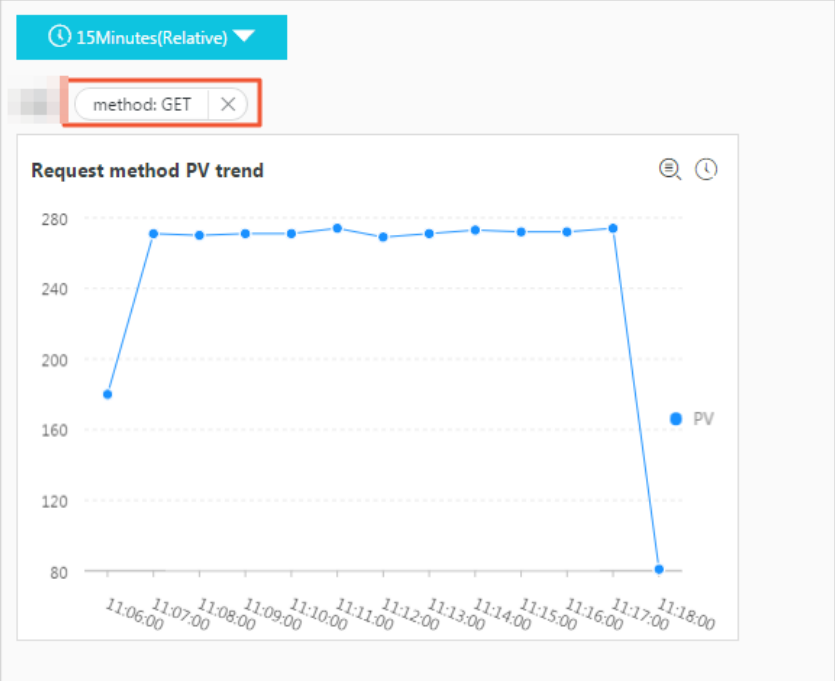
ii. Configure drill-down analysis for the `request_method` column in the table.

iii. Click the GET request on the RequestMethod dashboard.



iv. Redirected to the destination_drilldown dashboard.

You are redirected to the dashboard configured in step . The asterisk (*) in the query statement is replaced with GET . The dashboard shows how the PV of the GET request changes over time.



23.4.11.2.6. Configure and use a filter on a dashboard of a Logstore

This topic describes how to configure and use a filter on a dashboard of a Logstore. Filters help you refine search results or replace placeholder variables with specified values.

Prerequisites

- The index feature of the Logstore is enabled and configured. For more information, see Enable the index feature and configure indexes for a Logstore.
- A dashboard is created. For more information, see Create and delete a dashboard. A placeholder variable is specified for charts on the dashboard if the filter type is set to Replace Variable.

Context

Each chart on a dashboard is a visualized query statement. When you configure a filter on a dashboard, the specified filtering condition or variables apply to all charts on the dashboard. You can configure the following two types of filters:

- Filter: Add key-value pairs as a filtering condition before the query statement [search query] . The new query statement is key:value AND [search query] , which means to search the result of the original query statement for log entries that contain key:value . For the **Filter** type, you can select or enter multiple key-value pairs. When you select multiple key-value pairs as filtering conditions, the logical OR operator is used between the pairs.
- Replace Variable: Specify a variable. If the dashboard contains a chart configured with the same placeholder variable, the placeholder variable in the query statement of the chart is replaced with the selected value.

Components

Each filter chart has one or more filters. Each filter consists of the following two components:

- The key, which indicates a filter operation.

- The values of the key.

Procedure

1. Log on to the Log Service console.
2. Click a project name.
3. In the left-side navigation pane, click the **Dashboard** icon.
4. In the dashboard list, click the name of the target dashboard.
5. On the dashboard page, click **Edit** to enter the edit mode.
6. Click the icon, and then set the filter parameters. Click **OK**.

Parameters of a filter

Parameter	Description
Filter Name	The name of the filter.
Display Settings	Valid values: ○ Title: specifies to add a title for a filter. You can turn on the Title switch to add a title for a filter. ○ Border: specifies to add borders for a filter. You can turn on the Border switch to add borders for a filter. ○ Background: specifies to add a white background for a filter. You can turn on the Background switch to add a white background for a filter.
Type	The filter type. Valid values: ○ If you select **Filter**, a List Item is a value of a key that is used to filter the results of a query statement. You can set multiple values for a key. After the filter takes effect, you can select one or more values on the dashboard to filter query results based on your needs. ○ If you select **Replace Variable**, a List Item is the value that replaces a specified variable. You can set multiple values for a variable. After the filter takes effect, you can select one or more values on the dashboard to filter query results based on your needs.
Key	○ For the **Filter** type, the **Key** parameter specifies the key in the filtering condition. ○ For the **Replace Variable** type, the **Key** parameter specifies the variable. **Note** The variable must be the same as the placeholder variable that you specified for charts. Otherwise, the placeholder variable cannot be replaced.
Alias	The alias of the key. This parameter is available only when you select **Filter**. After you set an alias for a key, the alias is displayed in the filter on the dashboard.
Global filter	This switch indicates whether to filter the specified values in all fields. This switch is turned off by default. The switch is available only when you select the **Filter** type. ○ To filter the specified values in all fields, turn on the **Global filter** switch. ○ To filter the specified values in specified keys, turn off the **Global filter** switch.
Static List Items	The values of the key that is used as a filtering condition. Click the **plus sign** and enter a value for the key in the text box.

Parameter	Description
Add Dynamic List Item	The dynamic value of the key retrieved by running the specified query statement. Turn on the **Add Dynamic List Item** switch, select a Logstore, and turn on the Inherit Filtering Conditions switch (specifies whether to include the filtering condition in the query statement). Enter a query statement in the search box, specify a time range, and then click **Search** to preview the dynamic values.

Examples

You can use a filter to modify the query statements of charts on a dashboard and replace placeholder variables in the charts on the dashboard. Each chart represents a query statement in the format of `[search query] | [sql query]`. The filter query is appended to the original query statement to filter data.

- If the filter type is Filter, the key-value pairs to be filtered are added before `[search query]` to form a new query statement by using the logical `AND` operator. The new query statement is `key:value AND [search query]`.
- If the filter type is Replace Variable, the filter queries all charts that contain the specified placeholder variables on the dashboard and replaces the placeholder variables with the selected `values`.

Example 1: Use different time granularities to analyze logs

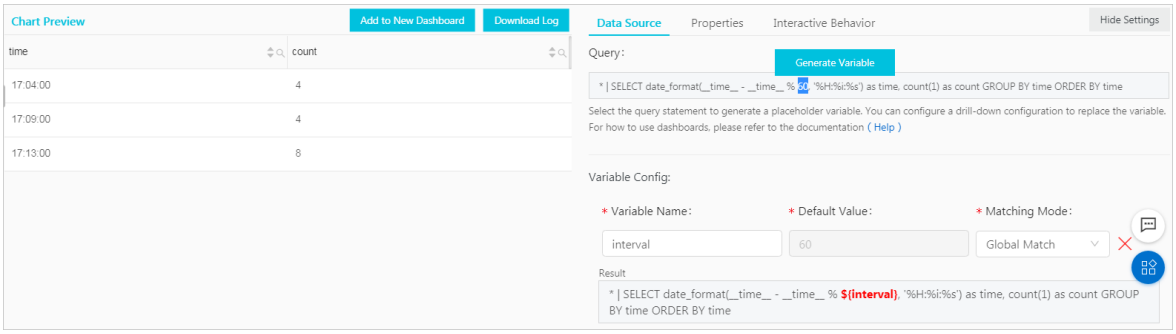
After you collect NGINX access logs, you need to query and analyze these logs in real time.

You can use a query statement to view the number of page views (PVs) per minute. However, if you want to view the number of PVs per second, you must modify the value of `__time__ - __time__ % 60` in the query statement. To simplify this operation, you can use a filter to replace variables in the query statement.

1. Use the following query statement to view the number of PVs per minute:

   ```
   * | SELECT date_format(__time__ - __time__ % 60, '%H:%i:%s') as time, count(1) as count GROUP BY time ORDER BY time
   ```

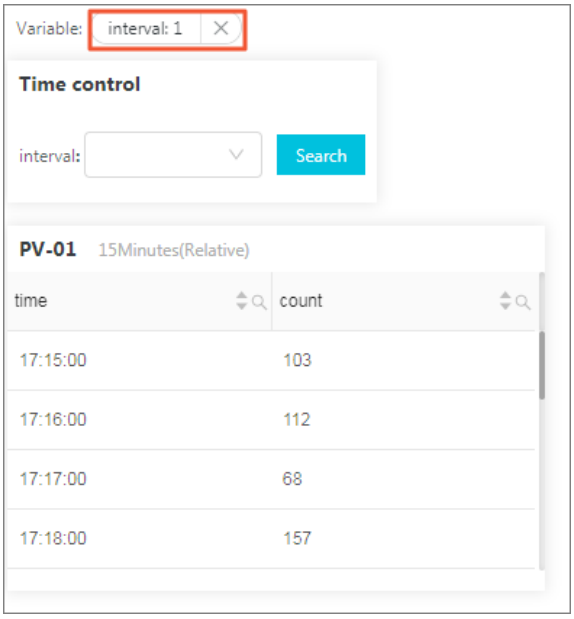
2. Add the chart to a dashboard, and select `60` generate a variable with the name `interval`.



3. Add a filter on the dashboard page.
   - **Type**: Select **Replace Variable**.
   - **Key**: Enter `interval`.
   - **Static List Items**: Add `1` and `120` as values of the key. The default unit is seconds.
4. In the Filter section of the dashboard, select `1` from the Interval drop-down list to view statistics by second.

   The following statement shows the query statement after the placeholder variable is replaced:

   ```
   * | SELECT date_format(__time__ - __time__ % 1, '%H:%i:%s') as time, count(1) as count GROUP BY time ORDER BY time
   ```



Example 2: Switch between request methods

You can add dynamic values to a filter to dynamically switch between request methods. In example 1, the query statement starts with an asterisk (`*`), which means no condition is set to filter the query results and all logs are queried. You can add another filter to view the PV data of different request `methods` .

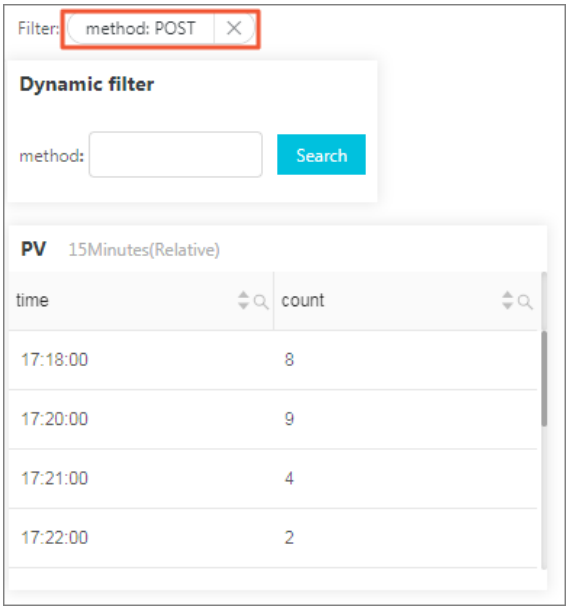
1. Add a filter on the dashboard and turn on the **Add Dynamic List Item** switch.

   Set the parameters as follows:

   - **Type**: Select Filter.
   - **Key**: Enter `method` .
   - **Select Logstore**: Select the Logstore to which the dashboard belongs.
   - **Add Dynamic List Item**: Enter a query statement to obtain the relevant dynamic values, and then click OK.
2. In the Filter section of the dashboard, select `POST` from the method drop-down list.

   Only the PV data whose `method` is `POST` is displayed in the chart. The query statement is changed as follows:

   ```
   (*) and (method: POST) | SELECT date_format(__time__ - __time__ % 60, '%H:%i:%s') as time, count(1) as count GROUP BY time ORDER BY time
   ```



23.4.11.2.7. Markdown chart

Log Service allows you to add a Markdown chart to a dashboard. In the Markdown chart, you can insert images, links, videos, and other elements to make your dashboard page more intuitive.

Context

You can create different Markdown charts based on your business needs. Markdown charts can make a dashboard more informative. You can insert text such as background information, chart description, notes, extension information, and custom images in a Markdown chart. You can also insert saved searches or dashboard links of other projects to redirect to other query pages.

Scenarios

You can insert links in a Markdown chart to redirect to other dashboard pages of the current project. You can also insert an image corresponding to each link for better recognition. In addition, you can use a Markdown chart to describe parameters of analysis charts.

Procedure

1. Log on to the Log Service console.
2. Click the destination project name.
3. In the left-side navigation pane, click the **Dashboard** icon.
4. In the dashboard list, click the name of the destination dashboard.
5. In the upper-right corner of the dashboard page, click **Edit** to enter the edit mode.
6. In edit mode, drag the Markdown icon from the menu bar to the specified location to create a Markdown chart.
7. Click the created Markdown chart, find the More icon in the upper-right corner of the chart, and click **edit**.

Parameter	Description
Chart Name	The name of the Markdown chart.
Show Border	Specifies whether to show the borders of a Markdown chart. You can turn on the **Show Border** switch to show the borders of a Markdown chart.

Parameter	Description
Show Title	Specifies whether to show the title of a Markdown chart. You can turn on the **Show Title** switch to show the title of a Markdown chart.
Show Background	Specifies whether to show the background of a Markdown chart. You can turn on the **Show Background** switch to show the background of a Markdown chart.
Query Binding	Specifies whether to bind a query statement to a Markdown chart. You can turn on the **Query Binding** switch and bind a query statement to a Markdown chart. Then, query results are dynamically displayed in the Markdown chart.

8. (Optional)Bind a query statement.
   i. Select the destination Logstore and enter a query statement in the search box. A query statement consists of a search statement and an analytic statement in the format of `search statement|analytic statement`.
   ii. On the Search & Analysis page, click **15 Minutes(Relative)** to set the time range for the query.
   iii. Click **Search** to display the first values of the returned query result.
   iv. Click the plus sign next to a field to insert the corresponding query result to **Markdown Content**.
9. Edit **Markdown Content**.

   Enter Markdown content in the **Markdown content** column. Then, data preview is displayed in real time in the **Show Chart** column on the right. You can modify the Markdown content based on the data preview.

Modify a Markdown chart

- Modify the location and size of a Markdown chart
  i. Click **Edit** in the upper-right corner of the **Dashboard** page.
  ii. Drag the Markdown icon to the specified location on the dashboard and drag the lower-right corner of the chart to adjust its size.
  iii. Click **Save** in the upper-right corner of the dashboard page to save the modification.
- Modify the title of a Markdown chart
  i. Click **Edit** in the upper-right corner of the **Dashboard** page.
  ii. Click the specified Markdown chart, find the More icon in the upper-right corner of the chart, and click **Edit**.
  iii. Enter a new title in the **Chart name** field and then click **OK**.
  iv. Click **Save** in the upper-right corner of the dashboard page. In the dialog box that appears, click **OK**.
- Modify the content of a Markdown chart
  i. Click **Edit** in the upper-right corner of the **Dashboard** page.
  ii. Click the specified Markdown chart, find the More icon in the upper-right corner of chart, and then click **Edit**.
  iii. Modify the chart content, and then click **OK**.
  iv. Click **Save** in the upper-right corner of the dashboard page. In the dialog box that appears, click **OK**.
- Delete a Markdown chart
  i. Click **Edit** in the upper-right corner of the **Dashboard** page.
  ii. Click the specified Markdown chart, find the More icon in the upper-right corner of chart, and then click **Delete**.
  iii. Click **Save** in the upper-right corner of the dashboard page. In the dialog box that appears, click **OK**.

Common Markdown syntax

- Title

  Markdown syntax:

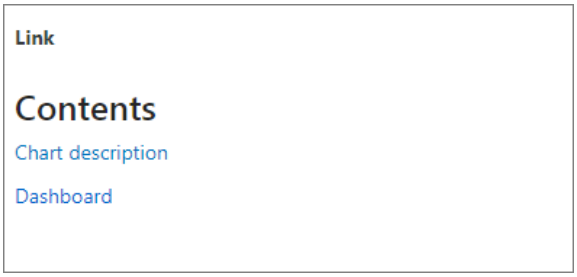
  ```
  # Level 1 heading
  ## Level 2 heading
  ### Level 3 heading
  ```

- Link

  Markdown syntax:

  ```
  ### Contents
  [Chart description](https:// xxx)
  [Dashboard](https:// xxx)
  ```

  Link preview

- Image

  Markdown syntax:

  ```
  <div align=center>
  ![ Alt txt][id]
  With a reference later in the document defining the URL location
  [id]: https://octodex.github.com/images/dojocat.jpg  "The Dojocat"
  ```

- Special tag

  Markdown syntax:

  ```
  ---
  __Advertisement :)__
  ==some mark==  `some code`
  > Classic markup: :wink: :crush: :cry: :tear: :laughing: :yum:
  >> Shortcuts (emoticons): :-)  8-) ;)
  __This is bold text__
  *This is italic text*
  ---
  ```

23.5. Alerts

23.5.1. Overview

Log Service enables you to configure alerts for charts on a dashboard to monitor the service status in real time.

You can configure alerts on the **Search & Analysis** page of a Logstore or on a **Dashboard** page. When you configure an alert, you must configure the alert name, trigger condition, notification method, and other parameters. After you Configure alerts, Log Service checks the query results on the dashboard at an interval and sends an alert notification if the check results meet the specified conditions. In this way, Log Service facilitates real-time monitoring of the service status.

Limits

Item	Description
Associated charts	The number of charts that can be associated with an alert ranges from 1 to 3.
String	If the length of a string exceeds 1,024 characters, only the first 1,024 characters are computed during a query.
Conditional expression	• The conditional expression must be 1 to 128 characters in length. • The conditional expression is evaluated based on the first 100 log entries returned for a query. • The conditional expression can be evaluated up to 1,000 times. If the conditional expression is not matched, the alert is not triggered.
Search Period	The time range of each query statement cannot exceed 24 hours.

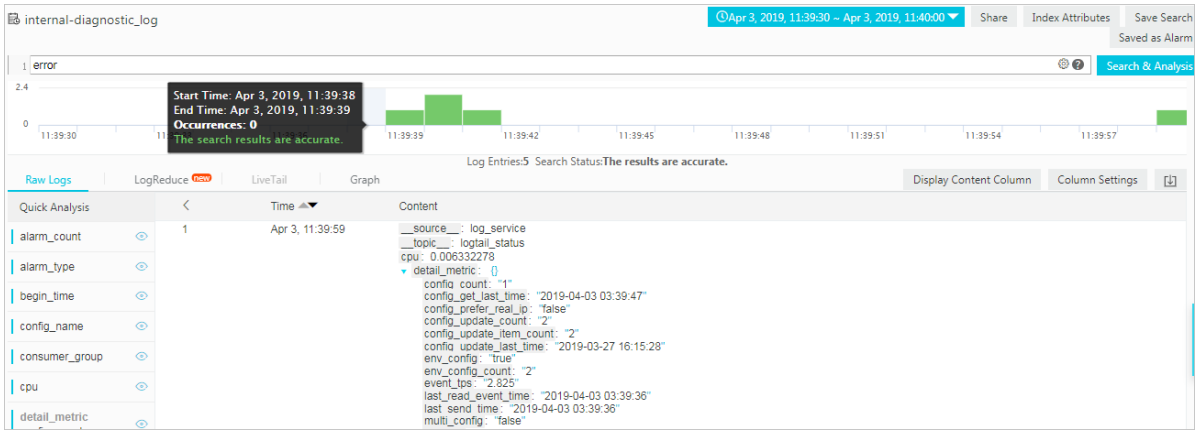
Query statement in an alert

An alert is configured based on analysis charts on a dashboard. An analysis chart is a visualized query result of a query statement. A query statement can include a search statement and an analytic statement.

- If you use only a search statement for a query, log data that matches the search condition is returned.
- If you include search and analytic statements for a query, log data that matches the search condition is analyzed before being returned.
- Search statement

  For example, you want to query the data that contains "error" information in the last 15 minutes. The search statement is error. A total of 154 log entries are retrieved. Each log entry consists of key-value pairs. You can set an alert rule for the value of a key.

  > **Note** If over 100 log entries are returned for a query, only the first 100 log entries are used for evaluating the conditions set in an alert. An alert is triggered when any of the first 100 log entries returned meets the conditions.

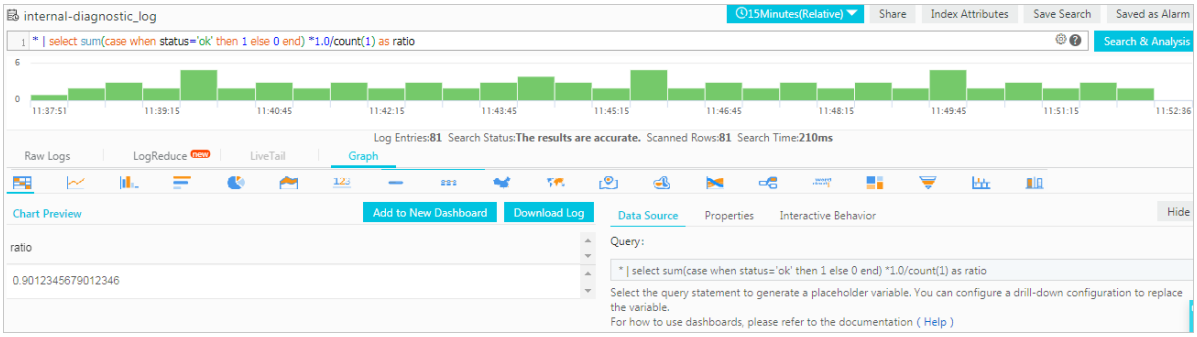
  


- Search and analytic statement

  For example, the following statement queries the ratio of log entries whose status field value is ok to all log entries. For more information about query syntax, see Query syntax.

  ```
  * | select sum(case when status='ok' then 1 else 0 end) *1.0/count(1) as ratio
  ```

If you set the trigger condition of an alert to `ratio < 0.9`, the alert is triggered when the ratio of log entries whose status field value is ok to all log entries is less than 90%.



23.5.2. Configure an alarm

23.5.2.1. Configure alerts

Log Service allows you to configure alerts on the Search & Analysis page of a Logstore or on a dashboard page. If the trigger condition of an alert is met, the alert is triggered and a notification is sent to specified recipients.

Prerequisites

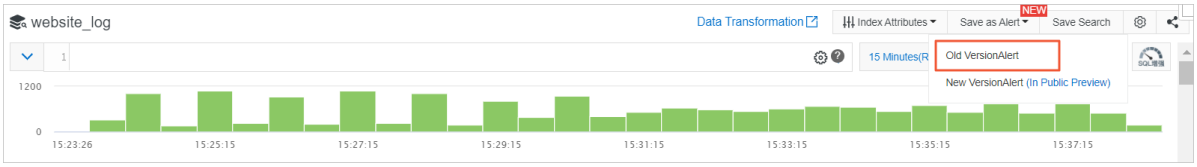
- Log data is collected.
- The indexing feature is enabled and indexes are configured. For more information, see Enable the index feature and configure indexes for a Logstore.

Context

Alerts are configured based on analysis charts. When you view an analysis chart, you can add the chart to a dashboard and configure an alert for the chart. You can also configure an alert for the existing charts on a dashboard.

- Create a chart and configure an alert for the chart

  You can save the results of a query statement as a chart on a dashboard, and configure an alert for the chart. When you configure an alert on the Search & Analysis page, you must specify the name of the dashboard on which the chart is saved and the chart name.



- Configure an alert for existing charts on a dashboard.

  You can configure an alert for one or more charts on a dashboard at a time. When you configure an alert for multiple charts, you can specify a conditional expression for each chart and combine the conditional expressions into the trigger condition for the alert.

This topic describes how to configure an alert for existing charts on a dashboard.

> **Note** If an alert is configured for a chart on a dashboard and you update the search and analytic statement of the chart, you must update the search and analytic statement in the alert configuration. For more information, see Modify an alert.

For information about example alert configurations, see FAQ about alerts.

Procedure

1. Log on to the Log Service console.
2. In the **Projects** section, click the name of a project.
3. In the left-side navigation pane, click the **Dashboard** icon.
4. Click the target dashboard name.
5. In the upper-right corner of the dashboard, choose **Alerts > Create**.
6. In the Create Alert wizard, configure an alert and click **Next**.

   The following table describes the configuration parameters of an alert.

Parameter	Description
Alert Name	The name of the alert. The name must be 1 to 64 characters in length.
Associated Chart	The chart that is associated with the alert. The **Search Period** parameter specifies the time range of log data that Log Service reads when you query data. You can select a relative time or a time frame. For example, if you set **Search Period** to 15 minutes (relative) and start the query at 14:30:06, Log Service reads the log data that was written from 14:15:06 to 14:30:06. If you set **Search Period** to 15 minutes (time frame) and start the query at 14:30:06, Log Service reads the log data that was written from 14:15:00 to 14:30:00. To associate the alert with multiple charts, you must separately add and configure the charts. The number before the chart name indicates the sequence number of the chart in the alert configuration. You can use the sequence number to associate a chart in the trigger condition.
Frequency	The time interval at which Log Service executes the alert.
Trigger Condition	The conditional expression that determines whether to trigger the alert. If the condition is met, Log Service sends an alert notification based on the specified **Check Frequency** and **Notification Interval**. For example, you can enter `pv%100 > 0 && uv > 0` in the Trigger Condition field. **Note** In the conditional expression, you can use `$sequence number` to differentiate charts. For example, you can use `$0` to identify the chart whose sequence number is 0.
Advanced	

Parameter	Description
Notification Trigger Threshold	If the number of times that the trigger condition is met exceeds this threshold and the specified **Notification Interval** elapses, Log Service sends an alert notification to the specified recipients. The default value of **Notification Trigger Threshold** is 1. This value indicates that each time the specified **Trigger Condition** is met, Log Service checks **Notification Interval** to determine whether to send notifications. You can set a custom value. This way, Log Service sends an alert notification to the specified recipient only after the trigger condition is met multiple times. For example, if you set the value to 100, Log Service checks **Notification Interval** only after the trigger condition is met 100 times. If the **Notification Trigger Threshold** and **Notification Interval** are reached, Log Service sends an alert notifications to the specified recipients. The overall count is then reset to zero. If Log Service fails to check log data due to exceptions such as network failures, the overall count does not change.
Notification Interval	The time interval at which Log Service sends an alert notification. If the number of times that the trigger condition is met exceeds the specified **Notification Trigger Threshold** and the specified notification interval elapses, Log Service sends an alert notification to the specified recipients. If you set this parameter to 5 minutes, you can receive up to one alert notification every 5 minutes. The default value is No Interval. **Note** You can use the Notification Trigger Threshold and Notification Interval parameters to control the number of alert notifications that you receive.

7. Set the notification method.

   Notifications can be sent to a custom webhook address in a specified format. To use this notification method, you must set the **Request URL**, **Request Method**, and **Request Content** parameters. For more information, see Notification methods.

   - **Request URL**: a custom webhook address, for example, https://webhook.com/notify.
   - **Request Method**: the request method. Request methods include GET, PUT, POST, DELETE, and OPTIONS.
   - **Request Content**: the content of the notification. The content must be 1 to 500 characters in length. Template variables are supported.
8. Click **OK**.

23.5.2.2. Grant permissions on alerts to a RAM user

This topic describes how to grant a RAM user the permissions to enable the alerting feature.

Context

Grant a RAM user the permissions only to create and modify alerts. Create a custom authorization policy, and apply the policy to the RAM user. For more information, see Procedure in this topic.

Procedure

1. Log on to the Apsara Uni-manager Management Console as an administrator.

For more information, see Log on to the Log Service console.

2. Create a RAM role.
3. Create a permission policy.

   Use the following policy and replace the `<Project name>` with the actual project name.

```
{
 "Version": "1",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "log:CreateLogStore",
    "log:CreateIndex",
    "log:UpdateIndex"
   ],
   "Resource": "acs:log:*:*:project/<Project name>/logstore/internal-alert-history"
  },
  {
   "Effect": "Allow",
   "Action": [
    "log:CreateDashboard",
    "log:CreateChart",
    "log:UpdateDashboard"
   ],
   "Resource": "acs:log:*:*:project/<Project name>/dashboard/*"
  },
  {
   "Effect": "Allow",
   "Action": [
    "log:*"
   ],
   "Resource": "acs:log:*:*:project/<Project name>/job/*"
  }
 ]
}
```

4. Create a user.
5. Create a RAM user group.
6. Add a RAM user to a RAM user group
7. Grant permissions to a RAM role.

23.5.2.3. Configure alert notification methods

This topic describes how to configure the notification methods for an alert in Log Service. Log Service supports the following alert notification methods: custom webhooks and DingTalk chatbot webhooks.

Custom webhooks

You can set the alert notification method to WebHook-Custom. If an alert is triggered, Log Service sends an alert notification to the custom webhook URL.

> **Note** The timeout period for this method is 5 seconds. If no response is received within 5 seconds after a notification is sent, it means that the notification has failed.

1. When you Configure alerts, select **WebHook-Custom** from the **Notifications** drop-down list.
2. Set the following parameters.

Parameter	Description
Request URL	The custom webhook URL.
Request Method	The method that is used to send the notification. Request available methods include GET, POST, DELETE, PUT, and OPTIONS. The default request header is Content-Type: application/json;charset=utf-8. If you need to add request headers, click **Add Request Headers**.
Content	The notification content is specified by default. The value must be 1 to 500 characters in length. You can specify a custom value. Template variables are supported. For more information, see Template variables.

3. Click **Submit**.

DingTalk chatbot webhooks

If you set the notification method to WebHook-DingTalk Bot, Log Service sends alert notifications by using a DingTalk chatbot to the DingTalk group to which a specified webhook URL points. The chatbot can also remind the specified contacts of the alert notifications.

> **Note** Each DingTalk chatbot can send a maximum of 20 alert notifications per minute.

1. Create a DingTalk chatbot.
   i. Open DingTalk and go to a DingTalk group.
   ii. In the upper-right corner of the chat window, click the **Group Settings** icon and choose **Group Assistant > Add Robot**.
   iii. In the **ChatBot** dialog box, click the **+** icon in the **Add Robot** section.
   iv. In the Robot details dialog box, select **Custom (Custom message services via Webhook)** and click **Add**.
   v. In the **Add Robot** dialog box, enter a **chatbot name** and select **security options** based on your business requirements. Then, select **I have read and accepted DingTalk Custom Robot Service Terms of Service** and click **Finished**.

      > **Note** We recommend that you set the **Security Settings** parameter to **Custom Keywords**. You can set a maximum of 10 keywords. Each message must contain at least one keyword. We recommend that you set a keyword to **Alert**. 关于安全设置，更多信息，请参见钉钉开放平台。

   vi. Click **Copy** to copy the webhook URL.
2. Configure a notification method in the Log Service console.
   i. When you Configure alerts, select **WebHook-DingTalk Bot** from the **Notifications** drop-down list.

ii. Set the following parameters.

Parameter	Description
Request URL	The webhook URL of the DingTalk chatbot. Paste the webhook URL that you copied in Step 1.
Title	The alert topic. The value must be 1 to 100 characters in length. You can specify a custom value. Template variables are supported. For more information, see Template variables.
Recipients	The group members whom you want to remind to read the alert notification. Valid values: None, All, and Specified Members. If you select **Specified Members**, enter the mobile phone numbers of the group members in the **Tagged List** field. Separate multiple mobile phone numbers with commas (,).
Content	The notification content is specified by default. You can modify the content based on your business requirements. The value must be 1 to 500 characters in length. You can specify a custom value. Template variables are supported. For more information, see Template variables. **Note** If you need to remind a group member to read the alert notification, use the **@<Mobile phone number of the group member>** syntax in the **Content** field.

iii. Click **Submit**.

Template variables

You must set **Content** for each notification method. In the notification content, you can reference some template variables in the ${fieldName} format for the alert. When Log Service sends an alert notification, Log Service replaces the template variables referenced in the **Content** field with the actual values. For example, Log Service replaces ${Project} with the name of the project to which the alert belongs.

Note You must reference valid variables. If a referenced variable does not exist or is invalid, Log Service processes the variable as a null string. If the value of a referenced variable is of the object type, the value is converted and displayed as a JSON string.

The following table describes all available variables and how to reference these variables for an alert.

Variable	Description	Example	Reference example
Aliuid	The ID of the Apsara Stack tenant account to which the project belongs.	1234567890	The alert that is configured by the user ${Aliuid} is triggered.
Project	The project to which the alert belongs.	my-project	The alert that is configured in the project ${Project} is triggered.
AlertID	The alert ID	0fdd88063a611aa114938f9371daeeb6-1671a52eb23	The ID of the triggered alert is ${AlertID}.
AlertName	The name of the alert. The name must be unique in a project.	alert-1542111415-153472	The ${AlertName} alert is triggered.

Variable	Description	Example	Reference example
AlertDisplayName	The display name of the alert rule.	My alert	The ${AlertDisplayName} alert is triggered.
Condition	The conditional expression that triggers the alert. Each variable in the conditional expression is replaced by the value that triggers the alert. The value is enclosed in brackets [].	[5] > 1	The conditional expression that triggers the alert is ${Condition}.
RawCondition	The original conditional expression that triggers the alert is ${RawCondition}.	count > 1	The trigger condition is ${RawCondition}.
Dashboard	The name of the dashboard with which the alert is associated.	mydashboard	The alert rule is associated with the ${Dashboard} dashboard.
DashboardUrl	The URL of the dashboard with which the alert is associated.	https://sls.console.aliyun.com/next/project/myproject/dashboard/mydashboard	The URL of the dashboard that is associated with the alert is ${DashboardUrl}.
FireTime	The time when the alert is triggered.	2018-01-02 15:04:05	The alert is triggered at ${FireTime}.
FullResultUrl	The URL that is used to query the history records that the alert was triggered.	https://sls.console.aliyun.com/next/project/my-project/logsearch/internal-alert-history?endTime=1544083998&queryString=AlertID%3A9155ea1ec10167985519fccede4d5fc7-1678293caad&queryTimeType=99&startTime=1544083968	Click ${FullResultUrl} to view details.

Variable	Description	Example	Reference example

Results	The parameters and results of each log data query. The value is of the array type. For more information, see Fields in alert log entries.
	Note A maximum of 100 alert notifications can be sent.
		[
		{
		"EndTime": 1542507580,
		"FireResult": {
		"__time__": "1542453580",
		"count": "0"
		},
		"LogStore": "test-logstore",
		"Query": "* | SELECT COUNT(*) as count",
		"RawResultCount": 1,
		"RawResults": [
		{
		"__time__": "1542453580",
		"count": "0"
		}
		],
		"StartTime": 1542453580
		}
		]
			The first query starts at ${Results[0].StartTime} and ends at ${Results[0].EndTime}. The alert has been triggered ${Results[0].FireResult.count} times.
			Note In this example the value 0 is the sequence number of a chart. For more information, see How can I view the serial number of a chart?

23.5.3. Modify and view an alarm

23.5.3.1. Modify an alert

This topic describes how to modify an alert. After you create an alert, you can modify the alert and then update the alert. To modify an alert associated with a search statement, you can directly modify the search statement.

Precautions

- You can modify only search statements with which alerts are associated. You cannot modify search statements to search and analytic statements, which are in the format of `search statement|analytic statement`.

  For example, after you associate the `request_method: GET` statement with an alert, you can modify the statement to `error`, but you cannot modify the statement to `error| select count(1) as c`.
- To modify an alert, you can click **Modify Settings** on the **Alert Overview** page, or choose **Alerts > Modify** on the associated dashboard.

Modify the search statement associated with an alert

If you associate a search statement with an alert, you can modify the search statement to modify the alert.

1. Log on to the Log Service console.
2. Click a project name.
3. In the left-side navigation pane, click the **Dashboard** icon.
4. In the dashboard list, click the name of the target dashboard.
5. On the dashboard, choose **Alerts > Modify**.
6. Find the search statement, and then click  .

   You can modify only search statements with which alerts are associated. You cannot modify search statements to search and analytic statements, which are in the format of `search statement|analytic statement`.
7. On the dialog box that appears, enter a new search statement, click **Preview**, and then click **OK** after the search statement is verified.
8. Modify other parameters specific to your environment, such as **Frequency** and **Trigger Condition**, and then click **Next**.
9. Set the notification method, and then click **Submit**.

Modify the chart associated with an alert

After you create an alert, you can modify the chart associated with the alert to modify the alert.

1. In the dashboard list, click the name of the target dashboard.
2. On the dashboard, choose **Alerts > Modify**.
3. Find the **Associated Chart**, and then click  next to **Query**.
4. On the dialog box that appears, enter a new query statement, click **Preview**, and then click **OK** after the query statement is verified.
5. Modify other parameters specific to your environment, such as **Frequency** and **Trigger Condition**, and then click **Next**.
6. Set the notification method.
7. Click **Submit**. The new settings take effect immediately.

23.5.3.2. View history alerts

This topic describes how to view history alerts in the Log Service console. Log Service records alerts as log data and creates a dashboard to display alert details.

View history alerts in the Logstore

When you create an alert, Log Service creates a Logstore named **internal-alert-history** for the project to which the alert belongs. A log entry is generated and written to the Logstore each time the alert rule is executed, regardless of whether the alert is triggered. For more information about the fields in the log entry, see Fields in alert log entries.

> **Note** The Logstore does not incur fees and cannot be deleted or modified. Each alert log entry is retained in the Logstore for seven days.

1. Log on to the Log Service console.
2. Click a project name.

3. Click the icon next to the **internal-alert-history** Logstore, and then select **Search & Analysis**.
4. On the page that appears, query alert log entries based on your needs.

View history alerts on the dashboard

After you create an alert, Log Service creates a dashboard named **internal-alert-analysis** for the project to which the alert belongs. The dashboard displays the statistics of all previous alerts, including the number of triggered alerts, percentage of successful alerts and notifications, and top 10 alerts whose alert rules are executed.

> **Note** The dashboard cannot be deleted or modified.

1. In the left-side navigation pane, click the **Dashboard** icon.
2. Click **Alert History Statistics** to open the dashboard page.

   On the **Alert History Statistics** dashboard, the details of history alerts are displayed, including whether the alerts are triggered, why the alerts are triggered, error information, and other information.

23.5.3.3. Manage an alert

This topic describes how to manage an alert after you create the alert.

Context

You can disable, enable, modify, and delete the alert, or view the details of the alert such as the update time.

View the details of an alert

1. Log on to the Log Service console.
2. Click a project name.
3. In the left-side navigation pane, click the **Alerts** icon.
4. In the alert list, click the name of the target alert.

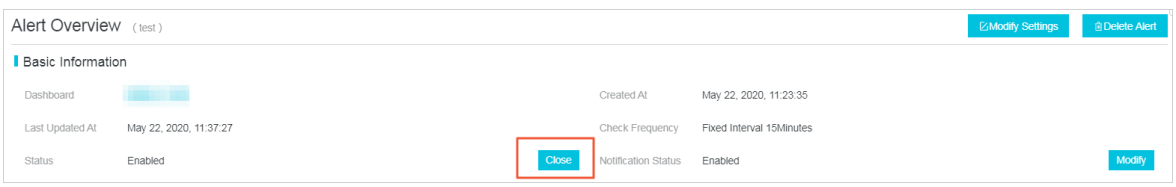
   On the **Alert Overview** page, you can view the details of the alert, such as the dashboard, creation time, last update time, check frequency, alert status, and notification status.

Disable and enable an alert

After you create an alert, you can disable or enable the alert. If you disable an alert, Log Service no longer checks the alert or send alert notifications.

1. In the left-side navigation pane, click the **Alerts** icon.
2. In the alert list, click the name of the target alert.

   On the **Alert Overview** page, click **Enable** or **Close** in the **Alert Status** field.

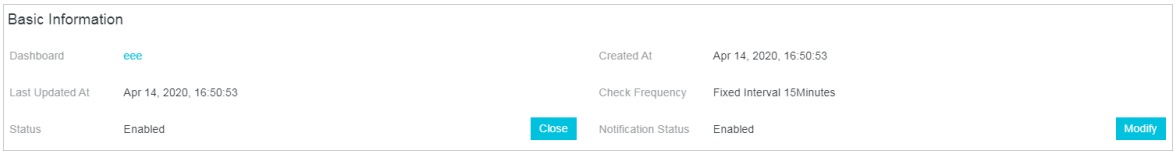


Disable and enable alert notifications

You can disable notifications of enabled alerts. After you disable notifications of an alert, alert notifications are not sent even if the trigger condition is met.

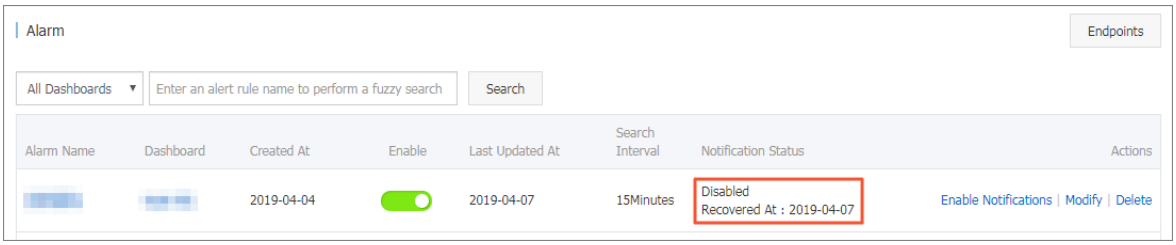
1. In the left-side navigation pane, click the **Alerts** icon.
2. In the alert list, click the name of the target alert.

   On the **Alert Overview** page, click **Modify** in the **Notification Status** field.



3. Set the time range for which notifications are disabled, and then click **Confirm**.

   After you disable alert notifications, you can view the time when alert notifications resume in the **Notification Status** field. You can click **Modify** in the **Notification Status** field to manually resume alert notifications.



Delete an alert

You cannot recover a deleted alert. Proceed with caution when you delete an alert.

1. In the left-side navigation pane, click the **Alerts** icon.
2. In the alert list, click the name of the target alert.
3. On the **Alert Overview** page, click **Delete Alert**.
4. In the dialog box that appears, click **OK**.

23.5.4. Relevant syntax and fields for reference

23.5.4.1. Conditional expression syntax of an alert

This topic describes how to configure a conditional expression for an alert in Log Service. An alert is triggered if the conditional expression configured for the alert is met.

In determining whether the conditional expression of an alert is met, the results of query statements configured for the alert are used as the inputs and the log fields in the conditional expression are used as the variables. If the conditional expression is met, the alert is triggered.

Limits

- Negative numbers must be enclosed with parentheses (), for example, x +(-100)<100.
- Numeric data is treated as 64-bit floating-point numbers. If a comparison is performed, errors may occur.
- A variable can contain only letters and digits and must start with a letter.
- A conditional expression can be up to 128 characters in length.
- A conditional expression can be evaluated up to 1,000 times. If an alert is configured for multiple charts and the conditional expression of the alert is not met after 1,000 times of evaluation, the alert is not triggered.
- A maximum of three charts can be associated with an alert.

- An alert is triggered if and only if the Boolean value of its conditional expression is true. For example, the result of the expression 100+100 is 200, which cannot trigger the alert.
- `true` , `false` , `$` , and `.` are reserved and cannot be used as variables.

Basic syntax

The following table lists the syntax supported in a conditional expression.

Syntax	Description	Examples
Basic operators	Supports the addition operator (+), subtraction operator (-), multiplication operator (*), division operator (/), and modulus operator (%).	x*100+y>200 x%10>5
Comparison operators	Supports eight comparison operators, including the greater than operator (>), greater than or equal to operator (>=), less than operator (<), less than or equal to operator (<=), equal to operator (==), not equal to operator (! =), match operator (=~), and mismatch operator (! ~). **Note** • Backslashes (/) must be escaped. • Regular expressions support the RE2 syntax.	x >= 0 x < 100 x <= 100 x == 100 x == "foo" Regular expression: x =~ "\\w +"
Logical operators	Supports the logical operators AND (&&) and OR (||).	x >=0&&y <=100 x > 0 || y > 0
Logical negation	Supports the logical negation operator (!).	!(a < 1 && a > 100)
Numeric constants	Numeric constants are processed as 64-bit floating-point numbers.	x > 100
String constants	String constants are formatted in a string enclosed in single quotation marks ('').	foo == 'string'
Boolean constants	Supports true and false.	(x > 100) == true
Parentheses	Parentheses () can be used to enforce precedence order.	x*(y+100)>100
contains function	Determines whether a substring is included in a string. For example, if the result of the contains(field, 'xxxx') function is true, the field string includes the xxxx substring.	contains(foo, 'hello')

Conditional expression for results of multiple query statements

- Syntax

  If you configure an alert for multiple charts, the variables in a conditional expression must be prefixed. In this way, you can specify from which query result to obtain the corresponding values of the variables when it evaluates your expression. The format is `$N.fieldname` , where N is the sequence number of the query statement. You can configure up to three query statements in an alert. Therefore the value range of N is 0 to 2. For example, $0.foo indicates to obtain the value of the foo field returned from the first query statement. If you configure one query statement in an alert, you do not need to specify the prefix.

> **Note** How can I view the sequence number of a query statement?
>
> In the Alert Configuration step, the **Associated Chart** parameter specifies the sequence number of each query statement (chart). The first query statement is numbered 0, the second query statement is numbered 1, and the third statement is numbered 2.

- Evaluate a conditional expression

  If multiple query results are returned, the variables specified in the conditional expression determine how to use the results to evaluate the conditional expression. For example, if you configure three query statements in an alert, x, y, and z log entries are returned when you execute each of the three statements. The conditional expression that you configure for the alert is $0.foo > 100 && $1.bar < 100. Then the first two query results are used to evaluate the conditional expression. A maximum of **x × y** times of evaluation (or 1,000 if x × y is greater than 1,000) is performed. If the conditional expression is met within the maximum times of evaluation, true is returned. Otherwise, false is returned.

Operations

> **Note**
> - 64-bit floating-point numbers are used in a conditional expression.
> - Each string constant must be enclosed in single quotation marks ('') or double quotation marks (""), for example, 'string', and "string".
> - Boolean values include true and false.

Operator	Operation		
	Operation between variables	Operation between non-string constants and variables	Operation between string constants and variables
Basic operators, including the addition operator (+), subtraction operator (-), multiplication operator (*), division operator (/), and modulus operator (%)	The left and right operands are converted to numbers before being operated.		Unsupported.

Operator	Operation		
	Operation between variables	Operation between non-string constants and variables	Operation between string constants and variables
Comparison operators, including the greater than operator (>), greater than or equal to operator (>=), less than operator (<), less than or equal to operator (<=), equal to operator (==), not equal to operator (! =)	Operations are performed based on the following priorities: 1. The left and right operands are converted to numbers before being operated based on the numerical order. If the conversion fails, 2. operands are operated based on the alphabetical order of strings.	The left and right operands are converted to numbers before being operated based on the numerical order.	The left and right operands are operated based on the alphabetical order of strings.
Regular expression match operator (=~) and regular expression mismatch operator (! ~)	The left and right operands are operated based on the alphabetical order of strings.	Unsupported.	The left and right operands are operated based on the alphabetical order of strings.
Logical operators, including AND (&&) and OR (||)	These two operators cannot be directly used on the fields in query results. The left and right operands must be sub-expressions, and the values of the sub-expressions are of the Boolean type.		
Logical negation (!)	This operator cannot be directly used on the fields in query results. The left and right operands must be sub-expressions, and the values of the sub-expressions are of the Boolean type.		
contains function	The left and right operands are operated based on the alphabetical order of strings.	Unsupported.	The left and right operands are operated based on the alphabetical order of strings.
Parentheses ()	Parentheses () enforce precedence order.		

23.5.4.2. Fields in alert log entries

After you configure an alert, Log Service automatically creates a Logstore to store log entries that are generated when alert rules are executed and notifications are sent. This topic describes fields in alert log entries.

Fields

Field	Description	Example
AlertDisplayName	The display name of an alert.	Test alert rules
AlertID	The unique ID of an alert.	0fdd88063a611aa114938f9371daeeb6-1671a52eb23
AlertName	The unique name of an alert in a project.	alert-1542111415-153472
Condition	The conditional expression configured for an alert.	$0.count > 1
Dashboard	The dashboard associated with an alert.	my-dashboard
FireCount	The cumulative times that an alert has been triggered since the last notification was sent.	1
Fired	Indicates whether an alert was triggered. Valid values: true and false.	true
LastNotifiedAt	The time when the last notification was sent. The time is displayed in a Unix timestamp.	1542164541
NotifyStatus	The status of a notification. Valid values: • Success: indicates that a notification was successfully sent. • Failed: indicates that a notification failed to be sent. • NotNotified: indicates that no notification was sent. • PartialSuccess: indicates that the notification sending partially succeeded.	Success
Reason	The reason that a notification failed to be sent or no notification was sent.	result type is not bool

Field	Description	Example

Results	The parameters and results of each log data query. The value is of the array type. For information about parameters in the Results field, see Parameters in the Result field.	[
		{
		"EndTime": 1542334900,
		"FireResult": null,
		"LogStore": "test-logstore",
		"Query": "* | select count(1) as count",
		"RawResultCount": 1,
		"RawResults": [
		{
		"__time__": "1542334840",
		"count": "0"
		}
		],
		"StartTime": 1542334840
		}
		]

Status	The execution result of an alert. Valid values: Success and Failed.	Success

Parameters in the Result field

Parameter	Description	Example
Query	The query statement that is configured in an alert.	* | select count(1) as count
LogStore	The target Logstore of a query.	my-logstore
StartTime	The time when a query starts.	2019-01-02 15:04:05
StartTimeTs	The time when a query starts. The time is in the Unix timestamp format.	1542334840
EndTime	The time when a query ends.	2019-01-02 15:19:05
EndTimeTs	The time when a query ends. The time is in the Unix timestamp format. The actual query time range is `[StartTime, EndTime)`.	1542334900

RawResults	The raw query result. The parameter value is formatted in an array where each element is a log entry. The maximum length of the array is 100.	[
		{
		"__time__": "1542334840",
		"count": "0"
		}
		]

Parameter	Description	Example
RawResultsAsKv	The query result that is formatted in key-value pairs. **Note** This parameter can only be used as a template variable. It is not saved to a Logstore.	[foo:0]
RawResultCount	The number of log entries that are returned in the RawResults parameter.	1
FireResult	The log entry that records the triggering of an alert. If an alert is not triggered, the parameter value is null.	{ "__time__": "1542334840", "count": "0" }
FireResultAsKv	The log entry that records the triggering of an alert, formatted in key-value pairs. **Note** This parameter can only be used as a template variable. It is not saved to a Logstore.	[foo:0]

23.6. Real-time consumption

23.6.1. Overview

Log Service allows you to consume log data by using multiple methods.

After data is collected to LogHub, you can consume the log data by using two methods. The following table describes the methods.

Method	Scenarios	Timeliness	Retention period
Real-time consumption (LogHub)	Real-time computing	Real time	Custom
Indexing and query (LogSearch)	Online query of hot data	Real time	Custom

Real-time consumption

LogHub allows you to pull log data and consume the data in real time. The following procedure describes how log data in a shard is consumed:

1. Obtain a cursor based on the start time and end time of data consumption.
2. Read log data based on the cursor and step parameters and return the position of the next cursor.
3. Move the cursor to continuously consume log data.

- Consume log data by using an SDK

You can use Log Service SDKs in multiple programming languages such as Java, Python, and Go to consume log data.

- Consume log data by using consumer groups

  Log Service provides an advanced method that allows you to consume logs by using consumer groups. A consumer group is a lightweight computing framework that allows multiple consumers to consume data from a Logstore at the same time. The consumers in a consumer group are automatically allocated shards. Data is consumed in order based on the time when it is written to the Logstore. In addition, the consumers can use checkpoints to resume consumption from a breakpoint. You can use consumer group SDKs in multiple programming languages such as Go, Python, and Java to consume log data.

- Log consumption by using real-time stream processing systems
  - Use Spark Streaming clients to consume log data.
  - Use Storm spouts to consume log data.
  - Use Flink Connector to consume log data.

- Log consumption by using open-source services

  Use Flume to consume log data and import log data to Hadoop file system (HDFS) instances.

Log search and analytics

- You can query log data in the Log Service console.
- You can also query log data by using an SDK or the API of Log Service. Log Service provides an HTTP-based RESTful API. You can call all log query API operations that are provided by Log Service.

23.6.2. Consume log data

Log Service provides SDKs in various programming languages, such as Java, Python, and Go. You can use an SDK to consume log data.

Use an SDK to consume log data

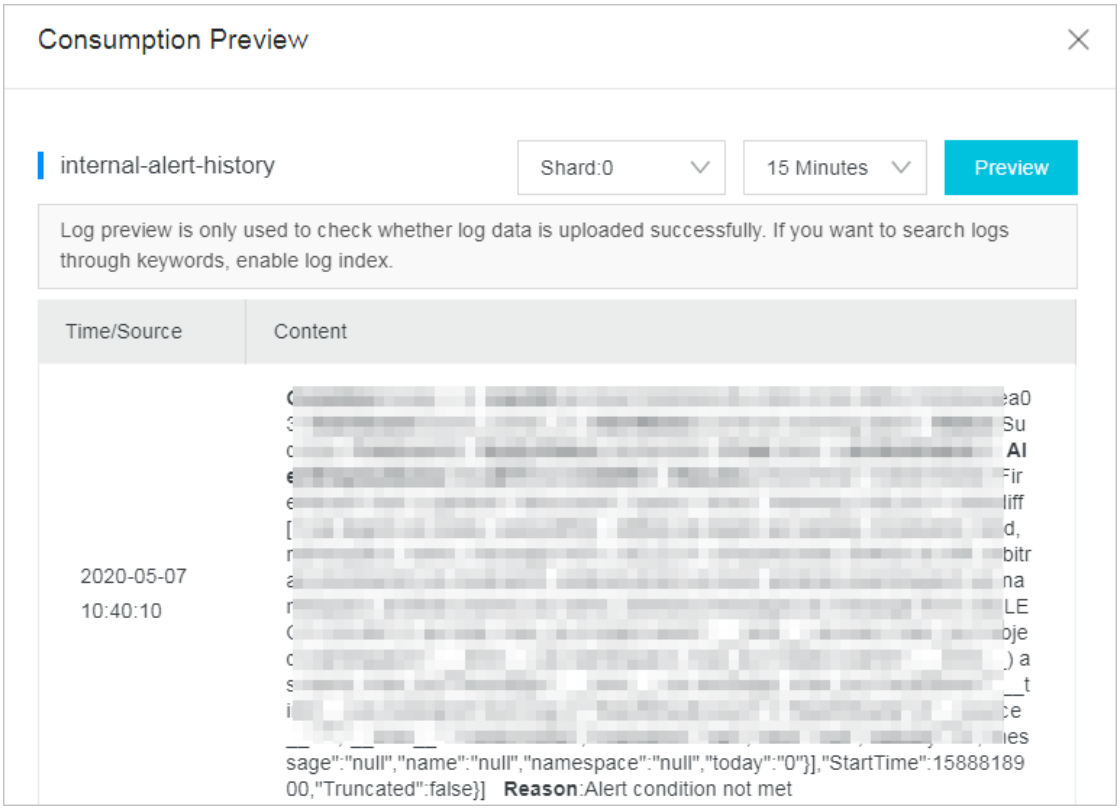
The following example shows how to use the SDK for Java to consume log data in a shard:

```
Client client = new Client(host, accessId, accessKey);
  String cursor = client.GetCursor(project, logStore, shardId, CursorMode.END).GetCursor();
  System.out.println("cursor = " +cursor);
  try {
   while (true) {
    PullLogsRequest request = new PullLogsRequest(project, logStore, shardId, 1000, cursor);
    PullLogsResponse response = client.pullLogs(request);
    System.out.println(response.getCount());
    System.out.println("cursor = " + cursor + " next_cursor = " + response.getNextCursor());
    if (cursor.equals(response.getNextCursor())) {
      break;
        }
    cursor = response.getNextCursor();
    Thread.sleep(200);
   }
  }
  catch(LogException e) {
   System.out.println(e.GetRequestId() + e.GetErrorMessage());
  }
```

Preview log data in the Log Service console

Log preview is a way of log data consumption. To preview log data that is stored in a Logstore in the Log Service console, perform the following steps:

1. Log on to the Log Service console.
2. In the Projects section, click the target project.
3. In the Logstore list, find the target Logstore, click the icon next to the Logstore, and then select **Consumption Preview**.
4. In the Consumption Preview dialog box, select a shard, set a time range, and then click **Preview**.
   The log preview page displays the log data of the first 10 packets in the specified time range.



23.6.3. Consumption by consumer groups

23.6.3.1. Use consumer groups to consume log data

Log consumption by using consumer groups

Consumer groups allow you to focus on the business logic during log data consumption. You do not need to consider factors such as Log Service implementation, load balancing among consumers, and failovers that may be introduced when you use an SDK to consume log data.

Terms

The following table describes the terms of consumer groups and consumers.

Term	Description
consumer group	A consumer group consists of multiple consumers. Each consumer in a consumer group consumes different data in a Logstore.
consumer	The consumers in a consumer group consume data from specified data sources. Each consumer name in a consumer group must be unique.

A Logstore has multiple shards. A consumer library allocates shards to consumers in a consumer group based on the following principles:

- Each shard can be allocated to one consumer.
- Each consumer can consume data from multiple shards.

After a new consumer joins a consumer group, the shards allocated to the consumer group are reallocated to each consumer for load balancing. The reallocation is based on the preceding principles and cannot be viewed by users.

A consumer library stores checkpoints. This allows consumers to resume consumption from a breakpoint and avoid repetitive consumption after a program fault is resolved.

Procedure

Log consumption by using consumer groups is implemented in Java or Python. The following procedure takes Java as an example to describe how consumer groups consume log data.

1. Add Maven dependencies.

```
<dependency>
 <groupId>com.google.protobuf</groupId>
 <artifactId>protobuf-java</artifactId>
 <version>2.5.0</version>
</dependency>
<dependency>
 <groupId>com.aliyun.openservices</groupId>
 <artifactId>loghub-client-lib</artifactId>
 <version>0.6.16</version>
</dependency>
```

2. Create a file named main.java.

```
import com.aliyun.openservices.loghub.client.ClientWorker;
import com.aliyun.openservices.loghub.client.config.LogHubConfig;
import com.aliyun.openservices.loghub.client.exceptions.LogHubClientWorkerException;
public class Main {
  // The endpoint of Log Service.
  private static String sEndpoint = "cn-hangzhou.log.aliyuncs.com";
  // The name of a Log Service project.
  private static String sProject = "ali-cn-hangzhou-sls-admin";
  // The name of a Logstore.
  private static String sLogstore = "sls_operation_log";
  // The name of a consumer group.
  private static String sConsumerGroup = "consumerGroupX";
  // The AccessKey pair of an Apsara Stack tenant account or RAM user that is used to consume data.
  private static String sAccessKeyId = "";
  private static String sAccessKey = "";
  public static void main(String[] args) throws LogHubClientWorkerException, InterruptedException {
    // The second parameter is the consumer name. Each consumer name in a consumer group must be unique. How
ever, the names of consumer groups can be the same. When different consumers start multiple processes on multip
le servers to consume the data of a Logstore, you can use a server IP address to identify a consumer. The ninth para
meter maxFetchLogGroupSize indicates the maximum number of log groups that are retrieved from the server at a t
ime. Valid values: 1 to 1000. You can use the default value or specify a value based on your requirements.
    LogHubConfig config = new LogHubConfig(sConsumerGroup, "consumer_1", sEndpoint, sProject, sLogstore, sAc
cessKeyId, sAccessKey, LogHubConfig.ConsumePosition.BEGIN_CURSOR);
    ClientWorker worker = new ClientWorker(new SampleLogHubProcessorFactory(), config);
    Thread thread = new Thread(worker);
    // The ClientWorker instance automatically runs after the thread is executed and extends the Runnable interface
.
    thread.start();
    Thread.sleep(60 * 60 * 1000);
    // The shutdown function of the ClientWorker instance is called to exit the consumption instance. The associate
d thread is  automatically stopped.
    worker.shutdown();
    // Multiple asynchronous tasks are generated when the ClientWorker instance is running. We recommend that y
ou wait for 30 seconds to ensure that all running tasks exit after shutdown.
    Thread.sleep(30 * 1000);
  }
}
```

3. Create a file named SampleLogHubProcessor.java.

```
import com.aliyun.openservices.log.common.FastLog;
import com.aliyun.openservices.log.common.FastLogContent;
import com.aliyun.openservices.log.common.FastLogGroup;

public class SampleLogHubProcessor implements ILogHubProcessor {
  private int shardId;
  // Record the last persistent checkpoint time.
  private long mLastCheckTime = 0;
  public void initialize(int shardId) {
    this.shardId = shardId;
  }
  // The main logic of data consumption. All exceptions must be captured and cannot be thrown.
  public String process(List<LogGroupData> logGroups,
            ILogHubCheckPointTracker checkPointTracker) {
```

```
    // Display the retrieved data.
    for (LogGroupData logGroup : logGroups) {
      FastLogGroup flg = logGroup.GetFastLogGroup();
      System.out.println(String.format("\tcategory\t:\t%s\n\tsource\t:\t%s\n\ttopic\t:\t%s\n\tmachineUUID\t:\t%s
",
          flg.getCategory(), flg.getSource(), flg.getTopic(), flg.getMachineUUID()));
      System.out.println("Tags");
      for (int tagIdx = 0; tagIdx < flg.getLogTagsCount(); ++tagIdx) {
        FastLogTag logtag = flg.getLogTags(tagIdx);
        System.out.println(String.format("\t%s\t:\t%s", logtag.getKey(), logtag.getValue()));
      }
      for (int lIdx = 0; lIdx < flg.getLogsCount(); ++lIdx) {
        FastLog log = flg.getLogs(lIdx);
        System.out.println("--------\nLog: " + lIdx + ", time: " + log.getTime() + ", GetContentCount: " + log.getContent
sCount());
        for (int cIdx = 0; cIdx < log.getContentsCount(); ++cIdx) {
          FastLogContent content = log.getContents(cIdx);
          System.out.println(content.getKey() + "\t:\t" + content.getValue());
        }
      }
    }
    long curTime = System.currentTimeMillis();
    // Write checkpoints to the server every 30 seconds. If a ClientWorker instance does not respond within 30 secon
ds,
    // a new ClientWorker instance consumes data starting from the last checkpoint. A small amount of duplicate da
ta may exist.
    if (curTime - mLastCheckTime > 30 * 1000) {
      try {
        // If the parameter is set to true, checkpoints are synchronized to the server immediately. If the parameter is
set to false, checkpoints are  locally cached. The default synchronization interval of checkpoints is 60 seconds.
        checkPointTracker.saveCheckPoint(true);
      } catch (LogHubCheckPointException e) {
        e.printStackTrace();
      }
      mLastCheckTime = curTime;
    }
    return null;
  }
  // The ClientWorker instance calls this function upon exit. You can perform a cleanup.
  public void shutdown(ILogHubCheckPointTracker checkPointTracker) {
    // Save consumption breakpoints to the server.
    try {
      checkPointTracker.saveCheckPoint(true);
    } catch (LogHubCheckPointException e) {
      e.printStackTrace();
    }
  }
}
class SampleLogHubProcessorFactory implements ILogHubProcessorFactory {
  public ILogHubProcessor generatorProcessor() {
    // Generate a consumption instance.
    return new SampleLogHubProcessor();
  }
}
```

> **Note** Run the preceding code to display all data in a Logstore. If you want multiple consumers to consume data from the same Logstore, you can modify the code based on the comments. You can use the same consumer group name and different consumer names to start new consumption processes.

Limits and troubleshooting

You can create a maximum of 10 consumer groups for each Logstore. The `ConsumerGroupQuotaExceed` error is reported if the number of consumer groups exceeds 10.

We recommend that you configure Log4j for the consumer program to throw error messages within consumer groups. This improves the troubleshooting efficiency. If you save the log4j.properties file to the resources directory and run the program, the following error message appears:

```
[WARN ] 2018-03-14 12:01:52,747 method:com.aliyun.openservices.loghub.client.LogHubConsumer.sampleLogError(Log
HubConsumer.java:159)
com.aliyun.openservices.log.exception.LogException: Invalid loggroup count, (0,1000]
```

The following example is a typical log4j. properties configuration file:

```
log4j.rootLogger = info,stdout
log4j.appender.stdout = org.apache.log4j.ConsoleAppender
log4j.appender.stdout.Target = System.out
log4j.appender.stdout.layout = org.apache.log4j.PatternLayout
log4j.appender.stdout.layout.ConversionPattern = [%-5p] %d{yyyy-MM-dd HH:mm:ss,SSS} method:%l%n%m%n
```

Advanced operations

The preceding code is suitable for log consumption in common scenarios. This section describes how to perform advanced operations in other scenarios.

- Consume data that is logged from a certain time point

  LoghubConfig in the preceding code has two constructors:

  ```
  // The value of the consumerStartTimeInSeconds parameter is a UNIX timestamp representing the number of seconds
  that have elapsed since 00:00:00 on January 1, 1970, 00:00:00 UTC.
  public LogHubConfig(String consumerGroupName,
              String consumerName,
              String loghubEndPoint,
              String project, String logStore,
              String accessId, String accessKey,
              int consumerStartTimeInSeconds);
  // The position parameter is an enumeration variable. LogHubConfig.ConsumePosition.BEGIN_CURSOR indicates that
  the consumption starts from the earliest data. LogHubConfig.ConsumePosition.END_CURSOR indicates that the cons
  umption starts from the latest data.
  public LogHubConfig(String consumerGroupName,
              String consumerName,
              String loghubEndPoint,
              String project, String logStore,
              String accessId, String accessKey,
              ConsumePosition position);
  ```

  You can use different constructors based on your requirements. However, if a checkpoint is stored on the server, you must start data consumption from this checkpoint.

- Reset a checkpoint

  In scenarios such as data padding or repeated computing, you may need to set the consumption position to a time point for a consumer group. Then data consumption is started from the consumption position. To set the consumption position, you can use either one of the following two methods:

- Delete the consumer group.
  a. Stop the consumption processes.
  b. Delete the consumer group from the Log Service console.
  c. Modify the code to specify the start time point for data consumption.
  d. Restart the consumption processes.
- Use an SDK to reset the start time point of data consumption for the consumer group.
  a. Stop the consumption processes.
  b. Use an SDK to modify the checkpoint.
  c. Restart the consumption processes.

```
public static void updateCheckpoint() throws Exception {
    Client client = new Client(host, accessId, accessKey);
    long timestamp = Timestamp.valueOf("2017-11-15 00:00:00").getTime() / 1000;
    ListShardResponse response = client.ListShard(new ListShardRequest(project, logStore));
    for (Shard shard : response.GetShards()) {
      int shardId = shard.GetShardId();
      String cursor = client.GetCursor(project, logStore, shardId, timestamp).GetCursor();
      client.UpdateCheckPoint(project, logStore, consumerGroup, shardId, cursor);
    }
  }
```

Use a RAM user to access consumer groups

Before you use a RAM user to access consumer groups, you must grant relevant permissions to the RAM user. For more information, see Grant permissions to a RAM role.

The following table lists the actions you can perform as a RAM user.

Action	Resource
log:GetCursorOrData	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*
log:CreateConsumerGroup	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*/consumergroup/*
log:ListConsumerGroup	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*/consumergroup/*
log:ConsumerGroupUpdateCheckPoint	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*/consumergroup/*${consumerGroupName}*
log:ConsumerGroupHeartBeat	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*/consumergroup/*${consumerGroupName}*
log:UpdateConsumerGroup	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*/consumergroup/*${consumerGroupName}*
log:GetConsumerGroupCheckPoint	acs:log:*${regionName}*:*${projectOwnerAliUid}*:project/*${projectName}*/logstore/*${logstoreName}*/consumergroup/*${consumerGroupName}*

For example, a project named project-test resides in the China (Hangzhou) region. The ID of the Apsara Stack tenant account to which the project belongs is 1234567. The name of the Logstore to be consumed is logstore-test and the consumer group name is consumergroup-test. To allow a RAM user to access the consumer group, you must grant the following permissions to the RAM user:

```
{
 "Version": "1",
 "Statement": [
  {
   "Effect": "Allow",
   "Action": [
    "log:GetCursorOrData"
   ],
   "Resource": "acs:log:cn-hangzhou:1234567:project/project-test/logstore/logstore-test"
  },
  {
   "Effect": "Allow",
   "Action": [
    "log:CreateConsumerGroup",
    "log:ListConsumerGroup"
   ],
   "Resource": "acs:log:cn-hangzhou:1234567:project/project-test/logstore/logstore-test/consumergroup/*"
  },
  {
   "Effect": "Allow",
   "Action": [
    "log:ConsumerGroupUpdateCheckPoint",
    "log:ConsumerGroupHeartBeat",
    "log:UpdateConsumerGroup",
    "log:GetConsumerGroupCheckPoint"
   ],
   "Resource": "acs:log:cn-hangzhou:1234567:project/project-test/logstore/logstore-test/consumergroup/consumergroup-test"
  }
 ]
}
```

23.6.3.2. View the status of a consumer group

This topic describes how to use the console, API, and SDK to view the status of a consumer group. Log data consumption by using consumer groups is an advanced real-time data consumption method provided by Log Service. Automatic load balancing is implemented among multiple consumption instances. Spark Streaming and Storm use consumer groups as the basic mode to consume log data.

View the consumption progress in the console

1. Log on to the Log Service console.
2. In the Projects section, click the target project.
3. Find the target Logstore, and choose > **Data Consumption**.
4. Click the consumer group whose data consumption progress you want to view. The data consumption progress of each shard in the Logstore is displayed.

Use an API or SDK to view the data consumption progress

The following example uses the SDK for Java to describe how to call API operations to view the data consumption progress.

```
package test;
import java.util.ArrayList;
import com.aliyun.openservices.log.Client;
import com.aliyun.openservices.log.common.Consts.CursorMode;
import com.aliyun.openservices.log.common.ConsumerGroup;
```

```
import com.aliyun.openservices.log.common.ConsumerGroupShardCheckPoint;
import com.aliyun.openservices.log.exception.LogException;
public class ConsumerGroupTest {
  static String endpoint = "";
  static String project = "";
  static String logstore = "";
  static String accesskeyId = "";
  static String accesskey = "";
  public static void main(String[] args) throws LogException {
    Client client = new Client(endpoint, accesskeyId, accesskey);
    //Query all consumer groups of this Logstore. If no consumer group exists, the length of consumerGroups is 0.
    ArrayList<ConsumerGroup> consumerGroups;
    try{
      consumerGroups = client.ListConsumerGroup(project, logstore).GetConsumerGroups();
    }
    catch(LogException e){
      if(e.GetErrorCode() == "LogStoreNotExist")
        System.out.println("this logstore does not have any consumer group");
      else{
        //internal server error branch
      }
      return;
    }
    for(ConsumerGroup c: consumerGroups){
      //Print consumer group properties, including the name, heartbeat timeout, and whether data is consumed in order
.
      System.out.println("Name: " + c.getConsumerGroupName());
      System.out.println("Heartbeat timeout: " + c.getTimeout());
      System.out.println("Consumption in order: " + c.isInOrder());
      for(ConsumerGroupShardCheckPoint cp: client.GetCheckPoint(project, logstore, c.getConsumerGroupName()).Get
CheckPoints()){
        System.out.println("shard: " + cp.getShard());
        //Format the returned time. The time is a long integer that is accurate to milliseconds.
        System.out.println("The last time when data was consumed: " + cp.getUpdateTime());
        System.out.println("Consumer name: " + cp.getConsumer());
        String consumerPrg = "";
        if(cp.getCheckPoint().isEmpty())
          consumerPrg = "Consumption not started";
        else{
          //The UNIX timestamp. Unit: seconds. Format the output value of the timestamp.
          try{
            int prg = client.GetPrevCursorTime(project, logstore, cp.getShard(), cp.getCheckPoint()).GetCursorTime();
            consumerPrg = "" + prg;
          }
          catch(LogException e){
            if(e.GetErrorCode() == "InvalidCursor")
              consumerPrg = "Invalid. The previous consumption time has exceeded the retention period of the data in th
e Logstore.";
            else{
              //internal server error
              throw e;
            }
          }
        }
        System.out.println("Consumption progress: " + consumerPrg);
        String endCursor = client.GetCursor(project, logstore, cp.getShard(), CursorMode.END).GetCursor();
        int endPrg = 0;
        try{
          endPrg = client.GetPrevCursorTime(project, logstore, cp.getShard(), endCursor).GetCursorTime();
        }
```

```
            }
            catch(LogException e){
              //do nothing
            }
            //The UNIX timestamp. Unit: seconds. Format the output value of the timestamp.
            System.out.println("The time when the last data entry was received: " + endPrg);
        }
      }
    }
}
```

23.6.4. Use LogHub Storm to consume log data

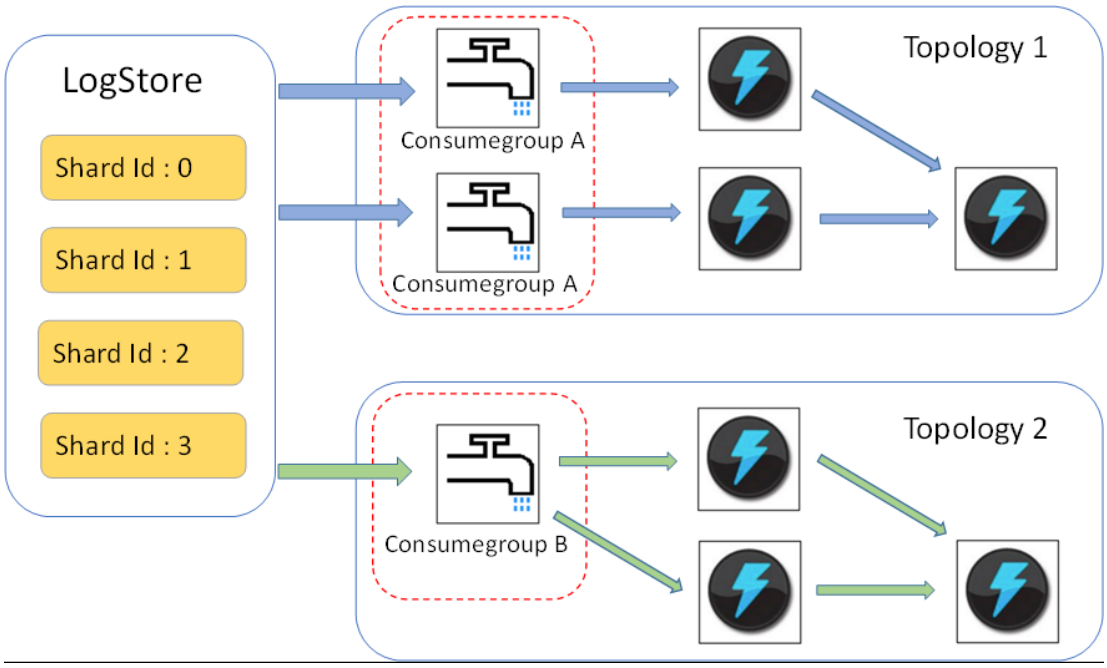
Log Service provides efficient and reliable log collection and consumption channels. You can use Logtail or the SDK to collect log data in real time. After logs are collected to LogHub, you can use Apache Spark Streaming, Apache Storm, and other real-time computation systems to consume the log data.

To reduce the consumption cost of LogHub data, Log Service provides LogHub Storm spouts for Storm users to read data from LogHub in real time.

Basic architecture and flowchart

- LogHub Storm spouts are enclosed in the boxes with red dashed lines. Each Storm topology has a group of spouts that read data from a Logstore. Spouts in different topologies are independent of each other.
- Each topology is identified by a unique LogHub consumer group name. Spouts in the same topology use a consumer library to achieve load balancing and automatic failover.
- Spouts read data from LogHub in real time, send data to bolts in the same topology, and then save consumption checkpoints to the LogHub server on a regular basis.

Basic architecture and flowchart



Limits

- You can create up to 10 consumer groups to consume log data from a Logstore. If a consumer group is no longer in use, you can call the DeleteConsumerGroup operation of the SDK for Java to delete the consumer group.
- We recommend that the number of spouts be equal to the number of shards in a Logstore. This is because a single spout may be unable to process a large amount of data in multiple shards.

- If the data volume in a shard exceeds the processing capacity of a single spout, you can split the shard to reduce its data volume.
- LogHub spouts and bolts must use the ack method to check whether log data is successfully sent from spouts to bolts and whether the data is successfully processed by the bolts.

Examples

- Use the following code to create spouts and construct a topology:

```
    public static void main( String[] args )
    {
        String mode = "Local"; // Specify to use the local test mode.
          String conumser_group_name = ""; // Specify a unique consumer group name for each topology. The name cannot be an empty string. It must be 3 to 63 characters in length and can contain lowercase letters, digits, hyphens (-), and underscores (_). It must start and end with a lowercase letter or digit.
        String project = ""; // Specify the project in Log Service.
        String logstore = ""; // Specify the Logstore in Log Service.
        String endpoint = ""; // Specify the endpoint of Log Service.
        String access_id = ""; // Specify the AccessKey ID of the user.
        String access_key = "";
        // Configure a LogHub Storm spout.
        LogHubSpoutConfig config = new LogHubSpoutConfig(conumser_group_name,
            endpoint, project, logstore, access_id,
            access_key, LogHubCursorPosition.END_CURSOR);
        TopologyBuilder builder = new TopologyBuilder();
        // Create a LogHub Storm spout.
        LogHubSpout spout = new LogHubSpout(config);
        // You can create the same number of spouts as that of shards in a Logstore in actual business scenarios.
        builder.setSpout("spout", spout, 1);
        builder.setBolt("exclaim", new SampleBolt()).shuffleGrouping("spout");
        Config conf = new Config();
        conf.setDebug(false);
        conf.setMaxSpoutPending(1);
        // Configure the serialization method of LogGroupData by using the LogGroupDataSerializSerializer class if Kryo is used to serialize and deserialize data.
        Config.registerSerialization(conf, LogGroupData.class, LogGroupDataSerializSerializer.class);
        if (mode.equals("Local")) {
          logger.info("Local mode...") ;
          LocalCluster cluster  = new LocalCluster();
          cluster.submitTopology("test-jstorm-spout", conf, builder.createTopology());
          try {
            Thread.sleep(6000 * 1000);   //waiting for several minutes
          } catch (InterruptedException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
          }
          cluster.killTopology("test-jstorm-spout");
          cluster.shutdown();
        } else if (mode.equals("Remote")) {
          logger.info("Remote mode...");
          conf.setNumWorkers(2);
          try {
            StormSubmitter.submitTopology("stt-jstorm-spout-4", conf, builder.createTopology());
          } catch (AlreadyAliveException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
          } catch (InvalidTopologyException e) {
            // TODO Auto-generated catch block
            e.printStackTrace();
          }
        } else {
          logger.error("invalid mode: " + mode);
        }
    }
}
```

- Use the following example code of bolts to consume log data and display the content of each log entry:

```
public class SampleBolt extends BaseRichBolt {
  private static final long serialVersionUID = 4752656887774402264L;
  private static final Logger logger = Logger.getLogger(BaseBasicBolt.class);
  private OutputCollector mCollector;
  @Override
  public void prepare(@SuppressWarnings("rawtypes") Map stormConf, TopologyContext context,
      OutputCollector collector) {
    mCollector = collector;
  }
  @Override
  public void execute(Tuple tuple) {
    String shardId = (String) tuple
        .getValueByField(LogHubSpout.FIELD_SHARD_ID);
    @SuppressWarnings("unchecked")
    List<LogGroupData> logGroupDatas = (ArrayList<LogGroupData>) tuple.getValueByField(LogHubSpout.FIELD_LO
GGROUPS);
    for (LogGroupData groupData : logGroupDatas) {
      // Each log group consists of one or more log entries.
      LogGroup logGroup = groupData.GetLogGroup();
      for (Log log : logGroup.getLogsList()) {
        StringBuilder sb = new StringBuilder();
        // Each log entry has a time field and other key-value pairs.
        int log_time = log.getTime();
        sb.append("LogTime:").append(log_time);
        for (Content content : log.getContentsList()) {
          sb.append("\t").append(content.getKey()).append(":")
              .append(content.getValue());
        }
        logger.info(sb.toString());
      }
    }
    // Spouts must use the ack method to indicate whether data has been successfully sent to bolts.
    // In addition, bolts must use the ack method to indicate whether data is successfully processed by the bolts.
    mCollector.ack(tuple);
  }
  @Override
  public void declareOutputFields(OutputFieldsDeclarer declarer) {
    //do nothing
  }
}
```

Maven

Use the following code to add Maven dependencies for Storm versions earlier than Storm 1.0 (for example, Storm 0.9.6):

```
<dependency>
 <groupId>com.aliyun.openservices</groupId>
 <artifactId>loghub-storm-spout</artifactId>
 <version>0.6.6</version>
</dependency>
```

Use the following code to add Maven dependencies for Storm 1.0 and later versions:

```
<dependency>
 <groupId>com.aliyun.openservices</groupId>
 <artifactId>loghub-storm-1.0-spout</artifactId>
 <version>0.1.3</version>
</dependency>
```

23.6.5. Use Flume to consume log data

This topic describes how to use Flume to consume log data. You can use the aliyun-log-flume plug-in to connect LogHub of Log Service to Flume, and then write and consume log data.

The aliyun-log-flume plug-in connects LogHub to Flume. When LogHub is connected to Flume, you can connect Log Service to other systems such as HDFS and Kafka through Flume. The aliyun-log-flume plug-in provides the Sink and Source methods to connect Log Service to Flume.

- Sink: uses Flume to read data from other data sources and then writes data to LogHub.
- Source: uses Flume to consume LogHub data and then writes data to other systems.

LogHub Sink

You can use the Sink method to transmit data from other data sources to LogHub through Flume. Data can be parsed into the following two formats:

- SIMPLE: writes a Flume event to LogHub as a field.
- DELIMITED: delimits a Flume event with delimiters, parses an event into fields based on the configured column names, and then writes the fields to LogHub.

The following table lists the parameters you can configure when you use the Sink method to read data.

Parameter	Required	Description
type	Yes	Valid value: com.aliyun.loghub.flume.sink.LoghubSink.
endpoint	Yes	The endpoint of Log Service.
project	Yes	The name of the project.
logstore	Yes	The name of the Logstore.
accessKeyId	Yes	The AccessKey ID of your Apsara Stack tenant account.
accessKey	Yes	The AccessKey secret of your Apsara Stack tenant account.
batchSize	No	The number of log entries that are written to LogHub at a time. Default value: 1000.
maxBufferSize	No	The maximum size of the queue in the buffer. Default value: 1000.

Parameter	Required	Description
serializer	No	The serialization format of log data. Valid values: • **DELIMITED**: Data is parsed into the DELIMITED format. If you set this parameter to DELIMITED, you must set the columns parameter. • **SIMPLE**: Data is parsed into the SIMPLE format. This is the default value. • Custom **serializer**: Data is parsed into a custom serialization format. If you set this parameter to a custom serializer, you must specify the full name of the class.
columns	No	The configured column names. You must set this parameter if you set the serializer parameter to **DELIMITED**. Separate multiple columns with commas (,). Ensure that the columns are sorted in the same order as those of the log data.
separatorChar	No	The delimiter, which must be a single character. You can set this parameter if you set the serializer parameter to **DELIMITED**. Default value: `,`.
quoteChar	No	The quote character. You can set this parameter if you set the serializer parameter to **DELIMITED**. Default value: `""`.
escapeChar	No	The escape character. You can set this parameter if you set the serializer parameter to **DELIMITED**. Default value: `""`.
useRecordTime	No	Specifies whether to use the value of the timestamp field as the time when log data is written to Log Service. The default value false indicates that the current time is used.

Loghub Source

You can use the Source method to ship data from LogHub to other data systems through Flume. Data can be output in the following two formats:

- DELIMITED: writes delimited log data to Flume.
- JSON: writes JSON-formatted log data to Flume.

The following table lists the parameters you can configure when you use the Source method to read data.

Parameter	Required	Description
type	Yes	Valid value: com.aliyun.loghub.flume.source.LoghubSource.
endpoint	Yes	The endpoint of Log Service.
project	Yes	The name of the project.
logstore	Yes	The name of the Logstore.
accessKeyId	Yes	The AccessKey ID of your Apsara Stack tenant account.

Parameter	Required	Description
accessKey	Yes	The AccessKey secret of your Apsara Stack tenant account.
heartbeatIntervalMs	No	The heartbeat interval between the Flume client and LogHub. Unit: milliseconds. Default value: 30000.
fetchIntervalMs	No	The interval for pulling data from LogHub. Unit: milliseconds. Default value: 100.
fetchInOrder	No	Specifies whether to consume log data in the order that log data was generated. Default value: false.
batchSize	No	The number of log entries that are read at a time. Default value: 100.
consumerGroup	No	The name of the consumer group that reads data. The name is randomly generated.
initialPosition	No	The start point from which data is read. Valid values: begin, end, and timestamp. Default value: begin. **Note** If a checkpoint exists on the server, the checkpoint is used.
timestamp	No	The Unix timestamp. You must set this parameter if you set the initialPosition parameter to **timestamp**. Unix timestamp.
deserializer	Yes	The deserialization format of log data. Valid values: • **DELIMITED**: Data is parsed into the DELIMITED format. This is the default value. If you set this parameter to DELIMITED, you must set the columns parameter. • **JSON**: Data is parsed into the JSON format. • Custom **deserializer**: Data is parsed into a custom deserialization format. If you set this parameter to a custom deserializer, you must specify the full name of the class.
columns	No	The configured column names. You must set this parameter if you set the deserializer parameter to **DELIMITED**. Separate multiple columns with commas (,). Ensure that the columns are sorted in the same order as those of the log data.
separatorChar	No	The delimiter, which must be a single character. You can set this parameter if you set the deserializer parameter to **DELIMITED**. Default value: `,`.
quoteChar	No	The quote character. You can set this parameter if you set the deserializer parameter to **DELIMITED**. Default value: `""`.
escapeChar	No	The escape character. You can set this parameter if you set the deserializer parameter to **DELIMITED**. Default value: `""`.

Parameter	Required	Description
appendTimestamp	No	Specifies whether to append the timestamp as a field to the end of each log entry. You can set this parameter if you set the deserializer parameter to **DELIMITED**. Default value: false.
sourceAsField	No	Specifies whether to add the log source as a field named __source__. You can set this parameter if you set the deserializer parameter to **JSON**. Default value: false.
tagAsField	No	Specifies whether to add the log tags as a field with the field name __tag__: {tag names}. You can set this parameter if you set the deserializer parameter to **JSON**. Default value: false.
timeAsField	No	Specifies whether to add the log time as a field named __time__. You can set this parameter if you set the deserializer parameter to **JSON**. Default value: false.
useRecordTime	No	Specifies whether to use the value of the timestamp field as the time when log data is read from Log Service. The default value false indicates that the current time is used. Default value: false.

23.6.6. Use open source Flink to consume log data

Log Service provides the flink-log-connector plug-in to connect with Flink. This topic describes how to integrate the flink-log-connector plug-in with Flink to consume log data.

Prerequisites

- An AccessKey pair, a Log Service project, and a Logstore are created.
- If you log on to Log Service with a RAM user, relevant permissions to access a Logstore are granted to a RAM user. For more information, see Grant permissions to a RAM role.

Context

The flink-log-collector plug-in includes flink-log-consumer and flink-log-producer.

- The flink-log-consumer plug-in reads data from Log Service. This plug-in supports the exactly-once semantics and load balancing among shards.
- The flink-log-producer plug-in writes data into Log Service. When you use the flink-log-producer plug-in, you must add the following Maven dependencies to a project:

```
<dependency>
  <groupId>com.aliyun.openservices</groupId>
  <artifactId>flink-log-connector</artifactId>
  <version>0.1.13</version>
</dependency>
<dependency>
  <groupId>com.google.protobuf</groupId>
  <artifactId>protobuf-java</artifactId>
  <version>2.5.0</version>
</dependency>
```

Log Consumer

The flink-log-consumer plug-in can consume the log data of a Logstore in Log Service. The exactly-once semantics is achieved during log consumption. The flink-log-consumer plug-in detects the change of the number of shards in a Logstore. This increases efficiency.

Each Flink subtask consumes data of some shards in a Logstore. If shards in a Logstore are split or merged, the shards consumed by the subtask also change.

When you use the flink-log-consumer plug-in to consume data from Log Service, you can call the following API operations:

- GetCursorOrData

  You can call this operation to pull log data from a shard. Frequent API requests may exceed the read speed and IOPS limits of the shard. You can specify the ConfigConstants.LOG_FETCH_DATA_INTERVAL_MILLIS and ConfigConstants.LOG_MAX_NUMBER_PER_FETCH parameters to control the interval of API requests and number of log entries pulled in each request.

  ```
  configProps.put(ConfigConstants.LOG_FETCH_DATA_INTERVAL_MILLIS, "100");
  configProps.put(ConfigConstants.LOG_MAX_NUMBER_PER_FETCH, "100");
  ```

- ListShards

  You can call this operation to view all shards in a Logstore and the status of each shard. If the shards are frequently split and merged, you can adjust the call interval to detect the changes in the number of shards.

  ```
  // Call the ListShards operation once every 30 seconds.
  configProps.put(ConfigConstants.LOG_SHARDS_DISCOVERY_INTERVAL_MILLIS, "30000");
  ```

- CreateConsumerGroup

  You can call this operation to create a consumer group to synchronize checkpoints. This operation can be called only when consumption progress monitoring is enabled.

- ConsumerGroupUpdateCheckPoint

  You can call this operation to synchronize snapshots of Flink to a consumer group.

The following table lists the Apsara Stack resources required for RAM users to call the preceding API operations.

API	Alibaba Resource Name (ARN)
GetCursorOrData	acs:log:${regionName}:${projectOwnerAliUid}:project/${projectName}/logstore/${logstoreName}
ListShards	acs:log:${regionName}:${projectOwnerAliUid}:project/${projectName}/logstore/${logstoreName}
CreateConsumerGroup	acs:log:${regionName}:${projectOwnerAliUid}:project/${projectName}/logstore/${logstoreName}/consumergroup/*
ConsumerGroupUpdateCheckPoint	acs:log:${regionName}:${projectOwnerAliUid}:project/${projectName}/logstore/${logstoreName}/consumergroup/${consumerGroupName}

For more information, see Grant permissions to a RAM role.

1. Configure startup parameters.

   The following example shows how to consume log data. The java.util.Properties class is used as the configuration tool. You can find all constants to be configured in the ConfigConstants class.

```
Properties configProps = new Properties();
// Specify the endpoint of Log Service.
configProps.put(ConfigConstants.LOG_ENDPOINT, "cn-hangzhou.log.aliyuncs.com");
// Specify the AccessKey pair.
configProps.put(ConfigConstants.LOG_ACCESSSKEYID, "");
configProps.put(ConfigConstants.LOG_ACCESSKEY, "");
// Specify the project.
configProps.put(ConfigConstants.LOG_PROJECT, "ali-cn-hangzhou-sls-admin");
// Specify the Logstore.
configProps.put(ConfigConstants.LOG_LOGSTORE, "sls_consumergroup_log");
// Specify the start position to consume logs.
configProps.put(ConfigConstants.LOG_CONSUMER_BEGIN_POSITION, Consts.LOG_END_CURSOR);
// Specify the data deserialization method.
RawLogGroupListDeserializer deserializer = new RawLogGroupListDeserializer();
final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
DataStream<RawLogGroupList> logTestStream = env.addSource(
    new FlinkLogConsumer<RawLogGroupList>(deserializer, configProps));
```

> **Note** The number of subtasks in the Flink Streaming is independent of the number of shards in a Logstore. If the number of shards is greater than that of subtasks, each subtask consumes multiple shards exactly once. If the number of shards is less than that of subtasks, some subtasks are idle until new shards are generated.

2. Specify the start consumption position.

   The flink-log-consumer plug-in enables you to specify the start consumption position of log data in a shard. By specifying the ConfigConstants.LOG_CONSUMER_BEGIN_POSITION parameter, you can start data consumption from the earliest, latest, or a specific time point. The flink-log-connector plug-in also allows a consumer group to resume consumption from a specific position. Valid values:

   - Consts.LOG_BEGIN_CURSOR: The consumption starts from the earliest data.
   - Consts.LOG_END_CURSOR: The consumption starts from the latest data.
   - Consts.LOG_FROM_CHECKPOINT: The consumption starts from a checkpoint that is stored in a specific consumer group. You can use the ConfigConstants.LOG_CONSUMERGROUP parameter to specify the consumer group.
   - UnixTimestamp: a string of the INTEGER data type. The timestamp is the number of seconds that have elapsed since 00:00:00 January 1, 1970. The value indicates that data in a shard is consumed from this time point.

   You can use the following code to specify a start consumption position:

   ```
   configProps.put(ConfigConstants.LOG_CONSUMER_BEGIN_POSITION, Consts.LOG_BEGIN_CURSOR);
   configProps.put(ConfigConstants.LOG_CONSUMER_BEGIN_POSITION, Consts.LOG_END_CURSOR);
   configProps.put(ConfigConstants.LOG_CONSUMER_BEGIN_POSITION, "1512439000");
   configProps.put(ConfigConstants.LOG_CONSUMER_BEGIN_POSITION, Consts.LOG_FROM_CHECKPOINT);
   ```

   > **Note** If you have configured consumption resumption from a state backend of Flink when you start a Flink job, the flink-log-connector plug-in uses checkpoints stored in the state backend.

3. (Optional)Configure consumption progress monitoring.

   The flink-log-consumer plug-in enables you to configure consumption progress monitoring. Consumption progress indicates the real-time consumption position of each shard. These positions are indicated by timestamps. For more information, see View the status of a consumer group.

   ```
   configProps.put(ConfigConstants.LOG_CONSUMERGROUP, "your consumer group name");
   ```

> **Note** This configuration item is optional. If you specify this configuration item and no consumer group exists, the flink-log-consumer plug-in creates a consumer group. Snapshots in the flink-log-consumer plug-in are automatically synchronized to the consumer group of Log Service, and you can view the consumption progress of the flink-log-consumer plug-in in the Log Service console.

4. Configure consumption resumption and the exactly-once semantics.

   If the checkpointing feature of Flink is enabled, the flink-log-consumer plug-in periodically stores the consumption progress of each shard. When a job fails, Flink restores the flink-log-consumer plug-in and starts to consume data from the latest checkpoint.

   While you configure the checkpointing period, the maximum amount of data to be re-consumed when a failure occurs is defined. You can use the following code to configure the checkpointing period:

   ```
   final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
   // Configure the exactly-once semantics.
   env.getCheckpointConfig().setCheckpointingMode(CheckpointingMode.EXACTLY_ONCE);
   // Store checkpoints every five seconds.
   env.enableCheckpointing(5000);
   ```

   For more information about the Flink checkpoints, see Checkpoints in the Flink documentation.

Log Producer

The flink-log-producer plug-in writes data into Log Service.

> **Note** The flink-log-producer plug-in supports the Flink at-least-once semantics. If a job fails, data written into Log Service may be duplicated but never lost.

When you use the flink-log-producer plug-in to writes data to Log Service, you can call the following API operations:

- PostLogStoreLogs
- ListShards

The following table lists the Apsara Stack resources required for RAM users to call the preceding API operations.

API	ARN
PostLogStoreLogs	acs:log:${regionName}:${projectOwnerAliUid}:project/${projectName}/logstore/${logstoreName}
ListShards	acs:log:${regionName}:${projectOwnerAliUid}:project/${projectName}/logstore/${logstoreName}

For more information about RAM users and how to authorize RAM users, see Grant permissions to a RAM role.

1. Initialize the flink-log-producer plug-in.

i. Configure startup parameters for the flink-log-producer plug-in.

The initialization process for the flink-log-producer plug-in is similar to that for the flink-log-consumer plug-in. The following code shows the available parameters that you can configure for the flink-log-producer plug-in. You can use the default values of these parameters. You can also specify the parameters based on your needs.

```
// The number of I/O threads used to send data. Default value: 8.
ConfigConstants.LOG_SENDER_IO_THREAD_COUNT
// The time it takes to send the data after log data is cached. Default value: 3000.
ConfigConstants.LOG_PACKAGE_TIMEOUT_MILLIS
// The number of logs in the cached package. Default value: 4096.
ConfigConstants.LOG_LOGS_COUNT_PER_PACKAGE
// The size of the cached package. Default value: 3 Mbits.
ConfigConstants.LOG_LOGS_BYTES_PER_PACKAGE
// The total memory size that the job can use. Default value: 100 Mbits.
ConfigConstants.LOG_MEM_POOL_BYTES
```

> **Note** These parameters are optional. You can use their default values.

ii. Reload LogSerializationSchema to define the method of serializing data into RawLogGroup.

To use the hash key to specify the shard for data writes, you can use the LogPartitioner method to generate the hash key for the data.

Example:

```
FlinkLogProducer<String> logProducer = new FlinkLogProducer<String>(new SimpleLogSerializer(), configProps);
logProducer.setCustomPartitioner(new LogPartitioner<String>() {
   // Generate a 32-bit hash value.
   public String getHashKey(String element) {
     try {
       MessageDigest md = MessageDigest.getInstance("MD5");
       md.update(element.getBytes());
       String hash = new BigInteger(1, md.digest()).toString(16);
       while(hash.length() < 32) hash = "0" + hash;
       return hash;
     } catch (NoSuchAlgorithmException e) {
     }
     return  "00000000000000000000000000000000000000000000000000000000000000000";
   }
 });
```

> **Note** The LogPartitioner method is optional. If you do not configure this method, data is randomly written into a shard.

2. Run the following code and write the generated strings to Log Service.

```
// Serialize data into the format of raw log groups.
class SimpleLogSerializer implements LogSerializationSchema<String> {
  public RawLogGroup serialize(String element) {
    RawLogGroup rlg = new RawLogGroup();
    RawLog rl = new RawLog();
    rl.setTime((int)(System.currentTimeMillis() / 1000));
    rl.addContent("message", element);
    rlg.addLog(rl);
    return rlg;
  }
}
public class ProducerSample {
  public static String sEndpoint = "cn-hangzhou.log.aliyuncs.com";
  public static String sAccessKeyId = "";
  public static String sAccessKey = "";
  public static String sProject = "ali-cn-hangzhou-sls-admin";
  public static String sLogstore = "test-flink-producer";
  private static final Logger LOG = LoggerFactory.getLogger(ConsumerSample.class);
  public static void main(String[] args) throws Exception {
    final ParameterTool params = ParameterTool.fromArgs(args);
    final StreamExecutionEnvironment env = StreamExecutionEnvironment.getExecutionEnvironment();
    env.getConfig().setGlobalJobParameters(params);
    env.setParallelism(3);
    DataStream<String> simpleStringStream = env.addSource(new EventsGenerator());
    Properties configProps = new Properties();
    // Specify the endpoint of Log Service.
    configProps.put(ConfigConstants.LOG_ENDPOINT, sEndpoint);
    // Specify the AccessKey pair to access Log Service.
    configProps.put(ConfigConstants.LOG_ACCESSSKEYID, sAccessKeyId);
    configProps.put(ConfigConstants.LOG_ACCESSKEY, sAccessKey);
    // Specify the project to which logs are written.
    configProps.put(ConfigConstants.LOG_PROJECT, sProject);
    // Specify the Logstore to which logs are written.
    configProps.put(ConfigConstants.LOG_LOGSTORE, sLogstore);
    FlinkLogProducer<String> logProducer = new FlinkLogProducer<String>(new SimpleLogSerializer(), configProp
s);
    simpleStringStream.addSink(logProducer);
    env.execute("flink log producer");
  }
  // Simulate log generation.
  public static class EventsGenerator implements SourceFunction<String> {
    private boolean running = true;
    @Override
    public void run(SourceContext<String> ctx) throws Exception {
      long seq = 0;
      while (running) {
        Thread.sleep(10);
        ctx.collect((seq++) + "-" + RandomStringUtils.randomAlphabetic(12));
      }
    }
    @Override
    public void cancel() {
      running = false;
    }
  }
}
```

23.6.7. Use Logstash to consume log data

Log Service allows you to use SDKs developed in various languages and various stream computing systems to consume log data. In addition, Log Service allows you to use Logstash to consume log data. You can configure the Logstash input plug-in to read log data from Log Service and write the data to other systems, such as Kafka and Hadoop Distributed File System (HDFS).

Features

- **Distributed collaborative consumption**: Multiple servers can be configured to consume log data from a Logstore at the same time.
- **High performance**: If you use consumer groups written in Java to consume log data, the consumption speed of a CPU core can reach up to 20 MB/s.
- **High reliability**: Log Service saves the consumption progress. This mechanism enables automatic resumption of log consumption from the last checkpoint after a consumption exception is solved.
- **Automatic load balancing**: Shards are automatically allocated based on the number of consumers in a consumer group. The shards are reallocated if consumers join or leave the consumer group.

23.6.8. Use Spark Streaming to consume log data

This topic describes how to use Spark Streaming to consume log data. After logs are collected to Log Service, you can use the Spark SDK provided by Log Service to process log data in Spark Streaming.

The Spark SDK supports two consumption modes: Receiver and Direct.

The Maven dependency is as follows:

```
<dependency>
 <groupId>com.aliyun.emr</groupId>
 <artifactId>emr-logservice_2.11</artifactId>
 <version>1.7.2</version>
</dependency>
```

Receiver mode

In the Receiver mode, a consumer group consumes data from Log Service and temporarily stores the data in Spark Executor. After a Spark Streaming job is started, it reads and processes data from Spark Executor. For more information, see Use consumer groups to consume log data. Each log entry is returned as a JSON string. The consumer group periodically saves checkpoints to Log Service. You do not need to update checkpoints.

- Example code

```
import org.apache.spark.storage.StorageLevel
import org.apache.spark.streaming.aliyun.logservice.LoghubUtils
import org.apache.spark.streaming.{ Milliseconds, StreamingContext}
import org.apache.spark.SparkConf
object TestLoghub {
 def main(args: Array[String]): Unit = {
  if (args.length < 7) {
   System.err.println(
    """Usage: TestLoghub <project> <logstore> <loghub group name> <endpoint>
     |      <access key id> <access key secret> <batch interval seconds>
    """.stripMargin)
   System.exit(1)
  }
  val project = args(0)
  val logstore = args(1)
  val consumerGroup = args(2)
  val endpoint = args(3)
  val accessKeyId = args(4)
  val accessKeySecret = args(5)
  val batchInterval = Milliseconds(args(6).toInt * 1000)
  def functionToCreateContext(): StreamingContext = {
   val conf = new SparkConf().setAppName("Test Loghub")
   val ssc = new StreamingContext(conf, batchInterval)
   val loghubStream = LoghubUtils.createStream(
    ssc,
    project,
    logstore,
    consumerGroup,
    endpoint,
    accessKeyId,
    accessKeySecret,
    StorageLevel.MEMORY_AND_DISK)
   loghubStream.checkpoint(batchInterval * 2).foreachRDD(rdd =>
    rdd.map(bytes => new String(bytes)).top(10).foreach(println)
   )
   ssc.checkpoint("hdfs:///tmp/spark/streaming") // set checkpoint directory
   ssc
  }
  val ssc = StreamingContext.getOrCreate("hdfs:///tmp/spark/streaming", functionToCreateContext _)
  ssc.start()
  ssc.awaitTermination()
 }
}
```

- Parameter description

Parameter	Type	Description
project	String	The project in Log Service.
logstore	String	The Logstore in Log Service.
consumerGroup	String	The name of the consumer group.
endpoint	String	The endpoint of the region to which the project belongs.
accessKeyId	String	The AccessKey ID used to access Log Service.

Parameter	Type	Description
accessKeySecret	String	The AccessKey secret used to access Log Service.

- Notes

  In the Receiver mode, data loss may occur in some cases. To avoid data loss, you can turn on the Write-Ahead Logs switch, which is supported in Spark 1.2 and later versions. For more information, visit Spark Streaming Programming Guide.

Direct mode

In the Direct mode, no consumer group is required. API operations are called to request data from Log Service. Compared with the Receiver mode, the Direct mode has the following benefits:

- Simplified parallelism. The number of Spark partitions is the same as the number of shards in a Logstore. You can split shards to improve the parallelism of tasks.
- Increased efficiency. You no longer need to turn on the Write-Ahead Logs switch to prevent data loss.
- Exactly-once semantics. Data is read directly from Log Service. Checkpoints are submitted after the task is successful. In some cases, data may be repeatedly consumed if the task is not ended due to unexpected exit of Spark.

You must configure the ZooKeeper service when you use the Direct mode. You must set a checkpoint directory in ZooKeeper to store intermediate state data. If you want to re-consume data after restarting a task, you must delete the directory from ZooKeeper and change the name of the consumer group.

- Example code

```
import com.aliyun.openservices.loghub.client.config.LogHubCursorPosition
import org.apache.spark.SparkConf
import org.apache.spark.streaming.{ Milliseconds, StreamingContext}
import org.apache.spark.streaming.aliyun.logservice.{ CanCommitOffsets, LoghubUtils}
object TestDirectLoghub {
 def main(args: Array[String]): Unit = {
  if (args.length < 7) {
   System.err.println(
    """Usage: TestDirectLoghub <project> <logstore> <loghub group name> <endpoint>
     |      <access key id> <access key secret> <batch interval seconds> <zookeeper host:port=localhost:2181>
    """.stripMargin)
   System.exit(1)
  }
  val project = args(0)
  val logstore = args(1)
  val consumerGroup = args(2)
  val endpoint = args(3)
  val accessKeyId = args(4)
  val accessKeySecret = args(5)
  val batchInterval = Milliseconds(args(6).toInt * 1000)
  val zkAddress = if (args.length >= 8) args(7) else "localhost:2181"
  def functionToCreateContext(): StreamingContext = {
   val conf = new SparkConf().setAppName("Test Direct Loghub")
   val ssc = new StreamingContext(conf, batchInterval)
   val zkParas = Map("zookeeper.connect" -> zkAddress,
    "enable.auto.commit" -> "false")
   val loghubStream = LoghubUtils.createDirectStream(
    ssc,
    project,
    logStore,
    consumerGroup,
    accessKeyId,
    accessKeySecret,
    endpoint,
    zkParas,
    LogHubCursorPosition.END_CURSOR)
   loghubStream.checkpoint(batchInterval).foreachRDD(rdd => {
    println(s"count by key: ${rdd.map(s => {
     s.sorted
     (s.length, s)
    }).countByKey().size}")
    loghubStream.asInstanceOf[CanCommitOffsets].commitAsync()
   })
   ssc.checkpoint("hdfs:///tmp/spark/streaming") // set checkpoint directory
   ssc
  }
  val ssc = StreamingContext.getOrCreate("hdfs:///tmp/spark/streaming", functionToCreateContext _)
  ssc.start()
  ssc.awaitTermination()
 }
}
```

- Parameter description

Parameter	Type	Description
project	String	The project in Log Service.
logstore	String	The Logstore in Log Service.

Parameter	Type	Description
consumerGroup	String	The name of the consumer group (only used to save consumption checkpoints).
endpoint	String	The endpoint of the region to which the project belongs.
accessKeyId	String	The AccessKey ID used to access Log Service.
accessKeySecret	String	The AccessKey secret used to access Log Service.
zkAddress	String	The endpoint of ZooKeeper.

- Parameter settings

  In the Direct mode, you must specify the number of log entries that are consumed in each shard in each batch. Otherwise, the data reading process cannot be ended. You can throttle the transmission rate of a single batch by setting the two parameters listed in the following table.

Parameter	Description	Default value
spark.loghub.batchGet.step	The number of log groups returned for a single request.	100
spark.streaming.loghub.maxRatePerShard	The maximum number of log entries that are read in a shard.	10,000

  The number of log entries processed in each batch is calculated as follows: `number of shards x max(spark.loghub.batchGet.step x n x number of log entries in a log group, spark.streaming.loghub.maxRatePerShard x duration)`.

  - n: the number of requests required to increase the returned rows to `spark.streaming.loghub.maxRatePerShard x duration`.
  - duration: the interval between batch processing. Unit: milliseconds.

  If you need to combine multiple data streams, the number of shards refers to the total number of shards in all Logstores.

  - Example

    For example, the number of shards is 100. Each log group contains 50 log entries. Batches are processed at an interval of two seconds. If you want to process 20,000 log entries in each batch, use the following configurations:

    - `spark.loghub.batchGet.step: 4`
    - `spark.streaming.loghub.maxRatePerShard: 100`

    If each log group contains 60 log entries and you want to process 20,000 log entries in each batch, 24,000 log entries will be processed based on the preceding configurations (`60 x 4 x 100 = 24,000`).

  - Accurate transmission rate throttling

    A smaller `spark.loghub.batchGet.step` value increases the accuracy of throttling and the number of requests. We recommend that you count the average number of log entries contained in a log group and then set the preceding two parameters.

23.6.9. Use Realtime Compute to consume log data

You can use Realtime Compute (Blink) to create a schema for Log Service data and consume the data.

Log Service stores streaming data. Therefore, Realtime Compute can use the streaming data as input data. In Log Service, each log entry contains multiple fields and each field is a key-value pair. The following example is a sample log entry:

```
__source__: 11.85.123.199
__tag__:__receive_time__: 1562125591
__topic__: test-topic
a: 1234
b: 0
c: hello
```

You can use the following data definition language (DDL) statement to create a table in Realtime Compute:

```
create table sls_stream(
 a int,
 b int,
 c varchar
) with (
 type ='sls',
 endPoint ='<your endpoint>',
 accessId ='<your access key id>',
 accessKey ='<your access key>',
 startTime = '2017-07-05 00:00:00',
 project ='ali-cloud-streamtest',
 logStore ='stream-test',
 consumerGroup ='consumerGroupTest1'
);
```

Attribute fields

Realtime Compute can extract fields from log content. In addition, Realtime Compute can extract three attribute fields and custom tag fields, such as `__receive_time__`. The following table lists the three attribute fields.

Attribute fields

Field name	Description
`__source__`	The source of the log entry.
`__topic__`	The topic of the log entry.
`__timestamp__`	The time when the log entry is generated.

To extract the preceding fields, you must add HEADERs in the DDL statement. For example:

```
create table sls_stream(
 __timestamp__ bigint HEADER,
 __receive_time__ bigint HEADER
 b int,
 c varchar
) with (
 type ='sls',
 endPoint ='<your endpoint>',
 accessId ='<your access key id>',
 accessKey ='<your access key>',
 startTime = '2017-07-05 00:00:00',
 project ='ali-cloud-streamtest',
 logStore ='stream-test',
 consumerGroup ='consumerGroupTest1'
);
```

Parameters in the WITH clause

The following table describes the parameters in the WITH clause.

Parameter	Required	Description
endPoint	Yes	The endpoint of Log Service.
accessId	Yes	The AccessKey ID of the Apsara Stack tenant account or RAM user that is used to access Log Service.
accessKey	Yes	The AccessKey secret of the Apsara Stack tenant account or RAM user that is used to access Log Service.
project	Yes	The name of the project in Log Service.
logStore	Yes	The name of the Logstore in Log Service.
consumerGroup	No	The name of the consumer group.
startTime	No	The time when Realtime Compute starts to consume data.
heartBeatIntervalMills	No	The heartbeat interval of the client that consumes log data. Unit: seconds. Default value: 10.
maxRetryTimes	No	The maximum number of retries to read data. Default value: 5.
batchGetSize	No	The number of log groups that are read at a time. Default value: 10. If the version of Blink is 1.4.2 or later, the default value is 100 and the maximum value is 1000.

Parameter	Required	Description
columnErrorDebug	No	Specifies whether to enable debugging. If debugging is enabled, log entries that fail to be parsed are displayed. Default value: `false`.

Field type mapping

All log fields in Log Service are of the string type. The following table lists the mapping between the type of Log Service fields and the type of Realtime Compute fields. We recommend that you declare the mapping in a data definition language (DDL) statement.

Data type of Log Service	Data type of Realtime Compute
STRING	VARCHAR

If you specify another data type to convert Log Service data, an automatic conversion attempt is performed. For example, you can specify *BIGINT* as the data type to convert the string "1000" and specify *timestamp* as the data type to convert the string "2018-01-12 12:00:00".

> **Note**
> - Blink versions earlier than 2.2.0 do not support shard scaling. If you split or merge shards when a job is reading data from a Logstore, the job fails and cannot continue. In this case, you must restart the job.
> - No versions of Blink allow you to delete or recreate a Logstore whose log data is being consumed.
> - For Blink version 1.6.0 and earlier, if you specify *consumerGroup* to consume log data from a Logstore that contains a large number of shards, the read performance may be affected.
> - When you create a schema, Log Service data cannot be converted to data of the map type.
> - Fields whose values are empty are set to *null*.
> - Unordered field conversions are supported. However, we recommend that you convert the fields in the same order as the fields in the schema.
> - The *batchGetSize* parameter specifies the number of log groups that are obtained based on the *logGroup* parameter. If the size of each log entry and the value of the *batchGetSize* parameter are both large, garbage collection (GC) of data in the memory may frequently occur.

Precautions

- If no new data is written to a shard, the overall latency of a job increases. In this case, you need to modify the number of concurrent tasks in the job to the number of shards from which data is read and written.
- We recommend that you set the number of concurrent tasks in a job to the same as the number of shards. Otherwise, data may be filtered out when the job reads historical data from two shards at significantly different speeds.
- To extract fields in tags such as `__tag__:__hostname__` and `__tag__:__path__`, you can delete the __tag__: prefix and use the method of extracting attribute fields.

  > **Note** This type of data cannot be extracted during debugging. We recommend that you use the local debugging method and the print method to display data in logs.

23.7. Data shipping

23.7.1. Ship logs to OSS

23.7.1.1. Overview

Log Service provides the data shipping feature. You can use this feature to ship logs to Object Storage Service (OSS) in real time by using the Log Service console. This topic describes the benefits and scenarios of the data shipping feature.

In the Log Service console, you can ship logs to other Apsara Stack services. Then, you can store or consume the log data by using other systems such as E-MapReduce. After you enable the log shipping feature, Log Service ships the collected logs to the specified cloud service at regular intervals.

Scenarios

The data shipping feature can be used to connect Log Service with data warehouses.

Benefits

The data shipping feature of Log Service has the following benefits:

- Ease of use

  You only need to complete a few settings in the Log Service console before you can ship logs from Logstores to other Apsara Stack services such as OSS.

- High efficiency

  Log Service stores logs that are collected from multiple servers. This improves efficiency when you ship log data to Apsara Stack services such as OSS.

- Effective management

  You can ship logs from different projects or Logstores to different OSS buckets. This way, you can efficiently manage the logs by log type or log source.

Log shipping destinations

For information about how to ship logs to OSS, see Ship log data from Log Service to OSS.

23.7.1.2. Ship log data from Log Service to OSS

You can use Log Service to collect log data and ship the log data to Object Storage Service (OSS) for storage and analysis. This topic describes how to ship log data from Log Service to OSS.

Prerequisites

- Log data is collected. For more information, see Log collection methods.
- OSS is activated. A bucket is created in the region where the Log Service project resides. For more information, see the **Create buckets** section in the *Service User Guide -Ojbect Storage Service(OSS)*.
- A Resource Access Management (RAM) role is created for the level-1 organization. For more information, see Obtain the ARN of a RAM role.

Context

Log Service can automatically ship log data from a Logstore to an OSS bucket.

- You can set a custom retention period for the log data in the OSS bucket. Permanent retention is supported.
- You can use data processing platforms such as E-MapReduce and Data Lake Analytics (DLA) or use custom programs to consume log data from the OSS bucket.

Procedure

1. Log on to the Log Service console.
2. In the Projects section, click the project from which you want to ship log data to OSS.

3. On the Logstores tab, click the > icon on the left of the specific Logstore and choose **Data Transformation > Export > Object Storage Service(OSS)**.
4. On the OSS Shipper page, click **Enable**.
5. In the **OSS LogShipper** pane, configure the shipping rules.

   The following table describes the required parameters.

Parameter	Description
OSS Shipper Name	The name of the shipping rule. The name can contain only lowercase letters, digits, hyphens (-), and underscores (_). The name must start and end with a lowercase letter or digit and must be 2 to 128 characters in length.
OSS Bucket	The name of the OSS bucket to which you want to ship log data. **Notice** You must specify the name of an existing OSS bucket. The specified OSS bucket must reside in the same region as the Log Service project.
OSS Prefix	The directory to which log data is shipped in the OSS bucket.
Partition format	The partition format of the bucket directory for the shipping task. The directory is automatically generated based on the time when the shipping task is created. The default format is %Y/%m/%d/%H/%M. The partition format cannot start with a forward slash (/). For information about partition format examples, see Partition format. For more information about parameters, see strptime API.
(Resource Access Management) RAM Role	The Alibaba Cloud Resource Name (ARN) of the RAM role. The RAM role is the identity that the OSS bucket owner creates for access control. Example: acs:ram::45643:role/aliyunlogdefaultrole. For information about how to obtain the ARN, see Obtain the ARN of a RAM role.
Shipping Size	The maximum size of raw log data that can be shipped to the OSS bucket in a shipping task. Valid values: 5 to 256. Unit: MB. If the size of shipped data exceeds the specified value, a new shipping task is automatically created.
Compress	Specifies whether to compress log data that is shipped to OSS. Valid values: ○ No Compress: The log data that is shipped to OSS is not compressed. ○ Compress (snappy): The snappy utility is used to compress the log data that is shipped to OSS. This way, the log data occupies less storage space of the OSS bucket.
Storage Format	The storage format of the log data that is shipped to OSS. Valid values: JSON, CSV, and Parquet. For more information, see Storage Formats.
Ship Tags	Specifies whether to ship log tags.
Shipping Time	The time period during which a shipping task runs. Valid values: 300 to 900. Default value: 300. Unit: seconds. If the specified time period expires, another shipping task is created.

6. Click **OK**.

> **Note**
> - After you configure a shipping rule, multiple shipping tasks can concurrently run. If the size of the data shipped from a shard reaches the specified threshold or the specified time period expires, another task is created.
> - After you create a shipping task, you can check whether the shipping rule satisfies your business requirements based on the task status and the data shipped to OSS.

View OSS data

After log data is shipped to OSS, you can access the log data in the OSS console, or by using the OSS API, an SDK, or another method. For more information, see the **Objects > Search for objects** section of the *Service User Guide -Ojbect Storage Service(OSS)*.

The following script shows a sample OSS directory:

```
oss://OSS-BUCKET/OSS-PREFIX/PARTITION-FORMAT_RANDOM-ID
```

OSS-BUCKET is the name of the OSS bucket. OSS-PREFIX is the prefix of the directory in the OSS bucket. PARTITION-FORMAT is the partition format of the directory for a shipping task. The partition format is calculated based on the time when the shipping task is created. For more information, see strptime API. RANDOM-ID is the unique identifier of the shipping task.

> **Note** The directory in the OSS bucket is created based on the time when the shipping task is created. For example, the shipping task is created at 00:00:00 on June 23, 2016 to ship data to OSS. The data is written to Log Service after 23:55:00 on June 22, 2016. The shipping interval is 5 minutes. To retrieve all logs shipped on June 22, 2016, you must check all objects in the *2016/06/22* directory. You must also check the *2016/06/23/00/* directory for the objects that are generated in the first 10 minutes of June 23, 2020.

Partition format

For each shipping task, log data is written to a directory of an OSS bucket. The directory is in the *oss://OSS-BUCKET/OSS-PREFIX/PARTITION-FORMAT_RANDOM-ID* format. A partition format is obtained by formatting the time when a shipping task is created. The following table describes the partition formats and directories that are obtained when a shipping task is created at 19:50:43 on January 20, 2017.

OSS Bucket	OSS Prefix	Partition format	OSS directory
test-bucket	test-table	%Y/%m/%d/%H/%M	*oss://test-bucket/test-table/2017/01/20/19/50_1484913043351525351_2850008*
test-bucket	log_ship_oss_example	year=%Y/mon=%m/day=%d/log_%H%M%s	*oss://test-bucket/log_ship_oss_example/year=2017/mon=01/day=20/log_195043_1484913043351525351_2850008.parquet*
test-bucket	log_ship_oss_example	ds=%Y%m%d/%H	*oss://test-bucket/log_ship_oss_example/ds=20170120/19_1484913043351525351_2850008.snappy*

OSS Bucket	OSS Prefix	Partition format	OSS directory
test-bucket	log_ship_oss_example	%Y%m%d/	*oss://test-bucket/log_ship_oss_example/20170120/_1484913043351525351_2850008* **Note** This format may prevent platforms such as Hive from parsing the log data in the OSS bucket. We recommend that you do not use this format.
test-bucket	log_ship_oss_example	%Y%m%d%H	*oss://test-bucket/log_ship_oss_example/2017012019_1484913043351525351_2850008*

You can use Hive, MaxCompute, or Data Lake Analytics (DLA) to analyze OSS data. In this case, if you want to use partition information, you can set PARTITION-FORMAT in the key=value format. For example, you can set the partition format to *oss://test-bucket/log_ship_oss_example/year=2017/mon=01/day=20/log_195043_1484913043351525351_2850008.parquet*. In this example, year, mon, and day are specified as three partition keys.

What to do next

After shipping tasks are created based on a shipping rule, you can modify the shipping rule. You can also disable the data shipping feature, view the statuses and error messages of the tasks, and retry failed tasks on the **OSS Shipper** page of a Logstore.

- Modify the shipping rule.

  Click **Settings** to modify the shipping rule. For information about the parameters, see Procedure.

- Disable the data shipping feature.

  Click **Disable**. The data in the Logstore is no longer shipped to OSS.

- View the statuses and error messages of the tasks.

  You can view the log shipping tasks of the last two days and their statuses.

  - Statuses of a shipping task

Status	Equivalent
Succeeded	The shipping task has succeeded.
Running	The shipping task is running. Check whether the task succeeds later.
Failed	The shipping task has failed. If the task cannot be restarted due to external causes, troubleshoot the failure based on the error message and retry the task.

- Error messages

  If a shipping task fails, an error message is returned for the task.

Error message	Error cause	Solution
UnAuthorized	The error message returned because the AliyunLogDefaultRole role does not have the required permissions.	To fix the error, check the following configurations: ■ Check whether the AliyunLogDefaultRole role is created by the OSS bucket owner. ■ Check whether the specified ID of the Alibaba Cloud account in the permission policy is valid. ■ Check whether the AliyunLogDefaultRole role is granted the write permissions on the OSS bucket. ■ Check whether the ARN of the AliyunLogDefaultRole role that you entered in the RAM Role field is valid.
ConfigNotExist	The error message returned because the task does not exist.	Check whether the data shipping feature is disabled. If the feature is disabled, enable the feature, configure a shipping rule, and then retry the shipping task.
InvalidOssBucket	The error message returned because the specified OSS bucket does not exist.	To fix the error, check the following configurations: ■ Check whether the OSS bucket resides in the same region as the Log Service project. ■ Check whether the specified bucket name is valid.
InternalServerError	The error message returned because an internal error has occurred in Log Service.	Retry the failed shipping task.

- Retry a shipping task

  By default, if a shipping task fails, Log Service retries the task based on the retry policy. You can also manually retry the task. By default, Log Service retries all tasks of the last two days. The minimum interval between two consecutive retries is 15 minutes. If a task fails for the first time, Log Service retries the task 15 minutes later. If the task fails for the second time, Log Service retries the task 30 minutes later. If the task fails for the third time, Log Service retries the task 60 minutes later. A similar method is used for subsequent attempts.

  To immediately retry a failed task, you can click **Retry All Failed Tasks** or **Retry** on the right of the task. You can also use the Log Service API or an SDK to retry a task.

23.7.1.3. Obtain the ARN of a RAM role

When you use a RAM user to ship data from Log Service to Object Storage Service (OSS), you must first create a Resource Access Management (RAM) role and specify the ARN of the RAM role. This topic describes how to create a RAM role and obtain the ARN of a RAM role.

Procedure

1. Log on to the Log Service console.
2. In the top navigation bar, click **Configurations**.

3. On the **Service-Linked Roles** page, click **Create RAM Role**.
4. In the **Organization Name** drop-down list, select the organization that you created. In the **Service Name** drop-down list, select **Log Service**, and click **OK**.
5. On the **RAM Service Role** page, enter `AliyunLogDefaultRole` in the **Role Name** search box and click **Search**.
6. Obtain the ARN of the RAM role.

   In the search results, the value in the **role identifier** column is the ARN of the RAM role.

23.7.1.4. Storage Formats

Different storage formats are supported when Log Service ships logs to OSS, including JSON, CSV, and Parquet. This topic describes the field details of the formats.

JSON format

You can set the storage format for the data that is shipped to OSS. The following table shows how to set the **storage format** to **JSON**. For more information, see Configure a data shipping rule.

Compression type	File extension	Example file address	Description
Uncompressed	N/A	oss://oss-shipper-shenzhen/ecs_test/2016/01/26/20/54_1453812893059571256_937	You can download the raw JSON object to the local host and open each object as a text file. The following example is the content of a sample file: {"__time__":1453809242,"__topic__":"","__source__":"10.170.***.***","ip":"10.200.**.***","time":"26/Jan/2016:19:54:02 +0800","url":"POST /PutData?Category=YunOsAccountOpLog&AccessKeyId=<yourAccessKeyId>&Date=Fri%2C%2028%20Jun%202013%2006%3A53%3A30%20GMT&Topic=raw&Signature=<yourSignature> HTTP/1.1","status":"200","user-agent":"aliyun-sdk-java"}
snappy	.snappy	oss://oss-shipper-shenzhen/ecs_test/2016/01/26/20/54_1453812893059571256_937.snappy	JSON objects are compressed by using Snappy. For more information, see Decompression tools for Snappy-compressed files.

CSV-format

You can set the storage format for the data that is shipped to OSS. The following table shows how to set the **storage format** to **CSV**. For more information, see Configure a data shipping rule.

The following table describes the parameters. For more information, see Common Format and MIME Type for Comma-Separated Values (CSV) Files and PostgreSQL 9.4.26 Documentation.

Parameter	Description
CSV Fields	The names of the log fields that you want to ship to OSS. You can view log fields on the **Raw Logs** tab of a Logstore and enter the names of the fields that you want to ship to OSS in the Key Name column. The log fields that you can ship to OSS include the fields in the log content and the reserved fields such as __time__, __topic__, and __source__. **Note** The keys that you enter in the **CSV Fields** section must be unique.
Delimiter	You can use commas (,), vertical bars (|), spaces, or tabs to delimit fields.
Escape Character	If a field contains a delimiter, you must use an escape character to enclose the field. This ensures that the field is not delimited.
Invalid Fields	If a key that you specify in the **CSV Fields** section does not exist, enter the value of the key in the Invalid Fields field.
Shipped Fields	If you turn on the **Shipped Fields** switch, field names are written in a CSV file.

The following table lists the directories in OSS buckets that store the data shipped from Log Service.

Compression type	File extension	Example	Description
No	.csv	oss://oss-shipper-shenzhen/ecs_test/2016/01/26/20/54_1453812893059571256_937.csv	You can download the raw JSON object to the local host and open the object as a text file.
snappy	.snappy.csv	oss://oss-shipper-shenzhen/ecs_test/2016/01/26/20/54_1453812893059571256_937.snappy.csv	Decompression tools for Snappy compressed files For more information, see Decompression tools for Snappy-compressed files.

Parquet-format

You can set the storage format for the data that is shipped to OSS. The following figure shows how to set the **storage format** to **Parquet**. For more information, see Configure a data shipping rule.

The following table describes the related parameters.

Parameter	Description

Parameter	Description
Key Name	The name of the log field that you want to ship to OSS. You can view log fields on the **Raw Logs** tab of a Logstore. You can also enter the names of the fields that you want to ship to OSS in the Key Name column. When the fields are shipped to OSS, they are stored in the Parquet format in the order that the field names are entered. The names of the fields are the column names in OSS. The log fields that you can ship to OSS include the fields in the log content and the reserved fields such as __time__, _topic__, and __source__. The value of a field in the Parquet format is null in the following two scenarios: • The field does not exist in logs. • The value of the field fails to be converted from the string type to a non-string type, for example, double or Int64. **Note** The keys that you enter in the **Parquet Keys** field must be unique.
Type	The Parquet storage format supports six data types: string, Boolean, Int32, Int64, float, and double. Log fields are converted from the string type to a data type that the Parquet storage format supports. If the data type of a log field fails to be converted, the value of the log field is null.

The following table lists the directories in OSS buckets that store data shipped from Log Service.

Compression type	File extension	Example	Description
Uncompressed	.parquet	oss://oss-shipper-shenzhen/ecs_test/2016/01/26/20/54_1453812893059571256_937.parquet	You can download the OSS buckets to the local host and use the parquet-tools utility to open the objects. For more information about the parquet-tools utility, visit parquet-tools.
Snappy	.snappy.parquet	oss://oss-shipper-shenzhen/ecs_test/2016/01/26/20/54_1453812893059571256_937.snappy.parquet	You can download the OSS buckets to the local host and use the parquet-tools utility to open the objects. For more information about the parquet-tools utility, visit parquet-tools.

23.7.1.5. Decompress Snappy compressed files

When you ship data from Log Service to Object Storage Service (OSS), you can use Snappy to compress OSS objects. After the data is shipped to OSS, you can decompress OSS objects by using the C++ library, Java library, Python library, and decompression tool for Linux.

Use the C++ library to decompress OSS objects

Download the C++ library from the snappy page and use the Snappy.Uncompress method to decompress Snappy compressed OSS objects.

Use the Java library to decompress OSS objects

Download the Java library from the xerial snappy-java page and use the Snappy.Uncompress or Snappy.SnappyInputStream method to decompress Snappy compressed OSS objects. The SnappyFramedInputStream method is not supported.

> **Note** If you use Java Library 1.1.2.1, some Snappy compressed OSS objects may fail to be decompressed. For more information, see Bad handling of the MAGIC HEADER. To fix this issue, you can use Java Library 1.1.2.6 or later.

```
<dependency>
<groupId>org.xerial.snappy</groupId>
<artifactId>snappy-java</artifactId>
<version>1.0.4.1</version>
<type>jar</type>
<scope>compile</scope>
</dependency>
```

- Snappy.Uncompress

```
String fileName = "C:\\Downloads\\36_1474212963188600684_4451886.snappy";
RandomAccessFile randomFile = new RandomAccessFile(fileName, "r");
int fileLength = (int) randomFile.length();
randomFile.seek(0);
byte[] bytes = new byte[fileLength];
int byteread = randomFile.read(bytes);
System.out.println(fileLength);
System.out.println(byteread);
byte[] uncompressed = Snappy.uncompress(bytes);
String result = new String(uncompressed, "UTF-8");
System.out.println(result);
```

- Snappy.SnappyInputStream

```
String fileName = "C:\\Downloads\\36_1474212963188600684_4451886.snappy";
SnappyInputStream sis = new SnappyInputStream(new FileInputStream(fileName));
byte[] buffer = new byte[4096];
int len = 0;
while ((len = sis.read(buffer)) != -1) {
  System.out.println(new String(buffer, 0, len));
}
```

Use the Python Library to decompress OSS objects

1. Download and install the Python library.
2. Run the decompression script.

   The following example is a sample decompression script:

```
import snappy
compressed = open('/tmp/temp.snappy').read()
snappy.uncompress(compressed)
```

> **Note** The following two commands cannot be used to decompress Snappy compressed OSS objects. These commands can be used only in Hadoop mode (hadoop_stream_decompress) or streaming mode (stream_decompress).
>
> ```
> python -m snappy -c uncompressed_file compressed_file.snappy
> python -m snappy -d compressed_file.snappy uncompressed_file
> ```

Use decompression tools for Linux to decompress OSS buckets

Log Service allows you to decompress Snappy compressed files by using the decompression tool for Linux. Click snappy_tool to download the tool. Replace 03_1453457006548078722_44148.snappy and 03_1453457006548078722_44148 in the following code with the values specific to your environment and then run the following code:

```
./snappy_tool 03_1453457006548078722_44148.snappy 03_1453457006548078722_44148
compressed.size: 2217186
snappy::Uncompress return: 1
uncompressed.size: 25223660
```

23.8. RAM

23.8.1. Overview

Resource Access Management (RAM) is a resource access control service provided by Apsara Stack.

You can use RAM to manage users, including employees, systems, and applications. You can also use RAM to grant users permissions to access resources.

RAM provides the following features:

- RAM Role

  To authorize a cloud service in a level-1 organization to use other resources in the organization, you must create a RAM role. This role specifies the operations that the cloud service can perform on the resources.

  Only system administrators and level-1 organization administrators can create RAM roles.

- User group

  You can create multiple RAM users for an organization and grant the users different permissions on the same cloud resources in the organization.

  You can create RAM user groups to classify and authorize RAM users within your Apsara Stack tenant account. This simplifies the management of RAM users and their permissions.

  You can create RAM policies to grant permissions to different user groups.

23.8.2. Create a RAM role

To authorize a cloud service in a level-1 organization to use other resources in the organization, you must create a RAM role. This role specifies the operations that the cloud service can perform on the resources.

Procedure

1. Log on to the Apsara Uni-manager Management Console as an administrator.

   For more information, see Log on to the Log Service console.

2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Roles**.

4. In the upper-right corner of the page, click **Create RAM Role**.
5. On the **Roles - Create RAM Role** page that appears, set the **Role Name** and **Description** parameters.
6. Click **Create**.

23.8.3. Create a user

This topic describes how an administrator creates a user and assigns a role to the user. The role varies based on the cloud resources that the user needs to access.

Procedure

1. Log on to the Apsara Uni-manager Management Console as an administrator.

   For more information, see Log on to the Log Service console.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Users**.
4. On the **Users** page, click **Create**.
5. In the dialog box that appears, set the parameters based on your requirements.

Parameter	Description
Username	The username.
Display Name	The display name of the user.
Roles	The role that you want to assign to the user.
Organization	The organization to which the user belongs.
Logon Policy	The logon policy that restricts the logon time and IP address of the user. If you do not specify this parameter, the default policy is attached to the created user.
Mobile Number	The mobile phone number of the user. If you need to send text messages about the usage and requests for resources to the mobile phone number, make sure that the specified mobile phone number is correct.
Landline Number	Optional. The landline number of the user.
Email	The email address of the user. If you need to send emails about the usage and requests for resources to the email address, make sure that the specified email address is correct.
DingTalk Key	Optional. The DingTalk key.
Notify User by SMS	Specifies whether to send text messages about the usage and requests for resources to the specified mobile phone number.
Notify User by Email	Specifies whether to send emails about the usage and requests for resources to the specified email address.
Notify User by DingTalk	Specifies whether to send messages about the usage and requests for resources to the specified DingTalk user.

6. Click **OK**.

23.8.4. Create a RAM user group

This topic describes how to create a RAM user group in an organization and grant permissions to RAM users in the RAM user group.

Prerequisites

An organization is created.

Context

The relationships between RAM user groups and RAM users:

- A RAM user group can contain zero or more RAM users.
- A RAM user does not need to belong to a RAM user group.
- You can add a RAM user to multiple RAM user groups.

The relationships between RAM user groups and organizations:

- A RAM user group belongs to only one organization.
- You can create multiple RAM user groups in an organization.

The relationships between RAM user groups and RAM roles:

- Only one RAM role can be assigned to each RAM user group.
- A RAM role can be assigned to multiple RAM user groups.
- When a RAM role is assigned to a RAM user group, the permissions that the RAM role has are automatically granted to RAM users in the RAM user group.

The relationships between RAM user groups and resource sets:

- You can add zero or more user groups to a resource set.
- A user group can be added to multiple resource sets.

Procedure

1. Log on to the Apsara Uni-manager Management Console as an administrator.

   For more information, see Log on to the Log Service console.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **User Groups**.
4. In the upper-right corner of the page, click **Create User Group**.
5. In the dialog box that appears, set the **User Group Name** and **Organization** parameters.
6. Click **OK**.

23.8.5. Add a RAM user to a RAM user group

This topic describes how to add a RAM user to a RAM user group.

Procedure

1. Log on to the Apsara Uni-manager Management Console as an administrator.

   For more information, see Log on to the Log Service console.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **User Groups**.
4. Find the user group to which you want to add a RAM user, and click **Add User** in the **Actions** column.
5. In the dialog box that appears, select a RAM user from the left pane, and click the right arrow to move the RAM user to the right pane.
6. Click **OK**.

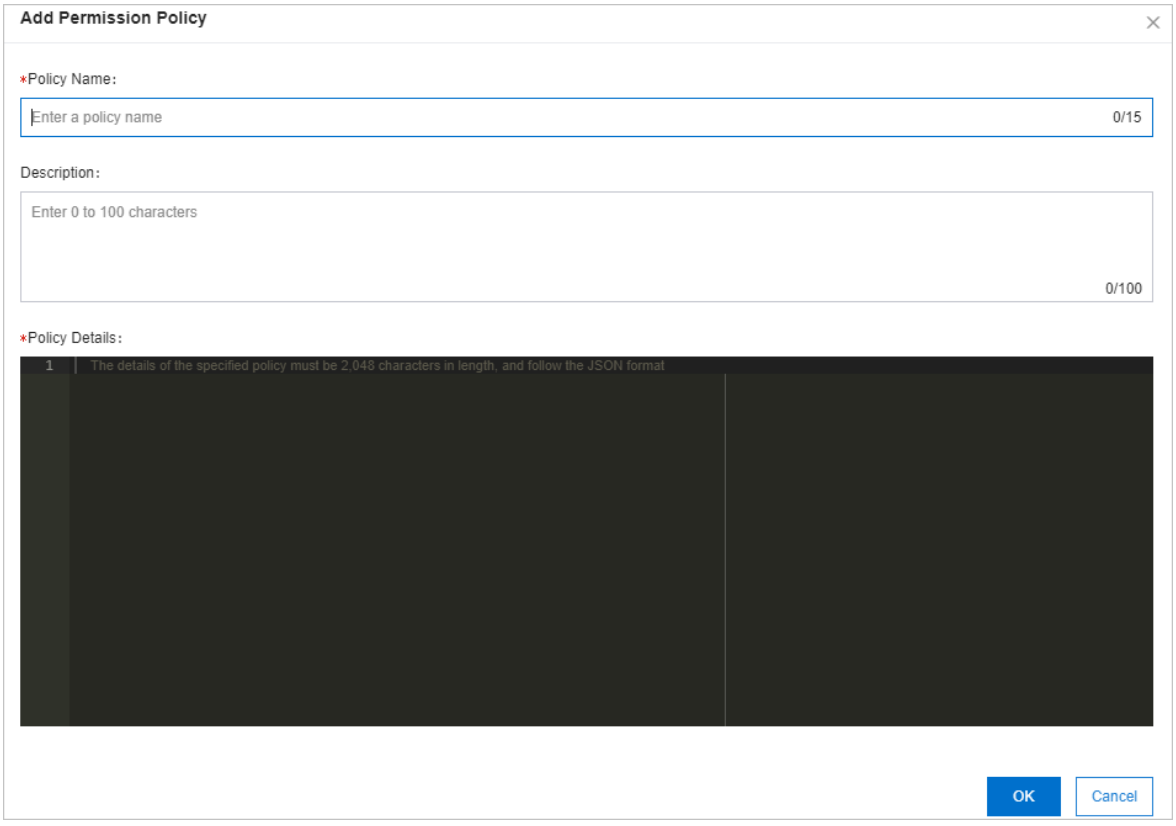
23.8.6. Create a permission policy

If you want to use a cloud service to access the resources of other cloud services, you must create a permission policy for a RAM role. Then, the policy is automatically attached to the RAM user group to which the RAM role is assigned.

Procedure

1. Log on to the Apsara Uni-manager Management Console as an administrator.

   For more information, see Log on to the Log Service console.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Roles**.
4. In the list of role names, find the RAM role for which you want to create a permission policy and choose **More > Modify**.
5. Click **Permissions**.
6. Click **Add Permission Policy**.
7. In the **Add Permission Policy** dialog box, enter the policy information.



For more information about how to specify the policy information, see Use custom policies to grant RAM user the required permissions.

23.8.7. Grant a RAM user the permissions to manage a project

This topic describes how to grant a Resource Access Management (RAM) user the permissions to manage a specified project.

Prerequisites

- A RAM user is created. For more information, see Create a user.
- A resource set is created and the RAM user is added to the resource set. For more information, see **Enterprise Center > Resource Sets** in *Apsara Uni-manager Management Console User Guide*.

Procedure

1. Log on to the Apsara Uni-manager Management Console as an administrator.

   For more information, see Log on to the Log Service console.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Data Permissions**.
4. Click the resource set that you want to manage, for example, ResourceSet(appstreaming).
5. In the **Product Type** section, click **Log Service**.
6. Find the instance that you want to manage and click **Authorize** in the Actions column.

   In this example, the instance is a Log Service project whose name is test-project.
7. Grant the RAM user the permissions to manage the project.

   If you turn on the Action switch of the **Update Project** permission, the RAM user can modify the project that is selected in Step .

23.8.8. Grant permissions to a RAM role

This topic describes how to grant permissions to a RAM role. After a RAM role is granted permissions, the RAM users in the associated RAM user group inherit the permissions.

Procedure

1. Log on to the Apsara Uni-manager Management Console as an administrator.

   For more information, see Log on to the Log Service console.
2. In the top navigation bar, click **Enterprise**.
3. In the left-side navigation pane of the **Enterprise** page, click **Roles**.
4. In the list of role names, find the RAM role for which you want to create a permission policy and choose **More > Modify**.
5. On the **Permissions** tab, click **Select Existing Permission Policy**.
6. In the **Select Existing Permission Policy** dialog box, select a permission policy and click **OK**.

   If no policies are available, create a policy. For more information, see Create a permission policy.

23.8.9. Use custom policies to grant RAM user the required permissions

This topic describes how to use custom Resource Access Management (RAM) policies to grant RAM users the required permissions. You can grant permissions to the RAM users under your Apsara Stack tenant account.

Context

For data security, we recommend that you follow the principle of least privilege (PoLP) when you grant permissions to RAM users. You must grant the read-only permission on the project list to RAM users. Otherwise, the RAM users cannot view the projects in the project list.

Use the RAM console to grant permissions to a RAM user

- The read-only permission on projects

  For example, you can use your Apsara Stack tenant account to grant RAM users the following permissions:

  - The permission to view the list of projects that belong to the Apsara Stack tenant account
  - The permission to read specific projects

  Use the following policy:

```
{
  "Version": "1",
  "Statement": [
   {
    "Action": ["log:ListProject"],
    "Resource": ["acs:log:*:*:project/*"],
    "Effect": "Alow"
   },
   {
    "Action": [
     "log:Get*",
     "log:List*"
    ],
    "Resource": "acs:log:*:*:project/<The name of the project>/*",
    "Effect": "Allow"
   }
  ]
 }
```

- The permission to read a Logstore, save searches, and use saved searches.

  For example, you can use your Apsara Stack tenant account to grant RAM users the following permissions:

  - The permission to view the project list of the Apsara Stack tenant account
  - The permission to read a Logstore, save searches, and use saved searches

  Use the following policy:

```
{
 "Version": "1",
 "Statement": [
  {
   "Action": [
    "log:ListProject"
   ],
   "Resource": "acs:log:*:*:project/*",
   "Effect": "Allow"
  },
  {
   "Action": [
    "log:List*"
   ],
   "Resource": "acs:log:*:*:project/<The name of the project>/logstore/*",
   "Effect": "Allow"
  },
  {
   "Action": [
    "log:Get*",
    "log:List*"
   ],
   "Resource": [
    "acs:log:*:*:project/<The name of the project>/logstore/<The name of the Logstore>"
   ],
   "Effect": "Allow"
  },
  {
   "Action": [
    "log:List*"
   ],
   "Resource": [
    "acs:log:*:*:project/<The name of the project>/dashboard",
    "acs:log:*:*:project/<The name of the project>/dashboard/*"
   ],
   "Effect": "Allow"
  },
  {
   "Action": [
    "log:Get*",
    "log:List*",
    "log:Create*"
   ],
   "Resource": [
    "acs:log:*:*:project/<The name of the project>/savedsearch",
    "acs:log:*:*:project/<The name of the project>/savedsearch/*"
   ],
   "Effect": "Allow"
  }
 ]
}
```

Note In the policy, a value of the Resource attribute that does not end with an asterisk (*) indicates the exact resource. A value that ends with an asterisk (*) indicates all resources that match the value.

- The permission to read a Logstore and view all saved searches and dashboards in a project

  For example, you can use your Apsara Stack tenant account to grant a RAM user the following permissions:

- The permission to view the project list of the Apsara Stack tenant account
- The permission to read a Logstore and view all saved searches and dashboards in a project

Use the following policy:

```
{
 "Version": "1",
 "Statement": [
  {
   "Action": [
    "log:ListProject"
   ],
   "Resource": "acs:log:*:*:project/*",
   "Effect": "Allow"
  },
  {
   "Action": [
    "log:List*"
   ],
   "Resource": "acs:log:*:*:project/<The name of the project>/logstore/*",
   "Effect": "Allow"
  },
  {
   "Action": [
    "log:Get*",
    "log:List*"
   ],
   "Resource": [
    "acs:log:*:*:project/<The name of the project>/logstore/<The name of the Logstore>"
   ],
   "Effect": "Allow"
  },
  {
   "Action": [
    "log:Get*",
    "log:List*"
   ],
   "Resource": [
    "acs:log:*:*:project/<The name of the project>/dashboard",
    "acs:log:*:*:project/<The name of the project>/dashboard/*"
   ],
   "Effect": "Allow"
  },
  {
   "Action": [
    "log:Get*",
    "log:List*"
   ],
   "Resource": [
    "acs:log:*:*:project/<The name of the project>/savedsearch",
    "acs:log:*:*:project/<The name of the project>/savedsearch/*"
   ],
   "Effect": "Allow"
  }
 ]
}
```

Grant RAM users the permissions that are required to call Log Service operations

- The permission to write data to a project

  To grant RAM users only the permission to write data to a project, use the following policy:

```
{
 "Version": "1",
 "Statement": [
  {
   "Action": [
    "log:Post*"
   ],
   "Resource": "acs:log:*:*:project/<The name of the project>/*",
   "Effect": "Allow"
  }
 ]
}
```

- The permission to consume data of a project

  To grant RAM users only the permission to consume data of a project, use the following policy:

```
{
 "Version": "1",
 "Statement": [
  {
   "Action": [
    "log:ListShards",
    "log:GetCursorOrData",
    "log:GetConsumerGroupCheckPoint",
    "log:UpdateConsumerGroup",
    "log:ConsumerGroupHeartBeat",
    "log:ConsumerGroupUpdateCheckPoint",
    "log:ListConsumerGroup",
    "log:CreateConsumerGroup"
   ],
   "Resource": "acs:log:*:*:project/<The name of the project>/*",
   "Effect": "Allow"
  }
 ]
}
```

- The permission to consume data of a Logstore

  To grant RAM users only the permission to consume data of a Logstore, use the following policy:

```
{
 "Version": "1",
 "Statement": [
  {
   "Action": [
    "log:ListShards",
    "log:GetCursorOrData",
    "log:GetConsumerGroupCheckPoint",
    "log:UpdateConsumerGroup",
    "log:ConsumerGroupHeartBeat",
    "log:ConsumerGroupUpdateCheckPoint",
    "log:ListConsumerGroup",
    "log:CreateConsumerGroup"
   ],
   "Resource": [
    "acs:log:*:*:project/<The name of the project>/logstore/<The name of the Logstore>",
    "acs:log:*:*:project/<the name of the project>/logstore/<the name of the Logstore>/*"
   ],
   "Effect": "Allow"
  }
 ]
}
```

23.9. FAQ

23.9.1. Log collection

23.9.1.1. How do I troubleshoot Logtail collection errors?

If the Logtail preview page is blank or "No Data" is displayed on the query page, perform the following steps:

Procedure

1. Check whether Log Service receives heartbeats from the server group.

   You can view the Logtail heartbeat status in the Log Service console. For more information, see View the status of a server group.

   If the heartbeat status is OK, go to the next step. If the heartbeat status is FAIL, proceed with further troubleshooting. For more information, see What can I do if no heartbeat packet is received from a Logtail client?.

2. Check whether the Logtail configuration is created.

   If the heartbeat status of Logtail is OK, check whether the Logtail configuration is created. Make sure that the path and name of monitored logs match the files that are stored on the server. The path can be a full path or a path that includes wildcards.

3. Make sure that the Logtail configuration is applied to the server group.

   Check whether the target Logtail configuration is applied to the server group. For more information, see Manage server group configurations.

4. Check collection errors.

   If Logtail is configured correctly, check whether new logs are generated in real time. Logtail only collects incremental log data. Logtail does not read log files in which no log is generated. If a log file is updated but the updates cannot be queried in Log Service, you can diagnose the problem as follows:

   - View logs of the Logtail client

The client logs include key INFO logs, all WARNING logs, and all ERROR logs. To view complete error information in real time, check the following client logs:

- Linux: */usr/local/ilogtail/ilogtail.LOG*.
- Linux: */usr/local/ilogtail/logtail_plugin.LOG*. The file contains the logs such as HTTP logs, MySQL binary logs, and MySQL query results.
- 64-bit Windows: *C:\Program Files (x86)\Alibaba\Logtail\logtail_*.log*.
- 32-bit Windows: *C:\Program Files\Alibaba\Logtail\logtail_*.log*.

- Check whether the log volume exceeds the limit.

  To collect large volumes of logs, you may need to modify the Logtail startup parameters for higher log collection throughput. For more information, see Set Logtail startup parameters.

23.9.1.2. What can I do if Log Service does not receive heartbeats from a Logtail client?

If Log Service does not receive heartbeats from a Logtail client, perform the steps that are described in the topic to troubleshoot the problem.

Context

After Logtail is installed on a server, the Logtail client sends heartbeats to Log Service. If the status page of the machine group shows that Log Service does not receive heartbeats from a Logtail client, it indicates that the Logtail client is not installed or disconnected from the server.

Step 1: Check whether Logtail is installed

Use the following method to check whether Logtail is installed:

- On a Linux server, run the following command:

  ```
  sudo /etc/init.d/ilogtaild status
  ```

  If the command returns `ilogtail is running`, it indicates that Logtail is installed. The following script shows an example command and response:

  ```
  [root@****************~]# sudo /etc/init.d/ilogtaild status
  ilogtail is running
  ```

- On a Windows server:
  i. Press Win+R. In the Run dialog box, enter services.msc and click **OK**.
  ii. In the **Services** window, check the status of the LogtailDaemon and LogtailWorker services. If the services are in the Running state, it indicates that Logtail is installed.

If Logtail is not installed, install it. For more information, see Install Logtail in Linux or Install Logtail in Windows. Ensure that the Log Service endpoint in the Logtail installation command corresponds to the region to which the Log Service project belongs. If Logtail is running, go to the next step.

Step 2: Check the Log Service endpoint in the Logtail installation command

When you install Logtail, you must specify a Log Service endpoint based on the region to which the Log Service project belongs. If the endpoint is incorrect or the Logtail installation command is invalid, Log Service cannot receive heartbeats from the Logtail client.

You can view the Log Service endpoint and installation method in the Logtail configuration file named *ilogtail_config.json*. The file is stored in the following path:

- Linux: */usr/local/ilogtail/ilogtail_config.json*

- 64-bit Windows: *C:\Program Files (x86)\Alibaba\Logtail\ilogtail_config.json*
- 32-bit Windows: *C:\Program Files\Alibaba\Logtail\ilogtail_config.json*

In the Logtail configuration file, check the value of the `config_server_address` parameter. This parameter specifies the Log Service endpoint. Then, check whether the Logtail client can connect to Log Service based on the endpoint. For example, if the endpoint that is recorded in the Logtail configuration file is `logtail.cn-qingdao-env25-d01.sls-pub.inter.env25.shuguang.com`, you can run the following command to check the connection:

- Linux:

```
curl logtail.cn-qingdao-env25-d01.sls-pub.inter.env25.shuguang.com
```

- Windows:

```
telnet logtail.cn-qingdao-env25-d01.sls-pub.inter.env25.shuguang.com 80
```

If the Log Service endpoint in the Logtail installation command is incorrect, re-install Logtail. For more information, see Install Logtail in Linux or Install Logtail in Windows.

If the Log Service endpoint in the Logtail installation command is correct, go to the next step.

Step 3: Check the server IP addresses in the machine group

The server IP address that is obtained by a Logtail client must be configured in the machine group. Otherwise, Log Service cannot receive heartbeats or collect logs from the Logtail client. Logtail uses the following methods to obtain the IP address of a server:

- If the server is not bound with a hostname, Logtail obtains the IP address of the first network interface controller (NIC) card of the server.
- If the server is bound with a hostname, Logtail obtains the IP address that corresponds to the hostname. You can view the hostname and IP address in the */etc/hosts* file.

> **Note** You can run the **hostname** command to query the hostname.

Perform the following steps to check whether the server IP address that is obtained by the Logtail client is configured in the machine group.

1. Check the server IP address that is obtained by Logtail.

   The `ip` field in the *app_info.json* file indicates the server IP address that is obtained by Logtail. The file is stored in the following path:

   - Linux: */usr/local/ilogtail/app_info.json*
   - 64-bit Windows: *C:\Program Files (x86)\Alibaba\Logtail\app_info.json*
   - 32-bit Windows: *C:\Program Files\Alibaba\Logtail\app_info.json*

   > **Note**
   > - If the `ip` field in the `app_info.json` file is empty, Logtail cannot work. In this case, you must configure an IP address for the server and restart Logtail.
   > - The `app_info.json` file is used only to record information. If you modify the IP address in the file, the server IP address obtained by Logtail is not updated.

2. Check the server IP addresses in the machine group.

   Log on to the Log Service console. In the **Projects** section, click the project to which the machine group belongs. In the left-side navigation pane, click the **Machine Groups** icon. In the **Machine Groups** pane, click the machine group. In the **Machine Group Status** section of the **Machine Group Settings** page, check the server IP addresses.

If no server IP address in the machine group is the same as the IP address that is obtained by Logtail, perform the following step to modify the IP address configurations in the Log Service console:

- If a server IP address in the machine group is incorrect, change the IP address to the IP address that is obtained by Logtail. Then, check the heartbeat status 1 minute after you save the change.
- If you have modified the IP address of the server where Logtail is installed (for example, the */etc/hosts* file is modified), restart Logtail. After Logtail obtains the new server IP address, set a server IP address in the machine group to the value of the `ip` field in the `app_info.json` file.

You can use the following method to restart Logtail:

- On a Linux server, run the following commands:

```
sudo /etc/init.d/ilogtaild stop
sudo /etc/init.d/ilogtaild start
```

- On a Windows server:

  Press Win+R. In the Run dialog box, enter services.msc and click OK. In the **Services** window, find and restart the LogtailWorker service.

23.9.1.3. How do I query the local log collection statuses?

You can use Logtail to query the health status of Logtail and log collection statuses. The statuses help you troubleshoot log collection issues and customize status monitoring for log collection.

Instructions

After a Logtail client that supports the status query feature is installed, you can query the local log collection statuses by running commands on the client. For more information about how to install Logtail, see Install Logtail in Linux.

You can run the `/etc/init.d/ilogtaild -h` command on the client to check whether a client supports the feature of querying the local log collection status. If the command output includes the `logtail insight, version` keyword, it indicates that the client supports the status query feature.

```
/etc/init.d/ilogtaild -h
Usage: ./ilogtaild { start | stop (graceful, flush data and save checkpoints) | force-stop | status | -h for help}$
logtail insight, version : 0.1.0
commond list :
    status all [index]
        get logtail running status
    status active [--logstore | --logfile] index [project] [logstore]
        list all active logstore | logfile. if use --logfile, please add project and logstore. default --logstore
    status logstore [--format=line | json] index project logstore
        get logstore status with line or json style. default --format=line
    status logfile [--format=line | json] index project logstore fileFullPath
        get log file status with line or json style. default --format=line
    status history beginIndex endIndex  project logstore [fileFullPath]
        query logstore | logfile history status.
index :  from 1 to 60. in all, it means last $(index) minutes; in active/logstore/logfile/history, it means last $(index)*10 min
utes
```

The following table describes the commands that are supported by Logtail:

Command	Function	Maximum time range that can be queried	Time window
all	Queries the status of Logtail.	Last 60 minutes	1 minute

Command	Function	Maximum time range that can be queried	Time window
active	Queries the active Logstores that are collecting logs and the active log files from which logs are being collected.	Last 600 minutes	10 minutes
logstore	Queries the collection status of a Logstore.	Last 600 minutes	10 minutes
logfile	Queries the collection status of a log file.	Last 600 minutes	10 minutes
history	Queries the collection status of a Logstore or log file in the query time window.	Last 600 minutes	10 minutes

Note

- The `index` parameter in the preceding commands indicates the index of the time window. Valid values: 1 to 60. The index of the latest time window is 1 and the time window ends at the current system time. If you specify a 1-minute time window, the status in the past interval of `(index, index-1]` minutes is returned. If you specify a 10-minute time window, the status in the past interval of `(10*index, 10*(index-1)]` minutes is returned.
- All commands in the preceding table is the subcommands of the status command.

Command all

Command syntax

```
/etc/init.d/ilogtaild status all [ index ]
```

Note The all command is used to query the status of Logtail. The index parameter is optional. Default value: 1.

Examples

```
/etc/init.d/ilogtaild status all 1
ok
/etc/init.d/ilogtaild status all 10
busy
```

Response

Status	Description	Priority	Troubleshooting
ok	Logtail is running as expected.	N/A	No action is required.
busy	The collection speed is high, and Logtail is running as expected.	N/A	No action is required.

Status	Description	Priority	Troubleshooting
many_log_files	A large number of log files are being collected by Logtail.	Low	You can check the Logtail configuration for log files that do not need to be collected.
process_block	The process of log parsing is blocked.	Low	You can check whether a large number of logs are generated in a short time. If you use the all command for multiple times and the returned value is always process_block, you can modify the limit of CPU usage or the limit of concurrent packet sending.
send_block	The process of sending log packets is blocked.	High	You can check whether a large number of logs are generated in a short time and the network connection is stable. If you use the all command for multiple times and the returned value is always send_block, you can modify the limit of CPU usage or the limit of concurrent packet sending.

Command active

Command syntax

```
/etc/init.d/ilogtaild status active [--logstore] index
/etc/init.d/ilogtaild status active --logfile index project-name logstore-name
```

> **Note**
>
> - You can use the `active [--logstore] index` command to query all active Logstores. The `--logstore` parameter is optional.
> - The command `active --logfile index project-name logstore-name` is used to query all active log files in the Logstore of a project.
> - The active command is used to query log files. We recommend that you query active Logstores before querying active log files in the Logstores.

Examples

```
/etc/init.d/ilogtaild status active 1
sls-zc-test : release-test
sls-zc-test : release-test-ant-rpc-3
sls-zc-test : release-test-same-regex-3
/etc/init.d/ilogtaild status active --logfile 1 sls-zc-test release-test
/disk2/test/normal/access.log
```

Response

- If you run the `active --logstore index` command, the names of the active Logstores are returned in the following format: `project-name : logstore-name`. If you run the command `active --logfile index project-name logstore-name`, the paths of active log files are returned.
- The status of the inactive Logstores or inactive log files in the query time window is not returned.

Command logstore

Command syntax

```
/etc/init.d/ilogtaild status logstore [--format={line|json}] index project-name logstore-name
```

Note

- The logstore command is used to query the collection status of the specified project and Logstore in the LINE or JSON format.
- The default value of the `--format=` parameter is `--format=line`, which indicates that the status is returned in the LINE format. Noted that the `--format=` parameter is placed after the `logstore` parameter.
- If the Logstore specified in the preceding command does not exist or is not active in the query time window, an empty response in LINE format or the `null` value in the JSON format is returned.

Examples

```
/etc/init.d/ilogtaild status logstore 1 sls-zc-test release-test-same
time_begin_readable : 17-08-29 10:56:11
time_end_readable : 17-08-29 11:06:11
time_begin : 1503975371
time_end : 1503975971
project : sls-zc-test
logstore : release-test-same
status : ok
config : ##1.0##sls-zc-test$same
read_bytes : 65033430
parse_success_lines : 230615
parse_fail_lines : 0
last_read_time : 1503975970
read_count : 687
avg_delay_bytes : 0
max_unsend_time : 0
min_unsend_time : 0
max_send_success_time : 1503975968
send_queue_size : 0
send_network_error_count : 0
send_network_quota_count : 0
send_network_discard_count : 0
send_success_count : 302
send_block_flag : false
sender_valid_flag : true
/etc/init.d/ilogtaild status logstore --format=json 1 sls-zc-test release-test-same
{
  "avg_delay_bytes" : 0,
  "config" : "##1.0##sls-zc-test$same",
  "last_read_time" : 1503975970,

  "time_end" : 1503975971,
  "time_end_readable" : "17-08-29 11:06:11"
}
```

Response

Parameter	Description	Unit

Parameter	Description	Unit
status	The status of the Logstore.For information about Logstore statuses and actions that are required to deal with each status, see the following table.	N/A
time_begin_readable	The time when logs become readable.	N/A
time_end_readable	The time when logs become unreadable.	N/A
time_begin	The time when statistics collection starts.	Unix timestamp in seconds
time_end	The time when statistics collection ends.	Unix timestamp in seconds
project	The name of the project.	N/A
logstore	The name of the Logstore.	N/A
config	The name of the Logtail configuration, which is globally unique. The format of the name is `##1.0##` + project + `$` + config.	N/A
read_bytes	The amount of the log data that is read in the query time window.	Byte
parse_success_lines	The number of the log lines that are parsed in the query time window.	Line
parse_fail_lines	The number of the log lines that fail to be parsed in the query time window.	Line
last_read_time	The last time when logs are read in the query time window.	Unix timestamp in seconds
read_count	The number of times that the log file is read in the query time window.	Times
avg_delay_bytes	The average of difference between the actual file size and the offset generated when reading log data each time in the query time window.	Byte
max_unsend_time	The maximum period of time for which an unsent packet waits in the sending queue. An unsent packet refers to a packet that has not been sent at the end of the query time window. If no packets exist in the queue, the value is 0.	Unix timestamp in seconds

Parameter	Description	Unit
min_unsend_time	The minimum period of time for which an unsent packet waits in the sending queue. Unsent packets refer to packets that have not been sent at the end of the query time window. If no packets exist in the queue, the value is 0.	Unix timestamp in seconds
max_send_success_time	The maximum period of time when a packet waited in the sending queue.	Unix timestamp in seconds
send_queue_size	The number of the unsent packets in the sending queue at the end of the query time window.	Number of packets
send_network_error_count	The number of the packets that cannot be sent due to network errors in the query time window.	Number of packets
send_network_quota_count	The number of the packets that cannot be sent due to quota limit in the query time window.	Number of packets
send_network_discard_count	The number of the packets that are discarded due to data errors or lack of permissions.	Number of packets
send_success_count	The number of the packets that are sent in the query time window.	Number of packets
send_block_flag	Indicates whether the sending queue is blocked at the end of the query time window.	N/A
sender_valid_flag	Indicates whether the sender flag of the Logstore is valid. The value true indicates that the sender flag is valid. The value false indicates that the sender flag is invalid and disabled because of a network error or quota error.	N/A

Logstore statuses

Status	Description	Troubleshooting
ok	Logtail is running as expected.	No action is required.
process_block	The process of log parsing is blocked.	You can check whether a large number of logs are generated in a short time. If you use the all command for multiple times and the returned value is always process_block, you can Set Logtail startup parametersmodify the limit of CPU usage or of concurrent packet sending.
parse_fail	Logtail fails to parse logs.	You can check whether the format of logs is consistent with that you set in the Logtail configuration.

Status	Description	Troubleshooting
send_block	The process of sending log packets is blocked.	You can check whether a large number of logs are generated in a short time and the network connection is stable. If you use the all command for multiple times and the returned value is always send_block, you can Set Logtail startup parametersmodify the limit of CPU usage or of concurrent packet sending.

Command logfile

Command syntax

```
/etc/init.d/ilogtaild status logfile [--format={line|json}] index project-name logstore-name fileFullPath
```

> **Note**
>
> - The logfile command is used to query the collection status of the specified log files in the LINE or JSON format.
> - The default value of the `--format=` parameter is `--format=line`, which indicates that the status is returned in the LINE format.
> - If the log file specified in the command does not exist or is not active in the query time window, an empty response in the LINE format or the `null` value in the JSON format is returned.
> - The `--format` parameter is placed after the `logfile` parameter.
> - The value of the `filefullpath` parameter must be the full path of the log file.

Examples

```
/etc/init.d/ilogtaild status logfile 1 sls-zc-test release-test-same /disk2/test/normal/access.log
time_begin_readable : 17-08-29 11:16:11
time_end_readable : 17-08-29 11:26:11
time_begin : 1503976571
time_end : 1503977171
project : sls-zc-test
logstore : release-test-same
status : ok
config : ##1.0##sls-zc-test$same
file_path : /disk2/test/normal/access.log
file_dev : 64800
file_inode : 22544456
file_size_bytes : 17154060
file_offset_bytes : 17154060
read_bytes : 65033430
parse_success_lines : 230615
parse_fail_lines : 0
last_read_time : 1503977170
read_count : 667
avg_delay_bytes : 0
/etc/init.d/ilogtaild status logfile --format=json 1 sls-zc-test release-test-same /disk2/test/normal/access.log
{
  "avg_delay_bytes" : 0,
  "config" : "##1.0##sls-zc-test$same",
  "file_dev" : 64800,
  "file_inode" : 22544456,
  "file_path" : "/disk2/test/normal/access.log",
  "file_size_bytes" : 17154060,
  "last_read_time" : 1503977170,
  "logstore" : "release-test-same",

  "time_end" : 1503977171,
  "time_end_readable" : "17-08-29 11:26:11"
}
```

Response

Parameter	Description	Unit
status	The collection status of the log file in the query time window. For more information, see the status parameter in the Command logstore section.	N/A
time_begin_readable	The time when logs become readable.	N/A
time_end_readable	The time when logs become unreadable.	N/A

Parameter	Description	Unit
time_begin	The time when statistics collection starts.	Unix timestamp in seconds
time_end	The time when statistics collection ends.	Unix timestamp in seconds
project	The name of the project.	N/A
logstore	The name of the Logstore.	N/A
file_path	The path of the log file.	N/A
file_dev	The ID of the device from which the log file is collected.	N/A
file_inode	The inode of the log file.	N/A
file_size_bytes	The size of the log file that is last scanned in the query time window.	Byte
read_offset_bytes	The parsing offset of the log file.	Byte
config	The name of the Logtail configuration, which is globally unique. The format of the name is `##1.0##` + project + `$` + config.	N/A
read_bytes	The amount of the log data that is read in the query time window.	Byte
parse_success_lines	The number of the log lines that are parsed in the query time window.	Line
parse_fail_lines	The number of the log lines that fail to be parsed in the query time window.	Line
last_read_time	The last time when logs are read in the query time window.	Unix timestamp in seconds
read_count	The number of times that the log file is read in the query time window.	Times
avg_delay_bytes	The average of difference between the actual file size and the offset generated when reading log data each time in the query time window.	Byte

Command history

Command syntax

```
/etc/init.d/ilogtaild status history beginIndex endIndex project-name logstore-name [fileFullPath]
```

> Note
>
> - The history command is used to query the collection status of a Logstore or log file in the query time window.
> - The `beginIndex` and `endIndex` parameters specify the start and end indexes of the range of time windows that you want to query. You must ensure that `beginIndex <= endIndex`.
> - The `fileFullPath` parameter is optional. If you specify the path of a log file, the collection status of the log file is queried. If the path is not specified, the collection status of the Logstore is queried.

Examples

```
/etc/init.d/ilogtaild status history 1 3 sls-zc-test release-test-same /disk2/test/normal/access.log
    begin_time      status    read  parse_success  parse_fail    last_read_time  read_count  avg_delay   device    inode  file_size  read_offset
 17-08-29 11:26:11        ok  62.12MB     231000       0  17-08-29 11:36:11     671     0B   64800 22544459  18.22MB   18.22MB
 17-08-29 11:16:11        ok  62.02MB     230615       0  17-08-29 11:26:10     667     0B   64800 22544456  16.36MB   16.36MB
 17-08-29 11:06:11        ok  62.12MB     231000       0  17-08-29 11:16:11     687     0B   64800 22544452  14.46MB   14.46MB
$/etc/init.d/ilogtaild status history 2 5 sls-zc-test release-test-same
    begin_time      status    read  parse_success  parse_fail    last_read_time  read_count  avg_delay  send_queue  network_error  quota_error  discard_error  send_success  send_block  send_valid      max_unsend      min_unsend      max_send_success
 17-08-29 11:16:11        ok  62.02MB     230615       0  17-08-29 11:26:10     667     0B      0       0       0       0       300    false     true  70-01-01 08:00:00  70-01-01 08:00:00  17-08-29 11:26:08
 17-08-29 11:06:11        ok  62.12MB     231000       0  17-08-29 11:16:11     687     0B      0       0       0       0       303    false     true  70-01-01 08:00:00  70-01-01 08:00:00  17-08-29 11:16:10
 17-08-29 10:56:11        ok  62.02MB     230615       0  17-08-29 11:06:10     687     0B      0       0       0       0       302    false     true  70-01-01 08:00:00  70-01-01 08:00:00  17-08-29 11:06:08
 17-08-29 10:46:11        ok  62.12MB     231000       0  17-08-29 10:56:11     692     0B      0       0       0       0       302    false     true  70-01-01 08:00:00  70-01-01 08:00:00  17-08-29 10:56:10
```

Response

- The collection status of the Logstore or log file in each query time window is listed in a line.
- For more information about response parameters, see the Command `logstore` and Command `logfile` sections.

Response status codes

Success code

If parameters that you specify in a command is valid (even if the queried Logstore or log file is not found), the code 0 is returned. The following section provides two examples:

```
/etc/init.d/ilogtaild status logfile --format=json 1 error-project error-logstore /no/this/file
null
echo $?
0
/etc/init.d/ilogtaild status all
ok
echo $?
0
```

Error codes

If a non-zero code is returned, it indicates that an error occurs. The following table describes the possible non-zero codes.

Code	Description	Message	Troubleshooting
10	The command is invalid or required parameters in the command are not specified.	`invalid param, use -h for help.`	You can run the `-h` command for help.
1	The value of the index parameter is not in the range from 1 to 60.	`invalid query interval`	You can run the `-h` command for help.
1	The collection status in the specified query time window cannot be queried.	`query fail, error: $(error)` . For more information, visit errno.	The startup time of Logtail is earlier than the query time window. Otherwise, you can submit a ticket for help.
1	The start time of querying is out of the query time window.	`no match time interval, please check logtail status`	You can check whether Logtail is running. If yes, you can submit a ticket for help.
1	No logs exist in the specified query time window.	`invalid profile, maybe logtail restart`	You can check whether Logtail is running. If yes, you can submit a ticket for help.

Examples

```
/etc/init.d/ilogtaild status nothiscmd
invalid param, use -h for help.
echo $?
10
/etc/init.d/ilogtaild status/all 99
invalid query interval
echo $?
1
```

Scenarios

You can query the overall status of Logtail, and specific metrics by querying the collection status during collection. You can customize a mechanism to monitor the log collection status based on the queried information.

Monitor the status of Logtail

You can monitor the status of Logtail by using the `all` command.

For example, you can run the command every minute to query Logtail status. If the `process_block` , `send_block` or `send_error` value is returned for 5 consecutive minutes, an alert is triggered.

You can adjust the alert duration and monitoring scope based on the priorities of the collected log files.

Monitor the log collection status

You can monitor the log collection status of a Logstore by using the `logstore` command.

For example, you can run the `logstore` command every 10 minutes to query the collection status of the Logstore. If the value of the `avg_delay_bytes` parameter exceeds 1 MB (1024 × 1024 bytes) or the value of the `status` parameter is not `ok` , an alert is triggered.

You can adjust the alert threshold for the `avg_delay_bytes` metric based on the size of data that is generated during the log collection.

Check whether Logtail has finished collecting log files

You can check whether Logtail has finished collecting log files by using the `logfile` command.

After Logtail stops collecting log files, you can run the `logfile` command every 10 minutes to query the status of the log file. If the value of the `read_offset_bytes` parameter is the same as that of the `file_size_bytes` parameter, it indicates that the log file is collected.

Troubleshoot log collection issues

If log collection latency occurs on a server, you can use the `history` command to query the status history of log collection.

1. The value of the `send_block_flag` parameter is true.This indicates that the log collection is blocked because of unstable network connections.
   - If the value of the `send_network_quota_count` parameter is greater than 0, split shards in the Logstore. For more information, see Split a shard.
   - If the value of the `send_network_error_count` parameter is greater than 0, check the network connections.
   - If no network error occurs, adjust the limit of concurrent packet sending and data transfer speed of Logtail.
2. The parameters related to packet sending are set to appropriate values. However, the value of the `avg_delay_bytes` parameter is large.
   - Use the value of the `read_bytes` parameter to calculate the average speed of parsing logs, and then determine whether a large amount of data is transferred during log collection based on the average speed.
   - Adjust the resource usage limits for Logtail.
3. The value of the `parse_fail_lines` parameter is greater than 0.

   Check whether the regular expression can match all required log fields as expected.

23.9.1.4. How do I test a regular expression?

If you select the full regex mode when you configure Logtail to collect and parse text logs, you must specify a regular expression based on your sample log entries. This topic describes how to test a regular expression.

Context

To test a regular expression that you have specified in the Log Service console, you can click **Validate** in the console and check the results as follows:

- For the regular expression that matches the first line of logs, check whether the regular expression can match the expected number of log entries.
- For the fields extracted by the regular expression, check whether the value of each field meets your expectations.

If you want to validate more items and test a regular expression, you can use online tools such as regex101.com and regextester.com. You can copy and paste the regular expression that is generated by Log Service to an online tool, and specify a sample log entry as the test string.

If you use the full regex mode, Log Service automatically generates a regular expression based on a sample log entry. However, the regular expression may fail to match the message field in multi-line log entries as expected. The following example describes how to use the regex101.com tool to test the regular expression.

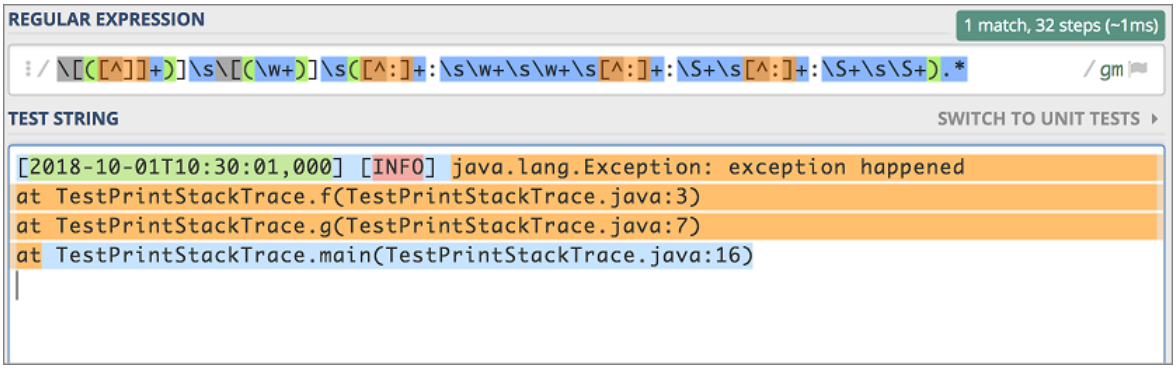
Procedure

1. Copy the generated regular expression.
2. Visit the regex101.com website.
3. Paste the regular expression in the **REGULAR EXPRESSION** field.

   On the right side of the page, you can view the explanation of the regular expression.

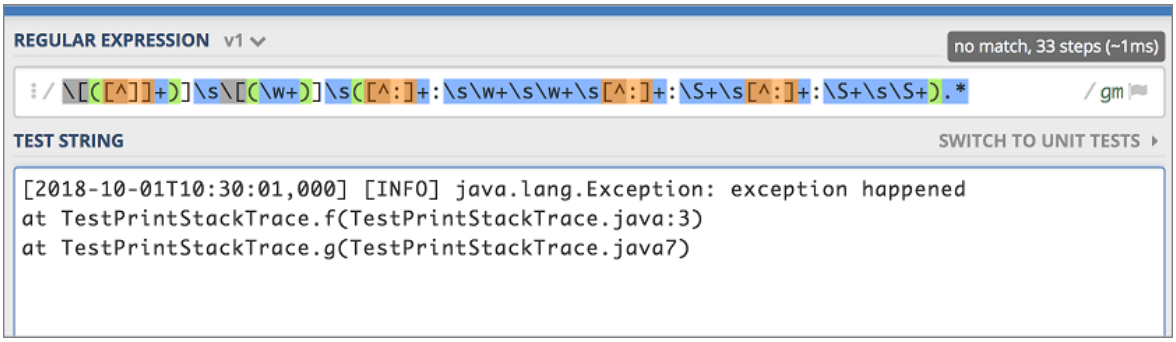
4. In the **TEST STRING** field, paste a log sample entry.

   In the following figure, the log contents that are included in the message field are highlighted in orange, and the log contents that are not included are highlighted in blue. The figure shows that the substring following the `at` word is not included in the `message` field. Therefore, this regular expression does not match fields in the sample log entry as expected and cannot be used to collect log data.



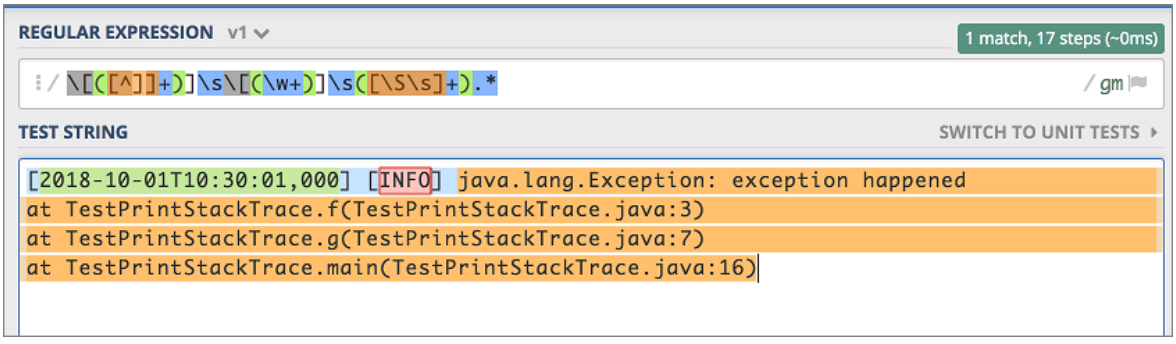
5. Check whether the regular expression can match fields in a sample log entry with two colons as expected.

   The following figure shows that the regular expression fails to match fields in the sample log entry as expected.

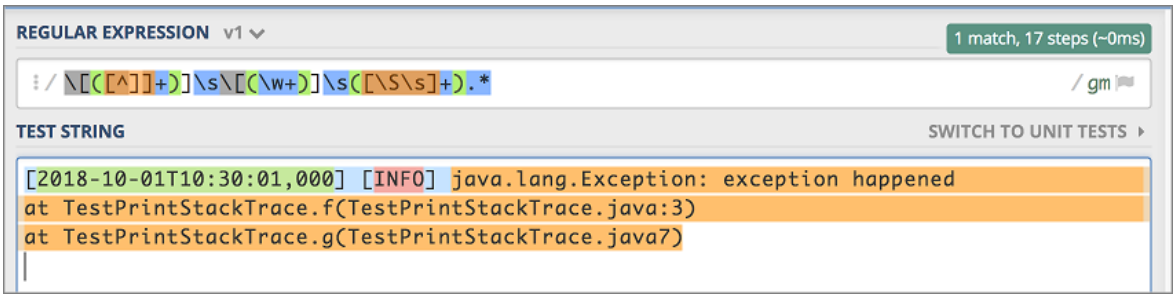


6. Replace the last subexpression in the regular expression with `[\S\s]+`, and check whether the regular expression can match fields in the sample log entries as expected.

   The following figure shows how the modified regular expression matches the substring following the `at` word.



The following figure shows how the modified regular expression matches the sample log entry with two colons.



You can follow the preceding instructions to test your regular expression. After you validate the regular expression, you can apply it to a Logtail configuration.

23.9.1.5. How do I optimize regular expressions?

You can optimize regular expressions to improve the Logtail performance.

When you optimize regular expressions, we recommend that you follow these rules:

- Use precise characters

  We recommend that you do not use the wildcard characters `.*` in a regular expression to match fields in log entries. Using wildcard characters may lead to mismatches and low matching performance. For example, if a field that you want to match only consists of letters, use `[A-Za-z]`.

- Use appropriate quantifiers

  We recommend that you do not use plus signs (+) or asterisks (*). For example, you can use `\d` instead of `\d+` or `\d{1,3}` to match the IP address.

- Test and modify regular expressions

  You can visit the **regex101.com** website to test and modify a regular expression to decrease the time required to match log entries.

23.9.1.6. How do I use the full regex mode to collect log entries in multiple formats?

The full regex mode requires that log entries to be collected be in the same format. Therefore, if you want to collect log entries that are in multiple formats, you must use the schema-on-write or schema-on-read solution.

Taking Java logs as an example, the following section lists the types of error log entry and normal log entry.

- Multi-line WARNING log entries
- Simple text INFO log entries
- Key-value DEBUG log entries

```
[2018-10-01T10:30:31,000] [WARNING] java.lang.Exception: another exception happened
  at TestPrintStackTrace.f(TestPrintStackTrace.java:3)
  at TestPrintStackTrace.g(TestPrintStackTrace.java:7)
  at TestPrintStackTrace.main(TestPrintStackTrace.java:16)
[2018-10-01T10:30:32,000] [INFO] info something
[2018-10-01T10:30:33,000] [DEBUG] key:value key2:value2
```

To collect log entries of these types, you can use the following solutions:

- Schema-on-write: To extract log fields, you must apply multiple Logtail configurations with different regular expressions to a log file.

> **Note** However, Logtail cannot apply multiple Logtail configurations directly to the same log file. Therefore, you must set up multiple symbolic links for the directory in which the log file resides. Each Logtail configuration applies to a symbolic link to collect log entries in a specific format.

- Schema-on-read: you can use a common regular expression to collect log entries in different formats.

  For example, if you want to collect log entries in multiple formats, you can configure a regular expression that matches the time and log level fields as the first line, and specify the rest of the log entries as the log message. If you want to parse the message, create an index for the message, specify a regular expression to extract log messages, and then extract target fields.

  > **Note** We recommend that you use this solution only for scenarios in which tens of millions of log entries are collected, or fewer.

23.9.1.7. How do I set the time format for logs?

You must be familiar with the following rules before setting the time format for logs in Logtail configurations.

- The unit of the timestamp in Log Service is seconds. Therefore, you cannot set the unit as milliseconds or microseconds.
- You only need to set the time field. Other parameters are not required.

The following section lists commonly used formats:

```
Custom1 2017-12-11 15:05:07
%Y-%m-%d %H:%M:%S
Custom2 [2017-12-11 15:05:07.012]
[%Y-%m-%d %H:%M:%S
RFC822    02 Jan 06 15:04 MST
%d %b %y %H:%M
RFC822Z    02 Jan 06 15:04 -0700
%d %b %y %H:%M
RFC850     Monday, 02-Jan-06 15:04:05 MST
%A, %d-%b-%y %H:%M:%S
RFC1123    Mon, 02 Jan 2006 15:04:05 MST
%A, %d-%b-%y %H:%M:%S
RFC3339    2006-01-02T15:04:05Z07:00
%Y-%m-%dT%H:%M:%S
RFC3339Nano 2006-01-02T15:04:05.999999999Z07:00
%Y-%m-%dT%H:%M:%S
```

23.9.1.8. How do I configure non-printable characters in a sample log?

This topic describes how to configure non-printable characters in a sample log entry.

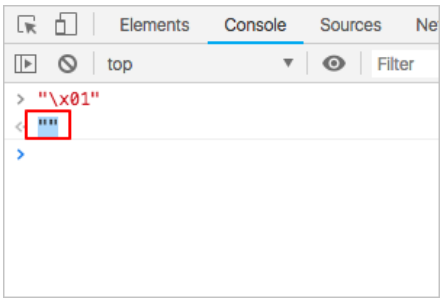
Context

Log Service allows you to specify a non-printable character as the delimiter or quote to collect logs. Non-printable characters are those whose decimal ASCII codes are in the range of 1 to 31 and 127. If you want to specify a non-printable character as the delimiter or quote, you must find the hexadecimal ASCII code of this character and enter this character in the following format: `0x` *the hexadecimal ASCII code of the non-printable character*. For example, a sample log entry is `123456780`. You can set 0x01 as the delimiter and 0x02 as the quote, and then enter a non-printable character 0x01 between the digits 5 and 6.

Procedure

1. Log on to the Log Service console.
2. Right-click the blank space on the browser and select **Inspect** from the shortcut menu.
3. Click the **Console** tab on the page that appears.
4. Enter `"\x01"` in the code editor and press Enter.
5. Copy the returned result.

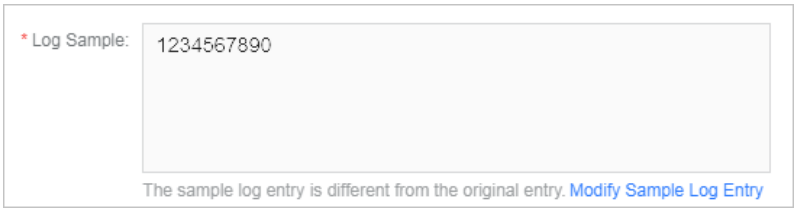
   A non-printable character is enclosed in quotation marks (").



6. Paste the returned result between the digits 5 and 6.

7. Delete the quotation marks between the digits 5 and 6.

   Then, a non-printable character is configured in a sample log entry.



23.9.1.9. How do I troubleshoot errors during container log collection?

Perform the steps that are described in this topic to troubleshoot an error that occurs when you use Logtail to collect logs from common containers or containers in a Kubernetes cluster.

Related O&M operations

- Log on to a Logtail container
- View the operational logs of Logtail
- Ignore the stdout logs of a Logtail container
- View the status of Log Service components in a Kubernetes cluster
- View the version number, IP address, and startup time of Logtail

Troubleshoot an error if Log Service does not receive heartbeats from Logtail clients

Perform the following steps to check whether Logtail is installed:

1. In the machine group, count the number of the servers whose heartbeat status is OK.
   i. Log on to the Log Service console.
   ii. Click the project to which the machine group belongs.
   iii. In the left-side navigation pane, click **Machine Groups**.
   iv. In the **Machine Groups** pane, click the name of the machine group.

   In the **Machine Group Status** section, count the number of the servers whose heartbeat status is **OK**.
2. Count the number of worker nodes in the cluster.

   Run the `kubectl get node | grep -v master` command to query the work nodes in the cluster. Count the number of the work nodes that are returned.

   ```
   $kubectl get node | grep -v master
   NAME                    STATUS   ROLES    AGE    VERSION
   cn-hangzhou.i-bp17enxc2us3624wexh2  Ready    <none>   238d   v1.10.4
   cn-hangzhou.i-bp1ad2b02jtqd1shi2ut  Ready    <none>   220d   v1.10.4
   ```
3. Check whether the number of servers whose heartbeat status is **OK** in the machine group is equal to the number of worker nodes in the cluster. Troubleshoot the error based on the check result.
   - The number of servers whose heartbeat status is OK is equal to the number of worker nodes. This means that the heartbeat status of all of the servers in the machine group is **Failed**.
     - If Logtail is installed into a common container, check whether the values of the *${your_region_name}*, *${your_aliyun_user_id}*, and *${your_machine_group_user_defined_id}* parameters are correct. For information about how to set these parameters, see Collect standard Docker logs.
     - If Logtail is installed into a container in a Container Service for Kubernetes cluster, submit a ticket.
     - If Logtail is installed into a container in a user-created Kubernetes cluster, check whether the values of the *{your-project-suffix}*, *{regionId}*, *{aliuid}*, *{access-kev-id}*, and *{access-kev-secret}* parameters are correct. If the value of a parameter is incorrect, run the `helm del --purge alibaba-log-controller` command to delete the installation package and re-install Logtail. For information about how to set these parameters, see Collect Kubernetes logs.
   - The number of servers whose heartbeat status is OK is less than the number of worker nodes.
     a. Check whether you used a YAML file to manually deploy a DaemonSet.

        Run the `kubectl get po -n kube-system -l k8s-app=logtail` command to perform the check. If the command returns pod information, it indicates that you manually deployed a DaemonSet by using a YAML file.
     b. Download the latest version of the Logtail DaemonSet template.
     c. Set the *${your_region_name}*, *${your_aliyun_user_id}*, and *${your_machine_group_name}* parameters to the values that are specific to your environment.
     d. Run the `kubectl apply -f ./logtail-daemonset.yaml` command to update the DaemonSet YAML file.

     Submit a ticket if the error persists.

Troubleshoot an error if Log Service collects no logs from containers

If no log is displayed in the **Consumption Preview** pane or on the **Search & Analysis** page of a Logstore, it indicates that Log Service does not collect logs from the machine group of the Logstore. Check the status of the containers that correspond to the servers in the machine group. If the containers are working as expected, perform the following steps to troubleshoot the error:

1. Check the heartbeat status of the servers in the machine group.
2. Check whether the parameter settings in the Logtail configuration files are correct.

   Check whether the values of the IncludeLabel, ExcludeLabel, IncludeEnv, and ExcludeEnv parameters in the Logtail collection configuration files meet your requirements.

> **Note** The `IncludeLabel` or `ExcludeLabel` parameter specifies whether to include or exclude the container images to which specified labels are attached. You can retrieve a list of container image labels by running the docker inspect command. The labels are not the labels that are defined by using Kubernetes. To check whether the parameter settings are correct in a Logtail configuration file, delete the IncludeLabel, ExcludeLabel, IncludeEnv, and ExcludeEnv parameters from the file. If Log Service can collect logs from the containers after the parameters are deleted, it indicates that the settings of the parameters are incorrect.

3. Check other items.

   Log Service does not collect logs from containers in the following scenarios:

   - Log files are not updated.
   - The log files of a container are stored in locations that are neither the default storage nor a storage attached to the container.

Log on to a Logtail container

- Common container
  i. Run the `docker ps | grep logtail` command on the host to search for the Logtail container.
  ii. Run the `docker exec -it ****** bash` command to log on to the container.

```
$docker ps | grep logtail
223fbd3ed2a6e      registry.cn-hangzhou.aliyuncs.com/log-service/logtail                "/usr/local/ilogta..."   8 days ago
Up 8 days                       logtail-iba
$docker exec -it 223fbd3ed2a6e bash
```

- Container in a Kubernetes cluster
  i. Run the `kubectl get po -n kube-system | grep logtail` command to search for the pod where the Logtail container resides.
  ii. Run the `kubectl exec -it -n kube-system ****** bash` command to log on to the pod.

```
$kubectl get po -n kube-system | grep logtail
logtail-ds-g5wgd                          1/1     Running   0      8d
logtail-ds-slpn8                          1/1     Running   0      8d
$kubectl exec -it -n kube-system logtail-ds-g5wgd bash
```

View the operational logs of Logtail

The operational logs of Logtail are saved in the files named *ilogtail.LOG* and *logtail_plugin.LOG* under the */usr/local/ilogtail/* directory of a Logtail container.

1. Log on to a Logtail container.
2. Open the */usr/local/ilogtail/* directory.

```
cd /usr/local/ilogtail
```

3. View the *ilogtail.LOG* and *logtail_plugin.LOG* files.

```
cat ilogtail.LOG
cat logtail_plugin.LOG
```

Ignore the stdout logs of a Logtail container

The standard output (stdout) logs of a Logtail container are useless for troubleshooting. Ignore the following stdout logs:

```
start umount useless mount points, /shm$|/merged$|/mqueue$
umount: /logtail_host/var/lib/docker/overlay2/3fd0043af174cb0273c3c7869500fbe2bdb95d13b1e110172ef57fe840c82155/merged: must be superuser to unmount
umount: /logtail_host/var/lib/docker/overlay2/d5b10aa19399992755de1f85d25009528daa749c1bf8c16edff44beab6e69718/merged: must be superuser to unmount
umount: /logtail_host/var/lib/docker/overlay2/5c3125daddacedec29df72ad0c52fac800cd56c6e880dc4e8a640b1e16c22dbe/merged: must be superuser to unmount
......
xargs: umount: exited with status 255; aborting
umount done
start logtail
ilogtail is running
logtail status:
ilogtail is running
```

View the status of Log Service components in a Kubernetes cluster

Run the `helm status alibaba-log-controller` command to view the status of Log Service components in a Kubernetes cluster.

View the version number, IP address, and startup time of Logtail

View the information in the *app_info.json* file under the */usr/local/ilogtail/* directory of the Logtail container. For example, you can run the following command to view the content of the file:

```
kubectl exec logtail-ds-gb92k -n kube-system cat /usr/local/ilogtail/app_info.json
{
  "UUID" : "",
  "hostname" : "logtail-gb92k",
  "instance_id" : "0EBB2B0E-0A3B-11E8-B0CE-0A58AC140402_10.10.10.10_1517810940",
  "ip" : "10.10.10.10",
  "logtail_version" : "0.16.2",
  "os" : "Linux; 3.10.0-693.2.2.el7.x86_64; #1 SMP Tue Sep 12 22:26:13 UTC 2017; x86_64",
  "update_time" : "2018-02-05 06:09:01"
}
```

23.9.2. Log search and analysis

23.9.2.1. FAQ about log query

This topic describes the common issues that may occur when you query log data in the Log Service console. It also includes solutions to these issues.

How do I identify the source server from which Logtail collects logs during a query?

If a server group uses IP addresses as its identifier when logs are collected by using Logtail, servers in the server group are distinguished from one another by internal IP addresses. When querying logs, you can use the hostname and custom IP address to identify the source server from which logs are collected.

For example, you can use the following statement to count the times different hostnames appear in logs:

> **Note** You must enable the index feature for the Logstore and enable the statistics feature for the __tag__:__hostname__ field in advance.

```
* | select "__tag__:__hostname__" , count(1) as count group by "__tag__:__hostname__"
```

How do I query IP addresses in logs?

You can use the exact match method to query IP addresses in logs. For example, you can specify IP addresses to query log data that includes or excludes the specified IP addresses. However, you cannot use the partial match method to query log data related to specified IP addresses. This is because decimal points contained in an IP address are not default delimiters in Log Service. If you want to use the partial match method, you can configure the decimal point as a delimiter for indexes. For example, you can use the SDK to download data and then use regular expressions or the string.indexof method in the code.

For example, you use the following statement to query projects that meet the specified conditions.

```
not ip:121.42.0 not status:200 not 360jk not DNSPod-Monitor not status:302 not jiankongbao
    not 301 and status:403
```

The retrieved log data still contains 121.42.0.x. An IP address such as 121.42.0.x is taken as a word in Log Service. To include or filter out 121.42.0.x in the query result, you must specify 121.42.0.x in the query statement. If you specify 121.42.0 in the query statement, you cannot retrieve log data that includes or excludes the keyword.

How do I query log data by using a keyword that contains a whitespace character?

If you use a keyword that contains a whitespace character to query log data, log data that contains the part of the keyword on the left or right of the whitespace character is retrieved. You can enclose the keyword that contains a whitespace character in double quotation marks (""). Then the entire enclosed content is regarded as a keyword to query the log data that you expect.

For example, you want to query log data that contains the keyword `POS version` from the following log data:

```
post():351]:&amp;nbsp;device_id:&amp;nbsp;BTAddr&amp;nbsp;:&amp;nbsp;B6:xF:xx:65:xx:A1&amp;nbsp;IMEI&amp;nbsp;:&amp;nbsp;35847xx22xx81x9&amp;
nbsp;WifiAddr&amp;nbsp;:&amp;nbsp;4c:xx:0e:xx:4e:xx&amp;nbsp;|&amp;nbsp;user_id:&amp;nbsp;bb07263xxd2axx43xx9exxea26e39e5f&amp;nbsp;P
OS&amp;nbsp;version:903
```

If you use `POS version` as the keyword, log data that contains `POS` and `version` is retrieved. This result does not meet your expectations. If you use `"POS version"` as the keyword, log data that contains the keyword `POS version` is retrieved.

How do I use two query conditions to query log data?

You can enter two query conditions at one time to query log data that you want.

For example, you want to query log data whose status field value is neither OK nor Unknown in a Logstore. You can use the `not OK not Unknown` statement to retrieve the expected result.

How can I query collected logs in Log Service?

You can use one of the following methods to query logs in Log Service:

- Use the Log Service console.
- Use the SDK.
- Use the Restful API.

23.9.2.2. What can I do if no log data is retrieved?

When you use the log search and analytics feature of Log Service to query data, you may not retrieve the data you want. In this case, you can troubleshoot the problem as follows:

Log collection failure

If log data fails to be collected by Log Service, the target log data cannot be queried. Check whether log data is available on the consumption preview page of the target Logstore.

If data is available, log data is collected by Log Service.

If data is unavailable, possible causes are as follows:

- The log source does not generate log data.

  In this case, no logs can be sent to Log Service. Check your log source.

- Logtail has no heartbeat.

  On the **Server Group Settings** page, check whether the relevant server has a heartbeat in the Server Group Status section. If it has no heartbeat, troubleshoot the problem. For more information, see What can I do if no heartbeat packet is received from a Logtail client?

- The monitoring file is not written in real time.

  If the monitoring file is written in real time, you can open the */usr/local/ilogtail/ilogtail.LOG* file to view the error message. Common error messages are as follows:

  - parse delimiter log fail: The error message is returned because an error has occurred when Log Service collects logs in the delimiter mode.
  - parse regex log fail: The error message is returned because an error has occurred when Log Service collects logs in the regex mode.

Delimiter setting errors

View the configured delimiters. Check whether you can use a keyword to query log data after the log content is split by using a delimiter. For example, the default delimiters `,;=()[]{}?@&<>/:'` are used. If a log entry contains abc"defg,hij, it is split into abc"defg and hij. In this case, you cannot retrieve this log entry by searching for abc.

Fuzzy match is also supported. For more information, see Query syntax.

> **Note**
>
> - To save your indexing cost, Log Service has optimized the index feature. If you configure an index for a field, full-text indexing is ineffective for the key of this field. For example, an index is configured for a log field whose key is message, and a whitespace character is used as a delimiter. To use a whitespace character as a delimiter, put it in the middle of delimiters that you have configured for an index. You can retrieve the log entries that contain "message: this is a test message" by searching for the key-value-pair-formatted keyword message:this. However, if you use the keyword this to query the log entries, you cannot retrieve the data because an index is configured for the message field and full-text indexing is ineffective.
> - You can create indexes or modify existing indexes. However, new or modified indexes take effect only for new data.
>
>   You can click Index Attributes to check whether the configured delimiters meet the requirements.

Other reasons

If log data is available, modify the time range of the query and try again. Log Service allows you to preview log data in real time. Due to a maximum latency of one minute, we recommend that you query log data at least one minute after logs are generated.

23.9.2.3. What are the differences between log consumption and log search and analytics?

Both the log consumption and log search and analytics features provided by Log Service need to read log data. The log consumption feature provides log collection and distribution channels. In contrast, the log search and analytics feature allows you to query log data.

Both the log consumption and log search and analytics features need to read log data:

Log collection and consumption (LogHub): provides public channels for log collection and distribution. It reads and writes full data in first-in, first-out (FIFO) order, which is similar to Kafka.

- Each Logstore has one or more shards. Data is written to a random shard.
- You can read multiple log entries at a time from a specified shard based on the order in which the log entries were written to the shard.
- You can set the start position (cursor) to pull log entries from shards based on the time when Log Service receives the log entries.

Log search and analytics: enables you to set conditions to search and analyze large amounts of log data based on LogHub.

- This feature allows you to search for required data based on query conditions.
- This feature allows you to include a combination of Boolean keywords AND, NOT, and OR and SQL statements in a query.
- This feature is independent of shards.

The following table lists the differences between the log search and analytics feature and the LogHub feature.

Feature	Log search and analytics (LogSearch)	LogHub
Search by keyword	Supported.	Not supported.
Data read (a small amount of data)	Fast.	Fast.
Data read (full data)	Slow. LogSearch reads 100 log entries in 100 milliseconds. This method is not recommended.	Fast. LogHub reads 1 MB of log data in 10 milliseconds. This method is recommended.
Data read by topic	Yes.	No. Data is identified only by shard.
Data read by shard	No. Data in all shards of a Logstore is queried.	Yes. You need to specify a shard each time to read data.
Price	Relatively high.	Low.
Scenario	Monitoring, problem investigation, and analysis.	Full data processing scenarios, such as stream computing and batch processing.

23.9.2.4. How do I resolve common errors returned in log data queries?

Common errors returned in log data queries are as follows:

line 1:44: Column 'my_key_field' cannot be resolved;please add the column in the index attribute

- Cause

  The `my_key_field` key cannot be included in the query statement because it does not exist.

- Solution

  In the upper-right corner of the Search & Analysis page, click Index Attributes to create an index for this field and enable the statistics feature for this field.

Column 'xxxxline' not in GROUP BY clause;please add the column in the index attribute

- Cause

  You use the GROUP BY clause and include a non-aggregated field in a SELECT statement. However, this field is not specified in the GROUP BY clause. For example, the key1 field in the `select key1, avg(latency) group by key2` statement is not specified in the GROUP BY clause.

- Solution

  An example correct statement is `select key1,avg(latency) group by key1,key2`.

sql query must follow search query,please read syntax doc

- Cause

  You do not include a filtering condition in a query statement, for example, `select ip,count(*) group by ip`.

- Solution

  An example correct statement is `*|select ip,count(*) group by ip`.

please read syntax document,and make sure all related fields are indexed. error after select .error detail:line 1:10: identifiers must not start with a digit; surround the identifier with double quotes

- Cause

  The column name or variable name referenced in an SQL statement starts with a number and does not comply with the rules.

- Solution

  Change the name so the name starts with a letter.

please read syntax document,and make sure all related fields are indexed. error after select .error detail:line 1:9: extraneous input '' expecting

- Cause

  Misspelled words exist in the query statement.

- Solution

  Correct the misspelled words.

key (category) is not config as key value config,if symbol : is in your log,please wrap : with quotation mark "

- Cause

  No index is configured for the category field. It cannot be used in a query statement.

- Solution

  Configure an index for this field in the index attributes. For more information, see Enable the index feature and configure indexes for a Logstore.

Query exceeded max memory size of 3GB

- Cause

  The size of memory used by the current query exceeds 3 GB. The common cause is that a large number of values are still returned in the query result after you use the GROUP BY clause to remove duplicates.

- Solution

Reduce the number of keys specified in the GROUP BY clause.

ErrorType:ColumnNotExists.ErrorPosition,line:0,column:1.ErrorMessage:line 1:123: Column '__raw_log__' cannot be resolved; it seems __raw_log__ is wrapper by ";if __raw_log__ is a string ,not a key field, please use '__raw_log__'

- Cause

  The `my_key_field` key cannot be included in the query statement because it does not exist.

- Solution

  In the upper-right corner of the Search & Analysis page, click Index Attributes to create an index for this field and enable the statistics feature for this field.

23.9.2.5. Why data queries are inaccurate?

This topic describes the causes for inaccurate data queries. It also includes solutions to these issues.

When you search and analyze log data, the message **The results are inaccurate** may prompt in the console. This indicates that the returned result is inaccurate because some log data in a Logstore was not queried.

Possible causes include:

The time range for queries is excessive.

- Cause

  The time range for a query is excessively wide, for example, three months or a year. In this case, Log Service cannot scan all log data generated within this time period for one query.

- Solution

  Narrow down the query time range and perform multiple queries.

Query statements are complex.

- Cause

  The query statement is exceedingly complex or contains multiple frequently used words. In this case, Log Service cannot scan all related log data or read the query results at one time.

- Solution

  Narrow down the query scope and perform multiple queries.

The SQL computing needs to read an excessively large amount of data.

- Cause

  The SQL computing needs to read an excessively large amount of data. In this case, query results are likely to become inaccurate. A maximum of 1 GB of data can be read from each shard. For example, if the SQL computing needs to read strings from multiple columns, which exceed the threshold data volume, inaccurate query results will be returned.

- Solution

  Narrow down the query scope and perform multiple queries.

23.9.3. Alarm

23.9.3.1. FAQ about alerts

This topic describes the common issues that may occur when you configure alerts in the Log Service console. It also includes solutions to these issues.

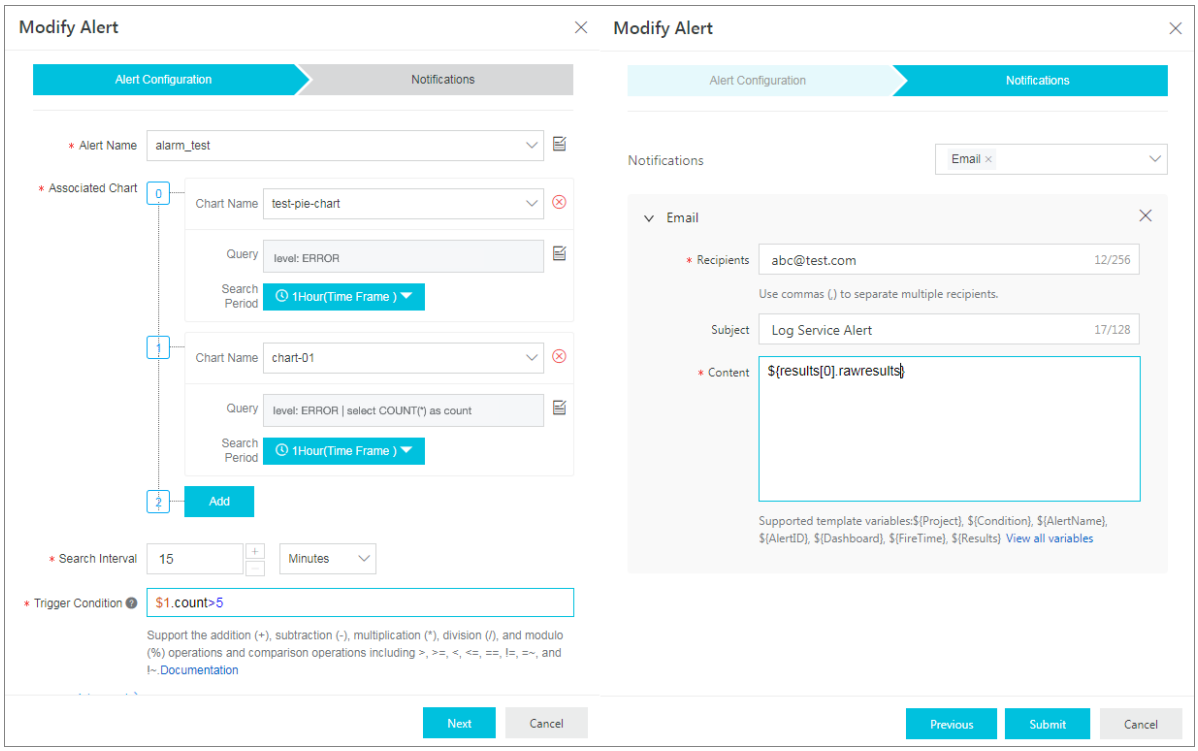
How can I include the raw error log entries in the notification content?

- Issue

  More than five error log entries were generated in the past five minutes, which triggered an alert. How can I include the raw error log entries in notifications that were sent when the alert was triggered?

- Solution
  - Associated query statements
    - Number 0: `level:ERROR`
    - Number 1: `level:ERROR | select COUNT(*) as count`
  - Trigger condition: `$1.count > 5`
  - Notification content: `${results[0].rawresults}`

- Configuration examples



24.Apsara Stack DNS

24.1. What is Apsara Stack DNS?

Apsara Stack DNS is a service that runs on Apsara Stack to resolve domain names. You can configure rules to map domain names to IP addresses. Apsara Stack DNS then distributes domain name requests from clients to cloud resources, business systems on your internal networks, or the business resources of Internet service providers (ISPs).

Apsara Stack DNS provides DNS resolution in VPCs. You can perform the following operations on your VPC by using Apsara Stack DNS:

- Access other ECS instances deployed in your VPC.
- Access cloud service instances provided by Apsara Stack.
- Access custom enterprise business systems.
- Access Internet services and businesses.
- Establish network connections between DNS and user-created DNS over a leased line.
- Manage internal domain names.
- Manage DNS records of internal domain names.
- Manage forwarding configurations.
- Manage recursive resolution configurations.

24.2. User roles and permissions

Role	Permission
System administrator	A user of this role has read, write, and execute permissions on all level-1 organization resources, global resources, and system configurations.
Level-1 organization administrator	A user of this role has read, write, and execute permissions on level-1 organization resources to which the user belongs, but does not have permissions on level-1 organization resources, global resources, or system configurations to which other users belong.
Lower-level organization administrator	A user of this role does not have permissions on Apsara Stack DNS. The user does not have permissions on level-1 organization resources to which the user belongs, and does not have permissions on level-1 organization resources, global resources, or system configurations to which other users belong.
Resource user	A user of this role does not have permissions on Apsara Stack DNS. The user does not have permissions on level-1 organization resources to which the user belongs, and does not have permissions on level-1 organization resources, global resources, or system configurations to which other users belong.
Other roles	A user of this role does not have permissions on Apsara Stack DNS. The user does not have permissions on level-1 organization resources to which the user belongs, and does not have permissions on level-1 organization resources, global resources, or system configurations to which other users belong.

24.3. Log on to the Apsara Stack DNS console

This topic describes how to log on to the Apsara Stack DNS console by using Google Chrome.

Prerequisites

- The URL of the Apsara Uni-manager Management Console is obtained from the deployment personnel before you log on to the Apsara Uni-manager Management Console.
- A browser is available. We recommend that you use the Google Chrome browser.

Procedure

1. In the address bar, enter the URL of the Apsara Uni-manager Management Console. Press the Enter key.
2. Enter your username and password.

   Obtain the username and password that you can use to log on to the console from the operations administrator.

   > **Note** When you log on to the Apsara Uni-manager Management Console for the first time, you must change the password of your username. Your password must meet complexity requirements. The password must be 8 to 20 characters in length and must contain at least two of the following character types:
   >
   > - Uppercase or lowercase letters
   > - Digits
   > - Special characters, which include ! @ # $ %

3. Click **Login**.
4. In the top navigation bar, choose **Products > Networking > Apsara Stack DNS**.

24.4. Internal DNS resolution management

Internal DNS resolution management allows you to manage global internal domain names, global forwarding configurations, and global recursive resolution configurations that you have created in Apsara Stack.

24.4.1. Global internal domain names

24.4.1.1. Overview

All the operations of this feature require administrator privileges.

24.4.1.2. View an internal domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domains > Global Internal Domains**.
3. In the **Domain Name** search box, enter the domain name that you want to view.
4. Click **Search**.

   The search result is displayed.

24.4.1.3. Add a domain name

This topic describes how to add a domain name in the Apsara Uni-manager Management Console.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Global Internal Domain Name**.
3. Click **Add Domain Name**.
4. In the dialog box that appears, enter **Global Internal Domain Name**.
5. Click **OK**.

24.4.1.4. Add a description for a domain name

This topic describes how to add a description for a domain name in the Apsara Uni-manager Management Console.

Context

You can add a description for a domain name to help you identify it. For example, you can add a hostname or internal system information to describe a domain name.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Global Internal Domain Name**.
3. Find the domain name for which you want to add a description, click the icon in the Actions column, and then select **Description**.
4. In the dialog box that appears, enter a description.
5. Click **OK**.

24.4.1.5. Delete a domain name

This topic describes how to delete a domain name in the Apsara Uni-manager Management Console.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Global Internal Domain Name**.
3. Find the domain name that you want to delete, click the icon in the **Actions** column, and then select **Delete**.
4. In the message that appears, click **OK**.

24.4.1.6. Delete multiple domain names

This topic describes how to delete unnecessary domain names at a time in the Apsara Uni-manager Management Console.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Global Internal Domain Name**.
3. Select one or more domain names that you want to delete and click **Delete** in the upper-right corner.
4. In the message that appears, click **OK**.

24.4.1.7. Configure DNS records

This topic describes how to configure DNS records in the Apsara Uni-manager Management Console.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Global Internal Domain Name**.
3. Find the domain name for which you want to configure DNS records, click the icon in the Actions column, and then select **Configure DNS Records**.
4. On the **Configure DNS Records** page, click **Add DNS Record** in the upper-right corner.
5. Perform the following operations as needed:
   - Add a description for a DNS record

     Select the DNS record for which you want to add a description, click in the Actions column, and then select **Description** from the shortcut menu. In the dialog box that appears, enter a description and click **OK**.
   - Delete a DNS record

     Select the DNS record that you want to delete, click in the Actions column, and then select **Delete** from the shortcut menu. In the message that appears, click **OK**.
   - Modify a DNS record

     Select the DNS record that you want to modify, click in the Actions column, and then select **Modify** from the shortcut menu. In the dialog box that appears, set the required parameters and click **OK**.
   - Delete DNS records in batches

     Select the DNS records that you want to delete and click **Delete** in the upper-right corner. In the message that appears, click **OK**.

24.4.1.8. View a resolution policy

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domains > Global Internal Domains**.
3. Find the target domain name, click the icon in the Actions column, and then select **Configure DNS Records**.
4. On the page that appears, select the domain name for which you want to configure DNS records, and click **Weight** in the **Resolution Policy** column.
5. On the page that appears, view the details of **Resolution Policy**.

24.4.2. Global forwarding configurations

24.4.2.1. Global forwarding domain names

24.4.2.1.1. Overview

All operations of this feature require administrator privileges.

Apsara Stack DNS forwards specific domain names to other DNS servers for resolution.

Two forwarding modes are available: forward all requests without recursion and forward all requests with recursion.

- Forward all requests without recursion: Only a specified DNS server is used to resolve domain names. If the specified DNS server cannot resolve the domain names or the request times out, a message is returned to the DNS client to indicate that the query failed.
- Forward all requests with recursion: A specified DNS server is preferentially used to resolve domain names. If the specified DNS server cannot resolve the domain names, the local DNS is used instead.

24.4.2.1.2. View global forwarding domain names

This topic describes how to view global forwarding domain names in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Forwarding Domain Names**.
3. In the **Domain Name** search box, enter the domain name that you want to query and click **Search**.

24.4.2.1.3. Add a domain name

This topic describes how to add a domain name in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Forwarding Domain Names**.
3. Click **Add Domain Name**.
4. In the dialog box that appears, configure *Global Forwarding Domain*, *Forwarding Mode*, and *Forwarder IP Addresses*. Then, click **OK**.

24.4.2.1.4. Add a description for a domain name

This topic describes how to add a description for a domain name in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Context

You can add a description for a domain name to help you identify it. For example, you can describe a domain name by using a hostname or internal system information.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Forwarding Domain Names**.

3. Select the domain name for which you want to add a description, click  in the Actions column, and then select **Description**.
4. In the dialog box that appears, enter a description and click **OK**.

24.4.2.1.5. Modify the forwarding configurations of a domain name

This topic describes how to modify the forwarding configurations of a domain name in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Forwarding Domain Names**.
3. Find the domain name whose forwarding configurations you want to modify, click the  icon in the Actions column, and then select **Modify**.
4. In the dialog box that appears, change the value of *Forwarding Mode* or *Forwarder IP Addresses*, and click **OK**.

24.4.2.1.6. Delete a domain name

This topic describes how to delete a domain name in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Forwarding Domain Names**.
3. Find the domain name that you want to delete, click the  icon in the Actions column, and then select **Delete**.
4. Click **OK**.

24.4.2.1.7. Delete multiple domain names

This topic describes how to delete multiple domain names at a time in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Domains > Forwarding Settings > Global Forwarding Domain Names**.
3. Select one or more domain names that you want to delete and click **Delete** in the upper-right corner.
4. In the message that appears, click **OK**.

24.4.2.2. Global default forwarding configurations

24.4.2.2.1. Enable default forwarding

This topic describes how to enable default forwarding in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Default Forwarding**.
3. Click the icon in the Actions column and select **Enable**.
4. In the dialog box that appears, configure *Default Forwarding Mode* and *Forwarder IP Addresses*. Then, click **OK**.

   Make sure that Enable Default Forwarding is set to ON.

24.4.2.2.2. Modify default forwarding configurations

This topic describes how to modify default forwarding configurations in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Default Forwarding**.
3. Click the icon in the Actions column and select **Modify**.
4. In the dialog box that appears, configure *Forwarding Mode* and *Forwarder IP Addresses*. Then, click **OK**.

24.4.2.2.3. Disable default forwarding

This topic describes how to disable default forwarding in the Apsara Uni-manager Management Console. This operation requires administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Internal Domain Names > Forwarding Settings > Global Default Forwarding**.
3. Click the icon in the Actions column and select **Disable**.
4. In the message that appears, click **OK**.

24.4.3. Global recursive resolution

24.4.3.1. Enable global recursive resolution

Prerequisites

You have administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. Choose **Internal Domains > Global Recursive Resolution**.
3. Click the icon in the Actions column and select **Enable**.
4. In the dialog box that appears, click **OK**.

24.4.3.2. Disable global recursive resolution

Prerequisites

You have administrator permissions.

Procedure

1. Log on to the Apsara Stack DNS console.
2. Choose **Internal Domains > Global Recursive Resolution**.
3. Click the icon in the Actions column and select **Disable**.
4. In the dialog box that appears, click **OK**.

24.5. PrivateZone (DNS Standard Edition only)

The PrivateZone feature allows you to create VPC-specific tenant domain names. You can bind the domain names to VPCs as required to achieve tenant isolation.

24.5.1. Tenant internal domain name

24.5.1.1. View a domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. In the **Domain Name** search box, enter the domain name that you want to view.
4. Click Search.

   The search result is displayed.

24.5.1.2. Add a domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Click **Add Domain Name**.
4. In the dialog box that appears, set *Tenant Internal Domain Name*.
5. Click **OK**.

24.5.1.3. Bind an organization to a VPC

Tenant domain names are isolated based on VPCs. To ensure that the DNS forwarding configurations take effect, you must bind the organization of domain names to a VPC.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Find the target domain name, click the  icon in the Actions column, and select **Associate VPCs**.
4. Select one or more VPCs from the list of VPCs to Select, click the right arrow to add them to the list of VPCs Selected, and then click **OK**.

24.5.1.4. Unbind a domain name from a VPC

This topic describes how to unbind a domain name from a VPC.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Find the target domain name and click the number in the **VPCs Associated** column.
4. On the **VPCs Associated** page, find the target VPC, click the  icon in the **Actions** column, and then select **Disassociate**.

   Make sure that the unbound VPC is no longer displayed on the VPCs Associated page.

24.5.1.5. Add a description for a domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Find the target domain name, click the  icon in the Actions column, and then select **Description**.
4. In the dialog box that appears, enter a description.
5. Click **OK**.

24.5.1.6. Delete a domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Find the target domain name, click the  icon in the Actions column, and then select **Delete**.
4. In the message that appears, click **OK**.

24.5.1.7. Delete multiple domain names

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Select one or more domain names that you want to delete and click **Delete** in the upper-right corner.
4. In the message that appears, click **OK**.

24.5.1.8. Configure DNS records

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Find the target domain name, click the icon in the Actions column, and then select **Configure DNS Records**.
4. In the upper-right corner of the **Configure DNS Records** page, click **Add DNS Record**.
5. In the **Add DNS Record** dialog box, configure *Host*, *Type*, *TTL*, *Resolution Policy*, and *Record Set*. Then, click **OK**.

   The following tables describe the types of DNS records.

   - A record

Resolution policy	Formatting rule
None	You can enter up to 100 unique IPv4 addresses, each in a separate row. Make sure that the IPv4 addresses are valid. Example: ■ 192.168.1.1 ■ 192.168.1.2 ■ 192.168.1.3
Weight	You can enter up to 100 unique IPv4 addresses, each in a separate row. Format: ■ [IPv4 address] [Weight] (The IPv4 address and weight are separated with a space.) ■ Make sure that the IPv4 addresses are valid. ■ The weight value is an integer ranging from 0 to 999. A larger value indicates a greater weight. Example: ■ 192.168.1.1 20 ■ 192.168.1.1 30 ■ 192.168.1.1 50

   - AAAA record

Resolution policy	Formatting rule

Resolution policy	Formatting rule
None	You can enter up to 100 unique IPv6 addresses, each in a separate row. Make sure that the IPv6 addresses are valid. Example: ■ 2400:3200::6666 ■ 2400:3200::6688 ■ 2400:3200::8888
Weight	You can enter up to 100 unique IPv6 addresses, each in a separate row. Format: ■ [IPv6 address] [Weight] (The IPv6 address and weight are separated with a space.) ■ Make sure that the IPv6 addresses are valid. ■ The weight value is an integer ranging from 0 to 999. A larger value indicates a greater weight. Example: ■ 2400:3200::6666 20 ■ 2400:3200::6688 20 ■ 2400:3200::8888 60

- CNAME record

Resolution policy	Formatting rule
None	You can enter only one domain name. The domain name must be a fully qualified domain name (FQDN) that ends with a dot (.). It must be 1 to 255 characters in length. Example: www.example.com.
Weight	You can enter up to 100 unique domain names, each in a separate row. Format: ■ [Domain name] [Weight] (The domain name and weight are separated with a space.) ■ The domain name must be an FQDN that ends with a period (.). It must be 1 to 255 characters in length. ■ The weight value is an integer ranging from 0 to 999. A larger value indicates a greater weight. Example: ■ www1.example.com. 20 ■ www2.example.com. 20 ■ www3.example.com. 60

- MX record

Resolution policy	Formatting rule

Resolution policy	Formatting rule
None	You can enter 100 unique email server hostnames, each in a separate row. Format: ■ [Priority] [Email server hostname] (The priority and hostname are separated with a space.) ■ The priority value is an integer ranging from 0 to 999. A smaller value indicates a higher priority. ■ The email server hostname must be an FQDN that ends with a period (.). It must be 1 to 255 characters in length. Example: ■ 10 mailserver1.example.com. ■ 20 mailserver2.example.com.

- TXT record

Resolution policy	Formatting rule
None	You can enter up to 100 unique character strings, each in a separate row. A string must be 1 to 255 characters in length. No row can be left blank. Example: "v=spf1 ip4:192.168.0.1/16 ip6:2001::1/96 ~all"

- PTR record

Resolution policy	Formatting rule
None	You can enter up to 100 unique domain names, each in a separate row. The DNS server address must be an FQDN that ends with a period (.). It must be 1 to 255 characters in length. Example: ■ www1.example.com. ■ www2.example.com. ■ www3.example.com.

- SRV record

Resolution policy	Formatting rule

Resolution policy	Formatting rule
None	You can enter up to 100 unique application server hostnames, each in a separate row. Format: ■ [Priority] [Weight] [Port number] [Application server hostname] (Every two items are separated with a space.) ■ The priority value is an integer ranging from 0 to 999. A smaller value indicates a higher priority. ■ The weight value is an integer ranging from 0 to 999. A larger value indicates a greater weight. ■ The port number is an integer ranging from 0 to 65535. It indicates the TCP or UDP port used for network communications. ■ The application server hostname must be an FQDN that ends with a period (.). It must be 1 to 255 characters in length. Example: ■ 1 10 8080 www1.example.com. ■ 2 20 8081 www2.example.com.

- NAPTR record

Resolution policy	Formatting rule
None	You can enter up to 100 unique NAPTR record values, each in a separate row. Format: ■ [Serial number] [Priority] [Flag] [Service information] [Regular expression] [Substitute domain name] (Every two items are separated with a space.) ■ The serial number is an integer ranging from 0 to 999. A smaller value indicates a higher priority. ■ The priority value is an integer ranging from 0 to 999. A smaller value indicates a higher priority. If two records have the same serial number, the one with a higher priority takes effect first. ■ The flag value can be left blank or be a character from A to Z, a to z, or 0 to 9. It is not case-sensitive and must be enclosed in double quotation marks (""). ■ The service information can be left blank or be a string of 1 to 32 characters. It must start with a letter and be enclosed in double quotation marks (""). ■ The regular expression can be left blank or be a string of 1 to 255 characters enclosed in double quotation marks (""). ■ The substitute domain name must be an FQDN that ends with a period (.). It must be 1 to 255 characters in length. Example: ■ 100 50 "S" "Z3950+I2L+I2C" "" _z3950._tcp.example.com. ■ 100 50 "S" "RCDS+I2C" "" _rcds._udp.example.com. ■ 100 50 "S" "HTTP+I2L+I2C+I2R" "" _http._tcp.example.com.

- CAA record

Resolution policy	Formatting rule

Resolution policy	Formatting rule
None	You can enter up to 100 unique CAA records, each in a separate row. Format: ■ [Certificate authority flag] [Certificate property tag] [Authorization information] (Every two items are separated with a space.) ■ The certification authority flag is an integer ranging from 0 to 255. ■ The certificate property tag can be issue, issuewild, or iodef. ■ The authorization information must be 1 to 255 characters in length and enclosed in double quotation marks (""). Example: ■ 0 issue "caa.example.com" ■ 0 issuewild ";" ■ 0 iodef "mailto:example@example.com"

- NS record

Resolution policy	Formatting rule
None	You can enter up to 100 unique DNS server addresses, each in a separate row. The DNS server address must be an FQDN that ends with a period (.). It must be 1 to 255 characters in length. Wildcard domain names are not allowed. Example: ■ ns1.example.com. ■ ns2.example.com.

6. After you add DNS records, perform the following operations as required:
   - Add a description for a DNS record.

     Find the target DNS record, click the icon in the Actions column, and then select **Description**. In the dialog box that appears, enter a description and click **OK**.
   - Delete a DNS record.

     Find the target DNS record, click the icon in the Actions column, and then select **Delete**. In the message that appears, click **OK**.
   - Modify a DNS record.

     Find the target DNS record, click the icon in the Actions column, and then select **Modify**. In the dialog box that appears, modify the required parameters and click **OK**.
   - Delete multiple DNS records.

     Select the DNS records that you want to modify and click **Delete** in the upper-right corner. In the message that appears, click **OK**.

24.5.1.9. View a resolution policy

This topic describes how to view the details of a resolution policy.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Internal Domains**.
3. Find the target domain name, click the icon in the Actions column, and then select Configure DNS Records.
4. View the resolution policy in the DNS Records list.

24.5.2. Tenant forwarding configurations

24.5.2.1. Tenant forwarding domain names

24.5.2.1.1. View a tenant forwarding domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. In the **Domain Name** search box, enter the domain name that you want to view.
4. Click **Search**.

   The search result is displayed.

24.5.2.1.2. Add a tenant forwarding domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Click **Add Domain Name**.
4. In the dialog box that appears, configure parameters such as *Domain Name*, *Forwarding Mode*, and *Forwarder IP Addresses*.

Parameter	Description
Domain Name	The domain name, which must meet the following formatting rules: ○ The domain name must be 1 to 255 characters in length. This includes the period (.) at the end of the domain name. ○ The domain name can contain multiple domain name segments that are separated with periods (.). A domain name segment must be 1 to 63 characters in length. It cannot contain consecutive periods (.) or be left blank. ○ The domain name can only contain letters (a to z, A to Z), digits (0 to 9), hyphens (-), and underscores (_). ○ The domain name must start with a letter, digit, or underscore (_) and end with a letter, digit, or period (.). ○ The domain name is not case-sensitive. The system saves the domain name in lowercase letters. ○ The period (.) at the end of the domain name is optional. The system adds a period (.) to the end of the domain name.

Parameter	Description
Forwarding Mode	For both domain name-based forwarding and default forwarding, the following two forwarding modes are supported: ○ Forward All Requests without Recursion: forwards DNS requests to the target DNS server. If the target DNS server cannot resolve the domain names, a message is returned to the DNS client indicating that the query failed. ○ Forward All Requests with Recursion: A specified DNS server is preferentially used to resolve domain names. If the specified DNS server cannot resolve the domain names, the local DNS is used instead. If you enter internal IP addresses in the Forwarder IP Addresses field, unexpected results may occur during recursive resolution. For example, a domain name used for internal network services may be resolved to a public IP address.
Forwarder IP Addresses	A list of destination IP addresses. **Note** Multiple IP addresses are separated with semicolons (;).

5. Click **OK**.

24.5.2.1.3. Bind an organization to a VPC

Tenant domain names are isolated based on VPCs. You must bind the organization of domain names to a VPC before the DNS forwarding configurations can take effect.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Find the target domain name, click the  icon in the Actions column, and then select **Associate VPCs**.
4. Select one or more VPCs from the list of VPCs to Select, click the right arrow to add them to the list of VPCs Selected, and then click **OK**.

24.5.2.1.4. Unbind a domain name from a VPC

This topic describes how to unbind a domain name from a VPC.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Find the target domain name and click the number in the **VPCs Associated** column.
4. On the VPCs Associated page, find the target VPC, click the  icon in the Actions column, and then select **Disassociate**.

   Make sure that the unbound VPC is no longer displayed on the VPCs Associated page.

24.5.2.1.5. Modify the forwarding configurations of a domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Find the target domain name, click the  icon in the Actions column, and then select **Modify**.
4. In the dialog box that appears, change the value of **Forwarding Mode** or **Forwarder IP Addresses**.
5. Click **OK**.

24.5.2.1.6. Add a description for a tenant forwarding domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Find the target domain name, click the  icon in the Actions column, and then select **Description**.
4. In the dialog box that appears, enter a description.
5. Click **OK**.

24.5.2.1.7. Delete a tenant forwarding domain name

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Find the target domain name, click the  icon in the Actions column, and then select **Delete**.
4. In the message that appears, click **OK**.

24.5.2.1.8. Delete multiple tenant forwarding domain names

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Forwarding Domains**.
3. Select one or more domain names that you want to delete and click **Delete** in the upper-right corner.
4. In the message that appears, click **OK**.

24.5.2.2. Tenant default forwarding configurations

24.5.2.2.1. View default forwarding configurations

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.

24.5.2.2.2. Add a default forwarding configuration

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Click **Add Settings**.
4. In the dialog box that appears, configure parameters such as *Forwarding Mode* and *Forwarder IP Addresses*.

Parameter	Description
Forwarding Mode	For both domain name-based forwarding and default forwarding, the following two forwarding modes are available: ◦ Forward All Requests without Recursion: Only a specified DNS server is used to resolve domain names. If the specified DNS server cannot resolve the domain names, a message is returned to the DNS client to indicate that the query failed. ◦ Forward All Requests with Recursion: A specified DNS server is preferentially used to resolve domain names. If the specified DNS server cannot resolve the domain names, a local DNS server is used instead. If you enter internal IP addresses in the Forwarder IP Addresses field, unexpected results may occur during recursive resolution. For example, a domain name used for internal network services may be resolved to a public IP address.
Forwarder IP Addresses	A list of destination IP addresses. **Note** Multiple IP addresses are separated with semicolons (;).

5. Click **OK**.

24.5.2.2.3. Bind an organization to a VPC

Tenant domain names are isolated based on VPCs. You must bind the organization of domain names to a VPC before the DNS forwarding configurations can take effect.

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Find the target organization, click the  icon in the Actions column, and then select **Associate VPCs**.
4. Select one or more VPCs from the list of VPCs to Select, click the right arrow to add them to the list of VPCs Selected, and then click **OK**.

24.5.2.2.4. Unbind a domain name from a VPC

This topic describes how to unbind a domain name from a VPC.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Find the target domain name and click the number in the **VPCs Associated** column.
4. On the VPCs Associated page, find the target VPC, click the  icon in the Actions column, and then select **Disassociate**.

   Make sure that the unbound VPC is no longer displayed on the VPCs Associated page.

24.5.2.2.5. Modify a default forwarding configuration

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Find the target organization, click the  icon in the Actions column, and then select **Modify**.
4. In the dialog box that appears, change the value of **Forwarding Mode** or **Forwarder IP Addresses**.
5. Click **OK**.

24.5.2.2.6. Add a default forwarding configuration

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Find the target organization, click the  icon in the Actions column, and then select **Description**.
4. In the dialog box that appears, enter **Description**.
5. Click **OK**.

24.5.2.2.7. Delete a default forwarding configuration

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Find the target organization, click the  icon in the Actions column, and then select **Delete**.
4. In the dialog box that appears, click **OK**.

24.5.2.2.8. Delete multiple default forwarding configurations

Prerequisites

You have the permissions of a system administrator or level-1 organization administrator.

Procedure

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, choose **Forwarding Configurations > Tenant Forwarding Settings > Tenant Default Forwarding**.
3. Select one or more domain names that you want to delete and click **Delete** in the upper-right corner.
4. In the message that appears, click **OK**.

24.6. Internal Global Traffic Manager (internal GTM Standard Edition only)

Internal Global Traffic Manager (GTM) supports multi-cloud disaster recovery for domain names of customers. This feature manages traffic loads between multiple Apsara Stack networks.

24.6.1. Scheduling instance management

24.6.1.1. Scheduling Instance

The Scheduling Instance tab displays all existing scheduling instances. You can add, delete, modify, and configure scheduling instances on this tab. When you create a scheduling instance, you must associate an address pool and scheduling domain with the instance.

24.6.1.1.1. Create a scheduling instance

After you create a scheduling instance, you can associate the scheduling instance with a scheduling domain and address pool.

1. In the left-side navigation pane, choose **Internal Global Traffic Manager** > **Scheduling Instances** > Scheduling Instance.

2. Click **Create Scheduling Instance** in the upper-right corner of the instance list.

3. In the dialog box that appears, configure Scheduling Instance Name, CNAME Access Domain Name, and Global TTL. Then, click **OK**.

24.6.1.1.2. Modify a scheduling instance

1. In the left-side navigation pane, choose **Internal Global Traffic Manager** > **Scheduling Instances** > Scheduling Instance.

2. Find the instance that you want to modify and click **Modify** in the Actions column.

3. Modify the parameter settings as prompted and click **OK**.

24.6.1.1.3. Configure a scheduling instance

You can create, delete, modify, and query access policies of scheduling instances.

1. In the left-side navigation pane, click **Internal Global Traffic Manager**. On the **Scheduling Instances** tab of the page that appears, click the **Scheduling Instances** tab.
2. Find the scheduling instance whose access policies you want to view and click **Configure** in the **Actions** column.
3. On the Access Policy Configuration page, view information about all the access policies of the scheduling instance. The information includes **Access Policy Name**, **DNS Request Source**, **Address Type**, **Effective Address Pool**, and **Last Modified At**.
4. Click the closing angle bracket (>) next to an access policy to view the details, including information about the primary and secondary address pools.
5. View the setting of **Address Pool Switchover Policy**. The default value is **Automatic**. You can change the value to **Manual**. If Address Pool Switchover Policy is set to Automatic, the system automatically selects an available address pool. If Address Pool Switchover Policy is set to Manual, you must manually specify whether to use the primary address pool or secondary address pool.

> **Note**
>
> Whether an address pool is available is determined based on the number of normal addresses in the address pool and Min. Number of Available Addresses that you specified when you configure the access policy. If the number of normal addresses in the address pool is less than the value of Min. Number of Available Addresses, the address pool is considered unavailable. You can perform a health check to obtain the number of normal addresses in the address pool.

Processing logic for automatic switchover

State of the primary address pool	State of the secondary address pool	Comparison between the numbers of normal addresses in the primary and secondary address pools	Effective address pool (list of available addresses)
Available	Available	-	Primary address pool (including the normal addresses that are intelligently returned and the addresses that are always online. Abnormal addresses that are intelligently returned are deleted or their weight values are set to 0.)
Available	Unavailable	-	Primary address pool (including the normal addresses that are intelligently returned and the addresses that are always online. Abnormal addresses that are intelligently returned are deleted or their weight values are set to 0.)
Unavailable	Available	-	Secondary address pool (including the normal addresses that are intelligently returned and the addresses that are always online. Abnormal addresses that are intelligently returned are deleted or their weight values are set to 0.)
Unavailable	Unavailable	Number of normal addresses in the primary address pool > Number of normal addresses in the secondary address pool	Primary address pool (including the normal addresses that are intelligently returned and the addresses that are always online. Abnormal addresses that are intelligently returned are deleted or their weight values are set to 0.)
Unavailable	Unavailable	Number of normal addresses in the primary address pool < Number of normal addresses in the secondary address pool	Secondary address pool (including the normal addresses that are intelligently returned and the addresses that are always online. Abnormal addresses that are intelligently returned are deleted or their weight values are set to 0.)

Unavailable	Unavailable	Number of normal addresses in the primary address pool = Number of normal addresses in the secondary address pool > 0	Primary address pool (including the normal addresses that are intelligently returned and the addresses that are always online. Abnormal addresses that are intelligently returned are deleted or their weight values are set to 0.)
Unavailable	Unavailable	Number of normal addresses in the primary address pool = Number of normal addresses in the secondary address pool = 0	If the DNS request source is a custom line, the system clears the DNS configurations of the line instead of selecting an address pool. The configurations of the custom line are deleted. If the DNS request source is the global default line, the system selects the primary address pool. The system returns all the configured addresses without considering their return mode.

When the system compares the numbers of normal addresses between the primary and secondary address pools, normal addresses include normal addresses that are intelligently returned and all addresses that are always online (with the health status ignored). The abnormal addresses that are intelligently returned and all addresses that are always offline (with the health status ignored) are not normal addresses.

The following table describes the processing logic for address types if a line is selected in two access policies.

Scenario	Address type for the effective address pool in two access policies		Processing logic
Same DNS request source: Scenario 1	IPv4	IPv6	IPv4 and IPv6 addresses take effect at the same time.
Same DNS request source: Scenario 2	IPv4	Domain name	Addresses of the domain name type take effect.
Same DNS request source: Scenario 3	IPv6	Domain name	Addresses of the domain name type take effect.

24.6.1.1.3.1. Create an access policy for a scheduling instance

You can create multiple access policies to resolve different address pools based on different DNS request sources.

1. Log on to the Apsara Stack DNS console. In the left-side navigation pane, click Internal Global Traffic Manager. On the Scheduling Instances tab of the Global Traffic Management on the Internal Network page, find the scheduling instance for which you want to create an access policy and click Configure in the Actions column. On the page that appears, click **Create Access Policy**.
2. In the Create Access Policy dialog box, specify **Access Policy Name**, select items in the **DNS Request Source** section, and then configure parameters in the **Primary/Secondary Address Pool Configuration** section. In the DNS Request Source section, if you select Global default, you cannot select other items. The parameters on the Primary Address Pool tab must be configured, and the parameters on the Secondary Address Pool tab can be left empty.

3. In the **Primary/Secondary Address Pool Configuration** section, you can set **Address Type** to IPv4, IPv6, or Domain Name to select different types of address pools. You can also set **Min. Number of Available Addresses**. If the number of healthy addresses in an address pool is less than the value of this parameter, the address pool is determined to be unavailable. The value of Min. Number of Available Addresses must be an integer ranging from 1 to 100.
4. Click **OK**.

The following table describes the limits on address type conflicts between the primary and secondary address pools for two access policies that have the same DNS request source.

Scenario	Address type of the primary address pool (access policy 1)	Address type of the secondary address pool (access policy 2)	Processing logic
Same DNS request source: Scenario 1	IPv4	IPv4	The address pools are allowed to be added.
Same DNS request source: Scenario 2	IPv4	IPv6	The address pools are not allowed to be added.
Same DNS request source: Scenario 3	IPv4	Domain name	The address pools are allowed to be added.
Same DNS request source: Scenario 4	IPv6	IPv4	The address pools are not allowed to be added.
Same DNS request source: Scenario 5	IPv6	IPv6	The address pools are allowed to be added.
Same DNS request source: Scenario 6	IPv6	Domain name	The address pools are allowed to be added.
Same DNS request source: Scenario 7	Domain name	IPv6	The address pools are allowed to be added.
Same DNS request source: Scenario 8	Domain name	IPv4	The address pools are allowed to be added.
Same DNS request source: Scenario 9	Domain name	Domain name	The address pools are allowed to be added.

The following tables describe the limits on address type conflicts between the primary address pools and those between the secondary address pools for two access policies that have the same DNS request source.

Scenario	Address type of the primary address pool (access policy 1)	Address type of the primary address pool (access policy 2)	Processing logic
Same DNS request source: Scenario 1	IPv4	IPv6	The address pools are allowed to be added and they can coexist.
Same DNS request source: Scenario 2	IPv4	IPv4	The address pools are not allowed to be added and they cannot coexist.
Same DNS request source: Scenario 3	IPv4	Domain name	The address pools are not allowed to be added and they cannot coexist.

Same DNS request source: Scenario 4	IPv6	IPv6	The address pools are not allowed to be added and they cannot coexist.
Same DNS request source: Scenario 5	Domain name	IPv6	The address pools are not allowed to be added and they cannot coexist.
Same DNS request source: Scenario 6	Domain name	Domain name	The address pools are allowed to be added and they can coexist. However, the following conditions must be met: (1) The two primary address pools are the same. (2) Both of the secondary address pools exist. In addition, one secondary address pool is of the IPv4 type and the other is of the IPv6 type.

Scenario	Address type of the secondary address pool (access policy 1)	Address type of the secondary address pool (access policy 2)	Processing logic
Same DNS request source: Scenario 1	IPv4	IPv6	The address pools are allowed to be added and they can coexist.
Same DNS request source: Scenario 2	IPv4	IPv4	The address pools are not allowed to be added and they cannot coexist.
Same DNS request source: Scenario 3	IPv4	Domain name	The address pools are not allowed to be added and they cannot coexist.
Same DNS request source: Scenario 4	IPv6	IPv6	The address pools are not allowed to be added and they cannot coexist.
Same DNS request source: Scenario 5	Domain name	IPv6	The address pools are not allowed to be added and they cannot coexist.
Same DNS request source: Scenario 6	Domain name	Domain name	The address pools are allowed to be added and they can coexist. However, the following conditions must be met: (1) The two secondary address pools are the same. (2) Both of the two primary address pools exist. In addition, one primary address pool is of the IPv4 type and the other is of the IPv6 type.

24.6.1.1.3.2. Modify the access policy of a scheduling instance

> **Notice**
>
> If you do not change the primary or secondary address pool when you modify an access policy, no primary/secondary switchover is triggered. If you change one of the address pools, the system complies with the following processing rules:
>
> 1. Manual switchover mode: If the secondary address pool is deleted, the system forcibly switches services to the primary address pool. If the secondary address pool is not deleted, the effective address pool does not change.
> 2. Automatic switchover mode: The system determines the address pool that takes effect based on the status of the newly selected address pools. Exercise caution when you change the address pools.

1. On the Access Policy Configuration page, find the access policy that you want to modify and click **Modify** in the Actions column.
2. In the Modify Access Policy dialog box, modify **Access Policy Name**, select items in the **DNS Request Source** section, and then configure parameters in the **Primary/Secondary Address Pool Configuration** section. In the DNS Request Source section, if you select Global default, you cannot select other items. The parameters on the Primary Address Pool tab must be configured, and the parameters on the Secondary Address Pool tab can be left empty.
3. In the Primary/Secondary Address Pool Configuration section, you can set **Address Type** to IPv4, IPv6, or Domain Name to select address pools of different types. You can also set Min. Number of Available Addresses. If the number of healthy addresses in an address pool is less than the value of this parameter, the address pool is determined to be unavailable. The value of this parameter must be an integer ranging from 1 to 100.
4. Click **OK**.

24.6.1.1.3.3. Delete the access policy of a scheduling instance

1. On the Access Policy Configuration page, find the target access policy and click Delete in the Actions column.

2. In the dialog box that appears, click OK after you verify that the displayed information is correct.

24.6.1.1.4. Delete a scheduling instance

1. Log on to the Apsara Stack DNS console and choose Recursion Configurations > Scheduling Instances > Scheduling Instance.

2. Find the target instance and click Delete in the Actions column.

3. In the dialog box that appears, click OK.

Note: After you delete the instance, its configuration data is also deleted.

24.6.1.2. Address Pool

The Address Pool tab allows you to manage address pools. You can associate address pools with scheduling instances. The address pools are classified into three types: IPv4 address pools, IPv6 address pools, and domain name address pools. The load balancing policy of an address pool can be set to polling or weight.

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, click **Internal Global Traffic Manager**. On the **Scheduling Instance** tab of the Global Traffic Management on the Internal Network page, click the **Address Pool** tab.
3. Find the address pool whose information you want to view and click the closing angle bracket (>) next to the name of the address pool to view its detailed information. The information includes Address Pool ID, Address Pool Name, Address Type, Load Balancing Policy (Among Addresses), Created At, Last Modified At, Health Check, and Health Check Status.

24.6.1.2.1. Create an address pool

You can define a list of addresses that form an address pool, which can be associated with access policies of scheduling instances when you configure the access policies.

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, click **Internal Global Traffic Manager**. On the Scheduling Instance tab of the Global Traffic Management on the Internal Network page, click the Address Pool tab.
3. On the Address Pool tab, click **Create Address Pool**.
4. In the Create Address Pool dialog box, specify **Address Pool Name**, **Address Type**, and **Load Balancing Policy (Among Addresses)**, and add addresses one by one in the **Address List** section. You can also click **Batch Add** to add multiple addresses at a time. After you enter the required information, click **OK**.

Parameter	Description
Address Pool Name	The name can contain a maximum of 20 characters.
Address Type	You can select IPv4, IPv6, or Domain Name from the drop-down list of this parameter. This configuration cannot be changed.
Load Balancing Policy (Among Addresses)	You can select Polling or Weight from the drop-down list of this parameter. This configuration cannot be changed.
Mode	Valid values: • Automatically Returned: The system determines whether the address is available based on the health check result of the address. • Always online: The system ignores the health check result of the address and sets the address to be always available. The health check task is still running. • Always Offline: The system ignores the health check result of the address and sets the address to be always unavailable. The health check task is still running.

24.6.1.2.2. Modify the configurations of an address pool

Notice After you modify the configurations of an address pool, the health check results of all addresses are reset to normal if health check is enabled. If the address pool has been associated with access policies and automatic switchover is enabled, a primary/secondary switchover may be triggered. Proceed with caution.

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, click **Internal Global Traffic Manager**. On the **Scheduling Instance** tab of the Global Traffic Management on the Internal Network page, click the **Address Pool** tab.
3. Find the address pool that you want to modify and click **Modify** in the Actions column.
4. In the Modify Address Pool dialog box, you can change only **Address Pool Name** and the addresses in **Address (One in Each Row)**.
5. Click **OK**.

24.6.1.2.3. Delete an address pool

1. Log on to the Apsara Stack DNS console and choose Recursion Configurations > Scheduling Instances > Address Pool.

2. Find the target address pool and click Delete in the Actions column.

3. In the dialog box that appears, click OK after you verify that the displayed information is correct.

24.6.1.2.4. Enable health check

You can enable health check to check the status of the addresses in an address pool. Only the addresses whose health check status is normal can be returned.

1. Log on to the Apsara Stack DNS console.
2. In the left-side navigation pane, click **Internal Global Traffic Manager**. On the **Scheduling Instance** tab of the Global Traffic Management on the Internal Network page, click the **Address Pool** tab.
3. Find the address pool for which you want to configure a health check, and click **Health Check** in the Actions column.
4. In the Health Check dialog box, turn on or turn off **Health Check Switch**, specify the parameters in the **Protocol Settings**, **Health Check Settings**, and **Node Settings** sections, and then click **OK**.

Section	Parameter	Description	Protocol
Protocol Settings	Port	The port number that is used for health checks on the destination address. The value must be an integer in the range of 1 to 65535. This parameter cannot be empty.	HTTP/HTTPS/TCP/UDP
	Path	The HTTP or HTTPS path that is used for health checks on the destination address. This path is used to check whether the HTTP or HTTPS service of the destination address is normal. If the HTTP status code returned from this path is 2xx or 3xx, the HTTP or HTTPS service is normal. The system automatically adds a forward slash (/) before the path name. The path can be empty. The default value is /. The path name can contain a maximum of 255 characters.	HTTP/HTTPS
	Host Configuration	The host configuration that is used for health checks. If you do not specify this parameter, the primary domain name is used.	HTTP/HTTPS
	Returned Error Code Greater Than or Equal to	The minimum value of the HTTP status code when the health check result is abnormal. The HTTP status code returned must be greater than or equal to the value of this parameter.	HTTP/HTTPS
	ICMP Packages Sent	The number of ICMP packets sent each time an Internet Control Message Protocol (ICMP) health check is performed.	ICMP
	Packet Loss Rate	The threshold of the packet loss rate. The threshold is used to determine whether the result of an ICMP health check is abnormal.	ICMP

Section	Parameter	Description	Protocol
Health Check Settings	Check interval	The time interval at which health checks are performed on the destination address.	
	Timeout Duration	The timeout duration for which the system waits after an exception occurs during a health check.	
	Failure Threshold	The minimum number of consecutive health check failures when the status of the destination address is abnormal during a health check.	
Node Settings	Selected node	The nodes that initiate health checks on the destination address.	

24.6.1.3. Scheduling Domain

The Scheduling Domain tab allows you to add, delete, and query scheduling domains.

You can log on to the Apsara Stack DNS console and choose Internal Global Traffic Manager > Scheduling Instances > Scheduling Domain to go to the scheduling domain list.

24.6.1.3.1. Create a scheduling domain

1. Log on to the Apsara Stack DNS console and choose Recursion Configurations > Scheduling Instances > Scheduling Domain. Then, click Create Scheduling Domain in the upper-right corner of the scheduling domain list.

2. In the dialog box that appears, enter the custom domain name and click OK.

24.6.1.3.2. Add a description for a scheduling domain

1. In the left-side navigation pane, choose Internal Global Traffic Manager > Scheduling Instances > Scheduling Domain.

2. Find the scheduling domain for which you want to add a description and click Edit in the Actions column.

3. In the dialog box that appears, add a description in the Edit field and click OK.

24.6.1.3.3. Delete a scheduling domain

1. In the left-side navigation pane, choose Internal Global Traffic Manager > Scheduling Instances > Scheduling Domain.

2. Find the scheduling domain that you want to delete and click Delete in the Actions column.

3. In the message that appears, click OK after you verify that the displayed information is correct.

24.6.1.4. View alert logs

> **Note**
>
> By default, the system saves alert logs of the last 90 days.

1. Log on to the Apsara Stack DNS console.

2. In the left-side navigation pane, click **Internal Global Traffic Manager**. On the **Scheduling Instance** tab of the Global Traffic Management on the Internal Network page, click the **Alert Logs** tab.
3. In the alert log list, view address pool information, such as the status of the address pool, health check results of addresses, and switchover between primary and secondary address pools. You can query alert logs of address pools by time or behavior, or by using a keyword.

24.6.2. Scheduling line management

24.6.2.1. IP Address Line Configuration

The IP Address Line Configuration tab allows you to define lines based on IP addresses. The lines are used to group request sources to achieve intelligent load balancing.

24.6.2.1.1. Add a line

1. In the left-side navigation pane, choose **Internal Global Traffic Manager** > **Scheduling Line Management** > IP Address Line Configuration.

2. Click **Add Line** in the upper-right corner of the line list.

3. In the dialog box that appears, configure the parameters as prompted and click **OK**.

24.6.2.1.2. Sort lines

1. In the left-side navigation pane, choose **Internal Global Traffic Manager** > **Scheduling Line Management** > IP Address Line Configuration.

2. Find the line whose sequence you want to change and click **Sort** in the Actions column.

3. Specify Sort Behavior as prompted and click **OK**.

24.6.2.1.3. Modify the configurations of a line

1. In the left-side navigation pane, choose **Internal Global Traffic Manager** > **Scheduling Line Management** > IP Address Line Configuration.

2. Find the line whose configurations you want to modify and click **Modify** in the Actions column.

3. Modify the configurations as prompted and click **OK**.

24.6.2.1.4. Delete a line

1. In the left-side navigation pane, choose **Internal Global Traffic Manager** > **Scheduling Line Management** > **IP Address Line Configuration**.

2. Find the line that you want to delete and click **Delete** in the Actions column.

3. In the message that appears, click **OK**.

24.6.3. Data synchronization management

Data synchronization management is used to synchronize Global Traffic Manager (GTM) data between clouds.

24.6.3.1. Synchronization cluster management

Synchronization clusters involve two operations: **Set Emergency Group** and **Merge GTM Control Domain**.

You can perform the following operations to go to the synchronization cluster management page:

1. Log on to the Apsara Stack DNS console.

2. In the left-side navigation pane, choose **Internal Global Traffic Manager**.
3. On the page that appears, click the **Data Synchronization** tab.

Set Emergency Group

You can select some service instances to form a cluster to provide services.

- Enable the emergency group feature: If the synchronization cluster is abnormal, click **Set Emergency Group**. In the Set Emergency Group dialog box, turn on Emergency Group Switch, select available service instances to form an emergency group, and then click **OK**.
- Disable the emergency group feature: If the synchronization cluster is restored to normal, click **Set Emergency Group**. In the Set Emergency Group dialog box, turn off the Emergency Group Switch and click **OK**.

Merge GTM Control Domain

In multi-cloud scenarios, you can click **Merge GTM Control Domain** and enter the IP address of the leader service instance of the merged Global Traffic Manager (GTM) control domain to form a large synchronization cluster.

View the status of the synchronization cluster

You can view the status of the synchronization cluster on the Synchronization Cluster Management tab.

View the service instances in the synchronization cluster

You can view the following information of the service instances in the current synchronization cluster:

Instance IP Address, Instance Role, Status, Latest Synchronization Log ID, IP Address, and Instance Description.

You can also perform the following operations to switch the role of a service instance in the synchronization cluster from follower to leader:

1. Find the service instance with the follower role and click **Switch Primary** in the Actions column.
2. In the message that appears, click **OK**.
